Length of `containers.Map` object

Syntax

```
mapLength = length(mapObj)
```

Description

`mapLength = length(mapObj)` returns the number of key-value pairs in `mapObj`.

Input Arguments

`mapObj`

Object of class `containers.Map`.

Output Arguments

`mapLength`

Scalar numeric value that indicates the number of key-value pairs in `mapObj`. This number is equivalent to `size(mapObj,1)` and to `mapObj.Count`.

Examples

Determine the Length of a Map

Create a map, and determine the number of key-value pairs:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);

mapLength = length(mapObj)
```

This code returns

```
mapLength =
     3
```

See Also

isKey | keys | values | containers.Map | size

length (serial)

Length of serial port object array

Syntax

```
length(obj)
```

Description

`length(obj)` returns the length of the serial port object, `obj`. It is equivalent to the command `max(size(obj))`.

See Also

`size`

Introduced before R2006a

length (tscollection)

Length of time vector

Syntax

```
length(tsc)
```

Description

`length(tsc)` returns an integer that represents the length of the time vector for the `tscollection` object `tsc`.

See Also

`tscollection` | `isempty (tscollection)` | `size (tscollection)`

Introduced before R2006a

libfunctions

Return information on functions in shared library

Syntax

```
libfunctions libname

m = libfunctions(libname)
___ = libfunctions( ___ ,'-full')
```

Description

`libfunctions libname` displays names of functions defined in library, libname. If you called `loadlibrary` using the `alias` option, then you must use the alias name for the libname argument.

`m = libfunctions(libname)` returns names of functions in cell array m.

`___ = libfunctions( ___ ,'-full')` returns function signatures.

Examples

Display Function Signatures

Load the example library, `shrlibsample`, and list the functions.

```
if not(libisloaded('shrlibsample'))
  addpath(fullfile(matlabroot,'extern','examples','shrlib'))
  loadlibrary('shrlibsample')
end
m = libfunctions('shrlibsample','-full')
```

```
m =

    '[double, doublePtr] addDoubleRef(double, doublePtr, double)'
    'double addMixedTypes(int16, int32, double)'
    '[double, c_structPtr] addStructByRef(c_structPtr)'
    'double addStructFields(c_struct)'
```

```
'c_structPtrPtr allocateStruct(c_structPtrPtr)'
'voidPtr deallocateStruct(voidPtr)'
'lib.pointer exportedDoubleValue'
'lib.pointer getListOfStrings'
'doublePtr multDoubleArray(doublePtr, int32)'
'[lib.pointer, doublePtr] multDoubleRef(doublePtr)'
'int16Ptr multiplyShort(int16Ptr, int32)'
'doublePtr print2darray(doublePtr, int32)'
'printExportedDoubleValue'
'cstring readEnum(Enum1)'
'[cstring, cstring] stringToUpper(cstring)'
```

Input Arguments

`libname` — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: `char`

Output Arguments

`m` — Function names

cell array

Functions names, returned as a cell array.

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

See Also

`calllib` | `libfunctionsview` | `loadlibrary`

Introduced before R2006a

libfunctionsview

Display shared library function signatures in window

Syntax

```
libfunctionsview libname
```

Description

`libfunctionsview libname` displays information about functions in library, libname, in a new window.

Input Arguments

`libname` — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: `char`

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

Examples

Display Function Signatures for Library libmx

```
if not(libisloaded('libmx'))
```

```
  hfile = fullfile(matlabroot,'extern','include','matrix.h');
  loadlibrary('libmx',hfile)
end
libfunctionsview libmx
```

MATLAB creates a new window displaying function signatures.

See Also

`libfunctions` | `calllib`

Introduced before R2006a

libisloaded

Determine if shared library is loaded

Syntax

```
tf = libisloaded(libname)
```

Description

`tf = libisloaded(libname)` returns logical `1` (`true`) if the shared library, libname, is loaded. Otherwise, it returns logical `0` (`false`).

Examples

Load Functions in Library

Load example library, `shrlibsample`, if it is not already loaded.

```
if ~libisloaded('shrlibsample')
  loadlibrary('shrlibsample')
end
```

Input Arguments

`libname` — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: `char`

See Also

`loadlibrary` | `unloadlibrary`

Introduced before R2006a

libpointer

Pointer object for use with shared library

Syntax

```
p = libpointer
p = libpointer(DataType)
p = libpointer(DataType,Value)
```

Description

`p = libpointer` creates `NULL` pointer `p` of type `voidPtr`.

`p = libpointer(DataType)` creates `NULL` pointer of specified `DataType`.

`p = libpointer(DataType,Value)` creates pointer initialized to a copy of `Value`.

Examples

Create NULL Pointer for string Argument

```
p = libpointer('string');
```

- "Multilevel Pointers"

Input Arguments

`DataType` — Type of pointer

string

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, refer to these tables in "C and MATLAB Equivalent Types".

- MATLAB Primitive Types

- MATLAB Extended Types

Example: `'int16Ptr'`

Data Types: `char`

`Value` — Value for pointer object

any valid value

Value, specified as any valid value for given type.

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

More About

Tips

- This is an advanced feature for experienced C programmers. MATLAB automatically converts data passed to and from external library functions to the data type expected by the external function. Use a `lib.pointer` object instead of automatic conversion in the following situations.
  - You want to modify the data in the input arguments.
  - You are passing large amounts of data, and you want to control when MATLAB makes copies of the data.
  - The library stores and uses the pointer for a period of time so you want the MATLAB function to control the lifetime of the `lib.pointer` object.
- "Working with Pointer Arguments"

See Also

`lib.pointer` | `calllib` | `libstruct`

Introduced before R2006a

lib.pointer class

Package: lib

Pointer object compatible with C pointer

Description

MATLAB automatically converts arguments that are passed by reference to a function in an external library. Use a pointer object instead of automatic conversion in the following situations.

- The function modifies data in an input argument.
- You are passing large amounts of data, and you want to control when MATLAB makes copies of the data.
- The library stores and uses the pointer for a period of time so you want the MATLAB function to control the lifetime of the `lib.pointer` object.

Construction

To create a `lib.pointer` object, use the MATLAB `libpointer` function.

A library function can return a `lib.pointer` object. Use the `setdatatype` method to manually convert the argument to use in MATLAB.

Properties

`DataType`

Type of pointer, specified as a string, of any MATLAB numeric type, structure defined in the library, or enumeration defined in the library. For a list of valid MATLAB numeric types, refer to these tables in “C and MATLAB Equivalent Types”.

- MATLAB Primitive Types
- MATLAB Extended Types

`Value`

Value, specified as any valid value for given type.

Methods

disp	Display lib.pointer type
isNull	Points to NULL pointer
plus	+ (plus) operator for pointer arithmetic
reshape	Reshape lib.pointer array
setdatatype	Initialize type and size of lib.pointer object

Definitions

A passed-by-reference argument in the function signature has type names ending with `Ptr` or `PtrPtr`.

Examples

Create Pointer

Create a pointer, `pv`, of type `int16`, initialized to `485`.

```
pv = libpointer('int16Ptr',485);
```

Display the properties of `pv`.

```
get(pv)
```

```
        Value: 485
```

```
    DataType: 'int16Ptr'
```

See Also

`libpointer`

More About

- “Working with Pointer Arguments”

Introduced before R2006a

disp

Class: lib.pointer
Package: lib

Display lib.pointer type

Syntax

```
disp(h)
```

Description

`disp(h)` displays type for `lib.pointer` object, h.

Input Arguments

`h` — `lib.pointer` object.

handle

`lib.pointer` object, specified as a handle.

Examples

Display lib.pointer Type

Create a `double` pointer set to `15`.

```
xp = libpointer('doublePtr',15);
```

Display pointer data type.

```
disp(xp)
```

```
libpointer
```

isNull

Class: lib.pointer
Package: lib

Points to NULL pointer

Syntax

```
tf = isNull(h)
```

Description

`tf = isNull(h)` returns true if h is a `lib.pointer` object.

Input Arguments

`h` — `lib.pointer` object.

handle

`lib.pointer` object, specified as a handle.

Examples

Create Null lib.pointer Object

```
nullp = libpointer('doublePtr',[]);
isNull(nullp)
```

plus

Class: lib.pointer
Package: lib

+ (plus) operator for pointer arithmetic

Syntax

```
hout = plus(h,offset)
hout = h + offset
```

Description

`hout = plus(h,offset)` returns pointer `hout`. Pointer `hout` is valid only as long as the original pointer, h, exists.

`hout = h + offset` is an alternative syntax.

Input Arguments

`h` — `lib.pointer` object.

handle

`lib.pointer` object, specified as a handle.

`offset` — Scalar increment

`uint64`

Scalar increment, specified as `uint64`, from h.

Related Examples

- "Iterate Through an Array"

reshape

Class: lib.pointer
Package: lib

Reshape lib.pointer array

Syntax

```
reshape(h,xdim,ydim)
```

Description

`reshape(h,xdim,ydim)` creates an xdim-by-ydim matrix from `lib.pointer` object h.

Input Arguments

`h` — `lib.pointer` object.

handle

`lib.pointer` object, specified as a handle.

`xdim` — Size of x dimension

double

Size of x dimension, specified as `double`.

`ydim` — Size of y dimension

double

Size of y dimension, specified as `double`.

setdatatype

Class: lib.pointer
Package: lib

Initialize type and size of lib.pointer object

Syntax

```
setdatatype(h,type,size)
```

Description

`setdatatype(h,type,size)` sets data type, type, of size, to `lib.pointer`, `h`.

Input Arguments

`h` — `lib.pointer` object.

handle

`lib.pointer` object, specified as a handle.

`type` — Data type

string

Data type, specified as a string.

`size` — Size

double

Size, specified as `double`.

Examples

Set Size and Type of lib.pointer Output Variable

Load the `shrlibsample` library.

```
if ~libisloaded('shrlibsample')
  addpath(fullfile(matlabroot,'extern','examples','shrlib'))
  loadlibrary('shrlibsample')
end
```

The `multDoubleRef` function takes a scalar value specified as `doubleptr`. Create variable `xp` as a `lib.pointer` object, and call the function.

```
xp = libpointer('doublePtr',99);
[xobj,xval] = calllib('shrlibsample','multDoubleRef',xp);
```

To use the variable `xobj`, set its size and data type.

```
setdatatype(xobj,'doublePtr',1,1)
xobj.Value
```

```
ans =

   495
```

libstruct

Convert MATLAB structure to C-style structure for use with shared library

Syntax

```
S = libstruct(structtype)
S = libstruct(structtype,mlstruct)
```

Description

`S = libstruct(structtype)` creates `NULL` pointer to MATLAB `libstruct` object S.

`S = libstruct(structtype,mlstruct)` creates pointer initialized to mlstruct.

Examples

Call Function with `c_struct` Input Argument

Call the `addStructFields` function by creating a variable of type `c_struct`.

Load the `shrlibsample` library, which contains the `c_struct` type.

```
if ~libisloaded('shrlibsample')
   addpath(fullfile(matlabroot,'extern','examples','shrlib'))
   loadlibrary('shrlibsample')
end
```

Display function signatures for `shrlibsample` and search the list for the `addStructFields` entry.

```
libfunctionsview shrlibsample
```

```
double addStructFields(c_struct)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `sm`.

```
sm.p1 = 476;   sm.p2 = -299;   sm.p3 = 1000;
```

Construct a `libstruct` object `sc` from the `c_struct` type.

```
sc = libstruct('c_struct',sm)
```

The fields of `sc` contain the values of the MATLAB structure, `sm`.

Call the `addStructFields` function.

```
calllib('shrlibsample','addStructFields',sc)
```

```
ans =
    1177
```

To clean up, first clear the `libstruct` object, and then unload the library.

```
clear sc
unloadlibrary shrlibsample
```

Input Arguments

`structtype` — C structure

structure

C structure defined in shared library.

`mlstruct` — MATLAB structure

structure

MATLAB structure used to initialize the fields in `S`.

Data Types: `struct`

Output Arguments

`S` — Pointer

MATLAB `libstruct` object

Pointer, returned as MATLAB `libstruct` object.

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.
- You can only use the `libstruct` function on scalar structures.
- When converting a MATLAB structure to a `libstruct` object, the structure must adhere to the requirements listed in “Structure Argument Requirements”.

More About

Tips

- If a function in the shared library has a structure argument, use `libstruct` to create the argument. The `libstruct` function creates a C-style structure that you pass to functions in the library. You handle this structure in MATLAB as you would a true MATLAB structure.
- “Working with Structure Arguments”

Introduced before R2006a

license

Get license number or perform licensing task

Syntax

```
license
license('inuse')

S = license('inuse')
S = license('inuse',feature)

status = license('test',feature)
license('test',feature,toggle)

[status,errmsg] = license('checkout',feature)
```

Description

`license` returns the license number for this MATLAB product. The return value also can be `'demo'` for a demonstration version of MATLAB, `'student'`, for a student version of MATLAB, or `'unknown'`, if the license number cannot be determined.

`license('inuse')` displays a list of licenses checked out in the current MATLAB session. The product list is alphabetical by license feature name. These names are the same as the valid values for the feature input.

`S = license('inuse')` returns an array of structures indicating checked-out licenses and the user name of each person who has a license checked out.

`S = license('inuse',feature)` checks if the product specified by `feature` is checked out in the current MATLAB session. If the product is checked out, then `license` returns the product name and the user name of the person who has it checked out. Otherwise, the fields of `S` are empty.

`status = license('test',feature)` tests if a license exists for the product specified by `feature`.

`license('test',feature,toggle)` enables or disables testing of the product specified by `feature`, depending on the value of `toggle`.

`[status,errmsg] = license('checkout',feature)` checks out a license for the specified product. If you specify the optional second output argument, `errmsg`, then license returns the text of any error message encountered if the checkout is unsuccessful.

Examples

Display Licenses in Use

Display a list of licenses currently being used.

```
license('inuse')
```

```
image_toolbox
map_toolbox
matlab
```

`license` displays a list of products in alphabetical order by the license feature name.

Get Licenses in Use and User Names

Get a list of licenses in use with information about each user.

```
S = license('inuse');
```

`license` returns a structure array.

View the first element of `S`.

```
S(1)
```

```
ans =

    feature: 'image_toolbox'
       user: 'juser'
```

Determine If License Is in Use

Determine if the license for MATLAB is in use.

```
S = license('inuse','MATLAB')

S =

    feature: 'matlab'
       user: 'jsmith'
```

If the license is in use, then `S` is a structure array with nonempty fields.

Determine If License Exists

Determine if a license exists for Mapping Toolbox™.

```
status = license('test','map_toolbox')

status =

    1
```

`license` returns `1` if a license exists.

Check Out License

Check out a license for Control System Toolbox.

```
[status,errmsg] = license('checkout','control_toolbox')

status =

     1

errmsg =

     ''
```

The `status` output is `1` and the `errmsg` output is empty if the checkout is successful.

Input Arguments

`feature` — License feature name

string

License feature name, specified as a string. The `INCREMENT` lines in a license file indicate the valid strings. To locate your license file, see Where are the license files for MATLAB located?

As an example, this table lists the `feature` value for a few commonly used products.

`feature` Value	MathWorks Product
`'MATLAB'`	MATLAB
`'SIMULINK'`	Simulink
`'Control_Toolbox'`	Control System Toolbox™
`'Curve_Fitting_Toolbox'`	Curve Fitting Toolbox™
`'Signal_Blocks'`	DSP System Toolbox™
`'Image_Toolbox'`	Image Processing Toolbox
`'Optimization_Toolbox'`	Optimization Toolbox™
`'Distrib_Computing_Toolbox'`	Parallel Computing Toolbox
`'Signal_Toolbox'`	Signal Processing Toolbox
`'Stateflow'`	Stateflow®
`'Statistics_Toolbox'`	Statistics and Machine Learning Toolbox
`'Symbolic_Toolbox'`	Symbolic Math Toolbox™

Values of `feature` are not case-sensitive.

`toggle` — Ability to test product license

`'enable' | 'disable'`

Ability to test the existence of a product license, specified as either `'enable'` or `'disable'`.

- If `toggle` is `'enable'`, then the syntax, `license('test',feature)` returns `1` when the product license exists and `0` when the product license does not exist.
- If `toggle` is `'disable'`, then the syntax, `license('test',feature)` always returns `0` (product license does not exist) for the specified product.

Note Disabling a test for a particular product can affect other tests for the existence of the license, not just tests performed by the `license` command.

Output Arguments

`S` — Checked out products

array of structures

Checked out products, returned as an array of structures, where each structure represents a checked-out license. The structures contain two fields:

- `feature` — license feature name
- `user` — user name of the person who has the license checked out

If the fields are empty, then the product is not currently checked out.

`status` — Test or checkout status

`1` | `0`

Test or checkout status, returned as `1` or `0`.

- When testing for the existence of a license, `1` indicates that the license exists, and `0` indicates that the license does not exist.

  The existence of a license does not necessarily mean that the license can be checked out or that the product is installed. `status` is `1` even if the license has expired or if a system administrator has excluded you from using the product.
- When checking out a license, `1` indicates that the checkout is successful, and `0` indicates that the `license` function could not check out a license.

`errmsg` — Error message

string

Error message for unsuccessful license checkout, returned as a string. If the checkout is successful, then `errmsg` is empty.

`isstudent`

Introduced before R2006a

light

Create light object

Syntax

```
light('PropertyName',propertyvalue,...)
handle = light(...)
```

Properties

For a list of properties, see Light Properties.

Description

`light` creates a light object in the current axes. Lights affect only patch and surface objects.

`light('PropertyName',propertyvalue,...)` creates a light object using the specified values for the named properties. For a description of the properties, see Light Properties. The MATLAB software parents the light to the current axes unless you specify another axes with the `Parent` property.

`handle = light(...)` returns the handle of the light object created.

Examples

Light the `peaks` surface plot with a local light source oriented along the direction defined by the vector `[-1 0 0]`, that is, looking from `0` along the positive x-axis.

```
surf(peaks,'FaceLighting','gouraud','FaceColor','interp',...
      'AmbientStrength',0.5)
light('Position',[-1 0 0],'Style','local')
```

Tutorials

For more information about lighting, see “Lighting Overview”.

More About

Tips

You cannot see a light object *per se*, but you can see the effects of the light source on patch and surface objects. You can also specify an axes-wide ambient light color that illuminates these objects. However, ambient light is visible only when at least one light object is present and visible in the axes.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

See also the Patch Properties and Primitive Surface Properties `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, `SpecularColorReflectance`, and `VertexNormals` properties. Also see the `lighting` and `material` commands.

See Also

`lighting` | `patch` | `material` | `surface`

Introduced before R2006a

Light Properties

Control light appearance and behavior

Light properties control the appearance and behavior of light objects. By changing property values, you can modify certain aspects of the light.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = light;
c = h.Color;
h.Style = 'local';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Color, Position, and Style

`Color` — Color of light

`[1 1 1]` (default) | RGB triplet | color string

Color of light emanating from the light object, specified as an RGB triplet or a color string. The default RGB triplet of `[1 1 1]` corresponds to white.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`

Long Name	Short Name	RGB Triplet
'black	'k'	[0 0 0]

Example: 'green'

Position — Location of light source

[1 0 1] (default) | three-element vector of the form [x y z]

Location of light source, specified as a three-element vector of the form [x y z]. Define the vector elements in data units from the axes origin to the (*x*, *y*, *z*) coordinate. The actual location of the light depends on the value of the Style property.

Example: [-40 -4 140]

Style — Type of light source

'infinite' (default) | 'local'

Type of light source, specified as one of these values:

- 'infinite' — Place the light at infinity. Use the Position property to specify the direction from which the light shines in parallel rays.
- 'local' — Place the light at the location specified by the Position property. The light is a point source that radiates from the location in all directions.

Visibility

Visible — Visibility of light from light source

'on' (default) | 'off'

Visibility of light from light source, specified as 'on' or 'off'.

Identifiers

Type — Type of graphics object

'light'

Type of graphics object, returned as the string 'light'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using findobj.

`Tag` — Tag to associate with light

`''` (default) | string

Tag to associate with the light, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with light

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the light object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent of light

axes object | group object | transform object

Parent of light, specified as an axes, group, or transform object.

`Children` — Children of light

empty `GraphicsPlaceholder` array

The light has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of light object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The light object handle is always visible.

- `'off'` — The light object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The light object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the light at the command-line, but allows callback functions to access it.

If the light object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the light. Setting the `CreateFcn` property on an existing light has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during light creation. MATLAB executes the callback after creating the light and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The light object — You can access properties of the light object from within the callback function. You also can access the light object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the light. MATLAB executes the callback before destroying the light so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The light object — You can access properties of the light object from within the callback function. You also can access the light object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of light

`'off'` (default) | `'on'`

Deletion status of light, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the light begins execution (see the

DeleteFcn property). The BeingDeleted property remains set to `'on'` until the light no longer exists.

Check the value of the BeingDeleted property to verify that the light is not about to be deleted before querying or modifying it.

Unused Properties

`ButtonDownFcn` — (unused) Mouse-click callback
`''` (default) | function handle | cell array | string

Light objects do not use this property.

`UIContextMenu` — (unused) Context menu
uicontextmenu object

Light objects do not use this property.

`Selected` — (unused) Selection state
`'off'` (default) | `'on'`

Light objects do not use this property.

`SelectionHighlight` — (unused) Display of selection handles when selected
`'on'` (default) | `'off'`

Light objects do not use this property.

`PickableParts` — (unused) Ability to capture mouse clicks
`'visible'` (default) | `'none'`

Light objects do not use this property.

`HitTest` — (unused) Response to captured mouse clicks
`'on'` (default) | `'off'`

Light objects do not use this property.

`Interruptible` — (unused) Callback interruption
`'on'` (default) | `'off'`

Light objects do not use this property.

`BusyAction` — (unused) Callback queuing
`'queue'` (default) | `'cancel'`

Light objects do not use this property.

- "Graphics Object Properties"

lightangle

Create or position light object in spherical coordinates

Syntax

```
lightangle(az,el)
light_handle = lightangle(az,el)
lightangle(light_handle,az,el)
[az,el] = lightangle(light_handle)
```

Description

`lightangle(az,el)` creates a light at the position specified by azimuth and elevation. `az` is the azimuthal (horizontal) rotation and `el` is the vertical elevation (both in degrees). The interpretation of azimuth and elevation is the same as that of the `view` command.

`light_handle = lightangle(az,el)` creates a light and returns the handle of the light in `light_handle`.

`lightangle(light_handle,az,el)` sets the position of the light specified by `light_handle`.

`[az,el] = lightangle(light_handle)` returns the azimuth and elevation of the light specified by `light_handle`.

Examples

```
surf(peaks)
axis vis3d
h = light;
for az = -50:10:50
   lightangle(h,az,30)
   pause(.2)
end
```

More About

Tips

By default, when a light is created, its style is `infinite`. If the light handle passed in to `lightangle` refers to a local light, the distance between the light and the camera target is preserved as the position is changed.

See Also

`light` | `camlight` | `view`

Introduced before R2006a

lighting

Specify lighting algorithm

Syntax

```
lighting flat
lighting gouraud
lighting none
```

Description

`lighting` selects the algorithm used to calculate the effects of `light` objects on all `surface` and `patch` objects in the current axes. In order for the `lighting` command to have any effects, however, you must create a lighting object by using the `light` function.

`lighting flat` produces uniform lighting across each of the faces of the object. Select this method to view faceted objects.

`lighting gouraud` calculates the vertex normals and interpolates linearly across the faces. Select this method to view curved surfaces.

`lighting none` turns off lighting.

More About

Tips

The `surf`, `mesh`, `pcolor`, `fill`, `fill3`, `surface`, and `patch` functions create graphics objects that are affected by light sources. The `lighting` command sets the `FaceLighting` and `EdgeLighting` properties of surfaces and patches appropriately for the graphics object.

- "Lighting Overview"

Introduced before R2006a

lin2mu

Convert linear audio signal to mu-law

Syntax

```
mu = lin2mu(y)
```

Description

`mu = lin2mu(y)` converts linear audio signal amplitudes in the range `-1 ≤ Y ≤ 1` to mu-law encoded "flints" in the range `0 ≤ u ≤ 255`.

See Also

`auwrite` | `mu2lin`

Introduced before R2006a

line

Create line object

Syntax

```
line
line(X,Y)
line(X,Y,Z)
line(X,Y,Z,'PropertyName',propertyvalue,...)
line('XData',x,'YData',y,'ZData',z,...)
h = line(...)
```

Properties

For a list of properties, see Primitive Line Properties.

Description

`line` creates a line object in the current axes with default values `x = [0 1]` and `y = [0 1]`. You can specify the color, width, line style, and marker type, as well as other characteristics.

The `line` function has two forms:

- Automatic color and line style cycling. When you specify multiple line coordinate data as a column array using the informal syntax (i.e., the first three arguments are interpreted as the coordinates),

  ```
  line(X,Y,Z)
  ```

  MATLAB cycles through the axes `ColorOrder` and `LineStyleOrder` property values the way the `plot` function does. However, unlike `plot`, `line` does not call the `newplot` function.
- Purely low-level behavior. When you call `line` with only property name/property value pairs,

```
line('XData',x,'YData',y,'ZData',z)
```

MATLAB draws a line object in the current axes using the default line color (see the `colordef` function for information on color defaults). Note that you cannot specify matrix coordinate data with the low-level form of the `line` function.

`line(X,Y)` adds the line defined in vectors `X` and `Y` to the current axes. If `X` and `Y` are matrices of the same size, `line` draws one line per column.

`line(X,Y,Z)` creates lines in three-dimensional coordinates.

`line(X,Y,Z,'`*`PropertyName`*`',propertyvalue,...)` creates a line using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Primitive Line Properties.

`line('XData',x,'YData',y,'ZData',z,...)` creates a line in the current axes using the property values defined as arguments. This is the low-level form of the `line` function, which does not accept matrix coordinate data as the other informal forms described above.

`h = line(...)` returns a column vector of primitive line handles corresponding to each line object the function creates.

Examples

This example uses the `line` function to add a shadow to plotted data. First, plot some data and save the line's handle:

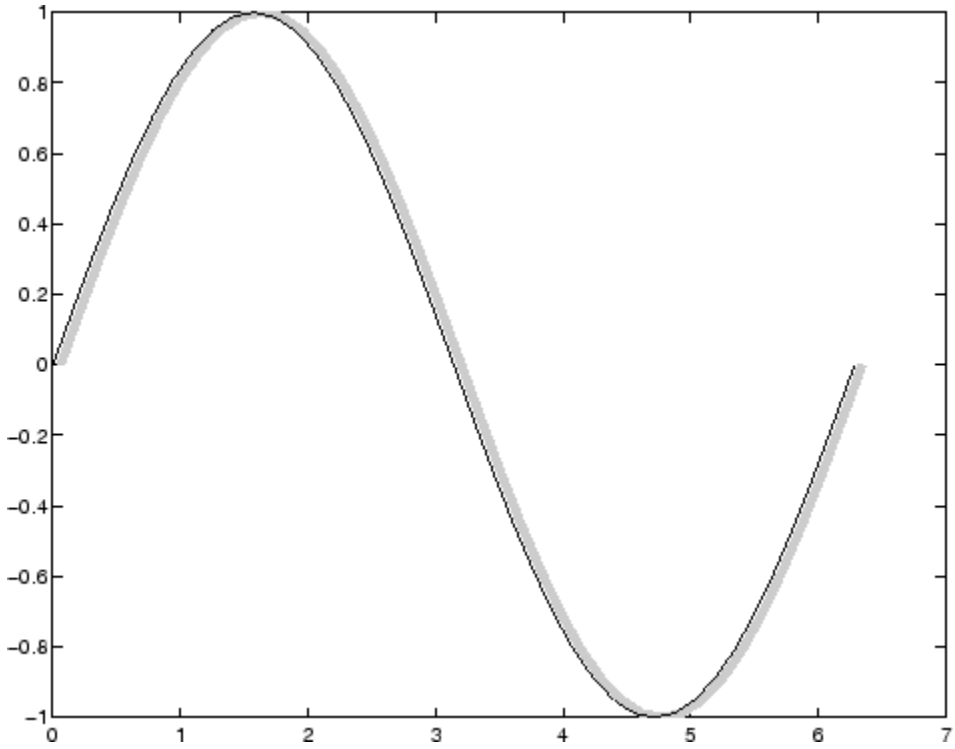
```
t = 0:pi/20:2*pi;
hline1 = plot(t,sin(t),'k');
ax = gca;
```

Next, add a shadow by offsetting the *x*-coordinates. Make the shadow line light gray and wider than the default `LineWidth`:

```
hline2 = line(t+.06,sin(t),...
   'LineWidth',4,...
   'Color',[.8 .8 .8],...
   'Parent',ax);
```

Finally, pull the first line to the front:

```
set(gca,'Children',[hline1 hline2])
```



Drawing Lines Interactively

You can use the `ginput` function to select points from a figure. For example:

```
[x,y] = ginput(5);
line(x,y)
```

Drawing with mouse motion

You can use the axes `CurrentPoint` property and the figure `WindowButtonDownFcn` and `WindowButtonMotionFcn` properties to select a point with a mouse click and draw a line to another point by dragging the mouse, like a simple drawing program. The following example illustrates a few useful techniques for doing this type of interactive drawing.

Click to view in editor — This example enables you to click and drag the cursor to draw lines.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

Input Argument Dimensions — Informal Form

This statement reuses the one-column matrix specified for `ZData` to produce two lines, each having four points.

```
line(rand(4,2),rand(4,2),rand(4,1))
```

If all the data has the same number of columns and one row each, MATLAB transposes the matrices to produce data for plotting. For example,

```
line(rand(1,4),rand(1,4),rand(1,4))
```

is changed to

```
line(rand(4,1),rand(4,1),rand(4,1))
```

This also applies to the case when just one or two matrices have one row. For example, the statement

```
line(rand(2,4),rand(2,4),rand(1,4))
```

is equivalent to

```
line(rand(4,2),rand(4,2),rand(4,1))
```

More About

Tips

In its informal form, the `line` function interprets the first three arguments (two for 2-D) as the `X`, `Y`, and `Z` coordinate data, allowing you to omit the property names. You must specify all other properties as name/value pairs. For example,

```
line(X,Y,Z,'Color','r','LineWidth',4)
```

The low-level form of the `line` function can have arguments that are only property name/property value pairs. For example,

```
line('XData',x,'YData',y,'ZData',z,...
     'Color','r','LineWidth',4)
```

Line properties control various aspects of the line object. You can also set and query property values after creating the line using dot notation or the `set` and `get` functions

Unlike high-level functions such as `plot`, `line` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds line objects to the current axes. However, axes properties that are under automatic control, such as the axis limits, can change to accommodate the line within the current axes.

Connecting the dots

The coordinate data is interpreted as vectors of corresponding x, y, and z values:

```
X = [x(1) x(2) x(3)...x(n)]
Y = [y(1) y(2) y(3)...y(n)]
Z = [z(1) z(2) z(3)...z(n)]
```

where a point is determined by the corresponding vector elements:

```
p1(x(i),y(i),z(i))
```

For example, to draw a line from the point located at `x = .3` and `y = .4` and `z = 1` to the point located at `x = .7` and `y = .9` and `z = 1`, use the following data:

```
axis([0 1 0 1])
line([.3 .7],[.4 .9],[1 1],'Marker','.','LineStyle','-')
```

Properties

Primitive Line Properties

Introduced before R2006a

LineSpec (Line Specification)

Line specification string syntax

Description

Plotting functions accept *string specifiers* as arguments and modify the graph generated accordingly. Three components can be specified in the *string specifiers* along with the plotting command. They are:

- Line style
- Marker symbol
- Color

For example:

```
plot(x,y,'-.or')
```

plots `y` versus `x` using a dash-dot line (`-.`), places circular markers (`o`) at the data points, and colors both line and marker red (`r`). Specify the components (in any order) as a quoted string after the data arguments. Note that linespecs are single strings, not property-value pairs.

Plotting Data Points with No Line

If you specify a marker, but not a line style, only the markers are plotted. For example:

```
plot(x,y,'d')
```

Line Style Specifiers

You indicate the line styles, marker types, and colors you want to display using *string specifiers*, detailed in the following tables:

Specifier	LineStyle
`'-'`	Solid line (default)
`'--'`	Dashed line

Specifier	LineStyle
':'	Dotted line
'-.'	Dash-dot line

Marker Specifiers

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)

Note: The point (.) marker type does not change size when the specified value is less than 5.

Color Specifiers

Specifier	Color
r	Red
g	Green
b	Blue

Specifier	Color
`c`	Cyan
`m`	Magenta
`y`	Yellow
`k`	Black
`w`	White

Related Properties

This page also describes how to specify the properties of lines used for plotting. MATLAB graphics give you control over these visual characteristics:

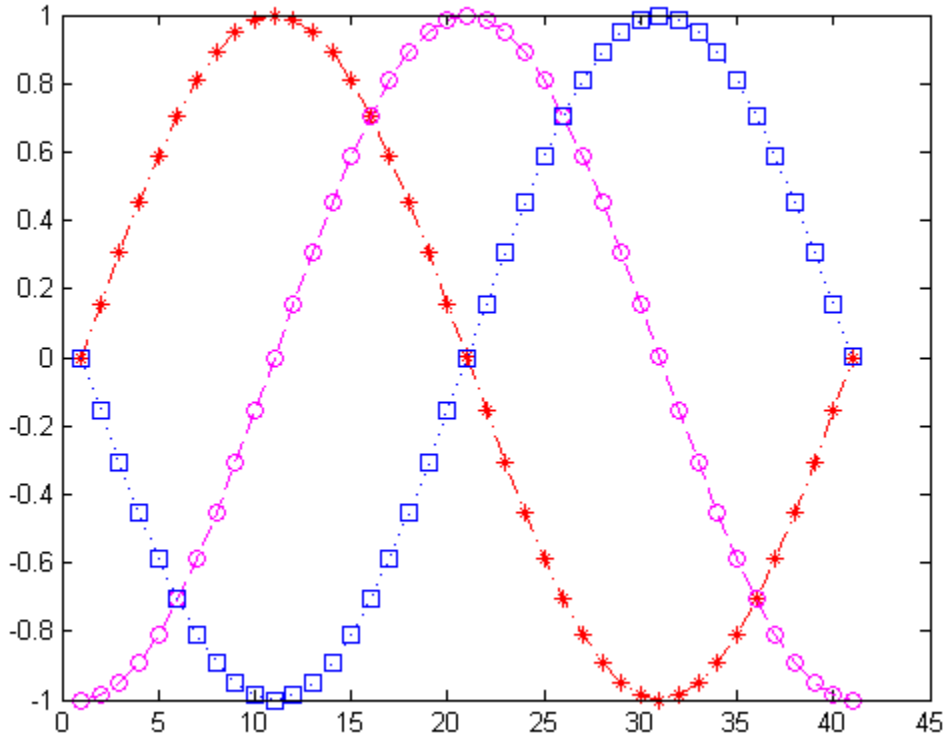
- `LineWidth` — Specifies the width (in points) of the line.
- `MarkerEdgeColor` — Specifies the color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).
- `MarkerFaceColor` — Specifies the color of the face of filled markers.
- `MarkerSize` — Specifies the size of the marker in points (must be greater than 0).

In addition, you can specify the `LineStyle`, `Color`, and `Marker` properties instead of using the symbol string. This is useful if you want to specify a color that is not in the list by using RGB triplet values. See Chart Line Properties for details on these properties and `ColorSpec` for more information on color.

Examples

Plot the sine function over three different ranges using different line styles, colors, and markers.

```
figure
t = 0:pi/20:2*pi;
plot(t,sin(t),'-.r*')
hold on
plot(t,sin(t-pi/2),'--mo')
plot(t,sin(t-pi),':bs')
hold off
```



Create a plot illustrating how to set line properties:

```
figure
plot(t,sin(2*t),'-mo',...
                'LineWidth',2,...
                'MarkerEdgeColor','k',...
                'MarkerFaceColor',[.49 1 .63],...
                'MarkerSize',10)
```

`axes` | `line` | `plot` | `patch` | `set` | `surface` | `ColorSpec`

linkaxes

Synchronize limits of specified 2-D axes

Syntax

```
linkaxes(axes_handles)
linkaxes(axes_handles,'option')
```

Description

Use `linkaxes` to synchronize the individual axis limits across several figures or subplots within a figure. Calling `linkaxes` makes all input axes have identical limits. Linking axes is best when you want to zoom or pan in one subplot and display the same range of data in another subplot.

Note: Use `linkaxes` for axes that remain in 2-D views.

`linkaxes(axes_handles)` links the *x*- and *y*-axis limits of the axes specified in the vector `axes_handles`. You can link any number of existing plots or subplots. The `axes_handles` input should be a vector of the handles for each plot or subplot. Entering an array of values results in an error message.

`linkaxes(axes_handles,'option')` links the axes' `axes_handles` according to the specified option. The `option` argument can be one of the following strings:

`x`	Link *x*-axis only.
`y`	Link *y*-axis only.
`xy`	Link *x*-axis and *y*-axis.
`off`	Remove linking.

See the `linkprop` function for more advanced capabilities that allow you to link object properties on any graphics object.

Examples

Create Subplots and Link Their Axes

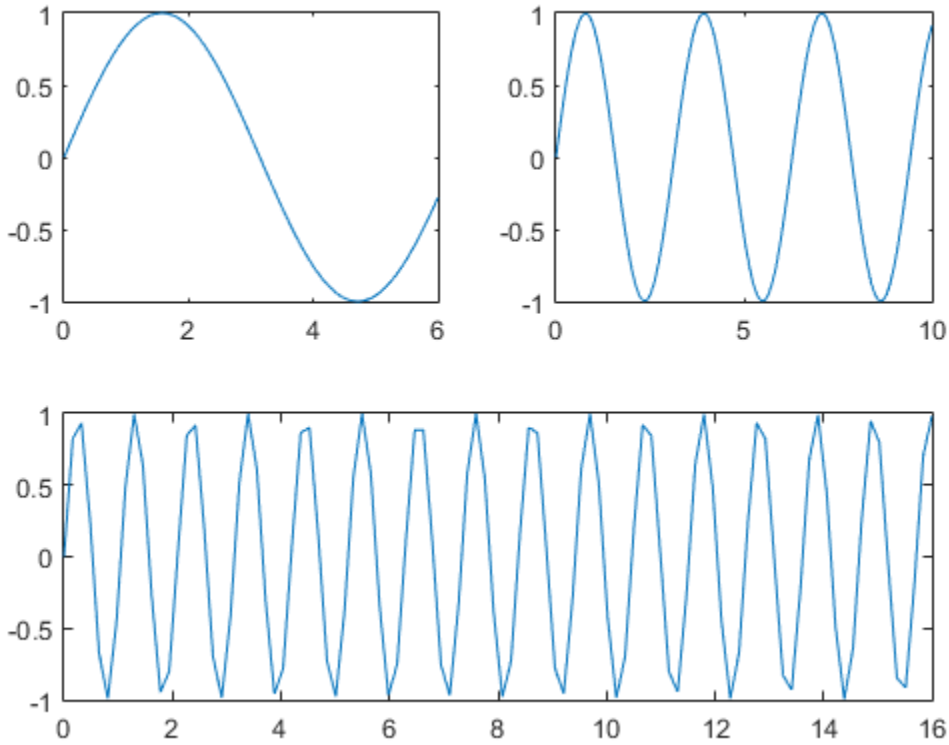
Create three subplots and link their *x*-axes and *y*-axes so that they are always in sync.

First, create a figure with three subplots. Plot data in each subplot.

```
figure
ax1 = subplot(2,2,1);
x1 = linspace(0,6);
y1 = sin(x1);
plot(x1,y1)

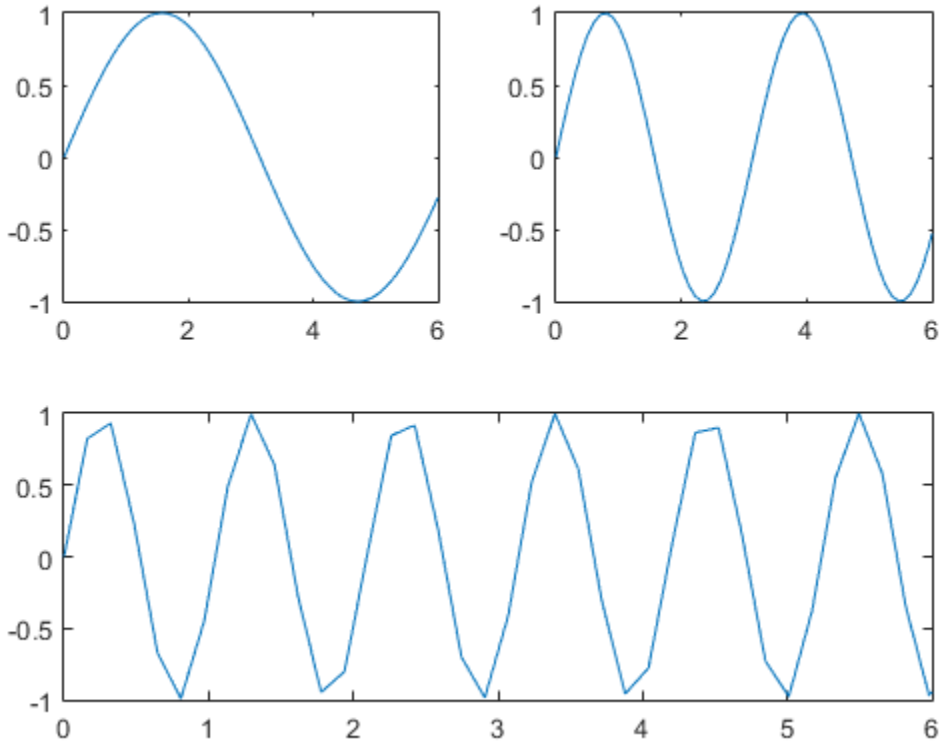
ax2 = subplot(2,2,2);
x2 = linspace(0,10);
y2 = sin(2*x2);
plot(x2,y2)

ax3 = subplot(2,2,[3,4]);
x3 = linspace(0,16);
y3 = sin(6*x3);
plot(x3,y3)
```



Now link the axes for the three subplots using the `linkaxes` function. Pass the string `'xy'` as an input argument to the function to link both the *x*-axes and *y*-axes. The `linkaxes` function uses the limits from the first axes passed to it.

```
linkaxes([ax1,ax2,ax3],'xy')
```



Panning or zooming into one of the subplots displays the same range of data in the other two subplots. To remove the linking, use `linkaxes([ax1,ax2,ax3]),'off'`.

Use Specific Subplot to Determine Limits for All Subplots

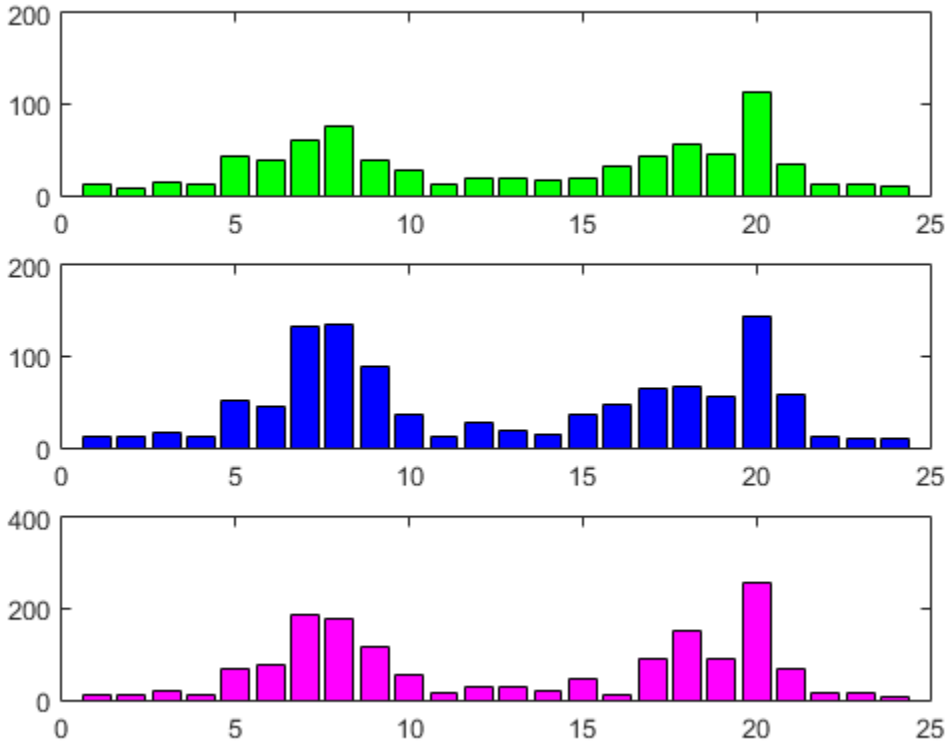
Load the `count.dat` data set which returns a three-column array named `count`. Create a new figure with three subplots and return the axes handles. In each subplot, create a bar graph.

```
load count.dat

figure
ax1 = subplot(3,1,1);
bar(count(:,1),'g');
```

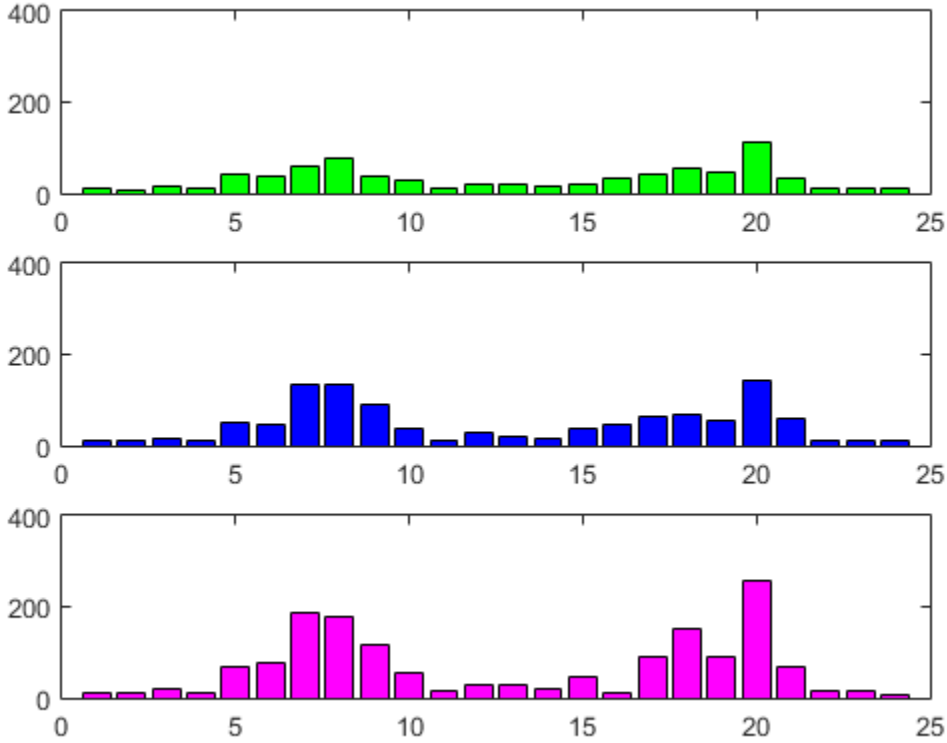
```
ax2 = subplot(3,1,2);
bar(count(:,2),'b');

ax3 = subplot(3,1,3);
bar(count(:,3),'m');
```



Link the *x*-axes and *y*-axes limits using `linkaxes` with the argument `'xy'`. Base the limits on the third subplot by passing its axes handle, `ax3`, as the first input to `linkaxes`.

```
linkaxes([ax3,ax2,ax1],'xy');
```



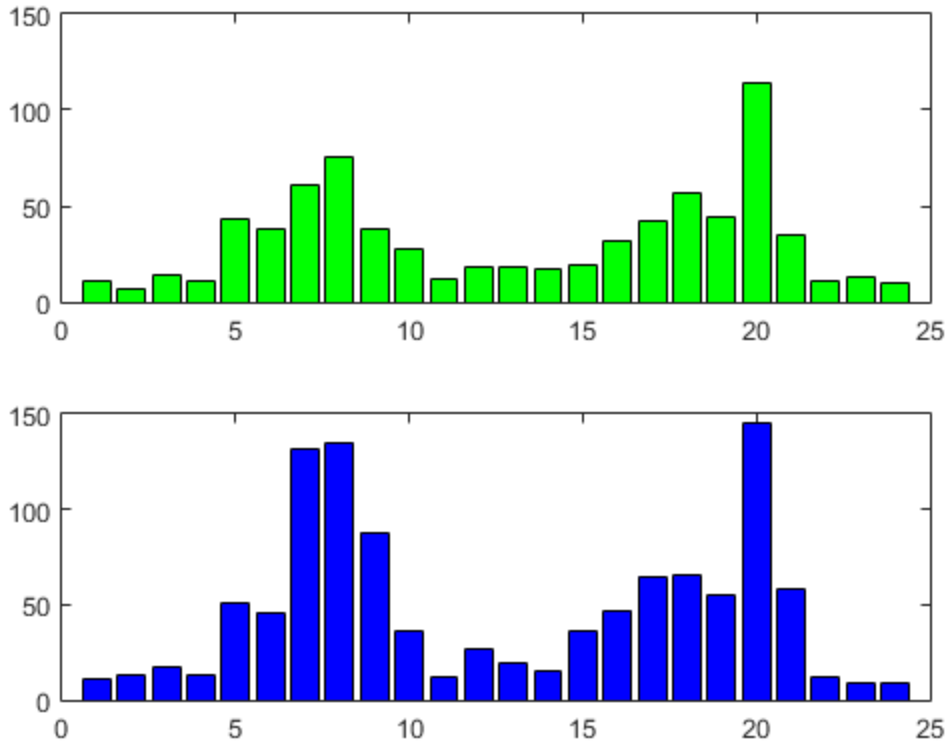
If you zoom in on one subplot, then the other two subplots behave in the same manner. To enable interactive zooming, use `zoom on`. To disable zooming, use `zoom off`.

Link x-Axes And Change Axis Limits

Load the `count.dat` data set which returns a three-column array named `count`. Create a new figure with two subplots and return the axes handles. In each subplot, create a bar graph.

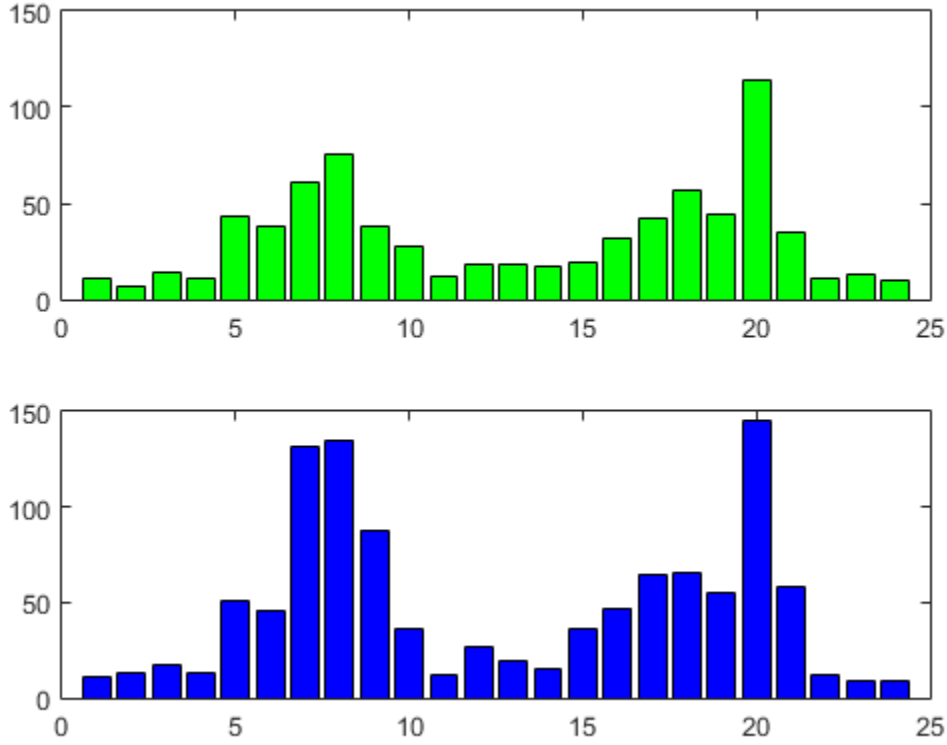
```
load count.dat
figure
ax1 = subplot(2,1,1);
bar(count(:,1),'g');
```

```
ax2 = subplot(2,1,2);
bar(count(:,2),'b');
```



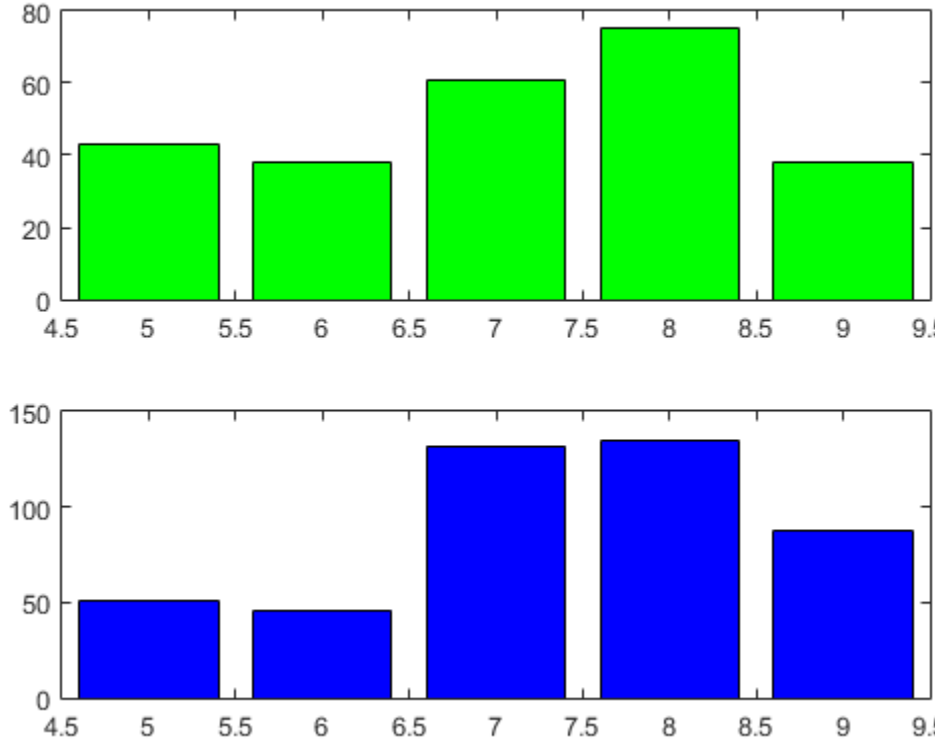
Link the *x*-axes for the two subplots.

```
linkaxes([ax1,ax2],'x');
```



Set the *x*-axis limits for the second subplot. Setting the limits overrides the limits initially set by `linkaxes`. Changing the *x*-axis limits effects both subplots.

```
ax2.XLim = [4.5,9.5];
```



If you pan either subplot, then both subplots pan uniformly in the *x*-direction, but only one subplot moves in the *y*-direction. To enable interactive panning, use `pan on`. To disable panning, use `pan off`.

More About

Tips

The first axes you supply to `linkaxes` determines the *x*- and *y*-limits for all linked axes. This can cause plots to partly or entirely disappear if their limits or scaling are very different. To override this behavior, after calling `linkaxes`, specify the limits of the axes that you want to control with the `set` command, as the third example illustrates.

Note: `linkaxes` is not designed to be transitive across multiple invocations. If you have three axes, `ax1`, `ax2`, and `ax3` and want to link them together, call `linkaxes` with `[ax1, ax2, ax3]` as the first argument. Linking `ax1` to `ax2`, then `ax2` to `ax3`, "unbinds" the `ax1`-`ax2` linkage.

Introduced before R2006a

linkdata

Automatically update graphs when variables change

Syntax

```
linkdata on
linkdata off
linkdata
linkdata(figure_handle,...)
linkobj = linkdata(figure_handle)
```

Description

`linkdata on` turns on data linking for the current figure.

`linkdata off` turns data linking off.

`linkdata` by itself toggles the state of data linking.

`linkdata(figure_handle,...)` applies the function to the specified figure handle.

`linkobj = linkdata(figure_handle)` returns a *linkdata object* for the specified figure. The object has one read-only property, `Enable`, the string `'on'` or `'off'`, depending on the linked state of the figure.

Data linking connects graphs in figure windows to variables in the base or a function's workspace via their `XDataSource`, `YDataSource`, and `ZDataSource` properties. When you turn on data linking for a figure, MATLAB compares variables in the current (base or function caller) workspace with the `XData`, `YData`, and `ZData` properties of graphs in the affected figure to try to match them. When a match is found, the appropriate `XDataSource`, `YDataSource` and/or `ZDataSource` for the graph are set to strings that name the matching variables.

Any subsequent changes to linked variables are reflected in graphs that use them as data sources and in the Variables editor, if the linked variables are displayed there.

Conversely, any changes to plotted data values made at the command line, in the Variables editor, or with the Brush tool (such as deleting or replacing data points), are immediately reflected in the workspace variables linked to the data points.

When a figure containing graphs is linked and any variable identified as `XDataSource`, `YDataSource`, and/or `ZDataSource` changes its values in the workspace, all graphs displaying it in that and other linked figures automatically update. This operation is equivalent to automatically calling the `refreshdata` function on the corresponding figure when a variable changes.

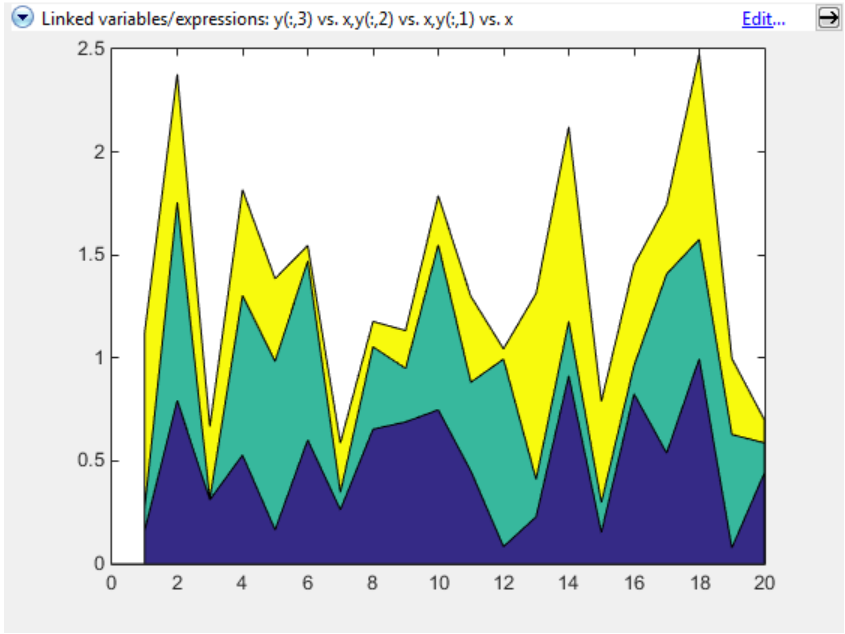
Linked figure windows identify themselves by the appearance of the Linked Plot information bar at the top of the window. When `linkdata` is `off` for a figure, the Linked Plot information bar is removed. If `linkdata` cannot unambiguously identify data sources for a graph in a linked figure, it reports this via the Linked Plot information bar, which gives the user an opportunity to identify data sources. The information bar displays a warning icon and a message, **No graphics have data sources** and also prompts **fix it**. Clicking **fix it** opens the Specify Data Source Properties dialog box for identifying variable names and ranges of data sources used in the graph.

Examples

Example 1

Create two variables, plot them as area charts, and link the plot to them:

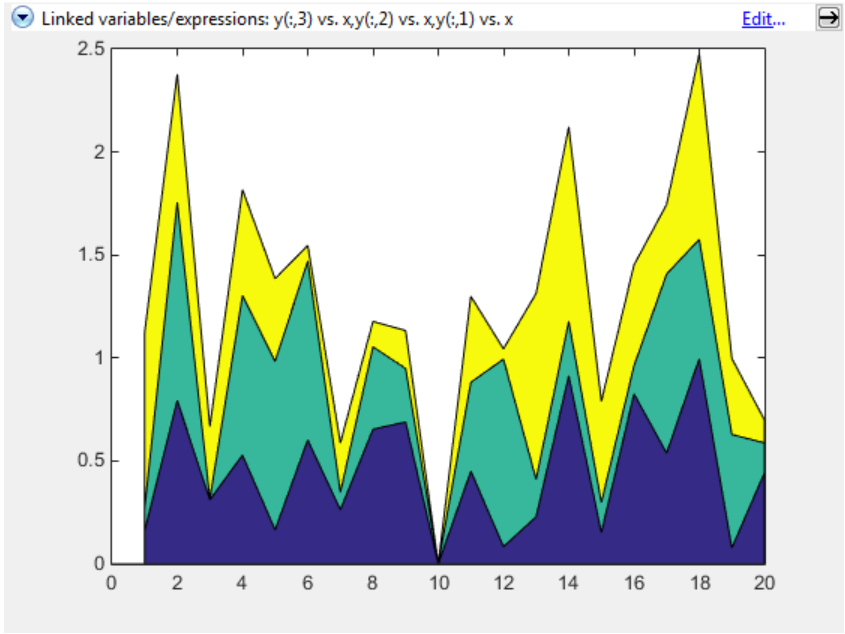
```
x = 1:20;
y = rand(20,3);
area(x,y)
linkdata on
```



Change values for linked variable `y` in the workspace:

```
y(10,:) = 0;
```

The area graph immediately updates.



Example 2

Delete a figure if it is not linked, based on a returned `linkdata` object:

```
fig = figure;
ld = linkdata(fig)
```

```
ld =
     graphics.linkdata
```

```
if strcmp(ld.Enable,'off')
    delete(fig)
end
```

Example 3

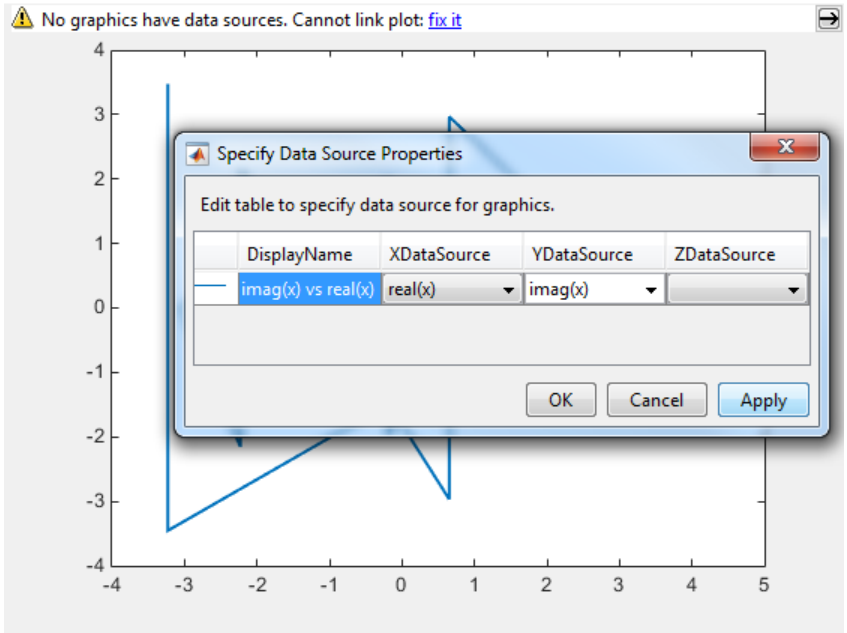
If a plotting function can display a complex variable, then you can link such plots. To do so, you need to describe the data sources as expressions to separate the real and imaginary parts of the variable. For example,

```
x = eig(randn(20,20));
whos
  Name        Size       Bytes  Class     Attributes
  x          20x1         320  double    complex
```

yields a complex vector. You can use `plot` to display the real portion as *x* and the imaginary portion as *y*, then link the graph to the variable:

```
plot(x)
linkdata
```

However, `linkdata` cannot unambiguously identify the graph's data sources, and you must tell it by typing `real(x)` and `imag(x)` into the Specify Data Source Properties dialog box that displays when you click **fix it** in the Linked Plot information bar.



To avoid having to type the data source names in the dialog box, you can specify them when you plot:

```
plot(x,'XDataSource','real(x)','YDataSource','imag(x)')
```

If you subsequently change values of `x` programmatically or manually, the plot updates accordingly.

Note: Although you can use data brushing on linked plots of complex data, your brush marks only appear in the plot you are brushing, not in other plots or in the Variables editor. This is because function calls, such as `real(x)` and `imag(x)`, that you specify as data sources are not interpreted when brushing graphed data.

More About

Tips

Types of Variables You Can Link

You can use `linkdata` to connect a graph with scalar, vector and matrix numeric variables of any class (including `complex`, if the graphing function can plot it) — essentially any data for which `isnumeric` equals `true`. See "Example 3" on page 1-4525 for instructions on linking complex variables. You can also link plots to numeric fields within structures. You can specify MATLAB expressions as data sources, for example, `sqrt(y)+1`.

Restoring Links that Break

Refreshing data on a linked plot fails if the strings in the `XDataSource`, `YDataSource`, or `ZDataSource` properties, when evaluated, are incompatible with what is in the current workspace, such that the corresponding `XData`, `YData`, or `ZData` are unable to respond. The visual appearance of the object in the graph is not affected by such failures, so graphic objects show no indication of broken links. Instead, a warning icon and the message **Failing links** appear on the Linked Plot information bar along with an **Edit** button that opens the Specify Data Sources dialog box.

Linking Rapidly Changing Data

`linkdata` buffers updates to data and dispatches them to plots at roughly half-second intervals. This makes data linking not suitable for smoothly animating changes in data

values unless they are updated in loops that are forced to execute two times per second or less.

One consequence of buffering link updates is that `linkdata` might not detect changes in data streams it monitors. If you are running a function that uses `assignin` or `evalin` to update workspace variables, `linkdata` can sometimes fail to process updates that change values but not the size and class of workspace variables. Such failures only happen when the function itself updates the plot.

Linking Brushed Graphs

If you link data sources to graphs that have been brushed, their brushing marks can change or vanish. This is because the workspace variables in those graphs now dictate which, if any, observations are brushed, superseding any brushing annotations that were applied to their graphical data (`YData`, etc.). For more details, see "How Data Linking Affects Data Brushing" in the `brush` reference page.

- "Making Graphs Responsive with Data Linking"

`brush` | `linkaxes` | `linkprop` | `refreshdata`

linkprop

Keep same value for corresponding properties of graphics objects

Syntax

```
hlink = linkprop(obj_handles,'PropertyName')
```

```
hlink = linkprop(obj_handles,{'PropertyName1','PropertyName2',...})
```

Description

Use `linkprop` to maintain the same values for the corresponding properties of different graphics objects.

Note: Use `linkprop` only with Handle Graphics objects.

`hlink = linkprop(obj_handles,'PropertyName')` maintains the same value for the property *`PropertyName`* on all objects whose handles appear in `obj_handles`. `linkprop` returns the link object in `hlink`. See “About Link Objects” on page 1-4530 for more information.

`hlink = linkprop(obj_handles,{'PropertyName1','PropertyName2',...})` maintains the same respective values for all properties passed as a cell array on all objects whose handles appear in `obj_handles`.

MATLAB updates the linked properties of all linked objects immediately when `linkprop` is called. The first object in the list `obj_handles` determines the property values for the other objects.

A set of graphics objects can have only one link object connecting their properties at any given time. Calling `linkprop` creates a new link object. This new link object replaces any existing link object that is associated with the objects specified in `obj_handles`. However, you can manage which properties and which objects are linked by calling methods on that object:

- To add an object to the list of linked objects, use the `addtarget` method.

- To link new properties of currently-linked objects, use the `addprop` method.
- To stop linking an object, use the `removetarget` method.
- To stop properties from linking, use the `removeprop` method.

About Link Objects

The link object that `linkprop` returns stores the mechanism that links the properties of different graphics objects. Therefore, the link object must exist within the context where you want property linking to occur (such as in the base workspace if users are to interact with the objects from the command line or figure tools).

The following list describes ways to maintain a reference to the link object.

- Return the link object as an output argument from a function and keep it in the base workspace while interacting with the linked objects.
- Make the `hlink` variable global.
- Store the `hlink` variable in an object's `UserData` property or in application data.

Updating a Link Object

If you want to change either the graphics objects or the properties that are linked, you need to use the link object methods designed for that purpose. These methods are functions that operate only on link objects. To use them, you must first create a link object using `linkprop`.

Method	Purpose
`addtarget`	Add specified graphics object to the link object's targets.
`removetarget`	Remove specified graphics object from the link object's targets.
`addprop`	Add specified property to the linked properties.
`removeprop`	Remove specified property from the linked properties.

Method Syntax

```
ddtarget(hlink,obj_handles)
```

```
removetarget(hlink,obj_handles)
addprop(hlink,'PropertyName')
removeprop(hlink,'PropertyName')
```

Method Arguments

- `hlink` — Link object returned by `linkprop`
- `obj_handles` — One or more graphic object handles
- *`PropertyName`* — Name of a property common to all target objects

Examples

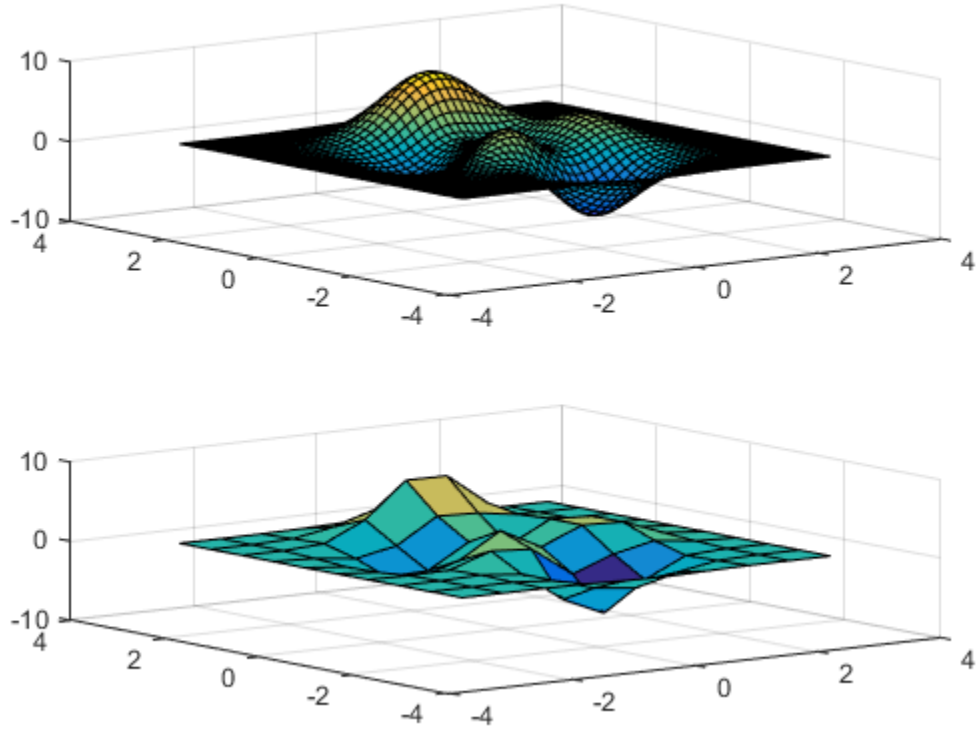
Link Axes So They Rotate Simultaneously

Link properties of two axes so that rotating one axes automatically rotates the other.

Create a figure with two axes and store the axes handles. Add plots to both axes.

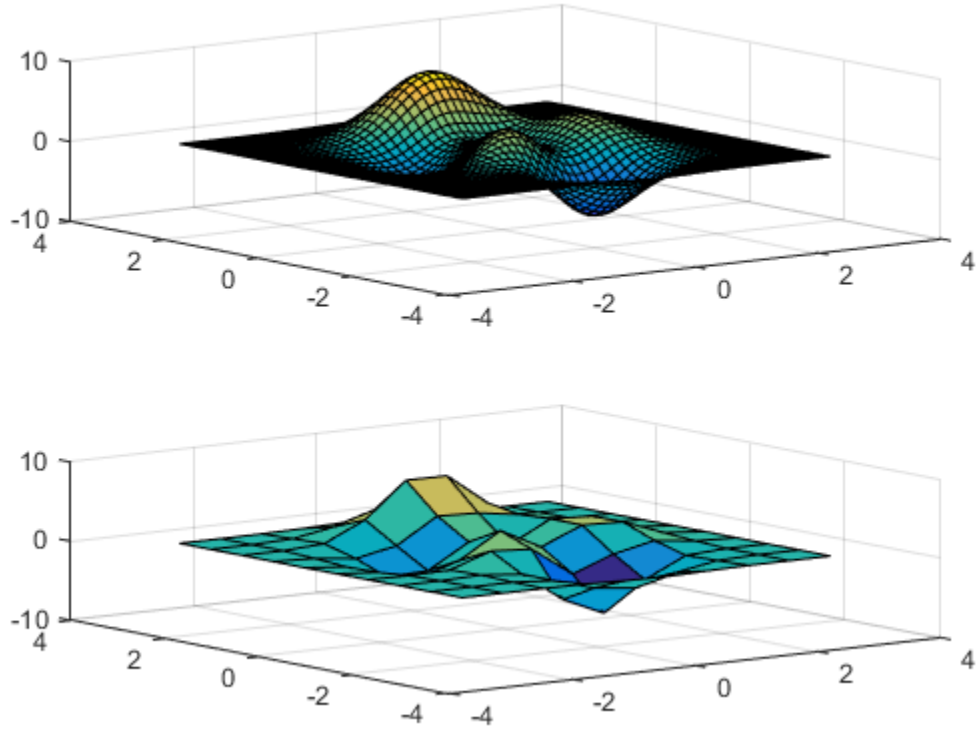
```
figure
ax1 = subplot(2,1,1);
[X1,Y1,Z1] = peaks;
surf(X1,Y1,Z1)

ax2 = subplot(2,1,2);
[X2,Y2,Z2] = peaks(10);
surf(X2,Y2,Z2)
```



Link the `CameraPosition` and `CameraUpVector` properties of the axes and return the link object handle. Then, enable interactive rotation and use the mouse to rotate either axes. Rotating one axes automatically rotates the other in the same manner.

```
hlink = linkprop([ax1,ax2],{'CameraPosition','CameraUpVector'});
rotate3d on
```



To disable interactive rotation, use `rotate3d off`.

Link an additional property by passing the link object handle and the property name to `addprop`.

```
addprop(hlink,'PlotBoxAspectRatio')
```

`getappdata` | `linkdata` | `setappdata` | `ishghandle` | `linkaxes`

Introduced before R2006a

linsolve

Solve linear system of equations

Syntax

```
X = linsolve(A,B)
X = linsolve(A,B,opts)
```

Description

`X = linsolve(A,B)` solves the linear system `A*X = B` using LU factorization with partial pivoting when A is square and QR factorization with column pivoting otherwise. The number of rows of `A` must equal the number of rows of `B`. If `A` is m-by-n and `B` is m-by-k, then `X` is n-by-k. `linsolve` returns a warning if `A` is square and ill conditioned or if it is not square and rank deficient.

`[X, R] = linsolve(A,B)` suppresses these warnings and returns `R`, which is the reciprocal of the condition number of `A` if `A` is square, or the rank of `A` if `A` is not square.

`X = linsolve(A,B,opts)` solves the linear system `A*X = B` or `A'*X = B`, using the solver that is most appropriate given the properties of the matrix `A`, which you specify in `opts`. For example, if `A` is upper triangular, you can set `opts.UT = true` to make `linsolve` use a solver designed for upper triangular matrices. If `A` has the properties in `opts`, `linsolve` is faster than `mldivide`, because `linsolve` does not perform any tests to verify that `A` has the specified properties.

Notes If `A` does not have the properties that you specify in `opts`, `linsolve` returns incorrect results and does not return an error message. If you are not sure whether `A` has the specified properties, use `mldivide` instead.

For small problems, there is no speed benefit in using `linsolve` on triangular matrices as opposed to using the `mldivide` function.

The `TRANSA` field of the `opts` structure specifies the form of the linear system you want to solve:

- If you set `opts.TRANSA = false`, `linsolve(A,B,opts)` solves `A*X = B`.
- If you set `opts.TRANSA = true`, `linsolve(A,B,opts)` solves `A'*X = B`.

The following table lists all the field of `opts` and their corresponding matrix properties. The values of the fields of `opts` must be `logical` and the default value for all fields is `false`.

Field Name	Matrix Property
`LT`	Lower triangular
`UT`	Upper triangular
`UHESS`	Upper Hessenberg
`SYM`	Real symmetric or complex Hermitian
`POSDEF`	Positive definite
`RECT`	General rectangular
`TRANSA`	Conjugate transpose — specifies whether the function solves `A*X = B` or `A'*X = B`

The following table lists all combinations of field values in `opts` that are valid for `linsolve`. A true/false entry indicates that `linsolve` accepts either true or false.

LT	UT	UHESS	SYM	POSDEF	RECT	TRANSA
true	false	false	false	false	true/false	true/false
false	true	false	false	false	true/false	true/false
false	false	true	false	false	false	true/false
false	false	false	true	true/fals	false	true/false
false	false	false	false	false	true/false	true/false

Examples

The following code solves the system `A'x = b` for an upper triangular matrix `A` using both `mldivide` and `linsolve`.

```
A = triu(rand(5,3)); x = [1 1 1 0 0]'; b = A'*x;
y1 = (A')\b
```

```
opts.UT = true; opts.TRANSA = true;
y2 = linsolve(A,b,opts)

y1 =

    1.0000
    1.0000
    1.0000
         0
         0

y2 =

    1.0000
    1.0000
    1.0000
         0
         0
```

Note If you are working with matrices having different properties, it is useful to create an options structure for each type of matrix, such as `opts_sym`. This way you do not need to change the fields whenever you solve a system with a different type of matrix `A`.

See Also

`mldivide`

Introduced before R2006a

linspace

Generate linearly spaced vector

Syntax

```
y = linspace(x1,x2)
y = linspace(x1,x2,n)
```

Description

`y = linspace(x1,x2)` returns a row vector of 100 evenly spaced points between `x1` and `x2`.

`y = linspace(x1,x2,n)` generates `n` points. The spacing between the points is `(x2-x1)/(n-1)`.

`linspace` is similar to the colon operator, "`:`", but gives direct control over the number of points and always includes the endpoints. "`lin`" in the name "`linspace`" refers to generating linearly spaced values as opposed to the sibling function `logspace`, which generates logarithmically spaced values.

Examples

Vector of Evenly Spaced Numbers

Create a vector of 100 evenly spaced points in the interval `[-5,5]`.

```
y = linspace(-5,5);
```

Vector with Specified Number of Values

Create a vector of 7 evenly spaced points in the interval `[-5,5]`.

```
y1 = linspace(-5,5,7)
```

```
y1 =
```

```
   -5.0000   -3.3333   -1.6667         0    1.6667    3.3333    5.0000
```

Vector of Evenly Spaced Complex Numbers

Create a vector of complex numbers with 8 evenly spaced points between `1+2i` and `10+10i`.

```
y = linspace(1+2i,10+10i,8)
```

```
y =

  Columns 1 through 5

   1.0000 + 2.0000i   2.2857 + 3.1429i   3.5714 + 4.2857i   4.8571 + 5.4286i   6.1429 +

  Columns 6 through 8

   7.4286 + 7.7143i   8.7143 + 8.8571i  10.0000 +10.0000i
```

Input Arguments

`x1,x2` — Point interval

pair of numeric scalars

Point interval, specified as a pair of numeric scalars. `x1` and `x2` define the interval over which `linspace` generates points. `x1` and `x2` can be real or complex, and `x2` can be either larger or smaller than `x1`. If `x2` is smaller than `x1`, then the vector contains descending values.

Data Types: `single` | `double` | `datetime` | `duration`
Complex Number Support: Yes

`n` — Number of points

100 (default) | real numeric scalar

Number of points, specified as a real numeric scalar.

- If `n` is `1`, `linspace` returns `x2`.
- If `n` is zero or negative, `linspace` returns an empty 1-by-0 matrix.
- If `n` is not an integer, `linspace` rounds down and returns `floor(n)` points.

See Also

`colon` | `logspace`

Introduced before R2006a

RandStream.list

Random number generator algorithms

Class

`RandStream`

Syntax

```
RandStream.list
```

Description

`RandStream.list` lists all the generator algorithms that can be used when creating a random number stream with `RandStream` or `RandStream.create`. The available generator algorithms and their properties are given in the following table.

Keyword	Generator	Multiple Stream and Substream Support	Approximate Period In Full Precision
mt19937ar	Mersenne twister (used by default stream at MATLAB startup)	No	$2^{19937}-1$
dsfmt19937	SIMD-oriented fast Mersenne twister	No	$2^{19937}-1$
mcg16807	Multiplicative congruential generator	No	$2^{31}-2$
mlfg6331_64	Multiplicative lagged Fibonacci generator	Yes	2^{124}
mrg32k3a	Combined multiple recursive generator	Yes	2^{127}

Keyword	Generator	Multiple Stream and Substream Support	Approximate Period In Full Precision
shr3cong	Shift-register generator summed with linear congruential generator	No	2^{64}
swb2712	Modified subtract with borrow generator	No	2^{1492}

See " Choosing a Random Number Generator" for details about these generator algorithms. See http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html for a full description of the Mersenne twister algorithm.

More About

- "Creating and Controlling a Random Number Stream"

listdlg

Create list-selection dialog box

Syntax

```
[Selection,ok] = listdlg(Name,Value,...)
```

Description

`[Selection,ok] = listdlg(Name,Value,...)` creates a modal dialog that allows the user to select one or more items from a list. The function returns two output arguments containing information about the items the user selected. The first output, `Selection`, contains the indices of the selected rows in the list. `Selection` is an empty array when no selection is made. The second output, `ok`, is 0 when no selection is made, or 1 when a selection is made.

The input arguments, `Name,Value`, are pairs of arguments that specify certain aspects of the dialog box. The pair, `'ListString',S` is required, but you can optionally specify any number of other pairs. This table lists all possible `Name,Value` input arguments:

Name	Value
`'ListString'` (required)	Cell array of strings that specify the list items.
`'SelectionMode'`	String indicating whether one or many items can be selected: `'single'` or `'multiple'` (the default).
`'ListSize'`	List box size in pixels, specified as a two-element vector `[width height]`. Default is `[160 300]`.
`'InitialValue'`	Vector of indices of the list box items that are initially selected. Default is 1, the first item.
`'Name'`	String for the dialog box's title. Default is an empty string.
`'PromptString'`	String matrix or cell array of strings that appears as text above the list box. Default is an empty cell array.

Name	Value
`'OKString'`	String for the OK button. Default is `'OK'`.
`'CancelString'`	String for the Cancel button. Default is `'Cancel'`.
`'uh'`	Uicontrol button height, in pixels. Default is 18.
`'fus'`	Frame/uicontrol spacing, in pixels. Default is 8.
`'ffs'`	Frame/figure spacing, in pixels. Default is 8.

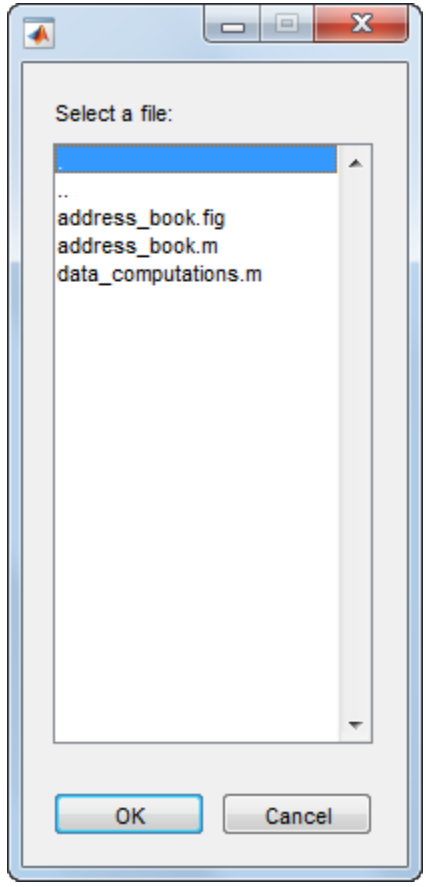
Double-clicking on an item or pressing **Return** when multiple items are selected has the same effect as clicking the **OK** button. The dialog box has a **Select all** button (when in multiple selection mode) that enables you to select all list items.

Examples

This example displays a dialog box that enables the user to select a file from the current directory.

The `listdlg` function returns two output arguments. The first output, `s`, is the index to the selected row in the list. The second output, `v`, is 0 when no selection is made, or 1 when a selection is made.

```
d = dir;
str = {d.name};
[s,v] = listdlg('PromptString','Select a file:',...
                'SelectionMode','single',...
                'ListString',str)
```



More About

Modal Dialog

A window that blocks interaction with other windows until the user closes the blocking window. For more information, see the figure `WindowStyle` property description.

`uigetfile` | `uigetdir` | `questdlg` | `uicontrol`

Introduced before R2006a

listfonts

List available system fonts

Syntax

```
c = listfonts
c = listfonts(h)
```

Description

`c = listfonts` returns sorted list of available system fonts.

`c = listfonts(h)` returns sorted list of available system fonts and includes the `FontName` property of the object with handle `h`.

Examples

Example 1

This example returns a list of available system fonts similar in format to the one shown.

```
list = listfonts
```

```
list =
    'Agency FB'
    'Algerian'
    'Arial'
    ...
    'ZapfChancery'
    'ZapfDingbats'
    'ZWAdobeF'
```

Example 2

This example returns a list of available system fonts with the value of the `FontName` property, for the object with handle `h`, included and sorted in the list.

```
 h = uicontrol('Style','text','String',...
     'My Font','FontName','MyFont');
 list = listfonts(h)
```

```
list =
    'Agency FB'
    'Algerian'
    'Arial'
    ...
    'MyFont'
    ...
    'ZapfChancery'
    'ZapfDingbats'
    'ZWAdobeF'
```

More About

Tips

Calling `listfonts` returns a list of all fonts on your system, possibly including fonts that you cannot use with MATLAB. Consider using the `uisetfont` function to preview fonts to that MATLAB can render in figure windows. Like `uisetfont`, the **Custom Fonts** pane of MATLAB Preferences also previews available fonts and only shows those that MATLAB can render.

See Also

`uisetfont`

load

Load variables from file into workspace

Syntax

```
load(filename)
load(filename,variables)
load(filename,'-ascii')
load(filename,'-mat')
load(filename,'-mat',variables)

S = load( ___ )

load filename
```

Description

`load(filename)` loads data from `filename`.

- If `filename` is a MAT-file, then `load(filename)` loads variables in the MAT-File into the MATLAB workspace.
- If `filename` is an ASCII file, then `load(filename)` creates a double-precision array containing data from the file.

`load(filename,variables)` loads the specified variables from the MAT-file, `filename`.

`load(filename,'-ascii')` treats `filename` as an ASCII file, regardless of the file extension.

`load(filename,'-mat')` treats `filename` as a MAT-file, regardless of the file extension.

`load(filename,'-mat',variables)` loads the specified variables from `filename`.

`S = load( ___ )` loads data into `S`, using any of the input arguments in the previous syntax group.

- If `filename` is a MAT-file, then `S` is a structure array.
- If `filename` is an ASCII file, then `S` is a double-precision array containing data from the file.

`load filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to load a file named `durer.mat`, these statements are equivalent:

```
load durer.mat      % command form
load('durer.mat')   % function form
```

You can include any of the inputs described in previous syntaxes. For example, to load the variable named `X`:

```
load durer.mat X       % command form
load('durer.mat','X')  % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

Examples

Load All Variables from MAT-File

Load all variables from the example MAT-file, `gong.mat`. Check the contents of the workspace before and after the load operation.

```
disp('Contents of workspace before loading file:')
whos

disp('Contents of gong.mat:')
whos('-file','gong.mat')

load('gong.mat')
disp('Contents of workspace after loading file:')
whos
```

You also can use command syntax to load the variables. Clear the previously loaded variables and repeat the `load` operation.

```
clear y Fs
```

```
load gong.mat
```

Load Specific Variable From MAT-File

Load only variable `y` from example file `handel.mat`. If the workspace already contains variable `y`, the `load` operation overwrites it with data from the file.

```
load('handel.mat','y')
```

You also can use command syntax to load the variable, `y`.

```
load handel.mat y
```

Use Regular Expressions to Load Specific Variables

View the contents of the example file, `accidents.mat`.

```
whos -file accidents.mat
```

```
 Name              Size             Bytes  Class     Attributes

  datasources       3x1              2724  cell
  hwycols           1x1                 8  double
  hwydata          51x17             6936  double
  hwyheaders        1x17              2758  cell
  hwyidx           51x1                408  double
  hwyrows           1x1                 8  double
  statelabel       51x1               6596  cell
  ushwydata         1x17               136  double
  uslabel           1x1                138  cell
```

Use function syntax to load all variables with names not beginning with `'hwy'`, from the file.

```
load('accidents.mat', '-regexp', '^(?!hwy)...')
```

Alternatively, use command syntax to load the same variables.

```
load accidents.mat -regexp '^(?!hwy)...'
```

Load List of Variables into Structure Array

The file, `durer.mat`, contains variables `X`, `caption`, and `map`. Create a cell array of variable names to load.

```
filename = 'durer.mat';
```

```
myVars = {'X','caption'};
S = load(filename,myVars{:})

S =

          X: [648x509 double]
    caption: [2x28 char]
```

Only the variables `X` and `caption` are loaded into the structure array, `S`.

Load ASCII File

Create an ASCII file from several 4-column matrices, and load the data back into a double-precision array.

```
a = magic(4);
b = ones(2, 4) * -5.7;
c = [8 6 4 2];
save -ascii mydata.dat a b c
clear a b c

load mydata.dat -ascii
```

`load` creates an array of type `double` named `mydata`.

View information about `mydata`.

```
whos mydata

Name        Size            Bytes  Class     Attributes

mydata      7x4               224  double
```

Input Arguments

`filename` — Name of file

`matlab.mat` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `load` function searches for a file named `matlab.mat`.

`filename` can include a file extension and a full or partial path. If `filename` has no extension (that is, no text after a period), `load` looks for a file named `filename.mat`. If

`filename` has an extension other than `.mat`, the `load` function treats the file as ASCII data.

When using the command form of `load`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, `load 'filename withspace.mat'`.

ASCII files must contain a rectangular table of numbers, with an equal number of elements in each row. The file delimiter (the character between elements in each row) can be a blank, comma, semicolon, or tab character. The file can contain MATLAB comments (lines that begin with a percent sign, `%`).

Example: `'myFile.mat'`

Data Types: `char`

`variables` — Names of variables to load

string

Names of variables to load, specified as one or more strings. When using the command form of `load`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of `variables` Input	Variables to Load
`var1,...,varN`	Load the listed variables, specified as individual strings. Use the `'*'` wildcard to match patterns. For example, `load('filename.mat','A*')` or `load filename.mat A*` loads all variables in the file whose names start with `A`.
`'-regexp',`*`expr1,...,exprN`*	Load only the variables or fields whose names match the regular expressions, specified as strings. For example, `load('filename.mat','-regexp','^Mon','^Tues')` or `load filename.mat -regexp ^Mon ^Tues` loads only the variables in the file whose names begin with `Mon` or `Tues`.

Data Types: `char`

Output Arguments

S — Loaded variables or data

structure array | m-by-n array

Loaded variables, returned as a structure array, if `filename` is a MAT-File.

Loaded data, returned as an `m`-by-`n` array of type `double`, if `filename` is an ASCII file. `m` is equal to the number of lines in the file, and `n` is equal to the number of values on a line.

More About

Algorithms

If you do not specify an output for the `load` function, MATLAB creates a variable named after the loaded file (minus any file extension). For example, the command

```
load mydata.dat
```

reads data into a variable called `mydata`.

To create the variable name, `load` precedes any leading underscores or digits in `filename` with an `X` and replaces any other nonalphabetic characters with underscores. For example, the command

```
load 10-May-data.dat
```

creates a variable called `X10_May_data`.

Introduced before R2006a

load (COM)

Initialize control object from file

Syntax

```
load(h,'filename')
```

Description

`load(h,'filename')` initializes the COM object associated with the interface represented by the MATLAB COM object `h` from file specified in the string `filename`. The file must have been created previously by serializing an instance of the same control.

COM functions are available on Microsoft Windows systems only.

Note The COM `load` function is only supported for controls at this time.

Examples

Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
save(h,'mwsample')
```

Now, alter the figure by changing its label and the radius of the circle.

```
h.Label = 'Circle';
h.Radius = 50;
Redraw(h);
```

Using the `load` function, you can restore the control to its original state.

```
load(h,'mwsample');
get(h)

ans =
     Label: 'Label'
```

```
Radius: 20
```

See Also

save (COM) | delete (COM) | actxcontrol | actxserver | release

Introduced before R2006a

load (serial)

Load serial port objects and variables into MATLAB workspace

Syntax

```
load filename
load filename obj1 obj2 ...
out = load('filename','obj1','obj2',...)
```

Description

`load filename` returns all variables from the file specified by `filename` into the MATLAB workspace.

`load filename obj1 obj2 ...` returns the serial port objects specified by `obj1 obj2 ...` from the file `filename` into the MATLAB workspace.

`out = load('filename','obj1','obj2',...)` returns the specified serial port objects from the file `filename` as a structure to `out` instead of directly loading them into the workspace. The field names in `out` match the names of the loaded serial port objects.

Examples

Note: This example is based on a Windows platform.

Suppose that you create the serial port objects `s1` and `s2`, configure a few properties for `s1`, and connect both objects to their instruments:

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s1,'Parity','mark','DataBits',7);
fopen(s1);
fopen(s2);
```

Save `s1` and `s2` to the file `MyObject.mat`, and then load the objects back into the workspace:

```
save MyObject s1 s2;
load MyObject s1;
load MyObject s2;

get(s1, {'Parity', 'DataBits'})

ans =
    'mark'    [7]

get(s2, {'Parity', 'DataBits'})

ans =
    'none'    [8]
```

More About

Tips

Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

See Also

`save` | `Status`

Introduced before R2006a

loadlibrary

Load C/C++ shared library into MATLAB

Syntax

```
loadlibrary(libname,hfile)
loadlibrary(libname)
loadlibrary(libname,hfile,Name,Value)

loadlibrary(libname,@protofile)

[notfound,warnings] = loadlibrary( ___ )
```

Description

`loadlibrary(libname,hfile)` loads functions from shared library, libname, defined in header file, hfile, into MATLAB.

`loadlibrary(libname)` loads the library if the name of the header file is the same as the name of the library file.

`loadlibrary(libname,hfile,Name,Value)` loads the library with one or more Name,Value arguments.

`loadlibrary(libname,@protofile)` uses a prototype file, `protofile`, in place of a header file.

`[notfound,warnings] = loadlibrary( ___ )` returns warning information, and can include any of the input arguments in previous syntaxes.

Examples

Load Functions in shrlibsample Library

Add path to `examples` folder.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

Load `shrlibsample`.

```
loadlibrary('shrlibsample')
```

Cleanup.

```
unloadlibrary shrlibsample
```

Load Library Using Header File

The header file for the `libmx` library is `matrix.h`.

```
hfile = fullfile(matlabroot,'extern','include','matrix.h');
loadlibrary('libmx',hfile)
```

Cleanup.

```
unloadlibrary libmx
```

Load Library Using Multiple Header Files

Suppose that you have a library, `mylib`, with the header file, `mylib.h`. The header file contains the statement, `#include header2.h`. To use functions defined in `header2.h`, call `loadlibrary` with the `addheader` option.

```
loadlibrary('mylib','mylib.h','addheader','header2')
```

Load Library Using an Alias Name

Create an alias, `lib`, for library, `shrlibsample`.

```
loadlibrary('shrlibsample','shrlibsample.h','alias','lib')
```

Use the alias name, `lib`, to call a function in the library.

```
str = 'This was a Mixed Case string';
calllib('lib','stringToUpper',str)
```

```
ans =
   THIS WAS A MIXED CASE STRING
```

Cleanup.

```
unloadlibrary lib
```

Search Alternative Paths for Header Files

Add path to folder containing `shrlibsample` and its header file, `shrlibsample.h`.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

The `shrlibsample.h` header file includes the header file, `shrhelp.h`. If `shrhelp.h` is in a different folder, for example, `c:\work`, use the `'includepath'` option to tell MATLAB where to find the file.

```
loadlibrary('shrlibsample','shrlibsample.h','includepath','c:\work')
```

Cleanup.

```
unloadlibrary shrlibsample
```

Create Alias Name for MATLAB mxGetNumberOfDimensions Function

This example shows how to replace the `mxGetNumberOfDimensions` function name in the MATLAB Matrix Library API with a shorter alias name, `mxGetDims`. Use a prototype file to define the alias name, then load the library using the prototype file as the header file.

Use a folder for which you have write-access.

```
cd('c:\work')
```

Create a prototype file, `mxproto.m`.

```
hfile = fullfile(matlabroot,'extern','include','matrix.h');
loadlibrary('libmx',hfile,'mfilename','mxproto')
```

MATLAB creates the prototype file in the current folder.

Add the alias name to the prototype file. Open the file in MATLAB Editor.

```
edit mxproto.m
```

Search for the function `mxGetNumberOfDimensions`.

The following command assigns the alias `mxGetDims`.

```
fcns.alias{fcnNum}='mxGetDims';
```

Add the command to the line before the command to increment `fcnNum`. The new function prototype, with the new command shown in bold, looks like this:

```
fcns.name{fcnNum}='mxGetNumberOfDimensions';
fcns.calltype{fcnNum}='cdecl';
fcns.LHS{fcnNum}='int32';
fcns.RHS{fcnNum}={'MATLAB array'};
fcns.alias{fcnNum}='mxGetDims'; % Alias defined
fcnNum=fcnNum+1; % Increment fcnNum
```

Reload `libmx` using the prototype file.

```
unloadlibrary libmx
loadlibrary('libmx',@mxproto)
```

Call the function by its alias name.

```
y = rand(4,7,2);
calllib('libmx','mxGetDims',y)

ans =
     3
```

Input Arguments

`libname` — Name of shared library

string

Name of shared library, specified as a string. The name is case-sensitive and must match the file on your system.

On Microsoft Windows systems, `libname` refers to the name of a shared library (`.dll`) file. On Linux systems, it refers to the name of a shared object (`.so`) file. On Apple Macintosh systems, it refers to a dynamic shared library (`.dylib`). If you do not include a file extension with the `libname` argument, `loadlibrary` attempts to find the library with either the appropriate platform MEX-file extension or the appropriate platform library extension. For a list of MEX-file extensions, use `mexext`.

MATLAB extracts the name portion of the `libname` string to identify the library in other shared library functions. For example, when you call the `calllib` function, do not include the path or file extension in the library argument name.

Data Types: char

hfile — Name of C header file
string

Name of C header file, specified as a string. The name is case-sensitive and must match the file on your system. If you do not include a file extension in the file name, loadlibrary uses .h for the extension.

Data Types: char

protofile — Name of prototype file
string

Name of prototype file, specified as a string. The name is case-sensitive and must match the file on your system. The string @protofile specifies a function handle to the prototype file. When using a prototype file, the only valid Name,Value pair argument is **alias**.

Data Types: char

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example:

'addheader' — Header file
string

Header file, specified as the comma-separated pair consisting of 'addheader' and a string. Specify the file name without a file extension.

Each file specified by addheader must have a corresponding #include statement in the base header file. To load only the functions defined in the header file that you want to use in MATLAB, use addheader.

MATLAB does not verify the existence of header files and ignores any that are not needed.

`'alias'` — Alternative name for library

string

Alternative name for library, specified as the comma-separated pair consisting of `'alias'` and a string. Associates the specified name with the library. All subsequent calls to MATLAB functions that reference this library must use this alias until the library is unloaded.

`'includepath'` — More search path for subordinate header files

string

more search path for subordinate header files—header files within header files, specified as the comma-separated pair consisting of `'includepath'` and a string.

`'mfilename'` — Prototype file

string

Prototype file, specified as the comma-separated pair consisting of `'mfilename'` and a string. Generates a prototype file in the current folder. The prototype file name must be different from the library name. Use this file in place of a header file when loading the library.

`'thunkfilename'` — Thunk file

string

Thunk file, specified as the comma-separated pair consisting of `'thunkfilename'` and a string. Overrides the default thunk file name.

Output Arguments

`notfound` — Names of functions

cell array

Names of functions found in header files but missing from the library, returned as cell array.

Data Types: `cell`

`warnings` — Warnings

character array

Warnings produced while processing the header file, returned as character array.

Limitations

- You must have a supported C compiler and Perl must be available.
- Do not call `loadlibrary` if the library is already in memory. To test this condition, call `libisloaded`.
- `loadlibrary` does not support libraries generated by the MATLAB Compiler product.
- The MATLAB Shared Library interface does not support library functions with function pointer inputs.
- For more information, see "Limitations to Shared Library Support".

More About

Prototype File

A prototype file is a file of MATLAB commands which you can modify and use in place of a header file.

Thunk File

A thunk file is a compatibility layer to a 64-bit library generated by MATLAB. The name of the thunk file is `BASENAME_thunk_COMPUTER.c` where *`BASENAME`* is either the name of the shared library or, if specified, the mfilename prototype name. *`COMPUTER`* is the string returned by the `computer` function.

MATLAB compiles this file and creates the file `BASENAME_thunk_COMPUTER.LIBEXT`, where *`LIBEXT`* is the platform-dependent default shared library extension, for example, `dll` on Windows.

Tips

- If you have more than one library file of the same name, load the first using the library file name. Then load the additional libraries using the **`alias`** option.
- Use the **`alias`** option as an alternate name for a library. Use the @protofile argument to load an alternate header file.

- “When to Use a Prototype File”
- Supported and Compatible Compilers

Introduced before R2006a

loadobj

Modify load process for object

Syntax

```
b = loadobj(a)
```

Description

`b = loadobj(a)` is called by the `load` function if the class of `a` defines a `loadobj` method. `load` returns `b` as the value loaded from a MAT-file.

Define a `loadobj` method when objects of the class require special processing when loaded from MAT-files. If you define a `saveobj` method, then define a `loadobj` method to restore the object to the desired state. Define `loadobj` as a static method so it can accept as an argument whatever object or structure that you saved in the MAT-file.

When loading a subclass object, `load` calls only the subclass `loadobj` method. If a superclass defines a `loadobj` method, the subclass inherits this method. However, it is possible that the inherited method does not perform the necessary operations to load the subclass object. Consider overriding superclass `loadobj` methods.

If any superclass in a class hierarchy defines a `loadobj` method, then the subclass `loadobj` method must ensure that the subclass and superclass objects load properly. Ensure proper loading by calling the superclass `loadobj` (or other methods) from the subclass `loadobj` method.

Input Arguments

a

The input argument, `a`, can be:

- The object as loaded from the MAT-file.
- A structure created by `load` (if `load` cannot resolve the object).

- A structure returned by the `saveobj` method that was saved instead of the object.

Implement your `loadobj` method to work with scalar objects or structures. When you have saved an object array, `load` calls `loadobj` on each element of the saved array.

`load` | `save` | `saveobj`

Tutorials

- "Save and Load"

Introduced before R2006a

localfunctions

Function handles to all local functions in MATLAB file

Syntax

```
fcns = localfunctions
```

Description

`fcns = localfunctions` returns a cell array of function handles, `fcns`, to all local functions in the current file.

You cannot define local functions in the context of the command line, scripts, or anonymous functions, so when you call `localfunctions` from these contexts, you get an empty cell array. Within the cell array, `localfunctions` returns the function handles in an undefined order.

Examples

Display Handles to Local Functions in File

Create a new file, `fileWithLocalFunctions.m`, in your MATLAB path. In the main function, call and display the results of `localfunctions`. In the same file, create two local functions.

```
function fileWithLocalFunctions

fcns = localfunctions;
display(fcns)

function alocalfunction

function anotherlocalfunction
```

From the command line, call your function.

```
fileWithLocalFunctions
```

```
fcns =

    @alocalfunction
    @anotherlocalfunction
```

More About

- "Local Functions"

See Also

`functiontests`

log

Natural logarithm

Syntax

```
Y = log(X)
```

Description

`Y = log(X)` returns the natural logarithm ln(x) of each element in array `X`.

The `log` function's domain includes negative and complex numbers, which can lead to unexpected results if used unintentionally. For negative and complex numbers `z = u + i*w`, the complex logarithm `log(z)` returns

```
log(abs(z)) + 1i*atan2(w,u)
```

If you want negative and complex numbers to return error messages rather than return complex results, use `reallog` instead.

Examples

Natural Logarithm of Negative Number

Show that the natural logarithm of -1 is $i\pi$.

```
log(-1)
```

```
ans =

   0.0000 + 3.1416i
```

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

`Y` — Logarithm values

scalar | vector | matrix | multidimensional array

Logarithm values, returned as a scalar, vector, matrix, or multidimensional array.

For positive real values of `X` in the interval (`0`, `Inf`), `Y` is in the interval (`-Inf`,`Inf`). For complex and negative real values of `X`, `Y` is complex. The data type of `Y` is the same as that of `X`.

See Also

`exp` | `log10` | `log1p` | `log2` | `loglog` | `logm` | `reallog` | `semilogx` | `semilogy`

Introduced before R2006a

log10

Common logarithm (base 10)

Syntax

```
Y = log10(X)
```

Description

`Y = log10(X)` returns the common logarithm of each element in array `X`. The function accepts both real and complex inputs. For real values of `X` in the interval (0, `Inf`), `log10` returns real values in the interval (`-Inf` ,`Inf`). For complex and negative real values of `X`, the `log10` function returns complex values.

Examples

Calculate Scalar Common Logarithm Values

Examine several values of the base 10 logarithm function.

Calculate the common logarithm of 1.

```
log10(1)
```

```
ans =

     0
```

The result is `0`, which is the x-intercept of the `log10` function.

Calculate the common logarithm of 10.

```
log10(10)
```

```
ans =

     1
```

The result is `1` since `10^1 = 10`.

Calculate the common logarithm of 100.

```
log10(100)
```

```
ans =

     2
```

The result is `2` since `10^2 = 100`.

Calculate the common logarithm of 0.

```
log10(0)
```

```
ans =

  -Inf
```

The result is `-Inf` since `10^(-Inf) = 0`.

Real-Valued Common Logarithm

Create a vector of real numbers in the interval `[0.5,10]`.

```
X = (0.5:0.5:10)';
```

Calculate the common logarithm of `X`.

```
Y = log10(X)
```

```
Y =

   -0.3010
         0
    0.1761
    0.3010
    0.3979
    0.4771
    0.5441
    0.6021
    0.6532
    0.6990
```

```
    0.7404
    0.7782
    0.8129
    0.8451
    0.8751
    0.9031
    0.9294
    0.9542
    0.9777
    1.0000
```

Complex-Valued Common Logarithm

Create two Cartesian grids for `X` and `Y`.

```
[X,Y] = meshgrid(0:0.5:1.5,-2:0.5:2);
```

Calculate the complex base 10 logarithm $log_{10}(X + iY)$ on the grid. Use `1i` for improved speed and robustness with complex arithmetic.

```
Z = log10(X + 1i*Y)
```

```
Z =

   0.3010 - 0.6822i   0.3142 - 0.5758i   0.3495 - 0.4808i   0.3979 - 0.4027i
   0.1761 - 0.6822i   0.1990 - 0.5425i   0.2559 - 0.4268i   0.3266 - 0.3411i
   0.0000 - 0.6822i   0.0485 - 0.4808i   0.1505 - 0.3411i   0.2559 - 0.2554i
  -0.3010 - 0.6822i  -0.1505 - 0.3411i   0.0485 - 0.2014i   0.1990 - 0.1397i
     -Inf + 0.0000i  -0.3010 + 0.0000i   0.0000 + 0.0000i   0.1761 + 0.0000i
  -0.3010 + 0.6822i  -0.1505 + 0.3411i   0.0485 + 0.2014i   0.1990 + 0.1397i
   0.0000 + 0.6822i   0.0485 + 0.4808i   0.1505 + 0.3411i   0.2559 + 0.2554i
   0.1761 + 0.6822i   0.1990 + 0.5425i   0.2559 + 0.4268i   0.3266 + 0.3411i
   0.3010 + 0.6822i   0.3142 + 0.5758i   0.3495 + 0.4808i   0.3979 + 0.4027i
```

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

`exp` | `log` | `log1p` | `log2` | `loglog` | `logm` | `reallog` | `semilogx` | `semilogy`

Introduced before R2006a

log1p

Compute log(1+x) accurately for small values of x

Syntax

```
y = log1p(x)
```

Description

`y = log1p(x)` computes `log(1+x)`, compensating for the roundoff in `1+x`. `log1p(x)` is more accurate than `log(1+x)` for small values of x. For small `x`, `log1p(x)` is approximately `x`, whereas `log(1+x)` can be zero.

See Also

`log` | `expm1`

Introduced before R2006a

log2

Base 2 logarithm and dissect floating-point numbers into exponent and mantissa

Syntax

```
Y = log2(X)
[F,E] = log2(X)
```

Description

`Y = log2(X)` computes the base 2 logarithm of the elements of `X`.

`[F,E] = log2(X)` returns arrays `F` and `E`. Argument `F` is an array of real values, usually in the range `0.5 <= abs(F) < 1`. For real `X`, `F` satisfies the equation: `X = F.*2.^E`. Argument `E` is an array of integers that, for real `X`, satisfy the equation: `X = F.*2.^E`.

Examples

For IEEE arithmetic, the statement `[F,E] = log2(X)` yields the values:

X	F	E
1	1/2	1
pi	pi/4	2
-3	-3/4	2
eps	1/2	-51
realmax	1-eps/2	1024
realmin	1/2	-1021

More About

Tips

This function corresponds to the ANSI C function `frexp()` and the IEEE floating-point standard function `logb()`. Any zeros in `X` produce `F = 0` and `E = 0`.

See Also

`log` | `pow2`

Introduced before R2006a

logical

Convert numeric values to logicals

Syntax

```
L = logical(A)
```

Description

`L = logical(A)` converts numeric input `A` into an array of logical values. Any nonzero element of input `A` is converted to logical `1` (`true`) and zeros are converted to logical `0` (`false`). Complex values and NaNs cannot be converted to logical values and result in a conversion error.

Examples

Pick Odd Elements from Numeric Matrix

Pick out the odd-numbered elements of a numeric matrix.

Create a numeric matrix.

```
A = [1 -3 2;5 4 7;-8 1 3];
```

Find the modulus, `mod(A,2)`, and convert it to a logical array for indexing.

```
L = logical(mod(A,2))
```

```
L =

     1     1     0
     1     0     1
     0     1     1
```

The array has logical `1` (`true`) values where `A` is odd.

Use `L` as a logical index to pick out the odd elements of `A`.

```
A(L)

ans =

     1
     5
    -3
     1
     7
     3
```

The result is a vector containing all odd elements of `A`.

Use the logical NOT operator, `~`, on `L` to find the even elements of `A`.

```
A(~L)

ans =

    -8
     4
     2
```

Input Arguments

A — Numeric input

scalar | vector | matrix | multidimensional array

Numeric input, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

More About

Tips

- Most arithmetic operations involving logical arrays return double values. For example, adding zero to a logical array returns a double array.
- Logical arrays also are created by the relational operators (==,<,>,~, etc.) and functions like `any`, `all`, `isnan`, `isinf`, and `isfinite`.

- " Using Logicals in Array Indexing"
- "Determine if Arrays Are Logical"

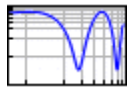
See Also

`false` | `islogical` | `true`

Introduced before R2006a

loglog

Log-log scale plot



Syntax

```
loglog(Y)
loglog(X1,Y1,...)
loglog(X1,Y1,LineSpec,...)
loglog(...,'PropertyName',PropertyValue,...)
h = loglog(...)
```

Description

`loglog(Y)` plots the columns of `Y` versus their index if `Y` contains real numbers. If `Y` contains complex numbers, `loglog(Y)` and `loglog(real(Y),imag(Y))` are equivalent. `loglog` ignores the imaginary component in all other uses of this function.

`loglog(X1,Y1,...)` plots all `Yn` versus `Xn` pairs. If only one of `Xn` or `Yn` is a matrix, `loglog` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`loglog(X1,Y1,LineSpec,...)` plots all lines defined by the `Xn,Yn,LineSpec` triples, where `LineSpec` determines line type, marker symbol, and color of the plotted lines. You can mix `Xn,Yn,LineSpec` triples with `Xn,Yn` pairs, for example,

```
loglog(X1,Y1,X2,Y2,LineSpec,X3,Y3)
```

`loglog(...,'PropertyName',PropertyValue,...)` sets line property values for all the charting lines created. For a list of properties, see Chart Line Properties.

`h = loglog(...)` returns a column vector of chart line handles, one handle per line.

If you do not specify a color when plotting more than one line, `loglog` automatically cycles through the colors and line styles in the order specified by the current axes.

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

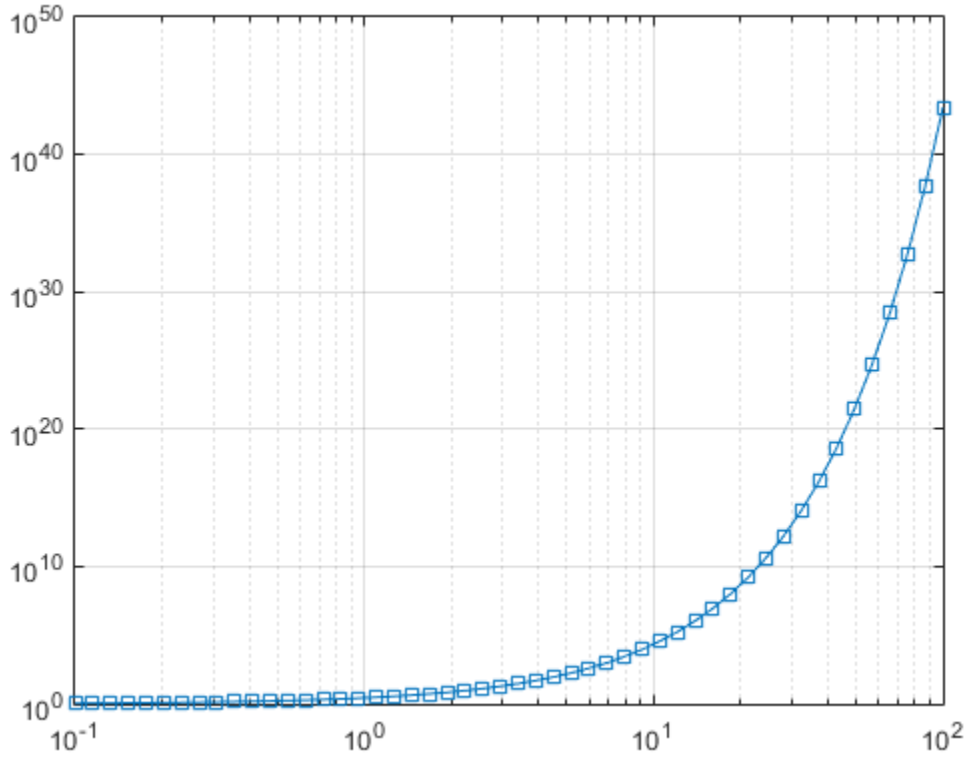
Examples

Logarithmic Scale for Both Axes

Create a plot using a logarithmic scale for both the x-axis and the y-axis. Set the `LineSpec` string so that `loglog` plots using a line with square markers. Display the grid.

```
x = logspace(-1,2);
y = exp(x);

figure
loglog(x,y,'-s')
grid on
```



See Also

Functions
`LineSpec` | `plot` | `semilogx` | `semilogy`

Properties
Chart Line Properties

Introduced before R2006a

logm

Matrix logarithm

Syntax

```
L = logm(A)
[L, exitflag] = logm(A)
```

Description

`L = logm(A)` is the principal matrix logarithm of A, the inverse of `expm(A)`. `L` is the unique logarithm for which every eigenvalue has imaginary part lying strictly between $-\pi$ and π. If `A` is singular or has any eigenvalues on the negative real axis, the principal logarithm is undefined. In this case, `logm` computes a nonprincipal logarithm and returns a warning message.

`[L, exitflag] = logm(A)` returns a scalar `exitflag` that describes the exit condition of `logm`:

- If `exitflag = 0`, the algorithm was successfully completed.
- If `exitflag = 1`, too many matrix square roots had to be computed. However, the computed value of `L` might still be accurate.

The input `A` can have class `double` or `single`.

Limitations

For most matrices:

```
logm(expm(A)) = A = expm(logm(A))
```

These identities may fail for some `A`. For example, if the computed eigenvalues of `A` include an exact zero, then `logm(A)` generates infinity. Or, if the elements of `A` are too large, `expm(A)` may overflow.

Examples

Suppose `A` is the 3-by-3 matrix

```
     1     1     0
     0     0     2
     0     0    -1
```

and `Y = expm(A)` is

```
Y =
    2.7183    1.7183    1.0862
         0    1.0000    1.2642
         0         0    0.3679
```

Then `A = logm(Y)` produces the original matrix `A`.

```
Y =
    1.0000    1.0000    0.0000
         0         0    2.0000
         0         0   -1.0000
```

But `log(A)` involves taking the logarithm of zero, and so produces

```
ans =
    0.0000                  0          -35.5119
     -Inf               -Inf            0.6931
     -Inf               -Inf            0.0000 + 3.1416i
```

More About

Tips

If `A` is real symmetric or complex Hermitian, then so is `logm(A)`.

Some matrices, like `A = [0 1; 0 0]`, do not have any logarithms, real or complex, so `logm` cannot be expected to produce one.

Algorithms

The algorithm `logm` uses is described in [1].

Introduced before R2006a

logspace

Generate logarithmically spaced vectors

Syntax

```
y = logspace(a,b)
y = logspace(a,b,n)
y = logspace(a,pi)
```

Description

The `logspace` function generates logarithmically spaced vectors. Especially useful for creating frequency vectors, it is a logarithmic equivalent of `linspace` and the ":" or colon operator.

`y = logspace(a,b)` generates a row vector `y` of 50 logarithmically spaced points between decades `10^a` and `10^b`.

`y = logspace(a,b,n)` generates `n` points between decades `10^a` and `10^b`.

`y = logspace(a,pi)` generates the points between `10^a` and `pi`, which is useful for digital signal processing where frequencies over this interval go around the unit circle.

More About

Tips

All the arguments to `logspace` must be scalars.

See Also

`linspace` | `colon operator`

Introduced before R2006a

lookfor

Search for keyword in all help entries

Alternatives

As an alternative to the `lookfor` function, use the Function Browser.

Syntax

```
lookfor topic
lookfor topic -all
```

Description

`lookfor topic` searches for the string `topic` in the first comment line (the H1 line) of the help text in all MATLAB program files found on the search path. For all files in which a match occurs, `lookfor` displays the H1 line.

`lookfor topic -all` searches the entire first comment block of a MATLAB program file looking for `topic`.

Examples

For example:

```
lookfor inverse
```

finds at least a dozen matches, including H1 lines containing "inverse hyperbolic cosine," "two-dimensional inverse FFT," and "pseudoinverse." Contrast this with

```
which inverse
```

or

```
what inverse
```

These functions run more quickly, but probably fail to find anything because MATLAB does not have a function `inverse`.

In summary, `what` lists the functions in a given folder, `which` finds the folder containing a given function or file, and `lookfor` finds all functions in all folders that might have something to do with a given keyword.

Even more extensive than the `lookfor` function are the find features in the Current Folder browser. For example, you can look for all occurrences of a specified word in all the MATLAB program files in the current folder and its subfolders. For more information, see "Find Files and Folders".

Introduced before R2006a

lower

Convert string to lowercase

Syntax

```
t = lower('str')
B = lower(A)
```

Description

`t = lower('str')` returns the string formed by converting any uppercase characters in `str` to the corresponding lowercase characters and leaving all other characters unchanged.

`B = lower(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `lower` to each string within `A`.

Examples

`lower('MathWorks')` is `mathworks`.

More About

Tips

Character sets supported:

- PC: Latin-1 for the Microsoft Windows operating system
- Other: ISO Latin-1 (ISO 8859-1)

`upper`

Introduced before R2006a

ls

List folder contents

Syntax

```
ls
ls name
list = ls(name)
```

Description

`ls` lists the contents of the current folder.

`ls name` lists the files and folders in the current folder that match the specified name. You can use wildcards.

`list = ls(name)` returns the files and folders in the current folder that match the specified name to `list`.

Input Arguments

`name`

A string value specifying a file or folder name.

Output Arguments

`list`

- On UNIX platforms, list is a character row vector of names separated by tab and space characters.
- On Microsoft Windows platforms, list is an `m`-by-`n` character array of names—`m` is the number of names and `n` is the number of characters in the longest name. MATLAB pads names shorter than `n` characters with space characters.

Examples

List all the files and folders in the current folder:

```
ls
```

List all the files and folders in the current folder that begin with the letter `h`:

```
ls h*
```

Return the list of all the files and folders in the current folder to `mylist`:

```
mylist = ls;
```

Alternatives

- View files and folders in the Current Folder browser.

  Open the Current Folder browser by issuing the `filebrowser` command.

More About

Tips

- On UNIX platforms, you can add any flags to `ls` that the operating system supports.

lscov

Least-squares solution in presence of known covariance

Syntax

```
x = lscov(A,B)
x = lscov(A,B,w)
x = lscov(A,B,V)
x = lscov(A,B,V,alg)
[x,stdx] = lscov(...)
[x,stdx,mse] = lscov(...)
[x,stdx,mse,S] = lscov(...)
```

Description

`x = lscov(A,B)` returns the ordinary least squares solution to the linear system of equations `A*x = B`, i.e., `x` is the n-by-1 vector that minimizes the sum of squared errors `(B - A*x)'*(B - A*x)`, where `A` is m-by-n, and `B` is m-by-1. `B` can also be an m-by-k matrix, and `lscov` returns one solution for each column of `B`. When `rank(A) < n`, `lscov` sets the maximum possible number of elements of `x` to zero to obtain a "basic solution".

`x = lscov(A,B,w)`, where `w` is a vector length m of real positive weights, returns the weighted least squares solution to the linear system `A*x = B`, that is, `x` minimizes `(B - A*x)'*diag(w)*(B - A*x)`. `w` typically contains either counts or inverse variances.

`x = lscov(A,B,V)`, where `V` is an m-by-m real symmetric positive definite matrix, returns the generalized least squares solution to the linear system `A*x = B` with covariance matrix proportional to `V`, that is, `x` minimizes `(B - A*x)'*inv(V)*(B - A*x)`.

More generally, `V` can be positive semidefinite, and `lscov` returns `x` that minimizes `e'*e`, subject to `A*x + T*e = B`, where the minimization is over `x` and `e`, and `T*T' = V`. When `V` is semidefinite, this problem has a solution only if `B` is consistent with `A` and `V` (that is, `B` is in the column space of `[A T]`), otherwise `lscov` returns an error.

By default, `lscov` computes the Cholesky decomposition of `V` and, in effect, inverts that factor to transform the problem into ordinary least squares. However, if `lscov` determines that `V` is semidefinite, it uses an orthogonal decomposition algorithm that avoids inverting `V`.

`x = lscov(A,B,V,alg)` specifies the algorithm used to compute `x` when `V` is a matrix. `alg` can have the following values:

- `'chol'` uses the Cholesky decomposition of `V`.
- `'orth'` uses orthogonal decompositions, and is more appropriate when `V` is ill-conditioned or singular, but is computationally more expensive.

`[x,stdx] = lscov(...)` returns the estimated standard errors of `x`. When `A` is rank deficient, `stdx` contains zeros in the elements corresponding to the necessarily zero elements of `x`.

`[x,stdx,mse] = lscov(...)` returns the mean squared error. If `B` is assumed to have covariance matrix σ^2`V` (or (σ^2)×`diag`(1./`W`)), then `mse` is an estimate of σ^2.

`[x,stdx,mse,S] = lscov(...)` returns the estimated covariance matrix of `x`. When `A` is rank deficient, `S` contains zeros in the rows and columns corresponding to the necessarily zero elements of `x`. `lscov` cannot return `S` if it is called with multiple right-hand sides, that is, if `size(B,2) > 1`.

The standard formulas for these quantities, when `A` and `V` are full rank, are

- `x = inv(A'*inv(V)*A)*A'*inv(V)*B`
- `mse = B'*(inv(V) - inv(V)*A*inv(A'*inv(V)*A)*A'*inv(V))*B./(m-n)`
- `S = inv(A'*inv(V)*A)*mse`
- `stdx = sqrt(diag(S))`

However, `lscov` uses methods that are faster and more stable, and are applicable to rank deficient cases.

`lscov` assumes that the covariance matrix of `B` is known only up to a scale factor. `mse` is an estimate of that unknown scale factor, and `lscov` scales the outputs `S` and `stdx` appropriately. However, if `V` is known to be exactly the covariance matrix of `B`, then that scaling is unnecessary. To get the appropriate estimates in this case, you should rescale `S` and `stdx` by `1/mse` and `sqrt(1/mse)`, respectively.

Examples

Example 1 — Computing Ordinary Least Squares

The MATLAB backslash operator (\) enables you to perform linear regression by computing ordinary least-squares (OLS) estimates of the regression coefficients. You can also use `lscov` to compute the same OLS estimates. By using `lscov`, you can also compute estimates of the standard errors for those coefficients, and an estimate of the standard deviation of the regression error term:

```
x1 = [.2 .5 .6 .8 1.0 1.1]';
x2 = [.1 .3 .4 .9 1.1 1.4]';
X = [ones(size(x1)) x1 x2];
y = [.17 .26 .28 .23 .27 .34]';

a = X\y
a =
    0.1203
    0.3284
   -0.1312

[b,se_b,mse] = lscov(X,y)
b =
    0.1203
    0.3284
   -0.1312
se_b =
    0.0643
    0.2267
    0.1488
mse =
    0.0015
```

Example 2 — Computing Weighted Least Squares

Use `lscov` to compute a weighted least-squares (WLS) fit by providing a vector of relative observation weights. For example, you might want to downweight the influence of an unreliable observation on the fit:

```
w = [1 1 1 1 1 .1]';

[bw,sew_b,msew] = lscov(X,y,w)
```

```
bw =
    0.1046
    0.4614
   -0.2621
sew_b =
    0.0309
    0.1152
    0.0814
msew =
  3.4741e-004
```

Example 3 — Computing General Least Squares

Use `lscov` to compute a general least-squares (GLS) fit by providing an observation covariance matrix. For example, your data may not be independent:

```
V = .2*ones(length(x1)) + .8*diag(ones(size(x1)));

[bg,sew_b,mseg] = lscov(X,y,V)
bg =
    0.1203
    0.3284
   -0.1312
sew_b =
    0.0672
    0.2267
    0.1488
mseg =
    0.0019
```

Example 4 — Estimating the Coefficient Covariance Matrix

Compute an estimate of the coefficient covariance matrix for either OLS, WLS, or GLS fits. The coefficient standard errors are equal to the square roots of the values on the diagonal of this covariance matrix:

```
[b,se_b,mse,S] = lscov(X,y);

S
S =
    0.0041   -0.0130    0.0075
   -0.0130    0.0514   -0.0328
    0.0075   -0.0328    0.0221
```

```
[se_b sqrt(diag(S))]
ans =
    0.0643    0.0643
    0.2267    0.2267
    0.1488    0.1488
```

More About

Algorithms

The vector `x` minimizes the quantity `(A*x-B)'*inv(V)*(A*x-B)`. The classical linear algebra solution to this problem is

```
x = inv(A'*inv(V)*A)*A'*inv(V)*B
```

but the `lscov` function instead computes the QR decomposition of `A` and then modifies `Q` by `V`.

`lsqnonneg` | `mldivide` | `mrdivide` | `qr`

Introduced before R2006a

lsqnonneg

Solve nonnegative least-squares constraints problem

Equation

Solves nonnegative least-squares curve fitting problems of the form

$$\min_x \|C \cdot x - d\|_2^2, \text{ where } x \geq 0.$$

Syntax

```
x = lsqnonneg(C,d)
x = lsqnonneg(C,d,options)
x = lsqnonneg(problem)
[x,resnorm] = lsqnonneg(...)
[x,resnorm,residual] = lsqnonneg(...)
[x,resnorm,residual,exitflag] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)
```

Description

`x = lsqnonneg(C,d)` returns the vector `x` that minimizes `norm(C*x-d)` subject to `x >= 0`. `C` and `d` must be real.

`x = lsqnonneg(C,d,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `lsqnonneg` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge.
`TolX`	Termination tolerance on `x`.

`x = lsqnonneg(problem)` finds the minimum for `problem`, where `problem` is a structure with the following fields:

`C`	Matrix
`d`	Vector
`solver`	`'lsqnonneg'`
`options`	Options structure created using `optimset`

`[x,resnorm] = lsqnonneg(...)` returns the value of the squared 2-norm of the residual: `norm(C*x-d)^2`.

`[x,resnorm,residual] = lsqnonneg(...)` returns the residual, `d-C*x`.

`[x,resnorm,residual,exitflag] = lsqnonneg(...)` returns a value `exitflag` that describes the exit condition of `lsqnonneg`:

>0	Indicates that the function converged to a solution `x`.
0	Indicates that the iteration count was exceeded. Increasing the tolerance (`TolX` parameter in `options`) may lead to a solution.

`[x,resnorm,residual,exitflag,output] = lsqnonneg(...)` returns a structure `output` that contains information about the operation in the following fields:

`algorithm`	`'active-set'`
`iterations`	The number of iterations taken
`message`	Exit message

`[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)` returns the dual vector (Lagrange multipliers) `lambda`, where `lambda(i)<=0` when `x(i)` is (approximately) `0`, and `lambda(i)` is (approximately) `0` when `x(i)>0`.

Examples

Compare the unconstrained least squares solution to the `lsqnonneg` solution for a 4-by-2 problem:

```
C = [
```

```
    0.0372    0.2869
    0.6861    0.7071
    0.6233    0.6245
    0.6344    0.6170];
d = [
    0.8587
    0.1781
    0.0747
    0.8405];
[C\d lsqnonneg(C,d)] =
    -2.5627         0
     3.1108    0.6929
[norm(C*(C\d)-d) norm(C*lsqnonneg(C,d)-d)] =
     0.6674 0.9118
```

The solution from `lsqnonneg` does not fit as well (has a larger residual), as the least squares solution. However, the nonnegative least squares solution has no negative components.

More About

Algorithms

`lsqnonneg` uses the algorithm described in [1]. The algorithm starts with a set of possible basis vectors and computes the associated dual vector `lambda`. It then selects the basis vector corresponding to the maximum value in `lambda` in order to swap out of the basis in exchange for another possible candidate. This continues until `lambda <= 0`.

`optimset`

Introduced before R2006a

lsqr

LSQR method

Syntax

```
x = lsqr(A,b)
lsqr(A,b,tol)
lsqr(A,b,tol,maxit)
lsqr(A,b,tol,maxit,M)
lsqr(A,b,tol,maxit,M1,M2)
lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
```

Description

`x = lsqr(A,b)` attempts to solve the system of linear equations `A*x=b` for `x` if `A` is consistent, otherwise it attempts to solve the least squares solution `x` that minimizes `norm(b-A*x)`. The `m`-by-`n` coefficient matrix `A` need not be square but it should be large and sparse. The column vector `b` must have length `m`. You can specify `A` as a function handle, `afun`, such that `afun(x,'notransp')` returns `A*x` and `afun(x,'transp')` returns `A'*x`.

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `lsqr` converges, a message to that effect is displayed. If `lsqr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`lsqr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `lsqr` uses the default, `1e-6`.

`lsqr(A,b,tol,maxit)` specifies the maximum number of iterations.

`lsqr(A,b,tol,maxit,M)` and `lsqr(A,b,tol,maxit,M1,M2)` use `n`-by-`n` preconditioner `M` or `M = M1*M2` and effectively solve the system `A*inv(M)*y = b` for `y`, where `y = M*x`. If `M` is `[]` then `lsqr` applies no preconditioner. `M` can be a function `mfun` such that `mfun(x,'notransp')` returns `M\x` and `mfun(x,'transp')` returns `M'\x`.

`lsqr(A,b,tol,maxit,M1,M2,x0)` specifies the `n`-by-`1` initial guess. If `x0` is `[]`, then `lsqr` uses the default, an all zero vector.

`[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a convergence flag.

Flag	Convergence
0	`lsqr` converged to the desired tolerance `tol` within `maxit` iterations.
1	`lsqr` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`lsqr` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `lsqr` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if you specify the `flag` output.

`[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns an estimate of the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of the residual norm estimates at each iteration, including `norm(b-A*x0)`.

`[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of estimates of the scaled normal equations residual at each iteration: `norm((A*inv(M))'*(B-A*X))/norm(A*inv(M),'fro')`. Note that the estimate of `norm(A*inv(M),'fro')` changes, and hopefully improves, at each iteration.

Examples

Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = lsqr(A,b,tol,maxit,M1,M2);
```

displays the following message:

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in a function `run_lsqr` that

- Calls `lsqr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_lsqr` are available to `afun`.

The following shows the code for `run_lsqr`:

```
function x1 = run_lsqr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = lsqr(@afun,b,tol,maxit,M1,M2);
```

```
    function y = afun(x,transp_flag)
       if strcmp(transp_flag,'transp')      % y = A'*x
          y = 4 * x;
          y(1:n-1) = y(1:n-1) - 2 * x(2:n);
          y(2:n) = y(2:n) - x(1:n-1);
       elseif strcmp(transp_flag,'notransp') % y = A*x
          y = 4 * x;
          y(2:n) = y(2:n) - 2 * x(1:n-1);
          y(1:n-1) = y(1:n-1) - x(2:n);
       end
    end
end
```

When you enter

```
x1=run_lsqr;
```

MATLAB software displays the message

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

Introduced before R2006a

lt, <

Determine less than

Syntax

```
A < B
lt(A,B)
```

Description

`A < B` returns an array with elements set to logical 1 (`true`) where `A` is less than `B`; otherwise, it returns logical `0` (`false`).

The test compares only the real part of numeric arrays. `lt` returns logical `0` (`false`) where `A` or `B` have NaN or undefined categorical elements.

`lt(A,B)` is an alternate way to execute `A < B`, but is rarely used. It enables operator overloading for classes.

Examples

Test Vector Elements

Determine if vector elements are less than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than `12`.

```
A < 12
```

```
ans =

     1     0     0     1     1     1     1     0
```

The result is a vector with values of logical 1 (`true`) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than 12.

```
A(A < 12)
```

```
ans =

     1     7     9    11     2
```

The result is a subset of the elements in A.

Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =

    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values less than 9 with the value 10.

```
A(A < 9) = 10
```

```
A =

    16    10    10    13
    10    11    10    10
     9    10    10    12
    10    14    15    10
```

The result is a new matrix whose smallest element is 9.

Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =

     large       medium      small
     medium      small       large
```

The array has three categories: `'small'`, `'medium'`, and `'large'`.

Find all values less than the category `'medium'`.

```
A < 'medium'
```

```
ans =

     0     0     1
     0     1     0
```

A value of logical `1` (`true`) indicates a value less than the category `'medium'`.

Compare the rows of `A`.

```
A(1,:) < A(2,:)
```

```
ans =

     0     0     1
```

The function returns logical `1` (`true`) where the first row has a category value less than the second row.

Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than `3`.

```
A(A < 3)
```

```
ans =

   1.0000 + 1.0000i   2.0000 - 2.0000i   1.0000 + 3.0000i   1.0000 - 2.0000i
```

`lt` compares only the real part of the elements in `A`.

Use `abs` to find which elements are within a radius of `3` from the origin.

```
A(abs(A) < 3)

ans =

   1.0000 + 1.0000i   2.0000 - 2.0000i   1.0000 - 2.0000i
```

The result has one less element. The element `1.0000 + 3.0000i` is not within a radius of `3` from the origin.

Compare Dates

Create a vector of dates.

```
A = datetime([2014,05,01;2014,05,31])

A =

   01-May-2014
   31-May-2014
```

Find the dates that occur before May 10, 2014.

```
A(A < '2014-05-10')

ans =

   01-May-2014
```

Input Arguments

A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

B — Right array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Introduced before R2006a

lu

LU matrix factorization

Syntax

```
Y = lu(A)
[L,U] = lu(A)
[L,U,P] = lu(A)
[L,U,P,Q] = lu(A)
[L,U,P,Q,R] = lu(A)
[...] = lu(A,'vector')
[...] = lu(A,thresh)
[...] = lu(A,thresh,'vector')
```

Description

The `lu` function expresses a matrix `A` as the product of two essentially triangular matrices, one of them a permutation of a lower triangular matrix and the other an upper triangular matrix. The factorization is often called the *LU*, or sometimes the *LR*, factorization. `A` can be rectangular.

`Y = lu(A)` returns matrix `Y` that, for sparse `A`, contains the strictly lower triangular `L`, i.e., without its unit diagonal, and the upper triangular `U` as submatrices. That is, if `[L,U,P] = lu(A)`, then `Y = U+L-eye(size(A))`. For nonsparse `A`, `Y` is the output from the LAPACK `dgetrf` or `zgetrf` routine. The permutation matrix `P` is not returned.

`[L,U] = lu(A)` returns an upper triangular matrix in `U` and a permuted lower triangular matrix in `L` such that `A = L*U`. Return value `L` is a product of lower triangular and permutation matrices.

`[L,U,P] = lu(A)` returns an upper triangular matrix in `U`, a lower triangular matrix `L` with a unit diagonal, and a permutation matrix `P`, such that `L*U = P*A`. The statement `lu(A,'matrix')` returns identical output values.

`[L,U,P,Q] = lu(A)` for sparse nonempty `A`, returns a unit lower triangular matrix `L`, an upper triangular matrix `U`, a row permutation matrix `P`, and a column reordering

matrix Q, so that P*A*Q = L*U. If A is empty or not sparse, lu displays an error message. The statement lu(A,'matrix') returns identical output values.

[L,U,P,Q,R] = lu(A) returns unit lower triangular matrix L, upper triangular matrix U, permutation matrices P and Q, and a diagonal scaling matrix R so that P*(R\A)*Q = L*U for sparse non-empty A. Typically, but not always, the row-scaling leads to a sparser and more stable factorization. The statement lu(A,'matrix') returns identical output values.

[...] = lu(A,'vector') returns the permutation information in two row vectors p and q. You can specify from 1 to 5 outputs. Output p is defined as A(p,:)=L*U, output q is defined as A(p,q)=L*U, and output R is defined as R(:,p)\A(:,q)=L*U.

[...] = lu(A,thresh) controls pivoting. This syntax applies to sparse matrices only. The thresh input is a one- or two-element vector of type single or double that defaults to [0.1, 0.001]. If A is a square matrix with a mostly symmetric structure and mostly nonzero diagonal, MATLAB uses a symmetric pivoting strategy. For this strategy, the diagonal where

```
A(i,j) >= thresh(2) * max(abs(A(j:m,j)))
```

is selected. If the diagonal entry fails this test, a pivot entry below the diagonal is selected, using thresh(1). In this case, L has entries with absolute value 1/min(thresh) or less.

If A is not as described above, MATLAB uses an asymmetric strategy. In this case, the sparsest row i where

```
A(i,j) >= thresh(1) * max(abs(A(j:m,j)))
```

is selected. A value of 1.0 results in conventional partial pivoting. Entries in L have an absolute value of 1/thresh(1) or less. The second element of the thresh input vector is not used when MATLAB uses an asymmetric strategy.

Smaller values of thresh(1) and thresh(2) tend to lead to sparser LU factors, but the solution can become inaccurate. Larger values can lead to a more accurate solution (but not always), and usually an increase in the total work and memory usage. The statement lu(A,thresh,'matrix') returns identical output values.

[...] = lu(A,thresh,'vector') controls the pivoting strategy and also returns the permutation information in row vectors, as described above. The thresh input must precede 'vector' in the input argument list.

Note In rare instances, incorrect factorization results in `P*A*Q` ≠ `L*U`. Increase `thresh`, to a maximum of `1.0` (regular partial pivoting), and try again.

Arguments

`A`	Rectangular matrix to be factored.
`thresh`	Pivot threshold for sparse matrices. Valid values are in the interval `[0,1]`. If you specify the fourth output `Q`, the default is `0.1`. Otherwise, the default is `1.0`.
`L`	Factor of `A`. Depending on the form of the function, `L` is either a unit lower triangular matrix, or else the product of a unit lower triangular matrix with `P'`.
`U`	Upper triangular matrix that is a factor of `A`.
`P`	Row permutation matrix satisfying the equation `L*U = P*A`, or `L*U = P*A*Q`. Used for numerical stability.
`Q`	Column permutation matrix satisfying the equation `P*A*Q = L*U`. Used to reduce fill-in in the sparse case.
`R`	Row-scaling matrix

Examples

Example 1

Start with

```
A = [ 1    2    3
      4    5    6
      7    8    0 ];
```

To see the LU factorization, call `lu` with two output arguments.

```
[L1,U] = lu(A)

L1 =
    0.1429    1.0000         0
```

```
    0.5714    0.5000    1.0000
    1.0000         0         0

U =
    7.0000    8.0000         0
         0    0.8571    3.0000
         0         0    4.5000
```

Notice that `L1` is a permutation of a lower triangular matrix: if you switch rows 2 and 3, and then switch rows 1 and 2, the resulting matrix is lower triangular and has `1`s on the diagonal. Notice also that `U` is upper triangular. To check that the factorization does its job, compute the product

```
L1*U
```

which returns the original `A`. The inverse of the example matrix, `X = inv(A)`, is actually computed from the inverses of the triangular factors

```
X = inv(U)*inv(L1)
```

Using three arguments on the left side to get the permutation matrix as well,

```
[L2,U,P] = lu(A)
```

returns a truly lower triangular `L2`, the same value of `U`, and the permutation matrix `P`.

```
L2 =

    1.0000         0         0
    0.1429    1.0000         0
    0.5714    0.5000    1.0000

U =
    7.0000    8.0000         0
         0    0.8571    3.0000
         0         0    4.5000

P =
    0    0    1
    1    0    0
    0    1    0
```

Note that `L2 = P*L1`.

```
P*L1
```

```
ans =

    1.0000         0         0
    0.1429    1.0000         0
    0.5714    0.5000    1.0000
```

To verify that `L2*U` is a permuted version of `A`, compute `L2*U` and subtract it from `P*A`:

```
P*A - L2*U

ans =
     0     0     0
     0     0     0
     0     0     0
```

In this case, `inv(U)*inv(L)` results in the permutation of `inv(A)` given by `inv(P)*inv(A)`.

The determinant of the example matrix is

```
d = det(A)

d =    27
```

It is computed from the determinants of the triangular factors

```
d = det(L)*det(U)
```

The solution to $Ax = b$ is obtained with matrix division

```
x = A\b
```

The solution is actually computed by solving two triangular systems

```
y = L\b
x = U\y
```

Example 2

The 1-norm of their difference is within roundoff error, indicating that `L*U = P*B*Q`.

Generate a 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster-Fuller geodesic dome.

```
B = bucky;
```

Use the sparse matrix syntax with four outputs to get the row and column permutation matrices.

```
[L,U,P,Q] = lu(B);
```

Apply the permutation matrices to `B`, and subtract the product of the lower and upper triangular matrices.

```
Z = P*B*Q - L*U;
norm(Z,1)

ans =
  7.9936e-015
```

Example 3

This example illustrates the benefits of using the `'vector'` option. Note how much memory is saved by using the `lu(F,'vector')` syntax.

```
F = gallery('uniformdata',[1000 1000],0);
g = sum(F,2);
[L,U,P] = lu(F);
[L,U,p] = lu(F,'vector');
whos P p

Name          Size            Bytes  Class      Attributes
P          1000x1000       8000000  double
p             1x1000          8000  double
```

The following two statements are equivalent. The first typically requires less time:

```
x = U\(L\(g(p,:)));
y = U\(L\(P*g));
```

More About

Tips

Most of the algorithms for computing LU factorization are variants of Gaussian elimination. The factorization is a key step in obtaining the inverse with `inv` and the

determinant with `det`. It is also the basis for the linear equation solution or matrix division obtained with `\` and `/`.

Introduced before R2006a

Primitive Line Properties

Control primitive line appearance and behavior

Primitive line properties control the appearance and behavior of a primitive line object. By changing property values, you can modify certain aspects of the line.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = line;
s = h.LineStyle;
h.LineStyle = ':';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Line

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	
`':'`	Dotted line	
`'-.'`	Dash-dotted line	
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`Color` — Line color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the color as `'none'`, then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`AlignVertexCenters` — Sharp vertical and horizontal lines

`'off'` (default) | `'on'`

Sharp vertical and horizontal lines, specified as `'off'` or `'on'`.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.

- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the primitive line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerSize` — Marker size

`6` (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Data

`XData` — x values

`[0 1]` (default) | vector

x values, specified as a vector. `XData` and `YData` must have equal lengths.

Example: `1:10`

`YData` — y values

`[0 1]` (default) | vector

y values, specified as a vector. `XData` and `YData` must have equal lengths.

Example: `1:10`

`ZData` — z values

empty matrix (default) | vector

z values, specified as a vector. `ZData` must have the same length as `XData` and `YData`.

Example: `1:10`

Visibility

`Visible` — Visibility of primitive line

`'on'` (default) | `'off'`

Visibility of primitive line, specified as one of these values:

- `'on'` — Display the primitive line.
- `'off'` — Hide the primitive line without deleting it. You still can access the properties of an invisible primitive line object.

`Clipping` — Clipping of primitive line to axes limits

`'on'` (default) | `'off'`

Clipping of primitive line to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the primitive line that are outside the axes limits.
- `'off'` — Display the entire primitive line, even if parts of it appear outside the axes limits. Parts of the primitive line might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the primitive line that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'line'`

Type of graphics object, returned as `'line'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — Tag to associate with primitive line

`''` (default) | string

Tag to associate with the primitive line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with primitive line

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the primitive line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the primitive line.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the primitive line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the primitive line from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the primitive line object in the legend as one entry (default).
   - `'off'` — Do not include the primitive line object in the legend.
   - `'children'` — Include only children of the primitive line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of primitive line

axes object | group object | transform object

Parent of primitive line, specified as an axes, group, or transform object.

`Children` — Children of primitive line

empty `GraphicsPlaceholder` array

The primitive line has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of primitive line object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The primitive line object handle is always visible.
- `'off'` — The primitive line object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

- `'callback'` — The primitive line object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the primitive line at the command-line, but allows callback functions to access it.

If the primitive line object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the primitive line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the primitive line. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the primitive line when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the primitive line.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the primitive line that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the primitive line responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'` and you can click a part of the primitive line that has no color. The HitTest property determines if the primitive line responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the primitive line passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the primitive line. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the primitive line that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the primitive line object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the primitive line is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the

`BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the primitive line tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the primitive line. Setting the `CreateFcn` property on an existing primitive line has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during primitive line creation. MATLAB executes the callback after creating the primitive line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function. You also can access the primitive line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the primitive line. MATLAB executes the callback before destroying the primitive line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive line object — You can access properties of the primitive line object from within the callback function. You also can access the primitive line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of primitive line

`'off'` (default) | `'on'`

Deletion status of primitive line, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the primitive line begins

execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the primitive line no longer exists.

Check the value of the BeingDeleted property to verify that the primitive line is not about to be deleted before querying or modifying it.

magic

Magic square

Syntax

```
M = magic(n)
```

Description

`M = magic(n)` returns an `n`-by-`n` matrix constructed from the integers `1` through `n^2` with equal row and column sums. The order n must be a scalar greater than or equal to `3`.

Examples

The magic square of order 3 is

```
M = magic(3)
```

```
M =

    8    1    6
    3    5    7
    4    9    2
```

This is called a magic square because the sum of the elements in each column is the same.

```
 sum(M) =

     15    15    15
```

And the sum of the elements in each row, obtained by transposing twice, is the same.

```
 sum(M')' =

     15
```

```
     15
     15
```

This is also a special magic square because the diagonal elements have the same sum.

```
sum(diag(M)) =

     15
```

The value of the characteristic sum for a magic square of order `n` is

```
sum(1:n^2)/n
```

which, when `n = 3`, is `15`.

Limitations

If you supply `n` less than `3`, `magic` returns either a nonmagic square, or else the degenerate magic squares `1` and `[]`.

More About

Tips

A magic square, scaled by its magic sum, is doubly stochastic.

Algorithms

There are three different algorithms:

- `n` odd
- `n` even but not divisible by four
- `n` divisible by four

To make this apparent, type

```
for n = 3:20
    A = magic(n);
    r(n) = rank(A);
end
```

For n odd, the rank of the magic square is n. For n divisible by 4, the rank is 3. For n even but not divisible by 4, the rank is n/2 + 2.

```
[(3:20)',r(3:20)']
ans =
      3      3
      4      3
      5      5
      6      5
      7      7
      8      3
      9      9
     10      7
     11     11
     12      3
     13     13
     14      9
     15     15
     16      3
     17     17
     18     11
     19     19
     20      3
```

Plotting A for n = 18, 19, 20 shows the characteristic plot for each category.

Introduced before R2006a

makehgtform

Create 4-by-4 transform matrix

Syntax

```
M = makehgtform
M = makehgtform('translate',[tx ty tz])
M = makehgtform('scale',s)
M = makehgtform('scale',[sx,sy,sz])
M = makehgtform('xrotate',t)
M = makehgtform('yrotate',t)
M = makehgtform('zrotate',t)
M = makehgtform('axisrotate',[ax,ay,az],t)
```

Description

Use `makehgtform` to create transform matrices for translation, scaling, and rotation of graphics objects. Apply the transform to graphics objects by assigning the transform to the `Matrix` property of a parent transform object.

`M = makehgtform` returns an identity transform.

`M = makehgtform('translate',[tx ty tz])` or M = makehgtform('translate',tx,ty,tz) returns a transform that translates along the *x*-axis by `tx`, along the *y*-axis by `ty`, and along the *z*-axis by `tz`.

`M = makehgtform('scale',s)` returns a transform that scales uniformly along the *x*-, *y*-, and *z*-axes.

`M = makehgtform('scale',[sx,sy,sz])` returns a transform that scales along the *x*-axis by `sx`, along the *y*-axis by `sy`, and along the *z*-axis by `sz`.

`M = makehgtform('xrotate',t)` returns a transform that rotates around the *x*-axis by `t` radians.

`M = makehgtform('yrotate',t)` returns a transform that rotates around the *y*-axis by `t` radians.

`M = makehgtform('zrotate',t)` returns a transform that rotates around the *z*-axis by `t` radians.

`M = makehgtform('axisrotate',[ax,ay,az],t)` Rotate around axis `[ax ay az]` by `t` radians.

Note that you can specify multiple operations in one call to `makehgtform` and the MATLAB software returns a transform matrix that is the result of concatenating all specified operations. For example,

```
m = makehgtform('xrotate',pi/2,'yrotate',pi/2);
```

is the same as

```
mx = makehgtform('xrotate',pi/2);
my = makehgtform('yrotate',pi/2);
m = mx*my;
```

mapreduce

Programming technique for analyzing data sets that do not fit in memory

Syntax

```
outds = mapreduce(ds,mapfun,reducefun)
outds = mapreduce(ds,mapfun,reducefun,mr)
outds = mapreduce( ___ ,Name,Value)
```

Description

`outds = mapreduce(ds,mapfun,reducefun)` applies map function `mapfun` to input datastore `ds`, and then passes the values associated with each unique key to reduce function `reducefun`. The output datastore is a `KeyValueDatastore` object that points to `.mat` files in the current folder.

`outds = mapreduce(ds,mapfun,reducefun,mr)` optionally specifies the run-time configuration settings for `mapreduce`. The `mr` input is the result of a call to the `mapreducer` function. Typically, this argument is used with Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler. For more information, see “Speed Up and Deploy MapReduce Using Other Products”.

`outds = mapreduce( ___ ,Name,Value)` specifies additional options with one or more Name,Value pair arguments using any of the previous syntaxes. For example, you can specify `'OutputFolder'` followed by a string specifying a path to the output folder.

Examples

- “Find Maximum Value with MapReduce”
- “Compute Mean Value with MapReduce”
- “Create Histograms Using MapReduce”
- “Compute Mean by Group Using MapReduce”
- “Simple Data Subsetting Using MapReduce”

- "Using MapReduce to Compute Covariance and Related Quantities"
- "Compute Summary Statistics by Group Using MapReduce"
- "Using MapReduce to Fit a Logistic Regression Model"
- "Tall Skinny QR (TSQR) Matrix Factorization Using MapReduce"

Input Arguments

`ds` — Input datastore

datastore object

Input datastore, specified as a datastore object. Use the `datastore` function to create a datastore object from your data set.

`mapfun` — Function handle to map function

function handle

Function handle to map function. `mapfun` receives chunks from input datastore `ds`, and then uses the `add` and `addmulti` functions to add key-value pairs to an intermediate `KeyValueStore` object. The number of calls to the map function by `mapreduce` is equal to the number of chunks in the `datastore` (the number of chunks is determined by the `ReadSize` property of the datastore).

The inputs to the map function are `data`, `info`, and `intermKVStore`, which `mapreduce` automatically creates and passes to the map function:

- The `data` and `info` inputs are the result of a call to the `read` function of `datastore`, which `mapreduce` executes automatically before each call to the map function.
- `intermKVStore` is the name of the intermediate `KeyValueStore` object to which the map function needs to add key-value pairs. If none of the calls to the map function add key-value pairs to `intermKVStore`, then `mapreduce` does not call the reduce function and the output datastore is empty.

An example of a template for the map function is

```
function myMapper(data, info, intermKVStore)
%do a calculation with the data chunk
add(intermKVStore, key, value)
end
```

Example: `@myMapper`

Data Types: `function_handle`

`reducefun` — Function handle to reduce function

function handle

Function handle to reduce function. `mapreduce` calls `reducefun` once for each unique key added to the intermediate `KeyValueStore` by the map function. In each call, `mapreduce` passes the values associated with the active key to `reducefun` as a `ValueIterator` object. The `reducefun` function loops through the values for each key using the `hasnext` and `getnext` functions. Then, after performing some calculation(s), it writes key-value pairs to the final output.

The inputs to the reduce function are `intermKey`, `intermValIter`, and `outKVStore`, which `mapreduce` automatically creates and passes to the reduce function:

- `intermKey` is the active key from the intermediate `KeyValueStore` object. Each call to the reduce function by `mapreduce` specifies a new unique key from the keys in the intermediate `KeyValueStore` object.
- `intermValIter` is the `ValueIterator` associated with the active key, `intermKey`. This `ValueIterator` object contains all of the values associated with the active key. Scroll through the values using the `hasnext` and `getnext` functions.
- `outKVStore` is the name for the final `KeyValueStore` object to which the reduce function needs to add key-value pairs. `mapreduce` takes the output key-value pairs from `outKVStore` and returns them in the output datastore, `outds`, which is a `KeyValueDatastore` object by default. If none of the calls to the reduce function add final key-value pairs to `outKVStore`, then the output datastore is empty.

An example of a template for the reduce function is

```
function myReducer(intermKey, intermValIter, outKVStore)
while hasnext(intermValIter)
    X = getnext(intermValIter);
    %do a calculation with the current value, X
end
add(outKVStore, key, value)
end
```

Example: `@myReducer`

Data Types: `function_handle`

`mr` — Execution environment

MapReducer object

Execution environment, specified as a MapReducer object. `mr` is the result of a call to the `mapreducer` function. The default `mr` argument is a call to `gcmr`, which uses the default global execution environment for `mapreduce` (in MATLAB the default is `mapreducer(0)`, which returns a `SerialMapReducer` object).

Note: This setting specifies the execution environment for `mapreduce` and is not necessary to run `mapreduce` on your local computer. For more information, see "Speed Up and Deploy MapReduce Using Other Products".

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `outds = mapreduce(ds, @mapfun, @reducefun, 'Display', 'off', 'OutputFolder', 'C:\Users\username\Desktop')`

`'OutputType'` — Type of datastore output

`'Binary'` (default) | `'TabularText'`

Type of datastore output, specified as `'Binary'` or `'TabularText'`. The default setting of `'Binary'` returns a `KeyValueDatastore` output datastore that points to binary (`.mat` or `.seq`) files in the output folder. The `'TabularText'` option returns a `TabularTextDatastore` output datastore that points to `.txt` files in the output folder.

The table provides the details for each of the output types.

`'OutputType'`	Type of datastore output	Datastore points to files of type	Values that the Reduce function can add	Keys that the Reduce function can add	Details
`'Binary'` (default)	`KeyValueDat`	`.mat` (or `.seq` when running	Any valid MATLAB object.	Strings, or numeric scalars that	N/A

'OutputType	Type of datastore output	Datastore points to files of type	Values that the Reduce function can add	Keys that the Reduce function can add	Details
		against Hadoop).		are not NaN, complex, logical, or sparse.	
'TabularTex	TabularTextD	.txt	Strings, or numeric scalars that are not NaN, complex, logical, or sparse.	Strings, or numeric scalars that are not NaN, complex, logical, or sparse.	• File is UTF-8 encoded. • Keys and values are tab (\t) separated. • The row delimiter is \r\n on Windows, and \n on Linux and Mac.

'OutputFolder' — Destination folder of mapreduce output
pwd (default) | file path

Destination folder for mapreduce output, specified as a file path. The default output folder is the current folder, pwd. You can specify a different path with a fully qualified path or with a path relative to the current folder.

Example: mapreduce(..., 'OutputFolder', 'MyOutputFolder\Results') specifies a file path relative to the current folder for the output.

'Display' — Toggle for command line progress output
'on' (default) | 'off'

Toggle for command line progress output, specified as 'on' or 'off'. The default is 'on', so that mapreduce displays progress information in the command window during the map and reduce phases of execution.

Output Arguments

`outds` — Output datastore

`KeyValueDatastore` (default) | `TabularTextDatastore`

Output datastore, returned as a `KeyValueDatastore` or `TabularTextDatastore` object. By default, `outds` is a `KeyValueDatastore` object that points to `.mat` files in the current folder. Use the `Name,Value` pair arguments for `'OutputType'` and `'OutputFolder'` to return a `TabularTextDatastore` object or change the location of the output files, respectively.

`mapreduce` does not sort the key-value pairs in `outds`. Their order may differ when using other products with `mapreduce`.

To view the contents of `outds`, use the `preview`, `read`, or `readall` functions of `datastore`.

More About

Tips

- Debugging your `mapreduce` algorithms to examine how key-value pairs move through the different phases is always useful. To examine the movement of data, set breakpoints in your map and reduce functions. The breakpoints stop execution of `mapreduce`, allowing you to examine the current status of relevant variables, like the `KeyValueStore` or `ValueIterator`. For more information, see "Debug MapReduce Algorithms".
- Some recommendations to optimize `mapreduce` performance on any platform are:
  - Minimize the number of calls to the map function. The easiest approach is to increase the value of the `ReadSize` property of the input datastore. The result is that `mapreduce` passes larger chunks of data to the map function, and the datastore depletes with fewer reads.
  - Decrease the amount of intermediate data sent between map and reduce functions. One approach is to use `unique` inside a map function to combine similar keys. See "Compute Mean by Group Using MapReduce" for an example of this technique.

`datastore` | `gcmr` | Using KeyValueStore Objects | `mapreducer` | Using ValueIterator Objects

Introduced in R2014b

mapreducer

Define execution environment for mapreduce

`mapreducer` is the execution configuration function for `mapreduce`. Use this function to set, change, or store the execution environment to run `mapreduce` using Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler.

Syntax

```
mapreducer
mapreducer(0)
mapreducer(mr)
mr = mapreducer( ___ )
mr = mapreducer( ___ ,'ObjectVisibility','Off')
```

Description

`mapreducer` sets the global execution environment for `mapreduce` to be the default (`SerialMapReducer` in MATLAB).

`mapreducer(0)` sets the global execution environment for `mapreduce` to be the local MATLAB session.

`mapreducer(mr)` sets the global execution environment for `mapreduce` using a previously created MapReducer object, `mr`.

`mr = mapreducer( ___ )` also returns a MapReducer object using any of the previous syntaxes. Use `mr` as a fourth input argument to `mapreduce` when you want to explicitly specify the execution environment.

`mr = mapreducer( ___ ,'ObjectVisibility','Off')` toggles the visibility of the MapReducer object, `mr`, using any of the previous syntaxes. Use this syntax to create new MapReducer objects without affecting the global execution environment of `mapreduce`.

Note: In MATLAB, the `mapreduce` function automatically runs using a `SerialMapReducer`, and it is unnecessary to specify configuration settings using

`mapreducer`. However, if you have Parallel Computing Toolbox, MATLAB Distributed Computing Server, or MATLAB Compiler, then additional `mapreducer` configuration options are available for running in parallel or deployed environments. For more information, see the documentation in each product.

Output Arguments

`mr` — Execution environment for `mapreduce`

MapReducer object

Execution environment for `mapreduce`, returned as a MapReducer object.

If the `ObjectVisibility` property of `mr` is set to `'On'` (the default), then `mr` defines the default execution environment for `mapreduce`. You can pass `mr` to the `mapreduce` function to explicitly specify the execution environment, even if its `ObjectVisibility` property is set to `'Off'`.

Pass `mr` to the `mapreduce` function when using the following products:

- Parallel Computing Toolbox enables you to run `mapreduce` computations using a parallel pool.
- MATLAB Distributed Computing Server extends Parallel Computing Toolbox, enabling you to run `mapreduce` computations on a remote cluster. This includes support for Hadoop.
- MATLAB Compiler enables you to create standalone applications or deployable archives, which you can share with colleagues or deploy to production Hadoop systems.

More About

Tips

- If you have Parallel Computing Toolbox, see the `mapreducer` function reference page for additional information.
- If you have MATLAB Compiler, see the `mapreducer` function reference page for additional information.
- “Speed Up and Deploy MapReduce Using Other Products”

`gcmr` | `mapreduce`

Introduced in R2014b

containers.Map class

Package: containers

Map values to unique keys

Description

A `Map` object is a data structure that allows you to retrieve values using a corresponding key. Keys can be real numbers or text strings and provide more flexibility for data access than array indices, which must be positive integers. Values can be scalar or nonscalar arrays.

Construction

`mapObj = containers.Map` constructs an empty `Map` container `mapObj`.

`mapObj = containers.Map(keySet,valueSet)` constructs a `Map` that contains one or more values and a unique key for each value.

`mapObj = containers.Map(keySet,valueSet,'UniformValues',isUniform)` specifies whether all values must be uniform (either all scalars of the same data type, or all strings). Possible values for `isUniform` are logical `true` (`1`) or `false` (`0`).

`mapObj = containers.Map('KeyType',kType,'ValueType',vType)` constructs an empty `Map` object and sets the `KeyType` and `ValueType` properties. The order of the key type and value type argument pairs is not important, but both pairs are required.

Input Arguments

`keySet`

1-by-`n` array that specifies `n` unique keys for the map.

All keys in a `Map` object are real numeric values or all keys are strings. If `n` > 1 and the keys are strings, `keySet` must be a cell array. The number of keys in `keySet` must equal the number of values in `valueSet`.

`valueSet`

1-by-`n` array of any class that specifies `n` values for the map. The number of values in `valueSet` must equal the number of keys in `keySet`.

`'UniformValues'`

Parameter string to use with the `isUniform` argument.

`isUniform`

Logical value that specifies whether all values are uniform. If `isUniform` is `true` (`1`), all values must be scalars of the same data type, or all values must be strings. If `isUniform` is `false` (`0`), then `containers.Map` sets the `ValueType` to `'any'`.

Default: `true` for empty `Map` objects, otherwise determined by the data types of values in `valueSet`.

`'KeyType'`

Parameter string to use with the `kType` argument.

`kType`

String that specifies the data type for the keys. Possible values are `'char'`, `'double'`, `'single'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

Default: `'char'` for empty `Map` objects, otherwise determined by the data types of keys in `keySet`. If you specify keys of different numeric types, `kType` is `'double'`.

`'ValueType'`

Literal string parameter to use with the `vType` argument.

`vType`

String that specifies the data type for the values. Possible values are `'any'`, `'char'`, `'logical'`, `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

Default: `'any'` when you create an empty `Map` object or when you specify values of different sizes or types, otherwise determined by the data type of `valueSet`.

Properties

`Count`

Unsigned 64-bit integer that represents the total number of key-value pairs contained in the `Map` object. Read only.

`KeyType`

Character array that indicates the data type of all keys in the `Map` object. The default `KeyType` for empty `Map` objects is `'char'`. Otherwise, `KeyType` is determined from the data type of the `keySet` inputs. Read only.

`ValueType`

Character array that indicates the data type of all values in the `Map` object. If you construct an empty `Map` object or specify values with different data types, then the value of `ValueType` is `'any'`. Otherwise, `ValueType` is determined from the data type of the `valueSet` inputs. Read only.

Methods

isKey	Determine if `containers.Map` object contains key
keys	Identify keys of `containers.Map` object
length	Length of `containers.Map` object
remove	Remove key-value pairs from `containers.Map` object
size	Size of `containers.Map` object
values	Identify values in `containers.Map` object

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Construct a Map and View Properties

Construct a `Map` object that contains rainfall data for several months:

```
keySet =   {'Jan', 'Feb', 'Mar', 'Apr'};
valueSet = [327.2, 368.2, 197.6, 178.4];
mapObj = containers.Map(keySet,valueSet)
```

This code returns a description of the map, including the property values:

```
mapObj =

  containers.Map handle
  Package: containers

  Properties:
        Count: 4
      KeyType: 'char'
    ValueType: 'double'

  Methods, Events, Superclasses
```

Get a specific property using dot notation, such as

```
mapObj.Count
```

which returns

```
ans =
                    4
```

Look Up Values in a Map

Use the map created in the previous example to find the rainfall data for February:

```
rainFeb = mapObj('Feb')
```

This code returns

```
rainFeb =
  368.2000
```

Add a Single Value and Key to a Map

Add data for the month of May to the map created in the first example:

```
mapObj('May') = 100.0;
```

Add Multiple Values and Keys by Concatenating Maps

Create a map that contains rainfall data for June, July, and August, and add the data to `mapObj` (from previous examples):

```
keySet   = {'Jun','Jul','Aug'};
valueSet = [ 69.9, 32.3, 37.3];
newMap = containers.Map(keySet,valueSet);

mapObj = [mapObj; newMap];
```

Map objects only support vertical concatenation (that is, adding columns with a semicolon, `;`). When concatenating maps, the data type of all values must be consistent with the `ValueType` of the leftmost map. In this example, both maps have the a `ValueType` of `double`.

Get the Keys or Values in a Map

Determine all the keys of `mapObj` (from previous examples) by calling the `keys` method:

```
allKeys = keys(mapObj)
```

This method returns the keys in alphabetical order:

```
allKeys =
    'Apr'    'Aug'    'Feb'    'Jan'    'Jul'    'Jun'    'Mar'    'May'
```

Get multiple values from the map by calling the `values` method. Like the `keys` method, you can request all values with the syntax `values(mapObj)`. Alternatively, request values for specific keys. For example, view the values for March, April, and May in `mapObj`:

```
springValues = values(mapObj,{'Mar','Apr','May'})
```

This method returns the values in a cell array, in the order corresponding to the specified keys:

```
springValues =
    [197.6000]    [178.4000]    [100]
```

Remove Keys and Values

Remove the data for March and April from `mapObj` (from previous examples) by calling the `remove` method, and view the remaining keys:

```
remove(mapObj,{'Mar','Apr'});
keys(mapObj)
```

This code returns

```
ans =
    'Aug'    'Feb'    'Jan'    'Jul'    'Jun'    'May'
```

Create a Map with Nonscalar Values

Map integer keys to nonscalar arrays, and view the value for one of the keys:

```
keySet = [5,10,15];
valueSet = {magic(5),magic(10),magic(15)};
mapObj = containers.Map(keySet,valueSet);
mapObj(5)
```

This code returns

```
ans =
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

Construct an Empty Map

Construct a map with no values, but set the `KeyType` and `ValueType` properties:

```
mapObj = containers.Map('KeyType','char','ValueType','int32')
```

This code returns

```
mapObj =

  containers.Map handle
  Package: containers

  Properties:
        Count: 0
      KeyType: 'char'
    ValueType: 'int32'

  Methods, Events, Superclasses
```

Specify Whether Values Are Uniform

Construct a map with numeric values, and specify that the values do not have to be uniform:

```
keySet = {'a','b','c'};
valueSet = {1,2,3};
mapObj = containers.Map(keySet,valueSet,'UniformValues',false);
```

This map allows nonnumeric values, so

```
mapObj('d') = 'OK';
values(mapObj)
```

returns

```
ans =
    [1]    [2]    [3]    'OK'
```

isKey | values | keys

mat2cell

Convert array to cell array with potentially different sized cells

Syntax

```
C = mat2cell(A,dim1Dist,...,dimNDist)
C = mat2cell(A,rowDist)
```

Description

`C = mat2cell(A,dim1Dist,...,dimNDist)` divides array `A` into smaller arrays within cell array `C`. Vectors `dim1Dist,...dimNDist` specify how to divide the rows, columns, and (when applicable) higher dimensions of `A`.

`C = mat2cell(A,rowDist)` divides array `A` into an `n`-by-1 cell array `C`, where `n == numel(rowDist)`.

Input Arguments

`A`

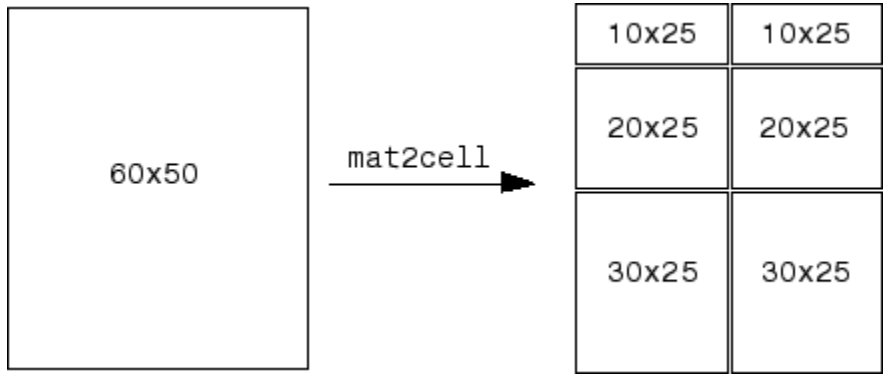
Any type of array.

`dim1Dist,...,dimNDist`

Numeric vectors that describe how to divide each dimension of `A`. For example, this command

```
c = mat2cell(x, [10, 20, 30], [25, 25])
```

divides a 60-by-50 array into six arrays contained in a cell array.



For the *k*th dimension, `sum(dim`*k*`Dist) == size(A, `*k*`)`.

If the *k*th dimension of `A` is zero, set the corresponding `dim`*k*`Dist` to the empty array, `[]`. For example,

```
a = rand(3, 0, 4);
c = mat2cell(a, [1, 2], [], [2, 1, 1]);
```

`rowDist`

Numeric vector that describes how to divide the rows of `A`. When you do not specify distributions for any other dimension, the `mat2cell` function creates an `n`-by-1 cell array `C`, where `n == numel(rowDist)`.

Output Arguments

`C`

Cell array. The *k*th dimension of array `C` is given by `size(C, `*k*`) == numel(dim`*k*`Dist)`. The *k*th dimension of the *i*th cell of `C` is given by `size(C{i}, `*k*`) == dim`*k*`Dist(i)`.

Examples

Divide the 5-by-4 matrix `X` into 2-by-3 and 2-by-2 matrices contained in a cell array.

```
X = reshape(1:20,5,4)'
```

```
C = mat2cell(X, [2 2], [3 2])
celldisp(C)
```

This code returns

```
X =
     1     2     3     4     5
     6     7     8     9    10
    11    12    13    14    15
    16    17    18    19    20

C =
    [2x3 double]    [2x2 double]
    [2x3 double]    [2x2 double]

C{1,1} =
     1     2     3
     6     7     8

C{2,1} =
    11    12    13
    16    17    18

C{1,2} =
     4     5
     9    10

C{2,2} =
    14    15
    19    20
```

Divide `X` (created in the previous example) into a 2-by-1 cell array.

```
C = mat2cell(X, [1 3])
celldisp(C)
```

This code returns

```
C =
    [1x5 double]
    [3x5 double]

C{1} =
     1     2     3     4     5
```

```
C{2} =
     6     7     8     9    10
    11    12    13    14    15
    16    17    18    19    20
```

`cell2mat` | `num2cell`

Introduced before R2006a

mat2str

Convert matrix to string

Syntax

```
str = mat2str(A)
str = mat2str(A,n)
str = mat2str(A, 'class')
str = mat2str(A, n, 'class')
```

Description

`str = mat2str(A)` converts matrix `A` into a string. This string is suitable for input to the `eval` function such that `eval(str)` produces the original matrix to within 15 digits of precision.

`str = mat2str(A,n)` converts matrix `A` using `n` digits of precision.

`str = mat2str(A, 'class')` creates a string with the name of the class of `A` included. This option ensures that the result of evaluating `str` will also contain the class information.

`str = mat2str(A, n, 'class')` uses `n` digits of precision and includes the class information.

Limitations

The `mat2str` function is intended to operate on scalar, vector, or rectangular array inputs only. An error will result if `A` is a multidimensional array.

Examples

Example 1

Consider the matrix

```
x = [3.85 2.91; 7.74 8.99]
x =
    3.8500    2.9100
    7.7400    8.9900
```

The statement

```
A = mat2str(x)
```

produces

```
A =
   [3.85 2.91;7.74 8.99]
```

where `A` is a string of 21 characters, including the square brackets, spaces, and a semicolon.

`eval(mat2str(x))` reproduces `x`.

Example 2

Create a 1-by-6 matrix of signed 16-bit integers, and then use `mat2str` to convert the matrix to a 1-by-33 character array, `A`. Note that output string `A` includes the class name, `int16`:

```
x1 = int16([-300 407 213 418 32 -125]);

A = mat2str(x1, 'class')
A =
   int16([-300 407 213 418 32 -125])

class(A)
ans =
   char
```

Evaluating the string `A` gives you an output `x2` that is the same as the original `int16` matrix:

```
x2 = eval(A);

if isnumeric(x2) && isa(x2, 'int16') && all(x2 == x1)
   disp 'Conversion back to int16 worked'
end
```

```
Conversion back to int16 worked
```

num2str | int2str | str2num | sprintf | fprintf

Introduced before R2006a

material

Control reflectance properties of surfaces and patches

Syntax

```
material shiny
material dull
material metal
material([ka kd ks])
material([ka kd ks n])
material([ka kd ks n sc])
material default
```

Description

`material` sets the lighting characteristics of `surface` and `patch` objects.

`material shiny` sets the reflectance properties so that the object has a high specular reflectance relative to the diffuse and ambient light, and the color of the specular light depends only on the color of the light source.

`material dull` sets the reflectance properties so that the object reflects more diffuse light and has no specular highlights, but the color of the reflected light depends only on the light source.

`material metal` sets the reflectance properties so that the object has a very high specular reflectance, very low ambient and diffuse reflectance, and the color of the reflected light depends on both the color of the light source and the color of the object.

`material([ka kd ks])` sets the ambient/diffuse/specular strength of the objects.

`material([ka kd ks n])` sets the ambient/diffuse/specular strength and specular exponent of the objects.

`material([ka kd ks n sc])` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects.

`material default` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects to their defaults.

More About

Tips

The `material` command sets the `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, and `SpecularColorReflectance` properties of all `surface` and `patch` objects in the axes. There must be visible `light` objects in the `axes` for lighting to be enabled. Look at the `materal.m` file to see the actual values set (enter the command `type material`).

`lighting` | `patch` | `light` | `surface`

Introduced before R2006a

matfile

Access and change variables directly in MAT-files, without loading into memory

Syntax

```
m = matfile(filename)
m = matfile(filename,'Writable',isWritable)
```

Description

`m = matfile(filename)` creates a MAT-file object, `m`, connected to the MAT-file named `filename`. The object allows you to access and change variables directly in a MAT-file, without having to load the variables into memory.

The partial loading and saving that the `matfile` function provides requires less memory than the `load` and `save` commands, which always operate on entire variables.

`m = matfile(filename,'Writable',isWritable)` enables or disables write access to the file.

Examples

Load Entire Variable

Load variable `topo` from the example file, `topography.mat`.

Open the example MAT-file, `topography.mat`.

```
filename = 'topography.mat';
m = matfile(filename);
```

Read the variable `topo` from the MAT-file.

```
topo = m.topo;
```

MATLAB loads the entire variable, `topo`, into the workspace.

Save Entire Variable to Existing MAT-file

Generate a 20-by-20 example array, `x`, and save it to a MAT-file called `myFile.mat`.

```
x = magic(20);
save('myFile.mat','x');
```

Create a MAT-file object connected to the existing MAT-file named `myFile.mat`. Enable write access to the MAT-file by setting `Writable` to `true`.

```
m = matfile('myFile.mat','Writable',true);
```

Generate a 15-by-15 example array, `y`.

```
y = magic(15);
```

Save `y` to the MAT-file. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y = y;
```

MATLAB adds a variable named `y` to the file.

Display all variables stored in the MAT-file, `myFile.mat`.

```
whos('-file','myFile.mat')
```

```
  Name        Size              Bytes  Class     Attributes

  x          20x20              3200  double
  y          15x15              1800  double
```

Load and Save Parts of Variables

Access specific elements of a MAT-file variable.

Open a new MAT-file, `myFile2.mat`.

```
m = matfile('myFile2.mat');
```

Save a 20-by-20 example array to part of a variable, `y`, in `myFile2.mat`. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y(81:100,81:100) = magic(20);
```

MATLAB inserts the 20-by-20 array into the elements of `y` specified by the indices `(81:100,81:100)`.

Read a subset of array `y` into a new workspace variable, `z`.

```
z = m.y(85:94,85:94);
```

MATLAB reads the 10-by-10 subarray specified by the indices `(85:94,85:94)` from the MAT-file into workspace variable `z`.

Determine Size of Variables

Determine the size of a variable, and then calculate the average of each column.

Open the example MAT-file, `stocks.mat`.

```
filename = 'stocks.mat';
m = matfile(filename);
```

Determine the size of the variable, `stocks`, in `stocks.mat`.

```
[nrows,ncols] = size(m,'stocks');
```

Compute the average of each column of the variable `stocks`.

```
avgs = zeros(1,ncols);
for i = 1:ncols
    avgs(i) = mean(m.stocks(:,i));
end
```

Enable Write Access to MAT-file

Enable write access to the MAT-file, `myFile.mat`, by setting `Writable` to `true` when you open the MAT-file.

```
filename = 'myFile.mat';
m = matfile(filename,'Writable',true);
```

Alternatively, set `Properties.Writable` in a separate step after you open the MAT-file.

```
m.Properties.Writable = true;
```

Input Arguments

`filename` — Name of MAT-file

string

Name of a MAT-file, specified as a string. If the file is not in the current folder, `filename` must include a full or a relative path. If `filename` does not include an extension, then `matfile` appends `.mat`.

If the file does not exist, then `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports efficient partial loading and saving for MAT-files in Version 7.3 format. If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

Example: `'myFile.mat'`

Data Types: `char`

`isWritable` — Write access to MAT-file

`true` | `false`

Write access to the MAT-file, specified as either `true` or `false`.

- `true` enables saving to the MAT-file. If the file is read only, MATLAB changes the system permissions with the `fileattrib` function.
- `false` disables saving to the MAT-file. MATLAB does not change the system permissions.

The default value is `true` for new files, and `false` for existing files.

Data Types: `logical`

Output Arguments

`m` — MAT-file object

`matlab.io.MatFile` object

MAT-file object connected to a MAT-file.

Access variables in the MAT-file with dot notation similar to accessing fields of structure arrays:

- To load part of variable `varName` from the MAT-file corresponding to `m`, call:

  ```
  loadedData = m.varName(indices);
  ```

- To save part of variable `varName` to the MAT-file corresponding to `m`, call:

  ```
  m.varName(indices) = dataToSave;
  ```

When accessing variables, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon `(:)`; for example:

```
m.varName(100:500,200:600)
m.varName(:,501:1000)
m.varName(1:2:1000,80)
```

Limitations

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Variables of tables
  - Cells of cell arrays
  - Fields of structure arrays
  - User-defined classes
  - Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using the `m` output. For example, if your MAT-file contains function handle `myfunc`, the syntax `m.myfunc()` attempts to index into the function handle, and does not invoke the function.
- Efficient partial loading and saving requires Version 7.3 MAT-files. To create a Version 7.3 MAT-file, call the `save` function with the `'-v7.3'` option. For example, to convert and existing MAT-file named `durer.mat` to Version 7.3, call:

  ```
  load('durer.mat');
  ```

```
save('mycopy_durer.mat','-v7.3');
```

More About

Tips

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in `Out of Memory` errors. Rather than using `end`, determine the extent of a variable, `myVar`, with the `size` method, such as:

  ```
  sizeMyVar = size(m,'myVar')
  ```

- "Load Parts of Variables from MAT-Files"
- "Save Parts of Variables to MAT-Files"
- MAT-File Versions

See Also

`load` | `save` | `size` | `whos`

Introduced in R2011b

matlab.codetools.requiredFilesAndProducts

List dependencies of MATLAB program files

Syntax

```
fList = matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] = matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] =
matlab.codetools.requiredFilesAndProducts( ___ ,'toponly')
```

Description

`fList = matlab.codetools.requiredFilesAndProducts(files)` returns a list of the MATLAB program files required to run the program files specified by `files`.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts(files)` also returns a list of the MathWorks products possibly required to run the program files specified by `files`.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts( ___ ,'toponly')` indicates that for a file or product to be included in the output, it must be used directly by at least one file specified in `files`. The `'toponly'` input string is case insensitive.

Examples

Identify Required Files and Products for MATLAB Toolbox Function

Determine the required files and products for the `edge` function in the Image Processing Toolbox.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('edge.m')
```

```
fList =

     {}
```

```
pList =

1x2 struct array with fields:

    Name
    Version
    ProductNumber
    Certain
```

There are no required MATLAB files, but there are two required products.

List the required products.

```
{pList.Name}'
```

```
ans =

    'MATLAB'
    'Image Processing Toolbox'
```

Identify Required Files and Products for Your MATLAB Program Files

In your current working folder, create a function in the file `getRandomNumber.m`.

```
function a = getRandomNumber
    rng shuffle
    a = rand;
end
```

Now, at the command line, determine the required files and products for `getRandomNumber.m`.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('getRandomNumber.m')
```

```
fList =

    'C:\work\getRandomNumber.m'

pList =

           Name: 'MATLAB'
        Version: '8.5'
```

```
    ProductNumber: 1
          Certain: 1
```

The only file required to run the `getRandomNumber` function is the function file itself. The only required MathWorks product is MATLAB.

In your current working folder, create a function in the file `displayNumber.m`.

```
function displayNumber
    a = getRandomNumber;
    disp(['Your number is ' num2str(a)])
end
```

Now, at the command line, determine the required files and products for `displayNumber.m`.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('displayNumber.m')
```

```
fList =

    'C:\work\displayNumber.m'    'C:\work\getRandomNumber.m'

pList =

             Name: 'MATLAB'
          Version: '8.5'
    ProductNumber: 1
          Certain: 1
```

In addition to the function file itself, the `displayNumber` function requires the `getRandomNumber.m` file. The only required MathWorks product is MATLAB.

Identify Top-Level Dependencies Only

In your current working folder, create a handle class in the file `ExampleHandle.m`.

```
classdef ExampleHandle < handle
    % class content
end
```

In your current working folder, create a class in the file `AnotherExampleHandle.m` that inherits from `ExampleHandle`.

```
classdef AnotherExampleHandle < ExampleHandle
```

```
    % class content
end
```

In your current working folder, create a function in the file `getHandles.m` that instantiates `AnotherExampleHandle` objects.

```
function [h1,h2] = getHandles()
    h1 = AnotherExampleHandle;
    h2 = AnotherExampleHandle;
end
```

Now, at the command line, determine the required files for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m');
fList'

ans =

    'C:\work\AnotherExampleHandle.m'
    'C:\work\ExampleHandle.m'
    'C:\work\getHandles.m'
```

Determine the required files that are directly required for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m','toponly')

fList =

    'C:\work\AnotherExampleHandle.m'    'C:\work\getHandles.m'
```

Although `AnotherExampleHandle.m` requires `ExampleHandle.m`, that file is not a direct requirement for `getHandles.m`.

Input Arguments

`files` — List of files for analysis

string or cell array of strings

List of files for analysis, specified as a string or cell array of strings. Each string is the name of a single MATLAB program file. For example, `files` is a list of MATLAB program files that you intend to provide to other users. The `matlab.codetools.requiredFilesAndProducts` function provides you with requirements information to pass along with your files.

To ensure an accurate dependency report, `files` and dependencies must be on the MATLAB path. `matlab.codetools.requiredFilesAndProducts` does not return information about dependent files not on the path.

Example: `'myFile.m'` or `'C:\Program Files\MATLAB\R2014a\my_work\myFile.m'`

Example: `{'myFile.m','myOtherFile.m'}`

Example: `cellstr(ls('*.m'))`

Output Arguments

`fList` — List of user-authored MATLAB program files

cell array of strings

List of user-authored MATLAB program files required by `files`, returned as a cell array of strings. Each string indicates the full path of the required file. `fList` does not include built-in MATLAB files, since these files are installed with the products listed in `pList`.

`pList` — List of MathWorks products

structure or array of structures

List of MathWorks products possibly required by `files`, returned as a structure or array of structures. Each product is described by name (`Name` field), version (`Version` field), product number (`ProductNumber` field), and a certainty indicator (`Certain` field). The `Certain` field has a value of 1 if `matlab.codetools.requiredFilesAndProducts` determines the product is required by the specified program files, `files`, or a value of 0 if the product is possibly required.

The `matlab.codetools.requiredFilesAndProducts` function is intended to provide you with information to pass on to consumers of your MATLAB program files. The version numbers indicate the version of the products you have installed when you execute the function. `Version` is not an indicator of backward compatibility.

More About

- "Identify Program Dependencies"

Introduced in R2014a

matlab.io.MatFile class

Package: matlab.io

Load and save parts of variables in MAT-files

Description

The `matfile` function constructs a `matlab.io.MatFile` object that corresponds to a MAT-File, such as

```
matObj = matfile('myFile.mat')
```

Access variables in the MAT-file as properties of `matObj`, with dot notation similar to accessing fields of structs. The syntax for loading and saving part of variable `varName` in the MAT-file corresponding to `matObj` is:

```
loadedData = matObj.varName(indices);    % Load into workspace
matObj.varName(indices) = dataToSave;    % Save to file
```

When indexing, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon `(:)`, such as

```
matObj.varName(100:500, 200:600)
matObj.varName(:, 501:1000)
matObj.varName(1:2:1000, 80)
```

Limitations

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in `Out of Memory` errors. Rather than using `end`, determine the extent of a variable with the `size` method, such as:

  ```
  sizeMyVar = size(matObj,'myVar')
  ```
- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Cells of cell arrays

  - Fields of structs
  - User-defined classes
  - Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using a `MatFile` object. For example, if your MAT-file contains function handle `myfunc`, the syntax `matObj.myfunc()` attempts to index into the function handle, and does not invoke the function.

Construction

`matObj = matfile(filename)` constructs a `matlab.io.MatFile` object that can load or save parts of variables in MAT-file `filename`. MATLAB does not load any data from the file into memory when creating the object.

`matObj = matfile(filename,'Writable',isWritable)` enables or disables write access to the file for object `matObj`. Possible values for `isWritable` are logical `true` (1) or `false` (0).

Input Arguments

`filename`

String enclosed in single quotation marks that specifies the name of a MAT-file.

`filename` can include a full or partial path, otherwise `matfile` searches for the file along the MATLAB search path. If `filename` does not include an extension, `matfile` appends `.mat`.

If the file does not exist, `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports partial loading and saving for MAT-files in Version 7.3 format (described in MAT-File Versions). If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

`'Writable'`

Parameter to use with the `isWritable` argument.

isWritable

Logical value that specifies whether to allow saving to the file. Possible values:

`true (1)`	Enable saving. If the file is read only, change the system permissions with `fileattrib`.
`false (0)`	Disable saving with `matfile`. MATLAB does not change the system permissions.

Default: `true` for new files, `false` for existing files

Properties

Properties.Source

String that contains the fully qualified path to the file. Read only.

Properties.Writable

Logical value that specifies whether to allow saving to the file. Possible values:

`true (1)`	Enable saving. If the file is read only, change the system permissions with `fileattrib`.
`false (0)`	Disable saving with `matfile`. MATLAB does not change the system permissions.

Default: `true` for new files, `false` for existing files

Methods

size	Array dimensions
who	Names of variables in MAT-file
whos	Names, sizes, and types of variables in MAT-file

You cannot access help for these methods using the `help` command. Find help on the methods from the command line using the `doc` command, such as `doc matlab.io.MatFile/size`.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create `myFile.mat` in a temporary folder and save data to part of variable `savedVar`:

```
filename = fullfile(tempdir,'myFile.mat');
matObj = matfile(filename);
matObj.savedVar(81:100,81:100) = magic(20);
```

Load part of the data into variable `loadVar`:

```
loadVar = matObj.savedVar(85:94,85:94);
```

Load or save an entire variable by omitting the indices. For example, load variable `topo` from `topography.mat`:

```
filename = 'topography.mat';
matObj = matfile(filename);
topo = matObj.topo;
```

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
    avgs(idx) = mean(matObj.stocks(:,idx));
end
```

By default, `matfile` only supports loading data from existing files. To enable saving, set `Writable` to `true` either during construction of the object,

```
filename = 'myFile.mat';
matObj = matfile(filename,'Writable',true);
```

or in a separate step, by setting `Properties.Writable`:

```
filename = 'myFile.mat';
matObj = matfile(filename);
matObj.Properties.Writable = true;
```

See Also

`load` | `save` | `size` | `whos`

matlab.io.fits.closeFile

Close FITS file

Syntax

```
closeFile(fptr)
```

Description

`closeFile(fptr)` closes an open FITS file.

This function corresponds to the `fits_close_file (ffclos)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits','READONLY');
fits.closeFile(fptr);
```

See Also

`createFile` | `openFile`

matlab.io.fits.createFile

Create FITS file

Syntax

```
fptr = createFile(filename)
```

Description

`fptr = createFile(filename)` creates a FITS file. An error will be returned if the specified file already exists, unless the filename is prefixed with an exclamation point (!). In that case CFITSIO will overwrite (delete) any existing file with the same name.

This function corresponds to the `fits_create_file (ffinit)` function in the CFITSIO library C API.

Examples

Create a new FITS file, overwriting any existing file by the same name.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[256 512]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

See Also

`closeFile` | `createImg` | `createTbl` | `openFile`

matlab.io.fits.deleteFile

Delete FITS file

Syntax

```
deleteFile(fptr)
```

Description

`deleteFile(fptr)` closes and deletes an open FITS file. This can be useful if a FITS file cannot be properly closed.

This function corresponds to the `fits_delete_file (ffdelt)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.deleteFile(fptr);
fptrs = fits.getOpenFiles()
```

See Also

`closeFile` | `createFile`

matlab.io.fits.fileName

Name of FITS file

Syntax

```
name = fileName(fptr)
```

Description

`name = fileName(fptr)` returns the name of the FITS file associated with the file handle.

This function corresponds to the `fits_file_name (ffflnm)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits','READONLY');
name = fits.fileName(fptr);
fits.closeFile(fptr);
```

See Also

`createFile` | `openFile`

matlab.io.fits.fileMode

I/O mode of FITS file

Syntax

```
mode = fileMode(fptr)
```

Description

`mode = fileMode(fptr)` returns the I/O mode of the opened FITS file. Possible values returned for `mode` are `'READONLY'` or `'READWRITE'`.

This function corresponds to the `fits_file_mode (ffflmd)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
mode = fits.fileMode(fptr);
fits.closeFile(fptr);
```

See Also

`createFile` | `openFile`

matlab.io.fits.openFile

Open FITS file

Syntax

```
fptr = openFile(filename)
fptr = openFile(filename,mode)
```

Description

`fptr = openFile(filename)` opens a existing FITS file in read-only mode and returns a file pointer, `fptr`, which references the primary array (first header data unit, or "HDU").

`fptr = openFile(filename,mode)` opens a existing FITS file according to the `mode`, which describes the type of access. `mode` may be either `'READONLY'` or `'READWRITE'`.

This function corresponds to the `fits_open_file (ffopen)` function in the CFITSIO library C API.

Examples

Open a file in read-only mode and read image data from the primary array.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
imagedata = fits.readImg(fptr);
fits.closeFile(fptr);
```

Open a file in read-write mode and add a comment to the primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.writeComment(fptr,'This is just a comment.');
```

```
fits.closeFile(fptr);
```

See Also

`closeFile` | `createFile`

matlab.io.fits.createImg

Create FITS image

Syntax

```
createImg(fptr,bitpix,naxes)
```

Description

`createImg(fptr,bitpix,naxes)` creates a new primary image or image extension with a specified datatype `bitpix` and size `naxes`. If the FITS file is currently empty then a primary array is created, otherwise a new image extension is appended to the file.

The first two elements of `naxes` correspond to the NAXIS2 and NAXIS1 keywords, while any additional elements correspond to the NAXIS3, NAXIS4 ... NAXISn keywords.

The datatype `bitpix` may be given as either a CFITSIO name or as the corresponding MATLAB datatype.

`'byte_img'`	`'uint8'`
`'short_img'`	`'int16'`
`'long_img'`	`'int32'`
`'longlong_img'`	`'int64'`
`'float_img'`	`'single'`
`'double_img'`	`'double'`

This function corresponds to the `fits_create_imgll (ffcrimll)` function in the CFITSIO library C API.

Examples

Create two images in a new FITS file. There are 100 rows (NAXIS2 keyword) and 200 columns (NAXIS1 keyword) in the first image, and 256 rows (NAXIS2 keyword), 512 columns (NAXIS1 keyword), and 3 planes (NAXIS3 keyword) in the second image.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'int16',[100 200]);
fits.createImg(fptr,'byte_img',[256 512 3]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

See Also

createTbl | insertImg | readImg | setCompressionType | writeImg

matlab.io.fits.getImgSize

Size of image

Syntax

```
imagesize = getImgSize(fptr)
```

Description

`imagesize = getImgSize(fptr)` returns the number of rows and columns of an image. This function corresponds to the `fits_get_img_size (ffgisz)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*;
fptr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
    htype = fits.movAbsHDU(fptr,j);
    sz = fits.getImgSize(fptr);
    fprintf('HDU %d:  "%s", [', j, htype);
    for k = 1:numel(sz)
        fprintf(' %d ', sz(k));
    end
    fprintf(']\n');
end
fits.closeFile(fptr);
```

See Also

`createImg` | `getImgType`

matlab.io.fits.getImgType

Data type of image

Syntax

```
datatype = getImgType(fptr)
```

Description

`datatype = getImgType(fptr)` gets the data type of an image. `datatype` can be one of the following strings:

```
'BYTE_IMG'
'SHORT_IMG'
'LONG_IMG'
'LONGLONG_IMG'
'FLOAT_IMG'
'DOUBLE_IMG'
```

This function corresponds to the `fits_get_img_type (ffgidt)` function in the CFITSIO library C API.

Examples

```
fptr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
    htype = fits.movAbsHDU(fptr,j);
    dtype = fits.getImgType(fptr);
    fprintf('HDU %d:  "%s", "%s"\n', j, htype, dtype);
end
fits.closeFile(fptr);
```

See Also

`getImgSize`

matlab.io.fits.insertImg

Insert FITS image after current image

Syntax

```
insertImage(fptr,bitpix,naxes)
```

Description

`insertImage(fptr,bitpix,naxes)` inserts a new image extension immediately following the current HDU. If the file has just been created, a new primary array is inserted at the beginning of the file. Any following extensions in the file will be shifted down to make room for the new extension. If the current HDU is the last HDU in the file, then the new image extension will be appended to the end of the file.

This function corresponds to the `fits_insert_imgll (ffiimgll)` function in the CFITSIO library C API.

Examples

Create a 150x300 image between the 1st and 2nd images in a FITS file.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.createImg(fptr,'byte_img',[200 400]);
fits.movAbsHDU(fptr,1);
fits.insertImg(fptr,'byte_img',[150 300]);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

See Also

`createImg`

matlab.io.fits.readImg

Read image data

Syntax

```
imgdata = readImg(fptr)
imgdata = readImg(fptr,fpixel,lpixel)
imgdata = readImg(fptr,fpixel,lpixel,inc)
```

Description

`imgdata = readImg(fptr)` reads the entire current image. The number of rows in `imgdata` will correspond to the value of the NAXIS2 keyword, while the number of columns will correspond to the value of the NAXIS1 keyword. Any further dimensions of `imgdata` will correspond to NAXIS3, NAXIS4, and so on.

`imgdata = readImg(fptr,fpixel,lpixel)` reads the subimage defined by pixel coordinates `fpixel` and `lpixel`. The `fpixel` argument is the coordinate of the first pixel and `lpixel` is the coordinate of the last pixel. `fpixel` and `lpixel` are one-based.

`imgdata = readImg(fptr,fpixel,lpixel,inc)` reads the subimage defined by `fpixel`, `lpixel`, and `inc`. The `inc` argument denotes the inter- element spacing along each extent.

This function corresponds to the `fits_read_subset (ffgsv)` function in the CFITSIO library C API.

Examples

Read an entire image.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

Read a 70x80 image subset.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
img = fits.readImg(fptr,[11 11],[80 90]);
fits.closeFile(fptr);
```

See Also

`createImg` | `writeImg`

matlab.io.fits.setBscale

Reset image scaling

Syntax

```
setBscale(fptr,BSCALE,BZERO)
```

Description

`setBscale(fptr,BSCALE,BZERO)` resets the scaling factors in the primary array or image extension according to the equation

```
output = (FITS array) * BSCALE + BZERO
```

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the BSCALE and BZERO keyword values.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.setBscale(fptr,2.0,0.5);
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

See Also

`readImg`

matlab.io.fits.writeImg

Write to FITS image

Syntax

```
writeImg(fptr,data)
writeImg(fptr,data,fpixel)
```

Description

`writeImg(fptr,data)` writes an entire image to the FITS data array. The number of rows and columns in `data` must equal the values of the NAXIS2 and NAXIS1 keywords, respectively. Any further extents must correspond to the NAXIS3, NAXIS4 ... NAXISn keywords respectively.

`writeImg(fptr,data,fpixel)` writes a subset of an image to the FITS data array. `fpixel` gives the coordinate of the first pixel in the image region.

This function corresponds to the `fits_write_subset (ffpss)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

Create an 80x40 `uint8` image and set all but the outermost pixels to 1.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[80 40]);
```

```
data = ones(78,38);
fits.writeImg(fptr,data,[1 1]);
fits.closeFile(fptr);
```

See Also

createImg | readImg

matlab.io.fits.deleteKey

Delete key by name

Syntax

```
deleteKey(fptr,keyname)
```

Description

`deleteKey(fptr,keyname)` deletes a keyword by name.

This function corresponds to the `fits_delete_key (ffdrec)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before key deletion...\n');
fitsdisp('myfile.fits','index',1);
fptr = fits.openFile('myfile.fits','readwrite');
fits.deleteKey(fptr,'DATE');
fits.closeFile(fptr);
fprintf('\n\n\nAfter key deletion...\n');
fitsdisp('myfile.fits','index',1);
```

See Also

`deleteRecord` | `writeKey`

matlab.io.fits.deleteRecord

Delete key by record number

Syntax

```
deleteRecord(fptr,keynum)
```

Description

`deleteRecord(fptr,keynum)` deletes a keyword by record number.

This function corresponds to the `fits_delete_record (ffdrec)` function in the CFITSIO library C API.

Examples

Delete the 18th keyword ("ORIGIN") in a primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
card = fits.readRecord(fptr,18);
fits.deleteRecord(fptr,18);
fits.closeFile(fptr);
```

See Also

`deleteKey` | `readRecord`

matlab.io.fits.getHdrSpace

Number of keywords in header

Syntax

```
[nkeys,morekeys] = fits.getHdrSpace(fptr)
```

Description

`[nkeys,morekeys] = fits.getHdrSpace(fptr)` returns the number of existing keywords (not counting the END keyword) and the amount of space currently available for more keywords. It returns `morekeys = -1` if the header has not yet been closed. Note that the CFITSIO library will dynamically add space if required when writing new keywords to a header so in practice there is no limit to the number of keywords that can be added to a header.

This function corresponds to the `fits_get_hdrspace (ffghsp)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
[nkeys,morekeys] = fits.getHdrSpace(fptr);
fits.closeFile(fptr);
```

matlab.io.fits.readCard

Header record of keyword

Syntax

```
card = readCard(fptr,keyname)
```

Description

`card = readCard(fptr,keyname)` returns the entire 80-character header record of the keyword, with any trailing blank characters stripped off.

This function corresponds to the `fits_read_card (ffgcrd)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
    fits.movAbsHDU(fptr,j);
    card = fits.readCard(fptr,'NAXIS');
    fprintf('HDU %d:  ''%s''\n', j, card);
end
fits.closeFile(fptr);
```

See Also

`readKey` | `readRecord`

matlab.io.fits.readKey

Keyword

Syntax

```
[value,comment] = readKey(fptr,keyname)
```

Description

`[value,comment] = readKey(fptr,keyname)` returns the specified key and comment. `value` is returned as a string.

This function corresponds to the `fits_read_key_str (ffgkys)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
    fits.movAbsHDU(fptr,j);
    [key,comment] = fits.readKey(fptr,'NAXIS');
    fprintf('HDU %d:  NAXIS %s, "%s"\n', j, key, comment);
end
fits.closeFile(fptr);
```

See Also

`readKeyCmplx` | `readKeyDbl` | `readKeyLongLong`

matlab.io.fits.readKeyCmplx

Keyword as complex scalar value

Syntax

```
[value,comment] = readKeyCmplx(fptr,keyname)
```

Description

`[value,comment] = readKeyCmplx(fptr,keyname)` returns the specified key and comment. `value` is returned as a double precision complex scalar value.

This function corresponds to the `fits_read_key_dblcmp" (ffgkym)` function in the CFITSIO library C API.

See Also

`readKey` | `readKeyDbl` | `readKeyLongLong`

matlab.io.fits.readKeyDbl

Keyword as double precision value

Syntax

```
[value,comment] = readKeyDbl(fptr,keyname)
```

Description

`[value,comment] = readKeyDbl(fptr,keyname)` returns the specified key and comment.

This function corresponds to the `fits_read_key_dbl (ffgkyd)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
    fits.movAbsHDU(fptr,j);
    [key,comment] = fits.readKeyDbl(fptr,'NAXIS');
    fprintf('HDU %d:  NAXIS %s, "%s"\n', j, key, comment);
end
fits.closeFile(fptr);
```

See Also

`readKey` | `readKeyCmplx` | `readKeyLongLong`

matlab.io.fits.readKeyLongLong

Keyword as `int64`

Syntax

```
[value,comment] = readKeyLongLong(fptr,keyname)
```

Description

`[value,comment] = readKeyLongLong(fptr,keyname)` returns the specified key and comment. `value` is returned an `int64` scalar value.

This function corresponds to the `fits_read_key_lnglng (ffgkyjj)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
    fits.movAbsHDU(fptr,j);
    [key,comment] = fits.readKeyLongLong(fptr,'NAXIS');
    fprintf('HDU %d:  NAXIS %d, "%s"\n', j, key, comment);
end
fits.closeFile(fptr);
```

See Also

`readKey` | `readKeyCmplx` | `readKeyDbl`

matlab.io.fits.readKeyLongStr

Long string value

Syntax

```
[value,comment] = readKeyLongStr(fptr,keyname)
```

Description

`[value,comment] = readKeyLongStr(fptr,keyname)` returns the specified long string value and comment.

This function corresponds to the `fits_read_key_longstr (ffgkls)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
idata = repmat(char(97:106),1,10);
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeKey(fptr,'mykey',idata);
odata1 = fits.readKey(fptr,'mykey');
odata2 = fits.readKeyLongStr(fptr,'mykey');
fits.closeFile(fptr);
```

See Also

`readKey`

matlab.io.fits.readKeyUnit

Physical units string from keyword

Syntax

```
units = readKeyUnit(fptr,keyname)
```

Description

`units = readKeyUnit(fptr,keyname)` returns the physical units string from an existing keyword. If no units are defined, `units` is returned as an empty string.

This function corresponds to the `fits_read_key_unit" (ffgunt)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[10 20]);
fits.writeKey(fptr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fptr,'VELOCITY','km/s');
units = fits.readKeyUnit(fptr,'VELOCITY');
fits.closeFile(fptr);
```

See Also

`readKey` | `writeKeyUnit`

matlab.io.fits.readRecord

Header record specified by number

Syntax

```
card = readRecord(fptr,keynum)
```

Description

`card = readRecord(fptr,keynum)` returns the entire 80-character header record identified by the numeric `keynum`. Trailing blanks are truncated.

This function corresponds to the `fits_read_record (ffgrec)` function in the CFITSIO library C API.

Examples

Read the second record in each HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHdrSpace(fptr);
for j = 1:n
    card = fits.readRecord(fptr,j);
    fprintf('record %d:  "%s"\n', j, card);
end
fits.closeFile(fptr);
```

See Also

`deleteRecord` | `readCard` | `readKey`

matlab.io.fits.writeComment

Write or append COMMENT keyword to CHU

Syntax

```
writeComment(fptr,comment)
```

Description

`writeComment(fptr,comment)` writes (appends) a COMMENT keyword to the CHU. The comment string will be continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the `fits_write_comment (ffpcom)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeComment(fptr,'this is a comment');
fits.writeComment(fptr,'this is another comment');
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`writeDate` | `writeHistory`

matlab.io.fits.writeDate

Write DATE keyword to CHU

Syntax

```
writeDate(FPTR)
```

Description

`writeDate(FPTR)` writes the DATE keyword to the CHU.

This function corresponds to the `fits_write_date (ffpdat)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeDate(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`writeComment` | `writeHistory`

matlab.io.fits.writeKey

Update or add new keyword into current HDU

Syntax

```
writeKey(fptr,keyname,value,comment)
writeKey(fptr,keyname,value,comment,decimals)
```

Description

`writeKey(fptr,keyname,value,comment)` adds a new record in the current HDU, or updates it if it already exists. `comment` is optional.

`writeKey(fptr,keyname,value,comment,decimals)` adds a new floating point keyword in the current HDU, or updates it if it already exists. You must use this syntax to write a keyword with imaginary components. `decimals` is ignored otherwise.

If a character `value` exceeds 68 characters in length, the LONGWARN convention is automatically employed.

This function corresponds to the `fits_write_key (ffpky)` and `fits_update_key (ffuky)` family of functions in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeKey(fptr,'mykey1','a char value','with a comment');
fits.writeKey(fptr,'mykey2',int32(1));
fits.writeKey(fptr,'mykey3',5+7*j,'with another comment');
fits.writeKey(fptr,'mykey4',4/3,'with yet another comment',2);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`deleteKey` | `readKey` | `readRecord`

matlab.io.fits.writeKeyUnit

Write physical units string

Syntax

```
writeKeyUnit(fptr,keyname,unit)
```

Description

`writeKeyUnit(fptr,keyname,unit)` writes a physical units string into an existing keyword.

This function corresponds to the `fits_write_key_unit (ffpunt)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myFitsFile.fits');
fits.createImg(fptr,'long_img',[10 20]);
fits.writeKey(fptr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fptr,'VELOCITY','km/s');
fits.closeFile(fptr);
```

See Also

`readKeyUnit`

matlab.io.fits.writeHistory

Write or append HISTORY keyword to CHU

Syntax

```
writeHistory(fptr,history)
```

Description

`writeHistory(fptr,history)` writes (appends) a HISTORY keyword to the CHU. The history string is continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the `fits_write_history (ffphis)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeHistory(fptr,'this is a history keyword');
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`writeComment` | `writeDate`

matlab.io.fits.copyHDU

Copy current HDU from one file to another

Syntax

```
copyHDU(infptr,outfptr)
```

Description

`copyHDU(infptr,outfptr)` copies the current HDU from the FITS file associated with `infptr` and appends it to the end of the FITS file associated with `outfptr`.

This function corresponds to the `fits_copy_hdu (ffcopy)` function in the CFITSIO library C API.

Examples

Copy the first, third, and fifth HDUs from one file to another.

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,3);
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,5);
fits.copyHDU(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
fitsdisp('tst0012.fits','mode','min','index',[1 3 5]);
fitsdisp('myfile.fits','mode','min');
```

See Also

`deleteHDU`

matlab.io.fits.deleteHDU

Delete current HDU in FITS file

Syntax

```
HDU_TYPE = deleteHDU(fptr)
```

Description

`HDU_TYPE = deleteHDU(fptr)` deletes the current HDU in the FITS file. Any following HDUs will be shifted forward in the file, filling the gap created by the deleted HDU. In the case of deleting the primary array (the first HDU in the file) then the current primary array will be replaced by a null primary array containing the minimum set of required keywords and no data. If there are more HDUs in the file following the HDU being deleted, then the current HDU will be redefined to point to the following HDU. If there are no following HDUs then the current HDU will be redefined to point to the previous HDU. `HDU_TYPE` returns the type of the new current HDU.

This function corresponds to the `fits_delete_hdu (ffdhdu)` function in the CFITSIO library C API.

Examples

Delete the second HDU in a FITS file.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fitsdisp('myfile.fits','mode','min');
fptr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fptr,2);
new_current_hdu = fits.deleteHDU(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

See Also

copyHDU

matlab.io.fits.getHDUnum

Number of current HDU in FITS file

Syntax

```
N = getHDUnum(fptr)
```

Description

`N = getHDUnum(fptr)` returns the number of the current HDU in the FITS file. The primary array has HDU number 1.

This function corresponds to the `fits_get_hdu_num (ffghdn)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHDUnum(fptr);
fits.closeFile(fptr);
```

See Also

`getHDUtype` | `getNumHDUs`

matlab.io.fits.getHDUtype

Type of current HDU

Syntax

```
htype = getHDUtype(fptr)
```

Description

`htype = getHDUtype(fptr)` returns the type of the current HDU in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_get_hdu_type (ffghdt)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
    fits.getHDUtype(fptr);
end
fits.closeFile(fptr);
```

See Also

`getHDUnum`

matlab.io.fits.getNumHDUs

Total number of HDUs in FITS file

Syntax

```
N = getNumHDUs(fptr)
```

Description

`N = getNumHDUs(fptr)` returns the number of completely defined HDUs in a FITS file. If a new HDU has just been added to the FITS file, then that last HDU will only be counted if it has been closed, or if data has been written to the HDU. The current HDU remains unchanged by this routine.

This function corresponds to the `fits_get_num_hdus (ffthdu)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
fits.closeFile(fptr);
```

See Also

`getHDUnum`

matlab.io.fits.movAbsHDU

Move to absolute HDU number

Syntax

```
htype = fits.movAbsHDU(fptr,HDUNUM)
```

Description

`htype = fits.movAbsHDU(fptr,HDUNUM)` moves to a specified absolute HDU number (starting with 1 for the primary array) in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_move_abs_hdu` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
    htype = fits.movAbsHDU(fptr,j);
    fprintf('HDU %d:  "%s"\n',j,htype);
end
fits.closeFile(fptr);
```

See Also

`getNumHDUs` | `movNamHDU` | `movRelHDU`

matlab.io.fits.movNamHDU

Move to first HDU having specific type and keyword values

Syntax

```
movNamHDU(fptr,hdutype,EXTNAME,EXTVER)
```

Description

`movNamHDU(fptr,hdutype,EXTNAME,EXTVER)` moves to the first HDU which has the specified extension type and `EXTNAME` and `EXTVER` keyword values (or `HDUNAME` and `HDUVER` keywords).

The `hdutype` parameter may have a value of:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
'ANY_HDU'
```

If `hdutype` is `'ANY_HDU'`, only the `EXTNAME` and `EXTVER` values are used to locate the correct extension. If the input value of `EXTVER` is 0, then the `EXTVER` keyword is ignored and the first HDU with a matching `EXTNAME` (or `HDUNAME`) keyword will be found.

This function corresponds to the `fits_movnam_hdu (ffmnhd)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movNamHDU(fptr,'IMAGE_HDU','quality',1);
fits.closeFile(fptr);
```

See Also

`movAbsHDU` | `movRelHDU`

matlab.io.fits.movRelHDU

Move relative number of HDUs from current HDU

Syntax

```
htype = moveRelHDU(fptr,nmove)
```

Description

`htype = moveRelHDU(fptr,nmove)` moves a relative number of HDUs forward or backward from the current HDU and returns the HDU type, `htype`, of the resulting HDU. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_movrel_hdu (ffmrhd)` function in the CFITSIO library C API.

Examples

Move through each HDU in succession, then move backwards twice by two HDUs.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
    htype = fits.movAbsHDU(fptr,j);
    fprintf('HDU %d:  "%s"\n',j,htype);
end
htype = fits.movRelHDU(fptr,-2);
n = fits.getHDUnum(fptr);
fprintf('HDU %d:  "%s"\n',n,htype);
htype = fits.movRelHDU(fptr,-2);
```

```
n = fits.getHDUnum(fptr);
fprintf('HDU %d:  "%s"\n',n,htype);
fits.closeFile(fptr);
```

See Also

movAbsHDU | movNamHDU

matlab.io.fits.writeChecksum

Compute and write checksum for current HDU

Syntax

```
writeChecksum(fptr)
```

Description

`writeChecksum(fptr)` computes and writes the `DATASUM` and `CHECKSUM` keyword values for the current HDU into the current header. If the keywords already exist, their values are updated only if necessary (for example, if the file has been modified since the original keyword values were computed).

This function corresponds to the `fits_write_chksum (ffpcks)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[10 20]);
fits.writeChecksum(fptr)
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`fitsdisp`

matlab.io.fits.imgCompress

Compress HDU from one file into another

Syntax

```
imgCompress(infptr,outfptr)
```

Description

`imgCompress(infptr,outfptr)` initializes the output HDU, copies all the keywords, and loops through the input image, compressing the data and writing the compressed data to the output HDU.

This function corresponds to the `fits_img_compress` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.setCompressionType(outfptr,'rice');
fits.imgCompress(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
```

See Also

`setCompressionType`

matlab.io.fits.isCompressedImg

Determine if current image is compressed

Syntax

```
TF = isCompressedImg(fptr)
```

Description

`TF = isCompressedImg(fptr)` returns true if the image in the current HDU is compressed.

This function corresponds to the `fits_is_compressed_image` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
bool = fits.isCompressedImg(fptr);
fits.closeFile(fptr);
```

See Also

`setCompressionType`

matlab.io.fits.setCompressionType

Set image compression type

Syntax

```
setCompressionType(fptr,comptype)
```

Description

`setCompressionType(fptr,comptype)` specifies the image compression algorithm that should be used when writing a FITS image.

Supported values for `comptype` include:

```
'GZIP'
'GZIP2'
'RICE'
'PLIO'
'HCOMPRESS'
'NOCOMPRESS'
```

This function corresponds to the `fits_set_compression_type` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'GZIP2');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

```
fitsdisp('myfile.fits','mode','full');
```

See Also

createImg | setTileDim

matlab.io.fits.setHCompScale

Set scale parameter for HCOMPRESS algorithm

Syntax

```
setHCompScale(fptr,scale)
```

Description

`setHCompScale(fptr,scale)` sets the scale parameter to be used with the HCOMPRESS compression algorithm. Setting the scale parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_scale` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
data = 50*ones(256,512,'double') + 10 * rand([256 512]);
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'HCOMPRESS_1');
fits.setHCompScale(fptr,2.5);
fits.createImg(fptr,'double_img',[256 512]);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`setCompressionType` | `setHCompSmooth`

matlab.io.fits.setHCompSmooth

Set smoothing for images compressed with HCOMPRESS

Syntax

```
setHCompSmooth(fptr,smooth)
```

Description

`setHCompSmooth(fptr,smooth)` sets the smoothing to be used when compressing an image with the HCOMPRESS algorithm. Setting either the scale or smoothing parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_smooth` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
data = int32(50*ones(256,512,'double') + 10 * rand([256 512]));
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'HCOMPRESS');
fits.setHCompSmooth(fptr,1);
fits.createImg(fptr,'long_img',[256 512]);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`setCompressionType` | `setHCompScale`

matlab.io.fits.setTileDim

Set tile dimensions

Syntax

```
fits.setTileDim(fptr,tiledims)
```

Description

`fits.setTileDim(fptr,tiledims)` specifies the size of the image compression tiles to be used when creating a compressed image.

This function corresponds to the `fits_set_tile_dim` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr,'RICE_1');
fits.setTileDim(fptr,[64 128]);
fits.createImg(fptr,'byte_img',[256 512]);
data = ones(256,512,'uint8');
fits.writeImg(fptr,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

See Also

`setCompressionType`

matlab.io.fits.createTbl

Create new ASCII or binary table extension

Syntax

```
fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)
```

Description

`fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)` creates a new ASCII or bintable table extension. `ttype` must be either `'binary'` or `'ascii'`. The `nrows` argument gives the initial number of rows to be created in the table and should normally be zero. `tunit` specifies the units for each column, but can be an empty cell array if no units are desired. `extname` specifies the extension name, but can be omitted.

`tform` specifies the format of the column. For binary tables, the values should be in the form of `'rt'`, where `'r'` is the repeat count and `'t'` is one of the following letters.

`'A'`	ASCII character
`'B'`	Byte or `uint8`
`'C'`	Complex (single precision)
`'D'`	Double precision
`'E'`	Single precision
`'I'`	`int16`
`'J'`	`int32`
`'K'`	`int64`
`'L'`	Logical
`'M'`	Complex (double precision)
`'X'`	Bit (`int8` zeros and ones)

A column can also be specified as having variable-width if the `tform` value has the form `'1Pt'` or `'1Qt'`, where `'t'` specifies the data type as above.

For ASCII tables, the `tform` values take the form:

Iw	`int16` column with width `'w'`
Aw	ASCII column with width `'w'`
Fww.dd	Fixed point
Eww.dd	Single precision with width `'ww'` and precision `'dd'`
Dww.dd	Double precision with width `'ww'` and precision `'dd'`

This function corresponds to the `fits_create_tbl (ffcrtb)` function in the CFITSIO library C API.

Examples

Create a binary table. The first column contains strings of nine characters each. The second column contains four-element sequences of bits. The third column contains three-element sequences of `uint8` values. The fourth column contains double-precision scalars.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'9A','4X','3B','1D'};
tunit = {'m/s','kg','kg/m^3','candela'};
fits.createTbl(fptr,'binary',10,ttype,tform,tunit,'my-table');
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

Create a two-column table where the first column has a single double-precision value, but the second column has a variable-length double-precision value.

```
import matlab.io.*
fptr = fits.createFile('myfile2.fits');
ttype = {'Col1','Col2'};
tform = {'1D','1PD'};
fits.createTbl(fptr,'binary',0,ttype,tform);
fits.closeFile(fptr);
fitsdisp('myfile2.fits');
```

See Also

`createImg` | `insertATbl` | `insertBTbl` | `readCol` | `writeCol`

matlab.io.fits.deleteCol

Delete column from table

Syntax

```
deleteCol(fptr,colnum)
```

Description

`deleteCol(fptr,colnum)` deletes the column from an ASCII or binary table.

This function corresponds to the `fits_delete_col (ffdcol)` function in the CFITSIO library C API.

Examples

Delete the second column in a binary table.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before:  '); fitsdisp('myfile.fits','index',2,'mode','min');
fptr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fptr,2);
fits.deleteCol(fptr,2);
fits.closeFile(fptr);
fprintf('After :  '); fitsdisp('myfile.fits','index',2,'mode','min');
```

See Also

`deleteRows`

matlab.io.fits.deleteRows

Delete rows from table

Syntax

```
deleteRows(fptr,firstrow,nrows)
```

Description

`deleteRows(fptr,firstrow,nrows)` deletes rows from an ASCII or binary table.

This function corresponds to the `fits_delete_rows (ffdrow)` function in the CFITSIO library C API.

Examples

Delete the second, third, and fourth rows in a binary table (second HDU).

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before:  '); fitsdisp('myfile.fits','index',2,'mode','min');
fptr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fptr,2);
fits.deleteRows(fptr,2,2);
fits.closeFile(fptr);
fprintf('After :  '); fitsdisp('myfile.fits','index',2,'mode','min');
```

See Also

`deleteCol` | `insertRows`

matlab.io.fits.insertRows

Insert rows into table

Syntax

```
insertRows(fptr,firstrow,nrows)
```

Description

`insertRows(fptr,firstrow,nrows)` inserts rows into an ASCII or binary table. `firstrow` is a one-based number.

This function corresponds to the `fits_insert_rows (ffirow)` function in the CFITSIO library C API.

Examples

Insert five rows into an empty table.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertRows(fptr,1,5);
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2);
```

See Also

`deleteRows` | `insertCol`

matlab.io.fits.getAColParms

ASCII table information

Syntax

```
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] =
getAColParms(fptr,colnum)
```

Description

`[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = getAColParms(fptr,colnum)` gets information about an existing ASCII table column.

This function corresponds to the `fits_get_acolparms (fffacl)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = fits.getAColParms(fptr,2);
fits.closeFile(fptr);
```

See Also

`getBColParms`

matlab.io.fits.getBColParms

Binary table information

Syntax

```
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp] =
getBColParms(fptr,colnum)
```

Description

`[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp] = getBColParms(fptr,colnum)` gets information about an existing binary table column.

This function corresponds to the `fits_get_bcolparms (ffgbcl)` function in the CFITSIO library C API.

Examples

Get information about the second column in a binary table.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp]= fits.getBColParms(fptr,2);
fits.closeFile(fptr);
```

See Also

`getAColParms`

matlab.io.fits.getColName

Table column name

Syntax

```
[colnum,colname] = getColNum(fptr,templt,casesen)
```

Description

`[colnum,colname] = getColNum(fptr,templt,casesen)` gets the table column numbers and names of the columns whose names match an input template name. If `casesen` is true, then the column name match is case-sensitive. `casesen` defaults to false.

The input column name template may be either the exact name of the column to be searched for, or it may contain wildcard characters (*, ?, or #), or it may contain the integer number of the desired column (with the first column = 1). The `'*'` wildcard character matches any sequence of characters (including zero characters) and the `'?'` character matches any single character. The # wildcard matches any consecutive string of decimal digits (0-9).

Examples

Return all the columns starting with the letter `'C'`.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[nums,names] = fits.getColName(fptr,'C*');
fits.closeFile(fptr);
```

See Also

`getAColParms` | `getBColParms`

matlab.io.fits.getColType

Scaled column data type, repeat value, width

Syntax

```
[dtype,repeat,width] = getColType(fptr,colnum)
```

Description

`[dtype,repeat,width] = getColType(fptr,colnum)` returns the data type, vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the `fits_get_coltypell (ffgtclll)` function in the CFITSIO library C API.

Examples

Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getColType(fptr,5);
fits.closeFile(fptr);
```

See Also

`getEqColType`

matlab.io.fits.getEqColType

Column data type, repeat value, width

Syntax

```
[dtype,repeat,width] = getColType(fptr,colnum)
```

Description

`[dtype,repeat,width] = getColType(fptr,colnum)` returns the scaled data type needed to store the scaled column data type, the vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the `fits_get_eqcoltypell (ffeqtyll)` function in the CFITSIO library C API.

Examples

Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getEqColType(fptr,5);
fits.closeFile(fptr);
```

See Also

`getColType`

matlab.io.fits.getNumCols

Number of columns in table

Syntax

```
ncols = getNumCols(fptr)
```

Description

`ncols = getNumCols(fptr)` gets the number of columns in the current FITS table. This function corresponds to the `fits_get_num_cols (ffgncl)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
ncols = fits.getNumCols(fptr);
nrows = fits.getNumRows(fptr);
fits.closeFile(fptr);
```

See Also

`getNumRows`

matlab.io.fits.getNumRows

Number of rows in table

Syntax

```
nrows = getNumRows(fptr)
```

Description

`nrows = getNumRows(fptr)` gets the number of rows in the current FITS table. This function corresponds to the `fits_get_num_rowsll` (ffgnrwll) function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
ncols = fits.getNumCols(fptr);
nrows = fits.getNumRows(fptr);
fits.closeFile(fptr);
```

See Also

`getNumCols`

matlab.io.fits.insertCol

Insert column into table

Syntax

```
insertCol(fptr,colnum,ttype,tform)
```

Description

`insertCol(fptr,colnum,ttype,tform)` inserts a column into an ASCII or binary table.

This function corresponds to the `fits_insert_col (fficol)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertCol(fptr,3,'Col3','3D');
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2);
```

See Also

`insertRows`

matlab.io.fits.insertATbl

Insert ASCII table after current HDU

Syntax

```
insertATbl(fptr,rowlen,nrows,ttype,tbcol,tform,tunit,extname)
```

Description

`insertATbl(fptr,rowlen,nrows,ttype,tbcol,tform,tunit,extname)` inserts a new ASCII table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions, then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the current HDU. If `rowlen` is 0, then CFITSIO calculates the default `rowlen` based on the `tbcol` and `ttype` values.

`tform` can take the following forms. In each case, `'w'` and `'ww'` represent the widths of the ASCII columns.

Iw	`int16` column
Aw	ASCII column
Fww.dd	Fixed point with `'dd'` digits after the decimal point
Eww.dd	Single precision with `'dd'` digits of precision
Dww.dd	Double precision with `'dd'` digits of precision

Binary tables are recommended instead of ASCII tables.

This function corresponds to the `fits_insert_atbl (ffitab)` function in the CFITSIO library C API.

Examples

Create an ASCII table between two images.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[20 30]);
fits.createImg(fptr,'int16',[30 40]);
fits.movRelHDU(fptr,-1);
ttype = {'Name','Short','Fix','Double'};
tbcol = [1 17 28 43];
tform = {'A15','I10','F14.2','D12.4'};
tunit = {'','m**2','cm','km/s'};
fits.insertATbl(fptr,0,0,ttype,tbcol,tform,tunit,'my-table');
fits.writeCol(fptr,1,1,char('abracadabra','hocus-pocus'));
fits.writeCol(fptr,2,1,int16([0; 1]));
fits.writeCol(fptr,3,1,[12.4; 4/3]);
fits.writeCol(fptr,4,1,[12.4; 4e8/3]);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

See Also

`createTbl` | `insertBTbl`

matlab.io.fits.insertBTbl

Insert binary table after current HDU

Syntax

```
insertBTbl(fptr,nrows,ttype,tform,tunit,extname,pcount)
```

Description

`insertBTbl(fptr,nrows,ttype,tform,tunit,extname,pcount)` inserts a new binary table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the CHDU. If there are following extensions in the file and if the table contains variable-length array columns then `pcount` must specify the expected final size of the data heap. Otherwise, `pcount` must be zero.

This function corresponds to the `fits_insert_btbl (ffibin)` function in the CFITSIO library C API.

Examples

Create a table following the primary array. Then, insert a new table just before it.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'9A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',10,ttype,tform,tunit,'my-table');
fits.movRelHDU(fptr,-1);
fits.insertBTbl(fptr,5,ttype,tform,tunit,'my-new-table',0);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

See Also

`createTbl` | `insertATbl`

matlab.io.fits.readATblHdr

Read header information from current ASCII table

Syntax

```
[rowlen,nrows,ttype,tbcol,tform,tunit,extname] = readATblHdr(fptr)
```

Description

`[rowlen,nrows,ttype,tbcol,tform,tunit,extname] = readATblHdr(fptr)` reads header information for the current ASCII table.

This function corresponds to the `fits_read_atblhdrll (ffghtbll)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[rowlen,nrows,ttype,tbcol,tform,tunit,extname] = fits.readATblHdr(fptr);
fits.closeFile(fptr);
```

See Also

`readBTblHdr`

matlab.io.fits.readBTblHdr

Read header information from current binary table

Syntax

```
[nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr)
```

Description

`[nrows,ttype,tform,tunit,extname,pcount] = readBTblHdr(fptr)` reads header information for the current binary table.

This function corresponds to the `fits_read_btblhdrll (ffghbnll)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[nrows,ttype,tform,tunit,extname,pcount] = fits.readBTblHdr(fptr);
fits.closeFile(fptr);
```

See Also

`readATblHdr`

matlab.io.fits.readCol

Read rows of ASCII or binary table column

Syntax

```
[coldata,nullval] = readCol(fptr,colnum)
[coldata,nullval] = readCol(fptr,colnum,firstrow,numrows)
```

Description

`[coldata,nullval] = readCol(fptr,colnum)` reads an entire column from an ASCII or binary table column. `nullval` is a logical array specifying if a particular element of `coldata` should be treated as undefined. It is the same size as `coldata`.

`[coldata,nullval] = readCol(fptr,colnum,firstrow,numrows)` reads a subsection of rows from an ASCII or binary table column.

The MATLAB data type returned by `readCol` corresponds to the data type returned by `getEqColType`.

This function corresponds to the `fits_read_col (ffgcv)` function in the CFITSIO library C API.

Examples

Read an entire column.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
colnum = fits.getColName(fptr,'flux');
fluxdata = fits.readCol(fptr,colnum);
fits.closeFile(fptr);
```

Read the first five rows in a column.

```
import matlab.io.*
```

```
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
colnum = fits.getColName(fptr,'flux');
fluxdata = fits.readCol(fptr,colnum,1,5);
fits.closeFile(fptr);
```

See Also

writeCol

matlab.io.fits.setTscale

Reset image scaling

Syntax

```
setTscale(fptr,colnum,tscale,tzero)
```

Description

`setTscale(fptr,colnum,tscale,tzero)` resets the scaling factors for a table column according to the equation:

```
output = (FITS array) * tscale + tzero
```

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the `tscale` and `tzero` keyword values.

Examples

Turn off automatic scaling in a table column where the `tscale` and `tzero` keywords are present.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
scaled_data = fits.readCol(fptr,3);
fits.setTscale(fptr,3,1.0,0.0);
unscaled_data = fits.readCol(fptr,3);
fits.closeFile(fptr);
```

See Also

`readImg`

matlab.io.fits.writeCol

Write elements into ASCII or binary table column

Syntax

```
writeCol(fptr,colnum,firstrow,coldata)
```

Description

`writeCol(fptr,colnum,firstrow,coldata)` writes elements into an ASCII or binary table extension column.

When writing rows of data to a variable length field, `coldata` must be a cell array.

This function corresponds to the `fits_write_col" (ffpcl)` function in the CFITSIO library C API.

Examples

Write to a table with ASCII, `uint8`, double-precision, and variable-length double-precision columns.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'3A','3B','1D','1PD'};
tunit = {'m/s','kg/m^3','candela','parsec'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.writeCol(fptr,1,1,['dog'; 'cat']);
fits.writeCol(fptr,2,1,[0 1 2; 3 4 5; 6 7 8; 9 10 11]);
fits.writeCol(fptr,3,1,[1; 2; 3; 4]);
fits.writeCol(fptr,4,1,{1;[1 2];[1 2 3];[1 2 3 4]});
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2,'mode','full');
```

Write to a table with logical, bit, double precision, and variable-length complex single-precision columns.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'2L','3X','1D','1PC'};
tunit = {'','kg/m^3','candela','parsec'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.writeCol(fptr,1,1,[false false; true false]);
fits.writeCol(fptr,2,1,int8([0 1 1; 1 1 1; 1 1 1; 1 0 1]));
fits.writeCol(fptr,3,1,[1; 2; 3; 4]);
data = cell(4,1);
data{1} = single(1);
data{2} = single(1+2j);
data{3} = single([1j 2 3+j]);
data{4} = single([1 2+3j 3 4]);
fits.writeCol(fptr,4,1,data);
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2,'mode','full');
```

See Also

createTbl | readCol

matlab.io.fits.getConstantValue

Numeric value of named constant

Syntax

```
N = getConstantValue(name)
```

Description

`N = getConstantValue(name)` returns the numeric value corresponding to the named CFITSIO constant.

Examples

```
import matlab.io.*
n = fits.getConstantValue('BYTE_IMG');
```

matlab.io.fits.getVersion

Revision number of the CFITSIO library

Syntax

```
V = getVersion()
```

Description

`V = getVersion()` returns the revision number of the CFITSIO library. This function corresponds to the `fits_get_version (ffvers)` function in the CFITSIO library C API.

Examples

```
import matlab.io.*
v = fits.getVersion();
```

matlab.io.fits.getOpenFiles

List of open FITS files

Syntax

```
fptrs = getOpenFiles()
```

Description

`fptrs = getOpenFiles()` returns a list of file pointers of all open FITS files.

Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
clear fptr;
fptr = fits.getOpenFiles();
fits.closeFile(fptr);
```

`closeFile` | `openFile`

matlab.io.hdf4.sd

Interact directly with HDF4 multifile scientific data set (SD) interface

Description

To use these MATLAB functions, you should be familiar with the HDF SD C API. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF library function. The functions are implemented as the package `matlab.io.hdf4.sd`. To use this package, prefix the function name with a package path, or use the import function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','read');
```

Access

matlab.io.hdf4.sd.close	Terminate access to SD interface
matlab.io.hdf4.sd.endAccess	Terminate access to data set
matlab.io.hdf4.sd.getFilename	Name of file
matlab.io.hdf4.sd.select	Identifier of data set with specified index
matlab.io.hdf4.sd.setExternalFile	Store data in external file
matlab.io.hdf4.sd.start	Open HDF file and initialize SD interface

Read/Write

matlab.io.hdf4.sd.create	Create new data set

matlab.io.hdf4.sd.readData	Read subsample of data
matlab.io.hdf4.sd.setFillMode	Set current fill mode of file
matlab.io.hdf4.sd.writeData	Write to data set

Inquiry

matlab.io.hdf4.sd.fileInfo	Number of data sets and global attributes in file
matlab.io.hdf4.sd.getCompInfo	Information about data set compression
matlab.io.hdf4.sd.getFillValue	Fill value for data set
matlab.io.hdf4.sd.getInfo	Information about data set
matlab.io.hdf4.sd.idToRef	Reference number corresponding to data set identifier
matlab.io.hdf4.sd.idType	Type of object
matlab.io.hdf4.sd.isCoordVar	Determine if data set is a coordinate variable
matlab.io.hdf4.sd.isRecord	Determine if data set is appendable
matlab.io.hdf4.sd.nameToIndex	Index value of named data set
matlab.io.hdf4.sd.nameToIndices	List of data sets with same name
matlab.io.hdf4.sd.refToIndex	Index of data set corresponding to reference number

Dimensions

matlab.io.hdf4.sd.dimInfo	Information about dimension
matlab.io.hdf4.sd.getDimID	Dimension identifier
matlab.io.hdf4.sd.getDimScale	Scale data for dimension
matlab.io.hdf4.sd.setDimName	Associate name with dimension
matlab.io.hdf4.sd.setDimScale	Set scale values for dimension

User-defined Attributes

matlab.io.hdf4.sd.attrInfo	Information about attribute
matlab.io.hdf4.sd.findAttr	Index of specified attribute
matlab.io.hdf4.sd.readAttr	Read attribute value
matlab.io.hdf4.sd.setAttr	Write attribute value

Predefined Attributes

matlab.io.hdf4.sd.getCal	Data set calibration information
matlab.io.hdf4.sd.getDataStrs	Predefined attribute strings for data set
matlab.io.hdf4.sd.getDimStrs	Predefined attribute strings for dimension

matlab.io.hdf4.sd.getFillValue	Fill value for data set
matlab.io.hdf4.sd.getRange	Maximum and minimum range values
matlab.io.hdf4.sd.setCal	Set data set calibration information
matlab.io.hdf4.sd.setDataStrs	Set predefined attributes for data set
matlab.io.hdf4.sd.setDimStrs	Set label, unit, and format attribute strings
matlab.io.hdf4.sd.setFillValue	Set fill value for data set
matlab.io.hdf4.sd.setRange	Set maximum and minimum range value for data set

Chunking/Tiling Operations

matlab.io.hdf4.sd.getChunkInfo	Chunk size for data set
matlab.io.hdf4.sd.readChunk	Read chunk from data set
matlab.io.hdf4.sd.setChunk	Set chunk size and compression method of data set
matlab.io.hdf4.sd.writeChunk	Write chunk to data set

Compression

matlab.io.hdf4.sd.setCompress	Set compression method of data set

matlab.io.hdf4.sd.setNBitDataSet	Specify nonstandard bit length for data set values

matlab.io.hdf4.sd.attrInfo

Package: matlab.io.hdf4.sd

Information about attribute

Syntax

```
[name,datatype,nelts] = attrInfo(objID,idx)
```

Description

`[name,datatype,nelts] = attrInfo(objID,idx)` returns the name, data type, and number of elements in the specified attribute. The attribute is specified by its zero-based index value. `objID` can be either an SD interface identifier, a data set identifier, or a dimension identifier.

This function corresponds to the `SDattrinfo` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
[name,datatype,nelts] = sd.attrInfo(sdID,idx);
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

See Also

`sd.findAttr`

matlab.io.hdf4.sd.close

Package: matlab.io.hdf4.sd

Terminate access to SD interface

Syntax

```
sd.close(sdID)
```

Description

`sd.close(sdID)` closes the file identified by `sdID`.

This function corresponds to the `SDend` function in the HDF C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.start`

matlab.io.hdf4.sd.create

Package: matlab.io.hdf4.sd

Create new data set

Syntax

```
sdsID = create(sdID,name,datatype,dims)
```

Description

`sdsID = create(sdID,name,datatype,dims)` creates a data set with the given name `name`, data type `datatype`, and dimension sizes `dims`.

To create a data set with an unlimited dimension, the last value in `dims` should be set to 0.

This function corresponds to the `SDcreate` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

Examples

Create a 3D data set with an unlimited dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20 0]);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.endAccess`

matlab.io.hdf4.sd.dimInfo

Package: matlab.io.hdf4.sd

Information about dimension

Syntax

```
[name,dimlen,datatype,nattrs] = dimInfo(dimID)
```

Description

`[name,dimlen,datatype,nattrs] = dimInfo(dimID)` returns the name, length, data type, and number of attributes of the specified dimension.

This function corresponds to the `SDdiminfo` function in the HDF library C API.

Examples

Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'latitude');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[name,dimlen,datatype,nattrs] = sd.dimInfo(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.getDimID`

matlab.io.hdf4.sd.endAccess

Package: matlab.io.hdf4.sd

Terminate access to data set

Syntax

```
sd.endAccess(sdsID)
```

Description

`sd.endAccess(sdsID)` terminates access to the data set identified by `sdsID`. Failing to call this function after all operations on the specified data set are complete may result in loss of data.

This function corresponds to the `SDendaccess` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.close` | `sd.select`

matlab.io.hdf4.sd.fileInfo

Package: matlab.io.hdf4.sd

Number of data sets and global attributes in file

Syntax

```
[ndatasets,ngatts] = fileInfo(sdID)
```

Description

`[ndatasets,ngatts] = fileInfo(sdID)` returns the number of data sets `ndatasets` and the number of global attributes `ngatts` in the file identified by `sdID`.

`ndatasets` includes the number of coordinate variable data sets.

This function corresponds to the `SDfileinfo` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
[ndatasets,ngatts] = sd.fileInfo(sdID);
sd.close(sdID);
```

See Also

`sd.getInfo`

matlab.io.hdf4.sd.findAttr

Package: matlab.io.hdf4.sd

Index of specified attribute

Syntax

```
idx = findAttr(objID,attrname)
```

Description

`idx = findAttr(objID,attrname)` returns the index of the attribute specified by `attrname`. The `objID` input can be either an SD interface identifier, a data set identifier, or a dimension identifier.

The function corresponds to the `SDfindattr` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

See Also

`sd.getDimID` | `sd.readAttr` | `sd.select` | `sd.start`

matlab.io.hdf4.sd.getCal

Package: matlab.io.hdf4.sd

Data set calibration information

Syntax

```
[cal,calErr,offset,offsetErr,datatype] = getCal(sdsID)
```

Description

`[cal,calErr,offset,offsetErr,datatype] = getCal(sdsID)` retrieves the calibration information associated with a data set.

This function corresponds to the `SDgetcal` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[cal,calErr,offset,offsetErr,dtype] = sd.getCal(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.setCal`

matlab.io.hdf4.sd.getChunkInfo

Package: matlab.io.hdf4.sd

Chunk size for data set

Syntax

```
chunkDims = getChunkInfo(sdsID)
```

Description

`chunkDims = getChunkInfo(sdsID)` returns the chunk size for the data set specified by `sdsID`. If a data set is chunked, the dimensions of the chunks is returned in `chunkDims`. Otherwise `chunkDims` is `[]`.

This function corresponds to the `SDgetchunkinfo` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `chunkDims` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
cdims = sd.getChunkInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.getCompInfo` | `sd.setChunk`

matlab.io.hdf4.sd.getCompInfo

Package: matlab.io.hdf4.sd

Information about data set compression

Syntax

```
[comptype,compparms] = getCompType(sdsID)
```

Description

`[comptype,compparms] = getCompType(sdsID)` retrieves the compression type and compression information for a data set. `comptype` can be one of the following strings.

`'none'`	No compression
`'rle'`	Run-length encoding
`'nbit'`	NBIT compression
`'skphuff'`	Skipping Huffman compression
`'deflate'`	GZIP compression
`'szip'`	SZIP compression

If `comptype` is `'none'` or `'rle'`, then `compparms` is `[]`.

If `comptype` is `'nbit'`, then `compparms` is a 4-element array.

`compparm(1)`	sign_ext
`compparm(2)`	fill_one
`compparm(3)`	start_bit
`compparm(4)`	bit_len

If `comptype` is `'deflate'`, then `compparms` contains the deflation value, a number between 0 and 9.

If `comptype` is `'szip'`, them `compparms` is a 5-element array. Consult the HDF Reference Manual for details on SZIP compression.

This function corresponds to the `SDgetcompinfo` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[100 50]);
sd.setCompress(sdsID,'deflate',5);
[comptype,compparm] = sd.getCompInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.setCompress` | `sd.setNBitDataSet`

matlab.io.hdf4.sd.getDataStrs

Package: matlab.io.hdf4.sd

Predefined attribute strings for data set

Syntax

```
[label,unit,format,coordsys] = getDataStrs(sdsID)
[label,unit,format,coordsys] = getDataStrs(sdsID,maxlen)
```

Description

`[label,unit,format,coordsys] = getDataStrs(sdsID)` returns the label, unit, format, and coordsys attributes for the data set identified by `sdsID`.

`[label,unit,format,coordsys] = getDataStrs(sdsID,maxlen)` returns the label, unit, format, and coordsys attributes for the data set identified by `sdsID`. The `maxlen` input is the maximum length of any of the attribute strings. It defaults to 1000 if not specified.

This function corresponds to the `SDgetdatastrs` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[label,unit,fmt,coordsys] = sd.getDataStrs(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.setDataStrs`

matlab.io.hdf4.sd.getDimID

Package: matlab.io.hdf4.sd

Dimension identifier

Syntax

```
dimID = getDimID(sdsID,dimnumber)
```

Description

`dimID = getDimID(sdsID,dimnumber)` returns the identifier of the dimension given its index.

Note: MATLAB uses Fortran-style indexing while the HDF library uses C-style indexing. The order of the dimension identifiers retrieved with `sd.getDimID` are reversed from what would be retrieved via the C API.

This function corresponds to the `SDgetdimid` function in the HDF library C API.

Examples

Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID0 = sd.getDimID(sdsID,0);
dimID1 = sd.getDimID(sdsID,1);
sd.endAccess(sdsID);
sd.close(sdID);
```

`sd.setDimName`

matlab.io.hdf4.sd.getDimScale

Package: matlab.io.hdf4.sd

Scale data for dimension

Syntax

```
scale = getDimScale(dimID)
```

Description

`scale = getDimScale(dimID)` returns the scale values of the dimension identified by `dimID`.

This function corresponds to the `SDgetdimscale` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimScale(dimID,0:5:95);
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
scale = sd.getDimScale(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.dimInfo` | `sd.setDimScale`

matlab.io.hdf4.sd.getDimStrs

Package: matlab.io.hdf4.sd

Predefined attribute strings for dimension

Syntax

```
[label,unit,format] = getDimStrs(dimID)
```

Description

`[label,unit,format] = getDimStrs(dimID)` returns the label, unit, and format attributes for the dimension identified by `dimID`.

This function corresponds to the `SDgetdimstrs` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimStrs(dimID,'xdim','none','%d');
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[label,unit,fmt] = sd.getDimStrs(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.setDimStrs`

matlab.io.hdf4.sd.getFilename

Package: matlab.io.hdf4.sd

Name of file

Syntax

```
filename = getFilename(sdID)
```

Description

`filename = getFilename(sdID)` retrieves the name of a file previously opened with the `sd` package with identifier `sdID`.

This function corresponds to the `SDgetfilename` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
filename = sd.getFilename(sdID);
sd.close(sdID);
```

See Also

`sd.getInfo` | `sd.start`

matlab.io.hdf4.sd.getFillValue

Package: matlab.io.hdf4.sd

Fill value for data set

Syntax

```
fillvalue = getFillValue(sdsID)
```

Description

`fillvalue = getFillValue(sdsID)` returns the fill value for a data set.

This function corresponds to the `SDgetfillvalue` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
fillvalue = sd.getFillValue(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.setFillValue`

matlab.io.hdf4.sd.getInfo

Package: matlab.io.hdf4.sd

Information about data set

Syntax

```
[name,dims,datatype,nattrs] = getInfo(sdsID)
```

Description

`[name,dims,datatype,nattrs] = getInfo(sdsID)` returns the name, extents, and number of attributes of the data set identified by `sdsID`.

This function corresponds to the `SDgetinfo` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the dims parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[name,dims,datatype,nattrs] = sd.getInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.attrInfo` | `sd.dimInfo` | `sd.fileInfo`

matlab.io.hdf4.sd.getRange

Package: matlab.io.hdf4.sd

Maximum and minimum range values

Syntax

```
[maxval,minval] = getRange(sdsID)
```

Description

`[maxval,minval] = getRange(sdsID)` retrieves the "valid_range" two-element attribute value.

This function corresponds to the `SDgetrange` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[maxval,minval] = sd.getRange(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.setRange`

matlab.io.hdf4.sd.idToRef

Package: matlab.io.hdf4.sd

Reference number corresponding to data set identifier

Syntax

```
ref = idToRef(sdsID)
```

Description

`ref = idToRef(sdsID)` returns the reference number corresponding to the data set.

This function corresponds to the `SDidtoref` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
ref = sd.idToRef(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.refToIndex`

matlab.io.hdf4.sd.idType

Package: matlab.io.hdf4.sd

Type of object

Syntax

```
objtype = idType(objID)
```

Description

`objtype = idType(objID)` returns the type of object that `objID` represents. Possible values for `objtype` are:

`'NOT_SDAPI_ID'`	The object is not an HDF SD identifier.
`'SD_ID'`	The object is an SD identifier (file handle) .
`'SDS_ID'`	The object is a data set identifier.
`'DIM_ID'`	The object is a dimension identifier.

This function corresponds to the `SDidtype` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
objType = sd.idType(sdID);
sd.close(sdID);
```

matlab.io.hdf4.sd.isCoordVar

Package: matlab.io.hdf4.sd

Determine if data set is a coordinate variable

Syntax

```
TF = isCoordVar(sdsID)
```

Description

`TF = isCoordVar(sdsID)` returns `true` if a data set is a coordinate variable and returns `false` otherwise.

This function corresponds to the `SDiscoordvar` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
 sdsID = sd.select(sdID,idx);
 sdsName = sd.getInfo(sdsID);
 fprintf('%s (index %d) ', sdsName, idx);
 if ( sd.isCoordVar(sdsID) )
  fprintf('is a coordinate variable.\n');
 else
  fprintf('is not a coordinate variable.\n');
 end
 sd.endAccess(sdsID);
end
sd.close(sdID);
```

See Also

`sd.isRecord`

matlab.io.hdf4.sd.isRecord

Package: matlab.io.hdf4.sd

Determine if data set is appendable

Syntax

```
TF = isRecord(sdsID)
```

Description

`TF = isRecord(sdsID)` determines if the data set specified by `sdsID` is appendable, meaning that the slowest changing dimension is unlimited.

This function corresponds to the `SDisrecord` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
    sdsID = sd.select(sdID,idx);
    sdsName = sd.getInfo(sdsID);
    if sd.isRecord(sdsID)
        fprintf('%s is a record variable.\n',sdsName);
    else
        fprintf('%s is not a record variable.\n',sdsName);
    end
    sd.endAccess(sdsID);
end
sd.close(sdID);
```

See Also

`sd.isCoordVar`

matlab.io.hdf4.sd.nameToIndex

Package: matlab.io.hdf4.sd

Index value of named data set

Syntax

```
idx = nameToIndex(sdID,sdsname)
```

Description

`idx = nameToIndex(sdID,sdsname)` returns the index of the data set with the name specified by `sdsname`. If there is more than one data set with the same name, the routine returns the index of the first one.

This function corresponds to the `SDnametoindex` function in the HDF C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sd.close(sdID);
```

See Also

`sd.select`

matlab.io.hdf4.sd.nameToIndices

Package: matlab.io.hdf4.sd

List of data sets with same name

Syntax

```
varstruct = nameToIndices(sdID,sdsname)
```

Description

`varstruct = nameToIndices(sdID,sdsname)` returns a structure array for all data sets with the same name. Each element of `varstruct` has two fields.

`'index'`	Index of data set
`'type'`	Type of data set, either `'SDSVAR'`, `'COORDVAR'`, or `'UNKNOWN'`

This function corresponds to the `SDnametoindices` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
varlist = sd.nameToIndices(sdID,'latitude');
sd.close(sdID);
```

See Also

`sd.isCoordVar` | `sd.setDimScale`

matlab.io.hdf4.sd.readAttr

Package: matlab.io.hdf4.sd

Read attribute value

Syntax

```
data = readAttr(objID,idx)
```

Description

`data = readAttr(objID,idx)` reads the value of the attribute specified by index `idx`. The `objID` input can be an SD interface identifier, a data set identifier, or a dimension identifier. `idx` is a zero-based index.

This function corresponds to the `SDreadattr` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

See Also

`sd.findAttr` | `sd.setAttr`

matlab.io.hdf4.sd.readChunk

Package: matlab.io.hdf4.sd

Read chunk from data set

Syntax

```
datachunk = readChunk(sdsID,origin)
```

Description

`datachunk = readChunk(sdsID,origin)` reads an entire chunk of data from the data set identified by `sdsID`. The `origin` input specifies the location of the chunk in zero-based chunking coordinates, not in data set coordinates.

This function corresponds to the `SDreadchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the origin parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dataChunk = sd.readChunk(sdsID,[0 1]);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.writeChunk` | `sd.writeData`

matlab.io.hdf4.sd.readData

Package: matlab.io.hdf4.sd

Read subsample of data

Syntax

```
data = readData(sdsID)
data = readData(sdsID,start,count)
data = readData(sdsID,start,count,stride)
```

Description

`data = readData(sdsID)` reads all of the data for the data set identified by `sdsID`.

`data = readData(sdsID,start,count)` reads a contiguous hyperslab of data from the data set identified by `sdsID`. The `start` input specifies the starting position from where the hyperslab is read. `count` specifies the number of values to read along each data set dimension.

`data = readData(sdsID,start,count,stride)` reads a strided hyperslab of data from the data set identified by `sdsID`.

`start`, `count`, and `stride` use zero-based indexing.

This function corresponds to the `SDreaddata` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

Examples

Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
```

```
sdsID = sd.select(sdID,idx);
data = sd.readData(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
data = sd.readData(sdsID,[0 0],[2 3]);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

sd.writeData

matlab.io.hdf4.sd.refToIndex

Package: matlab.io.hdf4.sd

Index of data set corresponding to reference number

Syntax

```
idx = refToIndex(sdID,ref)
```

Description

`idx = refToIndex(sdID,ref)` returns the index of the data set identified by its reference number `ref`. The `idx` output can then be passed to `sd.select`, to obtain a data set identifier.

This function corresponds to the `SDreftoindex` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
ref = sd.idToRef(sdsID);
idx2 = sd.refToIndex(sdID,ref);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.idToRef` | `sd.select`

matlab.io.hdf4.sd.select

Package: matlab.io.hdf4.sd

Identifier of data set with specified index

Syntax

```
sdsID = select(sdID,IDX)
```

Description

`sdsID = select(sdID,IDX)` returns the identifier of the data set specified by its index.

This function corresponds to the `SDselect` function in the HDF C library.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.endAccess` | `sd.nametoIndex`

matlab.io.hdf4.sd.setAttr

Package: matlab.io.hdf4.sd

Write attribute value

Syntax

```
setAttr(objID,name,value)
```

Description

`setAttr(objID,name,value)` attaches an attribute to the object specified by `objID`. If `objID` is the SD interface identifier, then a global attribute is created. If a data identifier is specified, then the attribute is attached to the data set. If a dimension identifier is specified, then the attribute is attached to the dimension.

This function corresponds to the `SDsetattr` function in the HDF library C API.

Examples

Attach attributes to a file, a data set, and to a dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setAttr(sdID,'creation_date',datestr(now));
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setAttr(sdsID,'long_name','Temperature in sunlight.');
dimID0 = sd.getDimID(sdsID,0);
sd.setAttr(dimID0,'long_name','latitude');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.findAttr` | `sd.readAttr`

matlab.io.hdf4.sd.setCal

Package: matlab.io.hdf4.sd

Set data set calibration information

Syntax

```
setCal(sdsID,cal,calErr,offset,offsetErr,datatype)
```

Description

`setCal(sdsID,cal,calErr,offset,offsetErr,datatype)` sets the calibration information for a data set.

This function corresponds to the `SDsetcal` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_kelvin','%.3f','spherical');
sd.setCal(sdsID,1,0,273,0,'double');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.getCal`

matlab.io.hdf4.sd.setChunk

Package: matlab.io.hdf4.sd

Set chunk size and compression method of data set

Syntax

```
setChunk(sdsID,chunkSize,comptype,compparm)
```

Description

`setChunk(sdsID,chunkSize,comptype,compparm)` makes the data set specified by `sdsID` a chunked data set with chunk size given by `chunkSize` and compression specified by `comptype` and `compparm`. The `comptype` input can be one of the following strings.

`'none'`	No compression
`'skphuff'`	Skipping Huffman compression
`'deflate'`	GZIP compression
`'rle'`	Run-length encoding

- If `comptype` is `'none'` or `'rle'`, then `compparm` need not be specified.
- If `comptype` is `'skphuff'`, then `compparm` is the skipping size.
- If `comptype` is `'deflate'`, then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `chunkSize` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
```

```
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[200 100]);
sd.setChunk(sdsID,[20 10],'skphuff',16);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

sd.readChunk | sd.writeChunk

matlab.io.hdf4.sd.setCompress

Package: matlab.io.hdf4.sd

Set compression method of data set

Syntax

```
setCompress(sdsID,comptype,compparm)
```

Description

`setCompress(sdsID,comptype,compparm)` sets the compression scheme for the specified data set. The compression must be done before writing the data set. `comptype` can be one of the following strings.

`'none'`	No compression
`'skphuff'`	Skipping Huffman compression
`'deflate'`	GZIP compression
`'rle'`	Run-length encoding

- If `comptype` is `'none'` or `'rle'`, then `compparm` need not be specified.
- If `comptype` is `'skphuff'`, then `compparm` is the skipping size.
- If `comptype` is `'deflate'`, then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetcompress` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[200 100]);
sd.setCompress(sdsID,'deflate',5);
data = rand(200,100);
```

```
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

sd.setChunk

matlab.io.hdf4.sd.setDataStrs

Package: matlab.io.hdf4.sd

Set predefined attributes for data set

Syntax

```
setDataStrs(sdsID,label,unit,format,coordsys)
```

Description

`setDataStrs(sdsID,label,unit,format,coordsys)` sets the predefined attributes `'long_name'`, `'units'`, `'format'`, and `'coordsys'` for a data set.

This function corresponds to the `SDsetdatastrs` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'degrees_celsius','degrees_east','','geo');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.getDataStrs` | `sd.setDimStrs`

matlab.io.hdf4.sd.setDimName

Package: matlab.io.hdf4.sd

Associate name with dimension

Syntax

```
setDimName(dimID,dimname)
```

Description

`setDimName(dimID,dimname)` sets the name of the dimension identified by `dimID` to `dimname`.

This function corresponds to the `SDsetdimname` function in the HDF library C API.

Examples

Create a 2D data set with dimensions `'lat'` and `'lon'`.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.dimInfo`

matlab.io.hdf4.sd.setDimScale

Package: matlab.io.hdf4.sd

Set scale values for dimension

Syntax

```
setDimScale(dimID,scaledata)
```

Description

`setDimScale(dimID,scaledata)` sets the scale values for a dimension.

This function corresponds to the `SDsetdimscale` function in the HDF library C API.

Examples

Create a 2D data set with dimensions `'lat'` and `'lon'`.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
sd.setDimScale(dimID,0:10:90);
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimScale(dimID, -180:18:179);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.getDimScale`

matlab.io.hdf4.sd.setDimStrs

Package: matlab.io.hdf4.sd

Set label, unit, and format attribute strings

Syntax

```
setDimStrs(dimID,label,unit,format)
```

Description

`setDimStrs(dimID,label,unit,format)` sets the label, unit, and format attributes for the dimension identified by `dimID`.

This function corresponds to the `SDsetdimstrs` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimStrs(dimID,'Degrees of Longitude','degrees_east','%.2f');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.getDimStrs`

matlab.io.hdf4.sd.setExternalFile

Package: matlab.io.hdf4.sd

Store data in external file

Syntax

```
setExternalFile(sdsID,extfile,offset)
```

Description

`setExternalFile(sdsID,extfile,offset)` moves data values (not metadata) into the external data file `extfile` starting at the byte offset, `offset`.

Data can only be moved once for any given data set. The external file should be kept with the main file.

This function corresponds to the `SDsetexternalfile` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setExternalFile(sdsID,'myExternalFile.dat',0);
sd.writeData(sdsID,[0 0],rand(10,20));
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.create` | `sd.writeData`

matlab.io.hdf4.sd.setFillMode

Package: matlab.io.hdf4.sd

Set current fill mode of file

Syntax

```
prevmode = setFillMode(sdID,fillmode)
```

Description

`prevmode = setFillMode(sdID,fillmode)` returns the previous fill mode of a file and resets it to `fillmode`. This setting applies to all data sets contained in the file identified by `sdID`.

Possible values of `fillmode` are `'fill'`, and `'nofill'`. `'fill'` is the default mode and indicates that fill values will be written when the data set is created. `'nofill'` indicates that the fill values will not be written.

When a fixed-size data set is created, the first call to `sd.writeData` will fill the entire data set with the default or user-defined fill value if `fillmode` is `'fill'`. In data sets with an unlimited dimension, if a new write operation takes place along the unlimited dimension beyond the last location of the previous write operation, the array locations between these written areas will be initialized to the user-defined fill value, or the default fill value if a user-defined fill value has not been specified.

If it is certain that all data set values will be written before any read operation takes place, there is no need to write the fill values. Calling `sd.setFillMode` with `'nofill'` can improve performance in this case.

This function corresponds to the `SDsetfillmode` function in the HDF library C API.

Examples

Write two partial records. Write the first in `'nofill'` mode, and the second with `'fill'` mode.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setFillMode(sdID,'nofill');
sdsID = sd.create(sdID,'temperature','double',[10 10 0]);
sd.writeData(sdsID,[0 0 0], rand(5,5));
sd.setFillMode(sdID,'fill');
sd.setFillValue(sdsID,-999);
sd.writeData(sdsID,[0 0 1], rand(5,5));
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

sd.getFillValue | sd.setFillValue

matlab.io.hdf4.sd.setFillValue

Package: matlab.io.hdf4.sd

Set fill value for data set

Syntax

```
setFillValue(sdsID,fillValue)
```

Description

`setFillValue(sdsID,fillValue)` sets the fill value for a data set. The fill value must have the same data type as the data set.

This function corresponds to the `SDsetfillvalue` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setFillValue(sdsID,-999);
sd.endAccess(sdsID);
sd.close(sdID);
```

matlab.io.hdf4.sd.setNBitDataSet

Package: matlab.io.hdf4.sd

Specify nonstandard bit length for data set values

Syntax

```
setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)
```

Description

`setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)` specifies that the integer data set identified by `sdsID` contains data of a non-standard length defined by `startBit` and `bitlen`.

Any length between 1 and 32 bits can be specified. After `setNBitDataset` has been called for the data set array, any read or write operation will involve conversion between the new data length of the data set array and the data length of the read or write buffer.

Bit lengths of all data types are counted from the right of the bit field starting with 0. In a bit field containing the values 01111011, bits 2 and 7 are set to 0 and all the other bits are set to 1. The least significant bit is bit 0.

The `startBit` parameter specifies the left-most position of the variable-length bit field to be written. For example, in the bit field described in the preceding paragraph a `startBit` parameter set to 4 would correspond to the fourth bit value of 1 from the right.

The parameter `bitlen` specifies the number of bits of the variable-length bit field to be written. This number includes the starting bit and the count proceeds toward the right end of the bit field - toward the lower-bit numbers. For example, starting at bit 5 and writing 4 bits of the bit field described in the preceding paragraph would result in the bit field 1110 being written to the data set. This would correspond to a `startBit` value of 5 and a `bitlen` value of 4.

The parameter `ext` specifies whether to use the left-most bit of the variable-length bit field to sign-extend to the left-most bit of the data set data. For example, if 9-bit signed integer data is extracted from bits 17-25 and the bit in position 25 is 1, then when the

data is read back from disk, bits 26-31 will be set to 1. Otherwise bit 25 will be 0 and bits 26-31 will be set to 0. The `ext` parameter can be set to `true` (or 1) or `false` (or 0); specify `true` to sign-extend.

The parameter `fillone` specifies whether to fill the "background" bits with the value 1 or 0. This parameter is also set to either `true` (or 1) or `false` (or 0).

The "background" bits of a non-standard length data set are the bits that fall outside of the non-standard length bit field stored on disk. For example, if five bits of an unsigned 16-bit integer data set located in bits 5 to 9 are written to disk with the parameter `fillone` set to `true` (or 1), then when the data is reread into memory bits 0 to 4 and 10 to 15 would be set to 1. If the same 5-bit data was written with a `fillone` value of `false` (or 0), then bits 0 to 4 and 10 to 15 would be set to 0.

The operation on `fillone` is performed before the operation on `ext`. For example, using the `ext` example above, bits 0 to 16 and 26 to 31 will first be set to the background bit value, and then bits 26 to 31 will be set to 1 or 0 based on the value of the 25th bit.

This function corresponds to the `SDsetnbitdataset` in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','int32',[10 20]);
sd.setNBitDataSet(sdsID,6,4,0,0);
data = int32([1:200]);
data = reshape(data,10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.setCompress`

matlab.io.hdf4.sd.setRange

Package: matlab.io.hdf4.sd

Set maximum and minimum range value for data set

Syntax

```
setRange(sdsID,maxval,minval)
```

Description

`setRange(sdsID,maxval,minval)` sets the maximum and minimum range values of the data set identified by `sdsID`. These values form the "valid_range" attribute for `sdsID`.

The actual maximum and minimum values of the data set are not computed. The "valid_range" attribute is for informational purposes only.

This function corresponds to the `SDsetrange` function in the HDF library C interface.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_celsius','%.2f','');
sd.setRange(sdsID,1000,-273.15);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.getRange`

matlab.io.hdf4.sd.start

Package: matlab.io.hdf4.sd

Open HDF file and initialize SD interface

Syntax

```
sdID = start(filename)
sdID = start(filename,access)
```

Description

`sdID = start(filename)` opens the file `filename` in read-only mode. This routine must be called for each file before any other `sd` calls can be made on that file.

`sdID = start(filename,access)` opens the file `filename` with the access mode specified by `access`. This routine must be called before any other SD interface operations can be made on that file. `access` can be one of the following strings:

- `'read'`
- `'write'`
- `'create'`

`access` defaults to `'read'` if not supplied.

This function corresponds to the `SDstart` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
sd.close(sdID);
```

See Also

`sd.close`

matlab.io.hdf4.sd.writeChunk

Package: matlab.io.hdf4.sd

Write chunk to data set

Syntax

```
writeChunk(sdsID,origin,dataChunk)
```

Description

`writeChunk(sdsID,origin,dataChunk)` writes an entire chunk of data to the data set identified by `sdsID`. The `origin` input specifies the location of the chunk in chunking coordinates, not in data set coordinates.

This function corresponds to the `SDwritechunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the origin parameter is reversed with respect to the C library API.

Examples

Write to a 2D chunked and compressed data set. The chunked layout constitutes a 10-by-5 grid.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[100 50]);
sd.setChunk(sdsID,[10 10],'deflate',5);
for j = 0:9
    for k = 0:4
        origin = [j k];
        data = (1:100) + k*1000 + j*10000;
        data = reshape(data,10,10);
        sd.writeChunk(sdsID,origin,data);
    end
end
```

```
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.readChunk` | `sd.writeData`

matlab.io.hdf4.sd.writeData

Package: matlab.io.hdf4.sd

Write to data set

Syntax

```
writeData(sdsID,data)
writeData(sdsID,start,data)
writeData(sdsID,start,stride,data)
```

Description

`writeData(sdsID,data)` writes all the data to the data set identified by `sdsID`.

`writeData(sdsID,start,data)` writes a contiguous hyperslab to the data set. `start` specifies the zero-based starting index. The number of values along each dimension is inferred from the size of `data`.

`writeData(sdsID,start,stride,data)` writes a strided hyperslab of data to a grid datafield. The number of elements to write along each dimension is inferred either from the size of `data` or from the data set itself.

`start` and `stride` use zero-based indexing.

This function corresponds to the `SDreadchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

Examples

Write to a 2D data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
```

```
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

Write to a 2D unlimited data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 0]);
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
data = rand(10,30);
sd.writeData(sdsID,[0 20],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

`sd.readData`

matlab.io.hdfeos.gd

Low-level access to HDF-EOS grid data

Description

To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfeos.gd`. To use this package, prefix the function name with a package path, or use the import function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfeos.*
gfid = gd.open(filename,'read');
```

Access

matlab.io.hdfeos.gd.attach	Attach to existing grid
matlab.io.hdfeos.gd.close	Close HDF-EOS grid file
matlab.io.hdfeos.gd.detach	Detach from existing grid
matlab.io.hdfeos.gd.open	Open grid file

Definition

matlab.io.hdfeos.gd.create	Create new grid structure
matlab.io.hdfeos.gd.defComp	Set grid field compression
matlab.io.hdfeos.gd.defDim	Define new dimension within grid

matlab.io.hdfeos.gd.defField	Define new data field within grid
matlab.io.hdfeos.gd.defOrigin	Define origin of pixels in grid
matlab.io.hdfeos.gd.defPixReg	Define pixel registration within grid
matlab.io.hdfeos.gd.defProj	Define grid projection
matlab.io.hdfeos.gd.writeBlkSomOffset	Write Block SOM offset

Basic I/O

matlab.io.hdfeos.gd.getFillValue	Fill value for specified field
matlab.io.hdfeos.gd.readAttr	Read grid attribute
matlab.io.hdfeos.gd.readField	Read data from grid field
matlab.io.hdfeos.gd.setFillValue	Set fill value for specified field
matlab.io.hdfeos.gd.writeAttr	Write grid attribute
matlab.io.hdfeos.gd.writeField	Write data to grid field

Inquiry

matlab.io.hdfeos.gd.compInfo	Compression information for field
matlab.io.hdfeos.gd.dimInfo	Length of dimension

matlab.io.hdfeos.gd.fieldInfo	Information about data field
matlab.io.hdfeos.gd.gridInfo	Position and size of grid
matlab.io.hdfeos.gd.inqAttrs	Names of grid attributes
matlab.io.hdfeos.gd.inqDims	Information about dimensions defined in grid
matlab.io.hdfeos.gd.inqFields	Information about data fields defined in grid
matlab.io.hdfeos.gd.inqGrid	Names of grids in file
matlab.io.hdfeos.gd.nEntries	Number of specified objects
matlab.io.hdfeos.gd.originInfo	Origin code
matlab.io.hdfeos.gd.pixRegInfo	Pixel registration code
matlab.io.hdfeos.gd.projInfo	GCTP projection information about grid
matlab.io.hdfeos.gd.readBlkSomOffset	Read Block SOM offset

Subsetting

matlab.io.hdfeos.gd.defBoxRegion	Define region of interest by latitude and longitude
matlab.io.hdfeos.gd.defVrtRegion	Define vertical subset region
matlab.io.hdfeos.gd.extractRegion	Read region of interest from field

matlab.io.hdfeos.gd.getPixels	Pixel rows and columns for latitude/ longitude pairs
matlab.io.hdfeos.gd.getPixValues	Read data values for specified pixels
matlab.io.hdfeos.gd.regionInfo	Information about subsetted region

Tiling

matlab.io.hdfeos.gd.defTile	Define tiling parameters
matlab.io.hdfeos.gd.readTile	Read single tile of data from field
matlab.io.hdfeos.gd.setTileComp	Set tiling and compression for field with fill value
matlab.io.hdfeos.gd.tileInfo	Tile size of grid field
matlab.io.hdfeos.gd.writeTile	Write tile to field

Utility

matlab.io.hdfeos.gd.ij2ll	Convert row and column space to latitude and longitude
matlab.io.hdfeos.gd.ll2ij	Convert latitude and longitude to row and column space
matlab.io.hdfeos.gd.sphereCodeToName	Name corresponding to GCTP sphere code

matlab.io.hdfeos.gd.sphereNameToCode	Numeric GCTP code corresponding to sphere name

matlab.io.hdfeos.gd.attach

Package: matlab.io.hdfeos.gd

Attach to existing grid

Syntax

```
gridID = attach(gfID,gridName)
```

Description

`gridID = attach(gfID,gridName)` attaches to the grid dataset identified by `gridName` in the file identified by `gfID`. The `gridID` output is the identifier for the grid dataset.

This function corresponds to the `GDattach` function in the HDF-EOS library C API.

Examples

Attach to the grid named `'PolarGrid'` in the file `'grid.hdf'`.

```
import matlab.io.hdfeos.*
gfID = gd.open('grid.hdf');
gridID = gd.attach(gfID,'PolarGrid');
gd.detach(gridID);
gd.close(gfID);
```

See Also

`gd.detach` | `gd.inqGrid` | `gd.readField`

matlab.io.hdfeos.gd.close

Package: matlab.io.hdfeos.gd

Close HDF-EOS grid file

Syntax

```
close(gfID)
```

Description

`close(gfID)` closes an HDF-EOS grid file identified by `gfID`.

This function corresponds to the `GDclose` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfID = gd.open('grid.hdf');
gd.close(gfID);
```

See Also

`gd.create` | `gd.open`

matlab.io.hdfeos.gd.compInfo

Package: matlab.io.hdfeos.gd

Compression information for field

Syntax

```
[compCode,parms] = compInfo(gridID,fieldname)
```

Description

`[compCode,parms] = compInfo(gridID,fieldname)` returns the compression code and compression parameters for a given field. Refer to `gd.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `GDcompinfo` function in the HDF-EOS library C API.

Examples

Get compression information for the `ice_temp` field.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[compCode,compParms] = gd.compInfo(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defComp`

matlab.io.hdfeos.gd.create

Package: matlab.io.hdfeos.gd

Create new grid structure

Syntax

```
gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)
```

Description

`gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)` creates a new grid structure where `gfID` is the grid file identifier. `gridName` is the name of the new grid. `xdim` and `ydim` define the size of the grid. `upLeft` is a two-element vector containing the location of the upper left pixel, and `lowRight` is a two-element vector containing the location of the lower right pixel.

Note: `upLeft` and `lowRight` are in units of meters for all GCTP projections other than the geographic and bcea projections, which should have units of packed degrees.

Note: For certain projections, `upLeft` and `lowRight` can be given as `[]`.

- Polar Stereographic projection of an entire hemisphere.
- Goode Homolosine projection of the entire globe.
- Lambert Azimuthal entire polar or equatorial projection.

Note: MATLAB uses Fortran-style ordering, but the HDF-EOS library uses C-style ordering.

This function corresponds to the `GDcreate` function in the HDF-EOS library C API.

Examples

Create a polar stereographic grid of the northern hemisphere.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
gd.detach(gridID);
gd.close(gfid);
```

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude. Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,uplft,lowrgt);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defProj` | `gd.detach` | `gd.gridInfo`

matlab.io.hdfeos.gd.defBoxRegion

Package: matlab.io.hdfeos.gd

Define region of interest by latitude and longitude

Syntax

```
regionID = defBoxRegion(gridID,cornerLat,cornerLon)
```

Description

`regionID = defBoxRegion(gridID,cornerLat,cornerLon)` defines a latitude-longitude box region as a subset region for a grid. `regionID` can be used to read all the entries of a data field within the region.

This function corresponds to the `GDdefboxregion` function in the HDF-EOS library C API.

Examples

Define a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.extractRegion`

matlab.io.hdfeos.gd.defComp

Package: matlab.io.hdfeos.gd

Set grid field compression

Syntax

```
defComp(gridID,compscheme,compparm)
```

Description

`defComp(gridID,compscheme,compparm)` sets the HDF field compression for subsequent field definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

`'rle'`	Run-length encoding
`'skphuff'`	Skipping Huffman
`'deflate'`	Gzip deflate
`'none'`	No compression

When the compression scheme is `'deflate'`, `compparm` is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

If a field is defined with compression, it must be written with a single call to `gd.writeField`. If this is not possible, you should consider using tiling.

This function corresponds to the `GDdefcomp` function in the HDF-EOS library C API.

Examples

Create a grid with a polar stereographic `Pressure` field using run-length encoding, and then an `Opacity` field with deflate compression.

```
import matlab.io.hdfeos.*
```

```
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
dims = { 'XDim', 'YDim' };
gd.defComp(gridID,'rle');
gd.defField(gridID,'Pressure',dims,'float');
gd.defComp(gridID,'deflate',5);
gd.defField(gridID,'Opacity',dims,'float');
gd.detach(gridID);
gd.close(gfid);
```

See Also

gd.defField | gd.defTile

matlab.io.hdfeos.gd.defDim

Package: matlab.io.hdfeos.gd

Define new dimension within grid

Syntax

```
defDim(gridID,dimname,dimlen)
```

Description

`defDim(gridID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the grid structure identified by `gridID`.

To specify an unlimited dimension, you can use either 0 or `'unlimited'` for `dimlen`.

This function corresponds to the `GDdefdim` function in the HDF-EOS library C API.

Examples

Define a dimension `'Band'` with length of 15 and an unlimited dimension `'Time'`.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
gd.defDim(gridID,'Band',15);
gd.defDim(gridID,'Time',0);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defField` | `gd.dimInfo`

matlab.io.hdfeos.gd.defField

Package: matlab.io.hdfeos.gd

Define new data field within grid

Syntax

```
defField(gridID,fieldname,dimlist,dtype)
defField(gridID,fieldname,dimlist,dtype,mergeCode)
```

Description

`defField(gridID,fieldname,dimlist,dtype)` defines data fields for a grid specified by `gridID`. The `fieldname` input is the name of the new field. `dimlist` is a cell array of geolocation dimensions and should be listed in FORTRAN-style order, that is, the fastest varying dimension should be listed first. `dimlist` can also be a string if there is only one dimension. `dtype` is the data type of the field.

`defField(gridID,fieldname,dimlist,dtype,mergeCode)` defines a data field with a specific merge code. `mergeCode` can be either `'nomerge'` or `'automerge'`. The `mergeCode` input defaults to `'nomerge'` if not provided.

This function corresponds to the `GDdeffield` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

Define a single precision grid field `'Temperature'` with dimensions `'XDim'` and `'YDim'`. Then define a single precision field `'Spectra'` with dimensions `'XDim'`, `'YDim'`, and `'Bands'`.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
xdim = 120; ydim = 200;
gridID = gd.create(gfid,'geo',xdim,ydim,[],[]);
```

```
gd.defProj(gridID,'geo',[],[],[]);
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Temperature',dimlist,'single');
gd.defDim(gridID,'Bands',3);
dimlist = {'XDim','YDim','Bands'};
gd.defField(gridID,'Spectra',dimlist,'uint8');
gd.detach(gridID);
gd.close(gfid);
```

See Also

gd.create | gd.defDim

matlab.io.hdfeos.gd.defOrigin

Package: matlab.io.hdfeos.gd

Define origin of pixels in grid

Syntax

```
defOrigin(gridID,originCode)
```

Description

`defOrigin(gridID,originCode)` defines the origin of pixels in a grid. `gridID` is the identifier of the grid, and `originCode` can be one of the following four strings.

`'ul'`	Upper-left
`'ur'`	Upper-right
`'ll'`	Lower-left
`'lr'`	Lower-right

You can select any corner of the grid pixel as the origin. If this routine is not invoked, the grid defaults to using the upper-left corner for the origin.

This function corresponds to the `GDdeforigin` function in the HDF-EOS library C API.

Examples

Create a polar stereographic grid with the origin of the grid pixel in the lower right corner.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
```

```
gd.defOrigin(gridID,'lr');
gd.detach(gridID);
gd.close(gfid);
```

See Also

gd.defPixReg | gd.originInfo

matlab.io.hdfeos.gd.defPixReg

Package: matlab.io.hdfeos.gd

Define pixel registration within grid

Syntax

```
defPixReg(gridID,pixRegCode)
```

Description

`defPixReg(gridID,pixRegCode)` defines whether the pixel center or pixel corner is used when requesting the location (longitude and latitude) of a given pixel. `pixRegCode` can be one of the following strings.

`'center'`	Center of pixel cell
`'corner'`	Corner of pixel cell

If this routine is not invoked, the pixel registration is `'center'`.

This function corresponds to the `GDdefpixreg` function in the HDF-EOS library.

Examples

Define a grid with pixel registration in the center.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.defPixReg(gridID,'corner');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defOrigin` | `gd.pixRegInfo`

matlab.io.hdfeos.gd.defProj

Package: matlab.io.hdfeos.gd

Define grid projection

Syntax

```
defProj(gridID,projCode,zoneCode,sphereCode,projParm)
```

Description

`defProj(gridID,projCode,zoneCode,sphereCode,projParm)` defines a GCTP projection on the grid specified by `gridID`. The `projCode` argument can be one of the following strings.

`'geo'`	Geographic
`'utm'`	Universal Transverse Mercator
`'albers'`	Albers Canonical Equal Area
`'lamcc'`	Lambert Conformal Conic
`'ps'`	Polar Stereographic
`'polyc'`	Polyconic
`'tm'`	Transverse Mercator
`'lamaz'`	Lambert Azimuthal Equal Area
`'snsoid'`	Sinusoidal
`'hom'`	Hotine Oblique Mercator
`'som'`	Space Oblique Mercator
`'good'`	Interrupted Goode Homolosine
`'cea'`	Cylindrical Equal Area
`'bcea'`	Behrmann Cylindrical Equal Area
`'isinus'`	Integerized Sinusoidal

If `projCode` is `'geo'`, then `zoneCode`, `sphereCode`, and `projParm` should be specified as `[]`. Any other values for these parameters are ignored.

`zoneCode` is the Universal Transverse Mercator zone code. It should be specified as -1 for other projections.

`sphereCode` is the name of the GCTP spheroid or the corresponding numeric code.

`projParm` is a vector of up to 13 elements containing projection-specific parameters. For more details about `projCode`, `zoneCode`, `sphereCode`, and `projParm`, see Chapter 6 of HDF-EOS Library Users Guide for the ECS Project, Volume 1: Overview and Examples.

This function corresponds to the `GDdefproj` function in the HDF library C API.

Examples

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude (zone 40). Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,uplft,lowrgt);
gd.defProj(gridID,'utm',40,'Clarke 1866',[]);
gd.detach(gridID);
gd.close(gfid);
```

Add a polar stereographic projection of the northern hemisphere with true scale at 90 N, 0 longitude below the pole using the WGS 84 spheroid.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.create` | `gd.projInfo` | `gd.sphereCodeToName`

matlab.io.hdfeos.gd.defTile

Package: matlab.io.hdfeos.gd

Define tiling parameters

Syntax

```
defTile(gridID,tileDims)
```

Description

`defTile(gridID,tileDims)` defines tiling dimensions for subsequent field definitions. If `tileDims` is `[]`, then subsequently defined fields will have no tiling.

This function corresponds to the `GDdeftile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileDims` parameter is reversed with respect to the C library API.

Examples

Define a field with tiling, then a subsequent field with no tiling.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'GeoGrid',120,200,[],[]);
gd.defDim(gridID,'Bands',3);
gd.defProj(gridID,'geo',[],[],[]);
gd.defTile(gridID,[30 50 1]);
dimlist = {'XDim','YDim','Bands'};
gd.defField(gridID,'Spectra',dimlist,'float');
gd.defTile(gridID,[]);
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Temperature',dimlist,'int32');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defField` | `gd.tileInfo`

matlab.io.hdfeos.gd.defVrtRegion

Package: matlab.io.hdfeos.gd

Define vertical subset region

Syntax

```
out_RID = defVrtRegion(gridID,regionID,vobj,vRange)
```

Description

`out_RID = defVrtRegion(gridID,regionID,vobj,vRange)` defines a vertical subset region and can be used on either a monotonic field or contiguous elements of a dimension.

`regionID` should be `'noprevsub'` if no prior subsetting has occurred. Otherwise it should be a value as returned from a previous subsetting routine.

`vobj` is the name of either the dimension or field to subset. If `vobj` is a dimension, it should be prefixed with `'DIM:'`.

`vRange` is the minimum and maximum range for the vertical subset.

This function corresponds to the `GDdefvrtregion` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
range = [333 667];
regionID = gd.defVrtRegion(gridID,'noprevsub','Height',range);
data = gd.extractRegion(gridID,regionID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
range = [3 5];
regionID = gd.defVrtRegion(gridID,'noprevsub','DIM:Height',range);
data = gd.extractRegion(gridID,regionID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

See Also

gd.extractRegion

matlab.io.hdfeos.gd.detach

Package: matlab.io.hdfeos.gd

Detach from existing grid

Syntax

```
detach(gridID)
```

Description

`detach(gridID)` detaches from the grid identified by `gridID`.

This function corresponds to the `GDdetach` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfID = gd.open('grid.hdf');
gridID = gd.attach(gfID,'PolarGrid');
gd.detach(gridID);
gd.close(gfID);
```

See Also

`gd.attach`

matlab.io.hdfeos.gd.dimInfo

Package: matlab.io.hdfeos.gd

Length of dimension

Syntax

```
dimlen = diminfo(gridID,dimname)
```

Description

`dimlen = diminfo(gridID,dimname)` retrieves the length of the specified user-defined dimension.

Please note that the two extents used to create the grid are not considered user-defined dimensions. To retrieve the length of `XDim` and `YDim`, use `gd.gridInfo`. This function corresponds to the `GDdiminfo` function in the HDF-EOS library C API.

Examples

Inquire about a `'Bands'` dimension.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
dimlen = gd.dimInfo(gridID,'Height');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defDim` | `gd.gridInfo`

matlab.io.hdfeos.gd.extractRegion

Package: matlab.io.hdfeos.gd

Read region of interest from field

Syntax

```
data = extractRegion(gridID,regionID,fieldname)
```

Description

`data = extractRegion(gridID,regionID,fieldname)` extract data from a subsetted region.

This routine corresponds to the `GDextractregion` function in the HDF-EOS library C API.

Examples

Define and extract a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defBoxRegion` | `gd.defVrtRegion`

matlab.io.hdfeos.gd.fieldInfo

Package: matlab.io.hdfeos.gd

Information about data field

Syntax

```
[dims,ntype,dimlist] = fieldInfo(gridID,fieldname)
```

Description

`[dims,ntype,dimlist] = fieldInfo(gridID,fieldname)` returns information about a specific geolocation or data field in the grid. `dims` is a vector containing the dimension sizes of the field. `ntype` is a string containing the HDF number type of the field. `dimlist` is a cell array of strings containing the list of dimension names.

This function corresponds to the `GDfieldinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
[dims,ntype,dimlist] = gd.fieldInfo(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defField`

matlab.io.hdfeos.gd.getFillValue

Package: matlab.io.hdfeos.gd

Fill value for specified field

Syntax

```
fillvalue = getFillValue(gridID,fieldname)
```

Description

`fillvalue = getFillValue(gridID,fieldname)` retrieves the fill value for the specified field.

This function corresponds to the `GDgetfillvalue` function in the HDF-EOS library C API.

Examples

Return the fill value for the `'ice_temp'` field in the `'PolarGrid'` grid.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
fillvalue = gd.getFillValue(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.setFillValue`

matlab.io.hdfeos.gd.getPixels

Package: matlab.io.hdfeos.gd

Pixel rows and columns for latitude/longitude pairs

Syntax

```
[row,col] = getPixels(gridID,lat,lon)
```

Description

`[row,col] = getPixels(gridID,lat,lon)` converts latitude/longitude pairs into zero-based pixel row and column coordinates. The origin is the upper left-hand corner of the grid pixel. If the latitude/longitude pairs are outside the grid, then `row` and `col` are -1.

This function corresponds to the `GDgetpixels` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
[row,col] = gd.getPixels(gridID,cornerlat,cornerlon);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.getPixValues`

matlab.io.hdfeos.gd.getPixValues

Package: matlab.io.hdfeos.gd

Read data values for specified pixels

Syntax

```
data = getPixValues(gridID,rows,cols,fieldname)
```

Description

`data = getPixValues(gridID,rows,cols,fieldname)` reads data values for the pixels specified by the zero-based `rows` and `cols` coordinates. All entries along the non-geographic dimensions, i.e. NOT `XDim` and `YDim`, are returned.

This function corresponds to the `GDgetpixvalues` function in the HDF-EOS library C API.

Examples

Read the grid field's corner values.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
rows = [0 99 99  0];
cols = [0  0 99 99];
data = gd.getPixValues(gridID,rows,cols,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defBoxRegion` | `gd.extractRegion` | `gd.getPixels` | `gd.readField`

matlab.io.hdfeos.gd.gridInfo

Package: matlab.io.hdfeos.gd

Position and size of grid

Syntax

```
[xDim,yDim,upLeft,lowRight] = gridInfo(gridID)
```

Description

`[xDim,yDim,upLeft,lowRight] = gridInfo(gridID)` returns the size of a grid as well as the upper left and lower right corners of the grid.

Note: `upLeft` and `lowRight` are in units of meters for all GCTP projections other than the geographic and bcea projections, which will have units of packed degrees.

This function corresponds to the `GDgridinfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[xdimsize,ydimsize,upleft,lowright] = gd.gridInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.create`

matlab.io.hdfeos.gd.ij2ll

Package: matlab.io.hdfeos.gd

Convert row and column space to latitude and longitude

Syntax

```
[lat,lon] = ij2ll(gridID,row,col)
```

Description

`[lat,lon] = ij2ll(gridID,row,col)` converts a grid's row and column coordinates to latitude and longitude in decimal degrees.

`row` and `col` are zero-based and defined such that `col` increases monotonically with the `XDim` dimension and `row` increases monotonically with the `YDim` dimension in the HD-EOS library.

This routine corresponds to the `GDij2ll` function in the HDF-EOS C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[xdim,ydim] = gd.gridInfo(gridID);
r = 0:(xdim-1);
c = 0:(ydim-1);
[Col,Row] = meshgrid(c,r);
[lat,lon] = gd.ij2ll(gridID,Row,Col);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.ll2ij` | `gd.readField`

matlab.io.hdfeos.gd.inqAttrs

Package: matlab.io.hdfeos.gd

Names of grid attributes

Syntax

```
attrList = inqAttrs(gridID)
```

Description

`attrList = inqAttrs(gridID)` returns the list of grid attribute names. `attrList` is a cell array.

This function corresponds to the `GDinqattrs` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
attrList = gd.inqAttrs(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.readAttr` | `gd.writeAttr`

matlab.io.hdfeos.gd.inqDims

Package: matlab.io.hdfeos.gd

Information about dimensions defined in grid

Syntax

```
[dimnames,dimlens] = inqDims(gridID)
```

Description

`[dimnames,dimlens] = inqDims(gridID)` returns the names of the dimensions `dimnames` in a cell array and their respective lengths `dimlens`. This does not include the grid extent dimensions `XDim` and `YDim`.

This function corresponds to the `GDinqdims` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimnames` and `dimlens` parameters are reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
[dims,dimlens] = gd.inqDims(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defDim`

matlab.io.hdfeos.gd.inqFields

Package: matlab.io.hdfeos.gd

Information about data fields defined in grid

Syntax

```
[fldList,fldRank,fldType] = inqFields(gridID)
```

Description

`[fldList,fldRank,fldType] = inqFields(gridID)` returns the list of fields `fldList` as a cell array. `fldRank` contains the rank of each data field. `fldType` is a cell array containing the data type of each data field.

This function corresponds to the `GDinqfields` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[fldlist,fldrank,fldtype] = gd.inqFields(gridID);
gd.detach(gridID);
gd.close(gfid);
for j = 1:numel(fldrank)
    fprintf('%s: Rank %d, datatype %s\n', fldlist{j},fldrank(j),fldtype{j});
end
```

See Also

`gd.defField`

matlab.io.hdfeos.gd.inqGrid

Package: matlab.io.hdfeos.gd

Names of grids in file

Syntax

```
grids = inqGrid(filename)
```

Description

`grids = inqGrid(filename)` returns the names of all grids in the given file. `grids` is a cell array.

This function corresponds to the `GDinqgrid` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
grids = gd.inqGrid('grid.hdf');
```

See Also

`gd.create` | `sw.inqSwath`

matlab.io.hdfeos.gd.ll2ij

Package: matlab.io.hdfeos.gd

Convert latitude and longitude to row and column space

Syntax

```
[row,col] = ll2ij(gridID,lat,lon)
```

Description

`[row,col] = ll2ij(gridID,lat,lon)` converts latitude and longitude coordinates to a pre-defined grid's row and column coordinates.

`row` and `col` are zero-based and defined such that `col` increases monotonically with the `XDim` dimension and `row` increases monotonically with the `YDim` dimension in the HD-EOS library.

This routine corresponds to the `GDll2ij` function in the HDF-EOS C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
lat = [46 46 42 42];
lon = [-71 -67 -67 -71];
[row,col] = gd.ll2ij(gridID,lat,lon);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.ij2ll`

matlab.io.hdfeos.gd.nEntries

Package: matlab.io.hdfeos.gd

Number of specified objects

Syntax

```
nentries = nEntries(gridID,entType)
```

Description

`nentries = nEntries(gridID,entType)` returns the number of specified objects in a grid. `entType` can be either `'dims'` or `'fields'`.

This function corresponds to the `GDnentries` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
ndims = gd.nEntries(gridID,'dims');
nflds = gd.nEntries(gridID,'fields');
gd.detach(gridID);
gd.close(fid);
fprintf('The number of dimensions is %d.\n', ndims);
fprintf('The number of fields is %d.\n', nflds);
```

See Also

`gd.inqGrid`

matlab.io.hdfeos.gd.open

Package: matlab.io.hdfeos.gd

Open grid file

Syntax

```
gfid = open(filename,access)
```

Description

`gfid = open(filename,access)` opens or creates an HDF-EOS grid file identified by `filename` and returns a file ID. `access` can be one of the following string values:

`'read'`	Read-only
`'rdwr'`	Read-write
`'create'`	Creates a file, deleting it if it already exists

If `access` is not provided, it defaults to `'read'`.

This function corresponds to the `GDopen` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gd.close(gfid);
```

See Also

`gd.attach` | `gd.close`

matlab.io.hdfeos.gd.originInfo

Package: matlab.io.hdfeos.gd

Origin code

Syntax

```
originCode = originInfo(gridID)
```

Description

`originCode = originInfo(gridID)` retrieves the origin code for the grid specified by `gridID`. The `originCode` output is one of the following four string values.

`'ul'`	Upper-left
`'ur'`	Upper-right
`'ll'`	Lower-left
`'lr'`	Lower-right

This function corresponds to the `GDorigininfo` routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
origin = gd.originInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defOrigin`

matlab.io.hdfeos.gd.pixRegInfo

Package: matlab.io.hdfeos.gd

Pixel registration code

Syntax

```
pixRegCode = pixRegInfo(gridID)
```

Description

`pixRegCode = pixRegInfo(gridID)` retrieve the pixel registration code for the grid identified by `gridID`. The `pixRegCode` output can be one of the following strings.

`'center'`	Center of pixel cell
`'corner'`	Corner of pixel cell

This function corresponds to the `GDpixreginfo` routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
code = gd.pixRegInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defPixReg`

matlab.io.hdfeos.gd.projInfo

Package: matlab.io.hdfeos.gd

GCTP projection information about grid

Syntax

```
[projCode,zoneCode,sphereName,projParm] = projInfo(gridID)
```

Description

`[projCode,zoneCode,sphereName,projParm] = projInfo(gridID)` returns the GCTP projection code, zone code, spheroid, and projection parameters for the grid identified by `gridID`.

`zoneCode` is -1 if `projCode` is anything other than `'UTM'`.

This function corresponds to the `GDprojinfo` function in the HDF-EOS library C API.

For details about the GCTP projection code, zone code, spheroid code, and projection parameters, please consult the HDF-EOS User's Guide.

Examples

```
import matlab.io.hdfeos.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
[projCode,zoneCode,sphereCode,projParm] = gd.projInfo(gridID);
gd.detach(gridID);
gd.close(fid);
```

See Also

`gd.defProj` | `gd.sphereCodeToName` | `gd.sphereNameToCode`

matlab.io.hdfeos.gd.readAttr

Package: matlab.io.hdfeos.gd

Read grid attribute

Syntax

```
data = readAttr(gridID,attrname)
```

Description

`data = readAttr(gridID,attrname)` reads a grid attribute.

This function corresponds to the `GDreadattr` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
data = gd.readAttr(gridID,'creation_date');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.writeAttr`

matlab.io.hdfeos.gd.readBlkSomOffset

Package: matlab.io.hdfeos.gd

Read Block SOM offset

Syntax

```
offset = readBlkSomOffset(GID)
```

Description

`offset = readBlkSomOffset(GID)` reads the block SOM offset values, in pixels, from a standard SOM (Space Oblique Mercator) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection.

This function corresponds to the `GDblkSOMoffset` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360;  % 98.161 in DDDMMMSSS
projparm(5) = 87069061;  % 87.112 in DDDMMMSSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID,'som',[],[],projparm);
gd.writeBlkSomOffset(gridID,[5 10 12 8 2]);
gd.detach(gridID);
```

```
gd.close(gfid);
gfid = gd.open('myfile.hdf');
gridID = gd.attach(gfid,'SOM');
blk = gd.readBlkSomOffset(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also

gd.writeBlkSomOffset

matlab.io.hdfeos.gd.readField

Package: matlab.io.hdfeos.gd

Read data from grid field

Syntax

```
data = readField(gridID,fieldname)
data = readField(gridID,fieldname,start,count)
data = readField(gridID,fieldname,start,count,stride)
[data,lat,lon] = readField( ___ )
```

Description

`data = readField(gridID,fieldname)` reads the entire grid field identified by `fieldname` in the grid identified by `gridID`.

`data = readField(gridID,fieldname,start,count)` reads a contiguous hyperslab of data from the field. `start` specifies the zero-based starting index of the hyperslab. `count` specifies the number of values to read along each dimension.

`data = readField(gridID,fieldname,start,count,stride)` reads a strided hyperslab of data from the field. `stride` specifies the inter-element spacing along each dimension.

`[data,lat,lon] = readField( ___ )` reads the data and the associated geo-coordinates from the grid field. This syntax is only allowed when the leading two dimensions of the grid are `'XDim'` and `'YDim'`.

This function corresponds to the `GDreadfield` function in the HDF-EOS library C API.

Examples

Read the data, latitude, and longitude for the `'ice_temp'` field.

```
import matlab.io.hdfeos.*
```

```
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[data,lat,lon] = gd.readField(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

Read only the first 4x4 hyperslab of data, latitude, and longitude for the `'ice_temp'` field.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[data2,lat2,lon2] = gd.readField(gridID,'ice_temp',[0 0], [4 4]);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.writeField`

matlab.io.hdfeos.gd.readTile

Package: matlab.io.hdfeos.gd

Read single tile of data from field

Syntax

```
data = readTile(gridID,fieldname,tileCoords)
```

Description

`data = readTile(gridID,fieldname,tileCoords)` reads a single of data from a field. If the data is to be read tile by tile, this routine is more efficient than `gd.readField`. In all other cases, use `gd.readField`. The `tileCoords` argument has the form `[rownum colnum]` and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the `GDreadtile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileCoords` parameter is reversed with respect to the C library API.

Examples

Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
for h = 0:9
    data = gd.readTile(gridID,'pressure',[0 0 h]);
end
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.tileInfo` | `gd.writeTile`

matlab.io.hdfeos.gd.regionInfo

Package: matlab.io.hdfeos.gd

Information about subsetted region

Syntax

```
[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)
```

Description

`[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)` returns the dimensions and corner points for the specified field of a subsetted region identified by `regionID` in the grid identified by `gridID`.

This function corresponds to the `GDregioninfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
[dims,upleft,lowright] = gd.regionInfo(gridID,regionID,'ice_temp');
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defBoxRegion` | `gd.defVrtRegion`

matlab.io.hdfeos.gd.setFillValue

Package: matlab.io.hdfeos.gd

Set fill value for specified field

Syntax

```
setFillValue(gridID,fieldname,fillvalue)
```

Description

`setFillValue(gridID,fieldname,fillvalue)` sets the fill value for the specified field. The fill value should have the same data type as the field.

This function corresponds to the `GDsetfillvalue` function in the HDF-EOS library C API.

Examples

Create a new double-precision field with a fill value of -1.

```
import matlab.io.hdfeos.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.defComp(gridID,'none');
gd.defField(gridID,'newfield',{'XDim','YDim'},'double');
gd.setFillValue(gridID,'newfield',-1);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.getFillValue`

matlab.io.hdfeos.gd.setTileComp

Package: matlab.io.hdfeos.gd

Set tiling and compression for field with fill value

Syntax

```
setTileComp(gridID,fieldname,tilesize,compCode,compParm)
```

Description

`setTileComp(gridID,fieldname,tilesize,compCode,compParm)` sets the tiling and compression for a field that had a fill value. This function must be applied after `gd.defField` and `gd.setFillValue`. The `compCode` argument can be one of the following strings.

`'rle'`	Run-length encoding
`'skphuff'`	Skipping Huffman
`'deflate'`	Deflate
`'none'`	No compression

`compParm` need only be specified when the compression scheme is `'deflate'`, and then must be an integer between 0 and 9.

This function corresponds to the `GDsettilecomp` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tilesize` parameter is reversed with respect to the C library API.

Examples

Define a temperature field with a 2-by-2 tiling scheme, a fill value of -999, and deflate compression.

```
import matlab.io.hdfeos.*
```

```
gfid = gd.open('myfile.hdf','create');
upleft = [210584.50041 3322395.95445];
lowright = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,upleft,lowright);
spherecode = 0; zonecode = 40;
projparm = zeros(1,13);
gd.defProj(gridID,'utm',zonecode,spherecode,projparm);
gd.defDim(gridID,'Time',10);
gd.defField(gridID,'Pollution',{'XDim','YDim','Time'},'float');
gd.setFillValue(gridID,'Pollution',single(7));
gd.setTileComp(gridID,'Pollution',[40 20 1],'deflate',5);
gd.detach(gridID);
gd.close(gfid);
```

matlab.io.hdfeos.gd.sphereCodeToName

Package: matlab.io.hdfeos.gd

Name corresponding to GCTP sphere code

Syntax

```
name = sphereCodeToName(code)
```

Description

`name = sphereCodeToName(code)` returns the name for the spheroid corresponding to the spheroid code. The list of supported GCTP spheroids is as follows:

GCTP Spheroid Code	Spheroid Name
0	Clarke 1866
1	Clarke 1880
2	Bessel
3	International 1967
4	International 1909
5	WGS 72
6	Everest
7	WGS 66
8	GRS 1980
9	Airy
10	Modified Airy
11	Modified Everest
12	WGS 84
13	Southeast Asia
14	Australian National

GCTP Spheroid Code	Spheroid Name
15	Krassovsky
16	Hough
17	Mercury 1960
18	Modified Mercury 1968
19	Sphere of radius 6370997m
20	Sphere of radius 6371228m
21	Sphere of radius 6371007.181m

`gd.defProj` | `gd.sphereCodeToName`

matlab.io.hdfeos.gd.tileInfo

Package: matlab.io.hdfeos.gd

Tile size of grid field

Syntax

```
tileDims = tileInfo(gridID,fieldname)
```

Description

`tileDims = tileInfo(gridID,fieldname)` returns the tile dimensions of the field specified by `fieldname` in the grid specified by `gridID`. If the field is not tiled, then `tileDims` is `[]`.

This function corresponds to the `GDtileinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileDims` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
tileDims = gd.tileInfo(gridID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.defTile`

matlab.io.hdfeos.gd.writeAttr

Package: matlab.io.hdfeos.gd

Write grid attribute

Syntax

```
writeAttr(gridID,attrname,data)
```

Description

`writeAttr(gridID,attrname,data)` writes an attribute to a grid. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the `GDwriteattr` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.writeAttr(gridID,'modification_date',datestr(now));
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.readAttr`

matlab.io.hdfeos.gd.writeBlkSomOffset

Package: matlab.io.hdfeos.gd

Write Block SOM offset

Syntax

```
writeBlkSomOffset(gridID,offset)
```

Description

`writeBlkSomOffset(gridID,offset)` writes the block SOM offset values n pixels for a standard Solar Oblique Mercator (SOM) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection. You must take care to use this function properly in conjunction with `gd.defProj`. The 12th element of the projection parameters must be set to the total number of blocks to be defined. `offset` starts by listing the offset to the second block, so the 12th element of the projection parameters is always one more than the length of `offset`.

All fields defined after writing the block SOM offset values will automatically include "SOMBlockDim" as the slowest varying dimension.

This function corresponds to the `GDblkSOMoffset` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360;  % 98.161 in DDDMMMSSS
```

```
projparm(5) = 87069061;  % 87.112 in DDDMMMSSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID,'som',[],[],projparm);
gd.writeBlkSomOffset(gridID,[5 10 12 8 2]);
gd.detach(gridID);
gd.close(gfid);
```

See Also

gd.readBlkSomOffset

matlab.io.hdfeos.gd.writeField

Package: matlab.io.hdfeos.gd

Write data to grid field

Syntax

```
writeField(gridID,fieldname,data)
writeField(gridID,fieldname,start,data)
writeField(gridID,fieldname,start,stride,data)
```

Description

`writeField(gridID,fieldname,data)` writes all the data to a grid field. The field is identified by `fieldname` and the grid is identified by `gridID`.

`writeField(gridID,fieldname,start,data)` writes a contiguous hyperslab to the grid field. `start` specifies the zero-based starting index.

`writeField(gridID,fieldname,start,stride,data)` writes a strided hyperslab of data to a grid data field. `stride` specifies the inter-element spacing along each dimension. The number of elements to write along each dimension is inferred from the size of `data`.

This function corresponds to the `GDwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

Examples

Write all the data to a grid field.

```
import matlab.io.hdfeos.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
```

```
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
data = zeros(100,100,'uint16');
gd.writeField(gridID,'ice_temp',data);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.readField`

matlab.io.hdfeos.gd.writeTile

Package: matlab.io.hdfeos.gd

Write tile to field

Syntax

```
writeTile(gridID,fieldname,tileCoords,data)
```

Description

`writeTile(gridID,fieldname,tileCoords,data)` writes a single tile of data to a field. If the field data can be arranged tile by tile, this routine is more efficient than `gd.writeField`. In all other cases, use `gd.writeField`. The `tileCoords` argument has the form `[rownum colnum]` and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the `GDwritetile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileCoords` parameter is reversed with respect to the C library API.

Examples

Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
xdim = 200; ydim = 180;
gridID = gd.create(gfid,'PolarGrid',xdim,ydim,[],[]);
zonecode = 40;
spherecode = 0;
projParm = zeros(1,13);
projParm(6) =  90000000;
gd.defProj(gridID,'ps',[],spherecode,projParm);
tileSize = [100 60];
gd.defTile(gridID,tileSize);
```

```
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Pressure',dimlist,'int32');
for c = 0:2
    for r = 0:1
        data = (r+c)*ones(tileSize,'int32');
        gd.writeTile(gridID,'Pressure',[r c],data);
    end
end
gd.detach(gridID);
gd.close(gfid);
```

See Also

gd.readTile

matlab.io.hdfeos.sw

Low-level access to HDF-EOS swath files

Description

To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfeos.sw`. To use this package, prefix the function name with a package path, or use the import function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfeos.*
fileId = sw.open(filename);
```

Access

matlab.io.hdfeos.sw.attach	Attach to swath data set
matlab.io.hdfeos.sw.close	Close swath file
matlab.io.hdfeos.sw.create	Create new swath structure
matlab.io.hdfeos.sw.detach	Detach from swath
matlab.io.hdfeos.sw.open	Open swath file

Definition

matlab.io.hdfeos.sw.defComp	Set grid field compression

matlab.io.hdfeos.sw.defDataField	Define new data field within swath
matlab.io.hdfeos.sw.defDim	Define new dimension within swath
matlab.io.hdfeos.sw.defDimMap	Define mapping between geolocation and data dimensions
matlab.io.hdfeos.sw.defGeoField	Define new data field within swath

Basic I/O

matlab.io.hdfeos.sw.getFillValue	Fill value for specified field
matlab.io.hdfeos.sw.readAttr	Read swath attribute
matlab.io.hdfeos.sw.readField	Read data from swath field
matlab.io.hdfeos.sw.setFillValue	Set fill value for the specified field
matlab.io.hdfeos.sw.writeAttr	Write swath attribute
matlab.io.hdfeos.sw.writeField	Write data to swath field

Inquiry

matlab.io.hdfeos.sw.compInfo	Compression information for field
matlab.io.hdfeos.sw.dimInfo	Size of dimension
matlab.io.hdfeos.sw.fieldInfo	Information about swath field

matlab.io.hdfeos.sw.geoMapInfo	Type of dimension mapping for named dimension
matlab.io.hdfeos.sw.idxMapInfo	Indexed array of geolocation mapping
matlab.io.hdfeos.sw.inqAttrs	Names of swath attributes
matlab.io.hdfeos.sw.inqDataFields	Information about geolocation fields
matlab.io.hdfeos.sw.inqDims	Information about dimensions defined in swath
matlab.io.hdfeos.sw.inqGeoFields	Information about geolocation fields
matlab.io.hdfeos.sw.inqIdxMaps	Information about swath indexed geolocation mapping
matlab.io.hdfeos.sw.inqMaps	Information about swath geolocation relations
matlab.io.hdfeos.sw.inqSwath	Names of swaths in file
matlab.io.hdfeos.sw.mapInfo	Offset and increment of specific geolocation mapping
matlab.io.hdfeos.sw.nEntries	Number of entries for specific type

Subsetting

matlab.io.hdfeos.sw.defBoxRegion	Define latitude-longitude region for swath
matlab.io.hdfeos.sw.defTimePeriod	Define time period of interest

matlab.io.hdfeos.sw.defVrtRegion	Subset on monotonic field or dimension
matlab.io.hdfeos.sw.extractPeriod	Read data from subsetted time period
matlab.io.hdfeos.sw.extractRegion	Read subsetted region
matlab.io.hdfeos.sw.periodInfo	Information about subsetted period
matlab.io.hdfeos.sw.regionInfo	Information about subsetted region

matlab.io.hdfeos.sw.attach

Package: matlab.io.hdfeos.sw

Attach to swath data set

Syntax

```
swathID = attach(swfID,swathname)
```

Description

`swathID = attach(swfID,swathname)` attaches to the swath identified by `swathname` in the file identified by `swfID`. The `swathID` output is the identifier for the named swath.

This function corresponds to the `SWattach` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.detach`

matlab.io.hdfeos.sw.close

Package: matlab.io.hdfeos.sw

Close swath file

Syntax

```
close(swfID)
```

Description

`close(swfID)` closes an HDF-EOS swath file identified by `swfID`.

This function corresponds to the `SWclose` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'ExampleSwath');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.create` | `sw.open`

matlab.io.hdfeos.sw.compInfo

Package: matlab.io.hdfeos.sw

Compression information for field

Syntax

```
[code,parms] = compInfo(swathID,fieldname)
```

Description

`[code,parms] = compInfo(swathID,fieldname)` returns the compression code and compression parameters for a given field. Refer to `sw.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `SWcompinfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[compCode,parms] = sw.compInfo(swathID,'Spectra');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defComp`

matlab.io.hdfeos.sw.create

Package: matlab.io.hdfeos.sw

Create new swath structure

Syntax

```
swathID = create(swfID,swathname)
```

Description

`swathID = create(swfID,swathname)` creates a new swath structure where `swfID` is the swath file identifier and `swathname` is the name of the new swath. The swath is created as a Vgroup with the HDF file with the name `swathname` and HDF Vgroup class `'SWATH'`.

This function corresponds to the `SWcreate` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'ExampleSwath');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.detach`

matlab.io.hdfeos.sw.defBoxRegion

Package: matlab.io.hdfeos.sw

Define latitude-longitude region for swath

Syntax

```
regionID = defBoxRegion(swathID,lat,lon,mode)
```

Description

`regionID = defBoxRegion(swathID,lat,lon,mode)` defines a latitude-longitude box region for a swath. `lat` and `lon` are two-element arrays containing the latitude and longitude in decimal degrees of the box corners. A cross track is determined to be within the box if a condition is met according to the value of `mode`:

`'MIDPOINT'`	The cross track midpoint is within the box.
`'ENDPOINT'`	Either endpoint is within the box.
`'ANYPOINT'`	Any point of the cross track is within the box.

All elements of a cross track are within the region if the condition is met. The swath must have both Longitude and Latitude (or Colatitude) defined.

`regionID` is an identifier to be used by `sw.extractRegion` to read all the entries of a data field within the region.

This function corresponds to the `SWdefboxregion` and `SWregionindex` functions in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
```

```
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
data = sw.extractRegion(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

See Also

sw.extractRegion

matlab.io.hdfeos.sw.defComp

Package: matlab.io.hdfeos.sw

Set grid field compression

Syntax

```
defComp(swathID,compscheme,compparm)
```

Description

`defComp(swathID,compscheme,compparm)` sets the field compression for subsequent definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

`'rle'`	Run-length encoding
`'skphuff'`	Skipping Huffman
`'deflate'`	Gzip compression
`'none'`	No compression

When the compression scheme is `'deflate'`, the `compparm` input is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

Fields defined with compression must be written with a single call to `sw.writeField`.

This function corresponds to the `SWdefcomp` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',4000);
```

```
sw.defDim(swathID,'Xtrack',2000);
sw.defDim(swathID,'Bands',3);
sw.defComp(swathID,'rle');
dims = {'Xtrack','Track'};
sw.defDataField(swathID,'Pressure',dims,'float');
sw.defComp(swathID,'deflate',5);
sw.defDataField(swathID,'Opacity',dims,'float');
sw.defComp(swathID,'skphuff');
dims = {'Xtrack','Track','Bands'};
sw.defDataField(swathID,'Spectra',dims,'float');
sw.defComp(swathID,'none');
dims = {'Xtrack','Track'};
sw.defDataField(swathID,'Temperature',dims,'float');
sw.detach(swathID);
sw.close(swfid);
```

See Also

sw.compInfo

matlab.io.hdfeos.sw.defDataField

Package: matlab.io.hdfeos.sw

Define new data field within swath

Syntax

```
defDataField(swathID,fieldname,dimlist,dtype)
defDataField(swathID,fieldname,dimlist,dtype,mergeCode)
```

Description

`defDataField(swathID,fieldname,dimlist,dtype)` defines a data field to be stored in the swath identified by `swathID`. The `dimlist` input can be a cell array of dimension names, or a single char if there is only one dimension. `dtype` is the data type of the field and can be one of the following strings.

- `'double'`
- `'single'`
- `'int32'`
- `'uint32'`
- `'int16'`
- `'uint16'`
- `'int8'`
- `'uint8'`
- `'char'`

`dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defDataField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a data field that can be merged with other data fields according to the value of `mergeCode`. The `mergeCode` input can be one of two strings, `'automerge'` and `'nomerge'`. If `mergeCode` is `'automerge'`, then the HDF-EOS library will attempt to merge swath

fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is `'nomerge'`.

Note: To assure that the fields defined by `sw.defDataField` are properly established in the file, the swath should be detached and then reattached before writing to any fields.

This function corresponds to the `SWdefdatafield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDim(swathID,'Bands',3);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
dims = {'GeoXtrack','GeoTrack'};
sw.defGeoField(swathID,'Longitude',dims,'float');
sw.defGeoField(swathID,'Latitude',dims,'float');
dims = {'DataXtrack','DataTrack','Bands'};
sw.defDataField(swathID,'Spectra',dims,'float');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defGeoField` | `sw.inqDataFields`

matlab.io.hdfeos.sw.defDim

Package: matlab.io.hdfeos.sw

Define new dimension within swath

Syntax

```
defDim(swathID,dimname,dimlen)
```

Description

`defDim(swathID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the swath structure identified by `swathID`.

To specify an unlimited dimension, use either 0 or `'unlimited'` for `dimlen`.

This function corresponds to the `SWdefdim` function in the HDF-EOS library.

Examples

Define a dimension `'Band'` with length of 15 and an unlimited dimension `'Time'`.

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.dimInfo`

matlab.io.hdfeos.sw.defDimMap

Package: matlab.io.hdfeos.sw

Define mapping between geolocation and data dimensions

Syntax

```
defDimMap(swathID,geoDim,dataDim,offset,increment)
```

Description

`defDimMap(swathID,geoDim,dataDim,offset,increment)` defines a monotonic mapping between the geolocation and data dimensions, which usually have differing lengths. `offset` gives the index of the data element corresponding to the first geolocation element, and `increment` gives the number of data elements to skip for each geolocation element. If the geolocation dimension begins "before" the data dimension, then `offset` is negative. Similarly, if the geolocation dimension has higher resolution than the data dimension, then `increment` is negative.

This function corresponds to the `SWdefdimmap` function in the HDF-EOS library.

Examples

Create a dimension mapping such that the first element of the GeoTrack dimension corresponds to the first element of the DataTrack Dimension and such that the data dimension has twice the resolution as the geolocation dimension. Also create a dimension mapping such that the first element of the GeoXtrack dimension corresponds to the second element of the DataXtrack dimensions and such that the data dimension has twice the resolution as the geolocation dimension.

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
```

```
sw.defDim(swathID,'DataXtrack',2000);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defDim` | `sw.mapInfo`

matlab.io.hdfeos.sw.defGeoField

Package: matlab.io.hdfeos.sw

Define new data field within swath

Syntax

```
defGeoField(swathID,fieldname,dimlist,dtype)
defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)
```

Description

`defGeoField(swathID,fieldname,dimlist,dtype)` defines a geolocation field to be stored in the swath identified by `swathID`. The `dimlist` argument can be a cell array of dimension names or a single char if there is only one dimension. `dtype` is the data type of the field

`dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a geolocation field that may be merged with other geolocation fields according to the value of `mergeCode`. The `mergeCode` argument can be one of two strings, `'automerge'` and `'nomerge'`. If `mergeCode` is `'automerge'`, then the HDF-EOS library will attempt to merge swath fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is `'nomerge'`.

This function corresponds to the `SWdefgeofield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
```

```
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
dims = {'GeoXtrack','GeoTrack'};
sw.defGeoField(swathID,'Longitude',dims,'float');
sw.defGeoField(swathID,'Latitude',dims,'float');
sw.detach(swathID);
sw.close(swfid);
```

See Also

sw.defDataField | sw.inqGeoFields

matlab.io.hdfeos.sw.defTimePeriod

Package: matlab.io.hdfeos.sw

Define time period of interest

Syntax

```
outpID = defTimePeriod(swathID,start,stop,mode)
```

Description

`outpID = defTimePeriod(swathID,start,stop,mode)` defines a time period for a swath. `outpID` is a swath period ID that can be used to read all the entries of a data field within the time period. The swath structure must have the `'Time'` field defined. A cross track is within a time period if a condition is met according to the value of `mode`:

`'MIDPOINT'`	The midpoint is within the time period.
`'ENDPOINT'`	Either endpoint is within the time period.

This function corresponds to the `SWdeftimeperiod` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime =  25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
data = sw.extractPeriod(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

`sw.defBoxRegion` | `sw.defVrtRegion` | `sw.extractPeriod`

matlab.io.hdfeos.sw.defVrtRegion

Package: matlab.io.hdfeos.sw

Subset on monotonic field or dimension

Syntax

```
regionID_out = defVrtRegion(swathID,regionID,vertObj,range)
```

Description

`regionID_out = defVrtRegion(swathID,regionID,vertObj,range)` subsets on a monotonic field or contiguous elements of a dimension. Whereas `defBoxRegion` and `defTimePeriod` subset along the `'Track'` dimension, this routine allows the user to subset along any dimension. `regionID` specifies the subsetted region from a previous call. `vertObj` specifies the dimension by which to subset. `range` specifies the minimum and maximum values for `vertObj`.

If there is no current subsetted region, `regionID` should be `'noprevsub'`.

`vertObj` can be either a dimension or a field. If it is a dimension, then `range` should consist of dimension indices. If `vertObj` corresponds to a field, then `range` should consist of the minimum and maximum field values. `vertObj` must be one-dimensional in this case, and the its values must be monotonic.

This function corresponds to the `SWdefvrtregion` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
regionID = sw.defVrtRegion(swathID,'noprevsub','Bands',[450 600]);
data = sw.extractRegion(swathID,regionID,'Spectra');
sw.detach(swathID);
```

```
sw.close(swfid);
```

matlab.io.hdfeos.sw.detach

Package: matlab.io.hdfeos.sw

Detach from swath

Syntax

```
detach(swathID)
```

Description

`detach(swathID)` detaches from the swath identified by `swathID`.

This function corresponds to the `SWdetach` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfeos.sw.dimInfo

Package: matlab.io.hdfeos.sw

Size of dimension

Syntax

```
dimlen = dimInfo(swathID,dimname)
```

Description

`dimlen = dimInfo(swathID,dimname)` returns the length of the specified dimension.

This function corresponds to the `SWdiminfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
dimlen = sw.dimInfo(swathID,'GeoTrack');
sw.detach(swathID);
sw.close(swfid);
```

`sw.defDim`

matlab.io.hdfeos.sw.extractPeriod

Package: matlab.io.hdfeos.sw

Read data from subsetted time period

Syntax

```
data = extractPeriod(swathID,periodID,fieldname)
```

Description

`data = extractPeriod(swathID,periodID,fieldname)` reads data for the given field for the time period specified by `periodID`.

This routine corresponds to the `SWextractperiod` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime =  25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
data = sw.extractPeriod(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defTimePeriod`

matlab.io.hdfeos.sw.extractRegion

Package: matlab.io.hdfeos.sw

Read subsetted region

Syntax

```
data = extractRegion(swathID,regionID,fieldname)
```

Description

`data = extractRegion(swathID,regionID,fieldname)` reads data for a specified field from a subsetted region identified by `regionID`.

This function corresponds to the `SWextractregion` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
data = sw.extractRegion(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

`sw.defBoxRegion` | `sw.defVrtRegion`

matlab.io.hdfeos.sw.fieldInfo

Package: matlab.io.hdfeos.sw

Information about swath field

Syntax

```
[dimsizes,ntype,dimlist] = fieldInfo(swathID,fieldname)
```

Description

`[dimsizes,ntype,dimlist] = fieldInfo(swathID,fieldname)` returns the size, data type, and list of named dimensions for the specified swath geolocation or data field.

This function corresponds to the `SWfieldinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[fieldSize,ntype,dimlist] = sw.fieldInfo(swathID,'Spectra');
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfeos.sw.geoMapInfo

Package: matlab.io.hdfeos.sw

Type of dimension mapping for named dimension

Syntax

```
mappingType = geoMapInfo(swathID,dimname)
```

Description

`mappingType = geoMapInfo(swathID,dimname)` returns the type of dimension mapping for the named dimension. `mappingType` is one of `'indexed'`, `'regular'`, or `'unmapped'`.

This routine corresponds to the `SWgeomapinfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
maptype = sw.geoMapInfo(swathID,'GeoTrack');
sw.detach(swathID);
sw.close(swfid);
```

`sw.defDimMap`

matlab.io.hdfeos.sw.getFillValue

Package: matlab.io.hdfeos.sw

Fill value for specified field

Syntax

```
fillvalue = getFillValue(swathID,fieldname)
```

Description

`fillvalue = getFillValue(swathID,fieldname)` returns the fill value for the specified field.

This function corresponds to the `SWgetfillvalue` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
fv = sw.getFillValue(swathID,'Spectra');
sw.detach(swathID);
sw.close(swfid);
```

`sw.setFillValue`

matlab.io.hdfeos.sw.idxMapInfo

Package: matlab.io.hdfeos.sw

Indexed array of geolocation mapping

Syntax

```
idx = idxMapInfo(swathID,geodim,datadim)
```

Description

`idx = idxMapInfo(swathID,geodim,datadim)` retrieves the indexed elements of the geolocation mapping between `geodim` and `datadim`.

This function corresponds to the `SWidxmapinfo` function in the HDF-EOS C library API.

See Also

`sw.geoMapInfo`

matlab.io.hdfeos.sw.inqAttrs

Package: matlab.io.hdfeos.sw

Names of swath attributes

Syntax

```
attrlist = inqAttrs(swathID)
```

Description

`attrlist = inqAttrs(swathID)` returns the list of swath attribute names. `attrlist` is a cell array.

This function corresponds to the `SWinqattrs` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
attrList = sw.inqAttrs(swathID);
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.readAttr` | `sw.writeAttr`

matlab.io.hdfeos.sw.inqDataFields

Package: matlab.io.hdfeos.sw

Information about geolocation fields

Syntax

```
[fields,rank,datatype] = inqDataFields(swathID)
```

Description

`[fields,rank,datatype] = inqDataFields(swathID)` returns the list of geolocation field names, the rank of each field, and the data type of each field.

This function corresponds to the `SWinqdatafields` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `fields` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[fields,rank,datatype] = sw.inqDataFields(swathID);
sw.detach(swathID);
sw.close(swfid);
```

`sw.defDataField` | `sw.inqGeoFields`

matlab.io.hdfeos.sw.inqDims

Package: matlab.io.hdfeos.sw

Information about dimensions defined in swath

Syntax

```
[dimnames,dimlens] = inqDims(swathID)
```

Description

`[dimnames,dimlens] = inqDims(swathID)` returns the names of the dimensions `dimnames` as a cell array. The length of each respective dimension is returned in `dimlens`.

This function corresponds to the `SWinqdims` routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[dimnames,dimlens] = sw.inqDims(swathID);
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defDim`

matlab.io.hdfeos.sw.inqGeoFields

Package: matlab.io.hdfeos.sw

Information about geolocation fields

Syntax

```
[fields,rank,datatype] = inqGeoFields(swathID)
```

Description

`[fields,rank,datatype] = inqGeoFields(swathID)` returns the list of geolocation fields `fields`, the rank of each field, and the data type of each field.

This function corresponds to the `SWinqgeofields` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `fields` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[fields,rank,datatypes] = sw.inqGeoFields(swathID);
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfeos.sw.inqIdxMaps

Package: matlab.io.hdfeos.sw

Information about swath indexed geolocation mapping

Syntax

```
[idxMap,idxSize] = inqIdxMaps(swathID)
```

Description

`[idxMap,idxSize] = inqIdxMaps(swathID)` retrieves all indexed geolocation/data mappings defined in the swath. `idxMap` is a cell array with each element consisting of the names of the dimensions of a mapping, separated by a `'/'`. `idxSize` contains the size of the index arrays corresponding to each mapping.

This function corresponds to the `SWinqidxmaps` routine in the HDF-EOS library.

See Also

`sw.inqMaps`

matlab.io.hdfeos.sw.inqMaps

Package: matlab.io.hdfeos.sw

Information about swath geolocation relations

Syntax

```
[map,offset,increment] = inqMaps(swathID)
```

Description

`[map,offset,increment] = inqMaps(swathID)` returns the dimension mapping list, the offset of each geolocation relation, and the increment of each geolocation relation. These mappings are not indexed. `map` is a cell array where each element contains the names of the dimensions for each mapping, separated by a slash. `offset` and `increment` contain the offset and increment of each geolocation relation.

This function corresponds to the `SWinqmaps` routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[dimmap,offset,increment] = sw.inqMaps(swathID);
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfeos.sw.inqSwath

Package: matlab.io.hdfeos.sw

Names of swaths in file

Syntax

```
swaths = inqSwath(filename)
```

Description

`swaths = inqSwath(filename)` returns a cell array containing the names of all the swaths in a file.

This function corresponds to the `SWinqswath` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swaths = sw.inqSwath('swath.hdf');
```

See Also

`gd.inqGrid`

matlab.io.hdfeos.sw.mapInfo

Package: matlab.io.hdfeos.sw

Offset and increment of specific geolocation mapping

Syntax

```
[offset,increment] = mapInfo(swathID,geodim,datadim)
```

Description

`[offset,increment] = mapInfo(swathID,geodim,datadim)` retrieves the offset and increment of the geolocation mapping between the specified geolocation dimension and the specified data dimension.

This function corresponds to the `SWmapinfo` function in the HDF-EOS C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
sw.detach(swathID);
sw.close(swfid);
swfid = sw.open('myfile.hdf','read');
swathID = sw.attach(swfid,'MySwath');
[offset,increment] = sw.mapInfo(swathID,'GeoTrack','DataTrack');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defDimMap`

matlab.io.hdfeos.sw.nEntries

Package: matlab.io.hdfeos.sw

Number of entries for specific type

Syntax

```
nEnts = nEntries(swathID,type)
```

Description

`nEnts = nEntries(swathID,type)` returns the number of entries in a swath. Valid inputs for `type` include:

`'dims'`	or `'HDFE_NENTDIM'`
`'maps'`	or `'HDFE_NENTMAP'`
`'imaps'`	or `'HDFE_NENTIMAP'`
`'geofields'`	or `'HDFE_NENTGFLD'`
`'datafields'`	or `'HDFE_NENTFLD'`

This function corresponds to the `SWnentries` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
ndims = sw.nEntries(swathID,'dims');
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfeos.sw.open

Package: matlab.io.hdfeos.sw

Open swath file

Syntax

```
swfID = open(filename)
swfID = open(filename,access)
```

Description

`swfID = open(filename)` opens an HDF-EOS swath file for read-only access.

`swfID = open(filename,access)` opens or creates an HDF-EOS swath file identified by `filename` and returns a file ID. `access` can be one of the following string values.

`'read'` (default)	Read-only
`'rdwr'`	Read-write
`'create'`	Creates a file, deleting it if it already exists

This routine corresponds to the `SWopen` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
sw.close(swfid);
```

See Also

`sw.close`

matlab.io.hdfeos.sw.periodInfo

Package: matlab.io.hdfeos.sw

Information about subsetted period

Syntax

```
[datatype,dims] = periodInfo(swathID,periodID,fieldname)
```

Description

`[datatype,dims] = periodInfo(swathID,periodID,fieldname)` retrieves information about the period defined for the given field. `datatype` is the data type of the field. `dims` is the dimensions of the subsetted region.

This function corresponds to the `SWperiodinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime =  25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
[ntype,dims] = sw.periodInfo(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfeos.sw.readAttr

Package: matlab.io.hdfeos.sw

Read swath attribute

Syntax

```
data = readAttr(swathID,attrname)
```

Description

`data = readAttr(swathID,attrname)` reads a swath attribute.

This function corresponds to the `SWreadAttr` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
value = sw.readAttr(swathID,'creation_date');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.writeAttr`

matlab.io.hdfeos.sw.readField

Package: matlab.io.hdfeos.sw

Read data from swath field

Syntax

```
data = readField(swathID,fieldname)
data = readField(swathID,fieldname,start,count)
data = readField(swathID,fieldname,start,count,stride)
```

Description

`data = readField(swathID,fieldname)` reads an entire swath field.

`data = readField(swathID,fieldname,start,count)` reads a contiguous hyperslab of data from the swath field `fieldname`. The `start` input specifies the zero-based index of the first element to be read. `count` specifies the number of elements along each dimension to read.

`data = readField(swathID,fieldname,start,count,stride)` reads a strided hyperslab of data from the swath field `fieldname`. The `stride` input specifies the inter-element spacing along each dimension.

This function corresponds to the `SWreadfield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
data = sw.readField(swathID,'Longitude');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.writeField`

matlab.io.hdfeos.sw.regionInfo

Package: matlab.io.hdfeos.sw

Information about subsetted region

Syntax

```
[datatype,extent] = regionInfo(swathID,regionID,fieldname)
```

Description

`[datatype,extent] = regionInfo(swathID,regionID,fieldname)` returns the data type and extent of a subsetted region of a field. `regionID` is the identifier for the subsetted region.

This function corresponds to the `SWregioninfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `extent` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
[ntype,dims] = sw.regionInfo(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defBoxRegion` | `sw.defVrtRegion`

matlab.io.hdfeos.sw.setFillValue

Package: matlab.io.hdfeos.sw

Set fill value for the specified field

Syntax

```
setFillValue(swathID,fieldname,fillvalue)
```

Description

`setFillValue(swathID,fieldname,fillvalue)` sets the fill value for the specified field. The field must have more than two dimensions.

This function corresponds to the `SWsetfillvalue` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',400);
sw.defDim(swathID,'Xtrack',200);
dims = {'Track','Xtrack'};
sw.defDataField(swathID,'Temperature',dims,'float');
sw.setFillValue(swathID,'Temperature',single(-999));
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.getFillValue`

matlab.io.hdfeos.sw.writeAttr

Package: matlab.io.hdfeos.sw

Write swath attribute

Syntax

```
writeAttr(swathID,attrname,data)
```

Description

`writeAttr(swathID,attrname,data)` writes an attribute to a swath. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the `SWwriteattr` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.writeAttr(swathID,'creation_date', datestr(now));
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.readAttr`

matlab.io.hdfeos.sw.writeField

Package: matlab.io.hdfeos.sw

Write data to swath field

Syntax

```
writeField(swathID,fieldname,data)
writeField(swathID,fieldname,start,data)
writeField(swathID,fieldname,start,stride,data)
```

Description

`writeField(swathID,fieldname,data)` writes an entire swath data field.

`writeField(swathID,fieldname,start,data)` writes a contiguous hyperslab to a swath field. `start` specifies the index of the first element to write. The number of elements along each dimension is inferred from either the size of `data` or from the swath field itself.

`writeField(swathID,fieldname,start,stride,data)` writes a strided hyperslab to a swath field. `stride` specifies the inter-element spacing along each dimension.

This function corresponds to the `SWwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

Examples

Write data to a geolocation field `'Longitude'`.

```
lon = [-50:49];
data = repmat(lon(:),1,100);
data = single(data);
import matlab.io.hdfeos.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','swath.hdf');
```

```
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
swfid = sw.open('myfile.hdf','rdwr');
swathID = sw.attach(swfid,'Example Swath');
sw.writeField(swathID,'Longitude',data);
sw.detach(swathID);
sw.close(swfid);
```

See Also

sw.readField

matlab.io.saveVariablesToScript

Save workspace variables to MATLAB script

Syntax

```
matlab.io.saveVariablesToScript(filename)
matlab.io.saveVariablesToScript(filename,varnames)
matlab.io.saveVariablesToScript(filename,Name,Value)
[r1,r2] = matlab.io.saveVariablesToScript(filename)
```

Description

`matlab.io.saveVariablesToScript(filename)` saves variables in the current workspace to a MATLAB script named `filename.m`. The filename can include the `.m` suffix. If you do not include it, the function adds it when it creates the file.

Variables that MATLAB cannot generate code for are saved to a MAT-file named `filename.mat`.

If a file with the same name already exists, it is overwritten.

`matlab.io.saveVariablesToScript(filename,varnames)` saves only workspace variables specified by `varnames` to the MATLAB script.

`matlab.io.saveVariablesToScript(filename,Name,Value)` uses additional options specified by one or more Name,Value pair arguments.

`[r1,r2] = matlab.io.saveVariablesToScript(filename)` additionally returns two cell arrays:

- `r1` for variables that were saved to the MATLAB script
- `r2` for variables that were saved to a MAT-file

Examples

Save Workspace Variables to MATLAB Script

Save variables from a workspace to a MATLAB script, `test.m`.

```
matlab.io.saveVariablesToScript('test.m')
```

Save Specific Workspace Variables to MATLAB Script

Create and save variable `myVar` from a workspace to a MATLAB script, `test.m`.

```
myVar = 55.3;
matlab.io.saveVariablesToScript('test.m','myVar')
```

Append Specific Variables to Existing MATLAB Script

Create two variables, `a` and `b`, and save them to an existing MATLAB script `abfile.m`.

```
a = 72.3;
b = pi;
matlab.io.saveVariablesToScript('abfile.m',{'a','b'},...
'SaveMode','append')
```

Update Specific Variables in Existing MATLAB Script

Update and save two variables, `y` and `z`, to an existing MATLAB script `yzfile.m`.

```
y = 15.7;
z = 3 * pi;
matlab.io.saveVariablesToScript('yzfile.m',{'y','z'},...
'SaveMode','update')
```

Specify MATLAB Script Configuration for Saving Variable

Update and save variable `resistance` to an existing MATLAB script `designData.m` while specifying the configuration of the script file.

```
resistance = [10 20.5 11 13.7 15.1 7.7];
matlab.io.saveVariablesToScript('designData.m','resistance',...
'SaveMode','Update','MaximumArraySize',5,...
'MaximumNestingLevel',5,'MaximumTextWidth',30)
```

Specify 2-D Slice for Saving 3-D Array in MATLAB Script

Specify a 2-D slice for the output of the 3-D array `my3Dtable`, such that the 2-D slice expands along the first and third dimensions. Save the 2-D slice in the MATLAB script `sliceData.m`.

```
level1 = [1 2; 3 4];
```

```
level2 = [5 6; 7 8];
my3Dtable( :, :, 1) = level1;
my3Dtable( :, :, 2) = level2;
matlab.io.saveVariablesToScript('sliceData.m','MultidimensionalFormat',[1,3])
```

The resulting MATLAB code is similar to the following:

```
level1 = ...
 [1 2;
 3 4];

level2 = ...
 [5 6;
 7 8];
my3Dtable = zeros(2, 2, 2);
my3Dtable(:,1,:) = ...
 [1 5;
 3 7];

my3Dtable(:,2,:) = ...
 [2 6;
 4 8];
```

Save Variables Matching a Regular Expression

Save variables that match the expression `autoL*` to a MATLAB script `autoVariables.m`.

```
matlab.io.saveVariablesToScript('autoVariables.m','RegExp','autoL*')
```

Save Variables to Version 7.3 MATLAB Script

Create two variables, `p` and `q`, and save them to a version 7.3 MATLAB script `version73.m`.

```
p = 49;
q = 35.5;
matlab.io.saveVariablesToScript('version73.m','p','q',...
'MATFileVersion','v7.3')
```

Return Variables Saved to MATLAB Script

Save variables that were saved to a MATLAB script to the variable `r1`, and those that were saved to a MAT-file to the variable `r2`.

```
[r1,r2] = matlab.io.saveVariablesToScript('mydata.m')

r1 =

    'level1'
    'level2'
    'level3'
    'my3Dtable'

r2 =

   Empty cell array: 0-by-1
```

Input Arguments

`filename` — Name of MATLAB script for saving variables

filename | variable

Name of MATLAB script for saving variables, specified as a string giving a file name or a variable containing the file name.

Example: `matlab.io.saveVariablesToScript('myVariables.m')`

`varnames` — Name of variables to save

string | cell array

Name of variables to save, specified as a string or a cell array.

Example: `{'X','Y','Z'}`

Data Types: `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'MaximumArraySize',500,'MATFileVersion','v4'` specifies that the maximum number of array elements to save is `500` using MATLAB version 4 syntax.

'MATFileVersion' — MATLAB version whose syntax to use
'v7.3' (default) | 'v4' | 'v6' | 'v7'

MATLAB version whose syntax to use for saving MAT-files, specified as the comma-separated pair consisting of 'MATFileVersion' and one of the following version numbers:

- 'v4'
- 'v6'
- 'v7'
- 'v7.3'

Example: 'MATFileVersion','v6'

Data Types: char

'MaximumArraySize' — Maximum array elements to save
1000 (default) | integer

Maximum array elements to save, specified as the comma-separated pair consisting of 'MaximumArraySize' and an integer in the range of 1 to 10,000.

Example: 'MaximumArraySize',1050

'MaximumNestingLevel' — Maximum number of object levels or array hierarchies to save
20 (default) | integer

Maximum number of object levels or array hierarchies to save, specified as the comma-separated pair consisting of 'MaximumNestingLevel' and an integer in the range of 1 to 200.

Example: 'MaximumNestingLevel',67

'MaximumTextWidth' — Text wrap width during save
76 (default) | integer

Text wrap width during save, specified as the comma-separated pair consisting of 'MaximumTextWidth' and an integer in the range of 32 to 256.

Example: 'MaximumTextWidth',82

'MultidimensionalFormat' — Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data
'rowvector' (default) | integer cell array

Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data, specified as the comma-separated pair consisting of `'MultidimensionalFormat'` and one of these values:

- `'rowvector'` — Save multidimensional variables as a single row vector.
- `integer cell array` — Save a 2-D slice of multidimensional variables, where the dimensions satisfy all the following criteria:
  - Two positive integers represent dimensions.
  - The two integers are less than or equal to the dimensions of the n-D array.
  - The second integer is greater than the first.

Example: `'MultidimensionalFormat',[1,3]`

`'RegExp'` — Regular expression for matching

string

Regular expression for matching, specified as the comma-separated pair consisting of `'RegExp'` and one or more expressions given as a string.

Example: `'RegExp','level*'`

Data Types: `char`

`'SaveMode'` — Mode to save MATLAB script

`'create'` (default) | `'update'` | `'append'`

Mode to save MATLAB script, specified as the comma-separated pair consisting of `SaveMode` and one of these values:

- `'create'` — Save variables to a new MATLAB script.
- `'update'` — Only update variables that are already present in a MATLAB script.
- `'append'` — Update variables that are already present in a MATLAB script and append new variables to the end of the script.

Example: `'SaveMode','Update'`

Output Arguments

`r1` — Variables that were saved to a MATLAB script

cell array

Variables that were saved to a MATLAB script, returned as a cell array of variable names.

`r2` — Variables that were saved to a MAT-file
cell array

Variables that were saved to a MAT-file, returned as a cell array of variable names.

Limitations

- `matlab.io.saveVariablesToScript` does not save the following variables to a MATLAB script or a MAT-file.
  - Java objects
  - .NET objects
  - Python objects
- `matlab.io.saveVariablesToScript` saves the following variables only to a MAT-file.
  - MATLAB objects
  - Function handles
  - Anonymous functions

matlab.lang.makeUniqueStrings

Construct unique strings from input strings

Syntax

```
U = matlab.lang.makeUniqueStrings(S)

U = matlab.lang.makeUniqueStrings(S,excludedStrings)
U = matlab.lang.makeUniqueStrings(S,whichStrings)
U = matlab.lang.makeUniqueStrings(S, ___ , maxStringLength)

[U, modified] = matlab.lang.makeUniqueStrings( ___ )
```

Description

`U = matlab.lang.makeUniqueStrings(S)` constructs unique strings, `U`, from input strings, `S`, by appending an underscore and a number to duplicate strings.

`U = matlab.lang.makeUniqueStrings(S,excludedStrings)` constructs strings that are unique within `U` and with respect to `excludedStrings`. The `makeUniqueStrings` function does not check `excludedStrings` for uniqueness.

`U = matlab.lang.makeUniqueStrings(S,whichStrings)` specifies the subset of `S` to make unique within the entire set. `makeUniqueStrings` makes the strings in `S(whichStrings)` unique among themselves and with respect to the remaining strings. `makeUniqueStrings` returns the remaining strings unmodified in `U`. Use this syntax when you have an array of strings, and need to check that only some elements of the array are unique.

`U = matlab.lang.makeUniqueStrings(S, ___ , maxStringLength)` specifies the maximum length, `maxStringLength`, of strings in `U`. If `makeUniqueStrings` cannot make elements in `S` unique without exceeding `maxStringLength`, it returns an error. You can use this syntax with any of the input arguments of the previous syntaxes.

`[U, modified] = matlab.lang.makeUniqueStrings( ___ )` returns a logical array, `modified`, indicating modified strings.

Examples

Construct Unique Strings

Create an array of strings and make each element unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};
U = matlab.lang.makeUniqueStrings(S)
```

```
U =

    'John'    'Sue'    'Nick'    'John_1'    'Campion'    'John_2'    'Jason'
```

The `makeUniqueStrings` function appends the duplicate strings in elements 3 and 5 with underscores and incrementing numbers.

Construct Unique Strings and Specify Exclusions

Without specifying excluded strings, make the strings in `U` unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};
U = matlab.lang.makeUniqueStrings(S)
```

```
U =

    'John'    'Sue'    'Nick'    'John_1'    'Campion'    'John_2'    'Jason'
```

Specify that the string, `'Nick'`, should be excluded from the output.

```
U = matlab.lang.makeUniqueStrings(S, 'Nick')
```

```
U =

    'John'    'Sue'    'Nick_1'    'John_1'    'Campion'    'John_2'    'Jason'
```

`makeUniqueStrings` excludes `'Nick'` from `U` and instead modifies the first duplicate string, found in element 3, to be `'Nick_1'`.

Exclude workspace variables from the unique string array.

```
Sue = 42;
U = matlab.lang.makeUniqueStrings(S, who)

U =

    'John'    'Sue_1'    'Nick'    'John_1'    'Campion'    'John_2'    'Jason'
```

Since `'Sue'` exists in the workspace, `makeUniqueStrings` makes this string unique by appending an underscore and number.

Construct Unique Strings for Specified Array Elements

Create an array of strings and make only the first four elements unique.

```
S = {'quiz' 'quiz' 'quiz' 'exam' 'quiz' 'exam'};
U = matlab.lang.makeUniqueStrings(S, 1:4)

U =

    'quiz_1'    'quiz_2'    'quiz_3'    'exam_1'    'quiz'    'exam'
```

The first four elements in `U` are unique among themselves, and among the remaining strings in elements 5 and 6 (`'quiz'` and `'exam'`). Alternatively, you can use a logical array instead of a range of linear indices to achieve the same results: `U = matlab.lang.makeUniqueStrings(S, [true true true true false false])` or `U = matlab.lang.makeUniqueStrings(S, logical([1 1 1 1 0 0]))`.

Append a duplicate `'quiz'` onto the end of `S` and make the first four elements unique.

```
S{end+1} = 'quiz'
U = matlab.lang.makeUniqueStrings(S, 1:4)

S =

    'quiz'    'quiz'    'quiz'    'exam'    'quiz'    'exam'    'quiz'

U =

    'quiz_1'    'quiz_2'    'quiz_3'    'exam_1'    'quiz'    'exam'    'quiz'
```

The strings that `makeUniqueStrings` checks are still unique among themselves and among the remaining strings. Since `makeUniqueStrings` does not check any elements after element 4, duplicate strings remain.

Construct Unique Strings with Maximum Length

Create an array from `S` where the first three elements are unique and the maximum length of each string is 5.

```
S = {'sampleData' 'sampleData' 'sampleData' 'sampleData'};
U = matlab.lang.makeUniqueStrings(S, 1:3, 5)
```

```
U =

    'sampl'    'sam_1'    'sam_2'    'sampleData'
```

The first element is truncated to 5 characters. The second and third elements are truncated to 3 characters to allow `makeUniqueStrings` to append an underscore and number, and still not exceed 5 characters.

Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};
[N, modified] = matlab.lang.makeValidName(S)
```

```
N =

    'a_name'    'name_1'    'x2_name'

modified =

     1     0     1
```

`makeValidName` did not modify the second element.

Input Arguments

S — Input strings

string or cell array of strings

Input strings, specified as a string or cell array of strings.

`excludedStrings` — Strings to exclude

string or cell array of strings

Strings to exclude from `U`, specified as a string or cell array of strings.

Example: `'dontDuplicateThisString'`, `{'excludeS1','excludeS2'}`, `who`

`whichStrings` — Subset of strings to make unique

range of linear indices or logical array

Subset of strings, `S`, to make unique within the entire set, specified as a range of linear indices or as a logical array with the same size and shape as `S`. If there are duplicates in `S`, the `makeUniqueStrings` function only modifies those specified by `whichStrings`.

If `whichStrings` is a logical array, strings are checked for uniqueness when the array element in the same position has a value of `true`.

Example: `1:5`, `logical([1 0 1])`, `[true false true]`

`maxStringLength` — Maximum length of output strings

integer

Maximum length of output strings in `U`, specified as an integer. If `makeUniqueStrings` cannot make elements in `S` unique without exceeding `maxStringLength`, it returns an error.

Output Arguments

`U` — Unique strings

string | cell array of strings

Unique strings, returned as a string or cell array of strings. The output has the same dimension as the input, `S`.

`modified` — Indicator of modified strings

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same dimension as the input, `S`. A value of `1` (`true`) indicates that `makeUniqeStrings`

modified the input string in the corresponding location. A value of `0` (`false`) indicates that `makeUniqeStrings` did not need to modify the input string in the corresponding location.

More About

Tips

- To ensure strings are valid and unique, use `matlab.lang.makeValidName` before `matlab.lang.makeUniqueStrings`.

```
S = {'my.Name','my_Name','my_Name'};
validStrings = matlab.lang.makeValidName(S)
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings,...
    {},namelengthmax)
```

```
validStrings =

    'my_Name'    'my_Name'    'my_Name'

validUniqueStrings =

    'my_Name'    'my_Name_1'    'my_Name_2'
```

See Also

`matlab.lang.makeValidName` | `namelengthmax` | `who`

Introduced in R2014a

matlab.lang.makeValidName

Construct valid MATLAB identifiers from input strings

Syntax

```
N = matlab.lang.makeValidName(S)
N = matlab.lang.makeValidName(S,Name,Value)
[N, modified] = matlab.lang.makeValidName( ___ )
```

Description

`N = matlab.lang.makeValidName(S)` constructs valid MATLAB identifiers, `N`, from input strings, `S`. The `makeValidName` function does not guarantee the strings in `N` are unique.

A valid MATLAB identifier is a string of alphanumerics (A–Z, a–z, 0–9) and underscores, such that the first character is a letter and the length of the string is less than or equal to `namelengthmax`.

`makeValidName` deletes any whitespace characters prior to replacing any characters that are not alphanumerics or underscores. If a whitespace character is followed by a lowercase letter, `makeValidName` converts the letter to the corresponding uppercase character.

`N = matlab.lang.makeValidName(S,Name,Value)` includes additional options specified by one or more Name,Value pair arguments.

`[N, modified] = matlab.lang.makeValidName( ___ )` returns a logical array, `modified`, indicating modified strings. You can use this syntax with any of the input arguments of the previous syntaxes.

Examples

Construct Valid MATLAB Identifiers

```
S = {'Item_#','Price/Unit','1st order','Contact'};
N = matlab.lang.makeValidName(S)
```

```
N =

    'Item__'    'Price_Unit'    'x1stOrder'    'Contact'
```

In the first and second strings, `makeValidName` replaced the invalid characters (`#` and `/`), with underscores. In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Construct Valid MATLAB Identifiers Using Specified Replacement Style

Replace invalid characters with the corresponding hexadecimal representation.

```
S = {'Item_#','Price/Unit','1st order','Contact'};
N = matlab.lang.makeValidName(S,'ReplacementStyle','hex')
```

```
N =

    'Item_0x23'    'Price0x2FUnit'    'x1stOrder'    'Contact'
```

In the first and second strings, `makeValidName` replaced the invalid characters (`#` and `/`), with their hexadecimal representation. In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Delete invalid characters.

```
N = matlab.lang.makeValidName(S,'ReplacementStyle','delete')
```

```
N =

    'Item_'    'PriceUnit'    'x1stOrder'    'Contact'
```

`makeValidName` deleted the invalid characters (`#` and `/`). In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Construct Valid MATLAB Identifiers Using Specified Prefix

```
S = {'1stMeasurement','2ndMeasurement','Control'};
```

```
N = matlab.lang.makeValidName(S,'Prefix','m_')

N =

    'm_1stMeasurement'    'm_2ndMeasurement'    'Control'
```

Only the strings that do not start with a letter are prepended with a prefix.

Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};
[N, modified] = matlab.lang.makeValidName(S)

N =

    'a_name'    'name_1'    'x2_name'

modified =

     1     0     1
```

`makeValidName` did not modify the second element.

Input Arguments

S — Input strings

string or cell array of strings

Input strings, specified as a string or cell array of strings. If `S` is a cell array of strings, it must be a `1xN` or `Nx1` cell array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ReplacementStyle','delete'` deletes invalid characters.

`'ReplacementStyle'` — Replacement style

`'underscore'` (default) | `'delete'` | `'hex'`

Replacement style, specified as a string. The value controls how MATLAB replaces nonalphanumeric characters.

`ReplacementStyle` Value	Description
`'underscore'` (default)	Replaces all characters that are not alphanumerics or underscores with underscores. `'underscore'` deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase.
`'hex'`	Replaces each character that is not an alphanumeric or underscore with its corresponding hexadecimal representation. `'hex'` deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase.
`'delete'`	Deletes all characters that are not alphanumerics or underscores. `'delete'` deletes whitespace characters and changes any lowercase letter following a whitespace to uppercase.

`'Prefix'` — Character to prefix

`'x'` (default) | string

Character to prefix to input strings that do not begin with a letter after `makeValidName` replaces nonalphanumeric characters, specified as a string. A valid prefix must start with a letter, contain only alphanumeric characters and underscores, and not be longer than the value of `namelengthmax`.

Output Arguments

`N` — Valid MATLAB identifiers

string | cell array of strings

Valid MATLAB identifiers, returned as a string or cell array of strings. The output has the same number of dimensions as the input, `S`.

`modified` — Indicator of modified strings

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same number of dimensions as the input, `S`. A value of `1` (`true`) indicates that `makeValidName` modified the input string in the corresponding location. A value of `0` (`false`) indicates that `makeValidName` did not need to modify the input string in the corresponding location.

More About

Tips

- To ensure strings are valid and unique, use `matlab.lang.makeUniqueStrings` after `matlab.lang.makeValidName`.

```
S = {'my.Name','my_Name','my_Name'};
validStrings = matlab.lang.makeValidName(S)
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings,{},...
    namelengthmax)
```

```
validStrings =

    'my_Name'    'my_Name'    'my_Name'

validUniqueStrings =

    'my_Name'    'my_Name_1'    'my_Name_2'
```

- To customize an invalid character replacement, first use functions such as `strrep` or `regexprep` to convert to valid characters. For example, convert `'@'` characters in the string, `S`, to `'At'` using `strrep(S,'@','At')`. Then, use `matlab.lang.makeValidName` to ensure that all characters in the strings are valid.

Introduced in R2014a

matlabrc

Startup file for MATLAB program

Description

At startup time, MATLAB automatically executes the file `matlabrc.m`. This function establishes the MATLAB path, sets the default figure size, and sets some uicontrol defaults.

On multiuser or networked systems, system administrators can put messages, definitions, or other code that applies to all users in their `matlabrc.m` file.

The file `matlabrc.m` invokes the `startup.m` file, if it exists on the search path MATLAB uses.

Individual users should use the `startup.m` file to customize MATLAB startup. The `matlabrc.m` file, located in the *`matlabroot`*`/toolbox/local` folder, is reserved for system administrators.

Examples

Turning Off the Figure Window Toolbar

If you do not want the toolbar to appear in the figure window, remove the comment marks from the following line in the `matlabrc.m` file, or create a similar line in your own `startup.m` file.

```
%   set(0,'defaultfiguretoolbar','none')
```

More About

Tips

You can also start MATLAB using options you define at the Command Window prompt or in your Microsoft Windows shortcut for MATLAB.

Algorithms

MATLAB invokes `matlabrc` at startup. `matlabrc.m` contains the statements

```
if exist('startup') == 2
    startup
end
```

that invokes `startup.m`, if it exists. Extend this process to create additional startup files, if required.

- Startup Options

See Also

`matlabroot` | `quit` | `restoredefaultpath` | `startup`

matlabroot

Root folder

Syntax

```
matlabroot
mr = matlabroot
```

Description

`matlabroot` returns the name of the folder where the MATLAB software is installed. Use `matlabroot` to create a path to MATLAB and toolbox folders that does not depend on a specific platform, MATLAB version, or installation location.

`mr = matlabroot` returns the name of the folder in which the MATLAB software is installed and assigns it to `mr`.

Examples

Get the location where MATLAB is installed:

```
matlabroot
```

MATLAB returns:

```
C:\Program Files\MATLAB\R2009a
```

Produce a full path to the `toolbox/matlab/general` folder that is correct for the platform on which it is executed:

```
fullfile(matlabroot,'toolbox','matlab','general')
```

Change the current folder to the MATLAB root folder:

```
cd(matlabroot)
```

To add the folder `myfiles` to the MATLAB search path, run

```
addpath([matlabroot '/toolbox/local/myfiles'])
```

More About

Tips

matlabroot as Folder Name

The term *`matlabroot`* also refers to the folder where MATLAB files are installed. For example, “save to *`matlabroot`*`/toolbox/local`” means save to the `toolbox/local` folder in the MATLAB root folder.

Using $matlabroot as a Literal

In some files, `$matlabroot` is literal. In those files, MATLAB interprets `$matlabroot` as the full path to the MATLAB root folder. For example, including the line:

```
$matlabroot/toolbox/local/myfile.jar
```

in `javaclasspath.txt`, adds `myfile.jar`, which is located in the `toolbox/local` folder, to the static Java class path.

Sometimes, particularly in older code examples, the term `$matlabroot` or `$MATLABROOT` is not meant to be interpreted literally but is used to represent the value returned by the `matlabroot` function.

matlabroot on Macintosh Platforms

In R2008b (V7.7) and more recent versions, running `matlabroot` on Apple Macintosh platforms returns

```
/Applications/MATLAB_R2008b.app
```

In versions prior to R2008b (V7.7), such as R2008a (V7.6), running `matlabroot` on Macintosh platforms returns, for example

```
/Applications/MATLAB_R2008a
```

When you use GUIs on Macintosh platforms, you cannot directly view the contents of the MATLAB root folder. For more information, see “Navigating Within the MATLAB Root Folder on Macintosh Platforms”.

matlabshared.supportpkg.checkForUpdate

List of support packages that can be updated

Syntax

```
matlabshared.supportpkg.checkForUpdate
info = matlabshared.supportpkg.checkForUpdate
```

Description

`matlabshared.supportpkg.checkForUpdate` displays information about support package updates in the MATLAB Command Window. If an update is available, use `supportPackageInstaller` to install the updates.

`info = matlabshared.supportpkg.checkForUpdate` returns a structured array of information about installed support packages.

Examples

Check for support package updates

```
matlabshared.supportpkg.checkForUpdate
```

```
No support packages need updates.
```

If one or more updates are available, the command line displays that information in the response.

Get a structured array of support package updates

```
info = matlabshared.supportpkg.checkForUpdate
```

```
info =

                Name: 'Arduino'
    InstalledVersion: '3.0'
```

```
        BaseProduct: 'Simulink'
```

Output Arguments

`info` — Return argument from function
structure created using `matlabshared.supportpkg.checkForUpdate`

Information about support package updates, returned as a structured array.

See Also

`matlabshared.supportpkg.getInstalled` | `supportPackageInstaller` | `targetupdater`

matlabshared.supportpkg.getInstalled

List of installed support packages

Syntax

```
matlabshared.supportpkg.getInstalled
info = matlabshared.supportpkg.getInstalled
```

Description

`matlabshared.supportpkg.getInstalled` displays information about installed support packages in the MATLAB Command Window.

`info = matlabshared.supportpkg.getInstalled` returns a structured array of information about installed support packages.

Examples

Get a list of installed support packages

```
matlabshared.supportpkg.getInstalled
```

```
Name   Version Base Product
------- ------- ------------
Arduino 3.0     Simulink
```

Get a structured array of installed support packages

```
info = matlabshared.supportpkg.getInstalled
```

```
info =

               Name: 'Arduino'
    InstalledVersion: '3.0'
```

```
        BaseProduct: 'Simulink'
```

Output Arguments

`info` — Return argument from function
structure created using `matlabshared.supportpkg.getInstalled`

Information about installed support packages, returned as a structured array.

matlab (Linux)

Start MATLAB program from Linux system prompt

Syntax

```
matlab
matlab option1 ... optionN
```

Description

`matlab` is a Bourne shell script that starts the MATLAB program from a Linux system prompt. Here the term `matlab` refers to this script and MATLAB refers to the program.

`matlab option1 ... optionN` starts MATLAB with the specified startup options.

Alternatively, assign startup options in the MATLAB ".matlab7rc.sh Startup File" on page 1-4972. Modifying the `.matlab7rc.sh` file defines startup options every time you start MATLAB.

Input Arguments

`option1 ... optionN` — One or more startup options

strings

One or more startup options, specified as strings corresponding to valid startup options from the following tables.

Mode Options

Option	Result
`-desktop`	Start MATLAB without a controlling terminal. Use this option when you start MATLAB from a window manager menu or desktop icon.

Option	Result
`-nodesktop`	Run the JVM software without opening the MATLAB desktop. You can use development environment tools by calling them as functions. Use this option to run in batch processing mode. If you pipe to MATLAB using the > constructor, the `nodesktop` option is used automatically. Do not use `nodesktop` to provide a Command-Window-only interface. Instead, in the **Environment** section on the **Home** tab, click **Layout**. Then, under **Select Layout**, select **Command Window Only**.
`-nojvm`	Start MATLAB without the JVM software. Features that require Java software (such as the desktop tools and graphics) are not supported.

Display Options

Option	Result
`-noFigureWindows`	Disable the display of figure windows in MATLAB.
`-nosplash`	Do not display the splash screen during startup.
`-nodisplay`	Start the JVM software without starting the MATLAB desktop. This option does not display X commands. It overrides the `DISPLAY` environment variable.
`-display xDisp`	Send X commands to X Window Server display `xDisp`. This option overrides the `DISPLAY` environment variable.

Execute MATLAB Script or Function

Option	Result
`-r` *`statement`*	Execute the specified MATLAB *`statement`*, specified as a string or as the name of a MATLAB script or function. If

Option	Result
	statement is MATLAB code, enclose the string with double quotation marks. If *statement* is the name of a MATLAB function or script, do not specify the file extension and do not use quotation marks. Any required file must be on the MATLAB search path or in the startup folder. Example: `-r "disp(['Current folder: ' pwd])"` Example: `-r myscript`

Specify MATLAB Version

Option	Result
`v=`*variant*	Start the version of MATLAB in the `bin/`*variant* folder.

Debugging Options

Option	Result
`-logfile` *filename*	Copy Command Window output, including error reports, into *filename*, specified as a string. Example: `-logfile output.log`
`-n`	Display, without starting MATLAB, final values of the environment variables and arguments passed to the MATLAB executable. This option also displays other diagnostic information for use when working with a Technical Support Representative.
`-e`	Display, without starting MATLAB, all environment variables and their values to standard output. If the exit status is not `0` on return, then the variables and values might not be correct.
`-D`*debugger debugopts*	Start MATLAB in debug mode. This option uses the debugger program name, *debugger*, specified as a string, for example,

Option	Result
	`gdb`, `lldb`, or `dbx`. You can specify the full path to the debugger. This option must be the first option in the `matlab` command. Debugger program command-line options, *`debugopts`*, specified as a string of valid options for *`debugger`*. See your debugger documentation for details. Do not use any other `matlab` command options when using *`debugopts`*. Do not add a space between **D** and *`debugger`*. Example: `-Dgdb`
`-jdb` *`portnumber`*	Enable use of the Java debugger. The Java debugger uses the default *`portnumber`* value 4444 to communicate with MATLAB. The port number is optional. However, to use the Java debugger while running multiple MATLAB sessions, you must specify a port number. The *`portnumber`* value must be an integer in the range 0–65535. The integer cannot be reserved or currently in use by another application on your system.
`-debug`	Display information for debugging X-based problems. Use this option only when working with a Technical Support Representative from MathWorks, Inc.

Use Single Computational Thread

By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

Option	Result
`-singleCompThread`	Limit MATLAB to a single computational thread.

Disable Searching Custom Java Class Path

Option	Result
`-nouserjavapath`	Disable use of `javaclasspath.txt` and `javalibrarypath.txt` files. For more information, see "java.opts Files".

OpenGL Library Options

These options control the use of software OpenGL libraries when MATLAB detects a graphics driver with known issues. For more information, see "Features with OpenGL Requirements".

Option	Result
`-softwareopengl`	Force MATLAB to start with software OpenGL libraries.
`-nosoftwareopengl`	Disable auto-selection of OpenGL software.

Specify License File

Option	Result
`-c` *`license`*	Use the specified license file, *`license`*, specified as a string, a colon-separated list of license file names, or a `port@host` entry. For more information, see Understanding License Files in "License Management".

Help Options

Option	Result
`-h`	Display startup options without starting MATLAB.
`-help`	Same as `-h` option.

Examples

Start MATLAB Without Desktop or JVM

```
matlab -nojvm -nodisplay -nosplash
```

Display Current Folder at Startup

```
matlab -r "disp(['Current folder: ' pwd])"
```

Definitions

.matlab7rc.sh Startup File

The `.matlab7rc.sh` shell script contains variable definitions used by the `matlab` script.

Use the `.matlab7rc.sh` file to redefine variables defined in the `matlab` script. `matlab` looks for the first occurrence of `.matlab7rc.sh` in the:

- Current folder
- Home folder (`$HOME`)
- *`matlabroot`*`/bin` folder

To edit the `.matlab7rc.sh` file, use the template located in the *`matlabroot`*`/bin` folder.

This table lists the variables. For more information, see the comments in the `.matlab7rc.sh` file.

Variable	Definition and Standard Assignment Behavior
ARCH	The machine architecture. MATLAB checks for a valid architecture in this order: • The value ARCH passed with the `-arch` or `-arch/ext` argument to the script. • The value of the environment variable MATLAB_ARCH.

Variable	Definition and Standard Assignment Behavior
DISPLAY	The host name of the X Window display MATLAB uses for output. The value of Xdisplay passed with the -display argument to the script is used; otherwise, the value in the environment is used. MATLAB ignores DISPLAY if the -nodisplay argument is passed.
LD_LIBRARY_PATH	Final Load library path. The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in .matlab7rc.sh as LDPATH_PREFIX. The second sublist is computed in the script and includes folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of LD_LIBRARY_PATH from the environment possibly augmented in .matlab7rc.sh. The final sublist is defined in .matlab7rc.sh as LDPATH_SUFFIX.
MATLAB	The MATLAB root folder. MATLAB uses the default computed by the script unless MATLABdefault is reset in .matlab7rc.sh. Currently MATLABdefault is not reset in the shipping .matlab7rc.sh.
MATLABPATH	The MATLAB search path. The final value is a colon-separated list with the MATLABPATH from the environment prepended to a list of computed defaults. At startup, you can add subfolders of userpath to the MATLAB search path. See userpath for details.

Variable	Definition and Standard Assignment Behavior
SHELL	The shell to use when the "!" or unix command is issued in MATLAB. This value is taken from the environment, unless SHELL is reset in .matlab7rc.sh. Another environment variable called MATLAB_SHELL takes precedence over SHELL. MATLAB checks internally for MATLAB_SHELL first and, if empty or not defined, it checks SHELL. If SHELL is also empty or not defined, MATLAB uses /bin/sh. Use an absolute path for the value of MATLAB_SHELL, that is, /bin/sh, not simply sh. Currently, the shipping .matlab7rc.sh file does not reset SHELL. Also, this file does not reference or set MATLAB_SHELL.
TOOLBOX	Path of the toolbox folder. A nonempty value in the environment is used first. Otherwise, *matlabroot*/toolbox, computed by the script, is used unless TOOLBOX is reset in .matlab7rc.sh. Currently TOOLBOX is not reset in the shipping .matlab7rc.sh.

The matlab script determines the path of the MATLAB root folder by looking up the folder tree from the *matlabroot*/bin folder (where the matlab script is located). MATLAB use the MATLAB variable to locate all files within the MATLAB folder tree.

You can change the definition of MATLAB. For example, change the definition if you want to run a different version of MATLAB. Or change the definition if your system uses certain types of automounting schemes and the path determined by the matlab script is not correct.

matlab (Mac)

Start MATLAB program from Mac Terminal

Syntax

```
matlab
matlab option1 ... optionN
```

Description

`matlab` is a Bourne shell script that starts the MATLAB program from a Mac system prompt. Here the term `matlab` refers to this script and MATLAB refers to the program.

The `matlab` script is located in the MATLAB application package, `/Applications/MATLAB_`*`release`*`.app/bin/matlab`, where *`release`* is the MATLAB release number.

The `matlab` script:

- Determines the MATLAB root folder, the value returned by the `matlabroot` function.
- Processes command-line options, if any.
- Reads the MATLAB startup file, `.matlab7rc.sh`.
- Sets MATLAB environment variables.

`matlab option1 ... optionN` starts MATLAB with the specified startup options.

Alternatively, assign startup options in the MATLAB ".matlab7rc.sh Startup File" on page 1-4981. Modifying the `.matlab7rc.sh` file defines startup options every time you start MATLAB.

Input Arguments

`option1 ... optionN` — One or more startup options
strings

One or more startup options, specified as strings corresponding to valid startup options from the following tables.

Mode Options

Option	Result
`-desktop`	Start MATLAB without a controlling terminal. Use this option when you start MATLAB from a window manager menu or desktop icon.
`-nodesktop`	Run the JVM software without opening the MATLAB desktop. You can use development environment tools by calling them as functions. Use this option to run in batch processing mode. If you pipe to MATLAB using the > constructor, the `nodesktop` option is used automatically. Do not use `nodesktop` to provide a Command-Window-only interface. Instead, in the **Environment** section, on the **Home** tab, click **Layout**. Then, under **Select Layout**, select **Command Window Only**.
`-nojvm`	Start MATLAB without the JVM software. Features that require Java software (such as the desktop tools and graphics) are not supported.

Display Options

Option	Result
`-noFigureWindows`	Disable the display of figure windows in MATLAB.
`-nosplash`	Do not display the splash screen during startup.
`-nodisplay`	Start the JVM in headless mode, and MATLAB from displaying all windows.

Execute MATLAB Script or Function

Option	Result
`-r statement`	Execute the specified MATLAB *`statement`*, specified as a string or as the name of a MATLAB script or function. If *`statement`* is MATLAB code, enclose the string with double quotation marks. If *`statement`* is the name of a MATLAB function or script, do not specify the file extension and do not use quotation marks. Any required file must be on the MATLAB search path or in the startup folder. Example: `-r "disp(['Current folder: ' pwd])"` Example: `-r myscript`

Specify MATLAB Version

Option	Result
`v=variant`	Start the version of MATLAB in the `bin/variant` folder.

Debugging Options

Option	Result
`-logfile filename`	Copy Command Window output, including error reports, into *`filename`*, specified as a string. Example: `-logfile output.log`
`-n`	Display, without starting MATLAB, final values of the environment variables and arguments passed to the MATLAB executable. This option also displays other diagnostic information for use when working with a Technical Support Representative.

Option	Result
`-e`	Display, without starting MATLAB, all environment variables and their values to standard output. If the exit status is not `0` on return, then the variables and values might not be correct.
`-D`*`debugger debugopts`*	Start MATLAB in debug mode. This option uses the debugger program name, *`debugger`*, specified as a string, for example, `gdb`, `lldb`, or `dbx`. You can specify the full path to the debugger. This option must be the first option in the `matlab` command. Debugger program command-line options, *`debugopts`*, specified as a string of valid options for *`debugger`*. See your debugger documentation for details. Do not use any other `matlab` command options when using *`debugopts`*. Do not add a space between **D** and *`debugger`*. Example: `-Dlldb`
`-jdb` *`portnumber`*	Enable use of the Java debugger. The Java debugger uses the default *`portnumber`* value 4444 to communicate with MATLAB. The port number is optional. However, to use the Java debugger while running multiple MATLAB sessions, you must specify a port number. The *`portnumber`* value must be an integer in the range 0–65535. The integer cannot be reserved or currently in use by another application on your system.

Use Single Computational Thread

By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

Option	Result
`-singleCompThread`	Limit MATLAB to a single computational thread.

Disable Searching Custom Java Class Path

Option	Result
`-nouserjavapath`	Disable use of `javaclasspath.txt` and `javalibrarypath.txt` files. For more information, see "java.opts Files".

Specify License File

Option	Result
`-c` *`license`*	Use the specified license file, *`license`*, specified as a string, a colon-separated list of license file names, or a `port@host` entry. For more information, see Understanding License Files in "License Management".

Help Options

Option	Result
`-h`	Display startup options without starting MATLAB.
`-help`	Same as `-h` option.

Examples

Start MATLAB from Applications Folder

Move to the `bin` folder within the application package. For example:

```
cd /Applications/MATLAB_R2015a.app/bin
```

Preface the `matlab` command with `./` characters.

```
./matlab -nosplash
```

Start MATLAB from Any Folder

Start MATLAB from any Terminal folder by specifying the full path name.

```
/Applications/MATLAB_release.app/bin/matlab/matlab
```

where *`release`* is the MATLAB release number.

Startup MATLAB Without Desktop or JVM

```
matlab -nojvm -nodisplay -nosplash
```

Display Current Folder at Startup

```
matlab -r "disp(['Current folder: ' pwd])"
```

Definitions

.matlab7rc.sh Startup File

The `.matlab7rc.sh` shell script contains variable definitions used by the `matlab` script. Use the `.matlab7rc.sh` file to redefine variables defined in the `matlab` script.

`matlab` looks for the first occurrence of `.matlab7rc.sh` in the:

- Current folder
- Home folder (`$HOME`)
- *`matlabroot`*`/bin` folder

To edit the `.matlab7rc.sh` file, use the template located in the *`matlabroot`*`/bin` folder.

The following table lists the variables. For more information, see the comments in the `.matlab7rc.sh` file.

`.matlab7rc.sh` Variable	Definition and Standard Assignment Behavior
ARCH	The machine architecture. MATLAB checks for a valid architecture in this order: • The value ARCH passed with the `-arch` or `-arch/ext` argument to the script. • The value of the environment variable MATLAB_ARCH.

.matlab7rc.sh Variable	Definition and Standard Assignment Behavior
DYLD_LIBRARY_PATH	Final Load library path. The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in .matlab7rc.sh as LDPATH_PREFIX. The second sublist is computed in the script and includes folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of DYLD_LIBRARY_PATH from the environment possibly augmented in .matlab7rc.sh. The final sublist is defined in .matlab7rc.sh as LDPATH_SUFFIX.
MATLAB	The MATLAB root folder. MATLAB uses the default computed by the script unless MATLABdefault is reset in .matlab7rc.sh. Currently MATLABdefault is not reset in the shipping .matlab7rc.sh.
MATLABPATH	The MATLAB search path. The final value is a colon-separated list with the MATLABPATH from the environment prepended to a list of computed defaults. At startup, you can add subfolders of userpath to the MATLAB search path. See userpath for details.

.matlab7rc.sh Variable	Definition and Standard Assignment Behavior
SHELL	The shell to use when the "!" or unix command is issued in MATLAB. This value is taken from the environment, unless SHELL is reset in .matlab7rc.sh. Another environment variable called MATLAB_SHELL takes precedence over SHELL. MATLAB checks internally for MATLAB_SHELL first and, if empty or not defined, it checks SHELL. If SHELL is also empty or not defined, MATLAB uses /bin/sh. Use an absolute path for the value of MATLAB_SHELL, that is, /bin/sh, not simply sh. Currently, the shipping .matlab7rc.sh file does not reset SHELL. Also, this file does not reference or set MATLAB_SHELL.
TOOLBOX	Path of the toolbox folder. A nonempty value in the environment is used first. Otherwise, *matlabroot*/toolbox, computed by the script, is used unless TOOLBOX is reset in .matlab7rc.sh. Currently TOOLBOX is not reset in the shipping .matlab7rc.sh.

The matlab script determines the path of the MATLAB root folder by looking up the folder tree from the *matlabroot*/bin folder (where the matlab script is located). MATLAB use the MATLAB variable to locate all files within the MATLAB folder tree.

You can change the definition of MATLAB. For example, change the definition if you want to run a different version of MATLAB. Or change the definition if your system uses certain types of automounting schemes and the path determined by the matlab script is not correct.

More About

- "Startup Options"

matlab (Windows)

Start MATLAB program from Windows system prompt

Syntax

```
matlab
matlab option1 ... optionN
```

Description

`matlab` starts the MATLAB program from the Microsoft Windows system prompt. Here the term `matlab` refers to the command you type, and MATLAB refers to the program).

The `matlab` command:

- Determines the MATLAB root folder, the value returned by the `matlabroot` function.
- Determines the host machine architecture, 32-bit or 64-bit.
- Processes command-line options and passes other options to MATLAB.

`matlab option1 ... optionN` starts MATLAB with the specified startup options.

Input Arguments

`option1 ... optionN` — One or more startup options

strings

One or more startup options, specified as strings corresponding to valid startup options from the following tables.

Display Options

Option	Result
`-noFigureWindows`	Disable the display of figure windows in MATLAB.

Option	Result
`-nosplash`	Do not display the splash screen during startup.

Execute MATLAB Script or Function

Option	Result
`-r` *`statement`*	Execute the MATLAB *`statement`*, specified as a string or as the name of a MATLAB script or function. If *`statement`* is MATLAB code, enclose the string with double quotation marks. If *`statement`* is the name of a MATLAB function or script, do not specify the file extension and do not use quotation marks. Any required file must be on the MATLAB search path or in the startup folder. Example: `-r "disp(['Current folder: ' pwd])"` Example: `-r myscript`

Run 32-Bit MATLAB on 64-Bit Platforms

Option	Result
`-win32`	Run 32-bit MATLAB on 64-bit processors.

Debugging Options

Option	Result
`-logfile` *`filename`*	Copy Command Window output, including error log reports, in to *`filename`*, specified as a string. Example: `-logfile output.log`
`-jdb` *`portnumber`*	Enable use of the Java debugger. The Java debugger uses the default *`portnumber`* value 4444 to communicate with MATLAB.

Option	Result
	The port number is optional. However, to use the Java debugger while running multiple MATLAB sessions, you must provide a port number. The *`portnumber`* value must be an integer in the range 0–65535. The integer cannot be reserved or currently in use by another application on your system.

Use Single Computational Thread

By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

Option	Result
`-singleCompThread`	Limit MATLAB to a single computational thread.

Disable Searching Custom Java Class Path

Option	Result
`-nouserjavapath`	Disable use of `javaclasspath.txt` and `javalibrarypath.txt` files. For more information, see "java.opts Files".

OpenGL Library Options

These options control the use of software OpenGL libraries when MATLAB detects a graphics driver with known issues. For more information, see "Features with OpenGL Requirements".

Option	Result
`-softwareopengl`	Force MATLAB to start with software OpenGL libraries.
`-nosoftwareopengl`	Disable auto-selection of OpenGL software.

COM Automation Server Options

Option	Result
`-automation`	Start MATLAB as a Component Object Model (COM) Automation server. MATLAB does not display the splash screen and minimizes the window. Use for a single call to MATLAB.
`-regserver`	Register MATLAB as a COM Automation server in the Windows registry. MATLAB displays a minimized command window; close this window. You must have administrator privileges to change the Windows registry. Based on your User Account Control (UAC) settings, you might need to right-click a Windows Command Processor and select **Run as administrator**. If that option is not available, contact your system administrator. MATLAB remains registered until you use the `-unregserver` option. Alternatively, you can register MATLAB from the MATLAB command prompt. Type: `!matlab -regserver` MATLAB displays a minimized command window. Open this window and exit MATLAB to continue working with MATLAB.
`-unregserver`	Remove MATLAB COM server entries from the registry.

Wait for MATLAB to Terminate

By default, when you call the `matlab` command from a script, the command starts MATLAB and then immediately executes the next statements in the script. The `-wait` option pauses the script until MATLAB terminates.

Option	Result
`-wait`	Use in a startup script to process the results from MATLAB. Calling MATLAB with this option blocks the script from continuing until the results are generated.

Shield Options

For 32-bit Windows platforms only.

Shield options provide the specified level of protection of the address space used by MATLAB during startup. These options attempt to provide the largest contiguous block of memory available after startup, which is useful for processing large data sets. These options load resources, such as DLLs, into locations without fragmenting the address space. For shield option values other than `none`, address space is protected up to or after the processing of `matlabrc`. Use higher levels of protection to secure larger initial blocks of contiguous memory. However, a higher level might not always provide a larger size block and might cause startup problems. Therefore, start with a lower level of protection, and if successful, try the next higher level. Use the MATLAB `memory` function after startup to see the size of the largest contiguous block of memory. This function helps you determine the actual effect of the setting you used. If your `matlabrc.m` or `startup.m` file requires significant memory, a higher level of protection might cause startup to fail. In that event try a lower level.

Enter one of the options shown in the following table.

Option	Description
`-shield minimum`	Default setting. Protect the range `0x50000000`–`0x70000000` until startup processes `matlabrc`. This option ensures that there is at least approximately 500 MB of contiguous memory up to this point. Start with this option. If MATLAB fails to start successfully, use the `-shield none` option instead. If MATLAB starts successfully and you want to try to ensure an even larger contiguous block after startup, try using the `-shield medium` option.

Option	Description
`-shield medium`	Protect the same range as `-shield minimum` until after startup processes `matlabrc`. This option ensures that there is at least approximately 500 MB of contiguous memory at this point. If MATLAB fails to start successfully with this option, use `-shield minimum` instead. If MATLAB starts successfully and you want to try to ensure an even larger contiguous block after startup, try using the `-shield maximum` option.
`-shield maximum`	Protect the maximum range, which can be up to approximately 1.5 GB, until startup processes `matlabrc`. If MATLAB fails to start successfully, use the `-shield medium` option instead.
`-shield none`	Disable address shielding. Use this option if MATLAB fails to start successfully with the `-shield minimum` option.

Specify License File

For more information, see Understanding License Files in "License Management".

Option	Result
`-c` *`license`*	Use the License File, *`license`*, specified as a string, a colon-separated list of license file names, or a `port@host` entry. If specifying multiple files, separate the names by semicolons and enclose the entire list in quotation marks. If the path to your license file contains a space, enclose the path name in quotation marks. Example: `-c "c:\TMW license \license_agreement.txt"`

Help Options

Option	Result
`-h`	Display startup options without starting MATLAB.
`-help`	Same as `-h` option.
`-?`	Same as `-h` option.

Examples

Startup Without Splash Screen

```
matlab -nosplash
```

Copy Command Window Output into output.log File

```
matlab -logfile output.log
```

More About

- "Start MATLAB on Windows Platforms"
- "Startup Options"

max

Largest elements in array

Syntax

```
M = max(A)
M = max(A,[],dim)
[M,I] = max( ___ )

C = max(A,B)

___ = max( ___ ,nanflag)
```

Description

`M = max(A)` returns the largest elements of `A`.

- If `A` is a vector, then `max(A)` returns the largest element of `A`.
- If `A` is a matrix, then `max(A)` is a row vector containing the maximum value of each column.
- If `A` is a multidimensional array, then `max(A)` operates along the first array dimension whose size does not equal `1`, treating the elements as vectors. The size of this dimension becomes `1` while the sizes of all other dimensions remain the same. If `A` is an empty array with first dimension `0`, then `max(A)` returns an empty array of the same size as `A`.

`M = max(A,[],dim)` returns the largest elements along dimension `dim`. For example, if `A` is a matrix, then `max(A,[],2)` is a column vector containing the maximum value of each row.

`[M,I] = max( ___ )` finds the indices of the maximum values of `A` and returns them in output vector `I`, using any of the input arguments in the previous syntaxes. If the maximum value occurs more than once, then `max` returns the index corresponding to the first occurrence.

`C = max(A,B)` returns an array the same size as `A` and `B` with the largest elements taken from `A` or `B`. Either the dimensions of `A` and `B` are the same, or one can be a scalar.

`___ = max(___,nanflag)` specifies whether to include or omit `NaN` values in the calculation for any of the previous syntaxes. For the single input case, to specify `nanflag` without specifying `dim`, use `max(A,[],nanflag)`. For example, `max(A,[],'includenan')` includes all `NaN` values in `A` while `max(A,[],'omitnan')` ignores them.

Examples

Largest Vector Element

Create a vector and compute its largest element.

```
A = [23 42 37 18 52];
M = max(A)
```

```
M =

    52
```

Largest Complex Element

Create a complex vector and compute its largest element, that is, the element with the largest magnitude.

```
A = [-2+2i 4+i -1-3i];
max(A)
```

```
ans =

   4.0000 + 1.0000i
```

Largest Element in Each Matrix Column

Create a matrix and compute the largest element in each column.

```
A = [2 8 4; 7 3 9]
```

```
A =
```

```
     2     8     4
     7     3     9

M = max(A)

M =

     7     8     9
```

Largest Element in Each Matrix Row

Create a matrix and compute the largest element in each row.

```
A = [1.7 1.2 1.5; 1.3 1.6 1.99]

A =

    1.7000    1.2000    1.5000
    1.3000    1.6000    1.9900

M = max(A,[],2)

M =

    1.7000
    1.9900
```

Largest Element Indices

Create a matrix A and compute the largest elements in each column, as well as the row indices of A in which they appear.

```
A = [1 9 -2; 8 4 -5]

A =

     1     9    -2
     8     4    -5
```

```
[M,I] = max(A)

M =

     8     9    -2

I =

     2     1     1
```

Largest Element Comparison

Create a matrix and return the largest value between each of its elements compared to a scalar.

```
A = [1 7 3; 6 2 9]

A =

     1     7     3
     6     2     9

B = 5;
C = max(A,B)

C =

     5     7     5
     6     5     9
```

Largest Element in Matrix

Create a matrix `A` and use its column representation, `A(:)`, to find the value and index of the largest element.

```
A = [8 2 4; 7 3 9]

A =
```

```
     8     2     4
     7     3     9

A(:)

ans =

     8
     7
     2
     3
     4
     9

[M,I] = max(A(:))

M =

     9

I =

     6
```

`I` is the index of `A(:)` containing the largest element.

Now, use the `ind2sub` function to extract the row and column indices of `A` corresponding to the largest element.

```
[I_row, I_col] = ind2sub(size(A),I)

I_row =

     2

I_col =
```

```
     3
```

If you need only the maximum value of `A` and not its index, then call the `max` function twice.

```
M = max(max(A))
```

```
M =

     9
```

Largest Element Involving `NaN`

Create a vector and compute its maximum, excluding `NaN` values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
M = max(A,[],'omitnan')
```

```
M =

    3.9800
```

`max(A)` will also produce this result since `'omitnan'` is the default option.

Use the `'includenan'` flag to return `NaN`.

```
M = max(A,[],'includenan')
```

```
M =

   NaN
```

Input Arguments

`A` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

- If `A` is complex, then `max(A)` returns the complex number with the largest magnitude. If magnitudes are equal, then `max(A)` returns the value with the largest magnitude and the largest phase angle.
- If `A` is a scalar, then `max(A)` returns `A`.
- If `A` is a 0-by-0 empty array, then `max(A)` is as well.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `categorical` | `datetime` | `duration`
Complex Number Support: Yes

`dim` — Dimension to operate along

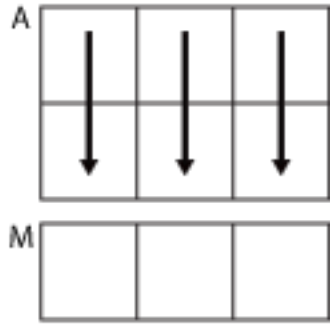
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

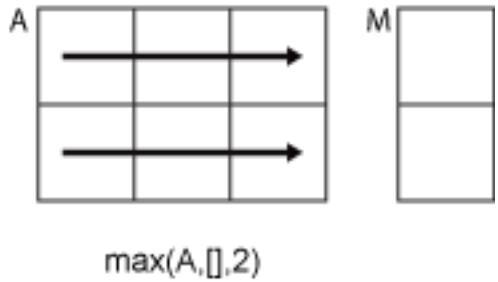
Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(M,dim)` is `1`, while the sizes of all other dimensions remain the same, unless `size(A,dim)` is `0`. If `size(A,dim)` is `0`, then `max` returns an empty array with the same dimension sizes.

Consider a two-dimensional input array, `A`:

- If `dim = 1`, then `max(A,[],1)` returns a row vector containing the largest element in each column.



- If `dim = 2`, then `max(A,[],2)` returns a column vector containing the largest element in each row.



`max` returns `A` if `dim` is greater than `ndims(A)`.

`B` — Additional input array

scalar | vector | matrix | multidimensional array

Additional input array, specified as a scalar, vector, matrix, or multidimensional array.

- The dimensions of `A` and `B` must match, or one can be a scalar.
- `A` and `B` can be the same data type or one can be `double` with the other `single`, `duration`, or any integer data type.
- If `A` and `B` are ordinal categorical arrays, they must have the same sets of categories with the same order.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `categorical` | `datetime` | `duration`
Complex Number Support: Yes

`nanflag` — `NaN` condition

'`omitnan`' (default) | '`includenan`'

`NaN` condition, specified as one of these values:

- '`omitnan`' — Ignore all `NaN` values in the input.
- '`includenan`' — Include the `NaN` values in the input for the calculation.

The `max` function does not support the `nanflag` option for `datetime`, `duration`, or `categorical` arrays.

Data Types: `char`

Output Arguments

`M` — Maximum values

scalar | vector | matrix | multidimensional array

Maximum values, returned as a scalar, vector, matrix, or multidimensional array. `size(M,dim)` is `1`, while the sizes of all other dimensions match the size of the corresponding dimension in `A`, unless `size(A,dim)` is `0`. If `size(A,dim)` is `0`, then `M` is an empty array with the same dimension sizes as `A`.

`I` — Index to maximum values of `A`

scalar | vector | matrix | multidimensional array

Index to maximum values of `A`, returned as a scalar, vector, matrix, or multidimensional array. `I` is the same size as `M`. If the largest element occurs more than once, then `I` contains the index to the first occurrence of the value.

`C` — Maximum elements from `A` or `B`

scalar | vector | matrix | multidimensional array

Maximum elements from `A` or `B`, returned as a scalar, vector, matrix, or multidimensional array.

The size of `C` depends on the sizes of `A` and `B`:

- If `A` and `B` are arrays of the same size, then the size of `C` matches the size of `A` and `B`.
- If either `A` or `B` is a scalar, then the size of `C` matches the size of the nonscalar input array.
- If either `A` or `B` is an empty array with the other a scalar, then `C` is an empty array.

The data type of `C` depends on the data types of `A` and `B`:

- If `A` and `B` are the same data type, then `C` matches the data type of `A` and `B`.
- If either `A` or `B` is `single`, then `C` is `single`.
- If either `A` or `B` is an integer data type with the other a scalar `double`, then `C` assumes the integer data type.

MaximizeCommandWindow

Open Automation server window

Syntax

IDL Method Signature

```
HRESULT MaximizeCommandWindow(void)
```

Microsoft Visual Basic Client

```
MaximizeCommandWindow
```

MATLAB Client

```
MaximizeCommandWindow(h)
```

Description

`MaximizeCommandWindow(h)` displays the window for the server attached to handle `h`, and makes it the currently active window on the desktop.

`MaximizeCommandWindow` restores the window to the size it had at the time it was minimized, not to the maximum size on the desktop. If the server window was not previously in a minimized state, `MaximizeCommandWindow` does nothing.

Examples

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server.

```
Dim Matlab As Object

Matlab = CreateObject("matlab.application")
```

```
Matlab.MinimizeCommandWindow

'Now return the server window to its former state on
'the desktop and make it the currently active window.

Matlab.MaximizeCommandWindow
```

MinimizeCommandWindow

Introduced before R2006a

maxNumCompThreads

Control maximum number of computational threads

Note: `maxNumCompThreads` will be removed in a future version. You can set the `-singleCompThread` option when starting MATLAB to limit MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

Syntax

```
N = maxNumCompThreads
LASTN = maxNumCompThreads(N)
LASTN = maxNumCompThreads('automatic')
```

Description

`N = maxNumCompThreads` returns the current maximum number of computational threads `N`.

`LASTN = maxNumCompThreads(N)` sets the maximum number of computational threads to `N`, and returns the previous maximum number of computational threads, `LASTN`.

`LASTN = maxNumCompThreads('automatic')` sets the maximum number of computational threads using what the MATLAB software determines to be the most desirable. It additionally returns the previous maximum number of computational threads, `LASTN`.

Currently, the maximum number of computational threads is equal to the number of computational cores on your machine.

Note Setting the maximum number of computational threads using `maxNumCompThreads` does not propagate to your next MATLAB session.

mean

Average or mean value of array

Syntax

```
M = mean(A)
M = mean(A,dim)
M = mean( ___ ,outtype)
M = mean( ___ ,nanflag)
```

Description

`M = mean(A)` returns the mean of the elements of `A` along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `mean(A)` returns the mean of the elements.
- If `A` is a matrix, then `mean(A)` returns a row vector containing the mean of each column.
- If `A` is a multidimensional array, then `mean(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors. This dimension becomes `1` while the sizes of all other dimensions remain the same.

`M = mean(A,dim)` returns the mean along dimension `dim`. For example, if `A` is a matrix, then `mean(A,2)` is a column vector containing the mean of each row.

`M = mean( ___ ,outtype)` returns the mean with a specified data type, using any of the input arguments in the previous syntaxes. `outtype` can be `'default'`, `'double'`, or `'native'`.

`M = mean( ___ ,nanflag)` specifies whether to include or omit `NaN` values from the calculation for any of the previous syntaxes. `mean(A,'includenan')` includes all `NaN` values in the calculation while `mean(A,'omitnan')` ignores them.

Examples

Mean of Matrix Columns

Create a matrix and compute the mean of each column.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =

     0     1     1
     2     3     2
     1     3     2
     4     2     2
```

```
M = mean(A)
```

```
M =

    1.7500    2.2500    1.7500
```

Mean of Matrix Rows

Create a matrix and compute the mean of each row.

```
A = [0 1 1; 2 3 2]
```

```
A =

     0     1     1
     2     3     2
```

```
M = mean(A,2)
```

```
M =

    0.6667
    2.3333
```

Mean of 3-D Array

Create a 4-by-2-by-3 array of integers between 1 and 10 and compute the mean values along the second dimension.

```
A = gallery('integerdata',10,[4,2,3],1);
M = mean(A,2)
```

```
M(:,:,1) =

    9.5000
    6.5000
    9.5000
    6.0000

M(:,:,2) =

    1.5000
    4.0000
    7.5000
    7.5000

M(:,:,3) =

    7.0000
    2.5000
    4.0000
    5.5000
```

Mean of Single-Precision Array

Create a single-precision vector of ones and compute its single-precision mean.

```
A = single(ones(1e8,1));
M = mean(A,'native')
```

```
M =

     1
```

The expected mean, 1, cannot be represented in single-precision due to saturation. Use the `double` output type to calculate the expected mean of `A`.

```
M = mean(A,'double')
```

```
M =

     1
```

Mean Excluding `NaN`

Create a vector and compute its mean, excluding `NaN` values.

```
A = [1 0 0 1 NaN 1 NaN 0];
M = mean(A,'omitnan')
```

```
M =

    0.5000
```

If you do not specify `'omitnan'`, then `mean(A)` returns `NaN`.

Input Arguments

`A` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

- If `A` is a scalar, then `mean(A)` returns `A`.
- If `A` is an empty 0-by-0 matrix, then `mean(A)` returns `NaN`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `datetime` | `duration`

`dim` — Dimension to operate along

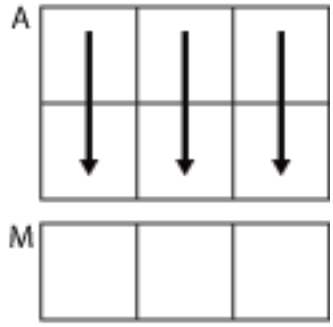
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(M,dim)` is `1`, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `mean(A,1)` returns a row vector containing the mean of the elements in each column.



mean(A,1)

- If `dim = 2`, then `mean(A,2)` returns a column vector containing the mean of the elements in each row.

mean(A,2)

`mean` returns `A` when `dim` is greater than `ndims(A)` or when `size(A,dim)` is `1`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`outtype` — Output data type

`'default'` (default) | `'double'` | `'native'`

Output data type, specified as `'default'`, `'double'`, or `'native'`. These options also specify the data type in which the operation is performed.

`outtype`	Output data type
`'default'`	`double`, unless the input data type is `single`, `duration`, or `datetime`, in which case, the output is `'native'`
`'double'`	`double`, unless the data type is `duration` or `datetime`, in which case, `'double'` is not supported
`'native'`	same data type as the input, unless • Input data type is `logical`, in which case, the output is `double` • Input data type is `char`, in which case, `'native'` is not supported

Data Types: `char`

`nanflag` — `NaN` condition

'`includenan`' (default) | '`omitnan`'

`NaN` condition, specified as one of these values:

- `'includenan'` — Include `NaN` values when computing the mean, resulting in `NaN`.
- `'omitnan'` — Ignore all `NaN` values in the input.

The `mean` function does not support the `nanflag` option for `datetime` or `duration` arrays.

Data Types: `char`

More About

Mean

For a random variable vector A made up of N scalar observations, the mean is defined as

$$\mu = \frac{1}{N}\sum_{i=1}^{N} A_i.$$

See Also

`mean` | `median` | `mode` | `std` | `sum` | `var`

median

Median value of array

Syntax

```
M = median(A)
M = median(A,dim)
M = median( ___ ,nanflag)
```

Description

`M = median(A)` returns the median value of `A`.

- If `A` is a vector, then `median(A)` returns the median value of `A`.
- If `A` is a nonempty matrix, then `median(A)` treats the columns of `A` as vectors and returns a row vector of median values.
- If `A` is an empty 0-by-0 matrix, `median(A)` returns `NaN`.
- If `A` is a multidimensional array, then `median(A)` treats the values along the first array dimension whose size does not equal `1` as vectors. The size of this dimension becomes `1` while the sizes of all other dimensions remain the same.

`median` computes natively in the numeric class of `A`, such that `class(M) = class(A)`.

`M = median(A,dim)` returns the median of elements along dimension `dim`. For example, if `A` is a matrix, then `median(A,2)` is a column vector containing the median value of each row.

`M = median( ___ ,nanflag)` optionally specifies whether to include or omit `NaN` values in the median calculation for any of the previous syntaxes. For example, `median(A,'omitnan')` ignores all `NaN` values in `A`.

Examples

Median of Matrix Columns

Define a 4-by-3 matrix.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =

     0     1     1
     2     3     2
     1     3     2
     4     2     2
```

Find the median value of each column.

```
M = median(A)
```

```
M =

    1.5000    2.5000    2.0000
```

For each column, the median value is the mean of the middle two numbers in sorted order.

Median of Matrix Rows

Define a 2-by-3 matrix.

```
A = [0 1 1; 2 3 2]
```

```
A =

     0     1     1
     2     3     2
```

Find the median value of each row.

```
M = median(A,2)
```

```
M =

     1
     2
```

For each row, the median value is the middle number in sorted order.

Median of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =

    10     8    10

A(:,:,2) =

     6     9     5

A(:,:,3) =

     9     6     1

A(:,:,4) =

     4     9     5
```

Find the median values of this 3-D array along the second dimension.

```
M = median(A)

M(:,:,1) =

    10

M(:,:,2) =

     6

M(:,:,3) =

     6

M(:,:,4) =

     5
```

This operation produces a 1-by-1-by-4 array by computing the median of the three values along the second dimension. The size of the second dimension is reduced to 1.

Compute the median along the first dimension of A.

```
M = median(A,1);
isequal(A,M)
```

```
ans =

     1
```

This command returns the same array as A because the size of the first dimension is 1.

Median of 8-Bit Integer Array

Define a 1-by-4 vector of 8-bit integers.

```
A = int8(1:4)
```

```
A =

    1    2    3    4
```

Compute the median value.

```
M = median(A),
class(M)
```

```
M =

    3

ans =

int8
```

M is the mean of the middle two numbers in sorted order returned as an 8-bit integer.

Median Excluding NaN

Create a vector and compute its median, excluding NaN values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
M = median(A,'omitnan')

M =
```

```
    0.2650
```

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. `A` can be a numeric array, ordinal categorical array, datetime array, or duration array.

dim — Dimension to operate along

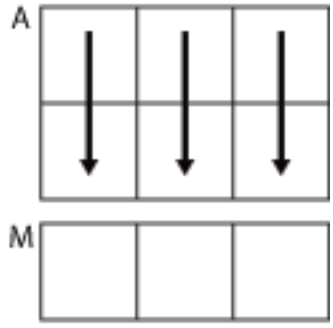
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(M,dim)` is `1`, while the sizes of all other dimensions remain the same.

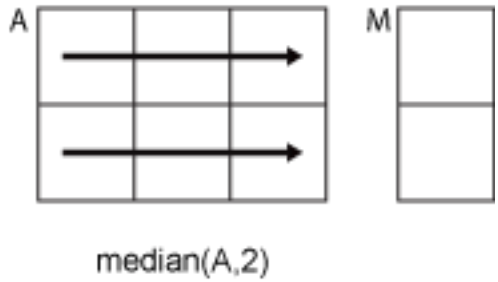
Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `median(A,1)` returns a row vector containing the median of the elements in each column.



median(A,1)

- If `dim = 2`, then `median(A,2)` returns a column vector containing the median of the elements in each row.



`median` returns `A` when `dim` is greater than `ndims(A)`.

`nanflag` — `NaN` condition
'`includenan`' (default) | '`omitnan`'

`NaN` condition, specified as one of these values:

- '`includenan`' — the median of input containing `NaN` values is also `NaN`.
- '`omitnan`' — all `NaN` values appearing in the input are ignored. Note: the `NaN` flags are not set to `0`.

The `nanflag` option does not support datetime arrays, duration arrays, or categorical arrays.

Data Types: `char`

More About

Algorithms

For ordinal categorical arrays, MATLAB interprets the median of an even number of elements as follows:

If the number of categories between the middle two values is ...	Then the median is ...
zero (values are from consecutive categories)	larger of the two middle values

If the number of categories between the middle two values is ...	Then the median is ...
an odd number	value from category occurring midway between the two middle values
an even number	value from larger of the two categories occurring midway between the two middle values

Introduced before R2006a

memmapfile

Create memory map to a file

Syntax

```
m = memmapfile(filename)
m = memmapfile(filename,Name,Value)
```

Description

`m = memmapfile(filename)` maps an existing file, `filename`, to memory and returns the memory map, `m`.

Memory-mapping is a mechanism that maps a portion of a file, or an entire file, on disk to a range of memory addresses within the MATLAB address space. Then, MATLAB can access files on disk in the same way it accesses dynamic memory, accelerating file reading and writing. Memory-mapping allows you to work with data in a file as if it were a MATLAB array.

`m = memmapfile(filename,Name,Value)` specifies the properties of `m` using one or more name-value pair arguments. For example, you can specify the format of the data in the file.

Examples

Map Entire File of `uint8` Data

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 `uint8` values.

```
myData = uint8(1:10)';

fileID = fopen('records.dat','w');
fwrite(fileID, myData,'uint8');
fclose(fileID);
```

Create a map for `records.dat`. When using `memmapfile`, the default data format is `uint8` so the file name is the only required input argument in this case.

```
m = memmapfile('records.dat')
```

```
m =

    Filename: 'd:\matlab\records.dat'
    Writable: false
      Offset: 0
      Format: 'uint8'
      Repeat: Inf
        Data: 10x1 uint8 array
```

MATLAB maps the entire `records.dat` file to memory, setting all properties of the memory map to their default values. The memory map is assigned to the variable, `m`. In this example, the command maps the entire file as a sequence of unsigned 8-bit integers and gives the caller read-only access to its contents.

View the mapped data by accessing the `Data` property of `m`.

```
m.Data
```

```
ans =

    1
    2
    3
    4
    5
    6
    7
    8
    9
   10
```

Map Entire File of Double-Precision Data

Create a memory map for double-precision data. The syntax is similar when specifying other data types.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 `double` values.

```
myData = (1:10)';
```

```
fileID = fopen('records.dat','w');
fwrite(fileID,myData,'double');
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `'double'`.

```
m = memmapfile('records.dat','Format','double')
```

```
m =

    Filename: 'd:\matlab\records.dat'
    Writable: false
      Offset: 0
      Format: 'double'
      Repeat: Inf
        Data: 10x1 double array
```

The `Data` property contains the 10 double-precision values in `records.dat`.

Map and Change Part of a File

Create a memory map for a large array of `int32` data. Specify write access, and nondefault `Format` and `Offset` values.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10,000 `int32` values.

```
myData = int32([1:10000]);

fileID = fopen('records.dat','w');
fwrite(fileID,myData,'int32');
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `int32`. Also, set the `Offset` property to disregard the first 9000 bytes in the file, and the `Writable` property to permit write access.

```
m = memmapfile('records.dat',...
               'Offset',9000,...
               'Format','int32',...
               'Writable',true);
```

An `Offset` value of `9000` indicates that the first 9000 bytes of `records.dat` are not mapped.

Type the name of the memory map to see the current settings for all properties.

```
m
```

```
m =
    Filename: 'd:\matlab\records.dat'
    Writable: true
      Offset: 9000
      Format: 'int32'
      Repeat: Inf
        Data: 7750x1 int32 array
```

The `Format` property indicates that any read or write operation made via the memory map reads and writes the file contents as a sequence of signed 32-bit integers. The `Data` property contains only 7750 elements because the first 9000 bytes of `records.dat`, representing the first 2250 values in the file, are not mapped.

View the first five elements of the mapped data by accessing the `Data` property of `m`.

```
m.Data(1:5)
```

```
ans =

        2251
        2252
        2253
        2254
        2255
```

Map Region of File to Specific Array Shape

Create a memory map for a region of a file containing 100 double-precision values.

At the command prompt, create a sample file in your current folder called `mybinary.bin`, containing 100 double-precision values.

```
randData = gallery('uniformdata',[100,1],0,'double');

fileID = fopen('mybinary.bin','w');
fwrite(fileID,randData,'double');
fclose(fileID);
```

Map the first 75 values in `mybinary.bin` to a 5-by-5-by-3 array of double-precision values that can be referenced in the structure of the memory map using the field name `x`. Specify these parameters with the `Format` name-value pair argument.

```
m = memmapfile('mybinary.bin',...
               'Format',{'double',[5 5 3],'x'})
```

```
m =

    Filename: 'd:\matlab\mybinary.bin'
    Writable: false
      Offset: 0
      Format: {'double' [5 5 3] 'x'}
      Repeat: Inf
        Data: 1x1 struct array with fields:
                x
```

The `Data` property is a structure array that contains the mapped values in the field, `x`.

Assign the mapped data to a variable, `A`. Because the `Data` property is a structure array, you must index into the field, `x`, to access the data.

```
A = m.Data.x;
```

View information about `A`.

```
whos A
```

```
  Name      Size              Bytes  Class     Attributes

  A         5x5x3               600  double
```

Map Segments of File to Multiple Arrays

Map segments of a file with different array shapes and data types to memory.

At the command prompt, create a sample file in your current folder called `mybinary.bin`. Write `uint16` data and double-precision data representing sample pressure, temperature, and volume values into the file. In this case, each of the `uint16` arrays are 50-by-1 and the double-precision arrays are 5-by-10. `k` is a sample scaling factor.

```
k = 8.21;
[pres1,temp1] = gallery('integerdata',[1,300],[50,1],0,'uint16');
vol1 = double(reshape(k*temp1./pres1,5,10));
```

```
[pres2,temp2] = gallery('integerdata',[5,500],[50,1],5,'uint16');
vol2 = double(reshape(k*temp2./pres2,5,10));

fileID = fopen('mybinary.bin','w');
fwrite(fileID,pres1,'uint16');
fwrite(fileID,temp1,'uint16');
fwrite(fileID,vol1,'double');
fwrite(fileID,pres2,'uint16');
fwrite(fileID,temp2,'uint16');
fwrite(fileID,vol2,'double');
fclose(fileID);
```

Map the file to arrays accessible by unique names. Define a field, `pressure`, containing a 50-by-1 array of `uint16` values, followed by a field, `temperature`, containing 50-by-1 `uint16` values. Define a field, `volume`, containing a 5-by-10 array of double-precision values. Use a cell array to define the format of the mapped region and repeat the pattern twice.

```
m = memmapfile('mybinary.bin',...
'Format',{'uint16',[50 1],'pressure';...
'uint16',[50,1],'temperature';...
'double',[5,10],'volume'},'Repeat',2)

m =

    Filename: 'd:\matlab\mybinary.bin'
    Writable: false
      Offset: 0
      Format: {'uint16' [50 1] 'pressure'
               'uint16' [50 1] 'temperature'
               'double' [5 10] 'volume'}
      Repeat: 2
        Data: 2x1 struct array with fields:
         pressure
      temperature
           volume
```

The `Data` property of the memory map, `m`, is a 2-by-1 structure array because the `Format` is applied twice.

Copy the `Data` property to a variable, `A`. Then, view the last block of `double` data, which you can access using the field name, `volume`.

```
A = m.Data;
```

```
myVolume = A(2).volume

myVolume =

     2    13    32     5     5    16     4    22     3     8
     2     9    53    38    13    19    23    85     2   120
    29    10     6     1     2     5     6    58    20    11
     7    15     4     1     5    18     1     4    14     8
     9     8     4     2     0     9     8     6     3     3
```

- “Map File to Memory”

Input Arguments

`filename` — Name of file to map

string

Name of the file to map including the file extension, specified as a string. The `filename` argument cannot include any wildcard characters (for example, `*` or `?`).

Example: `'myFile.dat'`

Data Types: `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `m = memmapfile('myFile.dat','Format','int32','Offset',255)` maps `int32` data in the file, `myFile.dat`, to memory starting from the 256th byte.

`'Writable'` — Type of access allowed to mapped region

`false` (default) | `true`

Type of access allowed to the mapped region, specified as the comma-separated pair consisting of `'Writable'` and either `true` or `false`. If the `Writable` property is set to `false`, the mapped region is read-only. If `true`, then write access is allowed.

Example: `'Writeable',true`

Data Types: `logical`

`'Offset'` — Number of bytes from start of file to start of mapped region

0 (default) | nonnegative integer

Number of bytes from the start of the file to the start of the mapped region, specified as the comma-separated pair consisting of `'Offset'` and a nonnegative integer. This value is zero-based. That is, an `Offset` value of 0 represents the start of the file.

Example: `'Offset',1024`

Data Types: `double`

`'Format'` — Format of mapped region

`'uint8'` (default) | string | `n`-by-3 cell array

Format of the mapped region contents, specified as the comma-separated pair consisting of `'Format'` and a single string or an `n`-by-3 cell array.

- If the file region you are mapping contains data of only one type, specify the `Format` value as a string identifying that type.
  Example: `'int16'`
- To specify an array shape to apply to the data read or written to the mapped file, and a field name to reference this array, specify the `Format` value as a 1-by-3 cell array. The first cell contains a string identifying the data type to apply to the mapped region. The second cell contains the array dimensions to apply to the region. The third cell contains a string specifying the field name to use in the `Data` structure array of the memory map.
  Example: `{'uint64',[30 4 10],'x'}`
- If the region you are mapping is composed of segments of varying data types or array shapes, you can specify an individual format for each segment using an `n`-by-3 cell array, where `n` is the number of segments.
  Example: `{'uint64',[30 4 10],'x'; 'uint32',[30 4 6],'y'}`

You can use any of the following data types when you specify a `Format` value:

- `'int8'`
- `'int16'`
- `'int32'`
- `'int64'`

- `'uint8'`
- `'uint16'`
- `'uint32'`
- `'uint64'`
- `'single'`
- `'double'`

Data Types: `char` | `cell`

`'Repeat'` — Number of times to apply `Format` parameter

`Inf` (default) | positive integer

Number of times to apply the `Format` parameter to the mapped region of the file, specified as the comma-separated pair consisting of `'Repeat'` and a positive integer. If the value of `Repeat` is `Inf`, then `memmapfile` applies the `Format` parameter until the end of the file.

Example: `'Repeat',2000`

Data Types: `double`

Output Arguments

`m` — Memory map

`memmapfile` object

Memory map, returned as a `memmapfile` object with the following properties.

Property	Description
`Filename`	Path and name of the mapped file
`Writable`	Type of access allowed to the mapped region
`Offset`	Number of bytes from the start of the file to the start of the mapped region
`Format`	Format of the contents of the mapped region, including data type, array size, and field name by which to access the data

Property	Description
`Repeat`	Number of times to apply the pattern specified by the `Format` property to the mapped region of the file
`Data`	Memory-mapped data from the file. `Data` can be a numeric array or a structure array with field names specified in the `Format` property

The values for any property (except for `Data`) are set at the time you call `memmapfile`, using name-value pair arguments.

Access any property of `m` with dot notation similar to accessing fields of a structure array. For example, to access the memory-mapped data in the `Data` property, do one of the following:

- If `Data` is a numeric array, call `m.Data`.
- If `Data` is a scalar (1-by-1) structure array, call `m.Data.`*`fieldname`*, where *`fieldname`* is the name of a field.
- If `Data` is a nonscalar structure array, call `m.Data(`*`index`*`).`*`fieldname`* where *`index`* is the index for the element in the structure array, and *`fieldname`* is the name of a field. For example, to access the file data in the `temperature` field of the first element of `Data`, call `m.Data(1).temperature`.

After you create a memory map, `m`, you can change the value of any of its properties, except for `Data`. To assign a new value, use dot notation. For example, to set a new `Offset` value for `m`, type:

```
m.Offset = 2048;
```

More About

Tips

- You can map only an existing file. You cannot create a new file and map that file to memory in one operation. Use the MATLAB file I/O functions to create the file before attempting to map it to memory.
- After `memmapfile` locates the file, MATLAB stores the file's absolute pathname internally, and then uses this stored path to locate the file from that point on. As

a result, you can work in other directories outside your current work directory and retain access to the mapped file.

- `memmapfile` does not expand or append to a mapped file. Use instead standard file I/O functions like `fopen` and `fwrite`.

Algorithms

The actual mapping of a file to the MATLAB address space does not take place when you construct a `memmapfile` object. A memory map, based on the information currently stored in the mapped object, is generated the first time you reference or modify the `Data` property for that object.

- "Overview of Memory-Mapping"

Introduced before R2006a

memory

Display memory information

Syntax

```
memory
userview = memory
[userview systemview] = memory
```

Limitations

- The `memory` function is available only on Microsoft Windows systems. Results are dependant on your computer hardware and the load on your computer.

Description

`memory` displays information showing how much memory is available and how much the MATLAB software is currently using. The information displayed at your computer screen includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-5031
- “Memory Available for All Arrays” on page 1-5032
- “Memory Used By MATLAB” on page 1-5033
- “Physical Memory (RAM)” on page 1-5033

`userview = memory` returns user-focused information on memory use in structure `userview`. The information returned in `userview` includes the following items, each of which is described in a section below:

- “Maximum Possible Array” on page 1-5031
- “Memory Available for All Arrays” on page 1-5032
- “Memory Used By MATLAB” on page 1-5033

`[userview systemview] = memory` returns both user- and system-focused information on memory use in structures `userview` and `systemview`, respectively.

The `userview` structure is described in the command syntax above. The information returned in `systemview` includes the following items, each of which is described in a section below:

- "Virtual Address Space" on page 1-5034
- "System Memory" on page 1-5034
- "Physical Memory (RAM)" on page 1-5033

Output Arguments

Each of the sections below describes a value that is displayed or returned by the `memory` function.

Maximum Possible Array

Maximum Possible Array is the size of the largest contiguous free memory block. As such, it is an upper bound on the largest single array MATLAB can create at this time.

MATLAB derives this number from the smaller of the following two values:

- The largest contiguous memory block found in the MATLAB virtual address space
- The total available system memory

To see how many array elements this number represents, divide by the number of bytes in the array class. For example, for a `double` array, divide by 8. The actual number of elements MATLAB can create is always fewer than this number.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
`memory`	String labelled `Maximum possible array:`
`user = memory`	Structure field `user.MaxPossibleArrayBytes`

All values are double-precision and in units of bytes.

Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the second footnote:

`Limited by contiguous virtual address space available.`

There is sufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

`Limited by System Memory (physical + swap file) available.`

There is insufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

Memory Available for All Arrays

Memory Available for All Arrays is the total amount of memory available to hold data. The amount of memory available is guaranteed to be at least as large as this field.

MATLAB derives this number from the smaller of the following two values:

- The total available MATLAB virtual address space
- The total available system memory

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
`memory`	String labelled `Memory available for all arrays:`
`user = memory`	Structure field `user.MemAvailableAllArrays`

Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems show either the first or second footnote; 64-bit systems show only the latter footnote:

`Limited by virtual address space available.`

There is sufficient system memory to allow mapping of all available virtual addresses in the MATLAB process virtual address space to system memory. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

`Limited by System Memory (physical + swap file) available.`

There is insufficient system memory to allow mapping of all available virtual addresses in the MATLAB process.

Memory Used By MATLAB

Memory Used By MATLAB is the total amount of system memory reserved for the MATLAB process. It is the sum of the physical memory and potential swap file usage.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
`memory`	String labelled `Memory used by MATLAB:`
`user = memory`	Structure field `user.MemUsedMATLAB`

Physical Memory (RAM)

Physical Memory is the available and total amounts of physical memory (RAM) on the computer running MATLAB.

When you enter the `memory` command without assigning its output, MATLAB displays the total memory as a string. When you do assign the output, MATLAB returns both the available and total memory in a structure field. See the table below.

Command	Value	Returned in
`memory`	Total memory	String labelled `Physical Memory (RAM):`
`[user,sys] = memory`	Available memory	Structure field `sys.PhysicalMemory.Available`
	Total memory	Structure field `sys.PhysicalMemory.Total`

Available physical memory is the same as `Available` found in the Windows Task Manager: Performance/Physical Memory, and the total physical memory is the same as `Total`.

You can use the amount of available physical memory as a measure of how much data you can access quickly.

Virtual Address Space

Virtual Address Space is the amount of available and total virtual memory for the MATLAB process. MATLAB returns the information in two fields of the return structure: `Available` and `Total`.

Command	Return Value	Returned in Structure Field
`[user,sys] = memory`	Available memory	`sys.VirtualAddressSpace.Available`
	Total memory	`sys.VirtualAddressSpace.Total`

You can monitor the difference:

```
VirtualAddressSpace.Total - VirtualAddressSpace.Available
```

as the Virtual Bytes counter in the Windows Performance program. (e.g., Windows XP Control Panel/Administrative Tool/Performance program).

System Memory

System Memory is the amount of available system memory on your computer system. This number includes the amount of available physical memory and the amount of available swap file space on the computer running MATLAB. MATLAB returns the information in the `SystemMemory` field of the return structure.

Command	Return Value	Returned in Structure Field
`[user,sys] = memory`	Available memory	`sys.SystemMemory`

This is the same as the difference:

```
limit - total (in bytes)
```

found in the Windows Task Manager: Performance/Commit Charge.

Examples

Display memory statistics on a 64-bit Windows system:

```
memory
```

```
Maximum possible array:            14253 MB (1.495e+10 bytes) *
Memory available for all arrays:           14253 MB (1.495e+10 bytes) *
Memory used by MATLAB:              747 MB (7.833e+08 bytes)
Physical Memory (RAM):            12279 MB (1.288e+10 bytes)

*  Limited by System Memory (physical + swap file) available.
```

Return in the structure `userview`, information on the largest array MATLAB can create at this time, how much memory is available to hold data, and the amount of memory currently being used by your MATLAB process:

```
userview = memory
```

```
userview =

    MaxPossibleArrayBytes: 1.4957e+10
    MemAvailableAllArrays: 1.4957e+10
            MemUsedMATLAB: 784044032
```

Assign the output to two structures, `user` and `sys`, to obtain the information shown here:

```
[user sys] = memory;

%  --- Largest array MATLAB can create ---
user.MaxPossibleArrayBytes
```

```
ans =
   1.4956e+10
```

```
%  --- Memory available for data ---
user.MemAvailableAllArrays
```

```
ans =
   1.4956e+10
```

```
%  --- Memory used by MATLAB process ---
user.MemUsedMATLAB
```

```
ans =
   784039936
```

```
%  --- Virtual memory for MATLAB process ---
sys.VirtualAddressSpace

ans =
    Available: 8.7910e+12
        Total: 8.7961e+12

%  --- Physical memory and paging file ---
sys.SystemMemory

ans =
    Available: 1.4956e+10

%   --- Computer's physical memory ---
sys.PhysicalMemory

ans =
    Available: 2.7093e+09
        Total: 1.2876e+10
```

More About

Tips

Details on Memory Used By MATLAB

MATLAB computes the value for Memory Used By MATLAB by walking the MATLAB process memory structures and summing all the sections that have physical storage allocated in memory or in the paging file on disk.

Using the Windows Task Manager, you have for the MATLAB.exe image:

```
Mem Usage < MemUsedMATLAB < Mem Usage + VM Size (in bytes)
```

where both of the following are true:

- `Mem Usage` is the working set size in kilobytes.
- `VM Size` is the page file usage, or private bytes, in kilobytes.

The working set size is the portion of the MATLAB virtual address space that is *currently* resident in RAM and can be referenced without a memory page fault. The page file usage gives the portion of the MATLAB virtual address space that requires a backup that

doesn't already exist. Another name for page file usage is *private bytes*. It includes all MATLAB variables and workspaces. Since some of the pages in the page file may also be part of the working set, this sum is an overestimate of `MemUseMATLAB`. Note that there are virtual pages in the MATLAB process space that already have a backup. For example, code loaded from EXEs and DLLs and memory-mapped files. If any part of those files is in memory when the memory builtin is called, that memory will be counted as part of `MemUsedMATLAB`.

Reserved Addresses

Reserved addresses are addresses sets aside in the process virtual address space for some specific future use. These reserved addresses reduce the size of `MemAvailableAllArrays` and can reduce the size of the current or future value of `MaxPossibleArrayBytes`.

Example 1 — Java Virtual Machine (JVM)

At MATLAB startup, part of the MATLAB virtual address space is reserved by the Java Virtual Machine (JVM) and cannot be used for storing MATLAB arrays.

Example 2 — Standard Windows Heap Manager

MATLAB, by default, uses the standard Windows heap manager except for a set of small preselected allocation sizes. One characteristic of this heap manager is that its behavior depends upon whether the requested allocation is less than or greater than the fixed number of 524,280 bytes. For, example, if you create a sequence of MATLAB arrays, each less than 524,280 bytes, and then clear them all, the `MemUsedMATLAB` value before and after shows little change, and the `MemAvailableAllArrays` value is now smaller by the total space allocated.

The result is that, instead of globally freeing the extra memory, the memory becomes reserved. It can *only* be reused for arrays less than 524,280 bytes. You cannot reclaim this memory for a larger array except by restarting MATLAB.

menu

Create multiple-choice dialog box

Syntax

```
choice = menu('mtitle','opt1','opt2',...,'optn')
choice = menu('mtitle',options)
```

Description

`choice = menu('mtitle','opt1','opt2',...,'optn')` displays the menu whose title is in the string variable `'mtitle'` and whose choices are string variables `'opt1'`, `'opt2'`, and so on. The menu opens in a modal dialog box. `menu` returns the number of the selected menu item, or 0 if the user clicks the close button on the window.

`choice = menu('mtitle',options)` , where options is a 1-by-N cell array of strings containing the menu choices.

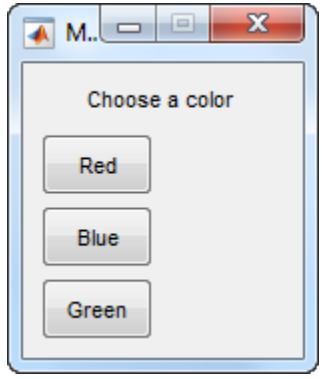
If the user's terminal provides a graphics capability, `menu` displays the menu items as push buttons in a figure window (Example 1). Otherwise. they will be given as a numbered list in the Command Window (Example 2).

Examples

Example 1

On a system with a display, `menu` displays choices as buttons in a dialog box:

```
choice = menu('Choose a color','Red','Blue','Green')
```
displays the following dialog box.



The number entered by the user in response to the prompt is returned as `choice` (i.e., `choice = 2` implies that the user selected `Blue`).

After input is accepted, the dialog box closes, returning the output in `choice`. You can use `choice` to control the color of a graph:

```
t = 0:.1:60;
s = sin(t);
color = ['r','b','g']
plot(t,s,color(choice))
```

Example 2

On a system without a display, `menu` displays choices in the Command Window:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following text.

```
----- Choose a color -----
1) Red
2) Blue
3) Green
Select a menu number:
```

More About

Tips

To call `menu` from a uicontrol or other ui object, set that object's Interruptible property to `'on'`. For more information, see Uicontrol Properties.

Introduced before R2006a

mergecats

Merge categories in categorical array

Syntax

```
B = mergecats(A,oldcats)
B = mergecats(A,oldcats,newcat)
```

Description

`B = mergecats(A,oldcats)` merges two or more categories in `A` into the first category, `oldcats(1)`. Any values in `A` from `oldcats` become `oldcats(1)` in `B`.

`B = mergecats(A,oldcats,newcat)` merges `oldcats` into a single new category, `newcat`. Any values in `A` from `oldcats` become `newcat` in `B`.

Examples

Merge Two Categories into One

Create a categorical array containing various colors.

```
A = categorical({'red';'blue';'pink';'red';'blue';'red'})
```

```
A =

     red
     blue
     pink
     red
     blue
     red
```

`A` is a 6-by-1 categorical array.

Display the categories of `A`.

```
categories(A)
```

```
ans =

    'blue'
    'pink'
    'red'
```

The three categories are in alphabetical order.

Merge the categories `red` and `pink` into the category `red`. Specify `red` first in `oldcats` to use it as the merged category.

```
oldcats = {'red','pink'};
B = mergecats(A,oldcats)
```

```
B =

     red
     blue
     red
     red
     blue
     red
```

`mergecats` replaces the value `pink` from `A(3)` with `red`.

Display the categories of `B`.

```
categories(B)
```

```
ans =

    'blue'
    'red'
```

`B` has two categories instead of three.

Merge Alphabetically Listed Categories

Create a categorical array containing various items.

```
A = categorical({'shirt' 'pants'; 'shoes' 'shirt'; 'dress' 'belt'})
```

```
A =

     shirt      pants
     shoes      shirt
```

```
     dress      belt
```

Display the categories of A.

```
categories(A)
```

```
ans =

    'belt'
    'dress'
    'pants'
    'shirt'
    'shoes'
```

The five categories are in alphabetical order.

Merge the categories `belt` and `shoes` into a new category called `other`.

```
B = mergecats(A,{'belt' 'shoes'},'other')
```

```
B =

     shirt      pants
     other      shirt
     dress      other
```

The value `other` replaces all instances of `belt` and `shoes`.

Display the categories of B.

```
categories(B)
```

```
ans =

    'other'
    'dress'
    'pants'
    'shirt'
```

B has four categories and the order is no longer alphabetical. `other` appears in place of `belt`.

Merge Categories of Ordinal Categorical Array

Create an ordinal categorical array.

```
A = categorical([1 2 3 2 1],1:3,{'poor','fair','good'},'Ordinal',true)
```

```
A =

     poor      fair      good      fair      poor
```

Display the categories of A.

```
categories(A)
```

```
ans =

    'poor'
    'fair'
    'good'
```

Since A is ordinal, the categories have the mathematical ordering `poor < fair < good`.

Consider all `fair` or `poor` values to be `bad`. Since A is ordinal, the categories to merge must be consecutive.

```
B = mergecats(A,{'fair' 'poor'},'bad')
```

```
B =

     bad       bad       good      bad       bad
```

The value `bad` replaces all instances of `fair` and `poor`.

Display the categories of B.

```
categories(B)
```

```
ans =

    'bad'
    'good'
```

B has two categories with the mathematical ordering: `bad < good`.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

`oldcats` — Categories to merge

cell array of strings

Categories to merge, specified as a cell array of strings. If `A` is ordinal, the categories to merge must be consecutive.

`newcat` — New category

`oldcats(1)` (default) | string

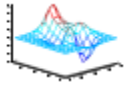
New category, specified as a string.

See Also

`addcats` | `categories` | `iscategory` | `removecats` | `renamecats` | `reordercats` | `setcats`

mesh

Mesh plot



Syntax

```
mesh(X,Y,Z)
mesh(Z)
mesh(...,C)
mesh(...,'PropertyName',PropertyValue,...)
mesh(axes_handles,...)
h = mesh(...)
```

Description

`mesh(X,Y,Z)` draws a wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, $(X(j), Y(i), Z(i,j))$ are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, $(X(i,j), Y(i,j), Z(i,j))$ are the intersections of the wireframe grid lines.

`mesh(Z)` draws a wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`mesh(...,C)` draws a wireframe mesh with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`mesh(...,'PropertyName',PropertyValue,...)` sets the value of the specified surface property. Multiple property values can be set with a single statement.

`mesh(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = mesh(...)` returns a handle to a Chart Surface Properties graphics object.

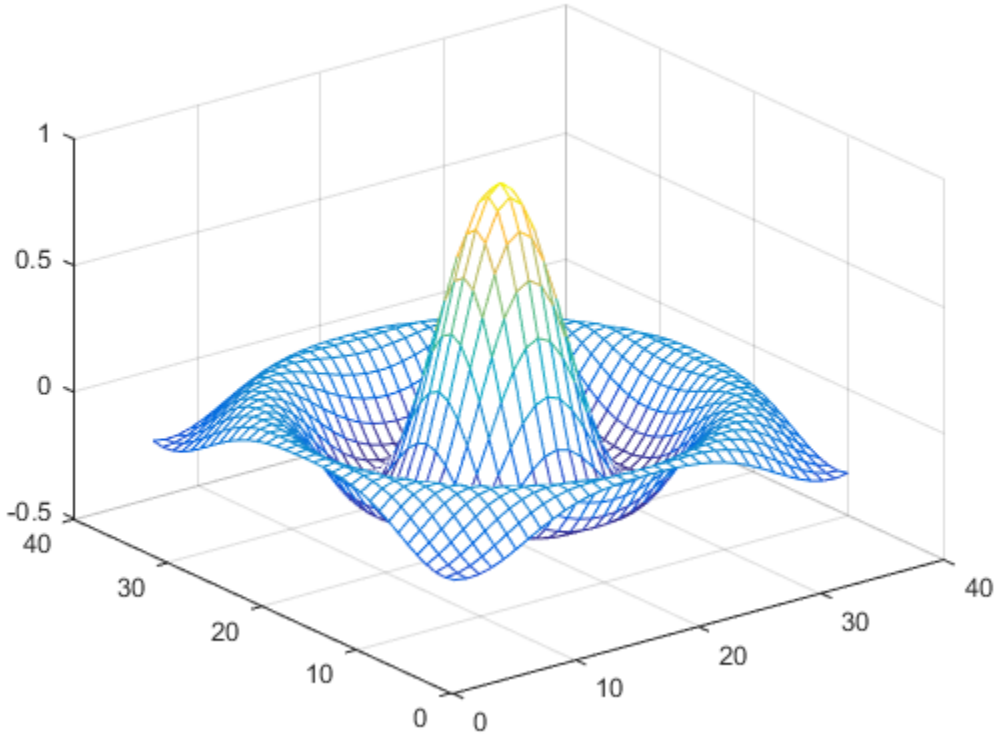
Examples

Create Mesh Plot of Sinc Function

Create a mesh plot of the sinc function, $z = \sin(r)/r$.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;

figure
mesh(Z)
```

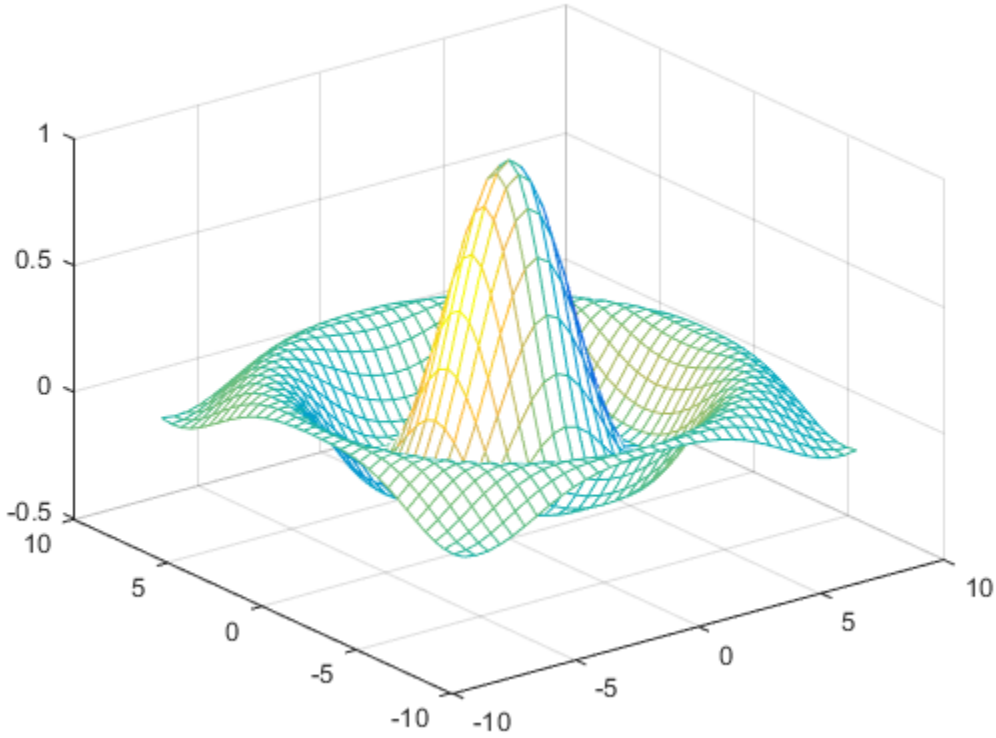


Specify Color for Mesh Plot

Specify a color matrix for a mesh plot.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
C = gradient(Z);

figure
mesh(X,Y,Z,C)
```

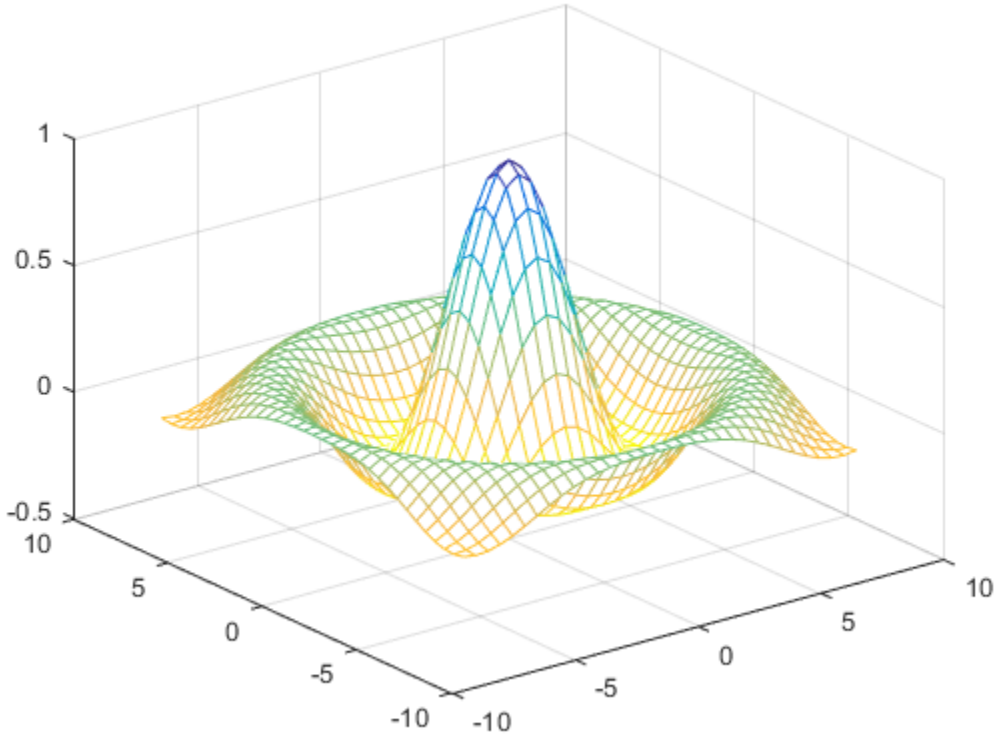


Change Lighting and Line Width for Mesh Plot

Change the lighting and the line width for a mesh plot using `Name,Value` pair arguments.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
C = del2(Z);

figure
mesh(X,Y,Z,C,'FaceLighting','gouraud','LineWidth',0.3)
```



More About

Tips

`mesh` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

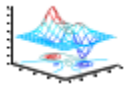
meshc

Plot a contour graph under mesh graph



Syntax

```
meshc(X,Y,Z)
meshc(Z)
meshc(...,C)
meshc(axes_handles,...)
h = meshc(...)
```

Description

`meshc(X,Y,Z)` draws a wireframe mesh and a contour plot under it with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(`X`(j)`, Y`(i)`, Z`(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(`X`(i,j)`, Y`(i,j)`, Z`(i,j))` are the intersections of the wireframe grid lines.

`meshc(Z)` draws a contour plot under wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshc(...,C)` draws a `meshc` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

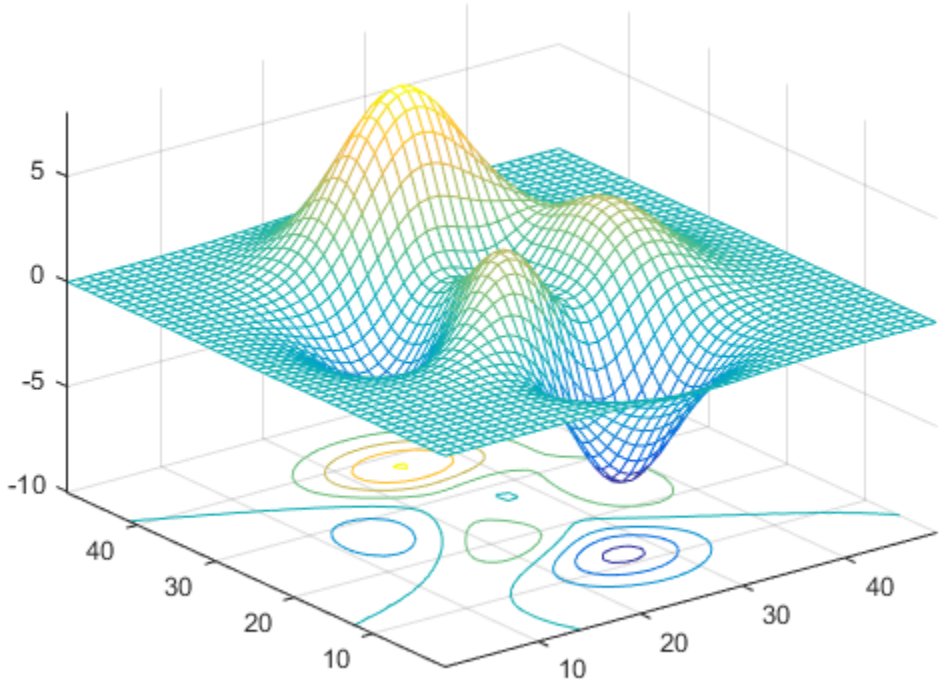
`h = meshc(...)` returns handles to the Chart Surface Properties and Contour Properties graphics object.

Examples

Display Contour Plot Under Mesh Plot

Use `meshc` to display a combination of a mesh plot and a contour plot of the `peaks` function.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshc(Z)
```



More About

Tips

`meshc` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

Algorithms

The range of `X`, `Y`, and `Z`, or the current settings of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties, determine the axis limits. `axis` sets these properties.

The range of `C`, or the current settings of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function), determine the color scaling. Use the scaled color values are used as indices into the current colormap.

The mesh rendering functions produce color values by mapping the *z* data values (or an explicit color array) onto the current colormap. The MATLAB default behavior is to compute the color limits automatically using the minimum and maximum data values (also set using `caxis auto`). The minimum data value maps to the first color value in the colormap and the maximum data value maps to the last color value in the colormap. MATLAB performs a linear transformation on the intermediate values to map them to the current colormap.

`meshc` calls `mesh`, turns `hold` on, and then calls `contour` and positions the contour on the *x*-*y* plane. For additional control over the appearance of the contours, issue these commands directly. You can combine other types of graphs in this manner, for example `surf` and `pcolor` plots.

`meshc` assumes that `X` and `Y` are monotonically increasing. If `X` or `Y` is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then it transforms the data to `X` or `Y`.

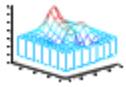
meshz

Plot a curtain around mesh plot



Syntax

```
meshz(X,Y,Z)
meshz(Z)
meshz(...,C)
meshz(axes_handles,...)
h = meshz(...)
```

Description

`meshz(X,Y,Z)` draws a curtain around the wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(`X`(j)`, Y`(i)`, Z`(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(`X`(i,j)`, Y`(i,j)`, Z`(i,j))` are the intersections of the wireframe grid lines.

`meshz(Z)` draws a curtain around the wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshz(...,C)` draws a `meshz` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshz(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

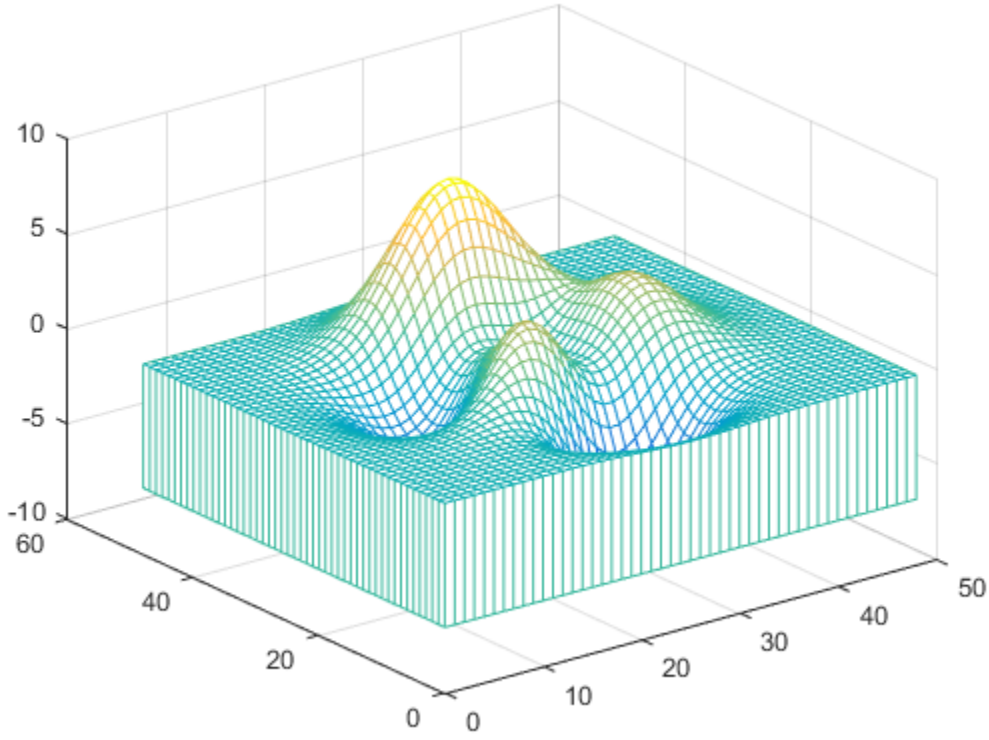
`h = meshz(...)` returns a handle to a Chart Surface Properties graphics object.

Examples

Curtain Plot of Peaks Function

Generate a curtain plot of the `peaks` function using `meshz`.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshz(Z)
```

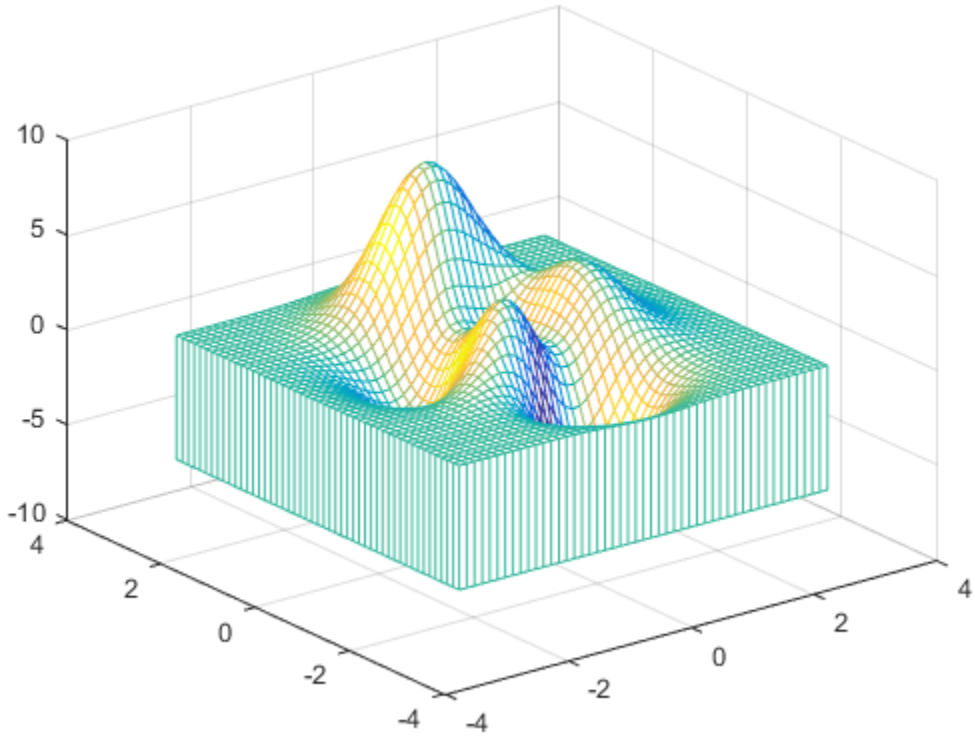


Specify Color for Curtain Plot

Specify a color matrix for a curtain plot.

```
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
C = gradient(Z);

figure
meshz(X,Y,Z,C)
```



More About

Tips

`meshz` does not accept complex inputs.

A mesh is drawn as a chart surface graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or `none` when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

Functions

`axis` | `caxis` | `colormap` | `contour` | `hidden` | `hold` | `mesh` | `meshc` | `meshgrid` | `shading` | `surf` | `surface` | `surfc` | `surfl` | `view` | `waterfall`

Properties

Chart Surface Properties

Introduced before R2006a

meshgrid

Rectangular grid in 2-D and 3-D space

Syntax

```
[X,Y] = meshgrid(xgv,ygv)
[X,Y,Z] = meshgrid(xgv,ygv,zgv)
[X,Y] = meshgrid(gv)
[X,Y,Z] = meshgrid(gv)
```

Description

`[X,Y] = meshgrid(xgv,ygv)` replicates the grid vectors `xgv` and `ygv` to produce a full grid. This grid is represented by the output coordinate arrays `X` and `Y`. The output coordinate arrays `X` and `Y` contain copies of the grid vectors `xgv` and `ygv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv` and `ygv` of length `M` and `N` respectively, `X` and `Y` will have `N` rows and `M` columns.

`[X,Y,Z] = meshgrid(xgv,ygv,zgv)` produces three-dimensional coordinate arrays. The output coordinate arrays `X`, `Y`, and `Z` contain copies of the grid vectors `xgv`, `ygv`, and `zgv` respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors `xgv`, `ygv`, and `zgv` of length `M`, `N`, and `P` respectively, `X`, `Y`, and `Z` will have `N` rows, `M` columns, and `P` pages.

`[X,Y] = meshgrid(gv)` is the same as `[X,Y] = meshgrid(gv,gv)`. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.

`[X,Y,Z] = meshgrid(gv)` is the same as `[X,Y,Z] = meshgrid(gv,gv,gv)`. Again, the dimensionality of the output arrays is determined by the number of output arguments.

The output coordinate arrays are typically used to evaluate functions of two or three variables. They are also frequently used to create surface and volumetric plots.

Input Arguments

`xgv,ygv,zgv`

Grid vectors specifying a series of grid point coordinates in the `x`, `y` and `z` directions, respectively.

`gv`

Generic grid vector specifying a series of point coordinates.

Output Arguments

`X,Y,Z`

Output arrays that specify the full grid.

Examples

2-D Grid From Vectors

Create a full grid from two monotonically increasing grid vectors:

```
[X,Y] = meshgrid(1:3,10:14)
X =
     1     2     3
     1     2     3
     1     2     3
     1     2     3
     1     2     3
Y =
    10    10    10
    11    11    11
    12    12    12
    13    13    13
    14    14    14
```

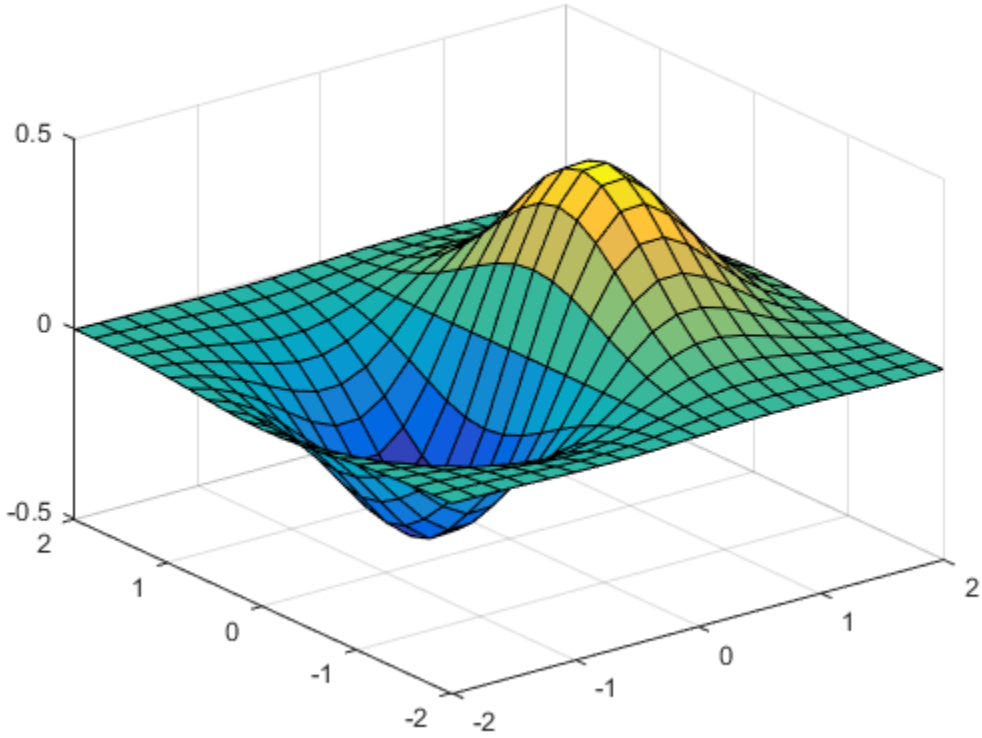
Plot 3-D Functional Surface

Use `meshgrid` to create a gridded *(X,Y)* domain.

```
[X,Y] = meshgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function $z(x,y) = xe^{-x^2-y^2}$ over this domain and generate a surface plot of the results.

```
Z = X .* exp(-X.^2 - Y.^2);
surf(X,Y,Z)
```



More About

Tips

The `meshgrid` function is similar to `ndgrid`, however `meshgrid` is restricted to 2-D and 3-D while `ndgrid` supports 1-D to N-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `meshgrid(x1gv, x2gv)` will output arrays of size `N`-by-`M` while `ndgrid(x1gv, x2gv)` outputs arrays of size `M`-by-`N`. Similarly, `meshgrid(x1gv, x2gv, x3gv)` will output arrays of size `N`-by-`M`-by-`P` while `ndgrid(x1gv, x2gv, x3gv)` outputs arrays of size `M`-by-`N`-by-`P`.

See “Grid Representation” in the MATLAB Mathematics documentation for more information.

meta.class

Describe MATLAB class

Description

Instances of the `meta.class` class contains information about MATLAB classes. The read/write properties of the `meta.class` class correspond to class attributes and are set only from within class definitions on the `classdef` line. You can query the read–only properties of the `meta.class` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class).

You cannot instantiate a `meta.class` object directly. You can construct a `meta.class` object from an instance of a class or using the class name:

- `metaclass` — returns a `meta.class` object representing the object passed as an argument.
- `?`*`ClassName`* — returns a `meta.class` object representing the named class.
- `fromName` — static method returns a `meta.class` object representing the named class.

For example, the `metaclass` function returns the `meta.class` object representing `MyClass`.

```
ob = MyClass;
obmeta = metaclass(ob);
obmeta.Name
```

```
ans =
MyClass
```

You can use the class name to obtain the `meta.class` object:

```
obmeta = ?MyClass;
```

You can also use the `fromName` static method:

```
obmeta = meta.class.fromName('MyClass');
```

Properties

Property	Purpose
`Abstract` attribute, default = `false`	If `true`, this class is an abstract class (cannot be instantiated). See “Abstract Classes” for more information.
`AllowedSubclasses` attribute, write only from `classdef` statement	List classes that can subclass this class. Specify subclasses as `meta.class` objects in the form: • A single `meta.class` object • A cell array of `meta.class` objects Specify `meta.class` objects using the `?ClassName` syntax only.
`ConstructOnLoad` attribute, default = `false`	If `true`, MATLAB calls the class constructor automatically when loading an object from a MAT-file. Therefore, the construction must be implemented so that calling it with no arguments does not produce an error. See “Save and Load Process”
`ContainingPackage` read only	A `meta.package` object describing the package within which this class is contained, or an empty object if this class is not in a package. See “Packages Create Namespaces”.
`Description` read only	Currently not used
`DetailedDescription` read only	Currently not used
`Enumeration` attribute, default = `false`	If `true`, this class is an enumeration class. See “Working with Enumerations”.
`EventList` read only	An array of `meta.event` objects describing each event defined by this class, including all inherited events. See “Events”.
`Events` read only	A cell array of `meta.event` objects describing each event defined by this class, including all inherited events.

Property	Purpose
Use `EventList` instead	
`EnumerationMemberList`	An array of `meta.EnumeratedValue` objects describing the member names defined by an enumeration class. See “Enumerations” for more information on enumeration classes.
`EnumeratedValues` read only Use `EnumeratedMemberList` instead	A cell array of `meta.EnumeratedValue` objects describing the member names defined by an enumeration class. See “Enumerations” for more information on enumeration classes.
`Hidden` attribute, default = `false`	If set to `true`, the class does not appear in the output of MATLAB commands or tools that display class names.
`InferiorClasses` attribute, default = `{}`	A cell array of `meta.class` objects defining the precedence of classes represented by the list as inferior to this class. See “Class Precedence”
`MethodList` read only	An array of `meta.method` objects describing each method defined by this class, including all inherited public and protected methods. See “How to Use Methods”.
`Methods` read only Use `MethodList` instead	A cell array of `meta.method` objects describing each method defined by this class, including all inherited public and protected methods.
`Name` read only	Name of the class associated with this `meta.class` object (`char` array)
`PropertyList` read only	An array of `meta.property` objects describing each property defined by this class, including all inherited public and protected properties. See “Properties”.

Property	Purpose
`Properties` read only Use `PropertyList` instead	A cell array of `meta.property` objects describing each property defined by this class, including all inherited public and protected properties. See “Properties”.
`Sealed` attribute, default = `false`	If `true`, the class cannot be subclassed.
`SuperClassList` read only	An array of `meta.class` objects describing each direct superclass from which this class is derived. See “Creating Subclasses — Syntax and Techniques”.
`SuperClasses` read only Use `SuperClassList` instead	A cell array of `meta.class` objects describing each direct superclass from which this class is derived.

Methods

Method	Purpose
`fromName`	Returns the `meta.class` object associated with the specified class name.
`tf = eq(Cls)`	Equality function (`a == b`). Use to test if two variables refer to equal classes (classes that contain exactly the same list of elements).
`tf = ne(Cls)`	Not equal function (`a ~= b`). Use to test if two variables refer to different meta–classes.
`tf = lt(ClsA,ClsB)`	Less than function (`ClsA < ClsB`). Use to determine if `ClsA` is a strict subclass of `ClsB` (i.e., a strict subclass means `ClsX < ClsX` is `false`).
`tf = le(ClsA,ClsB)`	Less than or equal to function (`ClsA <= ClsB`). Use to determine if `ClsA` is a subclass of `ClsB`.
`tf = gt(ClsA,ClsB)`	Greater than function (`ClsA > ClsB`). Use to determine if `ClsA` is a strict superclass of `ClsB` (i.e., a strict superclass means `ClsX > ClsX` is `false`).

Method	Purpose
`tf = ge(ClsA,ClsB)`	Greater than or equal to function (`ClsA >= ClsB`). Use to determine if `ClsA` is a superclass of `ClsB`.

Events

Event	Purpose
`InstanceCreated`	If the class is a handle class, this event occurs every time a new instance of this handle class is created, including new instances of any subclasses. The event occurs immediately after all constructor functions finish executing.
`InstanceDestroyed`	If the class is a handle class, this event occurs every time an instance of this handle class is destroyed, including all subclasses. The event occurs immediately before any destructor functions execute.

Examples

Find property attributes using the `handle` class `findobj` method and the `audioplayer` `meta.class` object. Determine if a class defines the property named `SampleRate` and does it have public set access.

```
mc = ?audioplayer;
mp = findobj(mc.PropertyList,'Name','SampleRate');
strcmp(mp.SetAccess,'public')
    ...
```

More About

- "Getting Information About Classes and Objects"

See Also

`fromName` | `meta.property` | `meta.method` | `meta.event` | `meta.package`

meta.class.fromName

Return `meta.class` object associated with named class

Syntax

```
mcls = meta.class.fromName('ClassName')
```

Description

`mcls = meta.class.fromName('ClassName')` is a static method that returns the `meta.class` object associated with the class *`ClassName`*. Note that you can also use the `?` operator to obtain the `meta.class` object for a class name:

```
mcls = ?ClassName;
```

The equivalent call to `meta.class.fromName` is:

```
mcls = meta.class.fromName('ClassName');
```

Use `meta.class.fromName` when using a `char` variable for the class name:

```
function mcls = getMetaClass(clname)
   % Do error checking
   mcls = meta.class.fromName(clname);
   ...
end
```

See Also

`meta.class`

meta.DynamicProperty

Describe dynamic property of MATLAB object

Description

The `meta.DynamicProperty` class contains descriptive information about dynamic properties that you have added to an instance of a MATLAB classes. The MATLAB class must be a subclass of `dynamicprops`. The properties of the `meta.DynamicProperty` class correspond to property attributes that you specify from within class definitions. Dynamic properties are not defined in `classdef` blocks, but you can set their attributes by setting the `meta.DynamicProperty` object properties.

You add a dynamic property to an object using the `addprop` method of the `dynamicprops` class. The `addprop` method returns a `meta.DynamicProperty` instance representing the new dynamic property. You can modify the properties of the `meta.DynamicProperty` object to set the attributes of the dynamic property or to add set and get access methods, which would be defined in the `classdef` for regular properties.

You cannot instantiate the `meta.DynamicProperty` class. You must use `addprop` to obtain a `meta.DynamicProperty` object.

To remove the dynamic property, call the `delete` handle class method on the `meta.DynamicProperty` object.

Obtain a `meta.DynamicProperty` object from the `addprops` method, which returns an array of `meta.DynamicProperty` objects, one for each dynamic property.

See “Dynamic Properties — Adding Properties to an Instance” for more information.

Properties

Property	Purpose
`Name`	Name of the property.
`Description`	Currently not used
`DetailedDescription`	Currently not used

Property	Purpose
`AbortSet`	If `true`, and this property belongs to a handle class, then MATLAB does not set the property value if the new value is the same as the current value. This approach prevents the triggering of property `PreSet` and `PostSet` events.
`Abstract` attribute, default = `false`	If `true`, the property has no implementation, but a concrete subclass must redefine this property without `Abstract` being set to `true`. • Abstract properties cannot define set or get access methods. See "Property Access Methods" • Abstract properties cannot define initial values. "Assigning a Default Value" • All subclasses must specify the same values as the superclass for the property `SetAccess` and `GetAccess` attributes. • `Abstract=true` should be used with the class attribute `Sealed=false` (the default).
`Access`	`public` – unrestricted access `protected` – access from class or subclasses `private` – access by class members only (not subclasses) List of classes that have get and set access to this property. Specify classes as `meta.class` objects in the form: • A single `meta.class` object • A cell array of `meta.class` objects. An empty cell array, `{}`, is the same as `private` access. Use `Access` to set both `SetAccess` and `GetAccess` to the same value. Query the values of `SetAccess` and `GetAccess` directly (not `Access`).

Property	Purpose
`Constant` attribute, default = `false`	Set to `true` if you want only one value for this property in all instances of the class. • Subclasses inherit constant properties, but cannot change them. • `Constant` properties cannot be `Dependent` • `SetAccess` is ignored. See “Properties with Constant Values”
`DefaultValue`	Querying this property returns an error because dynamic properties cannot define default values.
`DefiningClass`	The `meta.class` object representing the class that defines this property.
`GetAccess` attribute, default = `public`	`public` – unrestricted access `protected` – access from class or subclasses `private` – access by class members only
`SetAccess` attribute, default = `public`	`public` – unrestricted access `protected` – access from class or subclasses `private` – access by class members only
`Dependent` attribute, default = `false`	If `false`, property value is stored in object. If `true`, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name. See “Property Get Methods”
`Transient` attribute, default = `false`	If `true`, property value is not saved when object is saved to a file. See “Save and Load Process” for more about saving objects.
`Hidden` attribute, default = `false`	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to `properties`, etc.).

Property	Purpose
`GetObservable` attribute, default = `false`	If `true`, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See "Property-Set and Query Events"
`SetObservable` attribute, default = `false`	If `true`, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See "Property-Set and Query Events"
`GetMethod`	Function handle of the get method associated with this property. Empty if there is no get method specified. See "Get Method Syntax"
`SetMethod`	Function handle of the set method associated with this property. Empty if there is no set method specified. See "Property Set Methods"
`HasDefault`	Always `false`. Dynamic properties cannot define default values.

Events

See "Listen for Changes to Property Values" for information on using property events.

Event Name	Purpose
`PreGet`	Event occurs just before property is queried.
`PostGet`	Event occurs just after property has been queried
`PreSet`	Event occurs just before this property is modified
`PostSet`	Event occurs just after this property has been modified
`ObjectBeingDestroyed`	Inherited from `handle`

See Also

`addprop` | `handle`

meta.EnumeratedValue

Describe enumeration member of MATLAB class

Description

The `meta.EnumeratedValue` class contains information about enumeration members defined by MATLAB classes. The properties of a `meta.EnumeratedValue` object correspond the to attributes of the enumeration member being described.

All `meta.EnumeratedValue` properties are read-only. Query the `meta.EnumeratedValue` object to obtain information about the enumeration member it describes.

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object. `EnumerationMemberList` is an array of `Meta.EnumeratedValue` instances, one per enumeration member.

The `meta.EnumeratedValue` class is a subclass of the `handle` class.

Example

To access the `meta.EnumeratedValue` objects for a class, first create a `meta.class` object for that class. For example, give the following `OnOff` class definition:

```
classdef OnOff < logical
   enumeration
      On (true)
      Off (false)
   end
end
```

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object:

```
% Obtain the meta.class instance for the OnOff class
mc = ?OnOff;
% Get the array of EnumerateValue objects
enumList = mc.EnumerationMemberList;
% Access the Name property of the first object in the array
```

```
enumList(1).Name =
ans =
On
```

Properties

Property	Purpose
`Name` read only	Name of the enumeration member associated with this `meta.EnumeratedValue` object
`Description` read only	This property is not used
`DetailedDescription` read only	This property is not used

Methods

See the `handle` superclass for inherited methods.

Events

See the `handle` superclass for inherited events.

`meta.property` | `meta.event` | `meta.class` | `meta.method`

meta.event

Describe event of MATLAB class

Description

The `meta.event` class provides information about MATLAB class events. The read/write properties of the `meta.event` class correspond to event attributes and are specified only from within class definitions.

You can query the read-only properties of the `meta.event` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining the event).

You cannot instantiate a `meta.event` object directly. Obtain a `meta.event` object from the `meta.class` `EventList` property, which contains an array of `meta.event` objects, one for each event defined by the class. For example, replace *`ClassName`* with the name of the class whose events you want to query:

```
mco = ?ClassName;
elist = mco.EventList;
elist(1).Name; % name of first event in list
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

Properties

Property	Purpose
`Name` read only	Name of the event.
`Description` read only	Currently not used
`DetailedDescription` read only	Currently not used
`Hidden`	If `true`, the event does not appear in the list of events returned by the `events` function (or other event listing functions or viewers)
`ListenAccess`	Determines where you can create listeners for the event.

Property	Purpose

	• `public` — unrestricted access
	• `protected` — access from methods in class or subclasses
	• `private` — access by class methods only (not from subclasses)
	• List classes that have listen access to this event. Specify classes as `meta.class` objects in the form:
	  • A single `meta.class` object
	  • A cell array of `meta.class` objects. An empty cell array, `{}`, is the same as `private` access.
	See "Control Access to Class Members"

`NotifyAccess`	Determines where code can trigger the event.
	• `public` — any code can trigger event
	• `protected` — can trigger event from methods in class or subclasses
	• `private` — can trigger event by class methods only (not from subclasses)
	• List classes that have notify access to this event. Specify classes as `meta.class` objects in the form:
	  • A single `meta.class` object
	  • A cell array of `meta.class` objects. An empty cell array, `{}`, is the same as `private` access.
	See "Control Access to Class Members"

`DefiningClass`	The `meta.class` object representing the class that defines this event.

meta.property | meta.class | meta.method | metaclass

meta.MetaData class

Package: meta
Superclasses: matlab.mixin.Heterogeneous

Superclass for MATLAB object metadata

Description

The `meta.MetaData` class of objects represent MATLAB class definitions and the constituent parts of those definitions, such as properties and methods. Metadata enable a program to get information about a class definition.

The `meta.MetaData` class forms the root of the metadata class hierarchy, which enables the formation of arrays of metadata objects belonging to different specific classes.

MATLAB uses instances of the `meta.MetaData` class as the default object to fill in missing array elements.

`findobj` and `findprop`, can search the metadata hierarchy and return an array of different metadata objects. These function require the ability to form heterogeneous arrays containing various metaclass objects.

See the `matlab.mixin.Heterogeneous` class for more information on heterogeneous hierarchies.

Construction

You cannot create an instance of the `meta.MetaData` class directly. MATLAB constructs instances of this class as required.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

This example shows how the `meta.MetaData` class facilitates working with metaclasses.

Create a `meta.class` instance representing the MATLAB `timeseries` class:

```
>> mc = ?timeseries;
```

MATLAB uses `meta.MetaData` objects to fill empty array elements:

```
>> m(2) = mc
>> class(m(1))

ans =

meta.MetaData
>> class(m(2))

ans =

meta.class
```

Use `findobj` to find all properties and methods that have protected access:

```
>> protectedMembers = findobj(mc,{'Access','protected'},...
'-or',{'SetAccess','protected'},...
'-or',{'GetAccess','protected'});
```

The `timeseries` class defines both properties and methods that have protected access. Therefore, `findobj` returns a heterogeneous array of class `meta.MetaData`. This array contains both `meta.property` and `meta.method` objects.

```
>> protectedMembers

protectedMembers =

  11x1 heterogeneous meta.MetaData (meta.property, meta.method)
  handle with no properties.
  Package: meta
>> class(protectedMembers(1))

ans =

meta.property

>> protectedMembers(1).Name
```

```
ans =

Length
>> protectedMembers(1).SetAccess

ans =

protected
>> protectedMembers(1).GetAccess

ans =

public
```

`handle` | `matlab.mixin.Heterogeneous`

How To

- Class Attributes
- Property Attributes
- “Getting Information About Classes and Objects”

meta.method

Describe method of MATLAB class

Description

The `meta.method` class provides information about the methods of MATLAB classes. The read/write properties of the `meta.method` class correspond to method attributes and are specified only from within class definitions.

You can query the read-only properties of the `meta.method` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining a method).

You cannot instantiate a `meta.method` object directly. Obtain a `meta.method` object from the `meta.class` `MethodList` property, which contains an array of `meta.method` objects, one for each class method. For example, replace *`ClassName`* with the name of the class whose methods you want to query:

```
mco = ?ClassName;
mlist = mco.MethodList;
mlist(1).Name; % name of first method in the list
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

Properties

Property	Purpose
`Abstract`	If `true`, the method has no implementation. The method has a syntax line that can include arguments, which subclasses use when implementing the method. • Subclasses are not required to define the same number of input and output arguments. • The method can have comments after the `function` line

Property	Purpose
	• Does not contain `function` or `end` keywords, only the function syntax (e.g., `[a,b] = myMethod(x,y)`)
`Access` attribute, default = `public`	Determines what code can call this method. • `public` — unrestricted access • `protected` — access from methods in class or subclasses • `private` — access by class methods only (not from subclasses)
`DefiningClass`	The `meta.class` object representing the class that defines this method.
`Description` read only	Currently not used
`DetailedDescription` read only	Currently not used
`Hidden` attribute, default = `false`	When `false`, the method name shows in the list of methods displayed using the `methods` or `methodsview` commands. If set to `true`, the method name is not included in these listings.
`Name` read only	Name of the method.
`Sealed` attribute, default = `false`	If `true`, the method cannot be redefined in a subclass. Attempting to define a method with the same name in a subclass causes an error.

`Static` attribute, default = `false`	Set to `true` to define a method that does not depend on an object of the class and does not require an object argument. Call static methods using the class name in place of the object:
	`classname.methodname()`
	Or with an instance of the class, like any method:
	`o.methodname()`
	See “Static Methods”

`meta.property` | `meta.class` | `meta.event` | `metaclass`

meta.package

Describe MATLAB package

Description

The `meta.package` class contains information about MATLAB packages.

You cannot instantiate a `meta.package` object directly. Obtain a `meta.package` object from the `meta.class` `ContainingPackage` property, which contains a `meta.package` object, or an empty object, if the class is not in a package.

Properties

Property	Purpose
`Name` read only	Name of the package associated with this `meta.package` object
`ClassList` read only	List of classes that are scoped to this package. An object array of `meta.class` objects.
`Classes` read only Use `ClassList` instead	List of classes that are scoped to this package. A cell array of `meta.class` objects.
`FunctionList` read only	List of functions that are scoped to this package. An object array of function handles.
`Functions` read only Use `FunctionList` instead	List of functions that are scoped to this package. A cell array of function handles.
`PackageList` read only	List of packages that are scoped to this package. An object array of `meta.package` objects.
`Packages` read only Use `PackageList` instead	List of packages that are scoped to this package. A cell array of `meta.package` objects.

Property	Purpose
`ContainingPackage` read only	A `meta.package` object describing the package within which this package is contained, or an empty object if this package is not nested.

Methods

Method	Purpose
`fromName`	Static method returns a `meta.package` object for a specified package name.
`getAllPackages`	Static method returns a cell array of `meta.package` objects representing all top-level packages.

`meta.property` | `meta.event` | `meta.class` | `meta.method`

meta.abstractDetails

Package: meta

Find abstract methods and properties

Syntax

```
meta.abstractDetails(ClassName)
meta.abstractDetails(mc)
absMembers = meta.abstractDetails( ___ )
```

Description

`meta.abstractDetails(ClassName)` displays a list of abstract methods and properties for the class with name `ClassName`. Use the fully specified name for classes in packages. MATLAB displays all public and protected abstract methods and properties, including those declared `Hidden`.

`meta.abstractDetails(mc)` displays a list of abstract methods and properties for the class represented by the `meta.class` object `mc`.

`absMembers = meta.abstractDetails( ___ )` returns an array of the metaclass objects corresponding to the abstract members of the class, and can include any of the input arguments in previous syntaxes. If the class has both abstract methods and abstract properties, `absMembers` is a heterogeneous array of class `meta.MetaData` containing `meta.method` and `meta.property` objects.

A class can be abstract without defining any abstract methods or properties if it declares the `Abstract` class attribute. In this case, `meta.abstractDetails` returns no abstract members for that class, but the class is abstract. See “Determine If a Class Is Abstract” for more information.

Input Arguments

`ClassName`

Name of the class specified as a character string (for example, `'MyClass'`)

`mc`

`meta.class` object representing the class (for example, `?MyClass`)

Output Arguments

`absMembers`

Array of metaclass objects representing abstract class members

Examples

Display Abstract Member Names

Define the class, `AbsBase`, with an abstract property:

```
classdef AbsBase
   properties (Abstract)
      Prop1
   end
   methods(Abstract)
      result = methodOne(obj)
      output = methodTwo(obj)
   end
end
```

Pass the class name (`AbsBase`) as a string:

```
meta.abstractDetails('AbsBase')
```

`meta.abstractDetails` displays the names of the abstract properties and methods defined in the class `AbsBase`.

```
Abstract methods for class AbsBase:
    methodTwo   % defined in AbsBase
    methodOne   % defined in AbsBase

Abstract properties for class AbsBase:
```

```
    Prop1   % defined in AbsBase
```

Return Abstract Member Metaclass Objects

Pass a `meta.class` object representing the `AbsBase` class and return the metaclass objects for the abstract members. Use the definition of the `AbsBase` class from the previous example.

```
mc = ?AbsBase;
absMembers = meta.abstractDetails(mc);
```

`absMembers` is a heterogeneous array containing a `meta.property` object for the `Prop1` abstract property and `meta.method` objects for the `methodOne` and `methodTwo` abstract methods.

List the names of the metaclass objects.

```
for k=1:length(absMembers)
   disp(absMembers(k).Name)
end
```

```
methodTwo
methodOne
Prop1
```

Find Inherited Abstract Members

Derive the `SubAbsBase` class from `AbsBase`, which is defined in a previous example.

```
classdef SubAbsBase < AbsBase
   properties
      SubProp = 1;
   end
   methods
      function result = methodOne(obj)
         result = obj.SubProp + 1;
      end
   end
end
```

Display the names of the abstract members inherited by `SubAbsBase`.

```
meta.abstractDetails('SubAbsBase')
```

```
Abstract methods for class SubAbsBase:
```

```
    methodTwo   % defined in AbsBase

Abstract properties for class SubAbsBase:
    Prop1   % defined in AbsBase
```

To make `SubAbsBase` a concrete class, you need to implement concrete versions of `methodTwo` and `Prop1` in the subclass.

`meta.class` | `meta.class.fromName`

meta.package.fromName

Return `meta.package` object for specified package

Syntax

```
mpkg = meta.package.fromName('pkgname')
```

Description

`mpkg = meta.package.fromName('pkgname')` is a static method that returns the `meta.package` object associated with the named package. If `pkgname` is a nested package, then you must provide the fully qualified name (e.g., `'pkgname1.pkgname2'`).

Examples

List the classes in the `event` package:

```
mev = meta.package.fromName('event');
for k=1:length(mev.Classes)
   disp(mev.Classes{k}.Name)
end
event.EventData
event.PropertyEvent
event.listener
event.proplistener
```

See Also

`meta.package` | `meta.package.getAllPackages`

meta.package.getAllPackages

Get all top-level packages

Syntax

```
P = meta.package.getAllPackages
```

Description

`P = meta.package.getAllPackages` is a static method that returns a cell array of `meta.package` objects representing all the top-level packages that are visible on the MATLAB path or defined as top-level built-in packages. You can access subpackages using the `Packages` property of each `meta.package` object.

Note that the time required to find all the packages on the path might be excessively long in some cases. You should therefore avoid using this method in any code where execution time is a consideration. `getAllPackages` is generally intended for interactive use only.

See Also

`meta.package` | `meta.package.fromName`

meta.property

Describe property of MATLAB class

Description

The `meta.property` class provides information about the properties of MATLAB classes. The read/write properties of the `meta.property` class correspond to property attributes and are specified only from within your class definitions.

You can query the read-only properties of the `meta.property` object to obtain information that is specified syntactically by the class (for example, to obtain the function handle of a property's set access method).

You cannot instantiate a `meta.property` object directly. Obtain a `meta.property` object from the `meta.class` `PropertyList` property, which contains an array of `meta.property` objects, one for each class property. For example, replace *`ClassName`* with the name of the class whose properties you want to query:

```
mco = ?ClassName;
plist = mco.PropertyList;
plist(1).Name; % name of first property
```

Use the `metaclass` function to obtain a `meta.class` object from a class instance:

```
mco = metaclass(obj);
```

Properties

Property	Purpose
`Name` read only	Name of the property.
`Description` read only	Currently not used
`DetailedDescription` read only	Currently not used
`AbortSet` attribute, default = `false`	If `true`, and this property belongs to a handle class, then MATLAB does not set the property value if the new

Property	Purpose
	value is the same as the current value. This prevents the triggering of property `PreSet` and `PostSet` events. See “Listen for Changes to Property Values”
`Abstract` attribute, default = `false`	If `true`, the property has no implementation, but a concrete subclass must redefine this property without `Abstract` being set to `true`. • Abstract properties cannot define set or get access methods. See “Property Access Methods” • Abstract properties cannot define initial values. “Assigning a Default Value” • All subclasses must specify the same values as the superclass for the property `SetAccess` and `GetAccess` attributes. • `Abstract=true` should be used with the class attribute `Sealed=false` (the default).
`Access`	`public` – unrestricted access `protected` – access from class or subclasses `private` – access by class members only (not subclasses) List of classes that have get and set access to this property. Specify classes as `meta.class` objects in the form: • A single `meta.class` object • A cell array of `meta.class` objects. An empty cell array, `{}`, is the same as `private` access. Use `Access` to set both `SetAccess` and `GetAccess` to the same value. Query the values of `SetAccess` and `GetAccess` directly (not `Access`).

Property	Purpose
`Constant` attribute, default = `false`	Set to `true` if you want only one value for this property in all instances of the class. • Subclasses inherit constant properties, but cannot change them. • `Constant` properties cannot be `Dependent` • `SetAccess` is ignored. See “Properties with Constant Values”
`DefaultValue`	Property default value (if specified in class definition). See also `HasDefault` property. Abstract, dependent and dynamic properties cannot specify default values.
`DefiningClass`	The `meta.class` object representing the class that defines this property.
`GetAccess` attribute, default = `public`	`public` – unrestricted access `protected` – access from class or subclasses `private` – access by class members only List classes that have get access to this property. Specify classes as `meta.class` objects in the form: • A single `meta.class` object • A cell array of `meta.class` objects. An empty cell array, `{}`, is the same as `private` access. See “Control Access to Class Members”
`Dependent` attribute, default = `false`	If `false`, property value is stored in object. If `true`, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name. See “Property Get Methods”

Property	Purpose
`Transient` attribute, default = `false`	If `true`, property value is not saved when object is saved to a file. See "Save and Load Process" for more about saving objects.
`GetMethod` read only	Function handle of the get method associated with this property. Empty if there is no get method specified. See "Property Get Methods"
`GetObservable` attribute, default = `false`	If `true`, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See "Property-Set and Query Events"
`HasDefault`	Property contains a boolean value indicating if the property defines a default value. Test `HasDefault` before querying the `DefaultValue` property to avoid a `MATLAB:class:NoDefaultDefined` error.
`Hidden` attribute, default = `false`	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to `properties`, etc.).
`SetAccess` attribute, default = `public`	`public` – unrestricted access `protected` – access from class or subclasses `private` – access by class members only `immutable` — property can be set only in the constructor. See "Mutable and Immutable Properties" List classes that have set access to this property. Specify classes as `meta.class` objects in the form: • A single `meta.class` object • A cell array of `meta.class` objects. An empty cell array, `{}`, is the same as `private` access. See "Control Access to Class Members"

Property	Purpose
`SetMethod` read only	Function handle of the set method associated with this property. Empty if there is no set method specified. See "Property Set Methods"
`SetObservable` attribute, default = `false`	If `true`, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See "Property-Set and Query Events"

Events

See "Listen for Changes to Property Values" for information on using property events.

Event Name	Purpose
`PreGet`	Event occurs just before property is queried.
`PostGet`	Event occurs just after property has been queried
`PreSet`	Event occurs just before this property is modified
`PostSet`	Event occurs just after this property has been modified

More About

- "Properties"
- "Getting Information About Classes and Objects"

`meta.method` | `meta.class` | `meta.event` | `metaclass`

metaclass

Obtain `meta.class` object

Syntax

```
mc = metaclass(object)
mc = ?ClassName
```

Description

`mc = metaclass(object)` returns the `meta.class` object for the class of `object`. The `object` input argument can be a scalar or an array of objects. However, `metaclass` always returns a scalar `meta.class` object.

`mc = ?ClassName` returns the `meta.class` object for the class with name, *`ClassName`*. The `?` operator works only with a class name, not an object.

If you pass a class name as a string to the `metaclass` function, it returns the `meta.class` object for the `char` class. Use the `?` operator or the `meta.class.fromName` method to obtain the `meta.class` object from a class name. Use this method if you want to pass the class name in a string variable.

Examples

Return the `meta.class` object for an instance of the `MException` class:

```
obj = MException('Msg:ID','MsgTxt');
mc = metaclass(obj);
```

Use the `?` operator to get the `meta.class` object for the `matlab.mixin.SetGet` class:

```
mc = ?matlab.mixin.SetGet;
```

See Also

`meta.class` | `meta.class.fromName`

methods

Class method names

Syntax

```
methods('classname')
methods(...,'-full')
m = methods(...)
```

Description

`methods('classname')` displays the names of the methods for the class *`classname`*. If *`classname`* is a MATLAB or Java class, then `methods` displays only public methods, including those methods inherited from superclasses.

`methods(...,'-full')` displays a full description of the methods, including inheritance information and, for MATLAB and Java methods, method attributes and signatures. `methods` does not remove duplicate method names with different signatures. Do not use this option with classes defined before MATLAB 7.6.

`m = methods(...)` returns the method names in a cell array of strings.

`methods` is also a MATLAB class-definition keyword. See `classdef` for more information on class-definition keywords.

This function does not show generic methods from classes based on the Microsoft .NET Framework. Use your product documentation to get information on generic methods.

Examples

Retrieve the names of the static methods in class `MException`:

```
methods('MException')
```

```
Methods for class MException:
```

```
addCause     getReport      ne           throw
eq           isequal        rethrow      throwAsCaller

Static methods:

last
```

See Also

`methodsview` | `properties` | `events` | `what` | `which`

Introduced before R2006a

methodsview

View class methods

Syntax

```
methodsview packagename.classname
methodsview classname
methodsview(object)
```

Description

`methodsview packagename.classname` displays information about the methods in the class, `classname`. If the class is in a package, include `packagename`. If `classname` is a MATLAB or Java class, `methodsview` lists only public methods, including those methods inherited from superclasses.

`methodsview classname` displays information describing the class `classname`.

`methodsview(object)` displays information about the methods of the class of `object`.

`methodsview` creates a window that displays the methods defined in the specified class. `methodsview` provides additional information like arguments, returned values, and superclasses. It also includes method qualifiers (for example, `abstract` or `synchronized`) and possible exceptions thrown.

Examples

List information on all methods in the `java.awt.MenuItem` class:

```
methodsview java.awt.MenuItem
```

MATLAB displays this information in a new window.

See Also

`methods` | `import` | `class` | `javaArray`

Introduced before R2006a

mex

Build MEX-function from C/C++ or Fortran source code

Syntax

```
mex filenames
mex option1 ... optionN filenames

mex -setup lang
```

Description

`mex filenames` compiles and links one or more C, C++, or Fortran source files into a binary MEX-file, callable from MATLAB. filenames specify the source files. Also builds executable files for standalone MATLAB engine and MAT-file applications.

MATLAB automatically selects a compiler, if installed, based on the language of the filenames arguments.

`mex option1 ... optionN filenames` builds with the specified build options. The option1 ... optionN arguments supplement or override the default `mex` build configuration.

`mex -setup lang` selects a compiler for the given lang. Use this option when you want to change the default compiler for the given language.

Examples

Build C MEX-File

Build a single C program, `yprime.c`, into a MEX-file.

Each example is based on MEX examples in the *`matlabroot`*`/extern/examples` subfolders. To build the example code, copy the source file to a writable folder on your path, such as `c:\work`. Set the current folder to `c:\work`.

```
[s,msg,msgid] = mkdir('c:\work');
if (isempty(msgid))
    mkdir('c:\work')
end
cd c:\work
```

Copy the source code, `yprime.c`.

```
copyfile(fullfile(matlabroot,'extern','examples','mex','yprime.c'),'.','f');
```

Build the MEX-file.

```
mex yprime.c
```

```
Building with 'Microsoft Visual C++ 2010 (C)'.
MEX completed successfully.
```

The output displays information specific to your compiler.

Test.

```
T=1;
Y=1:4;
yprime(T,Y)
```

```
ans =
     2.0000    8.9685    4.0000    -1.0947
```

Display Detailed Build and Troubleshooting Information

To display the compile and link commands and other information useful for troubleshooting, use verbose mode.

```
mex -v -compatibleArrayDims yprime.c
```

The output displays information specific to your platform and compiler.

Override Default Compiler Switch Option

Build the `yprime.c` MEX-file by appending the value `-Wall` to the existing compiler flag. Because the value includes a space character, you must delineate the string; the character you use depends on the platform.

At the MATLAB prompt, use MATLAB single quotes (').

```
mex -v COMPFLAGS='$COMPFLAGS -Wall' yprime.c
```

At the Windows Command Prompt, use double quotes (").

```
mex -v COMPFLAGS="$COMPFLAGS -Wall" yprime.c
```

At the shell command line on Mac and Linux, use single quotes (').

```
mex -v CFLAGS='$CFLAGS -Wall' yprime.c
```

Build MEX-File from Multiple Source Files

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the source files to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
  'loadsparse.F'),'.','f');
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
  'fulltosparse.F'),'.','f');
```

Build the `fulltosparse` MEX-file.

```
mex -largeArrayDims fulltosparse.F loadsparse.F
```

The MEX-file name is `fulltosparse` because `fulltosparse.F` is the first file on the command line.

Test.

```
full = eye(5);
spar = fulltosparse(full)
```

```
spar =
   (1,1)        1
   (2,2)        1
   (3,3)        1
   (4,4)        1
   (5,5)        1
```

Preview Build Commands

To preview the build command details without executing the commands, use the `-n` option.

```
mex -n yprime.c
```

The output displays information specific to your platform and compiler.

Create and Link to Separate Object Files

You can link to object files that you compile separately from your source MEX-files.

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`. The `fulltosparse` file is the gateway routine (contains the `mexFunction` subroutine) and `loadsparse` contains the computational routine.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the computational subroutine to your current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
  'loadsparse.F'),'.','f');
```

Compile the subroutine and place the object file in a separate folder, `c:\objfiles`.

```
mkdir c:\objfiles
mex -largeArrayDims -c -outdir c:\objfiles loadsparse.F
```

Copy the gateway subroutine to your current folder. Compile and link with the `loadsparse` object file.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
  'fulltosparse.F'),'.','f');
mex -largeArrayDims fulltosparse.F c:\objfiles\loadsparse.obj
```

Specify Path to Include File

Use the `-I` option to specify the path to include the MATLAB LAPACK library subroutines for handling complex number routines. To use these subroutines, your MEX-file must access the header file, `fort.h`.

Copy the `matrixDivideComplex.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
  'matrixDivideComplex.c'),'.','f');
```

Create the `-I` argument by concatenating `'-I'` with the path to `fort.h` file.

```
ipath = ['-I' fullfile(matlabroot,'extern','examples','refbook')];
```

Create variables for the names and paths to the LAPACK library file and the file, `fort.c`, containing the complex number handling routines.

```
lapacklib = fullfile(matlabroot, ...
    'extern','lib',computer('arch'),'microsoft','libmwlapack.lib');
fortfile = fullfile(matlabroot,'extern','examples',...
    'refbook','fort.c');
```

Build the MEX-file.

```
mex('-v','-largeArrayDims',ipath, ...
    'matrixDivideComplex.c',fortfile,lapacklib)
```

Specify Path to Library File

Build the `matrixDivide.c` example on a Windows platform.

Use the `-L` and `-l` options to specify the `libmwlapack.lib` library, located in the folder, *`matlabroot`*`\extern\lib\`*`arch`*`\microsoft`.

Copy the `matrixDivide.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook','matrixDivide.c'),...
    '.','f');
```

Capture the value of *`matlabroot`*.

```
matlabroot
```

```
ans =

C:\Program Files\MATLAB\R2014a
```

Capture the value of *`arch`*.

```
arch
```

```
ans =

win64
```

To build the MEX-file, copy the values of *`matlabroot`* and *`arch`* into the `mex` command, as shown in the following statement.

```
mex -largeArrayDims '-LC:\Program Files\MATLAB\R2014a\extern\lib\win64\microsoft'...
   -llibmwlapack matrixDivide.c
```

You must use the ' characters because \Program Files in the path includes a space.

Define Directive

Define the character to use between strings in a matrix.

The MATLAB example, mxcreatecharmatrixfromstr.c, uses a #define symbol, SPACE_PADDING, to determine what character to use between strings in a matrix. To set the value, build the MEX-file with the -D option.

Copy the mxcreatecharmatrixfromstr.c example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','mx',...
  'mxcreatecharmatrixfromstr.c'),'.','f');
```

Set the SPACE_PADDING directive to add a space between strings.

```
mex mxcreatecharmatrixfromstr.c -DSPACE_PADDING
```

Build Engine Application

Copy the engwindemo.c engine example to the current folder.

```
copyfile(fullfile(matlabroot,...
  'extern','examples','eng_mat','engwindemo.c'),'.','f');
```

```
mex -client engine engwindemo.c
```

Run the example.

```
!engwindemo
```

Select C Compiler

```
mex -setup
```

MATLAB displays the options for your version and system based on the list of Supported and Compatible Compilers.

- "Table of MEX-File Source Code Files"

Input Arguments

`filenames` — One or more file names

string

One or more file names, including name and file extension, specified as a string. If the file is not in the current folder, specify the full path to the file. File names can be any combination of:

- C, C++, or Fortran language source files
- Simulink S-function files
- object files
- library files

The first source code file listed in filenames is the name of the binary MEX-file. To override this naming convention, use the `'-output'` option.

Data Types: `char`

`option1 ... optionN` — One or more build options

strings corresponding to valid option flags

One or more build options, specified as one of these values. Options can appear in any order on any platform, except where indicated.

Option	Description
`@rspfile`	Uses Windows RSP file. An RSP file is a text file containing command-line options.
`-c`	Compiles an object file only. Does not build a binary MEX-file.
`-client engine`	Build engine application.
`-compatibleArrayDims` (default) `-largeArrayDims`	Links with the specified MATLAB array-handling API. • `-compatibleArrayDims` — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to 2^{31}-1 elements. Default option. • `-largeArrayDims` — Uses the MATLAB large-array-handling API. This API handles arrays with more than 2^{31}-1 elements. Must use this option when calling LAPACK or BLAS functions. In verbose mode (`-v` option), if you do not specify either the `-compatibleArrayDims` or the `-largeArrayDims`

Option	Description
	option, MATLAB displays a message showing the default option.

`-Dsymbolname`
`-Dsymbolname=symbolvalu`
`-Usymbolname`
	The `-D` options define C preprocessor macros. Equivalent to the following in the source file:
	• `#define symbolname`
	• `#define symbolname symbolvalue`
	
	The `-U` option removes any initial definition of the C preprocessor macro, `symbolname`. Inverse of the `-D` option.
	
	Do not add a space between **D** or **U** and *`symbolname`*. Do not add spaces around the **=** sign.
	
	Example: "Define Directive" on page 1-5109

`-f filepath`	To build engine applications, use the `-client engine` option. Specifies name and location of the `mex` configuration file. Overrides the default compiler selection. For information about using a non-default compiler, see "Changing Default Compiler". *`filepath`* is the name and full path of the configuration file, specified as a string.
`-g`	Adds symbolic information and disables optimizing built object code. Use for debugging. To debug with optimization, add the `-O` option.
`-h[elp]`	Displays help for `mex`. Use from an operating system prompt.
`-Ipathname`	Adds *`pathname`* to the list of folders to search for `#include` files. Do not add a space between **I** and *`pathname`*. Example: "Specify Path to Include File" on page 1-5107

Option	Description
`-l`*`libname`* `-L`*`libfolder`* `-l`*`libname`*	Links with object library *`libname`* in (optional) *`libfolder`*. MATLAB expands *`libname`* to: • *`libname`*`.lib` or `lib`*`libname`*`.lib` — Windows systems • `lib`*`libname`*`.dylib` — Mac systems • `lib`*`libname`*`.so` — Linux systems If used, the `-L` option must precede the `-l` option. When using the `-L` option on Linux or Mac systems, you also must set the runtime library path, as explained in "Setting Run-Time Library Path". Do not add a space between **l** and *`libname`* or between **L** and *`libfolder`*. Specify the `-l` option with the lowercase letter **L**. Example: "Specify Path to Library File" on page 1-5108

`-largeArrayDims`
`-compatibleArrayDims`
(default)
	Links with the specified MATLAB array-handling API.
	
	• `-compatibleArrayDims` — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to 2^{31}-1 elements. Default option.
	• `-largeArrayDims` — Uses the MATLAB large-array-handling API. This API handles arrays with more than 2^{31}-1 elements. Must use this option when calling LAPACK or BLAS functions.
	
	In verbose mode (`-v` option), if you do not specify either the `-compatibleArrayDims` or the `-largeArrayDims` option, MATLAB displays a message showing the default option.

Option	Description
`-n`	Displays, but does not execute, commands that `mex` would execute. Example: "Preview Build Commands" on page 1-5106
`-O`	Optimizes the object code. Use this option to compile with optimization. Optimization is enabled by default. Optimization is disabled when the `-g` option appears without the `-O` option. Specify this option with the capital letter **O**.
`-outdir` *`dirname`*	Places all output files in folder *`dirname`*. Example: "Create and Link to Separate Object Files" on page 1-5107
`-output` *`mexname`*	Overrides the default MEX-file naming mechanism. Creates binary MEX-file named *`mexname`* with the appropriate MEX-file extension.
`-setup` *`lang`*	Change the default compiler to build *`lang`* language MEX-files. When you use this option, all other command-line options are ignored.
`-silent`	Suppresses informational messages. The `mex` function still reports errors and warnings, even when you specify `-silent`.
`-U`*`symbolname`*	Removes any initial definition of the C preprocessor macro *`symbolname`*. (Inverse of the `-D` option.) Do not add a space between **U** and *`symbolname`*.
`-v`	Builds in verbose mode. Displays values for internal variables after all command-line arguments are considered. Displays each compile and link step fully evaluated. Use for troubleshooting compiler setup problems. Example: "Display Detailed Build and Troubleshooting Information" on page 1-5105

Option	Description
varname=varvalue	Overrides default setting for variable *varname*. This option is processed after all command-line arguments are considered. Example: "Override Default Compiler Switch Option" on page 1-5105.

`lang` — Language
`C` (default) | `C++` | `CPP` | `Fortran`

Language, specified as one of these values.

`C`	C compilers, including C++.
`C++` or `CPP`	C++ compilers.
`Fortran`	Fortran compilers.

More About

Tips

- You can run `mex` from:
  - MATLAB Command Window
  - Windows system prompt
  - Mac Terminal
  - Linux shell

  For command-line usage outside of MATLAB, the `mex` program is located in the folder specified by `[matlabroot '/bin']`.
- The MEX-file has a platform-dependent extension. You can place binary MEX-files for different platforms in the same folder.

MEX-File Platform-Dependent Extension

Platform	Binary MEX-File Extension
Linux (64-bit)	`mexa64`

Platform	Binary MEX-File Extension
Apple Mac (64-bit)	`mexmaci64`
Microsoft Windows (32-bit)	`mexw32`
Windows (64-bit)	`mexw64`

To identify the MEX-file extension, use the `mexext` function.

- To use `mex` to build executable files for standalone MATLAB engine and MAT-file applications, use the `-client engine` option.

mex.getCompilerConfigurations

Get compiler configuration information for building MEX-files

Syntax

```
cc = mex.getCompilerConfigurations
cc = mex.getCompilerConfigurations(lang)
cc = mex.getCompilerConfigurations(lang,list)
```

Description

`cc = mex.getCompilerConfigurations` returns an object cc containing information about the default compiler configurations used by the `mex` command. There is one configuration for each supported language.

`cc = mex.getCompilerConfigurations(lang)` returns an array of objects for the given language, lang.

`cc = mex.getCompilerConfigurations(lang,list)` returns information about the set of configurations, list.

Examples

Display Information for C Compiler

```
myCCompiler = mex.getCompilerConfigurations('C','Selected')
```

```
myCCompiler =

  CompilerConfiguration with properties:

            Name: 'Microsoft Visual C++ 2010 (C)'
    Manufacturer: 'Microsoft'
        Language: 'C'
         Version: '10.0'
        Location: 'c:\Program Files (x86)\Microsoft Visual Studio 10.0'
       ShortName: 'MSVC100'
```

```
         Priority: 'A'
          Details: [1x1 mex.CompilerConfigurationDetails]
       LinkerName: 'link'
    LinkerVersion: ''
           MexOpt: 'C:\Users\auser\AppData\Roaming\MathWorks\MATLAB\R2014a\mex_C_win64
```

MATLAB displays information depending on your architecture and your version of MATLAB.

Display Number of Supported C Compilers

```
cLanguageCC = mex.getCompilerConfigurations('C','Supported');
length(cLanguageCC)
```

```
ans =
    10
```

The number of compilers for your version of MATLAB might be different.

Input Arguments

`lang` — Language

`'Any'` (default) | `'C'` | `'C++'` | `'CPP'` | `'Fortran'`

Language, specified as one of these values.

`'Any'`	All supported languages. This is the default value.
`'C'`	All C compiler configurations, including C++ configurations.
`'C++'` or `'CPP'`	All C++ compiler configurations.
`'Fortran'`	All Fortran compiler configurations.

`list` — Set of configurations

`'Selected'` (default) | `'Installed'` | `'Supported'`

Set of configurations, specified as one of these values.

`'Selected'`	The default compiler for each language.
`'Installed'`	All supported compilers `mex` finds installed on your system.

`'Supported'`	All compilers supported in the current release.

Output Arguments

`cc` — Compiler information

mex.CompilerConfiguration object or array of objects

Compiler information, specified as a `mex.CompilerConfiguration` object or array of `mex.CompilerConfiguration` objects. The `mex.CompilerConfiguration` class contains the following read-only properties.

Property	Purpose
`Name`	Compiler name.
`ShortName`	Character string used to identify options file for the compiler.
`Manufacturer`	Name of the manufacturer of the compiler.
`Language`	Compiler language.
`Version`	(Windows platforms only) Version of the compiler.
`Location`	(Windows platforms only) Folder where compiler is installed.
`Details`	More read-only properties about the compiler configuration. These properties might differ across compilers, platforms, and releases of MATLAB.
`LinkerName`	Linker name.
`LinkerVersion`	(Windows platforms only) Version of the linker.
`MexOpt`	Name and full path to options file.
`Priority`	The priority of this compiler.

`mex`

MException class

Capture error information

Description

Any MATLAB code that detects an error and throws an exception must construct an `MException` object. This class contains retrievable information about errors. MATLAB can throw either predefined exceptions or exceptions that you construct.

Construction

`ME = MException(msgID,msgtext)` captures information about a specific error and stores it in the `MException` object, ME. The `MException` object is constructed with a message identifier, `msgID`, and an error message string, `msgtext`.

`ME = MException(msgID,msgtext,A1,...,An)` allows formatting of the error message string using text or numeric values, `A1,...,An`, to replace conversion specifiers in msgtext at run time.

Input Arguments

`msgID` — Identifier for error

string

Identifier for the error, specified as a string. Use the message identifier with exception handling to better identify the source of the error or to control a selected subset of the exceptions in your program.

The message identifier includes a `component` and `mneumonic`. The identifier must always contain a colon and follows a simple format: `component:mnemonic`. The `component` and `mneumonic` fields must each begin with a letter. The remaining characters can be alphanumerics (A–Z, a–z, 0–9) and underscores. No white space characters can appear anywhere in msgID. For more information, see “Message Identifiers”.

Example: `'MyComponent:noSuchVariable'`

`msgtext` — Information about cause of error

string

Information about the cause of the error and how you might correct it, specified as a string. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1,...,An` input arguments. For more information, see "Formatting Strings".

Example: `'Error opening file.'`

Example: `'Error on line %d.'`

`A1,...,An` — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msgtext`.

Properties

`identifier` — Unique identifier of error

string

String that uniquely identifies the error, specified as a string by the `msgID` input argument. This property is read only. For more information, see "Message Identifiers".

`message` — Error message

string

String that contains the error message that is displayed when MATLAB throws the exception, specified by the `msgtext` and `A1,...,An` input arguments. This property is read only. For more information, see "Text of the Error Message".

`stack` — Stack trace information

array of structures

Structure array that contains stack trace information including the file name (`file`), function name (`name`), and line number (`line`) where MATLAB throws the exception. If the error occurs in a called function, the `stack` property also contains the file name,

function name, and line number for each of the called functions. MATLAB generates the stack only when it throws the exception.

`stack` is an N-by-1 `struct` array, where N represents the depth of the call stack. This property is read only. For more information, see "The Call Stack".

`cause` — Cause of the exception

cell array of `MException` objects

Cell array of `MException` objects that caused MATLAB to create this exception. Use the `addCause` method to add an exception to the `cause` field of the another exception. For more information, see "The Cause Array".

Methods

addCause	Record additional causes of exception
getReport	Get error message for exception
last	Return last uncaught exception
rethrow	Rethrow previously caught exception
throw	Throw exception
throwAsCaller	Throw exception as if occurs within calling function

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create MException Object

```
msgID = 'myComponent:inputError';
msgtext = 'Input does not have the expected format.';

ME = MException(msgID,msgtext)
```

```
ME =

  MException with properties:

    identifier: 'myComponent:inputError'
       message: 'Input does not have the expected format.'
         cause: {}
         stack: [0x1 struct]
```

Create MException with Formatted Error Message

```
msgID = 'MATLAB:test';
msgtext = 'There are %d errors on this page';
A1 = 10;

ME = MException(msgID,msgtext,A1)
```

```
ME =

  MException with properties:

    identifier: 'MATLAB:test'
       message: 'There are 10 errors on this page'
         cause: {}
         stack: [0x1 struct]
```

Create and Throw MException Object

Throw an exception if an input variable name does not exist in the workspace.

```
str = input('Type a variable name: ','s');
if ~exist(str,'var')
```

```
    ME = MException('MyComponent:noSuchVariable', ...
        'Variable %s not found',str);
    throw(ME)
end
```

At the input prompt, enter any variable that does not exist in your workspace. For example, enter `notaVariable`.

```
Variable notaVariable not found
```

Since `notVariable` doesn't exist in your workspace, MATLAB creates an `MException` object, and then throws it.

Use try/catch to Capture Exception

Catch the exception generated by calling a nonexistent function, `notaFunction`. If the function is not defined, issue a warning and assign the output a value of 0.

```
try
    a = notaFunction(5,6);
catch ME
    if strcmp(ME.identifier,'MATLAB:UndefinedFunction')
        warning('Function is undefined.  Assigning a value of 0.');
    else
        rethrow(ME)
    end
end
```

```
Warning: Function is undefined.  Assigning a value of 0.
```

By itself, the call to `notaFunction` results in an error. Using `try` and `catch`, this code catches the undefined function exception and repackages it as a warning, allowing MATLAB to continue executing subsequent commands. If the caught exception has a different error identifier, MATLAB rethrows the exception.

`MException.throw` | `MException.rethrow` | `MException.throwAsCaller` | `MException.addCause` | `MException.getReport` | `MException.last` | `assert` | `dbstack` | `error` | `try, catch`

addCause

Class: MException

Record additional causes of exception

Syntax

```
baseException = addCause(baseException,causeException)
```

Description

`baseException = addCause(baseException,causeException)` modifies the existing `MException` object baseException by appending causeException to its `cause` property. Catching the resulting exception in a `try/catch` statement makes the base exception, along with all of the appended cause records, available to help diagnose the error.

Input Arguments

`baseException` — Primary exception

`MException` object

Primary exception containing the primary cause and location of an error, specified as an `MException` object.

`causeException` — Related exception

`MException` object

Related exception containing the cause and location of an error related to `baseException`, specified as an `MException` object.

Examples

Add Causes to Exception

Create an array, and an index into it with a logical array.

```
A = [13 42; 7 20];
idx = [1 0 1; 0 1 0];
```

Create an exception that provides general information about an error. Test the index array and add exceptions with more detailed information about the source of the failure.

```
try
    A(idx);
catch
    msgID = 'MYFUN:BadIndex';
    msg = 'Unable to index into array.';
    baseException = MException(msgID,msg);

    try
        assert(islogical(idx),'MYFUN:notLogical',...
            'Indexing array is not logical.')
    catch causeException
        baseException = addCause(baseException,causeException);
    end

    if any(size(idx) > size(A))
        msgID = 'MYFUN:incorrectSize';
        msg = 'Indexing array is too large.';
        causeException2 = MException(msgID,msg);
        baseException = addCause(baseException,causeException2);
    end
    throw(baseException)
end
```

```
Unable to index into array.

Caused by:
    Indexing array is not logical.
    Indexing array is too large.
```

Examine the `baseException` object.

```
baseException
```

```
baseException =

  MException with properties:

    identifier: 'MYFUN:BadIndex'
       message: 'Unable to index into array.'
```

```
        cause: {2x1 cell}
        stack: [0x1 struct]
```

The value of the `cause` property is a `2x1` cell array.

Examine the first cause of the exception.

```
baseException.cause{1}
```

```
ans =

  MException with properties:

    identifier: 'MYFUN:notLogical'
       message: 'Indexing array is not logical.'
         cause: {0x1 cell}
         stack: [0x1 struct]
```

Examine the second cause of the exception.

```
baseException.cause{2}
```

```
ans =

  MException with properties:

    identifier: 'MYFUN:incorrectSize'
       message: 'Indexing array is too large.'
         cause: {}
         stack: [0x1 struct]
```

`MException` | `MException.throw` | `MException.rethrow` | `MException.throwAsCaller` | `MException.getReport` | `MException.last` | `assert` | `error` | `try, catch`

getReport

Class: MException

Get error message for exception

Syntax

```
msgString = getReport(exception)
msgString = getReport(exception,type)
msgString = getReport(exception,type,'hyperlinks',hlink)
```

Description

`msgString = getReport(exception)` gets the error message for an exception and returns it as a formatted string, `msgString`. The message string is the value of the `message` property of the `MException` object, `exception`. It is the same string that MATLAB displays when it throws the exception.

`msgString = getReport(exception,type)` returns the error message using the indicated level of detail, specified by `type`.

`msgString = getReport(exception,type,'hyperlinks',hlink)` uses the value of `hlink` to determine whether to include active hyperlinks to the failing lines of code within the error message.

Input Arguments

`exception` — Exception object that provides error message

`MException` object

Exception object that provides the error message, specified as a scalar `MException` object.

`type` — Detail indicator of message string

`'extended'` (default) | `'basic'`

Detail indicator of the message string returned, specified as `'extended'` or `'basic'`.

`type` Value	`msgString` Detail Level
`'extended'` (default)	`msgString` includes the line number, error message, cause, and stack summary. To display the proper stack, MATLAB first must throw an exception.
`'basic'`	`msgString` includes the error message.

`hlink` — Hyperlink indicator of message string

`'on'` (default) | `'off'` | `'default'`

Hyperlink indicator of the message string that includes active hyperlinks to the failing lines of code, specified as `'on'`, `'off'`, or `'default'`.

`hlink` Value	Action
`'on'`	Display hyperlinks to failing lines of code.
`'off'`	Do not display hyperlinks to failing lines of code.
`'default'`	Use the default for the Command Window to determine whether or not to use hyperlinks in the error message.

Examples

Get Error Message from Exception

Cause MATLAB to throw an exception.

```
plus
```

```
Error using +
Not enough input arguments.
```

Get the error message from the exception.

```
exception = MException.last;
msgString = getReport(exception)
```

```
msgString =

Error using +
```

```
Not enough input arguments.
```

Specify Detail Level in Error Message

In a file in your current working folder, create the following function in `testFunc.m`.

```
function a = testFunc
try
    a = notaFunction(5,6);
catch a

end
```

Since the function, `notaFunction`, does not exist, `testFunc` returns an `mException` object.

At the command prompt, call `testFunc` and get the error message.

```
m = testFunc;
msgString = getReport(m)
```

```
msgString =

Undefined function 'notaFunction' for input arguments of type 'double'.

Error in testFunc (line 3)
    a = notaFunction(5,6);
```

Specify that the error message only contains the error message and not the stack information.

```
msgString = getReport(m,'basic')
```

```
msgString =

Undefined function 'notaFunction' for input arguments of type 'double'.
```

Turn Off Hyperlinks in Error Message

Cause MATLAB to throw an exception.

```
try
    surf
catch exception
end
```

Get the error message from the exception.

```
msgString = getReport(exception)
```

```
msgString =

Error using surf (line 49)
Not enough input arguments.
```

Get the error message without active hyperlinks to `surf.m`.

```
msgString = getReport(exception,'extended','hyperlinks','off')
```

```
msgString =

Error using surf (line 49)
Not enough input arguments.
```

`MException.addCause` | `MException.rethrow` | `MException.last` | `MException.throw` | `MException.throwAsCaller` | `MException` | `assert` | `error` | `try, catch`

MException.last

Class: MException

Return last uncaught exception

Syntax

```
exception = MException.last
MException.last('reset')
```

Description

`exception = MException.last` returns the contents of the most recently thrown, uncaught `MException` object. `MException.last` is not set if the last exception is caught by a `try/catch` statement. `MException.last` is a static method of the `MException` class.

`MException.last('reset')` clears the properties of the exception returned from `MException.last`. It sets the `MException` `identifier` and `message` properties to an empty string, the `stack` property to a 0-by-1 structure, and the `cause` property to an empty cell array.

Tips

- Use `MException.last` only from the Command Window, not within a function.

Examples

Get Last Uncaught Exception

Cause MATLAB to throw, but not catch, an exception.

```
A = 25;
A(2)
```

```
Index exceeds matrix dimensions.
```

Get the uncaught exception.

```
exception = MException.last
```

```
exception =

  MException with properties:

    identifier: 'MATLAB:badsubscript'
       message: 'Index exceeds matrix dimensions.'
         cause: {}
         stack: [0x1 struct]
```

Reset Last Uncaught Exception

Call the `surf` function with no input arguments.

```
surf
```

```
Error using surf (line 49)
Not enough input arguments.
```

Get the uncaught exception.

```
exception = MException.last
```

```
exception =

  MException with properties:

    identifier: 'MATLAB:nargchk:notEnoughInputs'
       message: 'Not enough input arguments.'
         cause: {0x1 cell}
         stack: [1x1 struct]
```

Get the last, uncaught exception.

```
MException.last('reset')
exception = MException.last
```

```
exception =

  MException with properties:
```

```
    identifier: ''
       message: ''
         cause: {0x1 cell}
         stack: [0x1 struct]
```

See Also

MException.addCause | MException.getReport | MException.rethrow | MException.throw | MException.throwAsCaller | MException | assert | error | try, catch

rethrow

Class: MException

Rethrow previously caught exception

Syntax

```
rethrow(exception)
```

Description

`rethrow(exception)` rethrows a previously caught exception, `exception`. MATLAB typically responds to errors by terminating the currently running program. However, you can use a `try/catch` block to catch the exception. This interrupts the program termination so you can execute your own error handling procedures. End the `catch` block with a `rethrow` statement to terminate the program and redisplay the exception.

`rethrow` handles the stack trace differently from `error`, `assert`, and `throw`. Instead of creating the stack from where MATLAB executes the method, `rethrow` preserves the original exception information and enables you to retrace the source of the original error.

Input Arguments

`exception` — Exception containing cause and location of error

`MException` object

Exception containing the cause and location of an error, specified as a scalar `MException` object.

Examples

Catch and Rethrow Exception

Cause MATLAB to throw an error by calling `surf` with no inputs. Catch the exception, display the error identifier, and rethrow the exception.

```
try
    surf
catch ME
    disp(['ID: ' ME.identifier])
    rethrow(ME)
end
```

```
ID: MATLAB:nargchk:notEnoughInputs
Error using surf (line 49)
Not enough input arguments.
```

Compare Behavior of throw and rethrow

Create a function, `combineArrays`, in your working folder.

```
function C = combineArrays(A,B)
try
    C = catAlongDim1(A,B);       % Line 3
catch exception
    throw(exception)             % Line 5
end
end

function V = catAlongDim1(V1,V2)
V = cat(1,V1,V2);                % Line 10
end
```

Call the `combineArrays` function with arrays of different sizes.

```
A = 1:5;
B = 1:4;

combineArrays(A,B)
```

```
Error using combineArrays (line 5)
Dimensions of matrices being concatenated are not consistent.
```

The stack refers to line 5 where MATLAB throws the exception.

Replace `throw(exception)` with `rethrow(exception)` on line 5 of the `combineArrays` function, and call the function again.

```
combineArrays(A,B)
```

```
Error using cat
```

```
Dimensions of matrices being concatenated are not consistent.

Error in combineArrays>catAlongDim1 (line 10)
V = cat(1,V1,V2);               % Line 10

Error in combineArrays (line 3)
    C = catAlongDim1(A,B);      % Line 3
```

The `rethrow` method maintains the original stack and indicates the error is on line 3.

See Also

`MException.addCause` | `MException.getReport` | `MException.last` | `MException.throw` | `MException.throwAsCaller` | `MException` | `assert` | `error` | `try, catch`

throw

Class: MException

Throw exception

Syntax

```
throw(exception)
```

Description

`throw(exception)` throws an exception based on the information contained in the `MException` object, exception. The exception terminates the currently running function and returns control either to the keyboard or to an enclosing `catch` block. When you throw an exception from outside a `try/catch` statement, MATLAB displays the error message in the Command Window.

The `throw` method, unlike the `throwAsCaller` and `rethrow` methods, creates the stack trace from the location where MATLAB executes the method.

You can access the `MException` object via a `try/catch` statement or the `MException.last` method.

Input Arguments

`exception` — Exception containing cause and location of error

`MException` object

Exception containing the cause and location of an error, specified as a scalar `MException` object.

Examples

Create and Throw MException Object

Throw an exception if an input variable name does not exist in the workspace.

```
str = input('Type a variable name: ','s');
if ~exist(str,'var')
    ME = MException('MyComponent:noSuchVariable', ...
        'Variable %s not found',str);
    throw(ME)
end
```

At the input prompt, enter any variable that does not exist in your workspace. For example, enter `notaVariable`.

```
Variable notaVariable not found
```

Since `notVariable` doesn't exist in your workspace, MATLAB creates an `MException` object, and then throws it.

Compare Behavior of throw and rethrow

Create a function, `combineArrays`, in your working folder.

```
function C = combineArrays(A,B)
try
    C = catAlongDim1(A,B);       % Line 3
catch exception
    throw(exception)             % Line 5
end
end

function V = catAlongDim1(V1,V2)
V = cat(1,V1,V2);                % Line 10
end
```

Call the `combineArrays` function with arrays of different sizes.

```
A = 1:5;
B = 1:4;

combineArrays(A,B)
```

```
Error using combineArrays (line 5)
Dimensions of matrices being concatenated are not consistent.
```

The stack refers to line 5 where MATLAB throws the exception.

Replace `throw(exception)` with `rethrow(exception)` on line 5 of the `combineArrays` function, and call the function again.

```
combineArrays(A,B)

Error using cat
Dimensions of matrices being concatenated are not consistent.

Error in combineArrays>catAlongDim1 (line 10)
V = cat(1,V1,V2);               % Line 10

Error in combineArrays (line 3)
    C = catAlongDim1(A,B);      % Line 3
```

The `rethrow` method maintains the original stack and indicates the error is on line 3.

See Also

`MException` | `MException.rethrow` | `MException.throwAsCaller` | `MException.addCause` | `MException.getReport` | `MException.last` | | `error` | `try, catch`

throwAsCaller

Class: MException

Throw exception as if occurs within calling function

Syntax

```
throwAsCaller(exception)
```

Description

`throwAsCaller(exception)` throws an exception as if it occurs within the calling function. The exception terminates the currently running function and returns control to the keyboard or an enclosing `catch` block. When you throw an exception from outside a `try/catch` statement, MATLAB displays the error message in the Command Window.

You can access the `MException` object via a `try/catch` statement or the `MException.last` method.

In some cases, it is more informative for the error to point to the location in the calling function that results in the exception rather than pointing to the function that actually throws the exception. You can use `throwAsCaller` to simplify the error display.

Input Arguments

`exception` — Exception containing cause and location of error

`MException` object

Exception containing the cause and location of an error, specified as a scalar `MException` object.

Examples

Compare Behavior of throw and throwAsCaller

Create a function, `sayHello`, in your working folder.

```
function sayHello(N)
checkInput(N)
str = ['Hello, ' N '!'];
disp(str)

function checkInput(N)
if ~ischar(N)
    ME = MException('sayHello:inputError','Input must be char.');
    throw(ME)
end
```

At the command prompt, call the function with a numeric input.

```
sayHello(42)
```

```
Error using sayHello>checkInput (line 9)
Input must be char.

Error in sayHello (line 2)
checkInput(N)
```

The top of the stack refers to line 9 because this is where MATLAB throws the exception. After the initial stack frame, MATLAB displays information from the calling function.

Replace `throw(ME)` with `throwAsCaller(ME)` in line 9 of `sayHello.m` and call the function again.

```
sayHello(42)
```

```
Error using sayHello (line 2)
Input must be char.
```

The top of the stack refers to line 2 because that is the location of the error in the calling function.

mexext

Binary MEX-file-name extension

Syntax

```
ext = mexext
extlist = mexext('all')
```

Description

`ext = mexext` returns the file-name extension for the current platform.

`extlist = mexext('all')` returns the extensions for all platforms.

Examples

Display File Extension for Your Computer

Find the MEX-file extension for the system you are currently working on.

```
ext = mexext
```

```
ext =
   mexw32
```

Your results reflect your system.

Find File Extension for Specific Platform

Find the MEX-file extension for the Apple Macintosh systems.

Get the list for supported platforms.

```
extlist = mexext('all');
```

The `mex` function identifies a platform by its `arch` value, which is the output of the `computer('arch')` command. For Macintosh platforms, the value is `maci64`.

Search the `arch` field in the results, `extlist`, for `'maci64'`, and display the corresponding `ext` field.

```
for k=1:length(extlist)
   if strcmp(extlist(k).arch, 'maci64')
   disp(sprintf('Arch: %s      Ext: %s', ...
            extlist(k).arch, extlist(k).ext))
end, end
```

```
Arch: maci64       Ext: mexmaci64
```

The file extension is `mexmaci64`.

Output Arguments

`ext` — File-name extension

`mexa64 | mexmaci64 | mexw32 | mexw64`

File-name extension for MEX-file, returned as one of these values.

MEX-File Platform-Dependent Extension

Platform	Binary MEX-File Extension
Linux (64-bit)	`mexa64`
Apple Mac (64-bit)	`mexmaci64`
Microsoft Windows (32-bit)	`mexw32`
Windows (64-bit)	`mexw64`

`extlist` — All file-name extensions

structure

All file-name extensions, returned as a structure with these fields:

`arch` — Platform

string

Platform, specified as a string. The name of the platform is the output of the `computer('arch')` command.

`ext` — File extension

string

File extension, specified as a string.

More About

Tips

- To use the MEX-file-name extension in makefiles or scripts outside MATLAB, type one of the following from the system command prompt. The script is located in the *`matlabroot`*`\bin` folder.
  - `mexext.bat`—Windows platform.
  - `mexext.sh`—UNIX platform.

  For example, the following commands are in a GNU® makefile.

  ```
  ext = $(shell mexext)
  yprime.$(ext) : yprime.c
    mex yprime.c
  ```
- MATLAB continues to execute a MEX-file with a `.dll` extension, but future versions of MATLAB will not support this extension.

`computer` | `mex`

Introduced before R2006a

mfilename

File name of currently running function

Syntax

```
mfilename
p = mfilename('fullpath')
c = mfilename('class')
```

Description

`mfilename` returns a string containing the file name of the most recently invoked function. When called from within the file, it returns the name of that file. This allows a function to determine its name, even if the file name has been changed.

`p = mfilename('fullpath')` returns the full path and name of the file in which the call occurs, not including the filename extension.

`c = mfilename('class')` in a method, returns the class of the method, not including the leading `@` sign. If called from a nonmethod, it yields the empty string.

More About

Tips

If `mfilename` is called with any argument other than the above two, it behaves as if it were called with no argument.

When called from the command line, `mfilename` returns an empty string.

To get the names of the callers of a MATLAB function file, use `dbstack` with an output argument.

`dbstack` | `nargin` | `function` | `nargout` | `inputname`

Introduced before R2006a

mget

Class: FTP

Download files from FTP server

Syntax

```
mget(ftpobj,contents)
mget(ftpobj,contents,target)
```

Description

`mget(ftpobj,contents)` retrieves the file or folder specified by contents from an FTP server into the MATLAB current folder.

`mget(ftpobj,contents,target)` retrieves the file or folder into the local folder specified by target, which includes an absolute or relative path.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`contents`

String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (**`*`**).

`target`

String enclosed in single quotation marks that specifies the absolute or relative path of the local folder to contain the downloaded contents.

Examples

Connect to an FTP server and retrieve the file `README` into the current MATLAB folder:

```
mw = ftp('ftp.mathworks.com');
mget(mw, 'README');
close(mw);
```

See Also

`mput` | `cd` | `ftp`

Introduced before R2006a

milliseconds

Duration in milliseconds

Syntax

```
MS = milliseconds(X)
```

Description

`MS = milliseconds(X)` converts `duration` array `X` to a `double` array `MS`, where each element of `MS` is equivalent to the number of milliseconds in the corresponding element of `X`.

Examples

Convert Durations to Numeric Array of Milliseconds

Create a `duration` array.

```
X = minutes(2) + seconds(1:3)
```

```
X =
   2.0167 mins   2.0333 mins     2.05 mins
```

Convert each duration in `X` to a number of milliseconds.

```
MS = milliseconds(X)
```

```
MS =
      121000       122000       123000
```

`MS` is a `double` array.

Input Arguments

X — Input array

duration array

Input array, specified as a duration array.

See Also

`duration`

Introduced in R2015a

min

Smallest elements in array

Syntax

```
M = min(A)
M = min(A,[],dim)
[M,I] = min( ___ )

C = min(A,B)

___ = min( ___ ,nanflag)
```

Description

`M = min(A)` returns the smallest elements of `A`.

- If `A` is a vector, then `min(A)` returns the smallest element of `A`.
- If `A` is a matrix, then `min(A)` is a row vector containing the minimum value of each column.
- If `A` is a multidimensional array, then `min(A)` operates along the first array dimension whose size does not equal `1`, treating the elements as vectors. The size of this dimension becomes `1` while the sizes of all other dimensions remain the same. If `A` is an empty array with first dimension `0`, then `min(A)` returns an empty array of the same size as `A`.

`M = min(A,[],dim)` returns the smallest elements along dimension `dim`. For example, if `A` is a matrix, then `min(A,[],2)` is a column vector containing the minimum value of each row.

`[M,I] = min( ___ )` finds the indices of the minimum values of `A` and returns them in output vector `I`, using any of the input arguments in the previous syntaxes. If the minimum value occurs more than once, then `min` returns the index corresponding to the first occurrence.

`C = min(A,B)` returns an array the same size as `A` and `B` with the smallest elements taken from `A` or `B`.

Either the dimensions of A and B are the same, or one can be a scalar.

`___ = min( ___ ,nanflag)` specifies whether to include or omit `NaN` values in the calculation for any of the previous syntaxes. For the single input case, to specify `nanflag` without specifying `dim`, use `min(A,[],nanflag)`. For example, `min(A,[],'includenan')` includes all `NaN` values in `A` while `min(A,[],'omitnan')` ignores them.

Examples

Smallest Vector Element

Create a vector and compute its smallest element.

```
A = [23 42 37 15 52];
M = min(A)
```

```
M =

    15
```

Smallest Complex Element

Create a complex vector and compute its smallest element, that is, the element with the smallest magnitude.

```
A = [-2+2i 4+i -1-3i];
min(A)
```

```
ans =

  -2.0000 + 2.0000i
```

Smallest Element in Each Matrix Column

Create a matrix and compute the smallest element in each column.

```
A = [2 8 4; 7 3 9]
```

```
A =
```

```
     2     8     4
     7     3     9

M = min(A)

M =

     2     3     4
```

Smallest Element in Each Matrix Row

Create a matrix and compute the smallest element in each row.

```
A = [1.7 1.2 1.5; 1.3 1.6 1.99]

A =

    1.7000    1.2000    1.5000
    1.3000    1.6000    1.9900

M = min(A,[],2)

M =

    1.2000
    1.3000
```

Smallest Element Indices

Create a matrix A and compute the smallest elements in each column as well as the row indices of A in which they appear.

```
A = [1 9 -2; 8 4 -5]

A =

     1     9    -2
     8     4    -5
```

```
[M,I] = min(A)

M =

     1     4    -5

I =

     1     2     2
```

Smallest Element Comparison

Create a matrix and return the smallest value between each of its elements compared to a scalar.

```
A = [1 7 3; 6 2 9]

A =

     1     7     3
     6     2     9

B = 5;
C = min(A,B)

C =

     1     5     3
     5     2     5
```

Smallest Element in Matrix

Create a matrix `A` and use its column representation, `A(:)`, to find the value and index of the smallest element.

```
A = [8 2 4; 7 3 9]
```

```
A =

     8     2     4
     7     3     9
```

```
A(:)

ans =

     8
     7
     2
     3
     4
     9
```

```
[M,I] = min(A(:))

M =

     2

I =

     3
```

`I` is the index of `A(:)` containing the smallest element.

Now, use the `ind2sub` function to extract the row and column indices of `A` corresponding to the smallest element.

```
[I_row, I_col] = ind2sub(size(A),I)

I_row =

     1

I_col =
```

```
     2
```

If you need only the minimum value of `A` and not its index, call the `min` function twice.

```
M = min(min(A))
```

```
M =

     2
```

Smallest Element Involving `NaN`

Create a vector and compute its minimum, excluding `NaN` values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
M = min(A,[],'omitnan')
```

```
M =

   -2.9500
```

`min(A)` will also produce this result since `'omitnan'` is the default option.

Use the `'includenan'` flag to return `NaN`.

```
M = min(A,[],'includenan')
```

```
M =

   NaN
```

Input Arguments

`A` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

- If `A` is complex, then `min(A)` returns the complex number with the smallest magnitude. If magnitudes are equal, then `min(A)` returns the value with the smallest magnitude and the smallest phase angle.
- If `A` is a scalar, then `min(A)` returns `A`.
- If `A` is a 0-by-0 empty array, then `min(A)` is as well.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `categorical` | `datetime` | `duration`
Complex Number Support: Yes

`dim` — Dimension to operate along

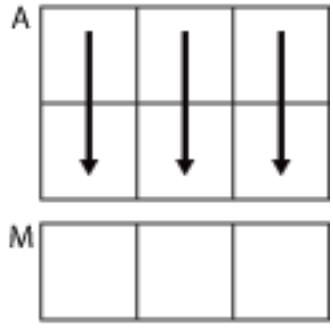
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(M,dim)` is `1`, while the sizes of all other dimensions remain the same, unless `size(A,dim)` is `0`. If `size(A,dim)` is `0`, then `min` returns an empty array with the same dimension sizes.

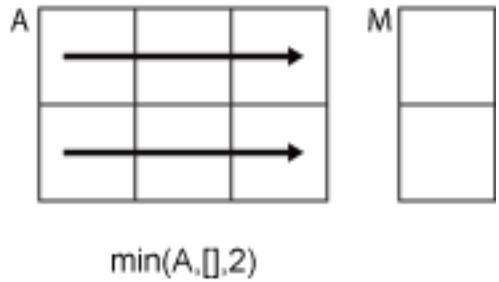
Consider a two-dimensional input array, `A`:

- If `dim = 1`, then `min(A,[],1)` returns a row vector containing the smallest element in each column.



min(A,[],1)

- If `dim = 2`, then `min(A,[],2)` returns a column vector containing the smallest element in each row.



`min` returns `A` if `dim` is greater than `ndims(A)`.

`B` — Additional input array

scalar | vector | matrix | multidimensional array

Additional input array, specified as a scalar, vector, matrix, or multidimensional array.

- The dimensions of `A` and `B` must match, or one can be a scalar.
- `A` and `B` can be the same data type or one can be `double` with the other `single`, `duration`, or any integer data type.
- If `A` and `B` are ordinal categorical arrays, they must have the same sets of categories with the same order.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `categorical` | `datetime` | `duration`
Complex Number Support: Yes

`nanflag` — `NaN` condition

'`omitnan`' (default) | '`includenan`'

`NaN` condition, specified as one of these values:

- '`omitnan`' — Ignore all `NaN` values in the input.
- '`includenan`' — Include the `NaN` values in the input for the calculation.

The `min` function does not support the `nanflag` option for `datetime`, `duration`, or `categorical` arrays.

Data Types: `char`

Output Arguments

`M` — Minimum values

scalar | vector | matrix | multidimensional array

Minimum values, returned as a scalar, vector, matrix, or multidimensional array. `size(M,dim)` is `1`, while the sizes of all other dimensions match the size of the corresponding dimension in `A`, unless `size(A,dim)` is `0`. If `size(A,dim)` is `0`, then `M` is an empty array with the same dimensions as `A`.

`I` — Index to minimum values of `A`

scalar | vector | matrix | multidimensional array

Index to minimum values of `A`, returned as a scalar, vector, matrix, or multidimensional array. `I` is the same size as `M`. If the smallest element occurs more than once, then `I` contains the index to the first occurrence of the value.

`C` — Minimum elements from `A` or `B`

scalar | vector | matrix | multidimensional array

Minimum elements from `A` or `B`, returned as a scalar, vector, matrix, or multidimensional array.

The size of `C` depends on the sizes of `A` and `B`:

- If `A` and `B` are arrays of the same size, then the size of `C` matches the size of `A` and `B`.
- If either `A` or `B` is a scalar, then the size of `C` matches the size of the nonscalar input array.
- If either `A` or `B` is an empty array with the other a scalar, then `C` is an empty array.

The data type of `C` depends on the data types of `A` and `B`:

- If `A` and `B` are the same data type, then `C` matches the data type of `A` and `B`.
- If either `A` or `B` is `single`, then `C` is `single`.
- If either `A` or `B` is an integer data type with the other a scalar `double`, then `C` assumes the integer data type.

MinimizeCommandWindow

Minimize size of Automation server window

Syntax

IDL Method Signature

```
HRESULT MinimizeCommandWindow(void)
```

Microsoft Visual Basic Client

```
MinimizeCommandWindow
```

MATLAB Client

```
MinimizeCommandWindow(h)
```

Description

`MinimizeCommandWindow(h)` minimizes the window for the server attached to handle `h`, and makes it inactive.

If the server window was already in a minimized state, `MinimizeCommandWindow` does nothing.

Examples

From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server.

```
Dim Matlab As Object

Matlab = CreateObject("matlab.application")
Matlab.MinimizeCommandWindow
```

```
'Now return the server window to its former state on
'the desktop and make it the currently active window.

Matlab.MaximizeCommandWindow
```

See Also

MaximizeCommandWindow

Introduced before R2006a

minres

Minimum residual method

Syntax

```
x = minres(A,b)
minres(A,b,tol)
minres(A,b,tol,maxit)
minres(A,b,tol,maxit,M)
minres(A,b,tol,maxit,M1,M2)
minres(A,b,tol,maxit,M1,M2,x0)
[x,flag] = minres(A,b,...)
[x,flag,relres] = minres(A,b,...)
[x,flag,relres,iter] = minres(A,b,...)
[x,flag,relres,iter,resvec] = minres(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)
```

Description

`x = minres(A,b)` attempts to find a minimum norm residual solution `x` to the system of linear equations `A*x=b`. The `n`-by-`n` coefficient matrix `A` must be symmetric but need not be positive definite. It should be large and sparse. The column vector `b` must have length `n`. You can specify `A` as a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `minres` converges, a message to that effect is displayed. If `minres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`minres(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `minres` uses the default, `1e-6`.

`minres(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `minres` uses the default, `min(n,20)`.

`minres(A,b,tol,maxit,M)` and `minres(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(sqrt(M))*A*inv(sqrt(M))*y = inv(sqrt(M))*b` for `y` and then return `x = inv(sqrt(M))*y`. If `M` is `[]` then `minres` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x)` returns `M\x`.

`minres(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `minres` uses the default, an all-zero vector.

`[x,flag] = minres(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`minres` converged to the desired tolerance `tol` within `maxit` iterations.
1	`minres` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`minres` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `minres` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = minres(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = minres(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = minres(A,b,...)` also returns a vector of estimates of the `minres` residual norms at each iteration, including `norm(b-A*x0)`.

`[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)` also returns a vector of estimates of the Conjugate Gradients residual norms at each iteration.

Examples

Using minres with a Matrix Input

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M1 = spdiags(4*on,0,n,n);

x = minres(A,b,tol,maxit,M1);
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

Using minres with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_minres` that

- Calls `minres` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_minres` are available to `afun`.

The following shows the code for `run_minres`:

```
function x1 = run_minres
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M = spdiags(4*on,0,n,n);
x1 = minres(@afun,b,tol,maxit,M);

       function y = afun(x)
          y = 4 * x;
          y(2:n) = y(2:n) - 2 * x(1:n-1);
          y(1:n-1) = y(1:n-1) - 2 * x(2:n);
       end
end
```

When you enter

```
x1=run_minres;
```

MATLAB software displays the message

```
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

Using minres instead of pcg

Use a symmetric indefinite matrix that fails with `pcg`.

```
A = diag([20:-1:1, -1:-1:-20]);
b = sum(A,2);      % The true solution is the vector of all ones.
x = pcg(A,b);      % Errors out at the first iteration.
```

displays the following message:

```
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, `minres` can handle the indefinite matrix `A`.

```
x = minres(A,b,1e-6,40);
minres converged at iteration 39 to a solution with relative
residual 1.3e-007
```

Introduced before R2006a

minus, -

Subtraction

Syntax

```
C = A - B
C = minus(A,B)
```

Description

`C = A - B` subtracts array `B` from array `A` and returns the result in `C`.

`C = minus(A,B)` is an alternate way to execute `A - B`, but is rarely used. It enables operator overloading for classes.

Examples

Subtract Scalar from Array

Create an array, `A`, and subtract a scalar value from it.

```
A = [2 1; 3 5];
C = A - 2
```

```
C =

     0    -1
     1     3
```

The scalar is subtracted from each entry of `A`.

Subtract Two Arrays

Create two arrays, `A` and `B`, and subtract the second, `B`, from the first, `A`.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
```

```
C = A - B

C =

    -4    -9
     0     3
```

The elements of `B` are subtracted from the corresponding elements of `A`.

Use the syntax `-C` to negate the elements of `C`.

```
-C

ans =

     4     9
     0    -3
```

Input Arguments

A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `A` can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs `A` and `B` must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

If one input is a datetime array, then the other input also can be a date string or a cell array containing date strings.

Complex Number Support: Yes

B — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `B` can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs `A` and `B` must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.

If one input is a datetime array, then the other input also can be a date string or a cell array containing date strings.
Complex Number Support: Yes

`diff` | `plus` | `uminus`

minute

Minute number

Syntax

```
m = minute(t)
```

Description

`m = minute(t)` returns the minute numbers of the datetime values in `t`. The `m` output is a `double` array the same size as `t` and contains integer values from 0 to 59.

The `minute` function returns the minute numbers of datetime values. To assign minute values to a datetime array, `t`, use `t.Minute` and modify the `Minute` property.

Examples

Find Minute Number of Datetime Values

```
t1 = datetime('now');
t = t1 + minutes(2:4)
```

```
t =

   23-Feb-2015 10:05:11   23-Feb-2015 10:06:11   23-Feb-2015 10:07:11
```

```
m = minute(t)
```

```
m =

     5     6     7
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

See Also

datetime Properties | `hms` | `hour` | `second` | `timeofday`

Introduced in R2014b

minutes

Duration in minutes

Syntax

```
M = minutes(X)
```

Description

`M = minutes(X)` returns an array of minutes equivalent to the values in `X`.

- If `X` is a numeric array, then `M` is a `duration` array in units of minutes.
- If `X` is a `duration` array, then `M` is a `double` array with each element equal to the number of minutes in the corresponding element of X.

The `minutes` function converts between `duration` and `double` values. To display a duration in units of minutes, set its `Format` property to `'m'`.

Examples

Create Duration Array of Minutes

```
X = magic(4);
M = minutes(X)
```

```
M =

   16 mins    2 mins    3 mins   13 mins
    5 mins   11 mins   10 mins    8 mins
    9 mins    7 mins    6 mins   12 mins
    4 mins   14 mins   15 mins     1 min
```

Convert Durations to Numeric Array of Minutes

Create a `duration` array.

```
X = hours(2:10:38) + minutes(30)

X =

    2.5 hrs   12.5 hrs   22.5 hrs   32.5 hrs
```

Convert each duration in `X` to a number of minutes.

```
M = minutes(X)

M =

         150         750        1350        1950
```

View the data type of `M`.

```
whos M
  Name      Size             Bytes  Class     Attributes

  M         1x4                 32  double
```

Input Arguments

X — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

See Also

`duration`

Introduced in R2014b

mislocked

Determine if function is locked in memory

Syntax

```
mislocked
mislocked(fun)
```

Description

`mislocked` by itself returns logical `1` (`true`) if the currently running function is locked in memory, and logical `0` (`false`) otherwise. Functions that are locked cannot be removed with the `clear` function unless you first unlock them using the `munlock` function. You can use locking on functions that reside in MATLAB `.m` files or `.mex` files.

`mislocked(fun)` returns logical `1` (`true`) if the function named *`fun`* is locked in memory, and logical `0` (`false`) otherwise.

See Also

`mlock` | `munlock` | `inmem`

Introduced before R2006a

mkdir

Make new folder

Syntax

```
mkdir('folderName')
mkdir('parentFolder','folderName')
status = mkdir( ___ )
[status,message,messageid] = mkdir( ___ )
```

Description

`mkdir('folderName')` creates the folder `folderName`, where `folderName` can be an absolute or a relative path.

`mkdir('parentFolder','folderName')` creates the folder `folderName` in `parentFolder`, where `parentFolder` is an absolute or relative path. If `parentFolder` does not exist, MATLAB attempts to create it. See the Tips section.

`status = mkdir( ___ )` creates the specified folder. When the operation is successful, it returns a `status` of logical 1. When the operation is unsuccessful, it returns logical 0.

`[status,message,messageid] = mkdir( ___ )` creates the specified folder, and returns the status, message string, and MATLAB message ID. The value given to `status` is logical `1` for success, and logical `0` for error.

Examples

Creating a Subfolder in the Current Folder

Create a subfolder called `newdir` in the current folder:

```
mkdir('newdir')
```

Creating a Subfolder in the Specified Parent Folder

Create a subfolder called `newFolder` in the folder `testdata`, using a relative path, where `newFolder` is at the same level as the current folder:

```
mkdir('../testdata','newFolder')
```

Returning Status When Creating a Folder

In this example, the first attempt to create `newFolder` succeeds, returning a status of `1`, and no error or warning message or message identifier:

```
[s, mess, messid] = mkdir('../testdata', 'newFolder')
s =
   1
mess =
   ''
messid =
   ''
```

Attempt to create the same folder again. `mkdir` again returns a success status, and also a warning and message identifier informing you that the folder exists:

```
[s,mess,messid] = mkdir('../testdata','newFolder')
s =
   1
mess =
   Directory "newFolder" already exists.
messid =
   MATLAB:MKDIR:DirectoryExists
```

More About

Tips

If an argument specifies a path that includes one or more nonexistent folders, MATLAB attempts to create the nonexistent folder. For example, for

```
mkdir('myFolder\folder1\folder2\targetFolder')
```

if `folder1` does not exist, MATLAB creates `folder1`, creates `folder2` within `folder1`, and creates `targetFolder` within `folder2`.

- “Manage Files and Folders”

`copyfile` | `rmdir` | `cd` | `dir` | `ls` | `movefile`

Introduced before R2006a

mkdir

Class: FTP

Create folder on FTP server

Syntax

```
mkdir(ftpobj,folder)
```

Description

`mkdir(ftpobj,folder)` creates the specified folder on the FTP server associated with ftpobj.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`folder`

String enclosed in single quotation marks that specifies a path relative to the current folder on the FTP server.

Examples

Suppose that a hypothetical host, `ftp.testsite.com`, contains a folder named `testfolder`. Connect to the server and add a subfolder:

```
test=ftp('ftp.testsite.com');
mkdir(test,'testfolder/newfolder');
close(test);
```

See Also

`rmdir | dir | ftp`

Introduced before R2006a

mkpp

Make piecewise polynomial

Syntax

```
pp = mkpp(breaks,coefs)
pp = mkpp(breaks,coefs,d)
```

Description

`pp = mkpp(breaks,coefs)` builds a piecewise polynomial, `pp`, from its breaks and coefficients.

- `breaks` is a vector of length `L+1` with strictly increasing elements which represent the start and end of each of `L` intervals.
- `coefs` is an `L`-by-`k` matrix with each row `coefs(i,:)` containing the local coefficients of an order `k` polynomial on the *i*th interval, `[breaks(i),breaks(i+1)]`. That is, the polynomial `coefs(i,1)*(X-breaks(i))^(k-1) + coefs(i,2)*(X-breaks(i))^(k-2) + ... + coefs(i,k-1)*(X-breaks(i)) + coefs(i,k)`. Notice that `mkpp` shifts the polynomial in each interval down by `(X-breaks(i))`.

`pp = mkpp(breaks,coefs,d)` indicates that the piecewise polynomial `pp` is `d`-vector valued, i.e., the value of each of its coefficients is a vector of length `d`. `breaks` is an increasing vector of length `L+1`. `coefs` is a `d`-by-`L`-by-`k` array with `coefs(r,i,:)` containing the `k` coefficients of the `i`th polynomial piece of the `r`th component of the piecewise polynomial.

Use `ppval` to evaluate the piecewise polynomial at specific points. Use `unmkpp` to extract details of the piecewise polynomial.

Note: The *order* of a polynomial tells you the number of coefficients used in its description. A *k*th order polynomial has the form

$$c_1 x^{k-1} + c_2 x^{k-2} + \ldots + c_{k-1} x + c_k$$

It has k coefficients, some of which can be 0, and maximum exponent $k-1$. So the order of a polynomial is usually one greater than its degree. For example, a cubic polynomial is of order 4.

Examples

Construct and Plot Piecewise Polynomial

The first plot shows the quadratic polynomial

$$1-\left(\frac{x}{2}-1\right)^2=\frac{-x^2}{4}+x$$

shifted to the interval [-8,-4]. The second plot shows its negative

$$\left(\frac{x}{2}-1\right)^2-1=\frac{x^2}{4}-x$$

but shifted to the interval [-4,0].

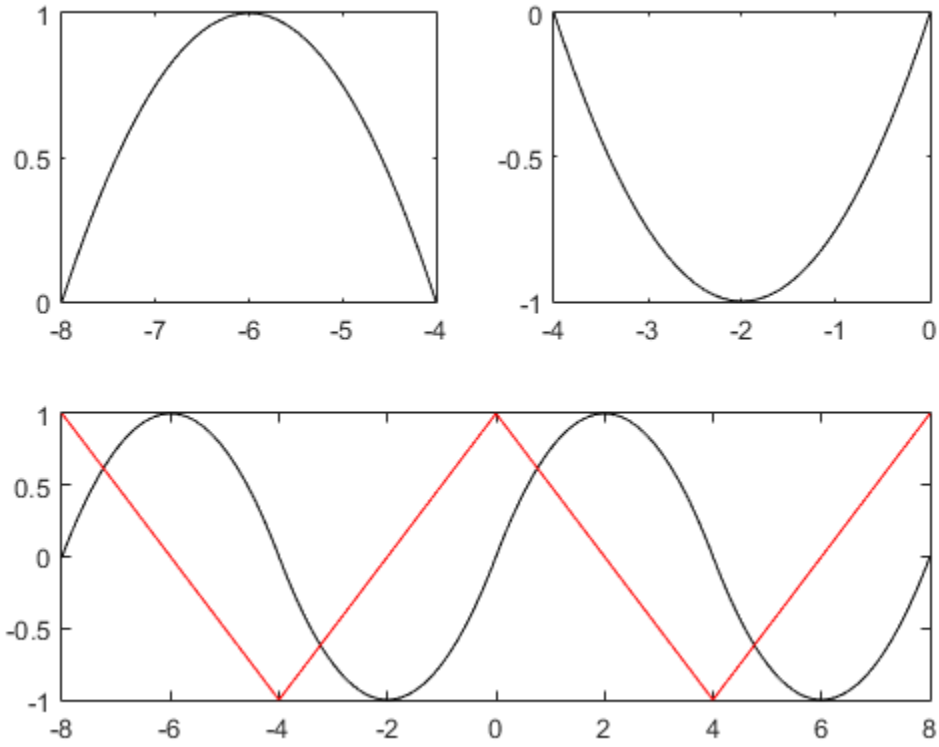
The last plot shows a piecewise polynomial constructed by alternating these two quadratic pieces over four intervals. It also shows its first derivative, which was constructed after breaking the piecewise polynomial apart using `unmkpp`.

```
subplot(2,2,1)
cc = [-1/4 1 0];
pp1 = mkpp([-8 -4],cc);
xx1 = -8:0.1:-4;
plot(xx1,ppval(pp1,xx1),'k-')

subplot(2,2,2)
pp2 = mkpp([-4 0],-cc);
xx2 = -4:0.1:0;
plot(xx2,ppval(pp2,xx2),'k-')

subplot(2,1,2)
pp = mkpp([-8 -4 0 4 8],[cc;-cc;cc;-cc]);
xx = -8:0.1:8;
plot(xx,ppval(pp,xx),'k-')
[breaks,coefs,l,k,d] = unmkpp(pp);
dpp = mkpp(breaks,repmat(k-1:-1:1,d*l,1).*coefs(:,1:k-1),d);
```

```
hold on, plot(xx,ppval(dpp,xx),'r-'), hold off
```



See Also

ppval | spline | unmkpp

Introduced before R2006a

mldivide, \

Solve systems of linear equations $Ax = B$ for x

Syntax

```
x = A\B
x = mldivide(A,B)
```

Description

`x = A\B` solves the system of linear equations `A*x = B`. The matrices A and B must have the same number of rows. MATLAB displays a warning message if A is badly scaled or nearly singular, but performs the calculation regardless.

- If A is a scalar, then `A\B` is equivalent to `A.\B`.
- If A is a square `n`-by-`n` matrix and B is a matrix with `n` rows, then `x = A\B` is a solution to the equation `A*x = B`, if it exists.
- If A is a rectangular `m`-by-`n` matrix with `m ~= n`, and B is a matrix with `m` rows, then A\B returns a least-squares solution to the system of equations `A*x= B`.

`x = mldivide(A,B)` is an alternative way to execute x = A\B, but is rarely used. It enables operator overloading for classes.

Examples

System of Equations

Solve a simple system of linear equations, `A*x = B`.

```
A = magic(3);
B = [15; 15; 15];
x = A\B
```

```
x =

    1.0000
    1.0000
```

```
    1.0000
```

Linear System with Singular Matrix

Solve a linear system of equations `A*x = b` involving a singular matrix, `A`.

```
A = magic(4);
b = [34; 34; 34; 34];
x = A\b
```

```
Warning: Matrix is close to singular or badly scaled. Results may be inaccurate. RCOND
1.306145e-17.

x =

    1.5000
    2.5000
   -0.5000
    0.5000
```

When `rcond` is between `0` and `eps`, MATLAB issues a nearly singular warning, but proceeds with the calculation. When working with ill-conditioned matrices, an unreliable solution can result even though the residual `(b-A*x)` is relatively small. In this particular example, the norm of the residual is zero, and an exact solution is obtained, although `rcond` is small.

When `rcond` is equal to `0`, the singular warning appears.

```
A = [1 0; 0 0];
b = [1; 1];
x = A\b
```

```
Warning: Matrix is singular to working precision.

x =

     1
   Inf
```

In this case, division by zero leads to computations with Inf and/or NaN, making the computed result unreliable.

Least-Squares Solution of Underdetermined System

Solve a system of linear equations, `A*x = b`.

```
A = [1 2 0; 0 4 3];
b = [8; 18];
x = A\b

ans =

         0
    4.0000
    0.6667
```

Linear System with Sparse Matrix

Solve a simple system of linear equations using sparse matrices.

Consider the matrix equation `A*x = B`.

```
A = sparse([0 2 0 1 0; 4 -1 -1 0 0; 0 0 0 3 -6; -2 0 0 0 2; 0 0 4 2 0]);
B = sparse([8; -1; -18; 8; 20]);
x = A\B

x =

   (1,1)       1.0000
   (2,1)       2.0000
   (3,1)       3.0000
   (4,1)       4.0000
   (5,1)       5.0000
```

Input Arguments

A — Coefficient matrix

vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If A has `m` rows, then B must have `m` rows.

Data Types: `single` | `double`
Complex Number Support: Yes

B — Right-hand side

vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If B has `m` rows, then A must have `m` rows.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

x — Solution

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If A is an `m`-by-`n` matrix and B is an `m`-by-`p` matrix, then x is an `n`-by-`p` matrix, including the case when `p==1`.

If `A` has full storage, `x` is also full. If `A` is sparse, then `x` has the same storage as `B`.

More About

Tips

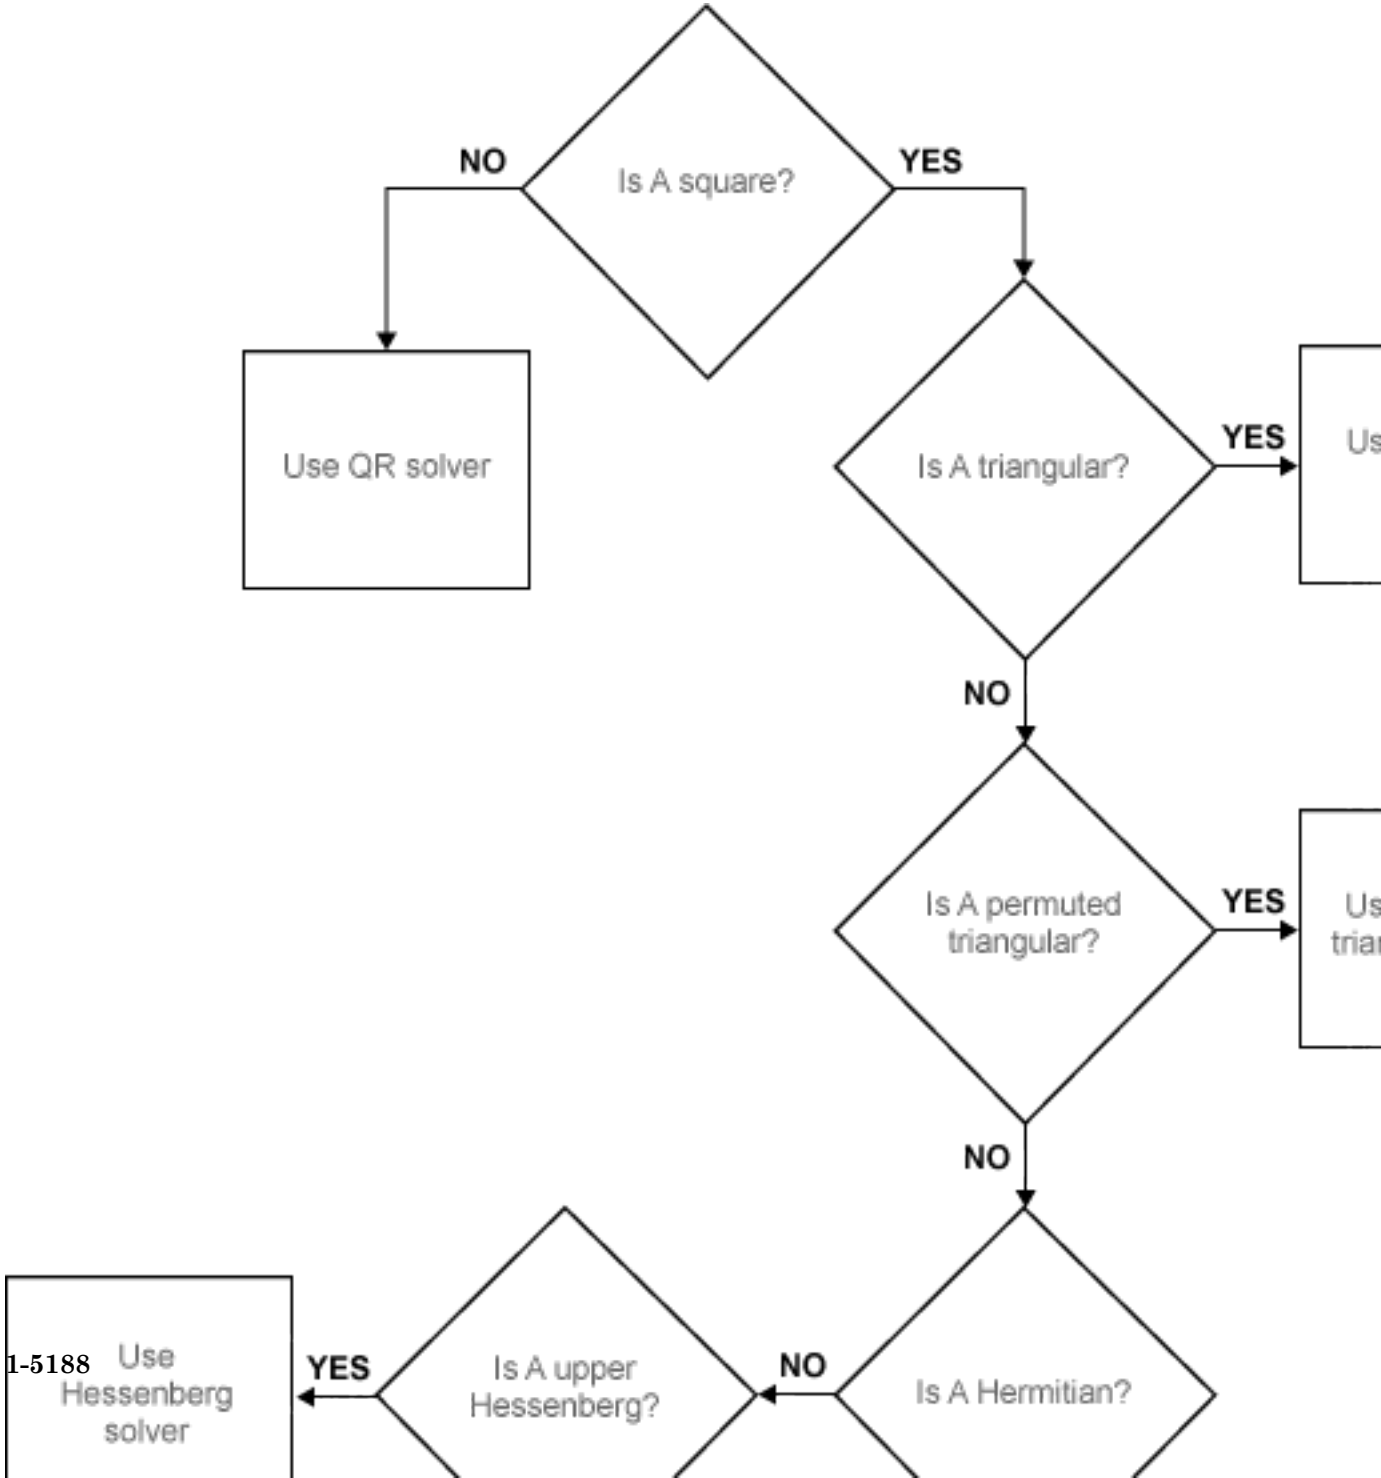
- If A is a square matrix, A\B is roughly equal to `inv(A)*B`, but MATLAB processes A\B differently and more robustly.
- If the rank of A is less than the number of columns in A, then x = A\B is not necessarily the minimum norm solution. The more computationally expensive `x = pinv(A)*B` computes the minimum norm least-squares solution.
- For full singular inputs, you can compute the least-squares solution using the function `linsolve`.

Algorithms

The versatility of `mldivide` in solving linear systems stems from its ability to take advantage of symmetries in the problem by dispatching to an appropriate solver. This approach aims to minimize computation time. The first distinction the function makes is between *full* (also called "*dense*") and *sparse* input arrays.

Algorithm for Full Inputs

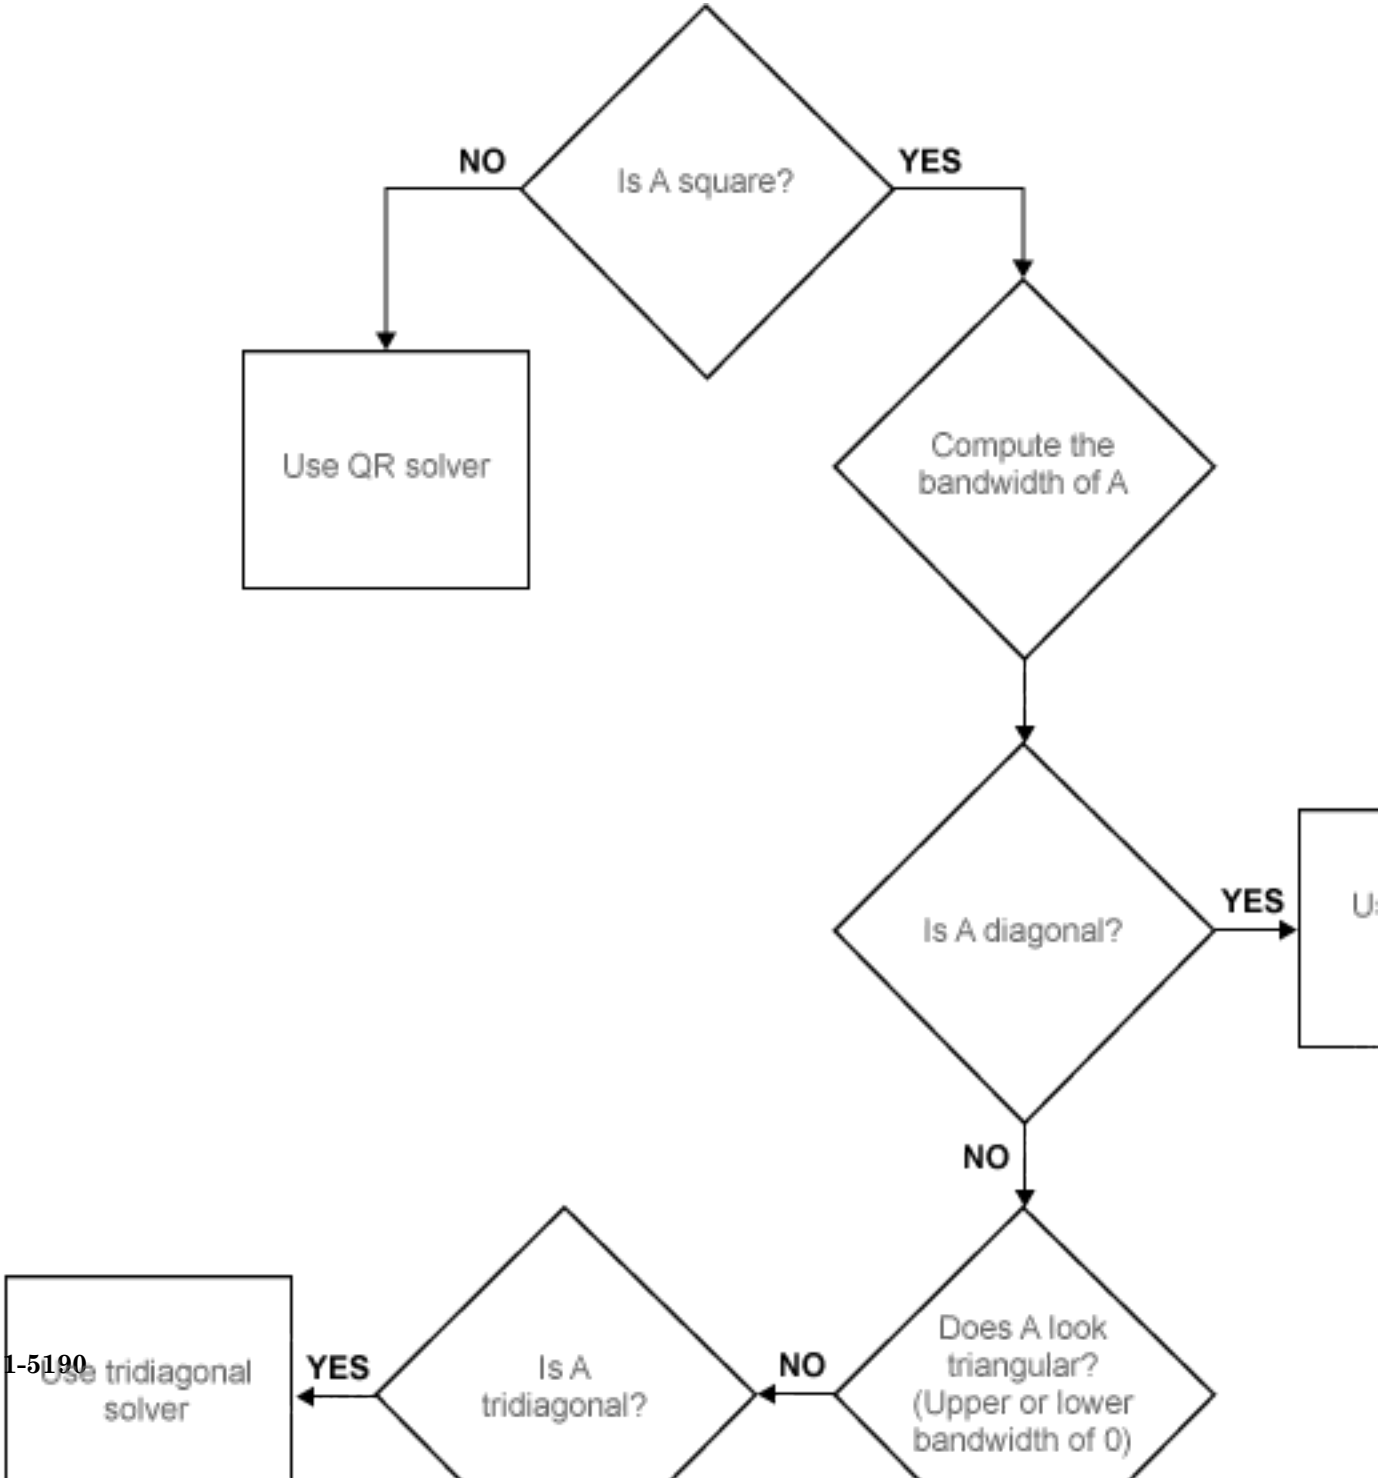
The flow chart below shows the algorithm path when inputs `A` and `B` are **full**.



Is A square?
NO
YES
Use QR solver
Is A triangular?
YES
NO
Is A permuted triangular?
YES
NO
Is A Hermitian?
NO
Is A upper Hessenberg?
YES
Use Hessenberg solver

Algorithm for Sparse Inputs

If A is full and B is sparse then `mldivide` converts B to a full matrix and uses the full algorithm path (above) to compute a solution with full storage. If A is sparse, the storage of the solution x is the same as that of B and `mldivide` follows the algorithm path for **sparse** inputs, shown below.



Is A square?
NO
YES
Use QR solver
Compute the bandwidth of A
Is A diagonal?
YES
NO
Does A look triangular? (Upper or lower bandwidth of 0)
NO
Is A tridiagonal?
YES
Use tridiagonal solver

Introduced before R2006a

mrdivide, /

Solve systems of linear equations $xA = B$ for x

Syntax

```
x = B/A
x = mrdivide(B,A)
```

Description

`x = B/A` solves the system of linear equations `x*A = B` for x. The matrices A and B must contain the same number of columns. MATLAB displays a warning message if A is badly scaled or nearly singular, but performs the calculation regardless.

- If A is a scalar, then `B/A` is equivalent to `B./A`.
- If A is a square `n`-by-`n` matrix and B is a matrix with `n` columns, then `x = B/A` is a solution to the equation `x*A = B`, if it exists.
- If A is a rectangular `m`-by-`n` matrix with `m ~= n`, and B is a matrix with `n` columns, then x = B/A returns a least-squares solution of the system of equations `x*A = B`.

`x = mrdivide(B,A)` is an alternative way to execute x = B/A, but is rarely used. It enables operator overloading for classes.

Examples

System of Equations

Solve a system of equations that has a unique solution, `x*A = B`.

```
A = [1 1 3; 2 0 4; -1 6 -1];
B = [2 19 8];
x = B/A
```

```
x =
```

```
    1.0000    2.0000    3.0000
```

Least-Squares on an Underdetermined System

Solve an underdetermined system, `x*C = D`.

```
C = [1 0; 2 0; 1 0];
D = [1 2];
x = D/C
```

```
Warning: Rank deficient, rank = 1, tol =  6.280370e-16.

x =

         0    0.5000         0
```

MATLAB issues a warning but proceeds with calculation.

Verify that `x` is not an exact solution.

```
x*C-D
```

```
ans =

     0    -2
```

Input Arguments

A — Coefficient matrix

vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If A has `n` columns, then B must have `n` columns.

Data Types: `single` | `double`
Complex Number Support: Yes

B — Right-hand side

vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If B has `n` columns, then A must have `n` columns.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

x — Solution

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If A is an `m`-by-`n` matrix and B is a `p`-by-`n` matrix, then x is a `p`-by-`m` matrix.

x is sparse only if both A and B are sparse matrices.

More About

Tips

- The operators `/` and `\` are related to each other by the equation `B/A = (A'\B')'`.
- If A is a square matrix, `B/A` is roughly equal to `B*inv(A)`, but MATLAB processes B/A differently and more robustly.

- "Array vs. Matrix Operations"
- "Operator Precedence"
- "Systems of Linear Equations"

Introduced before R2006a

mlint

Check MATLAB code files for possible problems

Note: `mlint` is not recommended. Use `checkcode` instead.

Alternatives

For information on using the graphical user interface to the Code Analyzer, see "Check Code for Errors and Warnings".

Syntax

```
mlint('filename')
mlint('filename','-config=settings.txt')
mlint('filename','-config=factory')
inform=mlint('filename','-struct')
msg=mlint('filename','-string')
[inform,filepaths]=mlint('filename')
inform=mlint('filename','-id')
inform=mlint('filename','-fullpath')
inform=mlint('filename','-notok')
mlint('filename','-cyc')
mlint('filename','-codegen')
mlint('filename','-eml')
```

Description

`mlint('filename')` displays Code Analyzer messages about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `mlint(F1,F2,F3,...)`, where each input is a character array, MATLAB software

displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `mlint` messages is subject to some change between versions.

`mlint('filename','-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

Note: If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

For information about creating a `settings.txt` file, see "Save and Reuse Code Analyzer Message Settings". If you specify an invalid file, `mlint` returns a message indicating that it cannot open or read the file you specified. In that case, `mlint` uses the factory default settings.

`mlint('filename','-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=mlint('filename','-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
`message`	Message describing the suspicious construct that code analysis caught.
`line`	Vector of file line numbers to which the message refers.
`column`	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=mlint('filename','-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as

input, `msg` contains a string where each file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **`-struct`** or **`-string`** argument and you specify an output argument, the default behavior is **`-struct`**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepaths]=mlint('filename')` additionally returns `filepaths`, the absolute paths to the file names, in the same order as you specified them.

`inform=mlint('filename','-id')` requests the message ID, where ID is a string of the form `ABC...`. When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=mlint('filename','-fullpath')` assumes that the input file names are absolute paths, so that `mlint` does not try to locate them.

`inform=mlint('filename','-notok')` runs `mlint` for all lines in `filename`, even those lines that end with the `mlint` suppression directive, `%#ok`.

`mlint('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`mlint('filename','-codegen')` enables code generation messages for display in the Command Window.

`mlint('filename','-eml')` `'-eml'` is not recommended. Use `'-codegen'` instead.

Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in *`matlabroot`*`/help/techdoc/matlab_env/examples`. If you want to run the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

Running mlint on a File with No Options

To run `mlint` on the example file, `lengthofline.m`, run

```
mlint('lengthofline')
```

MATLAB displays the M-Lint messages for `lengthofline.m` in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nothandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
                Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop.Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

Running mlint with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=mlint('lengthofline', '-id')
```

MATLAB returns

```
inform =

19x1 struct array with fields:
    message
    line
    column
    id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =

    message: 'The value assigned here to variable 'nothandle' might never be used.'
       line: 22
     column: [1 9]
         id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message `'The value assigned here to variable 'nothandle' might never be used.'`.

Displaying McCabe Complexity with mlint

To display the McCabe complexity of a MATLAB code file, run `mlint` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
mlint lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the M-Lint messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nothandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary.  Use parentheses to group, if needed.
```

See Also

`mlintrpt`, `profile`

How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages ”.

Introduced before R2006a

mlintrpt

Run `checkcode` for file or folder, reporting results in browser

Syntax

```
mlintrpt
mlintrpt('filename','file')
mlintrpt('dirname','dir')
mlintrpt('filename','file','settings.txt')
mlintrpt('dirname','dir','settings.txt')
```

Description

`mlintrpt` scans all files with an `.m` file extension in the current folder for Code Analyzer messages and reports the results in a MATLAB Web browser.

`mlintrpt('filename','file')` scans `filename` for Code Analyzer messages and reports results. You can omit `'file'` in this form of the syntax because it is the default.

`mlintrpt('dirname','dir')` scans the specified folder. Here, `dirname` can be in the current folder or can be a full path.

`mlintrpt('filename','file','settings.txt')` applies the Code Analyzer preference settings to enable or suppress messages as indicated in the specified `settings.txt` file.

`mlintrpt('dirname','dir','settings.txt')` applies the settings indicated in the specified `settings.txt` file.

Note: If you specify a `settings.txt` file, you must specify the full path to the file.

Examples

`lengthofline.m` is an example file with code that can be improved. It is found in *`matlabroot`*`/matlab/help/techdoc/matlab_env/examples`.

Run Report for All Files in a Folder

Run

```
mlintrpt(fullfile(matlabroot,'help','techdoc','matlab_env','examples'),'dir')
```

and MATLAB displays a report of potential problems and improvements for all files with an `.m` file extension in the `examples` folder.

For details about these messages and how to improve the code, see "Changing Code Based on Code Analyzer Messages".

Run Report Using Code Analyzer Preference Settings

You can save preference settings to a text file by clicking the **Preferences** button in the **Environment** section on the **Home** tab and selecting **Code Analyzer** in the left pane. To save a preferences file, select **Save as** under the  drop-down list. To apply those settings when you run `mlintrpt`, use the `file` option and supply the full path to the settings file name as shown in this example:

```
mlintrpt('lengthofline.m', 'file', ...
'C:\WINNT\Profiles\me\Application Data\MathWorks\MATLAB\R2012b\mymlint.txt')
```

Alternatively, use `fullfile` if the settings file is stored in the preferences folder:

```
 mlintrpt('lengthofline.m', 'file', fullfile(prefdir,'mymlint.txt'))
```

Assuming that in that example `mymlint.txt` file, the setting for `Terminate statement with semicolon to suppress output` has been disabled, the results of `mlintrpt` for `lengthofline` do not show that message for line 49.

When `mlintrpt` cannot locate the settings file, the first message in the report is

```
0: Unable to open or read the configuration file 'mymlint.txt'--using default settings.
```

`checkcode`

Introduced before R2006a

mlock

Prevent clearing function from memory

Syntax

```
mlock
```

Description

`mlock` locks the currently running function in memory so that subsequent `clear` functions do not remove it. Locking a function in memory also prevents any `persistent` variables defined in the file from getting reinitialized.

Use the `munlock` function to return the file to its normal, clearable state.

Examples

The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
  .
  .
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked('testfun')
ans =
     1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock('testfun')
```

```
mislocked('testfun')
ans =
     0
```

See Also

`mislocked` | `inmem` | `munlock` | `persistent`

Introduced before R2006a

mmfileinfo

Information about multimedia file

Syntax

```
info = mmfileinfo(filename)
```

Description

`info = mmfileinfo(filename)` returns a structure, `info`, with fields containing information about the contents of the multimedia file identified by `filename`. The `filename` input is a string enclosed in single quotation marks.

If `filename` is a URL, `mmfileinfo` might take a long time to return because it must first download the file. For large files, downloading can take several minutes. To avoid blocking the MATLAB command line while this processing takes place, download the file before calling `mmfileinfo`.

The `info` structure contains the following fields, listed in the order they appear in the structure.

Field	Description
`Filename`	String indicating the name of the file.
`Path`	String indicating the absolute path to the file.
`Duration`	Length of the file in seconds.
`Audio`	Structure containing information about the audio data in the file. See “Audio Data” on page 1-5206 for more information about this data structure.
`Video`	Structure containing information about the video data in the file. See “Video Data” on page 1-5206 for more information about this data structure.

Audio Data

The `Audio` structure contains the following fields, listed in the order they appear in the structure. If the file does not contain audio data, the fields in the structure are empty.

Field	Description
`Format`	Text string, indicating the audio format.
`NumberOfChannels`	Number of audio channels.

Video Data

The `Video` structure contains the following fields, listed in the order they appear in the structure. If the file does not contain video data, the fields in the structure are empty.

Field	Description
`Format`	Text string, indicating the video format.
`Height`	Height of the video frame.
`Width`	Width of the video frame.

Examples

Display information about the example file `xylophone.mpg`:

```
info = mmfileinfo('xylophone.mpg')
audio = info.Audio
video = info.Video
```

MATLAB returns:

```
info =
    Filename: 'xylophone.mpg'
        Path: 'matlabroot\toolbox\matlab\audiovideo'
    Duration: 4.7020
       Audio: [1x1 struct]
       Video: [1x1 struct]

audio =
              Format: 'MPEG'
```

```
    NumberOfChannels: 2

video =
    Format: 'MPEG1'
    Height: 240
     Width: 320
```

where `Path` is system-dependent.

See Also

`get` | `VideoReader`

Introduced before R2006a

mmreader class

Create object for reading video files

Note: `mmreader` has been removed. Use `VideoReader` instead.

Description

Use `mmreader` with the `read` method to read video data from a multimedia file into the MATLAB workspace.

The file formats that `mmreader` supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	Motion JPEG 2000 (`.mj2`)
Windows	AVI (`.avi`), MPEG-1 (`.mpg`), Windows Media Video (`.wmv`, `.asf`, `.asx`), and any format supported by Microsoft DirectShow.
Macintosh	AVI (`.avi`), MPEG-1 (`.mpg`), MPEG-4 (`.mp4`, `.m4v`), Apple QuickTime Movie (`.mov`), and any format supported by QuickTime as listed on http://support.apple.com/kb/HT3775.
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on http://gstreamer.freedesktop.org/documentation/plugins.html, including AVI (`.avi`) and Ogg Theora (`.ogg`).

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

Construction

obj = mmreader(*filename*) constructs *obj* to read video data from the file named *filename*. The mmreader constructor searches for the file on the MATLAB path. If it cannot construct the object for any reason, mmreader generates an error.

obj = mmreader(*filename*,'*PropertyName*',*PropertyValue*) constructs the object using options, specified as property name/value pairs. Property name/value pairs can be in any format that the set method supports: name/value string pairs, structures, or name/value cell array pairs.

Properties

BitsPerPixel

Bits per pixel of the video data. (Read-only)

Duration

Total length of the file in seconds. (Read-only)

FrameRate

Frame rate of the video in frames per second. (Read-only)

Height

Height of the video frame in pixels. (Read-only)

Name

Name of the file associated with the object. (Read-only)

NumberOfFrames

Total number of frames in the video stream. (Read-only)

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, mmreader cannot determine the number of frames until you read the last frame. When you construct the object, mmreader returns a warning and does not set the NumberOfFrames property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = mmreader('varFrameRateFile.wmv');
lastFrame = read(vidObj, inf);
numFrames = vidObj.NumberOfFrames;
```

`Path`

String containing the full path to the file associated with the reader. (Read-only)

`Tag`

User-defined string to identify the object.

Default: `''`

`Type`

Class name of the object: `'mmreader'`. (Read-only)

`UserData`

Generic field for user-defined data.

Default: `[]`

`VideoFormat`

String indicating the MATLAB representation of the video format, such as `'RGB24'`. (Read-only)

`Width`

Width of the video frame in pixels. (Read-only)

Methods

For backward compatibility, `mmreader` supports the following `VideoReader` methods:

get	Query property values for video reader object

getFileFormats	File formats that `VideoReader` supports
hasFrame	Determine if frame available to read
read	Read video frame data from file
readFrame	Read video frame from video file
set	Set property values for video reader object

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

Examples

Construct an `mmreader` object for the example movie file `xylophone.mpg` and view its properties:

```
xyloObj = mmreader('xylophone.mpg', 'Tag', 'My reader object');
get(xyloObj)
```

Read and play back the movie file `xylophone.mpg`:

```
xyloObj = mmreader('xylophone.mpg');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;

% Preallocate movie structure.
mov(1:nFrames) = ...
    struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...
           'colormap', []);

% Read one frame at a time.
```

```
for k = 1 : nFrames
    mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])

% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

See Also

`mmfileinfo` | `VideoReader`

How To

- "Read Video Files"

mod

Remainder after division (modulo operation)

Syntax

```
b = mod(a,m)
```

Description

`b = mod(a,m)` returns the remainder after division of `a` by `m`, where `a` is the dividend and `m` is the divisor. This function is often called the modulo operation and is computed using `b = a - m.*floor(a./m)`. The `mod` function follows the convention that `mod(a,0)` returns `a`.

Examples

Remainder After Division of Scalar

Compute 23 modulo 5.

```
b = mod(23,5)
```

```
b =

     3
```

Remainder After Division of Vector

Find the remainder after division for a vector of integers and the divisor 3.

```
a = 1:5;
m = 3;
b = mod(a,m)
```

```
b =
```

```
     1     2     0     1     2
```

Remainder After Division for Positive and Negative Values

Find the remainder after division for a set of integers including both positive and negative values. Note that nonzero results are always positive if the divisor is positive.

```
a = [-4 -1 7 9];
m = 3;
b = mod(a,m)

b =

     2     2     1     0
```

Remainder After Division for Negative Divisor

Find the remainder after division by a negative divisor for a set of integers including both positive and negative values. Note that nonzero results are always negative if the divisor is negative.

```
a = [-4 -1 7 9];
m = -3;
b = mod(a,m)

b =

    -1    -1    -2     0
```

Remainder After Division for Floating-Point Values

Find the remainder after division for several angles using a modulus of `2*pi`. Note that `mod` attempts to compensate for floating-point round-off effects to produce exact integer results when possible.

```
theta = [0.0 3.5 5.9 6.2 9.0 4*pi];
m = 2*pi;
b = mod(theta,m)

b =
```

```
     0    3.5000    5.9000    6.2000    2.7168         0
```

Input Arguments

a — Dividend

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. `a` must be a real-valued array of any numerical type. Inputs `a` and `m` must be the same size unless one is a scalar `double`. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

m — Divisor

scalar | vector | matrix | multidimensional array

Divisor, specified as a scalar, vector, matrix, or multidimensional array. `m` must be a real-valued array of any numerical type. Inputs `a` and `m` must be the same size unless one is a scalar `double`. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar `double`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

More About

Differences Between mod and rem

The concept of remainder after division is not uniquely defined, and the two functions `mod` and `rem` each compute a different variation. The `mod` function produces a result that is either zero or has the same sign as the divisor. The `rem` function produces a result that is either zero or has the same sign as the dividend.

Another difference is the convention when the divisor is zero. The `mod` function follows the convention that `mod(a,0)` returns `a`, whereas the `rem` function follows the convention that `rem(a,0)` returns `NaN`.

Both variants have their uses. For example, in signal processing, the `mod` function is useful in the context of periodic signals because its output is periodic (with period equal to the divisor).

Congruence Relationships

The `mod` function is useful for congruence relationships: `a` and `b` are congruent (mod m) if and only if `mod(a,m) == mod(b,m)`. For example, 23 and 13 are congruent (mod 5).

`rem`

Introduced before R2006a

mode

Most frequent values in array

Syntax

```
M = mode(A)
M = mode(A,dim)

[M,F] = mode( ___ )
[M,F,C] = mode( ___ )
```

Description

`M = mode(A)` returns the sample mode of `A`, which is the most frequently occurring value in `A`. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, the smallest value is the first value in a sorted list.

- If `A` is a vector, then `mode(A)` returns the most frequent value of `A`.
- If `A` is a nonempty matrix, then `mode(A)` returns a row vector containing the mode of each column of `A`.
- If `A` is an empty 0-by-0 matrix, `mode(A)` returns `NaN`.
- If `A` is a multidimensional array, then `mode(A)` treats the values along the first array dimension whose size does not equal `1` as vectors and returns an array of most frequent values. The size of this dimension becomes `1` while the sizes of all other dimensions remain the same.

`M = mode(A,dim)` returns the mode of elements along dimension `dim`. For example, if `A` is a matrix, then `mode(A,2)` is a column vector containing the most frequent value of each row

`[M,F] = mode( ___ )` also returns a frequency array `F`, using any of the input arguments in the previous syntaxes. `F` is the same size as `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

`[M,F,C] = mode(___)` also returns a cell array `C` of the same size as `M` and `F`. Each element of `C` is a sorted vector of all values that have the same frequency as the corresponding element of `M`.

Examples

Mode of Matrix Columns

Define a 3-by-4 matrix.

```
A = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
A =

     3     3     1     4
     0     0     1     1
     0     1     2     4
```

Find the most frequent value of each column.

```
M = mode(A)
```

```
M =

     0     0     1     4
```

Mode of Matrix Rows

Define a 3-by-4 matrix.

```
A = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
A =

     3     3     1     4
     0     0     1     1
     0     1     2     4
```

Find the most frequent value of each row.

```
M = mode(A,2)
```

```
M =
```

```
     3
     0
     0
```

Mode of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =

    10     8    10

A(:,:,2) =

     6     9     5

A(:,:,3) =

     9     6     1

A(:,:,4) =

     4     9     5
```

Find the most frequent values of this 3-D array along the second dimension.

```
M = mode(A)
```

```
M(:,:,1) =

    10

M(:,:,2) =

     5

M(:,:,3) =
```

```
     1

M(:,:,4) =

     4
```

This operation produces a 1-by-1-by-4 array by finding the most frequent value along the second dimension. The size of the second dimension reduces to 1.

Compute the mode along the first dimension of A.

```
M = mode(A,1);
isequal(A,M)

ans =

     1
```

This returns the same array as A because the size of the first dimension is 1.

Mode of Matrix Columns with Frequency Information

Define a 3-by-4 matrix.

```
A = [3 3 1 4; 0 0 1 1; 0 1 2 4]

A =

     3     3     1     4
     0     0     1     1
     0     1     2     4
```

Find the most frequent value of each column, as well as how often it occurs.

```
[M,F] = mode(A)

M =

     0     0     1     4

F =
```

```
     2     1     2     2
```

`F(1)` is `2` since `M(1)` occurs twice in the first column.

Mode of Matrix Rows with Frequency and Multiplicity Information

Define a 3-by-4 matrix.

```
A = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
A =

     3     3     1     4
     0     0     1     1
     0     1     2     4
```

Find the most frequent value of each row, how often it occurs, and which values in that row occur with the same frequency.

```
[M,F,C] = mode(A,2)
```

```
M =

     3
     0
     0

F =

     2
     2
     1

C =

    [         3]
    [2x1 double]
    [4x1 double]
```

`C{2}` is the 2-by-1 vector `[0;1]` since values `0` and `1` in the second row occur with frequency `F(2)`.

`C{3}` is the 4-by-1 vector `[0;1;2;4]` since all values in the third row occur with frequency `F(3)`.

Mode of 16-bit Unsigned Integer Array

Define a 1-by-4 vector of 16-bit unsigned integers.

```
A = gallery('integerdata',10,[1,4],3,'uint16')
```

```
A =

      6      3      2      3
```

Find the most frequent value, as well as the number of times it occurs.

```
[M,F] = mode(A),
class(M)
```

```
M =

      3

F =

     2

ans =

uint16
```

`M` is the same class as the input, `A`.

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. `A` can be a numeric array, categorical array, datetime array, or duration array.

`NaN` or `NaT` (Not a Time) values in the input array, `A`, are ignored. Undefined values in categorical arrays are similar to `NaN`s in numeric arrays.

`dim` — Dimension to operate along

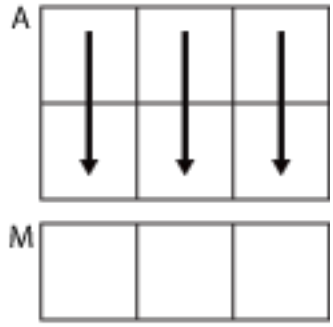
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(M,dim)` is `1`, while the sizes of all other dimensions remain the same.

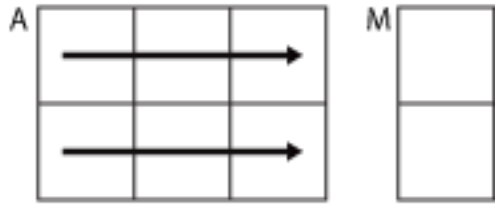
Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `mode(A,1)` returns a row vector containing the most frequent value in each column.



mode(A,1)

- If `dim = 2`, then `mode(A,2)` returns a column vector containing the most frequent value in each row.



mode(A,2)

`mode` returns `A` if `dim` is greater than `ndims(A)`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`M` — Most frequent values

scalar | vector | matrix | multidimensional array

Most frequent values returned as a scalar, vector, matrix, or multidimensional array. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, this is taken to be the first value in a sorted list of values.

The class of `M` is the same as the class of the input array, `A`.

`F` — Frequency array

scalar | vector | matrix | multidimensional array

Frequency array returned as a scalar, vector, matrix, or multidimensional array. The size of `F` is the same as the size of `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

The class of `F` is always `double`.

`C` — Most frequent values with multiplicity

cell array

Most frequent values with multiplicity returned as a cell array. The size of `C` is the same as the size of `M` and `F`, and each element of `C` is a sorted column vector of all values that have the same frequency as the corresponding element of `M`.

More About

Tips

- The `mode` function is most useful with discrete or coarsely rounded data. The mode for a continuous probability distribution is defined as the peak of its density function. Applying the `mode` function to a sample from that distribution is unlikely to provide a good estimate of the peak; it would be better to compute a histogram or density

estimate and calculate the peak of that estimate. Also, the `mode` function is not suitable for finding peaks in distributions having multiple modes.

Introduced before R2006a

month

Month number and name

Syntax

```
m = month(t)
m = month(t,monthType)
```

Description

`m = month(t)` returns the month numbers of the datetime values in `t`. The `m` output contains integer values from 1 to 12.

`m = month(t,monthType)` returns the type of month number or name specified by `monthType`.

The `month` function returns the month numbers or names of datetime values. To assign month numbers to datetime array `t`, use `t.Month` and modify the `Month` property.

Examples

Extract Month Number from Dates

Extract the month numbers from an array of dates.

```
t = datetime(2014,05,31):caldays(35):datetime(2014,10,15)
```

```
t =

   31-May-2014   05-Jul-2014   09-Aug-2014   13-Sep-2014
```

```
m = month(t)
```

```
m =

     5     7     8     9
```

Find Month Names of Dates

Get the month names from an array of dates.

```
t = datetime(2013,01,01):calweeks(12):datetime(2013,12,31)
```

```
t =

   01-Jan-2013   26-Mar-2013   18-Jun-2013   10-Sep-2013   03-Dec-2013
```

```
m = month(t,'name')
```

```
m =

    'January'    'March'    'June'    'September'    'December'
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`monthType` — Type of month values

`'monthofyear'` (default) | `'name'` | `'shortname'`

Type of month values, specified as one of the following strings.

Value of `monthType`	Description
`'monthofyear'`	Month-of-year number
`'name'`	Full month names, for example, `August` or `September`.

Value of `monthType`	Description
`'shortname'`	Abbreviated month names, for example, `Aug` or `Sep`.

Output Arguments

`m` — Month number or name

`double` array | cell array of strings

Month number or name, returned as a numeric array of type `double`, or a cell array of strings. `m` is the same size as `t`.

Introduced in R2014b

more

Control paged output for Command Window

Syntax

```
more on
more off
more(n)
A = more(state)
```

Description

`more on` enables paging of the output in the MATLAB Command Window. MATLAB displays output one page at a time. Use the keys defined in the table below to control paging.

`more off` disables paging of the output in the MATLAB Command Window.

`more(n)` defines the length of a page to be `n` lines.

`A = more(state)` returns in `A` the number of lines that are currently defined to be a page. The `state` input can be one of the quoted strings `'on'` or `'off'`, or the number of lines to set as the new page length.

By default, the length of a page is equal to the number of lines available for display in the MATLAB Command Window. Manually changing the size of the command window adjusts the page length accordingly.

If you set the page length to a specific value, MATLAB uses that value for the page size, regardless of the size of the command window. To have MATLAB return to matching page size to window size, type `more off` followed by `more on`.

To see the status of `more`, type `get(0,'More')`. MATLAB returns either `on` or `off`, indicating the `more` status.

When you have enabled `more` and are examining output, you can do the following.

Press the...	To...
Return key	Advance to the next line of output.
Space bar	Advance to the next page of output.
Q (for quit) key	Terminate display of the text. Do not use **Ctrl+C** to terminate `more` or you might generate error messages in the Command Window.

`more` is in the **`off`** state, by default.

`diary`

Introduced before R2006a

morebins

Increase number of histogram bins

Syntax

```
N = morebins(h)
```

Description

`N = morebins(h)` increases the number of bins in histogram `h` by 10% (rounded up to the nearest integer) and returns the new number of bins.

Examples

Increase Number of Histogram Bins

Plot a histogram of 1,000 random numbers and return a handle to the histogram object.

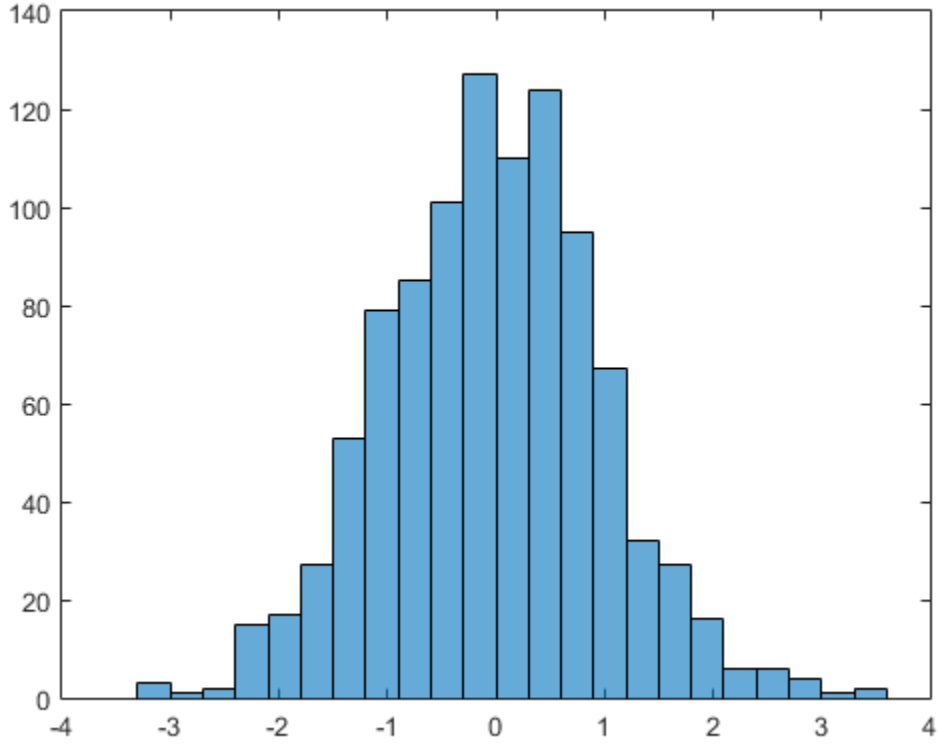
```
x = randn(1000,1);
h = histogram(x)
```

```
h =

  Histogram with properties:

            Data: [1000x1 double]
          Values: [1x23 double]
         NumBins: 23
        BinEdges: [1x24 double]
        BinWidth: 0.3000
       BinLimits: [-3.3000 3.6000]
    Normalization: 'count'
        FaceColor: 'auto'
        EdgeColor: [0 0 0]
```

```
Use GET to show all properties
```

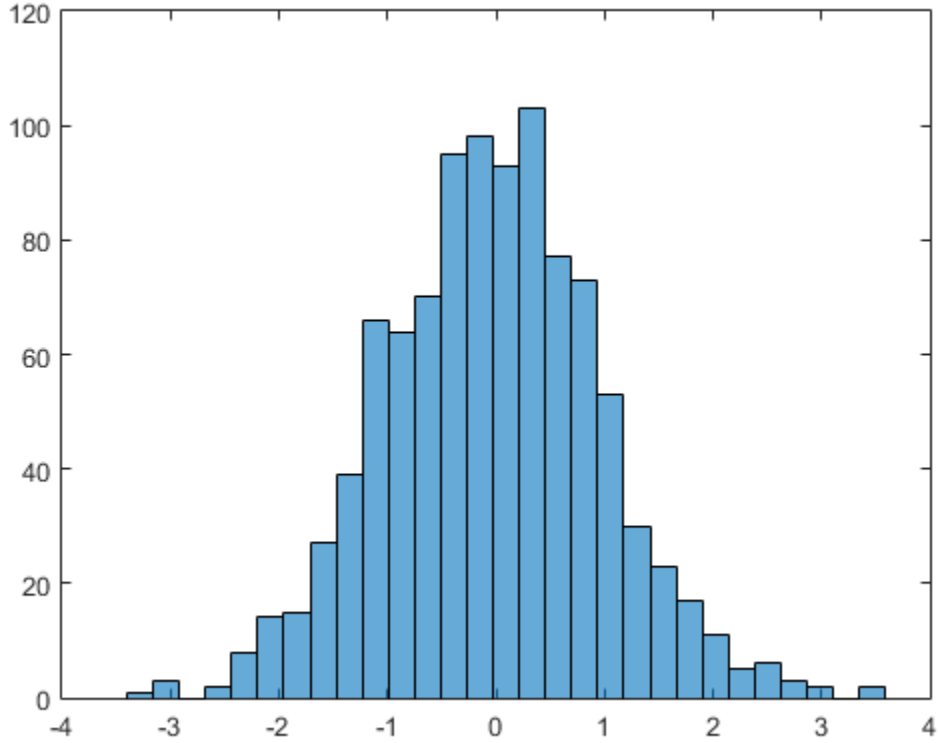


Use `morebins` to increase the number of bins in the histogram.

```
morebins(h);
morebins(h)
```

```
ans =

    29
```



Input Arguments

h — Input histogram

histogram object

Input histogram, specified as a histogram object. For more information, see Using histogram Objects.

Output Arguments

`N` — Number of bins

scalar

Number of bins, returned as a scalar. `N` is the new number of bins for the histogram after increase.

More About

- Using histogram Objects
- Histogram Properties

`fewerbins` | `histcounts` | `histogram`

Introduced in R2014b

move

Move or resize control in parent window

Syntax

```
V = move(h,position)
```

Description

`V = move(h,position)` moves the control to the position specified by the `position` argument. When you use `move` with only the handle argument, `h`, it returns a four-element vector indicating the current position of the control.

The position argument is a four-element vector specifying the position and size of the control in the parent figure window. The elements of the vector are:

```
[x, y, width, height]
```

where `x` and `y` are offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control, and `width` and `height` are the size of the control itself.

Examples

This example moves the control.

```
f = figure('Position',[100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);
pos = move(h,[50 50 200 200])
```

```
pos =
    50    50   200   200
```

The next example resizes the control to always be centered in the figure as you resize the figure window. Start by creating the script `resizectrl.m` that contains:

```
% Get the new position and size of the figure window
  fpos = get(gcbo,'position');
```

```
% Resize the control accordingly
  move(h,[0 0 fpos(3) fpos(4)]);
```

Now execute the following:

```
f = figure('Position',[100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200]);
set(f,'ResizeFcn','resizectrl');
```

As you resize the figure window, notice that the circle moves so that it is always positioned in the center of the window.

`set (COM)` | `get (COM)`

Introduced before R2006a

movefile

Move file or folder

Syntax

```
movefile('source')
movefile('source','destination')
movefile('source','destination','f')
[status,message,messageid] = movefile( ___ )
```

Description

`movefile('source')` moves the file or folder named `source` to the current folder, where `source` is the absolute or relative path name for the folder or file. To move multiple files or folders, use one or more wildcard characters (`*`) after the last file separator in `source`. The `source` argument permits a wildcard character in a path string. `movefile` does not preserve the archive attribute of `source`.

`movefile('source','destination')` moves the file or folder named `source` to the location `destination`, where `source` and `destination` are the absolute or relative paths for the folder or file. To move multiple files or folders, you can use one or more wildcard characters (`*`) after the last file separator in `source`. You cannot use a wildcard character in `destination`. To rename a file or folder when moving it, make `destination` a different name than `source`, and specify only one file for `source`. When `source` and `destination` have the same location, `movefile` renames `source` to `destination`.

`movefile('source','destination','f')` moves the file or folder named `source` to the location `destination`, regardless of the read-only attribute of `destination`.

`[status,message,messageid] = movefile( ___ )` moves the file or folder named `source` to the location `destination`, returning the status, a message, and the MATLAB message ID. Here, `status` is logical `1` for success or logical `0` for error. `movefile` requires only one output argument.

Examples

Moving a File to the Current Folder

Assuming `myfiles` is a subfolder within the current folder, move the file `myfunction.m` to the current folder:

```
movefile('myfiles/myfunction.m')
```

Assuming `projects/testcases` is the current folder, move `projects/myfiles` and its contents to the current folder:

```
movefile('../myfiles')
```

Renaming a File in the Current Folder

In the current folder, rename `oldname.m` to `newname.m`:

```
movefile('oldname.m','newname.m')
```

Using a Wildcard to Move All Matching Files

Assuming `myfiles` is a subfolder of the current folder, move all files whose names that begin with `my` from the `myfiles` folder, to the current folder:

```
movefile('myfiles/my*')
```

Moving a File to a Different Folder

Assuming `projects` and the current folder are at the same level, move the file `myfunction.m` from the current folder to the folder `projects`:

```
movefile('myfunction.m','../projects')
```

Moving a Folder Down One Level

Assuming `projects` is a subfolder of the current folder, move the folder `projects/testcases` and all its contents down a level in `projects` into `projects/myfiles`:

```
movefile('projects/testcases','projects/myfiles/')
```

Moving a File to a Read-Only Folder and Renaming the File

Move the file `myfile.m` from the current folder to `d:/work/restricted`, assigning it the name `test1.m`, where `restricted` is a read-only folder:

```
movefile('myfile.m','d:/work/restricted/test1.m','f')
```

The read-only file `myfile.m` is no longer in the current folder. The file `test1.m` is in `d:/work/restricted` and is read only.

Returning Status When Moving Files

Move all files in the folder `myfiles` whose names start with `new` to the current folder, when there is an error. You mistype `new*` as `nex*` and no items in the current folder start with `nex*`:

```
[s,mess,messid] = movefile('myfiles/nex*')

s =
     0

mess =

No matching files were found.

messid =

MATLAB:MOVEFILE:FileDoesNotExist
```

`cd` | `copyfile` | `delete` | `dir` | `fileattrib` | `ls` | `mkdir` | `rmdir`

Introduced before R2006a

movegui

Move UI figure to specified location on screen

Syntax

```
movegui(h,'position')
movegui(position)
movegui(h)
movegui
```

Description

`movegui(h,'position')` moves the figure identified by handle `h` to the specified screen location, preserving the figure's size. The *`position`* argument is either a string or a two-element vector, as defined in the tables that follow.

`movegui(position)` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the specified position.

`movegui(h)` moves the figure identified by the handle `h` to the `onscreen` position.

`movegui` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the `onscreen` position. You can specify `'movegui'` as a CreateFcn callback for a figure. Doing so ensures after you save a figure, that figure appears on screen when you reload it, regardless of its saved position. See the following example.

When it is a string, *`position`* is one of the following descriptors.

Position String	Description
`north`	Top center edge of screen
`south`	Bottom center edge of screen
`east`	Right center edge of screen
`west`	Left center edge of screen
`northeast`	Top right corner of screen

Position String	Description
`northwest`	Top left corner of screen
`southeast`	Bottom right corner of screen
`southwest`	Bottom left corner
`center`	Centered on screen
`onscreen`	Nearest location to current location that is entirely on screen

You can also specify the *`position`* argument as a two-element vector, `[h,v]`. Depending on sign, `h` specifies the figure's offset from the left or right edge of the screen, and `v` specifies the figure's offset from the top or bottom of the screen, in pixels. The following table summarizes the possible values.

`h` (for `h >= 0`)	Offset of left side from left edge of screen
`h` (for `h < 0`)	Offset of right side from right edge of screen
`v` (for `v >= 0`)	Offset of bottom edge from bottom of screen
`v` (for `v < 0`)	Offset of top edge from top of screen

Applying `movegui` to a maximized figure window moves the window towards the task bar and creates a gap on the opposite side of the screen about as wide as the task bar. The window might shrink in size by a few pixels. If you use the `onscreen` option with a maximized figure window, then `movegui` creates a gap on both the left and upper sides of the screen so that the top-left corner of the figure is visible.

`GUIDE` and `openfig` call `movegui` when loading figures to ensure they are visible.

Examples

Ensure that a saved UI window appears on screen when you reload it, regardless of the target computer screen size and resolution. Create a figure that is off the screen, assign `movegui` as its CreateFcn callback, save the figure, and then reload it.

```
f = figure('Position',[10000,10000,400,300]);
% The figure does not display because
% it is created offscreen.
```

```
f.CreateFcn = @movegui;
hgsave(f,'onscreenfig');
close(f);
f2 = hgload('onscreenfig');
% The reloaded figure is now visible
```

Move a figure to the bottom left corner of the screen.

```
f = figure;
movegui(f,'southwest');
```

Move a figure so that it is offset 100 pixels from the bottom and left side of the screen.

```
f = figure;
movegui(f,[100,100]);
```

`guide` | `openfig`

Introduced before R2006a

movie

Play recorded movie frames

Syntax

```
movie(M)
movie(M,n)
movie(M,n,fps)
movie(h,...)
movie(h,M,n,fps,loc)
```

Description

The `movie` function plays the movie defined by a matrix whose columns are movie frames (usually produced by `getframe`).

`movie(M)` plays the movie in matrix `M` once, using the current axes as the default target. If you want to play the movie in the figure instead of the axes, specify the figure handle (or `gcf`) as the first argument: `movie(figure_handle,...)`. `M` must be an array of movie frames (usually from `getframe`).

`movie(M,n)` plays the movie `n` times. If `n` is negative, each cycle is shown forward then backward. If `n` is a vector, the first element is the number of times to play the movie, and the remaining elements make up a list of frames to play in the movie.

For example, if `M` has four frames then `n = [10 4 4 2 1]` plays the movie ten times, and the movie consists of frame `4` followed by frame `4` again, followed by frame `2` and finally frame `1`.

`movie(M,n,fps)` plays the movie at `fps` frames per second. The default is 12 frames per second. Computers that cannot achieve the specified speed play as fast as possible.

`movie(h,...)` plays the movie centered in the figure or axes identified by the handle `h`. Specifying the figure or axes enables MATLAB to fit the movie to the available size.

`movie(h,M,n,fps,loc)` specifies `loc`, a four-element location vector, `[x y 0 0]`, where the lower left corner of the movie frame is anchored (only the first two elements in

the vector are used). The location is relative to the lower left corner of the figure or axes specified by `handle h` and in units of pixels, regardless of the object's `Units` property.

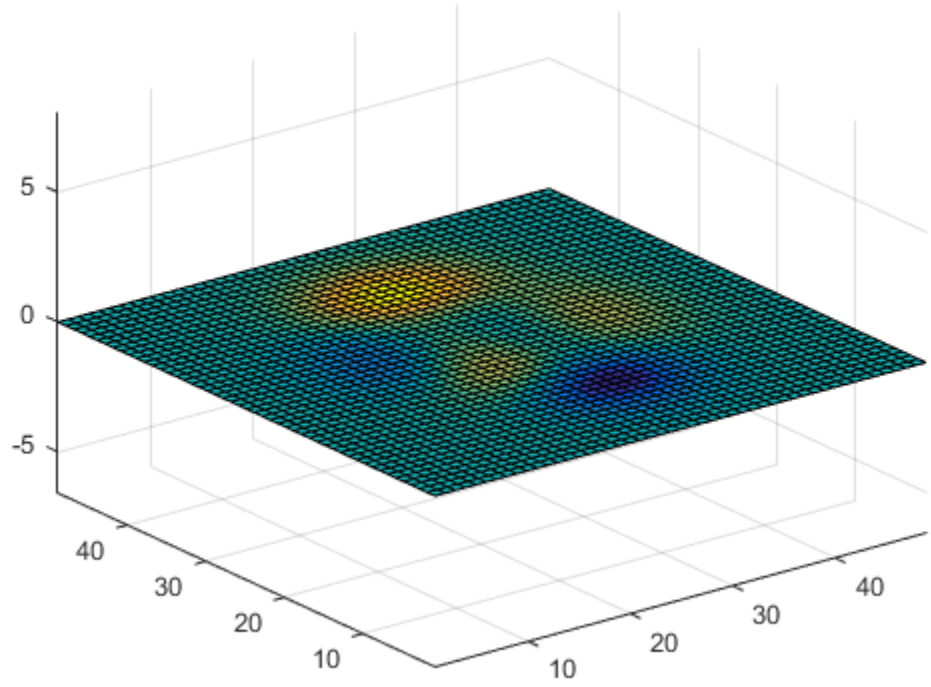
Examples

Record Frames and Play Movie

Use the `getframe` function in a loop to record frames of the `peaks` function vibrating. Preallocate an array to store the movie frames.

```
figure
Z = peaks;
surf(Z)
axis tight manual
ax = gca;
ax.NextPlot = 'replaceChildren';

loops = 40;
F(loops) = struct('cdata',[],'colormap',[]);
for j = 1:loops
    X = sin(j*pi/10)*Z;
    surf(X,Z)
    drawnow
    F(j) = getframe;
end
```



To play the movie two times, use `movie(F,2)`.

More About

Tips

The `movie` function uses a default figure size of 560-by-420 and does not resize figures to fit movies with larger or smaller frames. To accommodate other frame sizes, you can resize the figure to fit the movie, as shown in the second example below.

`movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale or 24–bit truecolor image frames.

Buffering the movie places all frames in memory. As a result, on Microsoft Windows and perhaps other platforms, a long movie (on the order of several hundred frames) can exhaust memory, depending on system resources. In such cases an error message is issued:

```
??? Error using ==> movie
Could not create movie frame
```

You can abort a movie by typing **Ctrl-C**.

`movie` is not a built-in function. Therefore, you cannot call `movie` using the `builtin` function.

Limitations with Renderer on Windows Systems

Setting the figure `Renderer` property to `painters` works around limitations of using `getframe` with the `OpenGL` renderer on some Windows systems.

- "Record Animation for Playback"

See Also

`getframe` | `frame2im` | `im2frame` | `VideoReader` | `VideoWriter`

Introduced before R2006a

movie2avi

Create Audio/Video Interleaved (AVI) file from MATLAB movie

Note: `movie2avi` will be removed in a future release. Use `VideoWriter` instead.

Syntax

```
movie2avi(mov, filename)
movie2avi(mov, filename, ParameterName, ParameterValue)
```

Description

`movie2avi(mov, filename)` creates the AVI file *`filename`* from the MATLAB movie *`mov`*. The *`filename`* input is a string. The *`mov`* input is a 1-by-*`n`* structure array, where *`n`* is the number of frames. Each frame is a structure with two fields: `cdata` and `colormap`. For more information, see `getframe`.

`movie2avi(mov, filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. The following table lists the available parameters and values.

Parameter Name	Value	Default
`'colormap'`	An *`m`*-by-3 matrix defining the colormap for indexed AVI movies, where *`m`* is no more than 256 (236 for `Indeo` compression). Valid only when the `'compression'` is `'MSVC'`, `'RLE'`, or `'None'`.	No default
`'compression'`	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of `'None'`. On UNIX operating systems, the only valid value is `'None'`.	`'Indeo5'` on Windows systems. `'None'` on UNIX systems.

Parameter Name	Value	Default
	On Windows systems, valid values include: • `'MSVC'` • `'RLE'` • `'Cinepak'` on 32-bit systems. • `'Indeo3'` or `'Indeo5'` on 32-bit Windows XP systems. Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.	
`'fps'`	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
`'keyframe'`	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
`'quality'`	A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes. Valid only for compressed movies.	75
`'videoname'`	A descriptive name for the video stream, no more than 64 characters.	*`filename`*

Examples

Create a movie and write to an uncompressed AVI file, `myPeaks.avi`:

```
nFrames = 20;

% Preallocate movie structure.
mov(1:nFrames) = struct('cdata', [],...
                        'colormap', []);
```

```
% Create movie.
Z = peaks; surf(Z);
axis tight manual
set(gca,'nextplot','replacechildren');
for k = 1:nFrames
   surf(sin(2*pi*k/20)*Z,Z)
   mov(k) = getframe(gcf);
end

% Create AVI file.
movie2avi(mov, 'myPeaks.avi', 'compression', 'None');
```

More About

Tips

- On some Windows systems, including all 64-bit systems, the default Indeo 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer. Consider specifying a `compression` value of `'None'`.

Introduced before R2006a

mpower, ^

Matrix power

Syntax

```
C = A^B
C = mpower(A,B)
```

Description

`C = A^B` computes `A` to the `B` power and returns the result in `C`.

`C = mpower(A,B)` is an alternate way to execute `A^B`, but is rarely used. It enables operator overloading for classes.

Examples

Square a Matrix

Create a 2-by-2 matrix and square it.

```
A = [1 2; 3 4];
C = A^2
```

```
C =

     7    10
    15    22
```

The syntax `A^2` is equivalent to `A*A`.

Matrix Exponents

Create a 2-by-2 matrix and use it as the exponent for a scalar.

```
B = [0 1; 1 0];
```

```
C = 2^B

C =

    1.2500    0.7500
    0.7500    1.2500
```

Compute `C` by first finding the eigenvalues `D` and eigenvectors `V` of the matrix `B`.

```
[V,D] = eig(B)

V =

   -0.7071    0.7071
    0.7071    0.7071

D =

    -1     0
     0     1
```

Next, use the formula `2^B = V*2^D/V` to compute the power.

```
C = V*2^D/V

C =

    1.2500    0.7500
    0.7500    1.2500
```

Input Arguments

A — Base

scalar | matrix

Base, specified as a scalar or matrix. Inputs `A` and `B` must be one of the following:

- Base `A` is a square matrix and exponent `B` is a scalar. If `B` is a positive integer, the power is computed by repeated squaring. For other values of `B` the calculation involves eigenvalues and eigenvectors.
- Base `A` is a scalar and exponent `B` is a square matrix. The calculation uses eigenvalues and eigenvectors.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

B — Exponent

scalar | matrix

Exponent, specified as a scalar or matrix. Inputs A and B must be one of the following:

- Base A is a square matrix and exponent B is a scalar. If B is a positive integer, the power is computed by repeated squaring. For other values of B the calculation involves eigenvalues and eigenvectors.
- Base A is a scalar and exponent B is a square matrix. The calculation uses eigenvalues and eigenvectors.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

mput

Class: FTP

Upload file or folder to FTP server

Syntax

```
mput(ftpobj,contents)
paths = mput(ftpobj,contents)
```

Description

`mput(ftpobj,contents)` uploads the file or folder specified by contents to the current folder on an FTP server.

`paths = mput(ftpobj,contents)` returns a cell array that lists the paths to the uploaded files on the server.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`contents`

String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (`*`).

Output Arguments

`paths`

Cell array that includes the paths to the uploaded files on the server.

Examples

Suppose that your current MATLAB folder contains files `myfile1.m` through `myfile10.m`, and that you want to upload to a hypothetical FTP server, `ftp.testsite.com`. Connect to the server and upload the files:

```
test = ftp('ftp.testsite.com');
mput(test, 'myfile*.m');
close(test);
```

Introduced before R2006a

msgbox

Create message dialog box

Syntax

```
h = msgbox(Message)
h = msgbox(Message,Title)
h = msgbox(Message,Title,Icon)
h = msgbox(Message,Title,'custom',IconData,IconCMap)
h = msgbox(___,CreateMode)
```

Description

`h = msgbox(Message)` creates a message dialog box that automatically wraps Message to fit an appropriately sized figure.

`h = msgbox(Message,Title)` specifies the title of the message box.

`h = msgbox(Message,Title,Icon)` specifies which built-in icon to display in the message dialog box.

`h = msgbox(Message,Title,'custom',IconData,IconCMap)` specifies a custom icon to include in the message dialog box. IconData is the image data that defines the icon. IconCMap is the colormap used for the image. If IconData is a true-color image, you do not need to specify an IconCMap.

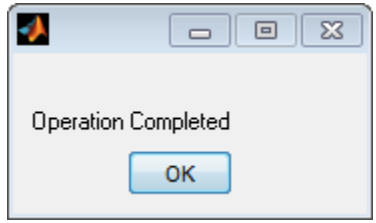
`h = msgbox(___,CreateMode)` specifies whether the message box is modal. Additionally, you can specify a TeX interpreter for Message and Title.

Examples

Simple Message Dialog Box

Specify the text you want displayed in the message dialog box.

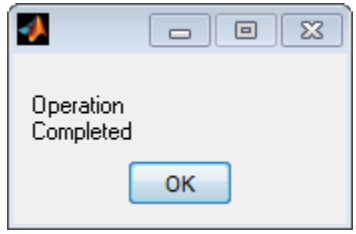
```
h = msgbox('Operation Completed');
```



Message Dialog Box Text with Line Breaks

Specify the message dialog box text using a cell array of strings to insert line breaks between the display of each string in the cell array.

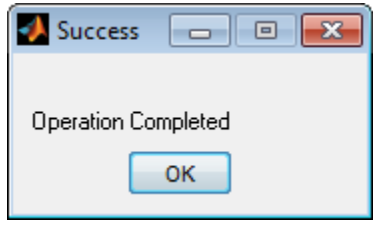
```
h = msgbox({'Operation' 'Completed'});
```



Message Dialog Box with a Title

Specify the message dialog box text and give the dialog box a title, `Success`.

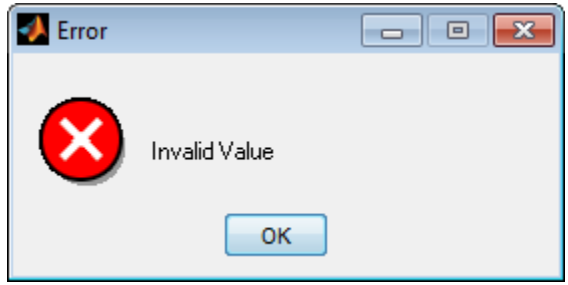
```
h = msgbox('Operation Completed','Success');
```



Message Dialog Box That Uses a Built-in Icon

Include a built-in error icon with an error message in a message dialog box entitled Error.

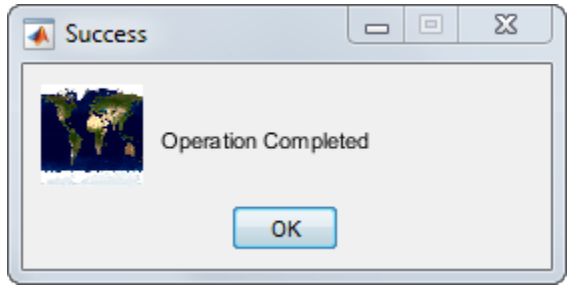
```
h = msgbox('Invalid Value', 'Error','error');
```



Message Dialog Box That Uses a True-Color Custom Icon

Read an RGB image into the workspace. Then, specify it as a custom icon in the dialog box.

```
myicon = imread('landOcean.jpg');
h=msgbox('Operation Completed','Success','custom',myicon);
```



Message Dialog Box That Uses an Indexed Color Icon

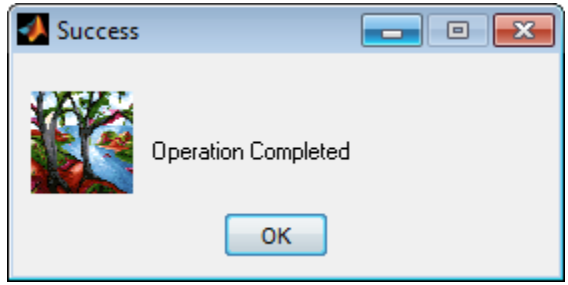
Use `trees.tiff` (which is on the MATLAB path) as an icon in your message dialog box. Because `.tiff` images use a colormap to define the colors, you must specify a colormap. Change the colormap to change the image colors.

Determine the value to specify for IconData by passing the image file to `imread`.

```
[cdata,map] = imread('trees.tif');
```

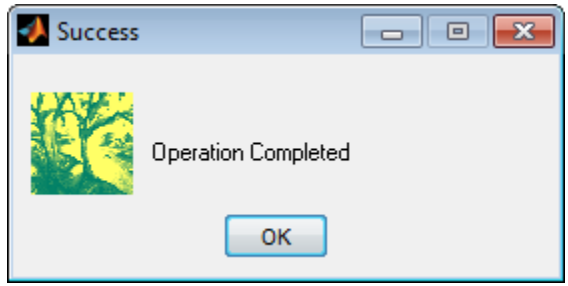
Create the message dialog box, including the custom icon.

```
h=msgbox('Operation Completed',...
         'Success','custom',cdata,map);
```



Adjust the image colors by specifying a different colormap. For instance, specify the MATLAB built-in colormap, `summer`

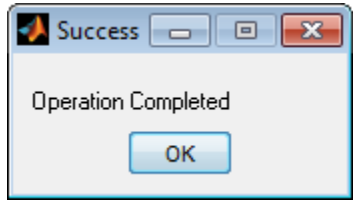
```
h=msgbox('Operation Completed','Success','custom',...
         cdata,summer);
```



Modal Message Dialog Box

Create a modal message dialog box, wrapping the call to `msgbox` with `uiwait` to make the message dialog box block MATLAB execution until the user responds to the message dialog box.

```
uiwait(msgbox('Operation Completed','Success','modal'));
```



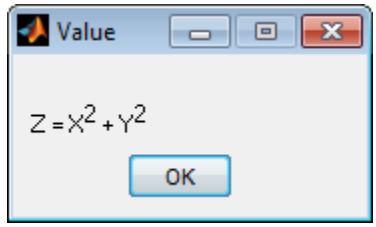
Modal Message Dialog Box That Uses a TeX Formatted Message

Create a structure to specify that the user must click OK before interacting with another window and that MATLAB interpret the message text as TeX format.

```
CreateStruct.Interpreter = 'tex';
CreateStruct.WindowStyle = 'modal';
```

Create the message dialog box.

```
h=msgbox('Z = X^2 + Y^2','Value',CreateStruct);
```



Input Arguments

`Message` — Message dialog box text

string vector | string matrix | cell array

Dialog box text specified as a string vector, string matrix, or cell array.

Example: `'Operation Completed'`

Example: `['Operation ', 'Completed']`

Example: `{'Operation', 'Completed'}`

`Title` — Message dialog box title bar text

string vector

Dialog box title bar text specified as a string vector.

Example: `'Success'`

`Icon` — Icon to include in message dialog box

`'none'` (default) | `'error'` | `'help'` | `'warn'` | `'custom'`

Icon to include in message dialog box specified as a string.

Built-in icons appear as follows:

-  Error
-  Help
-  Warn

`IconData` — Image data defining a custom icon

matrix

Image data defining a custom icon specified as a matrix. Each element of the matrix specifies the color of a rectangular segment in the image. Use `imread` to get the IconData value for an image that you want to use as a message dialog box icon.

Example: [1:64]'*[1:64])/64

`IconCMap` — Colormap for a custom icon that is not true-color

m–by–3 matrix | built-in colormap

Colormap for a custom icon that is not true-color, specified as an m-by-3 matrix of real numbers between `0.0` and `1.0`, or as a MATLAB built-in colormap. Use `imread` to get the IconCMap value for an image that you want to use as a message dialog box icon.

Example: [0.5 0.5 0.5]

Example: hot(64)

`CreateMode` — Message dialog box mode

`'nonmodal'` (default) | structure | `'modal'` | `'replace'`

Mode in which message dialog box is created, specified as a string or a structure.

- If CreateMode is a structure, it can have the fields `WindowStyle` and `Interpreter`. The `WindowStyle` field must be one of the strings listed in the list items that

follow this one. The `Interpreter` field must be the string `'tex'` or `'none'`. If the `Interpreter` value is `'tex'`, MATLAB interprets the Message and Title values as TeX. The default value for `Interpreter` is `'none'`.

- If CreateMode is `'nonmodal'`, MATLAB creates a new nonmodal message box with the specified parameters. Existing message boxes with the same Title remain.
- If CreateMode is `'modal'`, MATLAB replaces the existing message box with the specified Title that was last created or clicked on with the specified modal dialog box. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.
- If CreateMode is `'replace'`, MATLAB replaces the message box having the specified Title that was last created or clicked on with a nonmodal message box as specified. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.

Example: CreateStruct.Interpreter='tex';

Output Arguments

h — Message dialog box handle

scalar

Message dialog box handle returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific message dialog box.

More About

modal dialog box

A modal dialog box prevents a user from interacting with other windows before responding to the modal dialog box.

For more information about modal dialog boxes, see WindowStyle in the Figure Properties topic.

Tips

- Program execution continues even when a modal dialog box is active. To block MATLAB program execution until the user responds to the modal dialog box, use the `uiwait` function.

- Modal dialogs (created using `errordlg`, `msgbox`, or `warndlg`) replace any existing dialogs created with these functions that also have the same name.
- "Reading Image Data"

Introduced before R2006a

mtimes, *

Matrix Multiplication

Syntax

```
C = A*B
C = mtimes(A,B)
```

Description

`C = A*B` is the matrix product of `A` and `B`. If `A` is an m-by-p and `B` is a p-by-n matrix, then `C` is an m-by-n matrix defined by

$$C(i,j) = \sum_{k=1}^{p} A(i,k)B(k,j).$$

This definition says that `C(i,j)` is the inner product of the `i`th row of `A` with the `j`th column of `B`. You can write this definition using the MATLAB colon operator as

```
C(i,j) = A(i,:)*B(:,j)
```

For nonscalar `A` and `B`, the number of columns of `A` must equal the number of rows of `B`. Matrix multiplication is *not* universally commutative for nonscalar inputs. That is, `A*B` is typically not equal to `B*A`. If at least one input is scalar, then `A*B` is equivalent to `A.*B` and is commutative.

`C = mtimes(A,B)` is an alternative way to execute `A*B`, but is rarely used. It enables operator overloading for classes.

Examples

Multiply Two Vectors

Create a 1-by-4 row vector, `A`, and a 4-by-1 column vector, `B`.

```
A = [1 1 0 0];
B = [1; 2; 3; 4];
```

Multiply A times B.

```
C = A*B
```

```
C =

     3
```

The result is a 1-by-1 scalar, also called the *dot product* or *inner product* of the vectors A and B. Alternatively, you can calculate the dot product A · B with the syntax `dot(A,B)`.

Multiply B times A.

```
C = B*A
```

```
C =

     1     1     0     0
     2     2     0     0
     3     3     0     0
     4     4     0     0
```

The result is a 4-by-4 matrix, also called the *outer product* of the vectors A and B. The outer product of two vectors, A ⊗ B, returns a matrix.

Multiply Two Arrays

Create two arrays, A and B.

```
A = [1 3 5; 2 4 7];
B = [-5 8 11; 3 9 21; 4 0 8];
```

Calculate the product of A and B.

```
C = A*B
```

```
C =

    24    35   114
    30    52   162
```

Calculate the inner product of the second row of A and the third column of B.

```
A(2,:)*B(:,3)
```

```
ans =
```

```
162
```

This answer is the same as `C(2,3)`.

Input Arguments

`A` — Left Array

scalar | vector | matrix

Left Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in `A` must be equal to the number of rows in `B`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `duration` | `calendarDuration`
Complex Number Support: Yes

`B` — Right Array

scalar | vector | matrix

Right Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in `A` must be equal to the number of rows in `B`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `duration` | `calendarDuration`
Complex Number Support: Yes

Output Arguments

`C` — Product Array

scalar | vector | matrix

Product Array, returned as a scalar, vector, or matrix. Array `C` has the same number of rows as input `A` and the same number of columns as input `B`. For example, if `A` is an m-by-0 empty matrix and `B` is a 0-by-n empty matrix, then `A*B` is an m-by-n matrix of zeros.

Introduced before R2006a

mu2lin

Convert mu-law audio signal to linear

Syntax

```
y = mu2lin(mu)
```

Description

`y = mu2lin(mu)` converts mu-law encoded 8-bit audio signals, stored as “flints” in the range $0 \le$ `mu` ≤ 255, to linear signal amplitude in the range `-s < Y < s` where `s = 32124/32768 ~= .9803`. The input `mu` is often obtained using `fread(...,'uchar')` to read byte-encoded audio files. "Flints" are MATLAB integers — floating-point numbers whose values are integers.

`auread` | `lin2mu`

Introduced before R2006a

multibandread

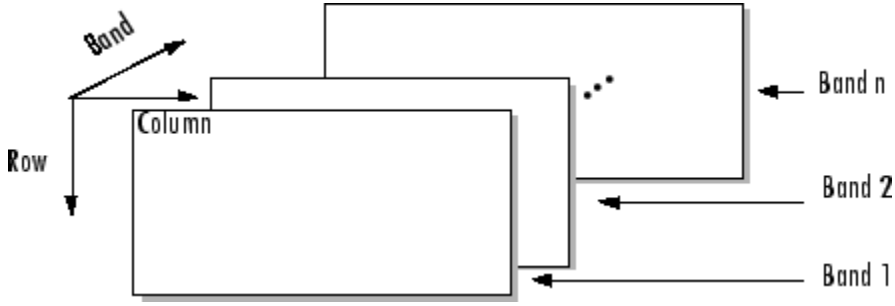
Read band-interleaved data from binary file

Syntax

```
X = multibandread(filename, size, precision, offset, interleave,
byteorder)
X = multibandread(...,subset1,subset2,subset3)
```

Description

`X = multibandread(filename, size, precision, offset, interleave, byteorder)` reads band-sequential (BSQ), band-interleaved-by-line (BIL), or band-interleaved-by-pixel (BIP) data from the binary file `filename`. The `filename` input is a string enclosed in single quotes. This function defines *band* as the third dimension in a 3-D array, as shown in this figure.



You can use the parameters to `multibandread` to specify many aspects of the read operation, such as which bands to read. See “Parameters” on page 1-5269 for more information.

`X` is a 2-D array if only one band is read; otherwise it is 3-D. `X` is returned as an array of data type `double` by default. Use the `precision` parameter to map the data to a different data type.

`X = multibandread(...,subset1,subset2,subset3)` reads a subset of the data in the file. You can use up to three subsetting parameters to specify the data subset along row, column, and band dimensions. See "Subsetting Parameters" on page 1-5270 for more information.

Note: In addition to BSQ, BIL, and BIP files, multiband imagery may be stored using the TIFF file format. In that case, use the `imread` function to import the data.

Parameters

This table describes the arguments accepted by `multibandread`.

Argument	Description
`filename`	String containing the name of the file to be read.
`size`	Three-element vector of integers consisting of `[height, width, N]`, where • `height` is the total number of rows • `width` is the total number of elements in each row • `N` is the total number of bands. This will be the dimensions of the data if it is read in its entirety.
`precision`	String specifying the format of the data to be read, such as `'uint8'`, `'double'`, `'integer*4'`, or any of the other precisions supported by the `fread` function. Note: You can also use the `precision` parameter to specify the format of the output data. For example, to read `uint8` data and output a `uint8` array, specify a precision of `'uint8=>uint8'` (or `'*uint8'`). To read `uint8` data and output it in the MATLAB software in single precision, specify `'uint8=>single'`. See `fread` for more information.
`offset`	Scalar specifying the zero-based location of the first data element in the file. This value represents the number of bytes from the beginning of the file to where the data begins.
`interleave`	String specifying the format in which the data is stored

Argument	Description
	• `'bsq'` — Band-Sequential • `'bil'` — Band-Interleaved-by-Line • `'bip'` — Band-Interleaved-by-Pixel For more information about these interleave methods, see the `multibandwrite` reference page.
`byteorder`	String specifying the byte ordering (machine format) in which the data is stored, such as • `'ieee-le'` — Little-endian • `'ieee-be'` — Big-endian See `fopen` for a complete list of supported formats.

Subsetting Parameters

You can specify up to three subsetting parameters. Each subsetting parameter is a three-element cell array, {*dim*,*method*,index}, where

Parameter	Description
dim	Text string specifying the dimension to subset along. It can have any of these values: • `'Column'` • `'Row'` • `'Band'`
method	Text string specifying the subsetting method. It can have either of these values: • `'Direct'` • `'Range'` If you leave out this element of the subset cell array, `multibandread` uses `'Direct'` as the default.

Parameter	Description
`index`	If `method` is `'Direct'`, `index` is a vector specifying the indices to read along the Band dimension. If `method` is `'Range'`, `index` is a three-element vector of `[start, increment, stop]` specifying the range and step size to read along the dimension specified in `dim`. If `index` is a two-element vector, `multibandread` assumes that the value of `increment` is `1`.

Examples

Example 1

Setup initial parameters for a data set.

```
rows=3; cols=3; bands=5;
filename = tempname;
```

Define the data set.

```
fid = fopen(filename, 'w', 'ieee-le');
fwrite(fid, 1:rows*cols*bands, 'double');
fclose(fid);
```

Read every other band of the data using the Band-Sequential format.

```
im1 = multibandread(filename, [rows cols bands], ...
                    'double', 0, 'bsq', 'ieee-le', ...
                    {'Band', 'Range', [1 2 bands]} )
```

Read the first two rows and columns of data using Band-Interleaved-by-Pixel format.

```
im2 = multibandread(filename, [rows cols bands], ...
                    'double', 0, 'bip', 'ieee-le', ...
                    {'Row', 'Range', [1 2]}, ...
                    {'Column', 'Range', [1 2]} )
```

Read the data using Band-Interleaved-by-Line format.

```
im3 = multibandread(filename, [rows cols bands], ...
```

```
                    'double', 0, 'bil', 'ieee-le')
```

Delete the file created in this example.

```
delete(filename);
```

Example 2

Read `int16` BIL data from the FITS file `tst0012.fits`, starting at byte 74880.

```
im4 = multibandread('tst0012.fits', [31 73 5], ...
                    'int16', 74880, 'bil', 'ieee-be', ...
                    {'Band', 'Range', [1 3]} );
im5 = double(im4)/max(max(max(im4)));
imagesc(im5);
```

`fread` | `fwrite` | `imread` | `memmapfile` | `multibandwrite`

Introduced before R2006a

multibandwrite

Write band-interleaved data to file

Syntax

```
multibandwrite(data,filename,interleave)
multibandwrite(data,filename,interleave,start,totalsize)
multibandwrite(...,param,value...)
```

Description

`multibandwrite(data,filename,interleave)` writes `data`, a two- or three-dimensional numeric or logical array, to the binary file specified by `filename`. The `filename` input is a string enclosed in single quotes. The length of the third dimension of `data` determines the number of bands written to the file. The bands are written to the file in the form specified by `interleave`. See "Interleave Methods" on page 1-5274 for more information about this argument.

If filename already exists, `multibandwrite` overwrites it unless you specify the optional `offset` parameter. See the last alternate syntax for `multibandwrite` for information about other optional parameters.

`multibandwrite(data,filename,interleave,start,totalsize)` writes `data` to the binary file `filename` in chunks. In this syntax, `data` is a subset of the complete data set.

`start` is a 1-by-3 array `[firstrow firstcolumn firstband]` that specifies the location to start writing data. `firstrow` and `firstcolumn` specify the location of the upper left image pixel. `firstband` gives the index of the first band to write. For example, `data(I,J,K)` contains the data for the pixel at `[firstrow+I-1, firstcolumn+J-1]` in the `(firstband+K-1)`-th band.

`totalsize` is a 1-by-3 array, `[totalrows,totalcolumns,totalbands]`, which specifies the full, three-dimensional size of the data to be written to the file.

Note In this syntax, you must call `multibandwrite` multiple times to write all the data to the file. The first time it is called, `multibandwrite` writes the complete file,

using the fill value for all values outside the data subset. In each subsequent call, `multibandwrite` overwrites these fill values with the data subset in `data`. The parameters `filename`, `interleave`, `offset`, and `totalsize` must remain constant throughout the writing of the file.

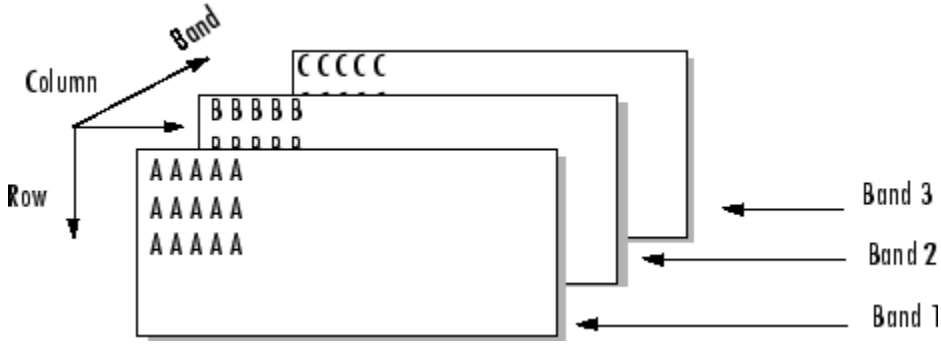
`multibandwrite(...,param,value...)` writes the multiband data to a file, specifying any of these optional parameter/value pairs.

Parameter	Description
`'precision'`	String specifying the form and size of each element written to the file. See the help for `fwrite` for a list of valid values. The default precision is the class of the data.
`'offset'`	The number of bytes to skip before the first data element. If the file does not already exist, `multibandwrite` writes ASCII null values to fill the space. To specify a different fill value, use the parameter `'fillvalue'`. This option is useful when you are writing a header to the file before or after writing the data. When writing the header to the file after the data is written, open the file with `fopen` using `'r+'` permission.
`'machfmt'`	String to control the format in which the data is written to the file. Typical values are `'ieee-le'` for little endian and `'ieee-be'` for big endian. See the help for `fopen` for a complete list of available formats. The default machine format is the local machine format.
`'fillvalue'`	A number specifying the value to use in place of missing data. `'fillvalue'` can be a single number, specifying the fill value for all missing data, or a 1-by-Number-of-bands vector of numbers specifying the fill value for each band. This value is used to fill space when data is written in chunks.

Interleave Methods

`interleave` is a string that specifies how `multibandwrite` interleaves the bands as it writes data to the file. If `data` is two-dimensional, `multibandwrite` ignores the

`interleave` argument. The following table lists the supported methods and uses this example multiband file to illustrate each method.



Supported methods of interleaving bands include those listed below.

Method	String	Description	Example
Band-Interleaved-by-Line	`'bil'`	Write an entire row from each band	AAAAABBBBBCCCCC AAAAABBBBBCCCCC AAAAABBBBBCCCCC
Band-Interleaved-by-Pixel	`'bip'`	Write a pixel from each band	ABCABCABCABCABC...
Band-Sequential	`'bsq'`	Write each band in its entirety	AAAAA AAAAA AAAAA BBBBB BBBBB BBBBB CCCCC CCCCC CCCCC

Examples

Note To run these examples successfully, you must be in a writable directory.

Example 1

Write all data (interleaved by line) to the file in one call.

```
data = reshape(uint16(1:600), [10 20 3]);
multibandwrite(data,'data.bil','bil');
```

Example 2

Write a single-band tiled image with one call for each tile. This is only useful if a subset of each band is available at each call to `multibandwrite`.

```
numBands = 1;
dataDims = [1024 1024 numBands];
data = reshape(uint32(1:(1024 * 1024 * numBands)), dataDims);

for band = 1:numBands
   for row = 1:2
      for col = 1:2

         subsetRows = ((row - 1) * 512 + 1):(row * 512);
         subsetCols = ((col - 1) * 512 + 1):(col * 512);

         upperLeft = [subsetRows(1), subsetCols(1), band];
         multibandwrite(data(subsetRows, subsetCols, band), ...
                        'banddata.bsq', 'bsq', upperLeft, dataDims);

      end
   end
end
```

`multibandread` | `fwrite` | `fread`

Introduced before R2006a

munlock

Allow clearing functions from memory

Syntax

```
munlock
munlock fun
munlock('fun')
```

Description

`munlock` unlocks the currently running `.m` or `.mex` function in memory so that subsequent `clear` functions can remove it.

`munlock fun` unlocks the `.m` or `.mex` file named `fun` from memory. By default, these files are unlocked so that changes to the file are picked up. Calls to munlock are needed only to unlock `.m` or `.mex` functions that have been locked with `mlock`.

`munlock('fun')` is the function form of `munlock`.

Examples

The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
  .
  .
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked testfun
ans =
```

```
     1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock testfun

mislocked testfun
ans =
     0
```

See Also

`mlock` | `mislocked` | `inmem` | `persistent`

Introduced before R2006a

namelengthmax

Maximum identifier length

Syntax

```
len = namelengthmax
```

Description

`len = namelengthmax` returns the maximum length allowed for MATLAB identifiers, which include:

- Variable names
- Structure field names
- Script, function, and class names
- Model names

Rather than hard-coding a specific maximum name length into your programs, use the `namelengthmax` function. This saves you the trouble of having to update these limits should the identifier length change in some future MATLAB release.

Examples

Call `namelengthmax` to get the maximum identifier length:

```
maxid = namelengthmax
maxid =
    63
```

See Also

`isvarname` | `matlab.lang.makeValidName` | `matlab.lang.makeUniqueStrings`

Introduced before R2006a

NaN

Not-a-Number

Syntax

```
NaN
N = NaN(n)
N = NaN(sz1,...,szN)
N = NaN(sz)

N = NaN(classname)
N = NaN(n,classname)
N = NaN(sz1,...szN,classname)
N = NaN(sz,classname)

N = NaN('like',p)
N = NaN(n,'like',p)
N = NaN(sz1,...szN,'like',p)
N = NaN(sz,'like',p)
```

Description

`NaN` returns the IEEE arithmetic representation for Not-a-Number (`NaN`). These values result from operations which have undefined numerical results.

`N = NaN(n)` is an `n`-by-`n` matrix of `NaN` values.

`N = NaN(sz1,...,szN)` is a `sz1`-by-...-by-`szN` array of `NaN` values where `sz1,...,szN` indicates the size of each dimension. For example, `NaN(3,4)` returns a 3-by-4 array of `NaN` values.

`N = NaN(sz)` is an array of `NaN` values where the size vector, `sz`, defines `size(N)`. For example, `NaN([3,4])` returns a 3-by-4 array of `NaN` values.

Note The size inputs `sz1,...,szN`, as well as the elements of the size vector `sz`, should be nonnegative integers. Negative integers are treated as 0.

`N = NaN(classname)` returns a `NaN` value where the string, `classname`, specifies the data type. `classname` can be either `'single'` or `'double'`.

`N = NaN(n,classname)` returns an `n`-by-`n` array of `NaN` values of data type `classname`.

`N = NaN(sz1,...szN,classname)` returns a `sz1`-by-...-by-`szN` array of `NaN` values of data type `classname`.

`N = NaN(sz,classname)` returns an array of `NaN` values where the size vector, `sz`, defines `size(N)` and `classname` defines `class(N)`.

`N = NaN('like',p)` returns a `NaN` value of the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`N = NaN(n,'like',p)` returns an `n`-by-`n` array of `NaN` values like `p`.

`N = NaN(sz1,...szN,'like',p)` returns a `sz1`-by-...-by-`szN` array of `NaN` values like `p`.

`N = NaN(sz,'like',p)` returns an array of `NaN` values like `p` where the size vector, `sz`, defines `size(N)`.

Examples

These operations produce `NaN`:

- Any arithmetic operation on a `NaN`, such as `sqrt(NaN)`
- Addition or subtraction, such as magnitude subtraction of infinities as `(+Inf)+(-Inf)`
- Multiplication, such as `0*Inf`
- Division, such as `0/0` and `Inf/Inf`
- Remainder, such as `rem(x,y)` where `y` is zero or `x` is infinity

More About

Tips

Because two `NaN`s are not equal to each other, logical operations involving `NaN`s always return false, except ~= (not equal). Consequently,

```
NaN ~= NaN
ans =
     1
NaN == NaN
ans =
     0
```

and the NaNs in a vector are treated as different unique elements.

```
unique([1 1 NaN NaN])
ans =
     1 NaN NaN
```

Use the `isnan` function to detect NaNs in an array.

```
isnan([1 1 NaN NaN])
ans =
     0     0     1     1
```

- "Class Support for Array-Creation Functions"

`inf` | `isfinite` | `isfloat` | `isnan`

Introduced before R2006a

nargchk

Validate number of input arguments

Note: `nargchk` will be removed in a future version. Use `narginchk` instead.

Syntax

```
msgstring = nargchk(minargs, maxargs, numargs)
msgstring = nargchk(minargs, maxargs, numargs, 'string')
msgstruct = nargchk(minargs, maxargs, numargs, 'struct')
```

Description

Use `nargchk` inside a function to check that the desired number of input arguments is specified in the call to that function.

`msgstring = nargchk(minargs, maxargs, numargs)` returns an error message string `msgstring` if the number of inputs specified in the call `numargs` is less than `minargs` or greater than `maxargs`. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty matrix.

It is common to use the `nargin` function to determine the number of input arguments specified in the call.

`msgstring = nargchk(minargs, maxargs, numargs, 'string')` is essentially the same as the command shown above, as `nargchk` returns a string by default.

`msgstruct = nargchk(minargs, maxargs, numargs, 'struct')` returns an error message structure `msgstruct` instead of a string. The fields of the return structure contain the error message string and a message identifier. If `numargs` is between `minargs` and `maxargs` (inclusive), `nargchk` returns an empty structure.

When too few inputs are supplied, the message string and identifier are

```
message: 'Not enough input arguments.'
```

```
    identifier: 'MATLAB:nargchk:notEnoughInputs'
```

When too many inputs are supplied, the message string and identifier are

```
       message: 'Too many input arguments.'
    identifier: 'MATLAB:nargchk:tooManyInputs'
```

Examples

Given the function `CheckInputs`,

```
function CheckInputs(x, y, z)
error(nargchk(2, 3, nargin))
```

Then typing `CheckInputs(1)` produces

```
Not enough input arguments.
```

More About

Tips

`nargchk` is often used together with the `error` function. The `error` function accepts either type of return value from `nargchk`: a message string or message structure. For example, this command provides the `error` function with a message string and identifier regarding which error was caught:

```
error(nargchk(2, 4, nargin, 'struct'))
```

If `nargchk` detects no error, it returns an empty string or structure. When `nargchk` is used with the `error` function, as shown here, this empty string or structure is passed as an input to `error`. When `error` receives an empty string or structure, it simply returns and no error is generated.

See Also

`narginchk` | `nargin` | `nargoutchk` | `nargout` | `varargin` | `varargout` | `error`

Introduced before R2006a

nargin

Number of function input arguments

Syntax

```
nargin
nargin(fx)
```

Description

`nargin` returns the number of input arguments passed in the call to the currently executing function. Use this `nargin` syntax only in the body of a function.

`nargin(fx)` returns the number of input arguments that appear in the definition statement for function `fx`. If the function includes `varargin` in its definition, then `nargin` returns the negative of the number of inputs. For example, if function `foo` declares inputs `a`, `b`, and `varargin`, then `nargin('foo')` returns `-3`.

Input Arguments

`fx`

Either a function handle or a string in single quotes that specifies the name of a function.

Examples

Inputs to Current Function

Create a function in a file named `addme.m` that accepts up to two inputs, and identify the number of inputs with `nargin`.

```
function c = addme(a,b)

switch nargin
    case 2
```

```
        c = a + b;
    case 1
        c = a + a;
    otherwise
        c = 0;
end
```

Inputs Defined for a Function

Determine how many inputs a function can accept.

The function `addme` created in the previous example has two inputs in its declaration statement (`a` and `b`).

```
fx = 'addme';
nargin(fx)
```

```
ans =
     2
```

Function with varargin Input

Determine how many inputs a function that uses `varargin` can accept.

Define a function in a file named `mynewplot.m` that accepts numeric inputs `x` and `y` and any number of additional plot inputs using `varargin`.

```
function mynewplot(x,y,varargin)
   figure
   plot(x,y,varargin{:})
   title('My New Plot')
```

At the command line, query how many inputs `newplot` can accept.

```
fx = 'mynewplot';
nargin(fx)
```

```
ans =
    -3
```

The minus sign indicates that the third input is `varargin`. The `mynewplot` function can accept an indeterminate number of additional input arguments.

See Also

`nargout` | `narginchk` | `nargoutchk` | `varargin` | `varargout` | `inputname`

Introduced before R2006a

narginchk

Validate number of input arguments

Syntax

```
narginchk(minargs, maxargs)
```

Description

`narginchk(minargs, maxargs)` throws an error if the number of inputs specified in the call to the currently executing function is less than `minargs` or greater than `maxargs`. If the number of inputs is between `minargs` and `maxargs` (inclusive), `narginchk` does nothing.

When too few inputs are supplied, the message identifier and message are:

```
    identifier: 'MATLAB:narginchk:notEnoughInputs'
       message: 'Not enough input arguments.'
```

When too many inputs are supplied, the message identifier and message are:

```
    identifier: 'MATLAB:narginchk:tooManyInputs'
       message: 'Too many input arguments.'
```

Examples

This function uses `narginchk` to verify that a minimum of 2 and maximum of 5 input arguments are received from the calling function:

```
function check_inputs(A, B, varargin)
minargs=2;  maxargs=5;

% Number of inputs must be >=minargs and <=maxargs.
narginchk(minargs, maxargs)

fprintf('Received 2 required, %d optional inputs.\n\n', ...
    size(varargin, 2))
```

Call the example function, passing 1 input argument:

```
check_inputs(23)
Error using check_inputs
Not enough input arguments.
```

Call the function, passing 5 arguments:

```
check_inputs(23, 9, 15, 34, 62)
Received 2 required, 3 optional inputs.
```

Call the function, passing 6 arguments:

```
check_inputs(23, 9, 15, 34, 62, 6)
Error using check_inputs
Too many input arguments.
```

More About

Tips

- To verify that there are a minimum of `N` arguments, specify `inf` as `maxargs`. For example: `narginchk(5,inf)` throws an error when there are not at least five inputs.

See Also

`nargin` | `nargoutchk` | `nargout` | `varargin` | `varargout`

nargout

Number of function output arguments

Syntax

```
nargout
nargout(fx)
```

Description

`nargout` returns the number of output arguments specified in the call to the currently executing function. Use this `nargout` syntax only in the body of a function.

`nargout(fx)` returns the number of outputs that appear in the definition statement of function `fx`. If the function includes `varargout` in its definition, then `nargout` returns the negative of the number of outputs. For example, if function `foo` declares outputs `a`, `b`, and `varargout`, then `nargout('foo')` returns `-3`.

Input Arguments

`fx`

Either a function handle or a string in single quotes that specifies the name of a function.

Examples

Outputs for Current Function

Create a function in a file named `subtract.m` that calculates a second return value only when requested.

```
function [dif,absdif] = subtract(y,x)
```

```
dif = y - x;
if nargout > 1
   disp('Calculating absolute value')
   absdif = abs(dif);
end
```

Outputs Defined for a Function

Determine how many outputs a function can return.

The function named `subtract` created in the previous example has two outputs in its declaration statement (`dif` and `absdif`).

```
fx = 'subtract';
nargout(fx)

ans =
     2
```

Function with varargout Output

Determine how many outputs a function that uses `varargout` can return.

Define a function in a file named `mysize.m` that returns a vector of dimensions from the `size` function and the individual dimensions using `varargout`.

```
function [sizeVector,varargout] = mysize(x)
   sizeVector = size(x);
   varargout = cell(1,nargout-1);
   for k = 1:length(varargout)
      varargout{k} = sizeVector(k);
   end
```

At the command line, query how many outputs `mysize` can return.

```
fx = 'mysize';
nargout(fx)

ans =
    -2
```

The minus sign indicates that the second output is `varargout`. The `mysize` function can return an indeterminate number of additional outputs.

More About

Tips

- When you use a function as part of an expression, MATLAB calls the function with one output argument, so `nargout` within the function returns `1`. For example, given the following `if` statement and the `subtract` function defined in the Examples section, the value of `nargout` within the `subtract` function is `1`.

```
a = 1;
b = 2;
if subtract(a,b) < 0
   disp('Result is negative')
end
```

See Also

`nargin` | `nargoutchk` | `narginchk` | `varargout` | `varargin` | `inputname`

Introduced before R2006a

nargoutchk

Validate number of output arguments

Syntax

```
nargoutchk(minargs, maxargs)
```

Description

`nargoutchk(minargs, maxargs)` throws an error if the number of outputs specified in the call is less than `minargs` or greater than `maxargs`. If the number of outputs is between `minargs` and `maxargs` (inclusive), `nargoutchk` does nothing.

When too few outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:notEnoughOutputs'
       message: 'Not enough output arguments.'
```

When too many outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:tooManyOutputs'
       message: 'Too many output arguments.'
```

Examples

This function uses `nargoutchk` to verify that a minimum of 2 and maximum of 5 input arguments are passed back to the calling function:

```
function [varargout] = check_outputs(array_in)
minargs=2;  maxargs=5;

% Number of outputs must be >=minargs and <=maxargs.
nargoutchk(minargs, maxargs)

for k=1:nargout
    varargout{k} = array_in(k)*3;
end
```

Initialize input array X to a vector of 6 elements:

```
X = 5:7:40
X =
     5    12    19    26    33    40
```

Call the example function with 1 output argument. This is less than the minimum (2) that was specified by `nargoutchk` and results in an error:

```
A = check_outputs(X);

Error using check_outputs
Not enough output arguments.
```

Call the function with 4 output arguments. This is within the allowable bounds (2 to 5) specified by `nargoutchk`:

```
[A, B, C, D] = check_outputs(X);

[A, B, C, D]
ans =
    15    36    57    78
```

Call the function with 6 output arguments. This exceeds the maximum (5) that was specified by `nargoutchk` and results in an error:

```
[A, B, C, D, E, F] = check_outputs(X);

Error using check_outputs
Too many output arguments.
```

More About

Tips

- To verify that there are a minimum of `N` arguments, specify `inf` as `maxargs`. For example: `nargoutchk(5,inf)` throws an error when there are not at least five outputs.

`narginchk` | `nargin` | `nargout` | `varargout` | `varargin`

Introduced before R2006a

native2unicode

Convert numeric bytes to Unicode character representation

Syntax

```
unicodestr = native2unicode(bytes)
unicodestr = native2unicode(bytes, encoding)
```

Description

`unicodestr = native2unicode(bytes)` converts a numeric vector, `bytes`, from the user default encoding to Unicode character representation. `bytes` is treated as a stream of 8-bit bytes, and each value must be in the range [0,255]. Return value `unicodestr` is a `char` vector having the same general array shape as `bytes`.

`unicodestr = native2unicode(bytes, encoding)` converts `bytes` to Unicode representation assuming that the byte stream is in the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string (`''`) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. If `encoding` is unspecified or is the empty string (`''`), the default encoding scheme is used.

Note If `bytes` is a `char` vector, it is returned unchanged.

Examples

This example begins with a vector of bytes in an unknown character encoding scheme. The user-written function `detect_encoding` determines the encoding scheme. If successful, it returns the encoding scheme name or alias as a string. If unsuccessful, it throws an error represented by an MException object, `ME`. The example calls `native2unicode` to convert the bytes to Unicode representation:

```
try
   enc = detect_encoding(bytes);
```

```
    str = native2unicode(bytes, enc);
    disp(str);
catch ME
    rethrow(ME);
end
```

Note that the computer must be configured to display text in a language represented by the detected encoding scheme for the output of `disp(str)` to be correct.

See Also

`unicode2native`

Introduced before R2006a

nchoosek

Binomial coefficient or all combinations

Syntax

```
b = nchoosek(n,k)
C = nchoosek(v,k)
```

Description

`b = nchoosek(n,k)` returns the binomial coefficient, defined as $n!/((n–k)!\,k!)$. This is the number of combinations of `n` items taken `k` at a time.

`C = nchoosek(v,k)` returns a matrix containing all possible combinations of the elements of vector `v` taken `k` at a time. Matrix `C` has `k` columns and $n!/((n–k)!\,k!)$ rows, where n is `length(v)`.

Examples

Binomial Coefficient, "5 Choose 4"

```
b = nchoosek(5,4)
```

```
b =

     5
```

All Combinations of Five Numbers Taken Four at a Time

```
v = 2:2:10;
C = nchoosek(v,4)
```

```
C =

     2     4     6     8
     2     4     6    10
     2     4     8    10
```

```
     2     6     8    10
     4     6     8    10
```

All Combinations of Three Unsigned Integers Taken Two at a Time

```
v = uint16([10 20 30]);
C = nchoosek(v,uint16(2))
```

```
C =

     10     20
     10     30
     20     30
```

Input Arguments

n — Number of possible choices

scalar, real, nonnegative value

Number of possible choices, specified as a scalar value of any numeric type that is real and nonnegative.

Example: `10`

Example: `int16(10)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

k — Number of selected choices

scalar, real, nonnegative value

Number of selected choices, specified as a scalar value that is real and nonnegative. `k` can be any numeric type. However, `nchoosek(n,k)` requires that `n` and `k` be the same type or that at least one of them be of type `double`.

There are no restrictions on combining inputs of different types for `nchoosek(v,k)`.

Example: `3`

Example: `int16(3)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

v — Set of all choices

vector of numeric, `logical`, or `char` values

Set of all choices, specified as a vector of numeric, `logical`, or `char` values.

Example: `[1 2 3 4 5]`

Example: `[1+1i 2+1i 3+1i 4+1i]`

Example: `int16([1 2 3 4 5])`

Example: `[true false true false]`

Example: `['abcd']`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

Output Arguments

b — Binomial coefficient

nonnegative scalar value

Binomial coefficient, returned as a nonnegative scalar value. `b` is the same type as `n` and `k`. If `n` and `k` are of different types, then `b` is returned as the nondouble type.

C — All combinations of v

matrix

All combinations of `v`, returned as a matrix of the same type as `v`. Matrix `C` has `k` columns and $n!/((n–k)!\ k!)$ rows, where n is `length(v)`.

Each row of `C` contains a combination of `k` items chosen from `v`. The elements in each row of `C` are listed in the same order as they appear in `v`.

Limitations

- When `b = nchoosek(n,k)` is sufficiently large, `nchoosek` displays a warning that the result might not be exact. In this case, the result is only accurate to 15 digits for double-precision inputs, or 8 digits for single-precision inputs.

- `C = nchoosek(v,k)` is only practical for situations where `length(v)` is less than about `15`.

See Also

`perms`

Introduced before R2006a

ndgrid

Rectangular grid in N-D space

Syntax

```
[X1,X2,X3,...,Xn] = ndgrid(x1gv,x2gv,x3gv,...,xngv)
[X1,X2,...,Xn] = ndgrid(xgv)
```

Description

`[X1,X2,X3,...,Xn] = ndgrid(x1gv,x2gv,x3gv,...,xngv)` replicates the grid vectors `x1gv`,`x2gv`,`x3gv`,`...`,`xngv` to produce a full grid. This grid is represented by the output coordinate arrays `X1`,`X2`,`X3`,`...`,`Xn`. The ith dimension of any output array `Xi` contains copies of the grid vector `xigv`.

`[X1,X2,...,Xn] = ndgrid(xgv)` is the same as `[X1,X2,...,Xn] = ndgrid(xgv,xgv,...,xgv)`. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.

The coordinate arrays `[X1,X2,X3,...,Xn]` are typically used to evaluate functions of several variables and to create surface and volumetric plots.

Input Arguments

`xigv`

Grid vector specifying a series of grid point coordinates in the ith dimension.

`xgv`

Generic grid vector specifying a series of point coordinates.

Output Arguments

`Xi`

The `i`th dimension of the output array `Xi` are copies of elements of the grid vector `xigv`. The output arrays specify the full grid.

Examples

Evaluate Function Over Gridded Domain

Evaluate the function $x_1 e^{-x_1^2 - x_2^2}$ over the gridded domain $-2 < x_1 < 2$ and $-2 < x_2 < 2$.

Create a grid of values for the domain.

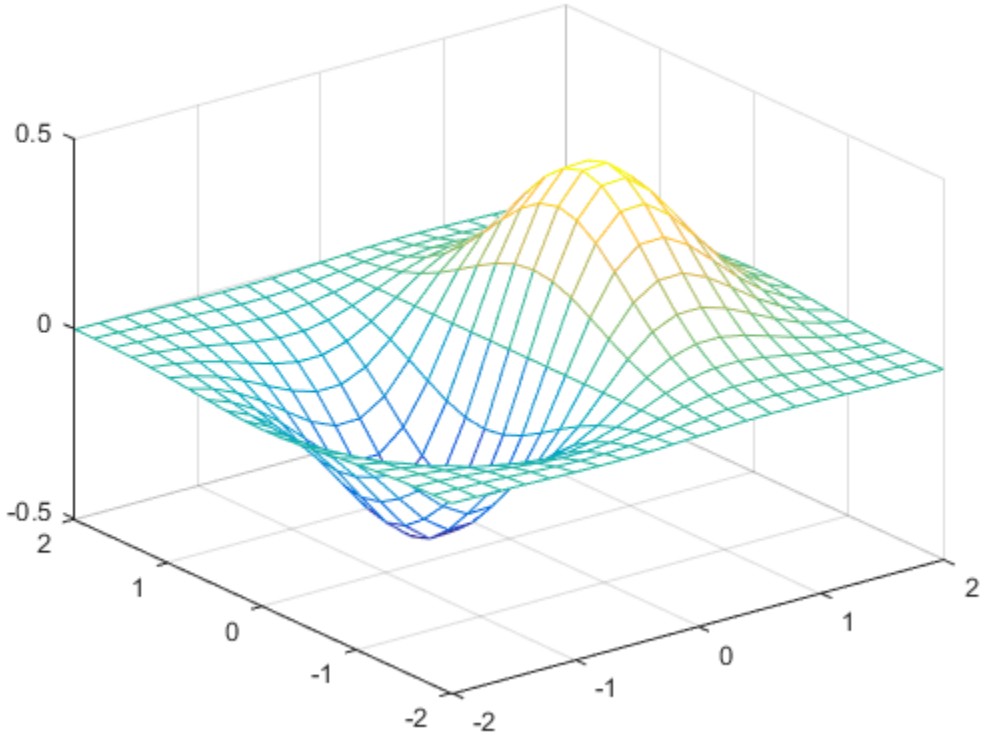
```
[X1,X2] = ndgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function over the domain.

```
Z = X1 .* exp(-X1.^2 - X2.^2);
```

Generate a mesh plot of the function.

```
mesh(X1,X2,Z)
```



More About

Tips

The `ndgrid` function is similar to `meshgrid`, however `ndgrid` supports 1-D to N-D while `meshgrid` is restricted to 2-D and 3-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `ndgrid(x1gv, x2gv)` will output arrays of size `M`-by-`N` while `meshgrid(x1gv, x2gv)` outputs arrays of size `N`-by-`M`. Similarly, `ndgrid(x1gv, x2gv, x3gv)` will output arrays of size `M`-by-`N`-by-`P` while `meshgrid(x1gv, x2gv, x3gv)` outputs arrays of size `N`-by-`M`-by-`P`.

See “Grid Representation” in the MATLAB Mathematics documentation for more information.

`griddedInterpolant` | `meshgrid` | `mesh` | `surf`

Introduced before R2006a

ndims

Number of array dimensions

Syntax

```
N = ndims(A)
```

Description

`N = ndims(A)` returns the number of dimensions in the array `A`. The number of dimensions is always greater than or equal to *2*. The function ignores trailing singleton dimensions, for which `size(A,dim) = 1`.

Examples

Find Dimensions of Vector

Create a row vector.

```
A = 1:5;
```

Find the number of dimensions in the vector.

```
ndims(A)
```

```
ans =

     2
```

The result is `2` because the vector has a size of 1-by-5.

Find Dimensions of Cell Array

Create a cell array of strings.

```
C{1,1,1} = 'cell_1';
C{1,1,2} = 'cell_2';
C{1,1,3} = 'cell_3'
```

```
C(:,:,1) =

    'cell_1'

C(:,:,2) =

    'cell_2'

C(:,:,3) =

    'cell_3'
```

Find the number of dimensions of the cell array.

```
ndims(A)
```

```
ans =

     3
```

The result is `3` because the cell array has a size of 1-by-1-by-3.

Input Arguments

A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, calendarDuration arrays, tables, structure arrays, cell arrays, and object arrays.

More About

Algorithms

The number of dimensions in an array is the same as the length of the size vector of the array. In other words, `ndims(A) = length(size(A))`.

See Also

`length` | `size`

Introduced before R2006a

ne, ~=

Determine inequality

Syntax

```
A ~= B
ne(A,B)
```

Description

`A ~= B` returns a logical array with elements set to logical `1` (`true`) where arrays `A` and `B` are not equal; otherwise, it returns logical `0` (`false`). The test compares both real and imaginary parts of numeric arrays. `ne` returns logical `1` (`true`) where `A` or `B` have NaN or undefined categorical elements.

`ne(A,B)` is an alternative way to execute `A ~= B`, but is rarely used. It enables operator overloading for classes.

Examples

Inequality of Two Vectors

Create two vectors containing both real and imaginary numbers.

```
A = [1+i 3 2 4+i];
B = [1 3+i 2 4+i];
```

Compare the two vectors for inequality.

```
A ~= B
```

```
ans =

     1     1     0     0
```

The `ne` function tests both real and imaginary parts for inequality, and returns logical `1` (`true`) where one or both parts are not equal.

Find Characters in String

Create a string of characters.

```
M = 'masterpiece';
```

Test the string for the presence of a specific character using `~=`.

```
M ~= 'n'
```

```
ans =

     1     1     1     1     1     1     1     1     1     1     1
```

The value of logical `1` (`true`) in the vector indicates the absence of the character `'n'`. The character is not present in the string.

Find Values in Categorical Array

Create a categorical array.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =

     heads      heads      tails
     tails      heads      tails
```

The array has two categories: `'heads'` and `'tails'`.

Find all values not in the `'heads'` category.

```
A ~= 'heads'
```

```
ans =

     0     0     1
     1     0     1
```

A value of logical `1` (`true`) indicates a value not in the category. Since `A` only has two categories, `A ~= 'heads'` returns the same answer as `A == 'tails'`.

Compare the rows of A for inequality.

```
A(1,:) ~= A(2,:)
```

```
ans =

     1     0     0
```

The function returns logical 1 (true) where the rows have unequal category values.

Compare Floating-Point Numbers

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the ~= operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in C.

```
C = 0.5-0.4-0.1
```

```
C =

  -2.7756e-17
```

Intuitively, C should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare C to zero for inequality.

```
C ~= 0
```

```
ans =

     1
```

The result is logical 1 (true).

Compare floating-point numbers using a tolerance, tol, instead of ~=.

```
tol = eps;
abs(C-0) > tol
```

```
ans =

     0
```

The two numbers, C and 0, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

Inequality of Two Datetime Arrays

Compare the elements of two `datetime` arrays for inequality.

Create two `datetime` arrays in different time zones.

```
t1 = [2014,04,14,9,0,0;2014,04,14,10,0,0];
A = datetime(t1,'TimeZone','America/Los_Angeles');
A.Format = 'd-MMM-y HH:mm:ss Z'
```

```
A =

   14-Apr-2014 09:00:00 -0700
   14-Apr-2014 10:00:00 -0700
```

```
t2 = [2014,04,14,12,0,0;2014,04,14,12,30,0];
B = datetime(t2,'TimeZone','America/New_York');
B.Format = 'd-MMM-y HH:mm:ss Z'
```

```
B =

   14-Apr-2014 12:00:00 -0400
   14-Apr-2014 12:30:00 -0400
```

Check where elements in A and B are not equal.

```
A~=B
```

```
ans =

     0
     1
```

Input Arguments

A — Left array

numeric array | logical array | character array | categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

B — Right array

numeric array | logical array | character array | categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.
Complex Number Support: Yes

Introduced before R2006a

nearestNeighbor

Class: DelaunayTri

(Will be removed) Point closest to specified location

Note: `nearestNeighbor(DelaunayTri)` will be removed in a future release. Use `nearestNeighbor(triangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
PI = nearestNeighbor(DT,QX)
PI = nearestNeighbor(DT,QX,QY)
PI = nearestNeighbor(DT,QX,QY,QZ)
[PI,D] = nearestNeighbor(DT,QX,...)
```

Description

`PI = nearestNeighbor(DT,QX)` returns the index of the nearest point in `DT.X` for each query point location in `QX`.

`PI = nearestNeighbor(DT,QX,QY)` and `PI = nearestNeighbor(DT,QX,QY,QZ)` allow the query points to be specified in column vector format when working in 2-D and 3-D.

`[PI,D] = nearestNeighbor(DT,QX,...)` returns the index of the nearest point in `DT.X` for each query point location in `QX`. The corresponding Euclidean distances between the query points and their nearest neighbors are returned in `D`.

Note: `nearestNeighbor` is not supported for 2-D triangulations that have constrained edges.

Input Arguments

`DT`	Delaunay triangulation.
`QX`	The matrix `QX` is of size `mpts`-by-`ndim`, `mpts` being the number of query points and `ndim` the dimension of the space where the points reside.

Output Arguments

`PI`	`PI` is a column vector of point indices that index into the points `DT.X`. The length of `PI` is equal to the number of query points `mpts`
`D`	`D` is a column vector of length `mpts`.

Examples

Create a Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
dt = DelaunayTri(x,y);
```

Create query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
```

Find the nearest neighbors to the query points:

```
pid = nearestNeighbor(dt, qrypts)
```

See Also

`delaunayTriangulation` | `pointLocation` | `triangulation`

neighbors

Class: TriRep

(Will be removed) Simplex neighbor information

Note: `neighbors(TriRep)` will be removed in a future release. Use `neighbors(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
SN = neighbors(TR, SI)
```

Description

`SN = neighbors(TR, SI)` returns the simplex neighbor information for the specified simplices `SI`.

Input Arguments

`TR`	Triangulation representation.
`SI`	`SI` is a column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`. If `SI` is not specified the neighbor information for the entire triangulation is returned, where the neighbors associated with simplex `i` are defined by the `i`'th row of `SN`.

Output Arguments

`SN`	`SN` is an `m`-by-`n` matrix, where `m = length(SI)` , the number of specified simplices, and `n` is the number of neighbors per simplex. Each row `SN(i,:)` represents the neighbors of the simplex `SI(i)`.

By convention, the simplex opposite `vertex(j)` of simplex `SI(i)` is `SN(i,j)`. If a simplex has one or more boundary facets, the nonexistent neighbors are represented by `NaN`.

Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

Examples

Example 1

Load a 3-D triangulation and use `TriRep` to compute the neighbors of all tetrahedra.

```
load tetmesh
trep = TriRep(tet, X)
nbrs = neighbors(trep)
```

Example 2

Query a 2-D triangulation created using `DelaunayTri`.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
```

Find the neighbors of the first triangle:

```
n1 = neighbors(dt, 1)
```

NET

Summary of functions in MATLAB .NET interface

Description

Use the following functions to bring assemblies from the Microsoft .NET Framework into the MATLAB environment. The functions are implemented as a package called NET. To use these functions, prefix the function name with package name NET.

BeginInvoke	Initiate asynchronous .NET delegate call
cell	Create cell array
Combine	Convenience function for static .NET System.Delegate Combine method
enableNETfromNetworkDrive	Enable access to .NET commands from network drive
EndInvoke	Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method
NET.addAssembly	Make .NET assembly visible to MATLAB
NET.Assembly	Members of .NET assembly
NET.convertArray	Convert numeric MATLAB array to .NET array
NET.createArray	Array for nonprimitive .NET types
NET.createGeneric	Create instance of specialized .NET generic type

NET.disableAutoRelease	Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object
NET.enableAutoRelease	Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object
NET.GenericClass	Represent parameterized generic type definitions
NET.invokeGenericMethod	Invoke generic method of object
NET.isNETSupported	Check for supported Microsoft .NET Framework
NET.NetException	Capture error information for .NET exception
NET.setStaticProperty	Static property or field name
Remove	Convenience function for static .NET System.Delegate Remove method
RemoveAll	Convenience function for static .NET System.Delegate RemoveAll method

More About

- “Call .NET Libraries”

NET.addAssembly

Package: NET

Make .NET assembly visible to MATLAB

Syntax

```
asmInfo = NET.addAssembly(globalName)
asmInfo = NET.addAssembly(privateName)
```

Description

`asmInfo = NET.addAssembly(globalName)` loads a global .NET assembly into MATLAB.

`asmInfo = NET.addAssembly(privateName)` loads a private .NET assembly.

Limitations

- `NET.addAssembly` does not support assemblies generated by the MATLAB Compiler SDK product.

Input Arguments

`globalName`

One of the following:

- String representing the name of a global assembly.
- Instance of `System.Reflection.AssemblyName` class.

Default:

`privateName`

String representing the full path of a private assembly.

Default:

Output Arguments

`asmInfo`

`NET.Assembly` object containing names of the members of the assembly.

Examples

Display today's date using `System.DateTime` in the `mscorlib` assembly.

```
System.DateTime.Now.ToLongDateString
```

Call the `System.Windows.Forms.MessageBox.Show` method in the global assembly `System.Windows.Forms`.

```
asm = NET.addAssembly('System.Windows.Forms');
import System.Windows.Forms.*;
MessageBox.Show('Simple Message Box')
```

Display classes in the private assembly `NetSample.dll`.

```
asm = NET.addAssembly('c:\work\NetSample.dll');
asm.Classes
```

More About

Tips

- MATLAB dynamically loads the `mscorlib.dll` and `system.dll` assemblies from the .NET Framework class library the first time you type `"NET."` or `"System."`. You do not need to call `NET.addAssembly` to access classes in these assemblies.
- Refer to your .NET product documentation for the name of the assembly and its deployment type (global or private).

- "Assembly is Library of .NET Classes"
- MSDN AssemblyName Class

See Also

`NET.Assembly`

Introduced in R2009a

NET.Assembly class

Package: NET

Members of .NET assembly

Description

`NET.Assembly` object returns names of the members of an assembly.

Construction

The `NET.addAssembly` function creates an instance of this class.

Properties

`AssemblyHandle`

Instance of `System.Reflection.Assembly` class of the added assembly.

`Classes`

`nClass`x`1` cell array of class names of the assembly, where `nClass` is the number of classes

`Enums`

`nEnum`x`1` cell array of enums of the assembly, where `nEnum` is the number of enums

`Structures`

`nStruct`x`1` cell array of structures of the assembly, where `nStruct` is the number of structures

`GenericTypes`

`nGenType`x`1` cell array of generic types of the assembly, where `nGenType` is the number of generic types

`Interfaces`

`nInterface`x`1` cell array of interface names of the assembly, where `nInterface` is the number of interfaces

`Delegates`

`nDelegate`x`1` cell array of delegates of the assembly, where `nDelegate` is the number of delegates

See Also

`NET.addAssembly`

How To

- "What Classes Are in a .NET Assembly?"

NET.convertArray

Package: NET

Convert numeric MATLAB array to .NET array

Note: MATLAB automatically converts arrays to .NET types. For information, see "Using Arrays with .NET Applications".

Syntax

```
arrObj = NET.convertArray(V,'arrType',[m,n])
```

Description

`arrObj = NET.convertArray(V,'arrType',[m,n])` converts a MATLAB array `V` to a .NET array. Optional value `arrType` is a string representing a namespace-qualified .NET array type. To convert a MATLAB vector to a two-dimensional .NET array (either 1-by-n or m-by-1), use optional values `m,n`. If `V` is a MATLAB vector and you do not specify the number of dimensions and their sizes, the output `arrObj` is a one-dimensional .NET array.

If you do not specify `arrType`, MATLAB converts the type according to the MATLAB Primitive Type Conversion Table. See "Pass Primitive .NET Types".

Examples

Create a list `aList` of random `System.Int32` integers using the `System.Collections.Generic.List` class, and then sort the results:

```
% Create array R of random integers
nInt = 5;
R = randi(100,1,nInt);
%Create .NET array A
```

```
A = NET.convertArray(R,'System.Int32');
%Put A into aList, a generic collections list
aList = NET.createGeneric(...
    'System.Collections.Generic.List',...
    {'System.Int32'},A.Length);
aList.AddRange(A);
%Sort the values in aList
aList.Sort;
```

See Also

NET.createArray

Introduced in R2009a

NET.createArray

Package: NET

Array for nonprimitive .NET types

Syntax

```
array = NET.createArray(typeName,[m,n,p,...])
array = NET.createArray(typeName,m,n,p,...)
```

Description

`array = NET.createArray(typeName,[m,n,p,...])` creates an `m`-by-`n`-by-`p`-by-`...` `array` of type `typeName`, which is either a fully qualified .NET array type name (`namespace` and array type name) or an instance of the `NET.GenericClass` class, in case of arrays of generic type. `m,n,p,...` are the number of elements in each dimension of the array.

`array = NET.createArray(typeName,m,n,p,...)` alternative syntax for creating an array.

You cannot specify the lower bound of an array.

Examples

Create .NET Array of Generic Type

This example creates a .NET array of `List<Int32>` generic type.

```
genType = NET.GenericClass('System.Collections.Generic.List',...
  'System.Int32');
arr = NET.createArray(genType, 5)
```

```
arr =
```

```
  List<System*Int32>[] with properties:

          Length: 5
      LongLength: 5
            Rank: 1
        SyncRoot: [1x1 System.Collections.Generic.List<System*Int32>[]]
      IsReadOnly: 0
     IsFixedSize: 1
  IsSynchronized: 0
```

Create and Initialize Jagged Array

This example creates a jagged .NET array of 3 elements.

```
jaggedArray = NET.createArray('System.Double[]', 3)
```

```
jaggedArray =

  Double[][] with properties

          Length: 3
      LongLength: 3
            Rank: 1
        SyncRoot: [1x1 System.Double[][]]
      IsReadOnly: 0
     IsFixedSize: 1
  IsSynchronized: 0
```

Assign values:

```
jaggedArray(1) = [1, 3, 5, 7, 9];
jaggedArray(2) = [0, 2, 4, 6];
jaggedArray(3) = [11, 22];
```

Access first value of 3rd array:

```
jaggedArray(3,1)
```

```
ans =
    11
```

Create Jagged Array of Generic Type

This example creates a jagged array of `List<Double>` generic type.

```
genCls = NET.GenericClass('System.Collections.Generic.List[]',...
  'System.Double');
```

Create the array, `genArr`.

```
genArr = NET.createArray(genCls,3)
```

```
genArr =

  List<System*Double>[][] with properties:

           Length: 3
       LongLength: 3
             Rank: 1
         SyncRoot: [1x1 System.Collections.Generic.List`1[][]]
       IsReadOnly: 0
      IsFixedSize: 1
    IsSynchronized: 0
```

Create Nested Jagged Array

This command creates a jagged array of type `System.Double[][][]`.

```
netArr = NET.createArray('System.Double[][]', 3)
```

```
netArr =

  Double[][][] with properties:

           Length: 3
       LongLength: 3
             Rank: 1
         SyncRoot: [1x1 System.Double[][][]]
       IsReadOnly: 0
      IsFixedSize: 1
    IsSynchronized: 0
```

See Also

`NET.convertArray` | `NET.createGeneric`

Introduced in R2009a

NET.createGeneric

Package: NET

Create instance of specialized .NET generic type

Syntax

```
genObj = createGeneric(className,paramTypes,varargin ctorArgs)
```

Description

`genObj = createGeneric(className,paramTypes,varargin ctorArgs)` creates an instance `genObj` of generic type `className`.

Input Arguments

`className`	Fully qualified string with the generic type name.
`paramTypes`	Allowed cell types are: strings with fully qualified parameter type names and instances of the `NET.GenericClass` class when parameterization with another parameterized type is needed.
`ctorArgs`	Optional, variable length (0 to N) list of constructor arguments matching the arguments of the .NET generic class constructor intended to be invoked.

Output Arguments

`genObj`	Handle to the specialized generic class instance.

Examples

Create a List of System.Double Objects

Create a strongly typed list `dblLst` of objects of type `System.Double`:

```
t = NET.createGeneric('System.Collections.Generic.List',...
  {'System.Double'},10);
```

Create a List with Key/Value Pairs

Create the `kvpType` generic association where `Key` is of `System.Int32` type and `Value` is a `System.String`:

```
pe = NET.GenericClass('System.Collections.Generic.KeyValuePair',...
  'System.Int32','System.String');
```

Create the list `kvpList` with initial storage capacity for 10 key-value pairs:

```
st = NET.createGeneric('System.Collections.Generic.List',...
  {kvpType},10);
```

Add an Item to the List

Create a `KeyValuePair` item.

```
kvpItem = NET.createGeneric('System.Collections.Generic.KeyValuePair',...
  {'System.Int32','System.String'},42,'myString');
```

Add this item to the list `kvpList`.

```
kvpList.Add(kvpItem);
```

See Also

`NET.GenericClass`

Introduced in R2009a

NET.disableAutoRelease

Package: NET

Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

Syntax

```
A = NET.disableAutoRelease(obj)
```

Description

`A = NET.disableAutoRelease(obj)` locks a .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release the COM object. `obj` is a .NET object representing a COM Wrapper.

Before passing a .NET object representing a COM Wrapper to another process, lock the object using this function so that MATLAB does not release it. After using the object, call `NET.enableAutoRelease` to release the COM object.

Examples

The following user-defined function, `GetComApp.m`, has access to a COM object defined in the **pseudo-class** `ComNamespace.ComClass`. One of its methods is `readData`, with the signature:

```
System.String RetVal readData(ComNamespace.ComClass this, System.String strIn)
```

The input argument is defined in the **pseudo-class** `NetDocTest.MyClass`, which has a property named `MyApp`.

```
function GetComApp(obj)
comObj = ComNamespace.ComClass;
obj.MyApp = comObj;
% To pass a COM object to another process, lock the object
NET.disableAutoRelease(comObj);
end
```

The example in `NET.enableAutoRelease` shows how to call the `GetComApp` function.

More About

- "How MATLAB Handles System.__ComObject"

See Also

`NET.enableAutoRelease`

Introduced in R2010b

NET.enableAutoRelease

Package: NET

Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object

Syntax

```
A = NET.enableAutoRelease(obj)
```

Description

`A = NET.enableAutoRelease(obj)` releases the COM wrapper when the object goes out of scope, where `obj` is a .NET object representing a COM Wrapper.

Call this function only if the object was locked using `NET.disableAutoRelease`.

Examples

The following **pseudo-code** shows how to call a function (`GetComApp.m`, described in `NET.disableAutoRelease`) which returns a COM object. The object, `mainObj` of type `NetDocTest.MyClass`, has a property, `MyApp`. Call `GetComApp` to get a COM object, and use its `readData` method.

```
mainObj = NetDocTest.MyClass;
GetComApp(mainObj);
app = mainObj.MyApp;
app.readData('hello');
% Unlock the COM object
NET.enableAutoRelease(mainObj.MyApp);
```

More About

- "How MATLAB Handles System.__ComObject"

See Also

`NET.disableAutoRelease`

Introduced in R2010b

NET.GenericClass class

Package: NET

Represent parameterized generic type definitions

Description

The `NET.createGeneric` function uses instances of this class to create a generic specialization that requires parameterization with another parameterized type.

Construction

```
genType = NET.GenericClass (className, paramTypes)
```

Input Arguments

`className`

Fully qualified string containing the generic type name.

Default:

`paramTypes`

Optional, variable length (1 to N) list of types for the generic class parameterization. Allowed argument types are:

- Fully qualified string containing the generic type name.
- Instance of the `NET.GenericClass` class when deeper nested parameterization with another parameterized type is needed.

Default:

Examples

Create an instance of `System.Collections.Generic.List` of `System.Collections.Generic.KeyValuePair` generic associations where `Key` is of

`System.Int32` type and `Value` is a `System.String` class with initial storage capacity for 10 key-value pairs.

```
kvpType = NET.GenericClass(...
    'System.Collections.Generic.KeyValuePair',...
    'System.Int32', 'System.String');
kvpList = NET.createGeneric('System.Collections.Generic.List',...
    { kvpType }, 10);
```

`NET.createGeneric` | `NET.createArray` | `NET.invokeGenericMethod`

How To

- ".NET Generic Classes"

Introduced in R2009a

NET.invokeGenericMethod

Package: NET

Invoke generic method of object

Syntax

```
[varargout] = NET.invokeGenericMethod(obj, 'genericMethodName',
paramTypes, args, ...)
```

Description

`[varargout] = NET.invokeGenericMethod(obj, '`*`genericMethodName`*`', paramTypes, args, ...)` calls instance or static generic method *`genericMethodName`*.

Input Arguments

`obj`	Allowed argument types are: • Instances of class containing the generic method • Strings with fully qualified class name, if calling static generic methods • Instances of `NET.GenericClass` definitions, if calling static generic methods of a generic class
`genericMethodName`	Generic method name to invoke
`paramTypes`	Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are: • Strings with fully qualified parameter type name. • Instances of `NET.GenericClass` definitions, if using nested parameterization with another parameterized type
`args`	Optional, variable length (0 to N) list of method arguments

Output Arguments

`varargout`	Variable-length output argument list, `varargout`, from method *`genericMethodName`*

Examples

The following syntax calls a generic method that takes two parameterized types and returns a parameterized type:

```
a = NET.invokeGenericMethod(obj, ...
  'myGenericSwapMethod', ...
  {'System.Double', 'System.Double'}, ...
  5, 6);
```

To display generic methods in MATLAB, see the example “Display .NET Generic Methods Using Reflection”.

`NET.GenericClass` | `NET.createGeneric` | `varargout`

Introduced in R2009b

NET.isNETSupported

Check for supported Microsoft .NET Framework

Syntax

```
tf = NET.isNETSupported
```

Description

`tf = NET.isNETSupported` returns logical `1` (`true`) if a supported version of the Microsoft .NET Framework is found. Otherwise, it returns logical `0` (`false`) and you cannot use the .NET Framework in MATLAB.

Introduced in R2013a

NET.NetException class

Package: NET

Capture error information for .NET exception

Description

Process information from a `NET.NetException` object to handle .NET errors. This class is derived from `MException`.

Construction

`e = NET.NetException(msgID,errMsg,netObj)` constructs instance e of `NET.NetException` class.

Input Arguments

`msgID`

message identifier

`errMsg`

error message string

`netObj`

`System.Exception` object that caused the exception

Properties

`ExceptionObject`

`System.Exception` class causing the error.

Methods

Inherited Methods

See the methods of the base class `MException`.

Examples

Display error information after trying to load an unknown assembly:

```
try
  NET.addAssembly('C:\Work\invalidfile.dll')
catch e
  e.message;
  if(isa(e, 'NET.NetException'))
    eObj = e.ExceptionObject
  end
end
```

```
ans =
Message: Could not load file or assembly
  'file:///C:\Work\invalidfile.dll' or
  one of its dependencies. The system cannot
  find the file specified.
Source: mscorlib
HelpLink:

eObj =
  FileNotFoundException with properties:

           Message: [1x1 System.String]
          FileName: [1x1 System.String]
         FusionLog: [1x1 System.String]
              Data: [1x1 System.Collections.ListDictionaryInternal]
    InnerException: []
        TargetSite: [1x1 System.Reflection.RuntimeMethodInfo]
        StackTrace: [1x1 System.String]
          HelpLink: []
            Source: [1x1 System.String]
```

How To

- Class Attributes
- Property Attributes

Introduced in R2009b

NET.setStaticProperty

Package: NET

Static property or field name

Syntax

```
NET.setStaticProperty('propName', value)
```

Description

`NET.setStaticProperty('propName', value)` sets the static property or field name specified in the string `propName` to the given `value`.

Examples

To set the `myStaticProperty` in the given class and namespace, use the syntax:

```
NET.setStaticProperty('MyTestObject.MyClass.myStaticProperty', 5);
```

Introduced in R2009b

nccreate

Create variable in NetCDF file

Syntax

```
nccreate(filename,varname)
nccreate(filename,varname,Name,Value)
```

Description

`nccreate(filename,varname)` creates a scalar `double` variable named `varname` in the NetCDF file specified by `filename`. If `filename` does not exist, then `nccreate` creates the file using the `netcdf4_classic` format.

`nccreate(filename,varname,Name,Value)` creates a variable with additional options specified by one or more name-value pair arguments. For example, to create a nonscalar variable, use the `Dimensions` name-value pair argument.

Examples

Create New Variables in NetCDF File

Create a NetCDF file named `myexample.nc` that contains a variable named `Var1`.

```
nccreate('myexample.nc','Var1')
```

Create a second variable in the same file.

```
nccreate('myexample.nc','Var2')
```

Display the contents of the NetCDF file.

```
ncdisp('myexample.nc')
```

```
Source:
```

```
           pwd\myexample.nc
Format:
           netcdf4_classic
Variables:
    Var1
           Size:       1x1
           Dimensions:
           Datatype:   double
    Var2
           Size:       1x1
           Dimensions:
           Datatype:   double
```

Create Variable and Specify Dimensions and File Format

Create a new two-dimensional variable named `peaks` in a classic (NetCDF 3) format file named `myncclassic.nc`. Use the `'Dimensions'` name-value pair argument to specify the names and lengths of the two dimensions. Use the `'Format'` name-value pair argument to specify the file format.

```
nccreate('myncclassic.nc','peaks',...
          'Dimensions',{'r',200,'c',200},...
          'Format','classic')
```

Write data to the variable.

```
ncwrite('myncclassic.nc','peaks',peaks(200))
```

Display the contents of the NetCDF file.

```
ncdisp('myncclassic.nc')
```

```
Source:
           pwd\myncclassic.nc
Format:
           classic
Dimensions:
           r = 200
           c = 200
Variables:
    peaks
           Size:       200x200
           Dimensions: r,c
```

```
            Datatype:   double
```

Input Arguments

`filename` — File name

string

File name, specified as a string. The file is an existing NetCDF file, or the name you want to assign to a new NetCDF file.

Example: `'myFile.nc'`

`varname` — Name of new variable

string

Name of the new variable, specified as a string.

Example: `'myVar'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:
`nccreate('myFile.nc','Var1','Datatype','double','Format','classic')` creates a variable named `Var1` of type `NC_DOUBLE` in a NetCDF 3 file named `myFile.nc`.

`'Dimensions'` — Dimensions of variable

cell array

Dimensions of the new variable, specified as the comma-separated pair consisting of `'Dimensions'` and a cell array. The cell array lists the dimension name as a string followed by its numerical length, in this form: `{dname1,dlength1,dname2,dlength2, ...}`. The `dname1` input is the name of the first dimension, `dlength1` is the length of the first dimension, `dname2` is the name of the second dimension, and so on. If a dimension exists, specifying its length is optional. A variable with a single dimension is always treated as a column vector.

Use `Inf` to specify an unlimited dimension. A `netcdf4` format file can have any number of unlimited dimensions in any order. All other formats can have only one unlimited dimension per file and it must be specified last in the cell array.

`nccreate` creates the dimension at the same location as the variable. For `netcdf4` format files, you can specify a different location for the dimension using a fully qualified dimension name.

Example: `'Dimensions',{'dim1',100,'dim2',150,'dim3','Inf'}`

`'Datatype'` — MATLAB data type

`'double'` (default) | string

MATLAB data type, specified as the comma-separated pair consisting of `'Datatype'` and a string. When `nccreate` creates the variable in the NetCDF file, it uses a corresponding NetCDF datatype. This table lists valid values for `'Datatype'` and the corresponding NetCDF variable type that `nccreate` creates.

Value of `Datatype`	NetCDF Variable Type
`'double'`	`NC_DOUBLE`
`'single'`	`NC_FLOAT`
`'int64'`	`NC_INT64*`
`'uint64'`	`NC_UINT64*`
`'int32'`	`NC_INT`
`'uint32'`	`NC_UINT*`
`'int16'`	`NC_SHORT`
`'uint16'`	`NC_USHORT*`
`'int8'`	`NC_BYTE`
`'uint8'`	`NC_UBYTE*`
`'char'`	`NC_CHAR`

* These data types are only available when the file is a `netcdf4` format file.

Example: `'Datatype','uint16'`

`'Format'` — NetCDF file format

`'netcdf4_classic'` (default) | string

NetCDF file format, specified as the comma-separated pair consisting of `'Format'` and one of the following strings.

Value of `Format`	Description
`'classic'`	NetCDF 3
`'64bit'`	NetCDF 3, with 64-bit offsets
`'netcdf4_classic'`	NetCDF 4 classic model
`'netcdf4'`	NetCDF 4 model (Use this format to enable group hierarchy)

If `varname` specifies a group (for example, `'/grid3/temperature'`), then `nccreate` sets the value of `Format` to `'netcdf4'`.

Example: `'Format','classic'`

`'FillValue'` — Replacement value for missing values

scalar | `'disable'`

Replacement value for missing values, specified as the comma-separated pair consisting of `'FillValue'` and a scalar or `'disable'`. The default value is specified by the NetCDF library. To disable replacement values, specify `'FillValue','disable'`.

This argument is available for `netcdf4` or `netcdf4_classic` formats only.

Example: `'FillValue',NaN`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

`'ChunkSize'` — Chunk size along each dimension

vector

Chunk size along each dimension, specified as the comma-separated pair consisting of `'ChunkSize'` and a vector. The first element specifies the number of rows, the second element specifies the number of columns, the third element specifies the length of the third dimension, and so on. The default value is specified by the NetCDF library.

This argument is available for `netcdf4` or `netcdf4_classic` formats only.

Example: `'ChunkSize',[5 6 9]`

Data Types: `double`

`'DeflateLevel'` — Amount of compression

`0` (default) | scalar value between `0` and `9`

Amount of compression, specified as the comma-separated pair consisting of `'DeflateLevel'` and a scalar value between `0` and `9`. `0` indicates no compression and `9` indicates the most compression.

This argument is available for `netcdf4` or `netcdf4_classic` formats only.

Example: `'DeflateLevel',5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'Shuffle'` — Status of shuffle filter

`false` (default) | `true`

Status of the shuffle filter, specified as the comma-separated pair consisting of `'Shuffle'` and `false` or `true`. `false` disables the shuffle filter and `true` enables it. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

This argument is available for `netcdf4` or `netcdf4_classic` formats only.

Example: `'Shuffle',true`

Data Types: `logical`

`ncdisp` | `ncinfo` | `ncwrite` | `ncwriteschema` | `netcdf`

Introduced in R2011a

ncdisp

Display contents of NetCDF data source in Command Window

Syntax

```
ncdisp(source)
ncdisp(source,location)
ncdisp(source,location,dispFormat)
```

Description

`ncdisp(source)` displays all the groups, dimensions, variable definitions, and all attributes in the NetCDF data source, `source`, as text in the Command Window.

`ncdisp(source,location)` displays information about the variable or group specified by `location`.

`ncdisp(source,location,dispFormat)` displays the contents of the NetCDF data source, in the display format specified by `dispFormat`.

Examples

Display Contents of NetCDF File

Display the contents of the example NetCDF file, `example.nc`.

```
ncdisp('example.nc')
```

```
Source:
           matlabroot\toolbox\matlab\demos\example.nc
Format:
           netcdf4
Global Attributes:
           creation_date = '29-Mar-2010'
Dimensions:
           x = 50
           y = 50
           z = 5
```

```
Variables:

        Variables:
            temp
                   Size:       []
                   Dimensions: x,y,time
                   Datatype:   int16

    /grid2/
        Attributes:
                   description = 'This is another group attribute.'
        Dimensions:
                   x    = 360
                   y    = 180
                   time = 0     (UNLIMITED)
        Variables:
            temp
```

```
                Size:       []
                Dimensions: x,y,time
                Datatype:   int16
```

MATLAB displays all the groups, dimensions, and variable definitions in `example.nc`.

Display Contents of NetCDF Variable

Display the contents of the variable `peaks` in the file, `example.nc`.

```
ncdisp('example.nc','peaks')
```

```
Source:
           matlabroot\toolbox\matlab\demos\example.nc
Format:
           netcdf4
Dimensions:
           x = 50
           y = 50
Variables:
    peaks
           Size:       50x50
           Dimensions: x,y
           Datatype:   int16
           Attributes:
                       description = 'z = peaks(50);'
```

Display Contents of NetCDF File and Hide Attributes

Display only the group hierarchy and variable definitions of the example file, `example.nc`.

```
ncdisp('example.nc','/','min')
```

```
Source:
           matlabroot\toolbox\matlab\demos\example.nc
Format:

                   Datatype:   int16

    /grid2/
        Variables:
            temp
                   Size:       []
                   Dimensions: x,y,time
                   Datatype:   int16
```

Input Arguments

`source` — Name of NetCDF file

string

Name of a NetCDF file, specified as a string. `source` also can be the URL of an OPeNDAP NetCDF data source that resolves to a NetCDF file or a variable in a NetCDF file.

Example: `'myNetCDFfile.nc'`

Data Types: `char`

`location` — Location of variable or group

`'/'` (default) | string

Location of a variable or group in the NetCDF file, specified as a string. Set `location` to `'/'`(forward slash) to display the entire contents of the file.

Data Types: `char`

`dispFormat` — Display format

`'full'` (default) | `'min'`

Display format, specified as one of the following strings.

`'full'`	Display group hierarchy with dimensions, attributes, and variable definitions.
`'min'`	Display group hierarchy and variable definitions.

Data Types: `char`

More About

Tips

- If `source` is an OPeNDAP URL with string constraints, use the syntax, `ncdisp(source)` with no other input arguments.
- "Import NetCDF Files and OPeNDAP Data"

See Also

`ncinfo` | `ncread` | `ncreadatt` | `ncwrite` | `netcdf`

Introduced in R2011a

ncinfo

Return information about NetCDF data source

Syntax

```
finfo = ncinfo(source)
vinfo = ncinfo(source,varname)
ginfo = ncinfo(source,groupname)
```

Description

`finfo = ncinfo(source)` returns information in the structure `finfo` about the entire NetCDF data source specified by `source`, where source can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

`vinfo = ncinfo(source,varname)` returns information in the structure `vinfo` about the variable `varname` in `source`.

`ginfo = ncinfo(source,groupname)` returns information in the structure `ginfo` about the group `groupname` in `source` (only NetCDF4 data sources).

Note: Use `ncdisp` for visual inspection of a NetCDF source.

Input Arguments

`source`

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

Default:

`varname`

Text string specifying the name of a variable in a NetCDF file or OPeNDAP data source.

Default:

`groupname`

Text string specifying the name of a group in a NetCDF file or OPeNDAP data source.

Default:

Output Arguments

`finfo`

A structure with the following fields.

Field	Description	
`Filename`	NetCDF file name or OPeNDAP URL	
`Name`	`'/'`, indicating the full file	
`Dimensions`	An array of structures with these fields:	
	`Name`	Dimension name
	`Length`	Current length of dimension
	`Unlimited`	Boolean flag, true for unlimited dimensions
`Variables`	An array of structures with these fields:	
	`Name`	Variable name
	`Dimensions`	Associated dimensions
	`Size`	Current variable size
	`Datatype`	MATLAB datatype
	`Attributes`	Associated variable attributes
	`ChunkSize`	Chunk size, if defined. `[]` otherwise
	`FillValue`	Fill value of the variable.
	`DeflateLevel`	Deflate filter level, if enabled.
	`Shuffle`	Shuffle filter enabled flag

Field	Description	
`Attributes`	An array of global attributes with these fields:	
	`Name`	Attribute name
	`Value`	Attribute value
`Groups`	An array of groups present in the file, for `netcdf4` files; An empty array ([ ]) for all other NetCDF file formats.	
`Format`	The format of the NetCDF file	

`vinfo`

A structure containing only the variable fields from `finfo`.

Field	Description
`Filename`	NetCDF file name
`Name`	Name of the variable
`Dimensions`	Dimensions of the variable
`Size`	Size of the current variable
`Datatype`	MATLAB datatype
`Attributes`	Attributes associated with the variable
`ChunkSize`	Chunk size, if defined. `[ ]` otherwise.
`FillValue`	Fill value used in the variable.
`DeflateLevel`	Deflate filter level, if enabled.
`Shuffle`	Shuffle filter enabled flag
`Format`	The format of the NetCDF file

`ginfo`

A structure containing only the group fields from `finfo`.

Field	Description
`Filename`	NetCDF file name
`Name`	Name of the group
`Dimensions`	Only dimensions defined in the specified group

Field	Description
`Variables`	Only variables defined in the specified group
`Attributes`	Attributes associated with the variable
`Groups`	Names of groups, if defined. `[ ]` otherwise.
`Format`	The format of the NetCDF file

Examples

Search for dimensions with names that start with the character `x` in the file.

```
finfo = ncinfo('example.nc');
disp(finfo);
dimNames = {finfo.Dimensions.Name};
dimMatch = strncmpi(dimNames,'x',1);
disp(finfo.Dimensions(dimMatch));
```

Obtain the size of a variable and check if it has any unlimited dimensions.

```
vinfo = ncinfo('example.nc','peaks');
varSize = vinfo.Size;
disp(vinfo);
hasUnLimDim = any([vinfo.Dimensions.Unlimited]);
```

Find all unlimited dimensions defined in a group.

```
ginfo = ncinfo('example.nc','/grid2/');
unlimDims = [ginfo.Dimensions.Unlimited];
disp(ginfo.Dimensions(unlimDims));
```

See Also

`ncdisp` | `ncwrite` | `ncread` | `ncwriteschema` | `netcdf`

Introduced in R2011a

ncread

Read data from variable in NetCDF data source

Syntax

```
vardata = ncread(source,varname)
vardata = ncread(source,varname,start,count,stride)
```

Description

`vardata = ncread(source,varname)` reads data from the variable `varname` in `source`, which can be either the name of a NetCDF file or an OPeNDAP NetCDF data source.

`vardata = ncread(source,varname,start,count,stride)` reads data from the variable `varname` in `source` beginning at the location given by `start`. `count` specifies the number of elements to read along the corresponding dimension. The optional argument `stride` specifies the inter-element spacing along each dimension.

Input Arguments

`source`

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

Default:

`varname`

Text string specifying the name of a variable in the NetCDF file or OPeNDAP NetCDF data source.

Default:

`start`

For an *N*-dimensional variable, `start` is a vector of length *N* of indices specifying the starting location. Indices are 1-based.

`count`

Vector of length *N* specifying the number of elements to read along the corresponding dimensions. If a particular element of `count` is `Inf`, `ncread` reads data until the end of the corresponding dimension.

`stride`

Optional argument that specifies the inter-element spacing along each dimension.

Default: Vector of 1s (ones)

Output Arguments

`vardata`

The data in the variable. `ncread` uses the MATLAB datatype that is the closest type to the corresponding NetCDF datatype, except when at least one of `_FillValue`, `scale_offset`, and `add_offset` variables attribute is present. `ncread` applies the following attribute conventions, in sequence, to `vardata` if the corresponding attribute exists for this variable:

- If the `_FillValue` attribute exists, `ncread` replaces values in `vardata` equal to the value of `_FillValue` with `NaN`s. If the`_FillValue` attribute does not exist, `ncread` queries the NetCDF library for the variable's fill value.
- If the `scale_factor` attribute exists, `ncread` multiplies `vardata` by the value of the `scale_factor` attribute.
- If the `add_offset` attribute exists, `ncread` adds the value of the `add_offset` attribute to `vardata`.

Examples

Read and display the data in the `peaks` variable in the example file.

```
ncdisp('example.nc','peaks');
peaksData  = ncread('example.nc','peaks');
peaksDesc  = ncreadatt('example.nc','peaks','description');
surf(double(peaksData));
title(peaksDesc);
```

Subsample the peaks data by a factor of 2 (read every other value along each dimension).

```
subsetdata = ncread('example.nc','peaks',...
                    [1 1], [Inf Inf], [2 2]);
surf(double(subsetdata));
```

ncdisp | ncinfo | netcdf | ncwrite | ncreadatt

Introduced in R2011a

ncreadatt

Read attribute value from NetCDF data source

Syntax

```
attvalue = ncreadatt(source,location,attname)
```

Description

`attvalue = ncreadatt(source,location,attname)` reads the attribute `attname` from the group or variable specified by `location` in `source`, where source is the name of a NetCDF file or the URL of a NetCDF data source.

Input Arguments

`source`

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

`location`

Text string specifying a group or variable in the NetCDF data source. To read global attributes, set `location` to `'/'` (forward slash).

`attname`

Text string specifying the name of an attribute that you want to read in the NetCDF data source.

Output Arguments

`attvalue`

Data associated with the attribute.

Examples

Read a global attribute.

```
creation_date = ncreadatt('example.nc','/','creation_date');
disp(creation_date);
```

Read an attribute associated with a variable.

```
scale_factor = ncreadatt('example.nc','temperature','scale_factor');
disp(scale_factor);
```

Read an attribute associated with a group (`netcdf4` format files only).

```
desc_value = ncreadatt('example.nc','/grid2','description');
disp(desc_value);
```

See Also

`ncdisp` | `ncinfo` | `ncread` | `netcdf` | `ncwriteatt`

Introduced in R2011a

ncwrite

Write data to NetCDF file

Syntax

```
ncwrite(filename,varname,vardata)
ncwrite(filename,varname,vardata,start,stride)
```

Description

`ncwrite(filename,varname,vardata)` writes the numerical or char data in `vardata` to an existing variable `varname` in the NetCDF file `filename`. `ncwrite` writes the data in `vardata` starting at the beginning of the variable and extends unlimited dimensions automatically, if needed.

If the NetCDF file or the variable do not exist, use `nccreate` to create them first.

`ncwrite(filename,varname,vardata,start,stride)` writes `vardata` to an existing variable `varname` in file `filename` beginning at the location given by `start`. `stride` is an optional argument that specifies the inter-element spacing of the data written. Use this syntax to append data to an existing variable or write partial data.

Input Arguments

`filename`

Text string specifying the name of a NetCDF file. If the file does not exist, use `nccreate` to create it first.

Default:

`varname`

Text string specifying the name of a variable in a NetCDF file. If the variable does not exist, use `nccreate` to create it first.

`vardata`

Data to write to the variable in the NetCDF file.

`start`

For an *N*-dimensional variable, `start` is a vector of indices of length *N* specifying the starting location. Indices are 1-based.

`stride`

(Optional) Vector of length *N*, specifying the inter-element spacing.

Default: Vector of ones

Examples

Create a new `netcdf4_classic` file, and write a scalar variable with no dimensions. Add the creation time as a global attribute.

```
nccreate('myfile.nc','pi');
ncwrite('myfile.nc','pi',3.1);
ncwriteatt('myfile.nc','/','creation_time',datestr(now));
% overwrite existing data
ncwrite('myfile.nc','pi',3.1416);
ncdisp('myfile.nc');
```

Create a `netcdf4_classic` file with a variable defined on an unlimited dimension. Write data incrementally to the variable.

```
nccreate('myncfile.nc','vmark',...
         'Dimensions', {'time', inf, 'cols', 6},...
         'ChunkSize',  [3 3],...
         'DeflateLevel', 2);
ncwrite('myncfile.nc','vmark', eye(3),[1 1]);
varData = ncread('myncfile.nc','vmark');
disp(varData);
ncwrite('myncfile.nc','vmark',fliplr(eye(3)),[1 4]);
varData = ncread('myncfile.nc','vmark');
disp(varData);
```

More About

Tips

- If the variable `varname` already exists, `ncwrite` expects the datatype of `vardata` to match the NetCDF variable data type.
- If the variable `varname` has a `_FillValue`, `scale_factor` or `add_offset` attribute, `ncwrite` expects data in `double` format and casts `vardata` to the NetCDF data type, after applying the following attribute conventions in sequence:

  1. Subtract the value of' the`add_offset` attribute from `vardata`.
  2. Divide `vardata` by the value of the `scale_factor` attribute.
  3. Replace `NaN`s in `vardata` by the value of the `_FillValue` attribute. If this attribute does not exist, `ncwrite` tries to use the fill value for this variable as reported by the NetCDF library.

Introduced in R2011a

ncwriteatt

Write attribute to NetCDF file

Syntax

```
ncwriteatt(filename,location,attname,attvalue)
```

Description

`ncwriteatt(filename,location,attname,attvalue)` creates or modifies the attribute specified by `attname` in the group or variable specified by `location`, in the NetCDF file specified by `filename`. `attvalue` can be a numeric vector or a string.

Input Arguments

`filename`

Text string specifying the name of a NetCDF file

`location`

Text string specifying a group or variable in the NetCDF file. To write global attributes, set `location` to `'/'` (forward slash).

`attname`

Text string specifying the name of an existing attribute in a NetCDF file or the name of the attribute that you want to create.

`attvalue`

Numeric vector or a string.

Examples

Create a global attribute.

```
copyfile(which('example.nc'),'myfile.nc');
fileattrib('myfile.nc','+w');
ncdisp('myfile.nc');
ncwriteatt('myfile.nc','/','creation_date',datestr(now));
ncdisp('myfile.nc');
```

Modify an existing attribute.

```
copyfile(which('example.nc'),'myfile.nc');
fileattrib('myfile.nc','+w');
ncdisp('myfile.nc','peaks');
ncwriteatt('myfile.nc','peaks','description','Output of PEAKS');
ncdisp('myfile.nc','peaks');
```

ncdisp | ncreadatt | ncwrite | ncread | nccreate | netcdf

Introduced in R2011a

ncwriteschema

Add NetCDF schema definitions to NetCDF file

Syntax

```
ncwriteschema(filename,schema)
```

Description

`ncwriteschema(filename,schema)` creates or adds attributes, dimensions, variable definitions and group structure defined in `schema` to the file `filename`.

Use `ncwriteschema` in combination with `ncinfo` to create a new NetCDF file based on the schema of an existing file. You can also use `ncwriteschema` to add variable definitions, attributes, dimensions, or group structure to an existing file.

Note: `ncwriteschema` does not write variable data. Use `ncwrite` to write data to the created variables. Created unlimited dimensions will have an initial size of 0 until you write data.

Note: `ncwriteschema` cannot change the format of an existing file. It cannot redefine existing variables and dimensions in `filename`. If your schema contains attributes, dimensions, variable definitions, or a group structure that already exist in the file, `writeschema` issues a warning but continues processing.

Input Arguments

`filename`

Text string specifying the name of a NetCDF file. If `filename` does not exist, `ncwriteschema` creates a new file using the `netcdf4_classic` format, unless the `Format` field in `schema` specifies another format.

Default:

`schema`

A structure, or array of structures, representing either a dimension, variable, an entire NetCDF file, or a `netcdf4` group. A group or file schema can contain a dimension or variable schema, or both. You can use the output returned by `ncinfo` as a `schema` structure. The following table lists the fields in the various types of schema structures. Optional fields are marked with asterisk (*).

Schema Type	Structure Field	Description
Group/File Schema	`Name`	Text string identifying the group name. Use `'/'` to indicate the entire file.
	`Dimensions*`	Dimension schema
	`Variables*`	Variable schema
	`Attributes*`	Structure array of group/global attributes with Name and Value fields
	`Format*`	Text string identifying a NetCDF file format
Dimension schema	`Name`	Text string identifying the dimension
	`Length`	Length of the dimension. Can be `Inf`.
	`Unlimited*`	Boolean flag indicating if the dimension is unlimited
	`Format*`	Text string identifying a NetCDF file format
Variable schema	`Name`	Text string identifying a variable name
	`Dimensions`	Variable's dimension schema
	`Datatype`	Text string identifying a MATLAB datatype
	`Attributes*`	Structure array of variable attributes with Name and Value fields
	`ChunkSize*`	Numeric value specifying chunk size of the variable
	`FillValue*`	Character or numeric fill value

Schema Type	Structure Field	Description
	`DeflateValue*`	Deflate compression level
	`Shuffle*`	Boolean flag to turn on the Shuffle filter
	`Format*`	Text string identifying a NetCDF file format

Default:

Examples

Create a classic format file with two dimension definitions.

```
mySchema.Name   = '/';
mySchema.Format = 'classic';
mySchema.Dimensions(1).Name   = 'time';
mySchema.Dimensions(1).Length = Inf;
mySchema.Dimensions(2).Name   = 'rows';
mySchema.Dimensions(2).Length = 10;
ncwriteschema('emptyFile.nc', mySchema);
ncdisp('emptyFile.nc');
```

Create a `netcdf4_classic` format file to store a single variable from an existing file. First use `ncinfo` to get the schema of the peaks variable from the file. Then use `ncwriteschema` to create a NetCDF file, defining the peaks variable. Use `ncread` to get the data associated with the peaks variable and then use `ncwrite` to write the data to the variable in the new NetCDF file.

```
myVarSchema = ncinfo('example.nc','peaks');
ncwriteschema('peaksFile.nc',myVarSchema);
peaksData   = ncread('example.nc','peaks');
ncwrite('peaksFile.nc','peaks',peaksData);
ncdisp('peaksFile.nc');
```

Introduced in R2011a

netcdf

Interact directly with NetCDF Library

Description

Functions in the MATLAB `netcdf` package provide interfaces to dozens of functions in the NetCDF library. The MATLAB functions enable reading data from and writing data to NetCDF files (known as *data sets* in NetCDF terminology). To use these functions, you should be familiar with the NetCDF C Interface.

MATLAB supports NetCDF version 4.1.3.

In most cases, the syntax of the MATLAB function matches the syntax of the NetCDF library function. The functions are implemented as a package called `netcdf`. To use these functions, prefix the function name with the package name, `netcdf`. For example, to call the NetCDF library routine used to open existing NetCDF files, use the following MATLAB syntax:

```
ncid = netcdf.open(ncfile,mode);
```

For copyright information, see the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

Note: For information about MATLAB support for the Common Data Format (CDF), which is a completely separate and incompatible format, see `cdflib`.

Library Functions

netcdf.getChunkCache	Retrieve chunk cache settings for NetCDF library
netcdf.inqLibVers	Return NetCDF library version information
netcdf.setChunkCache	Set default chunk cache settings for NetCDF library

netcdf.setDefaultFormat	Change default netCDF file format

File Operations

netcdf.abort	Revert recent netCDF file definitions
netcdf.close	Close netCDF file
netcdf.create	Create new NetCDF dataset
netcdf.endDef	End netCDF file define mode
netcdf.inq	Return information about netCDF file
netcdf.inqFormat	Determine format of NetCDF file
netcdf.inqGrps	Retrieve array of child group IDs
netcdf.inqUnlimDims	Return list of unlimited dimensions in group
netcdf.open	Open NetCDF data source
netcdf.reDef	Put open netCDF file into define mode
netcdf.setFill	Set netCDF fill mode
netcdf.sync	Synchronize netCDF file to disk

Dimensions

netcdf.defDim	Create netCDF dimension

netcdf.inqDim	Return netCDF dimension name and length
netcdf.inqDimID	Return dimension ID
netcdf.renameDim	Change name of netCDF dimension

Variables

netcdf.defVar	Create NetCDF variable
netcdf.defVarChunking	Define chunking behavior for NetCDF variable
netcdf.defVarDeflate	Define compression parameters for NetCDF variable
netcdf.defVarFill	Define fill parameters for NetCDF variable
netcdf.defVarFletcher32	Define checksum parameters for NetCDF variable
netcdf.getVar	Read data from NetCDF variable
netcdf.inqVarChunking	Determine chunking settings for NetCDF variable
netcdf.inqVarDeflate	Determine compression settings for NetCDF variable
netcdf.inqVarFill	Determine values of fill parameters for NetCDF variable

netcdf.inqVarFletcher32	Fletcher32 checksum setting for NetCDF variable
netcdf.inqVar	Information about variable
netcdf.inqVarID	Return ID associated with variable name
netcdf.putVar	Write data to netCDF variable
netcdf.renameVar	Change name of netCDF variable

Attributes

netcdf.copyAtt	Copy attribute to new location
netcdf.delAtt	Delete netCDF attribute
netcdf.getAtt	Return netCDF attribute
netcdf.inqAtt	Return information about netCDF attribute
netcdf.inqAttID	Return ID of netCDF attribute
netcdf.inqAttName	Return name of netCDF attribute
netcdf.putAtt	Write netCDF attribute
netcdf.renameAtt	Change name of attribute

Utilities

netcdf.getConstant	Return numeric value of named constant

netcdf.getConstantNames	Return list of constants known to netCDF library

netcdf.abort

Revert recent netCDF file definitions

Syntax

```
netcdf.abort(ncid)
```

Description

`netcdf.abort(ncid)` reverts a netCDF file to its previous state, backing out any definitions made since the file last entered define mode. A file enters define mode when you create it (using `netcdf.create`) or when you explicitly enter define mode (using `netcdf.redef`). Once you leave define mode (using `netcdf.endDef`), you cannot revert the definitions you made while in define mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. A call to `netcdf.abort` closes the file.

This function corresponds to the `nc_abort` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example creates a new file, performs an operation on the file, and then reverts the file back to its original state. To run this example, you must have write permission in your current directory.

```
% Create a netCDF file
ncid = netcdf.create('foo.nc','NC_NOCLOBBER');

% Perform an operation, such as defining a dimension.
dimid = netcdf.defDim(ncid, 'lat', 50);

% Revert the file back to its previous state.
netcdf.abort(ncid)

% Verify that the file is now closed.
```

```
dimid = netcdf.defDim(ncid, 'lat', 50); % should fail
??? Error using ==> netcdflib
NetCDF: Not a valid ID

Error in ==> defDim at 22
dimid = netcdflib('def_dim', ncid,dimname,dimlen);
```

See Also

netcdf.create | netcdf.endDef | netcdf.reDef

netcdf.close

Close netCDF file

Syntax

```
netcdf.close(ncid)
```

Description

`netcdf.close(ncid)` terminates access to the netCDF file identified by `ncid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_close` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example creates a new netCDF file, and then closes the file. You must have write permission in your current directory to run this example.

```
ncid = netcdf.open('foo.nc','NC_WRITE')

netcdf.close(ncid)
```

See Also

`netcdf.create` | `netCDF.open`

netcdf.copyAtt

Copy attribute to new location

Syntax

```
netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)
```

Description

`netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)` copies an attribute from one variable to another, possibly across files. `ncid_in` and `ncid_out` are netCDF file identifiers returned by `netcdf.create` or `netcdf.open`. `varid_in` identifies the variable with an attribute that you want to copy. `varid_out` identifies the variable to which you want to associate a copy of the attribute.

This function corresponds to the `nc_copy_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example makes a copy of the attribute associated with the first variable in the netCDF example file, `example.nc`, in a new file. To run this example, you must have write permission in your current directory.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier for a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Create new netCDF file.
ncid2 = netcdf.create('foo.nc','NC_NOCLOBBER');

% Define a dimension in the new file.
dimid2 = netcdf.defDim(ncid2,'x',50);
```

```
% Define a variable in the new file.
varid2 = netcdf.defVar(ncid2,'myvar','double',dimid2);

% Copy the attribute named 'description' into the new file,
% associating the attribute with the new variable.
netcdf.copyAtt(ncid,varid,'description',ncid2,varid2);
%
% Check the name of the attribute in new file.
attname = netcdf.inqAttName(ncid2,varid2,0)

attname =

description
```

See Also

netcdf.inqAtt | netcdf.inqAttID | netcdf.inqAttName | netcdf.putAtt | netcdf.renameAtt

netcdf.create

Create new NetCDF dataset

Syntax

```
ncid = netcdf.create(filename,cmode)
[chunksize_out,ncid] =
netcdf.create(filename,cmode,initsz,chunksize)
```

Description

`ncid = netcdf.create(filename,cmode)` creates a new NetCDF file according to the file creation mode. The return value `ncid` is a file ID. The `cmode` parameter is a text string that describes the type of file access, which can have any of the following values.

Value of `cmode`	Description
`NOCLOBBER`	Prevent overwriting of existing file with the same name.
`CLOBBER`	Overwrite any existing file with the same name.
`SHARE`	Allow synchronous file updates.
`64BIT_OFFSET`	Allow easier creation of files and variables which are larger than two gigabytes.
`NETCDF4`	Create a NetCDF-4/HDF5 file
`CLASSIC_MODEL`	Enforce the classic model; has no effect unless used in a bitwise-or with `NETCDF4`

Note: You can specify the mode as a numeric value, retrieved using the `netcdf.getConstant` function. To specify more than one mode, use a bitwise-OR of the numeric values of the modes.

`[chunksize_out,ncid] = netcdf.create(filename,cmode,initsz,chunksize)` creates a new NetCDF file, but with additional performance tuning parameters. `initsz` sets the initial size of the

file. `chunksize` can affect I/O performance. The actual value chosen by the NetCDF library might not correspond to the input value.

This function corresponds to the `nc_create` and `nc__create` functions in the NetCDF library C API. To use this function, you should be familiar with the NetCDF programming paradigm. See `netcdf` for more information.

Examples

Create NetCDF File Without Overwriting Existing File

Create a NetCDF dataset named `foo.nc`, only if no other file with the same name exists in the current directory. To run this example, you must have write permission in your current directory.

```
ncid = netcdf.create('foo.nc','NOCLOBBER')
```

```
ncid =

       65536
```

`netcdf.create` returns a file identifier.

Close the file

```
netcdf.close(ncid)
```

Create NetCDF-4 File Using Classic Model

Get the numeric values corresponding to the `NETCDF4` and `CLASSIC_MODEL` constants defined by the NetCDF library. Use a bitwise-OR of the numeric values to specify more than one creation mode.

```
cmode = netcdf.getConstant('NETCDF4');
cmode = bitor(cmode,netcdf.getConstant('CLASSIC_MODEL'));
```

Create a NetCDF-4 file that uses the classic model by specifying the creation mode value, `cmode`.

```
ncid = netcdf.create('myfile.nc',cmode);
```

Close the file.

```
netcdf.close(ncid);
```

See Also

`netcdf.getConstant` | `netcdf.open`

netcdf.defDim

Create netCDF dimension

Syntax

```
dimid = netcdf.defDim(ncid,dimname,dimlen)
```

Description

`dimid = netcdf.defDim(ncid,dimname,dimlen)` creates a new dimension in the netCDF file specified by `ncid`, where`dimname` is a character string that specifies the name of the dimension and `dimlen` is a numeric value that specifies its length. To define an unlimited dimension, specify the predefined constant `'NC_UNLIMITED'` for `dimlen`, using `netcdf.getConstant` to retrieve the value.

`netcdf.defDim` returns `dimid`, a numeric ID corresponding to the new dimension.

This function corresponds to the `nc_def_dim` function in the netCDF library C API.To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

Examples

Create a new file and define two dimensions in the file. One dimension is an unlimited dimension. To run this example, you must have write permission in your current folder.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_NOCLOBBER')

% Define a dimension.
lat_dimID = netcdf.defDim(ncid,'latitude',360);

% Define an unlimited dimension.
```

```
long_dimID = netcdf.defDim(ncid,'longitude',...
  netcdf.getConstant('NC_UNLIMITED'));
```

See Also

netcdf.getConstant

netcdf.defGrp

Create group in NetCDF file

Syntax

```
childGrpID = netcdf.defGrp(parentGroupId,childGroupName)
```

Description

`childGrpID = netcdf.defGrp(parentGroupId,childGroupName)` creates a child group with the name specified by `childGroupName`, that is the child of the parent group specified by `parentGroupId`

Input Arguments

`parentGroupId`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`childGroupName`

Text string specifying the name that you want to assign to the group.

Default:

Output Arguments

`childGrpID`

Identifier of a NetCDF group.

Examples

This example creates a NetCDF dataset and then defines a group.

```
ncid = netcdf.create('myfile.nc','netcdf4');
childGroupId = netcdf.defGrp(ncid,'mygroup');
netcdf.close(ncid);
```

References

This function corresponds to the `nc_def_grp` function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

See Also

`netcdf` | `netcdf.inqGrps`

netcdf.defVar

Create NetCDF variable

Syntax

```
varid = netcdf.defVar(ncid,varname,xtype,dimids)
```

Description

`varid = netcdf.defVar(ncid,varname,xtype,dimids)` creates a new variable in the dataset identified by `ncid`.

`varname` is a character string that specifies the name of the variable.

`xtype` specifies the NetCDF data type of the variable, using one of the following strings.

Value of `xtype`	MATLAB Class
`'NC_BYTE'`	`int8` or `uint8`[a]
`'NC_CHAR'`	`char`
`'NC_SHORT'`	`int16`
`'NC_INT'`	`int32`
`'NC_FLOAT'`	`single`
`'NC_DOUBLE'`	`double`

a. NetCDF interprets byte data as either signed or unsigned.

Alternatively, `xtype` can be the numeric equivalent returned by the `netcdf.getConstant` function.

`dimids` specifies a list of dimension IDs.

`netcdf.defVar` returns `varid`, a numeric identifier for the new variable.

This function corresponds to the `nc_def_var` function in the NetCDF library C API. Because MATLAB uses FORTRAN-style ordering, the fastest-varying dimension comes

first and the slowest comes last. Any unlimited dimension is therefore last in the list of dimension IDs. This ordering is the reverse of that found in the C API.To use this function, you should be familiar with the NetCDF programming paradigm. See `netcdf` for more information.

Examples

Define Dimension and Variable in NetCDF File

Create a new NetCDF file, define a dimension in the file, and then define a variable on that dimension. In NetCDF files, you must create a dimension before you can create a variable. To run this example, you must have write permission in your current folder.

Create a new NetCDF file named `foo.nc`.

```
ncid = netcdf.create('foo.nc','NC_NOCLOBBER');
```

Define a dimension in the new file.

```
dimid = netcdf.defDim(ncid,'x',50);
```

Define a variable in the new file using `netcdf.defVar`.

```
varid = netcdf.defVar(ncid,'myvar','double',dimid)
```

```
varid =

     0
```

`netcdf.defVar` returns a numeric identifier for the new variable.

Close the file.

```
netcdf.close(ncid)
```

See Also

`netCDF.getConstant` | `netCDF.inqVar` | `netCDF.putVar`

netcdf.defVarChunking

Define chunking behavior for NetCDF variable

Syntax

```
netcdf.defVarChunking(ncid,varid,storage,chunkDims)
```

Description

`netcdf.defVarChunking(ncid,varid,storage,chunkDims)`. sets the chunk settings for the variable specified by `varid`. Chunking is a technique to improve performance. `storage` specifies the type of chunking to use and `chunkDims` specifies the extents of the chunk size. You must specify the chunk size used with a variable after creating the variable but before you write data to the variable.

You cannot specify the chunk size for variables in a NetCDF file created with the netCDF-3 mode (`CLASSIC_MODEL`).

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

Default:

`storage`

Text string specifying whether NetCDF should break the variable into chunks when writing to a file. If set to `CHUNKED`, NetCDF breaks the variable into chunks; if set to `CONTIGUOUS`, NetCDF does not break the data into chunks.

Default:

`chunkDims`

Array specifying the dimensions of the chunk.

Because MATLAB uses FORTRAN-style ordering, the order of dimensions in `chunkdims` is reversed relative to what would be in the C API.

If storage is `CONTIGUOUS`, you can omit `chunkDims`.

Default: Chunk size determined by the NetCDF library.

Examples

This example creates a NetCDF file and specifies the chunking behavior of a variable.

```
ncid = netcdf.create('myfile.nc','NETCDF4');
latdimid = netcdf.defDim(ncid,'lat',1800);
londimid = netcdf.defDim(ncid,'col',3600);
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);
netcdf.defVarChunking(ncid,varid,'CHUNKED',[180 360]);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_def_var_chunking` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf` | `netcdf.inqVarChunking`

netcdf.defVarDeflate

Define compression parameters for NetCDF variable

Syntax

```
netcdf.defVarDeflate(ncid,varid,shuffle,deflate,deflateLevel)
```

Description

`netcdf.defVarDeflate(ncid,varid,shuffle,deflate,deflateLevel)` sets the compression parameters for the NetCDF variable specified by `varid` in the location specified by `ncid`.

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

Default:

`shuffle`

Boolean value. To turn on the shuffle filter, set this argument to `true`. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

Default:

`deflate`

Boolean value. To turn on compression, set this argument to `true` and set the `deflateLevel` argument to the desired compression level.

Default:

`deflateLevel`

Numeric value between `0` and `9` specifying the amount of compression, where `0` is no compression and `9` is the most compression.

Default:

Examples

This example create a variable with dimensions [1800 3600] and a compression level of 5. This results in a chunked layout that is a 10-by-10 grid.

```
ncid = netcdf.create('myfile.nc','NETCDF4');
latdimid = netcdf.defDim(ncid,'lat',1800);
londimid = netcdf.defDim(ncid,'col',3600);
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);
netcdf.defVarDeflate(ncid,varid,true,true,5);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_def_var_deflate` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.inqVarDeflate`

netcdf.defVarFill

Define fill parameters for NetCDF variable

Syntax

```
netcdf.defVarFill(ncid,varid,noFillMode,fillValue)
```

Description

`netcdf.defVarFill(ncid,varid,noFillMode,fillValue)` sets the fill parameters for the NetCDF variable identified by `varid`. `ncid` specifies the location.

For netCDF-4 files, you can only specify fill values when the NetCDF is in definition mode (before calling `netcdf.endDef`). For NetCDF files in classic and 64-bit offset modes, you can turn no-fill mode on and off at any time.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

Default:

`noFillMode`

Boolean value. When set to `true`, turns off use of fill values for the variable, which can be helpful in high performance applications. When `true`, `netcdf.defVarFill` ignores the value of the `fillValue` argument. To use the fill value, set this to `false`.

Default:

`fillValue`

Specifies the value to use in the variable when no other value is specified. The data type must be the same data type as the variable.

Default:

Examples

This example creates a NetCDF file and defines a fill value for a variable.

```
ncid = netcdf.create('myfile.nc','NETCDF4');
dimid = netcdf.defDim(ncid,'latitude',180);
varid = netcdf.defVar(ncid,'latitude','double',dimid);
netcdf.defVarFill(ncid,varid,false,-999);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_def_var_fill` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.setFill` | `netcdf.inqVarFill`

netcdf.defVarFletcher32

Define checksum parameters for NetCDF variable

Syntax

```
netcdf.defVarFletcher32(ncid,varid,setting)
```

Description

`netcdf.defVarFletcher32(ncid,varid,setting)` defines the checksum settings for the NetCDF variable specified by `varid` in the file specified by `ncid`.

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

Default:

`setting`

Text string specifying whether Fletcher32 checksum error detection is used with the variable. To turn on Fletcher32 checksum, specify the value `FLETCHER32`. To turn off the use of checksum error detection, specify the value `NOCHECKSUM`.

Default:

Examples

This example creates a NetCDF dataset and turns on the Fletcher32 checksum for a variable.

```
ncid = netcdf.create('myfile.nc','NETCDF4');
latdimid = netcdf.defDim(ncid,'lat',1800);
londimid = netcdf.defDim(ncid,'col',3600);
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);
netcdf.defVarFletcher32(ncid,varid,'FLETCHER32');
netcdf.close(ncid);
```

References

This function corresponds to the `nc_def_var_fletcher32` function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

See Also

`netcdf` | `netcdf.inqVarFletcher32`

netcdf.delAtt

Delete netCDF attribute

Syntax

```
netcdf.delAtt(ncid,varid,attName)
```

Description

`netcdf.delAtt(ncid,varid,attName)` deletes the attribute identified by the text string `attName`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric value that identifies the variable. To delete a global attribute, use `netcdf.getConstant('GLOBAL')` for the `varid`. You must be in define mode to delete an attribute.

This function corresponds to the `nc_del_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Determine number of global attributes in file.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

   1
```

```
% Get name of attribute; it is needed for deletion.
attname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

% Put file in define mode to delete an attribute.
netcdf.reDef(ncid);

% Delete the global attribute in the netCDF file.
netcdf.delAtt(ncid,netcdf.getConstant('GLOBAL'),attname);

% Verify that the global attribute was deleted.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

   0
```

See Also

netcdf.getConstant | netcdf.inqAttName

netcdf.endDef

End netCDF file define mode

Syntax

```
netcdf.endDef(ncid)
netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)
```

Description

`netcdf.endDef(ncid)` takes a netCDF file out of define mode and into data mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)` takes a netCDF file out of define mode, specifying four additional performance tuning parameters. For example, one reason for using the performance parameters is to reserve extra space in the netCDF file header using the `h_minfree` parameter:

```
ncid = netcdf.endDef(ncid,20000,4,0,4);
```

This reserves 20,000 bytes in the header, which can be used later when adding attributes. This can be extremely efficient when working with very large netCDF 3 files. To understand how to use these performance tuning parameters, see the netCDF library documentation.

This function corresponds to the `nc_enddef` and `nc__enddef` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

Take File out of Define Mode

When you create a file using `netcdf.create`, the functions opens the file in define mode. This example uses `netcdf.endDef` to take the file out of define mode.

Create a netCDF file.

```
ncid = netcdf.create('foo.c','NC_NOCLOBBER');
```

Define a dimension.

```
dimid = netcdf.defDim(ncid,'lat',50);
```

Leave define mode.

```
netcdf.endDef(ncid)
```

Test if still in define mode.

```
dimid = netcdf.defDim(ncid,'lon',50);
```

```
Error using netcdflib
The NetCDF library encountered an error during execution of 'defDim' function - 'Operat
(NC_ENOTINDEFINE)'.

Error in netcdf.defDim (line 25)
dimid = netcdflib('defDim', ncid,dimname,dimlen);
```

`netcdf.defDim` errors, as expected.

See Also

`netcdf.create` | `netcdf.reDef`

netcdf.getAtt

Return netCDF attribute

Syntax

```
attrvalue = netcdf.getAtt(ncid,varid,attname)
attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)
```

Description

`attrvalue = netcdf.getAtt(ncid,varid,attname)` returns `attrvalue`, the value of the attribute specified by the text string `attname`. When it chooses the data type of `attrvalue`, MATLAB attempts to match the netCDF class of the attribute. For example, if the attribute has the netCDF data type `NC_INT`, MATLAB uses the `int32` class for the output data. If an attribute has the netCDF data type `NC_BYTE`, the class of the output data is `int8` value.

`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)` returns `attrvalue`, the value of the attribute specified by the text string `attname`, using the output class specified by `output_datatype`. You can specify any of the following strings for the output data type.

`'int'`	`'double'`	`'int16'`
`'short'`	`'single'`	`'int8'`
`'float'`	`'int32'`	`'uint8'`

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and gets the value of the attribute associated with the first variable. The example also gets the value of the global variable in the file.

```
% Open a netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name of first variable.
[varname vartype vardimIDs varatts] = netcdf.inqVar(ncid,0);

% Get ID of variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get attribute name, given variable id.
attname = netcdf.inqAttName(ncid,varid,0);

% Get value of attribute.
attval = netcdf.getAtt(ncid,varid,attname);

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get value of global attribute.
gattval = netcdf.getAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname)

gattval =

09-Jun-2008
```

See Also

netcdf.inqAtt | netcdf.putAtt

netcdf.getChunkCache

Retrieve chunk cache settings for NetCDF library

Syntax

```
[csize, nelems, premp] = netcdf.getChunkCache()
```

Description

`[csize, nelems, premp] = netcdf.getChunkCache()` returns the default chunk cache settings.

Output Arguments

`csize`

Scalar double specifying the total size of the raw data chunk cache in bytes.

`nelems`

Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.

`premp`

Double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of zero means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.

Examples

Determine information about the chunk cache size used by the NetCDF library.

```
[csize, nelems, premp] = netcdf.getChunkCache();
```

References

This function corresponds to the `nc_get_chunk_cache` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.setChunkCache`

netcdf.getConstant

Return numeric value of named constant

Syntax

```
val = netcdf.getConstant(param_name)
```

Description

`val = netcdf.getConstant(param_name)` returns the numeric value corresponding to the name of a constant defined by the netCDF library. For example, `netcdf.getConstant('NC_NOCLOBBER')` returns the numeric value corresponding to the netCDF constant `NC_NOCLOBBER`.

The value for `param_name` can be either upper- or lowercase, and does not need to include the leading three characters `'NC_'`. To retrieve a list of all the names defined by the netCDF library, use the `netcdf.getConstantNames` function.

This function has no direct equivalent in the netCDF C interface. To find out more about NetCDF, see `netcdf`.

Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Determine contents of the file.
[ndims nvars natts dimm] = netcdf.inq(ncid);

% Get name of global attribute.
% Note: You must use netcdf.getConstant to specify NC_GLOBAL.
attname = netcdf.inqattname(ncid,netcdf.getConstant('NC_GLOBAL'),0)

attname =
```

```
creation_date
```

See Also

`netcdf.getConstantNames`

netcdf.getConstantNames

Return list of constants known to netCDF library

Syntax

```
val = netcdf.getConstantNames(param_name)
```

Description

`val = netcdf.getConstantNames(param_name)` returns a list of names of netCDF library constants, definitions, and enumerations. When these strings are supplied as actual parameters to MATLAB netCDF package functions, the functions automatically convert the constant to the appropriate numeric value.

This MATLAB function has no direct equivalent in the netCDF C interface. To find out more about netCDF, see `netcdf`.

Examples

```
nc_constants = netcdf.getConstantNames

nc_constants =

    'NC2_ERR'
    'NC_64BIT_OFFSET'
    'NC_BYTE'
    'NC_CHAR'
    'NC_CLOBBER'
    'NC_DOUBLE'
    'NC_EBADDIM'
    'NC_EBADID'
    'NC_EBADNAME'
    'NC_EBADTYPE'
  ...
```

See Also

`netCDF.getConstantNames`

netcdf.getVar

Read data from NetCDF variable

Syntax

```
data = netcdf.getVar(ncid,varid)
data = netcdf.getVar(ncid,varid,start)
data = netcdf.getVar(ncid,varid,start,count)
data = netcdf.getVar(ncid,varid,start,count,stride)
data = netcdf.getVar( ___ ,output_type)
```

Description

`data = netcdf.getVar(ncid,varid)` returns `data`, the value of the variable specified by `varid`. MATLAB attempts to match the class of the output data to NetCDF class of the variable.

`ncid` is a NetCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`data = netcdf.getVar(ncid,varid,start)` returns a single value starting at the specified index, `start`.

`data = netcdf.getVar(ncid,varid,start,count)` returns a contiguous section of a variable. `start` specifies the starting point and `count` specifies the amount of data to return.

`data = netcdf.getVar(ncid,varid,start,count,stride)` returns a subset of a section of a variable. `start` specifies the starting point, `count` specifies the extent of the section, and `stride` specifies which values to return.

`data = netcdf.getVar( ___ ,output_type)` specifies the data type of the return value `data`. You can specify any of the following strings for the output data type.

`'int8'`
`'uint8'`
`'int16'`

`'int32'`
`'single'`
`'double'`

This function corresponds to several functions in the NetCDF library C API. To use this function, you should be familiar with the NetCDF programming paradigm. See `netcdf` for more information.

Examples

Read Value of Variable in NetCDF File

Open the example file, `example.nc`.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

Get the name of the first variable in the file.

```
varname = netcdf.inqVar(ncid,0)
```

```
varname =

avagadros_number
```

Get variable ID of the first variable, given its name.

```
varid = netcdf.inqVarID(ncid,varname)
```

```
varid =

     0
```

Get the value of the variable. Use the variable ID as the second input to the `netcdf.getVar` function.

```
data = netcdf.getVar(ncid,varid)
```

```
data =

   6.0221e+23
```

Display the data type of the output value.

```
whos data
```

```
  Name      Size            Bytes  Class     Attributes

  data      1x1                 8  double
```

Get the value of the `avogadros_number` variable again, specifying that the output data type should be `single`.

```
data = netcdf.getVar(ncid,varid,'single');
```

Display the data type of the output value.

```
whos data
```

```
  Name      Size            Bytes  Class     Attributes

  data      1x1                 4  single
```

Close the NetCDF file.

```
netcdf.close(ncid)
```

See Also

`netcdf.create` | `netcdf.inqVarID` | `netcdf.open`

netcdf.inq

Return information about netCDF file

Syntax

```
[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)
```

Description

`[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)` returns the number of dimensions, variables, and global attributes in a netCDF file. The function also returns the ID of the dimension defined with unlimited length, if one exists.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. You can call `netcdf.inq` in either define mode or data mode.

This function corresponds to the `nc_inq` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and uses the `netcdf.inq` function to get information about the contents of the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE')

% Get information about the contents of the file.
[numdims, numvars, numglobalatts, unlimdimID] = netcdf.inq(ncid)

numdims =

     4
```

```
numvars =

     4

numglobalatts =

     1

unlimdimID =

     3
```

netcdf.create | netcdf.open

netcdf.inqDimIDs

Retrieve list of dimension identifiers in group

Syntax

```
dimIDs = netcdf.inqDimIDs(ncid)
dimIDs = netcdf.inqDimIDs(ncid,includeParents)
```

Description

`dimIDs = netcdf.inqDimIDs(ncid)` returns a list of dimension identifiers in the group specified by `ncid`.

`dimIDs = netcdf.inqDimIDs(ncid,includeParents)` includes all dimensions in all parent groups if `includeParents` is `true`.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`includeParents`

Boolean value. If set to `true`, `netcdf.inqDimIDs` includes the dimensions of all parent groups.

Default: `false`

Output Arguments

`dimIDs`

Array of dimension IDs

Examples

This example opens the NetCDF sample file and gets the IDs of all the dimensions.

```
ncid = netcdf.open('example.nc','NOWRITE');
gid = netcdf.inqNcid(ncid,'grid1');
dimids = netcdf.inqDimIDs(gid);
dimids_all = netcdf.inqDimIDS(gid, true);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_dimids` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.inqVarIDs`

netcdf.inqFormat

Determine format of NetCDF file

Syntax

```
format = netcdf.inqFormat(ncid)
```

Description

`format = netcdf.inqFormat(ncid)` returns the format for the file specified by NetCDF file identifier, `ncid`.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

Output Arguments

`format`

Text string that specifies the format of the NetCDF file. Values include:

Format String	Description
`FORMAT_CLASSIC`	Classic format — Original NetCDF format, used by all NetCDF files created between 1989 and 2004
`FORMAT_64BIT`	Classic format, 64–bit — Original format with 64–bit addressing capability to allow creation and access of much larger files.

Format String	Description
FORMAT_NETCDF4	Enhanced model, HDF5-based — Introduced in 2008, NetCDF, version 4, extends the classic model and is based on HDF5.
FORMAT_NETCDF4_CLASSIC	Classic model, HDF5-based — Introduced in 2008, NetCDF, version 4, implements classic model but is based on HDF5.

Examples

This example opens the sample NetCDF file and determines the format.

```
ncid = netcdf.open('example.nc','NOWRITE');
fmt = netcdf.inqFormat(ncid)

format =

FORMAT_NETCDF4

netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_format` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf.getConstant` | `netcdf`

netcdf.inqGrpName

Retrieve name of group

Syntax

```
groupName = netcdf.inqGrpName(ncid)
```

Description

`groupName = netcdf.inqGrpName(ncid)` returns the name of a group specified by `ncid`.

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

Output Arguments

`groupName`

Text string specifying name of a group. The root group has the name `'/'`.

Examples

This example opens the NetCDF sample file and gets the names of groups in the dataset.

```
ncid = netcdf.open('example.nc','nowrite');
name = netcdf.inqGrpName(ncid);
```

```
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_grpname` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.inqGrpNameFull`

netcdf.inqGrpNameFull

Complete pathname of group

Syntax

```
groupName = netcdf.inqGrpNameFull(ncid)
```

Description

`groupName = netcdf.inqGrpNameFull(ncid)` returns the complete pathname of the group specified by `ncid`.

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

Output Arguments

`groupName`

Text string specifying complete path of group.

The root group has the name `'/'`. The names of parent groups and child groups use the forward slash `'/'` separator, as in UNIX folder names, for example, `/group1/subgrp2/subsubgrp3`.

Examples

Open the NetCDF sample dataset and retrieve the names of all groups.

```
ncid = netcdf.open('example.nc','NOWRITE');
gid = netcdf.inqNcid(ncid,'grid2');
fullName = netcdf.inqGrpNameFull(gid);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_grpname_full` function in the netCDF library C API.

See Also

`netcdf` | `netcdf.inqGrpName`

netcdf.inqGrpParent

Retrieve ID of parent group.

Syntax

```
parentGroupID = netcdf.inqGrpParent(ncid)
```

Description

`parentGroupID = netcdf.inqGrpParent(ncid)` returns the ID of the parent group given the location of the child group, specified by `ncid`.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

Output Arguments

`parentGroupID`

Identifier of the NetCDF group or file that is the parent of the specified file or group.

Examples

This example opens the NetCDF sample file and gets the full path of the parent of the specified group.

```
ncid = netcdf.open('example.nc','NOWRITE');
```

```
gid = netcdf.inqNcid(ncid,'grid2');
parentId = netcdf.inqGrpParent(gid);
fullName = netcdf.inqGrpNameFull(parentId);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_grp_parent` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.inqGrps`

netcdf.inqGrps

Retrieve array of child group IDs

Syntax

```
childGrps = netcdf.inqGrps(ncid)
```

Description

`childGrps = netcdf.inqGrps(ncid)` returns all the child group IDs in the parent group, specified by `ncid`.

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

Output Arguments

`childGrps`

Array containing identifiers of child groups in the specified NetCDF file or group.

Examples

This example opens the sample NetCDF file and then gets information about the groups it contains.

```
ncid = netcdf.open('example.nc','nowrite');
```

```
childGroups = netcdf.inqGrps(ncid);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_grps` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.inqNcid`

netcdf.inqNcid

Return ID of named group

Syntax

```
childGroupId = netcdf.inqNcid(ncid,childGroupName)
```

Description

`childGroupId = netcdf.inqNcid(ncid,childGroupName)` returns the ID of the child group, specified by the name `childGroupName`, in the file or group specified by `ncid`.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`childGroupName`

Text string specifying the name of a NetCDF group.

Default:

Output Arguments

`childGroupID`

Identifier of a NetCDF group.

Examples

This example opens the sample NetCDF dataset and then gets the ID of a group in the dataset.

```
ncid = netcdf.open('example.nc','nowrite');
gid = netcdf.inqNcid(ncid,'grid1');
netcdf.close(ncid);
```

References

This function corresponds to the nc_inq_ncid function in the netCDF library C API. Read the files `netcdfcopyright.txt` and `mexnccopyright.txt` for more information.

See Also

`netcdf` | `netcdf.inqGrpName` | `netcdf.inqGrpNameFull`

netcdf.inqUnlimDims

Return list of unlimited dimensions in group

Syntax

```
unlimdimIDs = netcdf.inqUnlimDims(ncid)
```

Description

`unlimdimIDs = netcdf.inqUnlimDims(ncid)` returns the IDs of all unlimited dimensions in the group specified by `ncid`.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or group, returned by `netcdf.defGrp`.

Default:

Output Arguments

`unlimDimIDs`

An array containing the identifiers of each unlimited dimension. `unlimDimIDs` is empty if there are no unlimited dimensions.

Examples

This example opens the NetCDF sample dataset and gets the IDs of all the unlimited dimensions.

```
ncid = netcdf.open('example.nc','NOWRITE');
dimids = netcdf.inqUnlimDims(ncid)

dimids =

     []

netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_unlim_dims` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.defDim` | `netcdf.inqDim` | `netcdf.inqDimID` | `netcdf.renameDim` | `netcdf.inqDimIDs`

netcdf.inqVarIDs

IDs of all variables in group

Syntax

```
varids = netcdf.inqVarIDs(ncid)
```

Description

`varids = netcdf.inqVarIDs(ncid)` returns IDs of the all the variables in the group specified by `ncid`.

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

Output Arguments

`varids`

Array containing identifiers of variables in a NetCDF file or group.

Examples

This example opens the NetCDF sample file and gets the IDs of all the variables in a group.

```
ncid = netcdf.open('example.nc','NOWRITE');
```

```
gid = netcdf.inqNcid(ncid,'grid1');
varids = netcdf.inqVarIDs(gid);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_varids` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.inqDimIDs` | `netcdf.inqVarID`

netcdf.inqVarChunking

Determine chunking settings for NetCDF variable

Syntax

```
[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)
```

Description

`[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)` returns the type of chunking and the dimensions of a chunk for the NetCDF variable specified by `varid`, in the file or group specified by `ncid`.

Input Arguments

`ncid`

Identifier of NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of NetCDF variable, returned by `netcdf.defVar`.

Default:

Output Arguments

`storage`

Text string specifying if NetCDF breaks the data into chunks when writing to a file. `CHUNKED` indicates the data is chunked; `CONTIGUOUS` indicates that the data is not chunked.

`chunkSizes`

Array specifying the dimensions of the chunk.

Because MATLAB uses FORTRAN-style ordering, the order of dimensions in `chunkdims` is reversed relative to what would be in the NetCDF C API.

If the storage type specified is `CONTIGUOUS`, `netcdf.inqVarChunking` returns an empty array, `[]`.

Examples

This example opens the NetCDF sample dataset and gets the values of chunking parameters associated with a variable.

```
ncid = netcdf.open('example.nc','NOWRITE');
groupid = netcdf.inqNcid(ncid,'grid1');
varid = netcdf.inqVarID(groupid,'temp');
[storage,chunkSize] = netcdf.inqVarChunking(groupid,varid);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_var_chunking` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.defVar` | `netcdf.defVarChunking`

netcdf.inqVarDeflate

Determine compression settings for NetCDF variable

Syntax

```
[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid,varid)
```

Description

`[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(ncid,varid)` returns the compression parameters for the NetCDF variable specified by `varid` in the location specified by `ncid`.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of NetCDF variable, returned by `netcdf.defVar`.

Default:

Output Arguments

`shuffle`

Boolean value. `true` indicates that the shuffle filter is enabled for the specified variable. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.

`deflate`

Boolean value. `true` indicates that compression is enabled for this variable. The `deflateLevel` argument specifies the level of compression.

`deflateLevel`

Scalar value between `0` and `9` specifying the amount of compression, where `0` is no compression and `9` is the most compression

Examples

This example opens the NetCDF sample file and gets information about variable compression.

```
ncid = netcdf.open('example.nc','NOWRITE');
groupid = netcdf.inqNcid(ncid,'grid1');
varid = netcdf.inqVarID(groupid,'temp');
[shuffle,deflate,deflateLevel] = netcdf.inqVarDeflate(groupid,varid);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_var_deflate` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.defVarDeflate`

netcdf.inqVarFill

Determine values of fill parameters for NetCDF variable

Syntax

```
[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid)
```

Description

`[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid)` returns the fill mode and the fill value for the variable `varid` in the file or group specified by `ncid`.

Input Arguments

`ncid`

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or a NetCDF group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of NetCDF variable.

Default:

Output Arguments

`noFillMode`

Boolean value. `true` indicates that use of the fill values for the variable has been disabled.

`fillValue`

Specifies the value to use in the variable when no other value is specified and use of fill values has been enabled.

Examples

This example opens the NetCDF sample dataset and gets the fill mode and fill value used with a variable.

```
ncid = netcdf.open('example.nc','NOWRITE');
varid = netcdf.inqVarID(ncid,'temperature');
[noFillMode,fillValue] = netcdf.inqVarFill(ncid,varid);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_var_fill` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.defVarFill` | `netcdf.setFill`

netcdf.inqVarFletcher32

Fletcher32 checksum setting for NetCDF variable

Syntax

```
setting = netcdf.inqVarFletcher32(ncid,varid)
```

Description

`setting = netcdf.inqVarFletcher32(ncid,varid)` returns the Fletcher32 checksum setting for the NetCDF variable specified by `varid` in the file or group specified by `ncid`.

Input Arguments

`ncid`

Identifier for NetCDF file, returned by `netcdf.create` or `netcdf.open`, or group, returned by `netcdf.defGrp`.

Default:

`varid`

Identifier of NetCDF variable.

Default:

Output Arguments

`setting`

Text string specifying whether the Fletcher32 checksum is turned on for the specified variable. `netcdf.inqVarFletcher32` returns the text string `FLETCHER32` if the checksum is turned on for the variable; otherwise, `NOCHECKSUM`.

Examples

This example opens the sample NetCDF file and gets information about the checksum setting for a variable.

```
ncid = netcdf.open('example.nc','NOWRITE');
varid = netcdf.inqVarID(ncid,'temperature');
setting = netcdf.inqVarFletcher32(ncid,varid);
netcdf.close(ncid);
```

References

This function corresponds to the `nc_inq_var_fletcher32` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` for more information.

See Also

`netcdf` | `netcdf.defVarFletcher32`

netcdf.inqAtt

Return information about netCDF attribute

Syntax

```
[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)
```

Description

`[xtype,attlen] = netcdf.inqAtt(ncid,varid,attname)` returns the data type, `xtype`, and length, `attlen`, of the attribute identified by the text string `attname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable that the attribute is associated with. To get information about a global attribute, specify `netcdf.getConstant('NC_GLOBAL')` in place of `varid`.

This function corresponds to the `nc_inq_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and gets information about an attribute in the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NOWRITE');

% Get identifier of a variable in the file, given its name.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Get attribute name, given variable id and attribute number.
attname = netcdf.inqAttName(ncid,varid,0);
```

```
% Get information about the attribute.
[xtype,attlen] = netcdf.inqAtt(ncid,varid,'description')

xtype =

     2

attlen =

    31

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get information about global attribute.
[gxtype gattlen] = netcdf.inqAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname)

gxtype =

     2

gattlen =

    11
```

See Also

netcdf.inqAttID | netcdf.inqAttName

netcdf.inqAttID

Return ID of netCDF attribute

Syntax

```
attnum = netcdf.inqAttID(ncid,varid,attname)
```

Description

`attnum = netcdf.inqAttID(ncid,varid,attname)` retrieves `attnum`, the identifier of the attribute specified by the text string `attname`.

`varid` specifies the variable the attribute is associated with.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_attid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the netCDF example file included with MATLAB, `example.nc`.

```
% Open the netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get the identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number');

% Retrieve the identifier of the attribute associated with the variable.
attid = netcdf.inqAttID(ncid,varid,'description');
```

See Also

`netcdf.inqAtt` | `netcdf.inqAttName`

netcdf.inqAttName

Return name of netCDF attribute

Syntax

```
attname = netcdf.inqAttName(ncid,varid,attnum)
```

Description

`attname = netcdf.inqAttName(ncid,varid,attnum)` returns `attname`, a text string specifying the name of an attribute.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric identifier of a variable in the file. If you want to get the name of a global attribute in the file, use `netcdf.getConstant('NC_GLOBAL')` in place of `attnum` is a zero-based numeric value specifying the attribute, with 0 indicating the first attribute, 1 the second attribute, and so on.

This function corresponds to the `nc_inq_attname` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get identifier of a variable in the file.
varid = netcdf.inqVarID(ncid,'avagadros_number')

% Get the name of the attribute associated with the variable.
attname = netcdf.inqAttName(ncid,varid,0)
```

```
attname =

description

% Get the name of the global attribute associated with the variable.
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

gattname =

creation_date
```

See Also

netcdf.inqAtt | netcdf.inqAttID

netcdf.inqDim

Return netCDF dimension name and length

Syntax

```
[dimname, dimlen] = netcdf.inqDim(ncid,dimid)
```

Description

`[dimname, dimlen] = netcdf.inqDim(ncid,dimid)` returns the name, `dimname`, and length, `dimlen`, of the dimension specified by `dimid`. If `ndims` is the number of dimensions defined for a netCDF file, each dimension has an ID between 0 and `ndims-1`. For example, the dimension identifier of the first dimension is 0, the second dimension is 1, and so on.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

The example opens the example netCDF file include with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0)

dimname =

x

dimlen =
```

```
    50
```

See Also

`netcdf.inqDimID`

netcdf.inqDimID

Return dimension ID

Syntax

```
dimid = netcdf.inqDimID(ncid,dimname)
```

Description

`dimid = netcdf.inqDimID(ncid,dimname)` returns `dimid`, the identifier of the dimension specified by the character string `dimname`. You can use the `netcdf.inqDim` function to retrieve the dimension name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dimid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0);

% Retrieve identifier of dimension.
dimid = netcdf.inqDimID(ncid,dimname)

dimid =

     0
```

See Also

`netcdf.inqDim`

netcdf.inqLibVers

Return NetCDF library version information

Syntax

```
libvers = netcdf.inqLibVers
```

Description

`libvers = netcdf.inqLibVers` returns a string identifying the version of the NetCDF library.

This function corresponds to the `nc_inq_libvers` function in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

```
libvers = netcdf.inqLibVers

libvers =

4.1.3
```

netcdf.inqVar

Information about variable

Syntax

```
[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)
```

Description

`[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)` returns information about the variable identified by `varid`. The argument, `ncid`, is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

The output argument, `varname`, is the name of the variable. `xtype` is the data type, `dimids` is the dimension IDs, and `natts` is the number of attributes associated with the variable. Dimension IDs are zero-based.

This function corresponds to the `nc_inq_var` function in the netCDF library C API. Because MATLAB uses FORTRAN-style ordering, however, the order of the dimension IDs is reversed relative to what would be obtained from the C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

Open the example netCDF file included with MATLAB, `example.nc`, and get information about a variable in the file.

```
% Open the example netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about third variable in the file.
[varname, xtype, dimids, numatts] = netcdf.inqVar(ncid,2)

varname =
```

```
peaks

xtype =

     5

dimids =

     0     1

numatts =

     1     1
```

See Also

netcdf.create | netcdf.inqVarID | netcdf.open

netcdf.inqVarID

Return ID associated with variable name

Syntax

```
varid = netcdf.inqVarID(ncid,varname)
```

Description

`varid = netcdf.inqVarID(ncid,varname)` returns `varid`, the ID of a netCDF variable specified by the text string, `varname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_varid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the example netCDF file included with MATLAB, `example.nc`, and uses several inquiry functions to get the ID of the first variable.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about first variable in the file.
[varname, xtype, dimids, atts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name
varid = netcdf.inqVarID(ncid,varname)

varid =

     0
```

See Also

`netcdf.create` | `netcdf.inqVar` | `netcdf.open`

netcdf.open

Open NetCDF data source

Syntax

```
ncid = netcdf.open(source)
ncid = netcdf.open(source,mode)
[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)
```

Description

`ncid = netcdf.open(source)` opens `source`, which can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source, for read-only access. Returns a NetCDF ID in `ncid`.

`ncid = netcdf.open(source,mode)` opens `source` with the type of access specified by `mode`, which can have any of the following values.

Value	Description
`'WRITE'`	Read-write access
`'SHARE'`	Synchronous file updates
`'NOWRITE'`	Read-only access (Default)

You can also specify `mode` as a numeric value that can be retrieved using `netcdf.getConstant`. Use these numeric values when you want to specify a bitwise-OR of several modes.

`[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)` opens `source`, an existing netCDF data source, specifying the additional I/O performance tuning parameter, `chunksize`. The actual value used by the NetCDF library might not correspond to the input value you specify.

This function corresponds to the `nc_open` and `nc__open` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens the example NetCDF file included with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NOWRITE');
netcdf.close(ncid);
```

See Also

`netcdf.close` | `netcdf` | `netcdf.getConstant`

netcdf.putAtt

Write netCDF attribute

Syntax

```
netcdf.putAtt(ncid,varid,attrname,attrvalue)
```

Description

`netcdf.putAtt(ncid,varid,attrname,attrvalue)` writes the attribute named `attrname` with value `attrvalue` to the netCDF variable specified by `varid`. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

`ncid` is a netCDF file identifier returned by `netCDF.create` or `netCDF.open`.

Note: You cannot use `netcdf.putAtt` to set the `'_FillValue'` attribute of NetCDF4 files. Use the `netcdf.defVarFill` function to set the fill value for a variable.

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example creates a new netCDF file, defines a dimension and a variable, adds data to the variable, and then creates an attribute associated with the variable. To run this example, you must have writer permission in your current directory.

```
% Create a variable in the workspace.
my_vardata = linspace(0,50,50);

% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');
```

```
% Define a dimension in the file.
dimid = netcdf.defDim(ncid,'my_dim',50);

% Define a new variable in the file.
varid = netcdf.defVar(ncid,'my_var','double',dimid);

% Leave define mode and enter data mode to write data.
netcdf.endDef(ncid);

% Write data to variable.
netcdf.putVar(ncid,varid,my_vardata);

% Re-enter define mode.
netcdf.reDef(ncid);

% Create an attribute associated with the variable.
netcdf.putAtt(ncid,0,'my_att',10);

% Verify that the attribute was created.
[xtype xlen] = netcdf.inqAtt(ncid,0,'my_att')

xtype =

     6

xlen =

     1
```

This example creates a new netCDF file, specifies a global attribute, and assigns a value to the attribute.

```
ncid = netcdf.create('myfile.nc','CLOBBER');
varid = netcdf.getConstant('GLOBAL');
netcdf.putAtt(ncid,varid,'creation_date',datestr(now));
netcdf.close(ncid);
```

See Also

`netcdf.getAtt` | `netcdf.defVarFill` | `netcdf.getConstant`

netcdf.putVar

Write data to netCDF variable

Syntax

```
netcdf.putVar(ncid,varid,data)
netcdf.putVar(ncid,varid,start,data)
netcdf.putVar(ncid,varid,start,count,data)
netcdf.putVar(ncid,varid,start,count,stride,data)
```

Description

`netcdf.putVar(ncid,varid,data)` writes `data` to a netCDF variable identified by `varid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.putVar(ncid,varid,start,data)` writes a single data value into the variable at the index specified by `start`.

`netcdf.putVar(ncid,varid,start,count,data)` writes a section of values into the netCDF variable at the index specified by the vector `start` to the extent specified by the vector `count`, along each dimension of the specified variable.

`netcdf.putVar(ncid,varid,start,count,stride,data)` writes the subsection specified by sampling interval, `stride`, of the values in the section of the variable beginning at the index `start` and to the extent specified by `count`.

This function corresponds to several variable I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

Write Variable to New netCDF File

Create a new netCDF file and write a variable to the file.

Create a 50 element vector for a variable.

```
my_vardata = linspace(0,50,50);
```

Open the netCDF file.

```
ncid = netcdf.create('foo.nc','NOCLOBBER');
```

Define the dimensions of the variable.

```
dimid = netcdf.defDim(ncid,'my_dim',50);
```

Define a new variable in the file.

```
my_varID = netcdf.defVar(ncid,'my_var','double',dimid);
```

Leave define mode and enter data mode to write data.

```
netcdf.endDef(ncid);
```

Write data to variable.

```
netcdf.putVar(ncid,my_varID,my_vardata);
```

Verify that the variable was created.

```
[varname xtype dimid natts ] = netcdf.inqVar(ncid,0)
```

```
varname =

my_var

xtype =

     6

dimid =

     0

natts =

     0
```

Close the file.

```
netcdf.close(ncid)
```

Write Elements of Variable

Write to the first ten elements of the example `temperature` variable.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.nc');
copyfile(srcFile,'myfile.nc');
fileattrib('myfile.nc','+w');
ncid = netcdf.open('myfile.nc','WRITE');
varid = netcdf.inqVarID(ncid,'temperature');
data = [100:109];
netcdf.putVar(ncid,varid,0,10,data);
netcdf.close(ncid);
```

See Also

`netcdf.getVar`

netcdf.reDef

Put open netCDF file into define mode

Syntax

```
netcdf.reDef(ncid)
```

Description

`netcdf.reDef(ncid)` puts an open netCDF file into define mode so that dimensions, variables, and attributes can be added or renamed. Attributes can also be deleted in define mode. `ncid` is a valid NetCDF file ID, returned from a previous call to `netcdf.open` or `netcdf.create`.

This function corresponds to the `nc_redef` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Try to define a dimension.
dimid = netcdf.defdim(ncid, 'lat', 50); % should fail.
??? Error using ==> netcdflib
NetCDF: Operation not allowed in data mode

Error in ==> defDim at 22
dimid = netcdflib('def_dim', ncid,dimname,dimlen);

% Put file in define mode.
netcdf.reDef(ncid);
```

```
% Try to define a dimension again. Should succeed.
dimid = netcdf.defDim(ncid, 'lat', 50);
```

See Also

netcdf.create | netcdf.endDef | netcdf.open

netcdf.renameAtt

Change name of attribute

Syntax

```
netcdf.renameAtt(ncid,varid,oldName,newName)
```

Description

`netcdf.renameAtt(ncid,varid,oldName,newName)` changes the name of the attribute specified by the character string `oldName`.

`newName` is a character string that specifies the new name.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable to which the attribute is associated. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

This function corresponds to the `nc_rename_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Get the ID of a variable the attribute is associated with.
varID = netcdf.inqVarID(ncid,'avagadros_number')

% Rename the attribute.
netcdf.renameAtt(ncid,varID,'description','Description');
```

```
% Verify that the name changed.
attname = netcdf.inqAttName(ncid,varID,0)

attname =

Description
```

See Also

netcdf.inqAttName

netcdf.renameDim

Change name of netCDF dimension

Syntax

```
netcdf.renameDim(ncid,dimid,newName)
```

Description

`netcdf.renameDim(ncid,dimid,newName)` renames the dimension identified by the dimension identifier, `dimid`.

`newName` is a character string specifying the new name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`

This function corresponds to the `nc_rename_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This examples modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file is define mode.
netcdf.reDef(ncid)

% Get the identifer of a dimension to rename.
dimid = netcdf.inqDimID(ncid,'x');

% Rename the dimension.
netcdf.renameDim(ncid,dimid,'Xdim')
```

```
% Verify that the name changed.
data = netcdf.inqDim(ncid,dimid)

data =

Xdim
```

See Also

netcdf.defDim

netcdf.renameVar

Change name of netCDF variable

Syntax

```
netcdf.renameVar(ncid,varid,newName)
```

Description

`netcdf.renameVar(ncid,varid,newName)` renames the variable identified by `varid` in the netCDF file identified by `ncid`.`newName` is a character string specifying the new name.

This function corresponds to the `nc_rename_var` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file in define mode.
netcdf.redef(ncid)

% Get name of first variable
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname

varname =

avagadros_number
```

```
% Rename the variable, using a capital letter to start the name.
netcdf.renameVar(ncid,0,'Avagadros_number')

% Verify that the name of the variable changed.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname

varname =

Avagadros_number
```

See Also

netCDF.defVar | netCDF.inqVar | netCDF.putVar

netcdf.setChunkCache

Set default chunk cache settings for NetCDF library

Syntax

```
netcdf.setChunkCache(csize,nelems,premp)
```

Description

`netcdf.setChunkCache(csize,nelems,premp)` sets the default chunk cache settings used by the NetCDF library.

Settings apply for subsequent file open or create operations, for the remainder of the MATLAB session or until you issue a `clear mex` call. This function does not change the chunk cache settings of files already open.

Input Arguments

`csize`

Scalar double specifying the total size of the raw data chunk cache in bytes.

Default:

`nelems`

Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.

Default:

`premp`

Scalar double, between `0` and `1`, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of `0` means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based

on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.

Default:

Examples

This example sets the cache chunk size used by the NetCDF library.

```
netcdf.setChunkCache(32000000, 2003, .75)
```

References

This function corresponds to the `nc_set_chunk_cache` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

See Also

`netcdf` | `netcdf.getChunkCache`

netcdf.setDefaultFormat

Change default netCDF file format

Syntax

```
oldFormat = netcdf.setDefaultFormat(newFormat)
```

Description

`oldFormat = netcdf.setDefaultFormat(newFormat)` changes the default format used by `netCDF.create` when creating new netCDF files, and returns the value of the old format. You can use this function to change the format used by a netCDF file without having to change the creation mode flag used in each call to `netCDF.create`.

`newFormat` can be either of the following values.

Value	Description
`'NC_FORMAT_CLASSIC'`	Original netCDF file format
`'NC_FORMAT_64BIT'`	64-bit offset format; relaxes limitations on creating very large files

You can also specify the numeric equivalent of these values, as retrieved by `netcdf.getConstant`.

This function corresponds to the `nc_set_default_format` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

```
oldFormat = netcdf.setDefaultFormat('NC_FORMAT_64BIT');
```

See Also

`netcdf.create`

netcdf.setFill

Set netCDF fill mode

Syntax

```
old_mode = netcdf.setFill(ncid,new_mode)
```

Description

`old_mode = netcdf.setFill(ncid,new_mode)` sets the fill mode for a netCDF file identified by `ncid`.

`new_mode` can be either `'FILL'` or `'NOFILL'` or their numeric equivalents, as retrieved by `netcdf.getConstant`. The default mode is `'FILL'`. netCDF pre-fills data with fill values. Specifying `'NOFILL'` can be used to enhance performance, because it avoids the duplicate writes that occur when the netCDF writes fill values that are later overwritten with data.

This function corresponds to the `nc_set_fill` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example creates a new file and specifies the fill mode used by netCDF with the file.

```
ncid = netcdf.open('foo.nc','NC_WRITE');

% Set filling behavior
old_mode = netcdf.setFill(ncid,'NC_NOFILL');
```

See Also

`netcdf.getConstant`

netcdf.sync

Synchronize netCDF file to disk

Syntax

```
netcdf.sync(ncid)
```

Description

`netcdf.sync(ncid)` synchronizes the state of a netCDF file to disk. The netCDF library normally buffers accesses to the underlying netCDF file, unless you specify the `NC_SHARE` mode when you opened the file with `netcdf.open` or `netcdf.create`. To call `netcdf.sync`, the netCDF file must be in data mode.

This function corresponds to the `nc_sync` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

Examples

This example creates a new netCDF file for write access, performs an operation on the file, takes the file out of define mode, and then synchronizes the file to disk.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');

% Perform an operation.
dimid = netcdf.defDim(ncid,'Xdim',50);

% Take file out of define mode.
netcdf.endDef(ncid);

% Synchronize the file to disk.
netcdf.sync(ncid)
```

See Also

`netcdf.close` | `netcdf.create` | `netcdf.open` | `netcdf.endDef`

newplot

Determine where to draw graphics objects

Syntax

```
newplot
h = newplot
h = newplot(hsave)
```

Description

`newplot` prepares a figure and axes for subsequent graphics commands.

`h = newplot` prepares a figure and axes for subsequent graphics commands and returns a handle to the current axes.

`h = newplot(hsave)` prepares and returns an axes, but does not delete any objects whose handles you have assigned to the `hsave` argument, which can be a vector of handles. If `hsave` is not empty, the figure and axes containing `hsave` are prepared for plotting instead of the current axes of the current figure. If `hsave` is empty, `newplot` behaves as if it were called without any inputs.

More About

Tips

To create a simple 2-D plot, use the `plot` function instead.

Use `newplot` at the beginning of high-level graphics code to determine which figure and axes to target for graphics output. Calling `newplot` can change the current figure and current axes. Basically, there are three options when you are drawing graphics in existing figures and axes:

- Add the new graphics without changing any properties or deleting any objects.
- Delete all existing objects whose handles are not hidden before drawing the new objects.

- Delete all existing objects regardless of whether or not their handles are hidden, and reset most properties to their defaults before drawing the new objects (refer to the following table for specific information).

The figure and axes `NextPlot` properties determine how `newplot` behaves. The following two tables describe this behavior with various property values.

First, `newplot` reads the current figure's `NextPlot` property and acts accordingly.

NextPlot	What Happens
`new`	Create a new figure and use it as the current figure.
`add`	Draw to the current figure without clearing any graphics objects already present.
`replacechildren`	Remove all child objects whose `HandleVisibility` property is set to `on` and reset figure `NextPlot` property to `add`. This clears the current figure and is equivalent to issuing the `clf` command.
`replace`	Remove all child objects (regardless of the setting of the `HandleVisibility` property) and reset figure properties to their defaults, except `NextPlot` is reset to `add` regardless of user-defined defaults. • `Position`, `Units`, `PaperPosition`, and `PaperUnits` are not reset. This clears and resets the current figure and is equivalent to issuing the `clf reset` command.

After `newplot` establishes which figure to draw in, it reads the current axes' `NextPlot` property and acts accordingly.

NextPlot	Description
`add`	Draw into the current axes, retaining all graphics objects already present.

NextPlot	Description
`replacechildren`	Remove all child objects whose `HandleVisibility` property is set to `on`, but do not reset axes properties. This clears the current axes like the `cla` command.
`replace`	Remove all child objects (regardless of the setting of the `HandleVisibility` property) and reset axes properties to their defaults, except `Position` and `Units`. This clears and resets the current axes like the `cla reset` command.

nextDirectory

Class: Tiff

Make next IFD current IFD

Syntax

```
nextDirectory(tiffobj)
```

Description

`nextDirectory(tiffobj)` makes the next image file directory (IFD) in the file the current IFD. `Tiff` object methods operate on the current IFD. Use this method to navigate among IFDs in a TIFF file containing multiple images.

Examples

Make Next Directory the Current Directory

Open a `Tiff` object and change the current IFD to the next IFD in the file.

```
t = Tiff('example.tif','r');
nextDirectory(t);
close(t);
```

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

References

This method corresponds to the `TIFFReadDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

See Also

`Tiff.setDirectory`

nextpow2

Exponent of next higher power of 2

Syntax

```
P = nextpow2(A)
```

Description

`P = nextpow2(A)` returns the exponents for the smallest powers of two that satisfy

$$2^p \geq |A|$$

for each element in `A`.

You can use `nextpow2` to pad the signal you pass to `fft`. Doing so can speed up the computation of the FFT when the signal length is not an exact power of 2.

Examples

Next Power of 2 of Double Integer Values

Define a vector of `double` integer values and calculate the exponents for the next power of 2 higher than those values.

```
a = [1 -2 3 -4 5 9 519];
p = nextpow2(a)
```

```
p =

     0     1     2     2     3     4    10
```

Calculate the positive next powers of 2.

```
np2 = 2.^p
```

```
np2 =

     1     2     4     4     8    16  1024
```

Preserve the sign of the original input values.

```
np2.*sign(a)

ans =

     1    -2     4    -4     8    16  1024
```

Next Power of 2 of Unsigned Integer Values

Define a vector of unsigned integers and calculate the exponents for the next power of 2 higher than those values.

```
a = uint32([1020 4000 32700]);
p = nextpow2(a)

p =

      10      12      15
```

Calculate the next powers of 2 higher than the values in `a`.

```
2.^p

ans =

      1024      4096     32768
```

Optimize FFT with Padding

Use `nextpow2` to increase the performance of `fft` when the length of your signal is not a power of 2.

Create a 1-D vector containing 8191 sample values.

```
x = gallery('uniformdata',[1,8191],0);
```

Calculate the next power of 2 higher than 8191.

```
p = nextpow2(8191);
n = 2^p
```

```
n =

        8192
```

Pass the signal and the next power of 2 to the `fft` function.

```
y = fft(x,n);
```

Input Arguments

A — Input values

scalar, vector, or array of real numbers

Input values, specified as a scalar, vector, or array of real numbers of any numeric type.

Example: `15`

Example: `[-15.123 32.456 63.111]`

Example: `int16([-15 32 63])`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

See Also

`fft` | `log2` | `pow2`

Introduced before R2006a

nnz

Number of nonzero matrix elements

Syntax

```
n = nnz(X)
```

Description

`n = nnz(X)` returns the number of nonzero elements in matrix `X`.

The density of a sparse matrix is `nnz(X)/prod(size(X))`.

Examples

The matrix

```
w = sparse(wilkinson(21));
```

is a tridiagonal matrix with `20` nonzeros on each of three diagonals, so `nnz(w) = 60`.

`find` | `isa` | `nonzeros` | `nzmax` | `size` | `whos`

Introduced before R2006a

noanimate

Change `EraseMode` of all objects to `normal`

Note: `noanimate` has been removed.

Syntax

```
noanimate(state,fig_handle)
noanimate(state)
```

Description

`noanimate(state,fig_handle)` sets the `EraseMode` of all image, line, patch, surface, and text graphics objects in the specified figure to `normal`. `state` can be the following strings:

- `'save'` — Set the values of the `EraseMode` properties to `normal` for all the appropriate objects in the designated figure.
- `'restore'` — Restore the `EraseMode` properties to the previous values (i.e., the values before calling `noanimate` with the `'save'` argument).

`noanimate(state)` operates on the current figure.

`noanimate` is useful if you want to print the figure to a TIFF or JPEG format.

See Also

`print`

Introduced before R2006a

nonzeros

Nonzero matrix elements

Syntax

```
s = nonzeros(A)
```

Description

`s = nonzeros(A)` returns a full column vector of the nonzero elements in `A`, ordered by columns.

This gives the `s`, but not the `i` and `j`, from `[i,j,s] = find(A)`. Generally,

```
length(s) = nnz(A) <= nzmax(A) <= prod(size(A))
```

See Also

`find` | `isa` | `nnz` | `nzmax` | `size` | `whos`

Introduced before R2006a

norm

Vector and matrix norms

Syntax

```
n = norm(v)
n = norm(v,p)

n = norm(X)
n = norm(X,p)
n = norm(X,'fro')
```

Description

`n = norm(v)` returns the 2-norm or Euclidean norm of vector `v`.

`n = norm(v,p)` returns the vector norm defined by `sum(abs(v)^p)^(1/p)`, where `p` is any positive real value, `Inf`, or `-Inf`.

- If `p` is `Inf`, then `n = max(abs(v))`.
- If `p` is `-Inf`, then `n = min(abs(v))`.

`n = norm(X)` returns the 2-norm or maximum singular value of matrix `X`.

`n = norm(X,p)` returns the *p*-norm of matrix `X`, where `p` is `1`, `2`, or `Inf`.

`n = norm(X,'fro')` returns the Frobenius norm, `sqrt(sum(diag(X'*X)))`.

Examples

1- and 2- Norm of Vector

Calculate the 2-norm of a vector corresponding to the point (-2,3,-1) in 3-D space. The 2-norm is equal to the Euclidean length of the vector.

```
X = [-2 3 -1];
n = norm(X)
```

```
n =

    3.7417
```

Calculate the 1-norm of the vector, which is the sum of the element magnitudes.

```
n = norm(X,1)
```

```
n =

    6
```

2-Norm of Matrix

Calculate the 2-norm of a matrix, which is the largest singular value.

```
X = [2 0 1;-1 1 0;-3 3 0];
n = norm(X)
```

```
n =

    4.7234
```

Frobenius Norm of Sparse Matrix

Use `'fro'` to calculate the Frobenius norm of a sparse matrix, which calculates the 2-norm of the column vector, `S(:)`.

```
S = sparse(1:25,1:25,1);
n = norm(S,'fro')
```

```
n =

     5
```

Input Arguments

v — Input vector

vector

Input vector.

Data Types: `single` | `double`
Complex Number Support: Yes

X — Input matrix

matrix

Input matrix. Use `norm(X,'fro')` when `X` is sparse.

Data Types: `single` | `double`
Complex Number Support: Yes

p — Norm type

2 (default) | positive integer scalar | `Inf` | `-Inf`

Norm type, specified as `2` (default), a different positive integer scalar, `Inf`, or `-Inf`. The valid values of `p` and what they return depend on whether the first input to `norm` is a matrix or vector, as shown in the table.

Note: This table does not reflect the actual algorithms used in calculations.

p	Matrix	Vector
1	`max(sum(abs(X)))`	`sum(abs(X))`
2	`max(svd(X))`	`sum(abs(X).^2)^(1/2)`
Positive, real-valued numeric `p`	—	`sum(abs(X).^p)^(1/p)`
`Inf`	`max(sum(abs(X')))`	`max(abs(X))`
`-Inf`	—	`min(abs(X))`

Output Arguments

n — Matrix or vector norm

scalar

Matrix or vector norm, returned as a scalar. The norm gives a measure of the magnitude of the elements. By convention, `norm` returns `NaN` if the input contains `NaN` values.

See Also

`cond` | `condest` | `hypot` | `normest` | `rcond`

Introduced before R2006a

normest

2-norm estimate

Syntax

```
nrm = normest(S)
nrm = normest(S,tol)
[nrm,count] = normest(...)
```

Description

This function is intended primarily for sparse matrices, although it works correctly and may be useful for large, full matrices as well.

`nrm = normest(S)` returns an estimate of the 2-norm of the matrix `S`.

`nrm = normest(S,tol)` uses relative error `tol` instead of the default tolerance `1.e-6`. The value of `tol` determines when the estimate is considered acceptable.

`[nrm,count] = normest(...)` returns an estimate of the 2-norm and also gives the number of power iterations used.

More About

Algorithms

The power iteration involves repeated multiplication by the matrix `S` and its transpose, `S'`. The iteration is carried out until two successive estimates agree to within the specified relative tolerance.

See Also

`cond` | `condest` | `norm` | `rcond` | `svd`

Introduced before R2006a

not, ~

Find logical NOT

Syntax

```
~A
not(A)
```

Description

~A performs a logical NOT of input array A, and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if the input array contains a zero value element at that same array location. Otherwise, that element is set to 0.

The input of the expression can be an array or can be a scalar value. If the input is an array, then the output is an array of the same dimensions. If the input is scalar, then the output is scalar.

`not(A)` is called for the syntax ~A when A is an object.

Examples

If matrix A is

```
     0    29     0    36     0
    23    34    35     0    39
     0    24    31    27     0
     0    29     0     0    34
```

then

```
~A
ans =
     1     0     1     0     1
     0     0     0     1     0
```

```
     1     0     0     0     1
     1     0     1     1     0
```

`all` | `and` | `any` | `bitcmp` | `or` | `xor`

Introduced before R2006a

notebook

Open MATLAB Notebook in Microsoft Word software (on Microsoft Windows platforms)

Syntax

```
notebook
notebook('filename')
notebook('-setup')
```

Description

`notebook` starts Microsoft Word software and creates a new MATLAB Notebook titled `Document 1`.

`notebook('filename')` starts Microsoft Word and opens the notebook `filename`, where `filename` is either in the MATLAB current folder or is a full path. If `filename` does not exist, MATLAB creates a new notebook titled `filename`. If the file name extension is not specified, MATLAB assumes `.doc`.

`notebook('-setup')` runs an interactive setup function for MATLAB Notebook. It copies the notebook template, `m-book.dot`, to the Microsoft Word template folder, whose location MATLAB automatically determines from the Windows system registry. Upon completion, MATLAB displays a message indicating whether or not the setup was successful.

More About

- "Create a MATLAB Notebook with Microsoft Word"
- "Publishing MATLAB Code"

Introduced before R2006a

now

Current date and time as serial date number

Syntax

```
t = now
```

Description

`t = now` returns the current date and time as a serial date number. A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`floor(now)` returns the current date as a serial date number, and `rem(now,1)` returns the current time as a serial date number. `datestr(now)` returns the current date and time as a string.

Examples

```
t1 = now, t2 = rem(now,1)

t1 =

   7.2908e+05

t2 =

    0.4013
```

More About

Tips

- To return a datetime scalar representing the current date and time, type:

```
t = datetime('now')
```

See Also

clock | date | datenum | datestr | datetime

Introduced before R2006a

nthroot

Real nth root of real numbers

Syntax

```
Y = nthroot(X,N)
```

Description

`Y = nthroot(X,N)` returns the real nth root of the elements of `X`. Both `X` and `N` must be real scalars or arrays of the same size. If an element in `X` is negative, then the corresponding element in `N` must be an odd integer.

Examples

Calculate Real Root of Negative Number

Find the real cube root of `-27`.

```
nthroot(-27, 3)
```

```
ans =

    -3
```

For comparison, also calculate `(-27)^(1/3)`.

```
(-27)^(1/3)
```

```
ans =

   1.5000 + 2.5981i
```

The result is the complex cube root of `-27`.

Calculate Several Real Roots of Scalar

Create a vector of roots to calculate, `N`.

```
N = [5 3 -1];
```

Use `nthroot` to calculate several real roots of `-8`.

```
Y = nthroot(-8,N)
```

```
Y =

   -1.5157   -2.0000   -0.1250
```

The result is a vector of the same size as `N`.

Elementwise Roots of Matrix

Create a matrix of bases, `X`, and a matrix of nth roots, `N`.

```
X = [-2 -2 -2; 4 -3 -5]
N = [1 -1 3; 1/2 5 3]
```

```
X =

    -2    -2    -2
     4    -3    -5

N =

    1.0000   -1.0000    3.0000
    0.5000    5.0000    3.0000
```

Each element in `X` corresponds to an element in `N`.

Calculate the real nth roots of the elements in `X`.

```
Y = nthroot(X,N)
```

```
Y =

   -2.0000   -0.5000   -1.2599
   16.0000   -1.2457   -1.7100
```

Except for the signs (which are treated separately), the result is comparable to `abs(X).^(1./N)`. By contrast, you can calculate the complex roots using `X.^(1./N)`.

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `X` can be either a scalar or an array of the same size as `N`. The elements of `X` must be real.

Data Types: `single` | `double`

N — Roots to calculate

scalar | array of same size as `X`

Roots to calculate, specified as a scalar or array of the same size as `X`. The elements of `N` must be real. If an element in `X` is negative, the corresponding element in `N` must be an odd integer.

Data Types: `single` | `double`

More About

Tips

- While `power` is a more efficient function for computing the roots of numbers, in cases where both real and complex roots exist, `power` returns only the complex roots. In these cases, use `nthroot` to obtain the real roots.

`power` | `sqrt`

Introduced before R2006a

null

Null space

Syntax

```
Z = null(A)
Z = null(A,'r')
```

Description

`Z = null(A)` is an orthonormal basis for the null space of `A` obtained from the singular value decomposition. That is, `A*Z` has negligible elements, `size(Z,2)` is the nullity of `A`, and `Z'*Z = I`.

`Z = null(A,'r')` is a "rational" basis for the null space obtained from the reduced row echelon form. `A*Z` is zero, `size(Z,2)` is an estimate for the nullity of `A`, and, if `A` is a small matrix with integer elements, the elements of the reduced row echelon form (as computed using `rref`) are ratios of small integers.

The orthonormal basis is preferable numerically, while the rational basis may be preferable pedagogically.

Examples

Example 1

Compute the orthonormal basis for the null space of a matrix A.

```
A = [1     2     3
     1     2     3
     1     2     3];

Z = null(A);
A*Z

ans =
```

```
  1.0e-015 *
     0.2220    0.2220
     0.2220    0.2220
     0.2220    0.2220

Z'*Z

ans =
    1.0000   -0.0000
   -0.0000    1.0000
```

Example 2

Compute the 1-norm of the matrix A*Z and determine that it is within a small tolerance.

```
norm(A*Z,1) < 1e-12
ans =
    1
```

Example 3

Compute the rational basis for the null space of the same matrix A.

```
ZR = null(A,'r')

ZR =
    -2    -3
     1     0
     0     1

A*ZR

ans =

     0     0
     0     0
     0     0
```

orth | rank | rref | svd

Introduced before R2006a

num2cell

Convert array to cell array with consistently sized cells

Syntax

```
C = num2cell(A)
C = num2cell(A,dim)
```

Description

`C = num2cell(A)` converts array A into cell array C by placing each element of A into a separate cell in C. Array A need not be numeric.

`C = num2cell(A,dim)` splits the contents of A into separate cells of C, where dim specifies which dimensions of A to include in each cell. dim can be a scalar or a vector of dimensions. For example, if A has 2 rows and 3 columns, then:

- `num2cell(A,1)` creates a 1-by-3 cell array `C`, where each cell contains a 2-by-1 column of `A`.
- `num2cell(A,2)` creates a 2-by-1 cell array `C`, where each cell contains a 1-by-3 row of `A`.
- `num2cell(A,[1 2])` creates a 1-by-1 cell array `C`, where the cell contains the entire array `A`.

Examples

Convert Arrays to Cell Array

Place all elements of a numeric array into separate cells.

```
a = magic(3)
c = num2cell(a)
```

```
a =
```

```
     8     1     6
     3     5     7
     4     9     2

c =

    [8]    [1]    [6]
    [3]    [5]    [7]
    [4]    [9]    [2]
```

Place individual letters of a word into separate cells of an array.

```
a = ['four';'five';'nine']
c = num2cell(a)

a =

four
five
nine

c =

    'f'    'o'    'u'    'r'
    'f'    'i'    'v'    'e'
    'n'    'i'    'n'    'e'
```

Create Cell Array of Numeric Arrays

Generate a 4-by-3-by-2 numeric array, and then create a 1-by-3-by-2 cell array of 4-by-1 column vectors.

```
A = reshape(1:12,4,3);
A(:,:,2) = A*10
C = num2cell(A,1)

A(:,:,1) =
```

```
     1     5     9
     2     6    10
     3     7    11
     4     8    12

A(:,:,2) =

    10    50    90
    20    60   100
    30    70   110
    40    80   120

C(:,:,1) =

    [4x1 double]    [4x1 double]    [4x1 double]

C(:,:,2) =

    [4x1 double]    [4x1 double]    [4x1 double]
```

Each 4-by-1 vector contains elements from along the *first* dimension of `A`:

```
C{1}
```

```
ans =

     1
     2
     3
     4
```

Create a 4-by-1-by-2 cell array of 1-by-3 numeric arrays.

```
C = num2cell(A,2)
```

```
C(:,:,1) =

    [1x3 double]
```

```
    [1x3 double]
    [1x3 double]
    [1x3 double]

C(:,:,2) =

    [1x3 double]
    [1x3 double]
    [1x3 double]
    [1x3 double]
```

Each 1-by-3 row vector contains elements from along the *second* dimension of A:

```
C{1}

ans =

     1     5     9
```

Finally, create a 4-by-3 cell array of 1-by-1-by-2 numeric arrays.

```
C = num2cell(A,3)

C =

    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
    [1x1x2 double]    [1x1x2 double]    [1x1x2 double]
```

Each 1-by-1-by-2 vector contains elements from along the *third* dimension of A:

```
C{1}

ans(:,:,1) =

     1
```

```
ans(:,:,2) =

    10
```

Combine Across Multiple Dimensions

Create a cell array by combining elements into numeric arrays along several dimensions.

```
A = reshape(1:12,4,3);
A(:,:,2) = A*10
c = num2cell(A,[1 3])
```

```
A(:,:,1) =

     1     5     9
     2     6    10
     3     7    11
     4     8    12

A(:,:,2) =

    10    50    90
    20    60   100
    30    70   110
    40    80   120

c =

    [4x1x2 double]    [4x1x2 double]    [4x1x2 double]
```

Each 4-by-1-by-2 array contains elements from along the first and third dimension of `A`:

```
c{1}
```

```
ans(:,:,1) =

     1
     2
```

```
     3
     4

ans(:,:,2) =

    10
    20
    30
    40

c = num2cell(A,[2 3])

c =

    [1x3x2 double]
    [1x3x2 double]
    [1x3x2 double]
    [1x3x2 double]
```

Input Arguments

A — Input

any type of multidimensional array

Input, specified as any type of multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell` | `function_handle`

dim — Dimension of A

positive integer | positive vector of integers

Dimension of A, specified as a positive integer or a vector of positive integers. dim must be between 1 and `ndims`(A).

Elements need not be in numeric order. However, `num2cell` permutes the dimensions of the arrays in each cell of C to match the order of the specified dimensions.

Data Types: `double`

Output Arguments

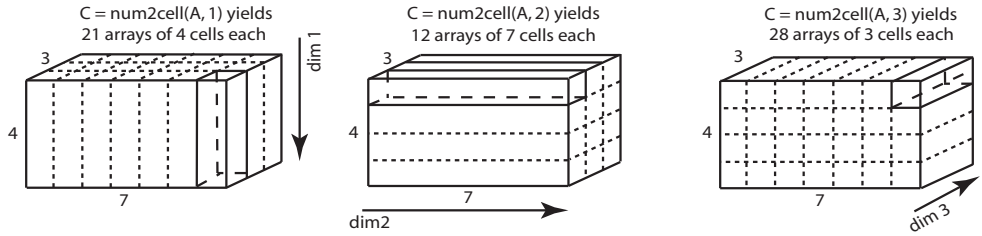
C — Resulting array

cell array

Resulting array, returned as a cell array. The size of C depends on the size of A and the values of dim.

- If dim is not specified, then C is the same size as A.
- If dim is a scalar, then C contains `numel(A)/size(A,dim)` cells. If dim is 1 or 2, then each cell contains a column or row vector, respectively. If dim > 2, then each cell contains an array whose dimth dimensional length is `size(A,dim)`, and whose other dimensions are all singletons.

  For example, given a 4-by-7-by-3 array, `A`, this figure shows how `num2cell` creates cells corresponding to dim values of `1`, `2`, and `3`.



- If dim is a vector containing `N` values, then C has `numel(A)/prod([size(A,dim(1)),...,size(A,vdim(N))])` cells. Each cell contains an array whose `dim(i)`th dimension has a length of `size(A,dim(i))` and whose other dimensions are singletons.

  For example, given a 4-by-7-by-3 array, you can specify dim as an positive integer vector to create cell arrays of different dimensions.

`cat` | `cell2mat` | `mat2cell`

Introduced before R2006a

num2hex

Convert singles and doubles to IEEE hexadecimal strings

Syntax

```
num2hex(X)
```

Description

If `X` is a single or double precision array with n elements, `num2hex(X)` is an n-by-8 or n-by-16 char array of the hexadecimal floating-point representation. The same representation is printed with format `hex`.

Examples

```
num2hex([1 0 0.1 -pi Inf NaN])
```

returns

```
ans =

3ff0000000000000
0000000000000000
3fb999999999999a
c00921fb54442d18
7ff0000000000000
fff8000000000000
num2hex(single([1 0 0.1 -pi Inf NaN]))
```

returns

```
ans =

3f800000
00000000
3dcccccd
c0490fdb
```

```
7f800000
ffc00000
```

`hex2num` | `format` | `dec2hex`

Introduced before R2006a

num2str

Convert number to string

Syntax

```
s = num2str(A)
s = num2str(A,precision)
s = num2str(A,formatSpec)
```

Description

`s = num2str(A)` converts a numeric array into a string representation. The output format depends on the magnitudes of the original values. `num2str` is useful for labeling and titling plots with numeric values.

`s = num2str(A,precision)` returns a string representation with the maximum number of significant digits specified by `precision`.

`s = num2str(A,formatSpec)` applies a format specified by `formatSpec` to all elements of `A`.

Examples

Default Conversions of Floating-Point Values

Convert the floating-point values returned by `pi` and `eps` to strings.

```
s = num2str(pi)
```

```
s =

3.1416
```

```
s = num2str(eps)
```

```
s =

2.2204e-16
```

Specify Precision

Specify the maximum number of significant digits for floating-point values.

```
A = gallery('normaldata',[2,2],0);
s = num2str(A,3)
```

```
s =

-0.433      0.125
 -1.67      0.288
```

Specify Formatting

Specify the width, precision, and other formatting for an array of floating-point values.

```
A = gallery('uniformdata',[2,3],0) * 9999;
s = num2str(A,'%10.5e\n')
```

```
s =

9.50034e+03
6.06782e+03
8.91210e+03
2.31115e+03
4.85934e+03
7.62021e+03
```

The format `'%10.5e'` prints each value in exponential format with five decimal places, and `'\n'` prints a new line character.

Input Arguments

A — Input array

numeric array

Input array, specified as a numeric array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`
Complex Number Support: Yes

`precision` — Maximum number of significant digits

positive integer

Maximum number of significant digits in the output string, specified as a positive integer.

Note: If you specify `precision` to exceed the precision of the input floating-point data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

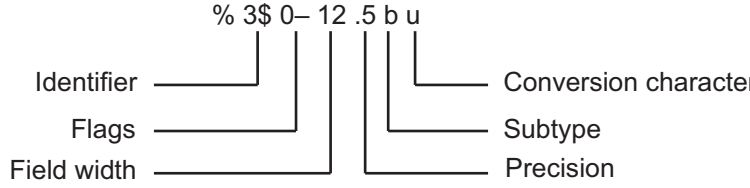
`formatSpec` — Format of output fields

string containing formatting operators

Format of the output fields, specified as a string containing formatting operators. `formatSpec` also can include ordinary text and special characters.

Formatting Operator

A formatting operator starts with a percent sign, `%`, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier, flags, field width, precision, and subtype operators between `%` and the conversion character. (Spaces are invalid between operators and are shown here only for readability).



Conversion Character

This table shows conversion characters to format numeric and character data as strings.

Value Type	Conversion	Details
Integer, signed	`%d` or `%i`	Base 10
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal), lowercase letters `a`–`f`
	`%X`	Same as `%x`, uppercase letters `A`–`F`
Floating-point number	`%f`	Fixed-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	`%e`	Exponential notation, such as `3.141593e+00` (Use a precision operator to specify the number of digits after the decimal point.)
	`%E`	Same as `%e`, but uppercase, such as `3.141593E+00` (Use a precision operator to specify the number of digits after the decimal point.)
	`%g`	The more compact of `%e` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
	`%G`	The more compact of `%E` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
Characters	`%c`	Single character
	`%s`	String of characters

Optional Operators

The optional identifier, flags, field width, precision, and subtype operators further define the format of the output string.

- **Identifier**

Order for processing values from the input list. Use the syntax *n*$, where *n* represents the position of the value in the input list.

Example: `'%3$s %2$s %1$s %2$s'` prints inputs `'A'`, `'B'`, `'C'` as follows: `C B A B`.

- **Flags**

`'–'`	Left-justify. **Example:** `%-5.2f`
`'+'`	Always print a sign character (+ or –) for any value. **Example:** `%+5.2f`
`' '`	Insert a space before the value. **Example:** `% 5.2f`
`'0'`	Pad to field width with zeros before the value. **Example:** `%05.2f`
`'#'`	Modify selected numeric conversions: • For `%o`, `%x`, or `%X`, print `0`, `0x`, or `0X` prefix. • For `%f`, `%e`, or `%E`, print decimal point even when precision is 0. • For `%g` or `%G`, do not remove trailing zeros or decimal point. **Example:** `%#5.0f`

- **Field Width**

Minimum number of characters to print. The field width operator can be a number, or an asterisk (`*`) to refer to an argument in the input list.

Example: The input list `('%12d',intmax)` is equivalent to `('%*d', 12, intmax)`.

The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For `%f`, `%e`, or `%E`	Number of digits to the right of the decimal point **Example:** `'%.4f'` prints `pi` as `'3.1416'`

For `%g` or `%G`	Number of significant digits **Example:** `'%.4g'` prints `pi` as `' 3.142'`

The precision operator can be a number, or an asterisk (`*`) to refer to an argument in the input list.

Example: The input list `('%6.4f', pi)` is equivalent to `('%*.*f', 6, 4, pi)`.

Note: If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

- **Subtypes**

Certain conversion characters can support a subtype. The subtype operator immediately precedes the conversion character. This table shows the conversions that can use subtypes.

Input Value Type	Subtype and Conversion Character	Output Value Type

Floating-point number	`%bx` or `%bX`
	`%bo`
	`%bu`
		Double-precision hexadecimal, octal, or decimal value
		Example: `%bx` prints `pi` as `400921fb54442d18`

	`%tx` or `%tX`
	`%to`
	`%tu`
		Single-precision hexadecimal, octal, or decimal value
		Example: `%tx` prints `pi` as `40490fdb`

Integer	`%ld` or `%li`
	`%lo`
	`%lu`
	`%lx` or `%lX`
		64-bit value

Integer	`%hd` or `%hi`
	`%ho`
	`%hu`
		16-bit value

Input Value Type	Subtype and Conversion Character	Output Value Type
	`%hx` or `%hX`	

Text Before or After Formatting Operators

`formatSpec` can also include additional text before a percent sign, `%`, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in `formatSpec`.

Special Character	Representation
Single quotation mark	`''`
Percent character	`%%`
Backslash	`\\`
Alarm	`\a`
Backspace	`\b`
Form feed	`\f`
New line	`\n`
Carriage return	`\r`
Horizontal tab	`\t`
Vertical tab	`\v`
Character whose ASCII code is the hexadecimal number, `N`	`\xN`
Character whose ASCII code is the octal number, `N`	`\N`

Notable Behavior of Conversions with Formatting Operators

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.

  Example: `'%s'` converts `pi` to `3.141593e+00`.

- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters.

  Example: `'%s'` converts `[65 66 67]` to `ABC`.

Output Arguments

s — String representation of input array

character array

String representation of the input array, returned as a character array.

More About

Algorithms

`num2str` trims any leading spaces from a string, even when formatSpec includes a space character flag. For example, `num2str(42.67,'% 10.2f')` returns a 1-by-5 character array `'42.67'`.

`cast` | `int2str` | `mat2str` | `sprintf` | `str2num`

Introduced before R2006a

numberOfStrips

Class: Tiff

Total number of strips in image

Syntax

```
numStrips = numberOfStrips(tiffobj)
```

Description

`numStrips = numberOfStrips(tiffobj)` returns the total number of strips in the image.

Examples

Determine Number of Strips in Image

Determine the number of strips in the second image of a file.

Create a `Tiff` object associated with the example file, `example.tif`.

```
t = Tiff('example.tif','r');
```

When the `Tiff` object is created, the first image in the file is the current image file directory.

Make the second image the current directory.

```
nextDirectory(t)
```

Get the number of strips in the image if the image has a stripped organization.

```
if ~isTiled(t)
 numStrips = numberOfStrips(t)
end
```

```
numStrips =
```

```
     7
```

The image has 7 strips.

Close the `Tiff` object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

References

This method corresponds to the `TIFFNumberOfStrips` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

See Also

`Tiff.numberOfTiles` | `Tiff.isTiled`

numberOfTiles

Class: Tiff

Total number of tiles in image

Syntax

```
numTiles = numberOfTiles(tiffobj)
```

Description

`numTiles = numberOfTiles(tiffobj)` returns the total number of tiles in the image.

Examples

Determine Number of Tiles in Image

Create a `Tiff` object associated with the example file, `example.tif`. Get the number of tiles in the image if the image has a tiled organization.

```
t = Tiff('example.tif','r');
if isTiled(t)
 nTiles = numberOfTiles(t)
end
```

```
nTiles =

   110
```

The image has 110 tiles.

Close the `Tiff` object.

```
close(t)
```

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

`Tiff.numberOfStrips` | `Tiff.isTiled`

numel

Number of array elements

Syntax

```
n = numel(A)
```

Description

`n = numel(A)` returns the number of elements, `n`, in array `A`, equivalent to `prod(size(A))`.

Examples

Number of Elements in 3-D Matrix

Create a 4-by-4-by-2 matrix.

```
A = magic(4);
A(:,:,2) = A'
```

```
A(:,:,1) =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

A(:,:,2) =
    16     5     9     4
     2    11     7    14
     3    10     6    15
    13     8    12     1
```

`numel` counts 32 elements in the matrix.

```
n = numel(A)
```

```
n =

    32
```

Number of Elements in Cell Array of Strings

Create a cell array of strings.

```
A = {'dog','cat','fish','horse'};
```

`numel` counts 4 string elements in the array.

```
n = numel(A)
```

```
n =

     4
```

Number of Elements in Table

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

A = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
A =

                Age    Height    Weight     BloodPressure
                ---    ------    ------    ---------------
    Smith       38     71        176       124          93
    Johnson     43     69        163       109          77
    Williams    38     64        131       125          83
    Jones       40     67        133       117          75
    Brown       49     64        119       122          80
```

Find the number of elements in the table.

```
n = numel(A)
```

```
n =

    20
```

`numel` returns a value equivalent to `prod(size(A))` corresponding to the 5 rows and 4 variables.

Input Arguments

A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, calendarDuration arrays, tables, structure arrays, cell arrays, and object arrays.

Limitations

- If `A` is a table, `numel` returns the number of elements in the table, `A`, equivalent to `prod(size(A))`. Variables in a table can have multiple columns, but `numel(A)` only accounts for the number of rows and number of variables.

Introduced before R2006a

nzmax

Amount of storage allocated for nonzero matrix elements

Syntax

```
n = nzmax(S)
```

Description

`n = nzmax(S)` returns the amount of storage allocated for nonzero elements.

If `S` is a sparse matrix...	`nzmax(S)` is the number of storage locations allocated for the nonzero elements in `S`.
If `S` is a full matrix...	`nzmax(S) = prod(size(S))`.

Often, `nnz(S)` and `nzmax(S)` are the same. But if `S` is created by an operation which produces fill-in matrix elements, such as sparse matrix multiplication or sparse LU factorization, more storage may be allocated than is actually required, and `nzmax(S)` reflects this. Alternatively, `sparse(i,j,s,m,n,nzmax)` or its simpler form, `spalloc(m,n,nzmax)`, can set `nzmax` in anticipation of later fill-in.

Introduced before R2006a

matlab.lang.ObjectUpdateFailure class

Package: matlab.lang

Class representing objects that cannot be updated to new class definition

Description

MATLAB converts objects to instances of `matlab.lang.ObjectUpdateFailure` when a class definition changes, but existing objects of that class cannot be updated to conform to the new definition. When objects cannot be updated, the automatic update process replaces existing objects of the class with `matlab.lang.ObjectUpdateFailure` objects.

Typical cases where objects are converted to `matlab.lang.ObjectUpdateFailure` objects include cases where a class:

- Is made abstract
- Is converted to an enumeration class
- Changes its heterogeneous root
- Inherits subsref, subsasgn, cat, vertcat, or horzcat methods

Attributes

`Sealed`	`true`
`HandleCompatible`	`true`

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

ode15i

Solve fully implicit differential equations, variable order method

Syntax

```
[T,Y] = ode15i(odefun,tspan,y0,yp0)
[T,Y] = ode15i(odefun,tspan,y0,yp0,options)
[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)
sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)
```

Arguments

The following table lists the input arguments for `ode15i`.

`odefun`	A function handle that evaluates the left side of the differential equations, which are of the form $f(t,y,y') = 0$.
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.
`y0, yp0`	Vectors of initial conditions for y and y' respectively.
`options`	Optional integration argument created using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for `ode15i`.

`T`	Column vector of time points
`Y`	Solution array. Each row in `y` corresponds to the solution at a time returned in the corresponding row of `t`.

Description

`[T,Y] = ode15i(odefun,tspan,y0,yp0)` with `tspan = [t0 tf]` integrates the system of differential equations $f(t,y,y') = 0$ from time `t0` to `tf` with initial conditions `y0` and `yp0`. `odefun` is a function handle. Function `ode15i` solves ODEs and DAEs of index 1. The initial conditions must be consistent, meaning that $f(t0,y0,yp0) = 0$. You

can use the function `decic` to compute consistent initial conditions close to guessed values. Function `odefun(t,y,yp)`, for a scalar `t` and column vectors `y` and `yp`, must return a column vector corresponding to $f(t,y,y')$. Each row in the solution array `Y` corresponds to a time returned in the column vector `T`. To obtain solutions at specific times `t0,t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `odefun`, if necessary.

`[T,Y] = ode15i(odefun,tspan,y0,yp0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used options include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components `1e-6` by default). See `odeset` for details.

`[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)` with the `'Events'` property in `options` set to a function `events`, solves as above while also finding where functions of (t,y,y'), called event functions, are zero. The function `events` is of the form `[value,isterminal,direction] = events(t,y,yp)` and includes the necessary event functions. Code the function `events` so that the `i`th element of each output vector corresponds to the `i`th event. For the `i`th event function in `events`:

- `value(i)` is the value of the function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Output `TE` is a column vector of times at which events occur. Rows of `YE` are the corresponding solutions, and indices in vector `IE` specify which event occurred. See "Integrator Options" in the MATLAB Mathematics documentation for more information.

`sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)` returns a structure that can be used with `deval` to evaluate the solution at any point between `t0` and `tfinal`. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver. If you specify the `Events` option and a terminal event is detected, `sol.x(end)` contains the end of the step at which the event occurred.
`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

Options

`ode15i` accepts the following parameters in `options`. For more information, see `odeset` and Changing ODE Integration Properties in the MATLAB Mathematics documentation.

Error control	`RelTol`, `AbsTol`, `NormControl`
Solver output	`OutputFcn`, `OutputSel`, `Refine`, `Stats`
Event location	`Events`
Step size	`MaxStep`, `InitialStep`
Jacobian matrix	`Jacobian`, `JPattern`, `Vectorized`

Solver Output

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

Jacobian Matrices

The Jacobian matrices $\partial f/\partial y$ and $\partial f/\partial y'$ are critical to reliability and efficiency. You can provide these matrices as one of the following:

- Function of the form `[dfdy,dfdyp] = FJAC(t,y,yp)` that computes the Jacobian matrices. If `FJAC` returns an empty matrix `[]` for either `dfdy` or `dfdyp`, then `ode15i` approximates that matrix by finite differences.
- Cell array of two constant matrices `{dfdy,dfdyp}`, either of which could be empty.

Use `odeset` to set the `Jacobian` option to the function or cell array. If you do not set the `Jacobian` option, `ode15i` approximates both Jacobian matrices by finite differences.

For `ode15i`, `Vectorized` is a two-element cell array. Set the first element to `'on'` if `odefun(t,[y1,y2,...],yp)` returns `[odefun(t,y1,yp),odefun(t,y2,yp),...]`. Set the second element to `'on'` if `odefun(t,y,[yp1,yp2,...])` returns `[odefun(t,y,yp1),odefun(t,y,yp2),...]`. The default value of `Vectorized` is `{'off','off'}`.

For `ode15i`, `JPattern` is also a two-element sparse matrix cell array. If $\partial f/\partial y$ or $\partial f/\partial y'$ is a sparse matrix, set `JPattern` to the sparsity patterns, `{SPDY,SPDYP}`. A sparsity pattern of $\partial f/\partial y$ is a sparse matrix `SPDY` with `SPDY(i,j) = 1` if component `i` of `f(t,y,yp)` depends on component `j` of `y`, and `0` otherwise. Use `SPDY = []` to indicate that $\partial f/\partial y$ is a full matrix. Similarly for $\partial f/\partial y'$ and `SPDYP`. The default value of `JPattern` is `{[],[]}`.

Examples

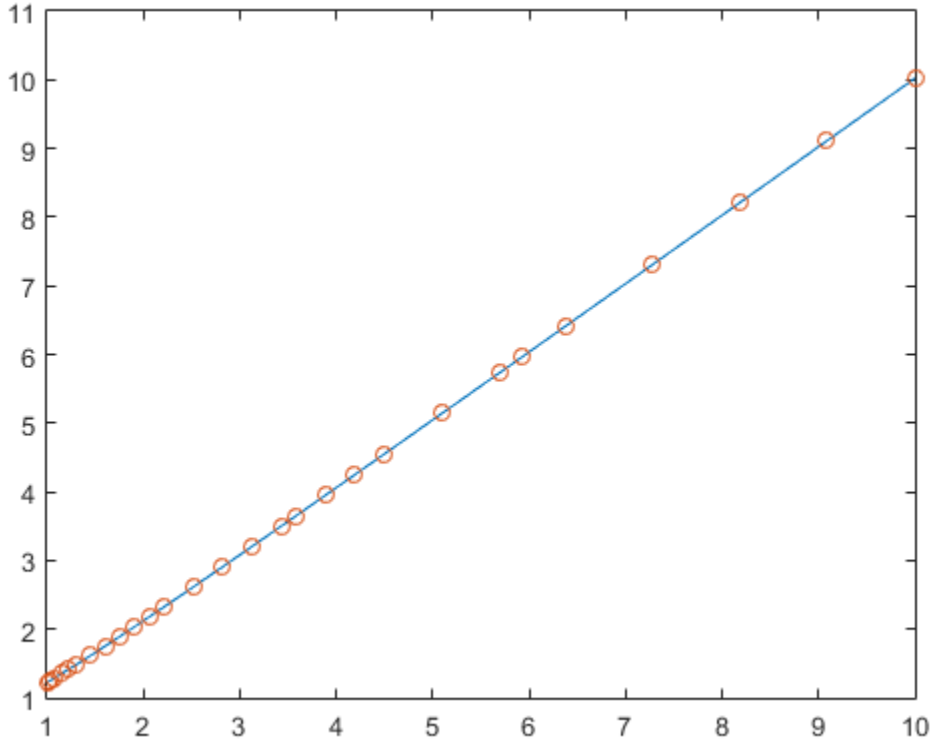
Solve Weissinger Implicit ODE

This example uses a helper function, `decic`, to hold fixed the initial value for *y(t0)* and compute a consistent initial value for *y'(t0)* for the Weissinger implicit ODE. The Weissinger function evaluates the residual of the implicit ODE.

```
t0 = 1;
y0 = sqrt(3/2);
yp0 = 0;
[y0,yp0] = decic(@weissinger,t0,y0,1,yp0,0);
```

Use `ode15i` to solve the ODE, and then plot the numerical solution, `y`, against the analytical solution, `ytrue`.

```
[t,y] = ode15i(@weissinger,[1 10],y0,yp0);
ytrue = sqrt(t.^2 + 0.5);
plot(t,y,t,ytrue,'o')
```



Other Examples

The files, `ihb1dae.m` and `iburgersode.m`, are examples of implicit ODEs.

ode15s

Solve stiff differential equations and DAEs; variable order method

Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, *`solver`*, with any of the function names.

Arguments

The following table describes the input arguments to the solvers.

`odefun`	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$. The `ode23s` solver can solve only equations with constant mass matrices. `ode15s` and `ode23t` can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. The solver imposes the initial conditions at `tspan(1)`, and integrates from `tspan(1)` to `tspan(end)`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`. For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points. Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
`y0`	A vector of initial conditions.
`options`	Structure of optional parameters that change the default integration properties. This is the fourth input argument. `[t,y] = solver(odefun,tspan,y0,options)` You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

`T`	Column vector of time points.
`Y`	Solution array. Each row in `Y` corresponds to the solution at a time returned in the corresponding row of `T`.
`TE`	The time at which an event occurs.
`YE`	The solution at the time of the event.
`IE`	The index `i` of the event function that vanishes.
`sol`	Structure to evaluate the solution.

Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations $y' = f(t,y)$ from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to $f(t,y)$. Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of (t,y), called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver.

`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.
`sol.solver`	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix $\partial f/\partial y$ is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian $\partial f/\partial y$ or to the matrix $\partial f/\partial y$ if the Jacobian is constant. If the `Jacobian` property is not set (the default), $\partial f/\partial y$ is approximated by finite differences. Set the `Vectorized` property `'on'` if the ODE function is coded so that `odefun(T, [Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If $\partial f/\partial y$ is a sparse matrix, set the `JPattern` property to the sparsity pattern of $\partial f/\partial y$, i.e., a sparse matrix `S` with `S(i,j) = 1` if the `i`th component of $f(t,y)$ depends on the `j`th component of y, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form $M(t,y)y' = f(t,y)$, with time- and state-dependent mass matrix M. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable y and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to `'none'`.
- If the mass matrix depends weakly on y, set `MStateDependence` to `'weak'` (the default); otherwise, set it to `'strong'`. In either case, the function `MASS` is called with the two arguments (`t`,`y`).

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse $M(t,y)$.
- Supply the sparsity pattern of $\partial f/\partial y$ using the `JPattern` property or a sparse $\partial f/\partial y$ using the `Jacobian` property.
- For strongly state-dependent $M(t,y)$, set `MvPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the (`i`,`k`) component of $M(t,y)$ depends on component `j` of y, and `0` otherwise.

If the mass matrix M is singular, then $M(t,y)y' = f(t,y)$ is a system of differential algebraic equations. DAEs have solutions only when y_0 is consistent, that is, if there is a vector yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that `y0` is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to `'yes'`, `'no'`, or `'maybe'`. The default value of `'maybe'` causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and `y0` and `yp0` are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
`ode45`	Nonstiff	Medium	Most of the time. This should be the first solver you try.
`ode23`	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
`ode113`	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
`ode15s`	Stiff	Low to medium	If `ode45` is slow because the problem is stiff.
`ode23s`	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
`ode23t`	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
`ode23tb`	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5544 for more details.

Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Examples

Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

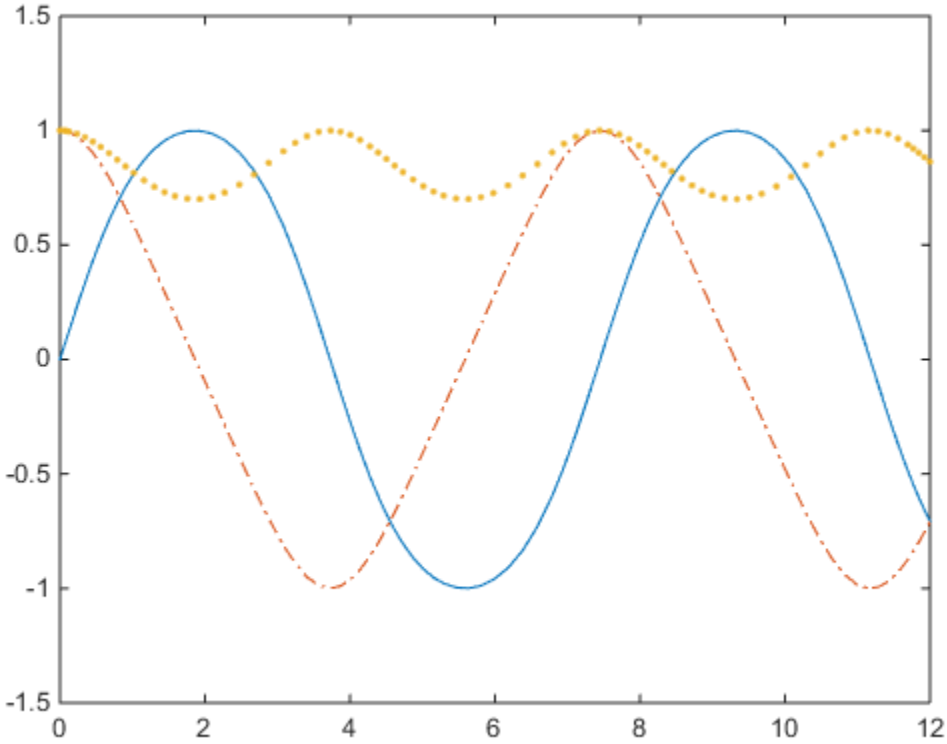
```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```



Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$y_1' = y_2 \qquad y_1(0) = 2$$
$$y_2' = 1000(1 - y_1^2)y_2 - y_1 \qquad y_2(0) = 0$$

To simulate this system, create a function `vdp1000` containing the equations

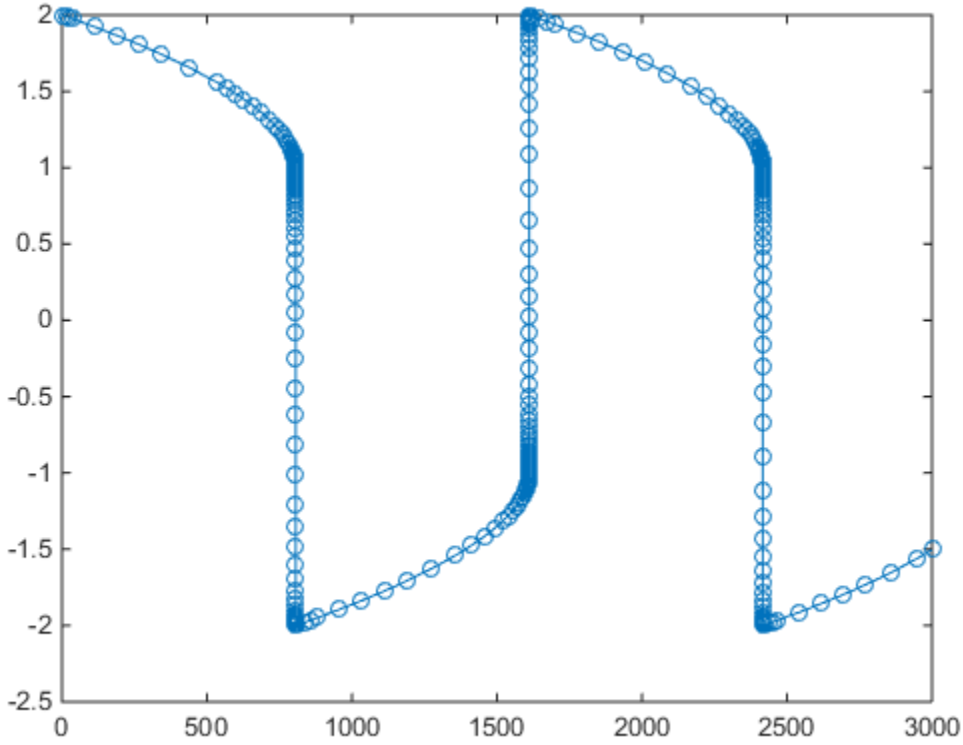
```
function dy = vdp1000(t,y)
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances (`1e-3` and `1e-6`, respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time `0`.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```



Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

`y'(t) + f(t)y(t) = g(t)`
The initial condition is `y(1) = 1`, where the function `f(t)` is defined by the `n`-by-`1` vector `f` evaluated at times `ft`, and the function `g(t)` is defined by the `m`-by-`1` vector `g` evaluated at times `gt`.

First, define the time-dependent parameters `f(t)` and `g(t)` as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution `y(t)` as a function of time:

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```

Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing $y(t_n)$, it needs only the solution at the immediately preceding time point, $y(t_{n-1})$. In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

ode23

Solve nonstiff differential equations; low order method

Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, *`solver`*, with any of the function names.

Arguments

The following table describes the input arguments to the solvers.

`odefun`	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$. The `ode23s` solver can solve only equations with constant mass matrices. `ode15s` and `ode23t` can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. The solver imposes the initial conditions at `tspan(1)`, and integrates from `tspan(1)` to `tspan(end)`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`. For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points. Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
`y0`	A vector of initial conditions.
`options`	Structure of optional parameters that change the default integration properties. This is the fourth input argument. `[t,y] = solver(odefun,tspan,y0,options)` You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

`T`	Column vector of time points.
`Y`	Solution array. Each row in `Y` corresponds to the solution at a time returned in the corresponding row of `T`.
`TE`	The time at which an event occurs.
`YE`	The solution at the time of the event.
`IE`	The index `i` of the event function that vanishes.
`sol`	Structure to evaluate the solution.

Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations $y' = f(t,y)$ from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to $f(t,y)$. Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of (t,y), called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver.

`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.
`sol.solver`	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix $\partial f/\partial y$ is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian $\partial f/\partial y$ or to the matrix $\partial f/\partial y$ if the Jacobian is constant. If the `Jacobian` property is not set (the default), $\partial f/\partial y$ is approximated by finite differences. Set the `Vectorized` property `'on'` if the ODE function is coded so that `odefun(T, [Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If $\partial f/\partial y$ is a sparse matrix, set the `JPattern` property to the sparsity pattern of $\partial f/\partial y$, i.e., a sparse matrix `S` with `S(i,j) = 1` if the `i`th component of $f(t,y)$ depends on the `j`th component of y, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form $M(t,y)y' = f(t,y)$, with time- and state-dependent mass matrix M. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable y and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to `'none'`.
- If the mass matrix depends weakly on y, set `MStateDependence` to `'weak'` (the default); otherwise, set it to `'strong'`. In either case, the function `MASS` is called with the two arguments (`t`,`y`).

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse $M(t,y)$.
- Supply the sparsity pattern of $\partial f/\partial y$ using the `JPattern` property or a sparse $\partial f/\partial y$ using the `Jacobian` property.
- For strongly state-dependent $M(t,y)$, set `MvPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the (`i`,`k`) component of $M(t,y)$ depends on component `j` of y, and `0` otherwise.

If the mass matrix M is singular, then $M(t,y)y' = f(t,y)$ is a system of differential algebraic equations. DAEs have solutions only when y_0 is consistent, that is, if there is a vector yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that `y0` is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to `'yes'`, `'no'`, or `'maybe'`. The default value of `'maybe'` causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and `y0` and `yp0` are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
`ode45`	Nonstiff	Medium	Most of the time. This should be the first solver you try.
`ode23`	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
`ode113`	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
`ode15s`	Stiff	Low to medium	If `ode45` is slow because the problem is stiff.
`ode23s`	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
`ode23t`	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
`ode23tb`	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5558 for more details.

Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb

Examples

Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

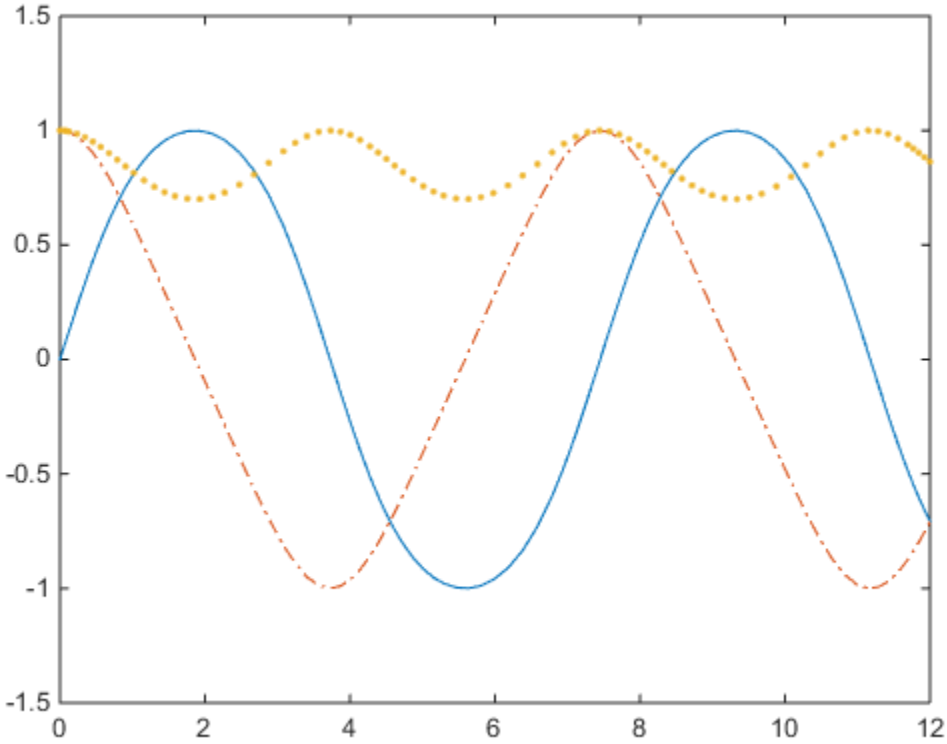
```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```



Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$y_1' = y_2 \qquad y_1(0) = 2$$
$$y_2' = 1000(1 - y_1^2)y_2 - y_1 \qquad y_2(0) = 0$$

To simulate this system, create a function `vdp1000` containing the equations

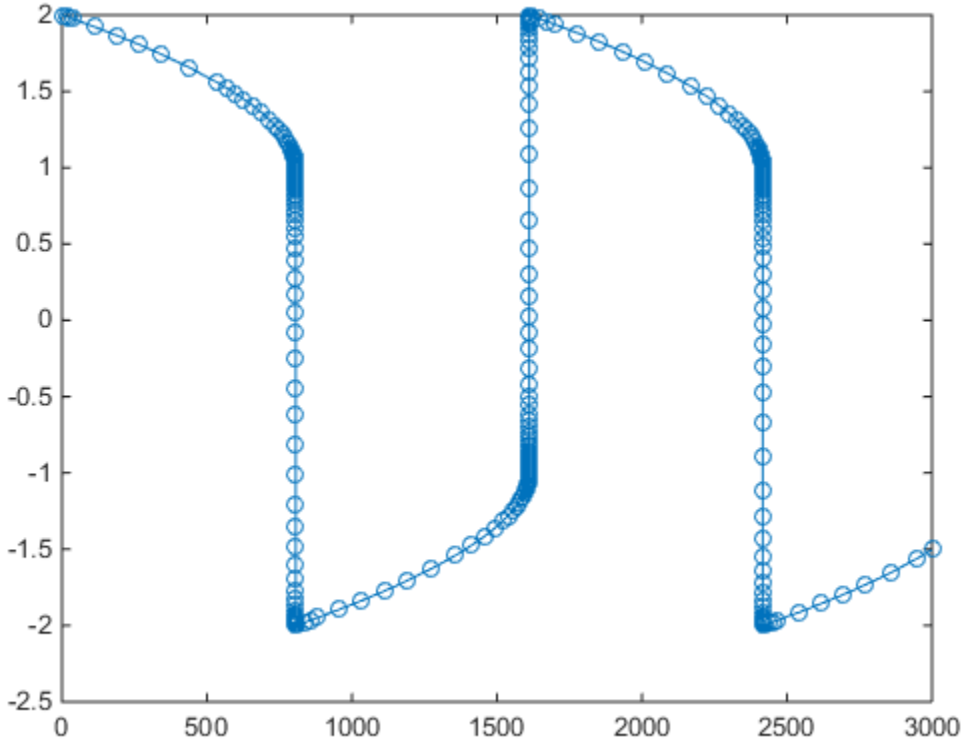
```
function dy = vdp1000(t,y)
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances (`1e-3` and `1e-6`, respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time `0`.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```



Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

`y'(t) + f(t)y(t) = g(t)`
The initial condition is `y(1) = 1`, where the function `f(t)` is defined by the `n`-by-`1` vector `f` evaluated at times `ft`, and the function `g(t)` is defined by the `m`-by-`1` vector `g` evaluated at times `gt`.

First, define the time-dependent parameters `f(t)` and `g(t)` as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

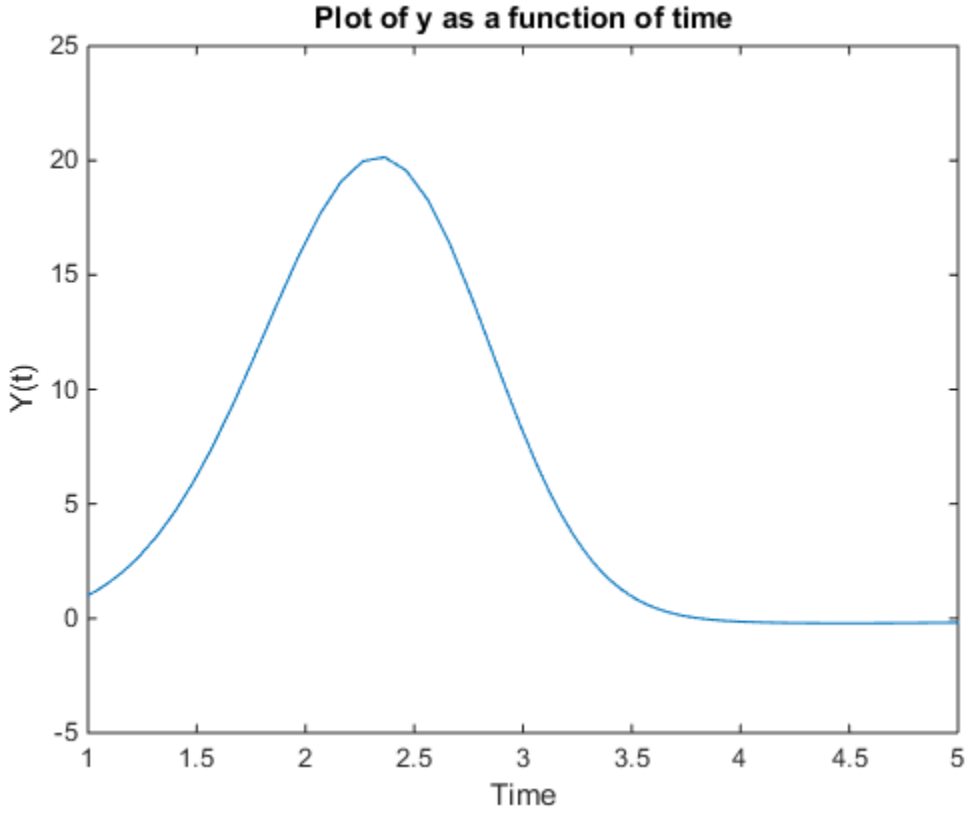
```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution `y(t)` as a function of time:

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```



More About

Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing `y(t`$_n$`)`, it needs only the solution at the immediately preceding time point, `y(t`$_{n-1}$`)`. In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

ode23s

Solve stiff differential equations; low order method

Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, *`solver`*, with any of the function names.

Arguments

The following table describes the input arguments to the solvers.

`odefun`	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$. The `ode23s` solver can solve only equations with constant mass matrices. `ode15s` and `ode23t` can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. The solver imposes the initial conditions at `tspan(1)`, and integrates from `tspan(1)` to `tspan(end)`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`. For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points. Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
`y0`	A vector of initial conditions.
`options`	Structure of optional parameters that change the default integration properties. This is the fourth input argument. `[t,y] = solver(odefun,tspan,y0,options)` You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

`T`	Column vector of time points.
`Y`	Solution array. Each row in `Y` corresponds to the solution at a time returned in the corresponding row of `T`.
`TE`	The time at which an event occurs.
`YE`	The solution at the time of the event.
`IE`	The index `i` of the event function that vanishes.
`sol`	Structure to evaluate the solution.

Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations $y' = f(t,y)$ from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to $f(t,y)$. Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of (t,y), called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver.

`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.
`sol.solver`	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix $\partial f/\partial y$ is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian $\partial f/\partial y$ or to the matrix $\partial f/\partial y$ if the Jacobian is constant. If the `Jacobian` property is not set (the default), $\partial f/\partial y$ is approximated by finite differences. Set the `Vectorized` property `'on'` if the ODE function is coded so that `odefun(T, [Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If $\partial f/\partial y$ is a sparse matrix, set the `JPattern` property to the sparsity pattern of $\partial f/\partial y$, i.e., a sparse matrix `S` with `S(i,j) = 1` if the `i`th component of $f(t,y)$ depends on the `j`th component of y, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form $M(t,y)y' = f(t,y)$, with time- and state-dependent mass matrix M. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable y and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to `'none'`.
- If the mass matrix depends weakly on y, set `MStateDependence` to `'weak'` (the default); otherwise, set it to `'strong'`. In either case, the function `MASS` is called with the two arguments (`t`,`y`).

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse $M(t,y)$.
- Supply the sparsity pattern of $\partial f/\partial y$ using the `JPattern` property or a sparse $\partial f/\partial y$ using the `Jacobian` property.
- For strongly state-dependent $M(t,y)$, set `MvPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the (`i`,`k`) component of $M(t,y)$ depends on component `j` of y, and `0` otherwise.

If the mass matrix M is singular, then $M(t,y)y' = f(t,y)$ is a system of differential algebraic equations. DAEs have solutions only when y_0 is consistent, that is, if there is a vector yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that `y0` is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to `'yes'`, `'no'`, or `'maybe'`. The default value of `'maybe'` causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and `y0` and `yp0` are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
`ode45`	Nonstiff	Medium	Most of the time. This should be the first solver you try.
`ode23`	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
`ode113`	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
`ode15s`	Stiff	Low to medium	If `ode45` is slow because the problem is stiff.
`ode23s`	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
`ode23t`	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
`ode23tb`	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5572 for more details.

Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb

Note You can use the `NonNegative` parameter with `ode15s`, `ode23t`, and `ode23tb` only for those problems for which there is no mass matrix.

Examples

Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

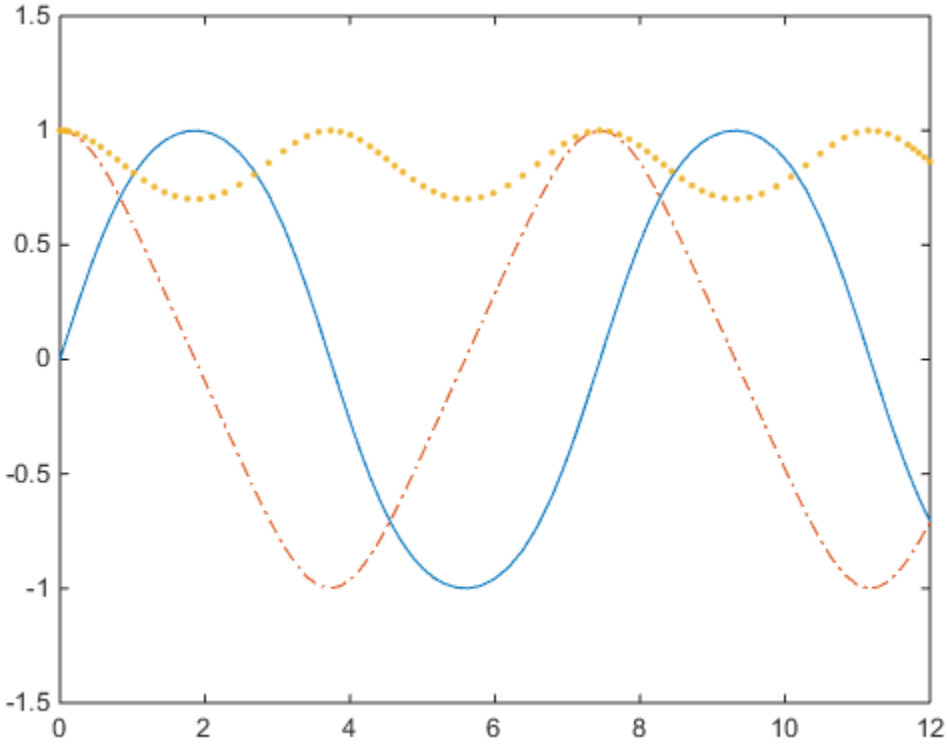
```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```



Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$y_1' = y_2 \qquad y_1(0) = 2$$
$$y_2' = 1000(1 - y_1^2)y_2 - y_1 \qquad y_2(0) = 0$$

To simulate this system, create a function `vdp1000` containing the equations

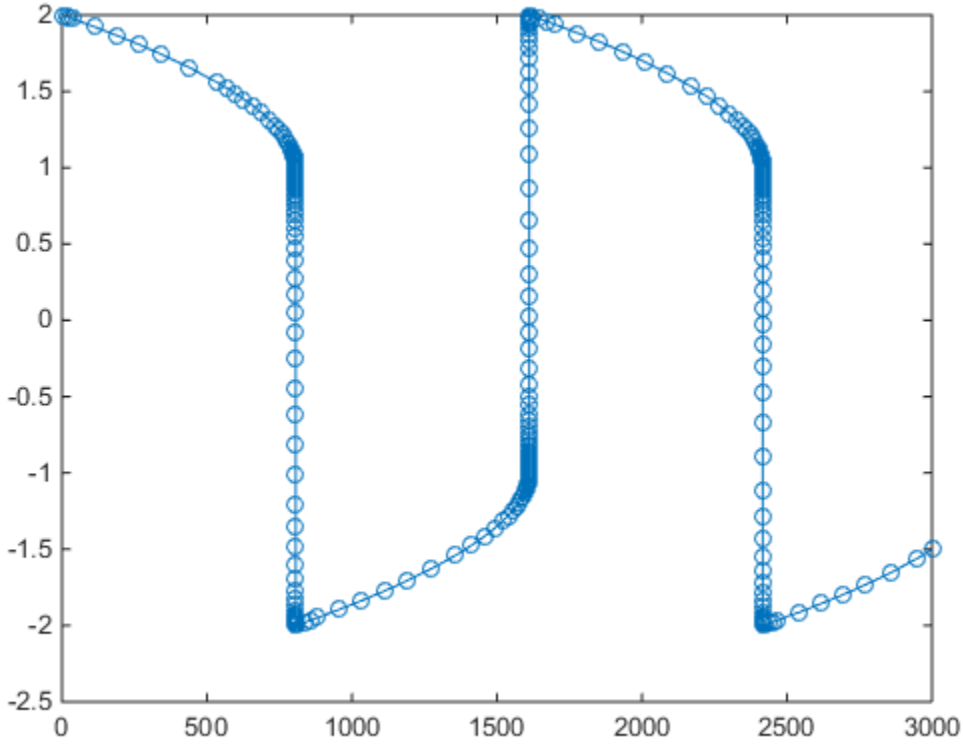
```
function dy = vdp1000(t,y)
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances (`1e-3` and `1e-6`, respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time `0`.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```



Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

`y'(t) + f(t)y(t) = g(t)`
The initial condition is `y(1) = 1`, where the function `f(t)` is defined by the `n`-by-`1` vector `f` evaluated at times `ft`, and the function `g(t)` is defined by the `m`-by-`1` vector `g` evaluated at times `gt`.

First, define the time-dependent parameters `f(t)` and `g(t)` as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

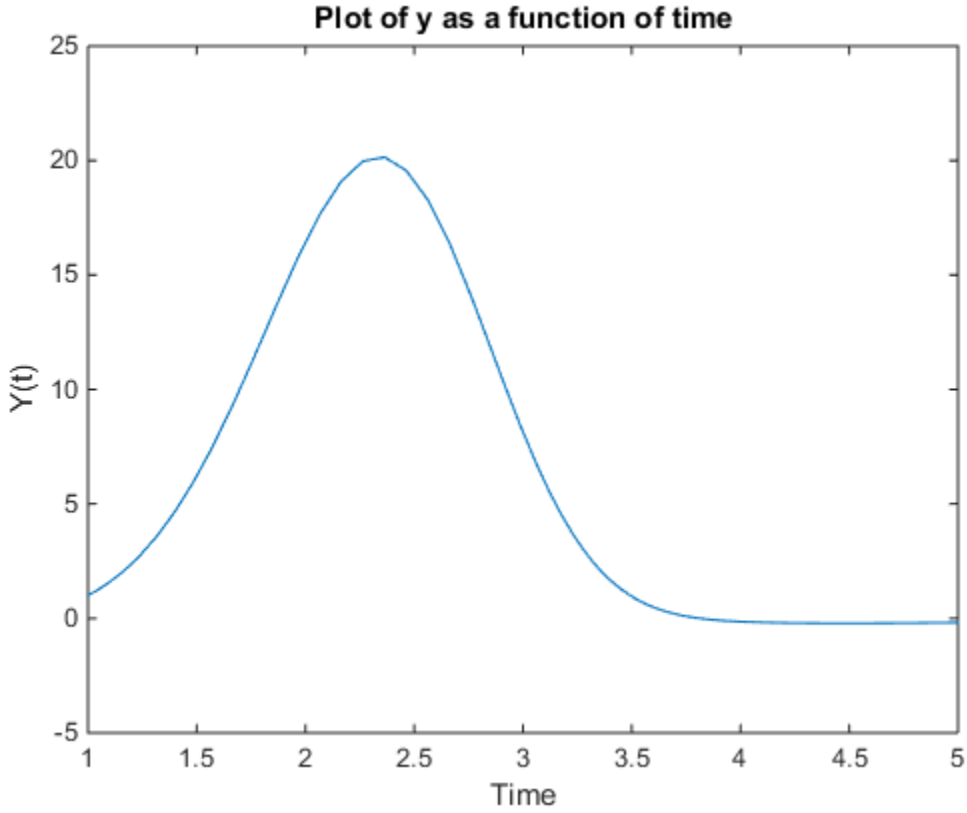
```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution `y(t)` as a function of time:

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```



More About

Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing `y(`t_n`)`, it needs only the solution at the immediately preceding time point, `y(`t_{n-1}`)`. In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

Introduced before R2006a

ode23t

Solve moderately stiff ODEs and DAEs; trapezoidal rule

Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, *`solver`*, with any of the function names.

Arguments

The following table describes the input arguments to the solvers.

`odefun`	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$. The `ode23s` solver can solve only equations with constant mass matrices. `ode15s` and `ode23t` can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. The solver imposes the initial conditions at `tspan(1)`, and integrates from `tspan(1)` to `tspan(end)`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`. For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points. Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
`y0`	A vector of initial conditions.
`options`	Structure of optional parameters that change the default integration properties. This is the fourth input argument. `[t,y] = solver(odefun,tspan,y0,options)` You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

`T`	Column vector of time points.
`Y`	Solution array. Each row in `Y` corresponds to the solution at a time returned in the corresponding row of `T`.
`TE`	The time at which an event occurs.
`YE`	The solution at the time of the event.
`IE`	The index `i` of the event function that vanishes.
`sol`	Structure to evaluate the solution.

Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations $y' = f(t,y)$ from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to $f(t,y)$. Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of (t,y), called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver.

`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.
`sol.solver`	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix $\partial f/\partial y$ is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian $\partial f/\partial y$ or to the matrix $\partial f/\partial y$ if the Jacobian is constant. If the `Jacobian` property is not set (the default), $\partial f/\partial y$ is approximated by finite differences. Set the `Vectorized` property `'on'` if the ODE function is coded so that `odefun(T, [Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If $\partial f/\partial y$ is a sparse matrix, set the `JPattern` property to the sparsity pattern of $\partial f/\partial y$, i.e., a sparse matrix `S` with `S(i,j) = 1` if the `i`th component of $f(t,y)$ depends on the `j`th component of y, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form $M(t,y)y' = f(t,y)$, with time- and state-dependent mass matrix M. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable y and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to `'none'`.
- If the mass matrix depends weakly on y, set `MStateDependence` to `'weak'` (the default); otherwise, set it to `'strong'`. In either case, the function `MASS` is called with the two arguments (`t`,`y`).

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse $M(t,y)$.
- Supply the sparsity pattern of $\partial f/\partial y$ using the `JPattern` property or a sparse $\partial f/\partial y$ using the `Jacobian` property.
- For strongly state-dependent $M(t,y)$, set `MvPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the (`i`,`k`) component of $M(t,y)$ depends on component `j` of y, and `0` otherwise.

If the mass matrix M is singular, then $M(t,y)y' = f(t,y)$ is a system of differential algebraic equations. DAEs have solutions only when y_0 is consistent, that is, if there is a vector yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that `y0` is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to `'yes'`, `'no'`, or `'maybe'`. The default value of `'maybe'` causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and `y0` and `yp0` are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
`ode45`	Nonstiff	Medium	Most of the time. This should be the first solver you try.
`ode23`	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
`ode113`	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
`ode15s`	Stiff	Low to medium	If `ode45` is slow because the problem is stiff.
`ode23s`	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
`ode23t`	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
`ode23tb`	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5586 for more details.

Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb

Examples

Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

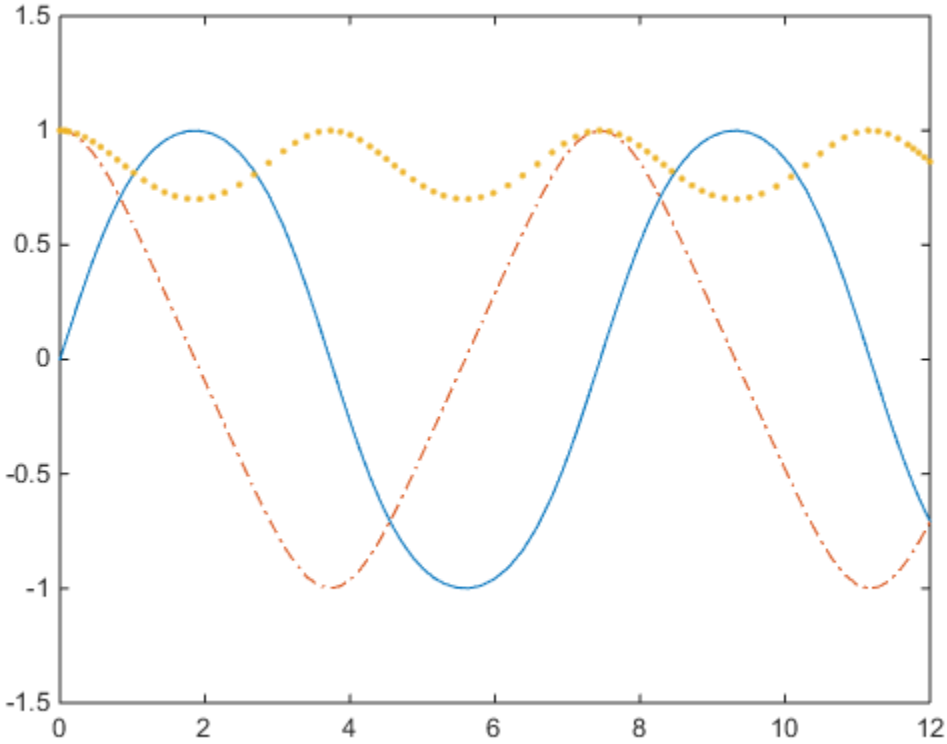
```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```



Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$y_1' = y_2 \qquad y_1(0) = 2$$
$$y_2' = 1000(1 - y_1^2)y_2 - y_1 \qquad y_2(0) = 0$$

To simulate this system, create a function `vdp1000` containing the equations

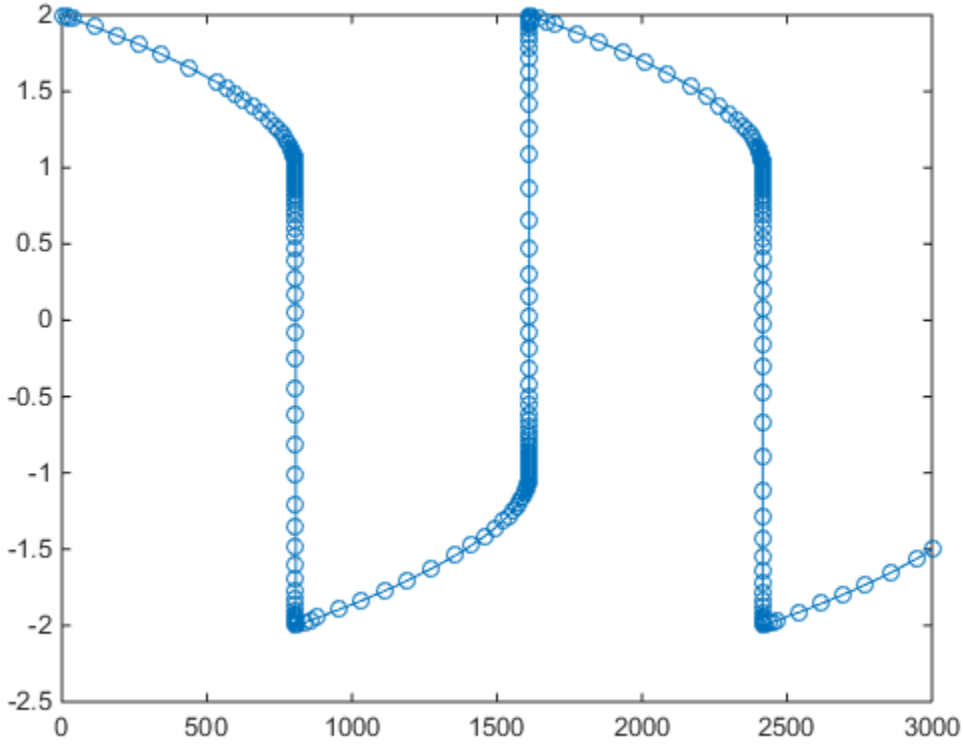
```
function dy = vdp1000(t,y)
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances (`1e-3` and `1e-6`, respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time `0`.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```



Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

`y'(t) + f(t)y(t) = g(t)`
The initial condition is `y(1) = 1`, where the function `f(t)` is defined by the `n`-by-`1` vector `f` evaluated at times `ft`, and the function `g(t)` is defined by the `m`-by-`1` vector `g` evaluated at times `gt`.

First, define the time-dependent parameters `f(t)` and `g(t)` as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

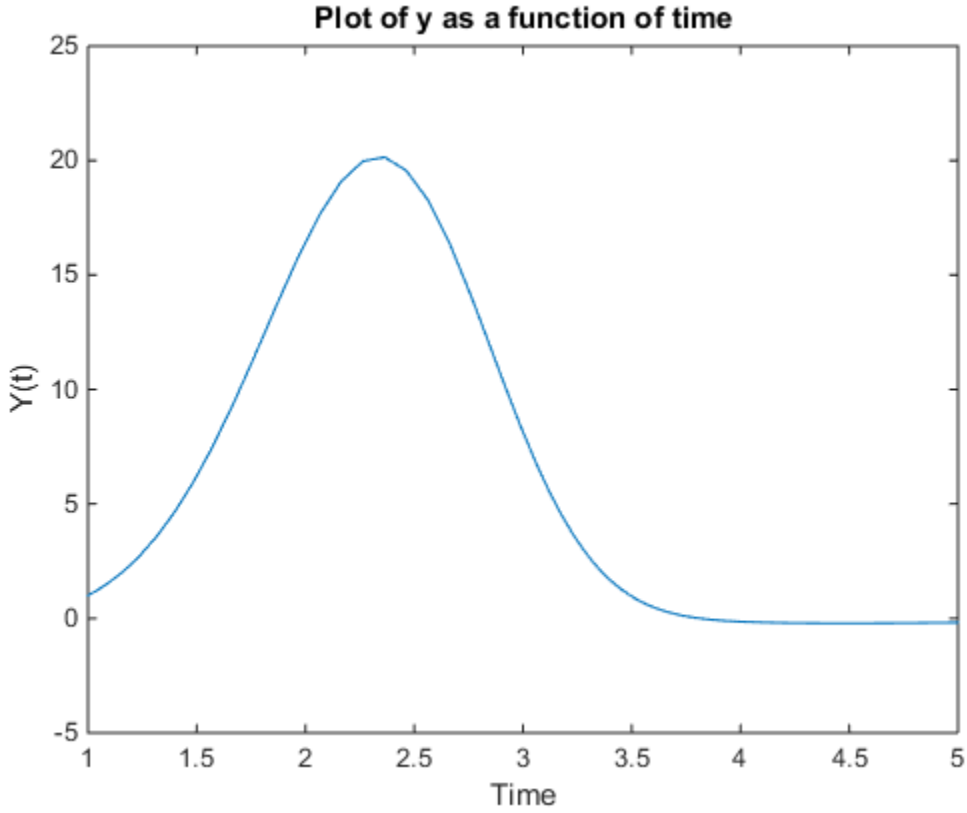
```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution `y(t)` as a function of time:

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```



More About

Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing $y(t_n)$, it needs only the solution at the immediately preceding time point, $y(t_{n-1})$. In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

Introduced before R2006a

ode23tb

Solve stiff differential equations; low order method

Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, *`solver`*, with any of the function names.

Arguments

The following table describes the input arguments to the solvers.

`odefun`	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$. The `ode23s` solver can solve only equations with constant mass matrices. `ode15s` and `ode23t` can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. The solver imposes the initial conditions at `tspan(1)`, and integrates from `tspan(1)` to `tspan(end)`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`. For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points. Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
`y0`	A vector of initial conditions.
`options`	Structure of optional parameters that change the default integration properties. This is the fourth input argument. `[t,y] = solver(odefun,tspan,y0,options)` You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

`T`	Column vector of time points.
`Y`	Solution array. Each row in `Y` corresponds to the solution at a time returned in the corresponding row of `T`.
`TE`	The time at which an event occurs.
`YE`	The solution at the time of the event.
`IE`	The index `i` of the event function that vanishes.
`sol`	Structure to evaluate the solution.

Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations $y' = f(t,y)$ from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to $f(t,y)$. Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of (t,y), called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver.

`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.
`sol.solver`	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix $\partial f/\partial y$ is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian $\partial f/\partial y$ or to the matrix $\partial f/\partial y$ if the Jacobian is constant. If the `Jacobian` property is not set (the default), $\partial f/\partial y$ is approximated by finite differences. Set the `Vectorized` property `'on'` if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If $\partial f/\partial y$ is a sparse matrix, set the `JPattern` property to the sparsity pattern of $\partial f/\partial y$, i.e., a sparse matrix `S` with `S(i,j) = 1` if the `i`th component of $f(t,y)$ depends on the `j`th component of y, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form $M(t,y)y' = f(t,y)$, with time- and state-dependent mass matrix M. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable y and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to `'none'`.
- If the mass matrix depends weakly on y, set `MStateDependence` to `'weak'` (the default); otherwise, set it to `'strong'`. In either case, the function `MASS` is called with the two arguments (`t`,`y`).

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse $M(t,y)$.
- Supply the sparsity pattern of $\partial f/\partial y$ using the `JPattern` property or a sparse $\partial f/\partial y$ using the `Jacobian` property.
- For strongly state-dependent $M(t,y)$, set `MvPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the (`i`,`k`) component of $M(t,y)$ depends on component `j` of y, and `0` otherwise.

If the mass matrix M is singular, then $M(t,y)y' = f(t,y)$ is a system of differential algebraic equations. DAEs have solutions only when y_0 is consistent, that is, if there is a vector yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that `y0` is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to `'yes'`, `'no'`, or `'maybe'`. The default value of `'maybe'` causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and `y0` and `yp0` are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
`ode45`	Nonstiff	Medium	Most of the time. This should be the first solver you try.
`ode23`	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
`ode113`	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
`ode15s`	Stiff	Low to medium	If `ode45` is slow because the problem is stiff.
`ode23s`	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
`ode23t`	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
`ode23tb`	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5600 for more details.

Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Examples

Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

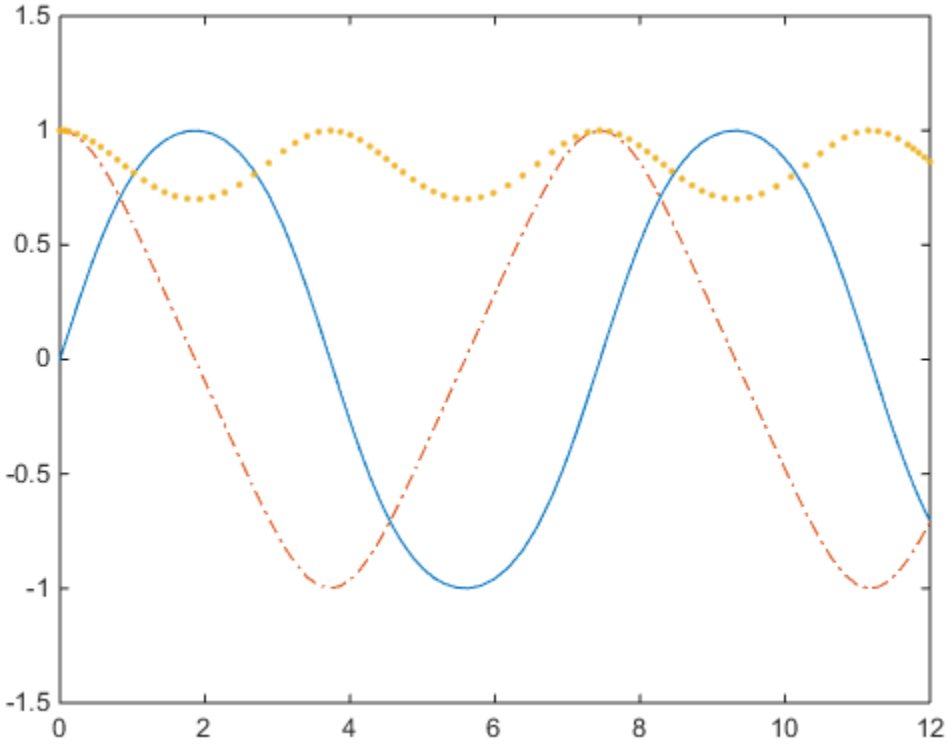
```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```



Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$y_1' = y_2 \qquad y_1(0) = 2$$
$$y_2' = 1000(1 - y_1^2)y_2 - y_1 \qquad y_2(0) = 0$$

To simulate this system, create a function `vdp1000` containing the equations

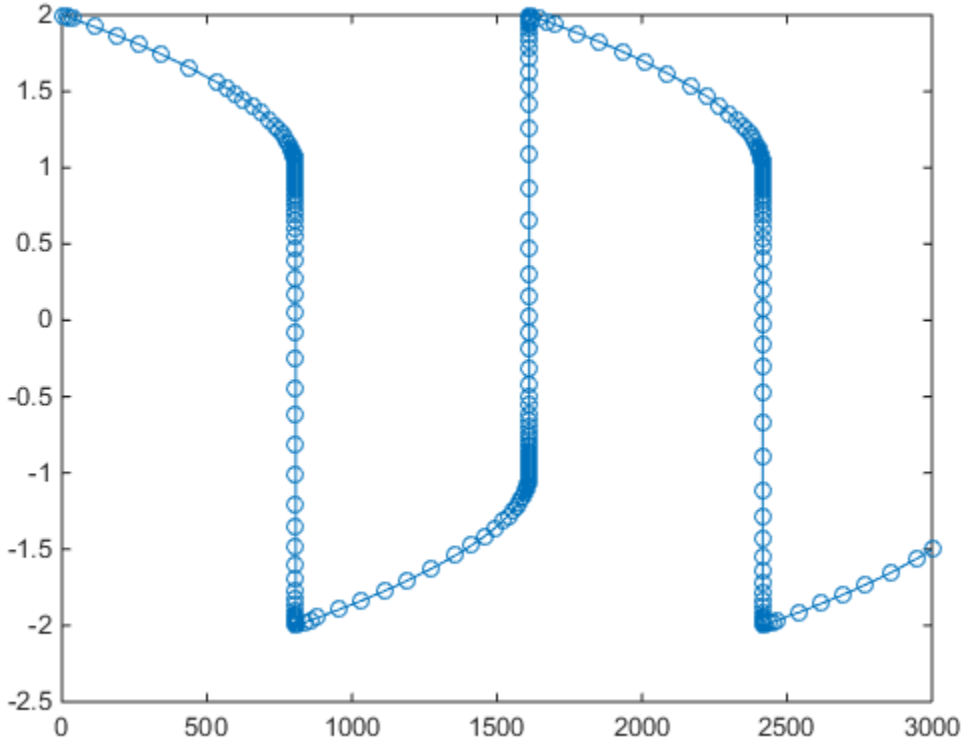
```
function dy = vdp1000(t,y)
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances (`1e-3` and `1e-6`, respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time `0`.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```



Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

`y'(t) + f(t)y(t) = g(t)`
The initial condition is `y(1) = 1`, where the function `f(t)` is defined by the `n`-by-`1` vector `f` evaluated at times `ft`, and the function `g(t)` is defined by the `m`-by-`1` vector `g` evaluated at times `gt`.

First, define the time-dependent parameters `f(t)` and `g(t)` as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

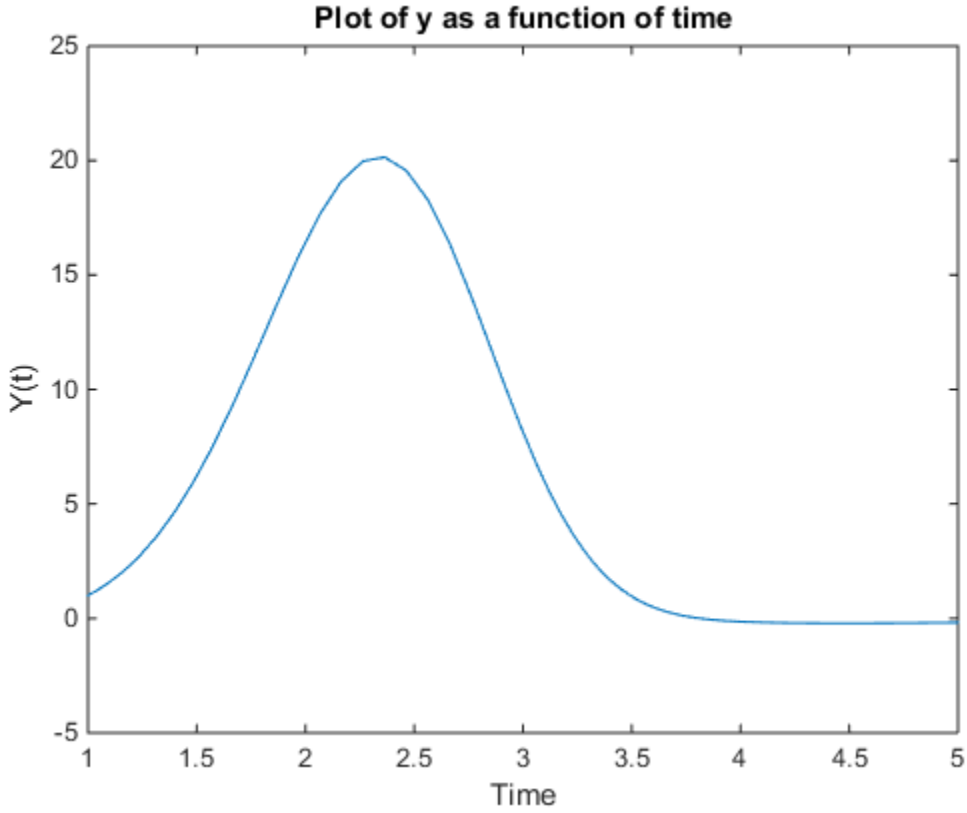
```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution `y(t)` as a function of time:

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```



More About

Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing $y(t_n)$, it needs only the solution at the immediately preceding time point, $y(t_{n-1})$. In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

ode45

Solve nonstiff differential equations; medium order method

Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, *`solver`*, with any of the function names.

Arguments

The following table describes the input arguments to the solvers.

`odefun`	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$. The `ode23s` solver can solve only equations with constant mass matrices. `ode15s` and `ode23t` can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. The solver imposes the initial conditions at `tspan(1)`, and integrates from `tspan(1)` to `tspan(end)`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`. For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points. Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
`y0`	A vector of initial conditions.
`options`	Structure of optional parameters that change the default integration properties. This is the fourth input argument. `[t,y] = solver(odefun,tspan,y0,options)` You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

`T`	Column vector of time points.
`Y`	Solution array. Each row in `Y` corresponds to the solution at a time returned in the corresponding row of `T`.
`TE`	The time at which an event occurs.
`YE`	The solution at the time of the event.
`IE`	The index `i` of the event function that vanishes.
`sol`	Structure to evaluate the solution.

Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations $y' = f(t,y)$ from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to $f(t,y)$. Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of (t,y), called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver.

`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.
`sol.solver`	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix $\partial f/\partial y$ is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian $\partial f/\partial y$ or to the matrix $\partial f/\partial y$ if the Jacobian is constant. If the `Jacobian` property is not set (the default), $\partial f/\partial y$ is approximated by finite differences. Set the `Vectorized` property `'on'` if the ODE function is coded so that `odefun(T, [Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If $\partial f/\partial y$ is a sparse matrix, set the `JPattern` property to the sparsity pattern of $\partial f/\partial y$, i.e., a sparse matrix `S` with `S(i,j) = 1` if the `i`th component of $f(t,y)$ depends on the `j`th component of y, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form $M(t,y)y' = f(t,y)$, with time- and state-dependent mass matrix M. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable y and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to `'none'`.
- If the mass matrix depends weakly on y, set `MStateDependence` to `'weak'` (the default); otherwise, set it to `'strong'`. In either case, the function `MASS` is called with the two arguments (`t`,`y`).

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse $M(t,y)$.
- Supply the sparsity pattern of $\partial f/\partial y$ using the `JPattern` property or a sparse $\partial f/\partial y$ using the `Jacobian` property.
- For strongly state-dependent $M(t,y)$, set `MvPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the (`i`,`k`) component of $M(t,y)$ depends on component `j` of y, and `0` otherwise.

If the mass matrix M is singular, then $M(t,y)y' = f(t,y)$ is a system of differential algebraic equations. DAEs have solutions only when y_0 is consistent, that is, if there is a vector yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that `y0` is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to `'yes'`, `'no'`, or `'maybe'`. The default value of `'maybe'` causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and `y0` and `yp0` are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
`ode45`	Nonstiff	Medium	Most of the time. This should be the first solver you try.
`ode23`	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
`ode113`	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
`ode15s`	Stiff	Low to medium	If `ode45` is slow because the problem is stiff.
`ode23s`	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
`ode23t`	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
`ode23tb`	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5614 for more details.

Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb

Examples

Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

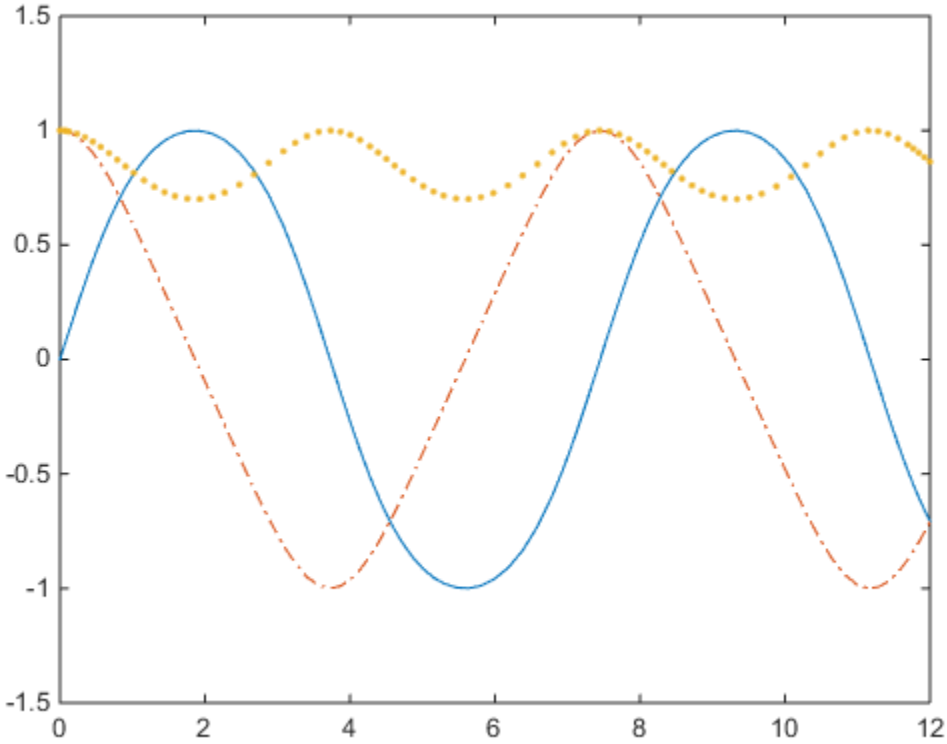
```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```



Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$y_1' = y_2 \qquad y_1(0) = 2$$
$$y_2' = 1000(1 - y_1^2)y_2 - y_1 \qquad y_2(0) = 0$$

To simulate this system, create a function `vdp1000` containing the equations

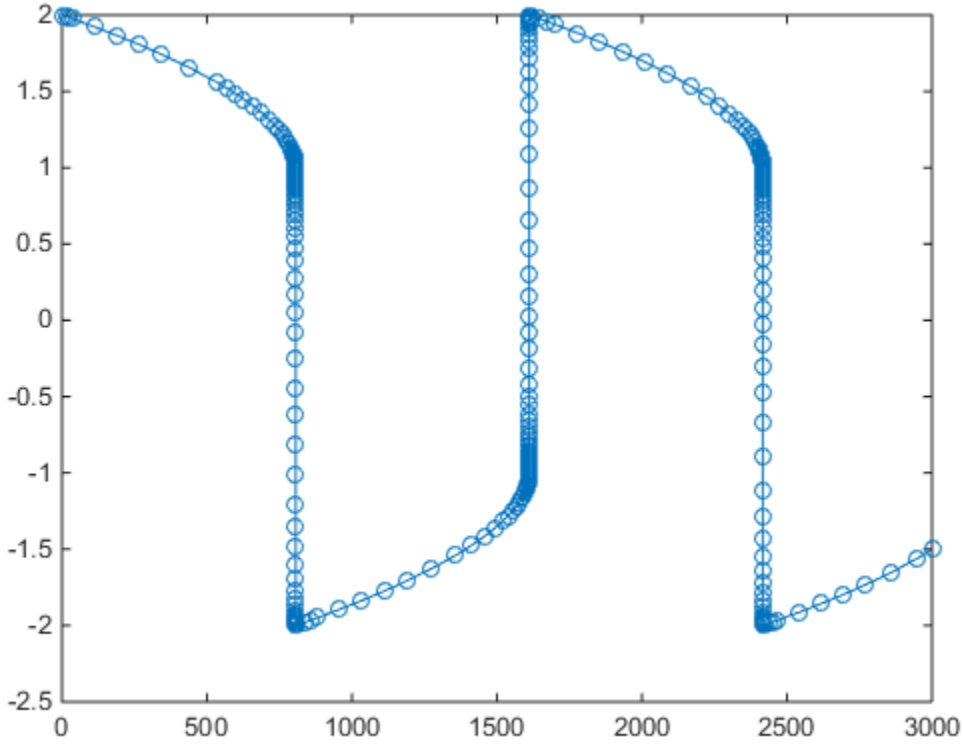
```
function dy = vdp1000(t,y)
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances (`1e-3` and `1e-6`, respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time `0`.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```



Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

`y'(t) + f(t)y(t) = g(t)`
The initial condition is `y(1) = 1`, where the function `f(t)` is defined by the `n`-by-`1` vector `f` evaluated at times `ft`, and the function `g(t)` is defined by the `m`-by-`1` vector `g` evaluated at times `gt`.

First, define the time-dependent parameters `f(t)` and `g(t)` as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

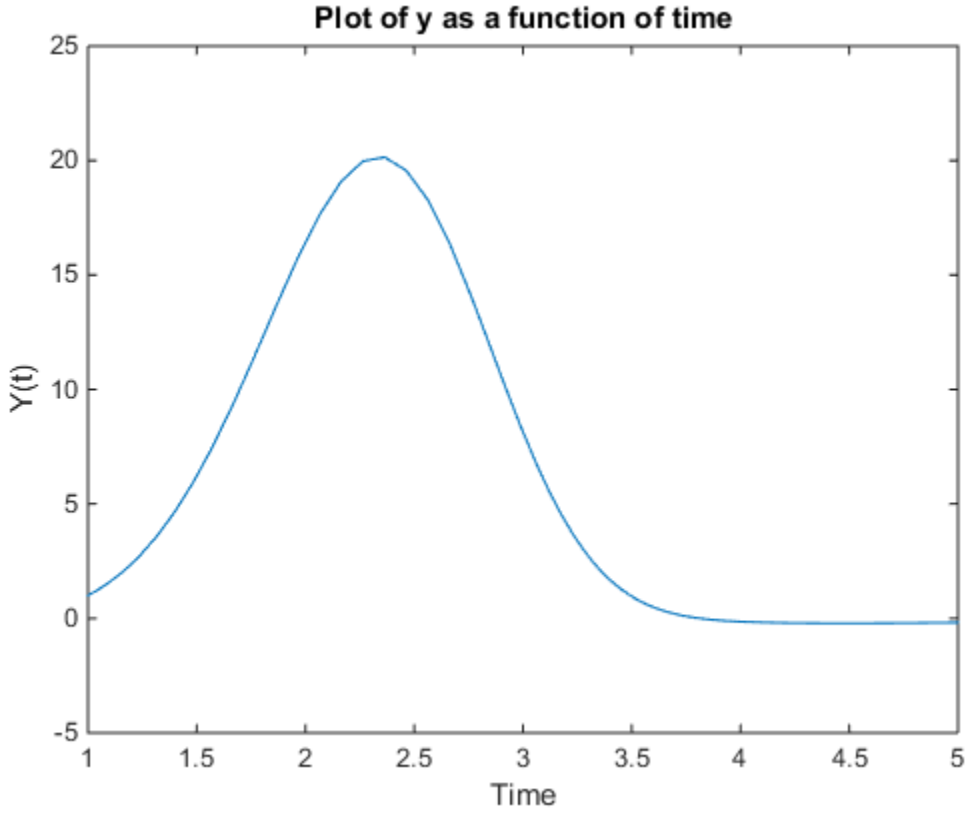
```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution `y(t)` as a function of time:

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```



More About

Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing $y(t_n)$, it needs only the solution at the immediately preceding time point, $y(t_{n-1})$. In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

ode113

Solve nonstiff differential equations; variable order method

Syntax

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, *`solver`*, with any of the function names.

Arguments

The following table describes the input arguments to the solvers.

`odefun`	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$. The `ode23s` solver can solve only equations with constant mass matrices. `ode15s` and `ode23t` can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
`tspan`	A vector specifying the interval of integration, `[t0,tf]`. The solver imposes the initial conditions at `tspan(1)`, and integrates from `tspan(1)` to `tspan(end)`. To obtain solutions at specific times (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`. For `tspan` vectors with two elements `[t0 tf]`, the solver returns the solution evaluated at every integration step. For `tspan` vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

	Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points. Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.
`y0`	A vector of initial conditions.
`options`	Structure of optional parameters that change the default integration properties. This is the fourth input argument. `[t,y] = solver(odefun,tspan,y0,options)` You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

`T`	Column vector of time points.
`Y`	Solution array. Each row in `Y` corresponds to the solution at a time returned in the corresponding row of `T`.
`TE`	The time at which an event occurs.
`YE`	The solution at the time of the event.
`IE`	The index `i` of the event function that vanishes.
`sol`	Structure to evaluate the solution.

Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations $y' = f(t,y)$ from time `t0` to `tf` with initial conditions `y0`. The first

input argument, `odefun`, is a function handle. The function, `f = odefun(t,y)`, for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to $f(t,y)$. Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0`, `t1,...,tf` (all increasing or all decreasing), use `tspan = [t0,t1,...,tf]`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` (`1e-3` by default) and a vector of absolute error tolerances `AbsTol` (all components are `1e-6` by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of (t,y), called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the `'Events'` property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the `i`th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and `0` otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

`sol.x`	Steps chosen by the solver.

`sol.y`	Each column `sol.y(:,i)` contains the solution at `sol.x(i)`.
`sol.solver`	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

`sol.xe`	Points at which events, if any, occurred. `sol.xe(end)` contains the exact point of a terminal event, if any.
`sol.ye`	Solutions that correspond to events in `sol.xe`.
`sol.ie`	Indices into the vector returned by the function specified in the `Events` option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix $\partial f/\partial y$ is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian $\partial f/\partial y$ or to the matrix $\partial f/\partial y$ if the Jacobian is constant. If the `Jacobian` property is not set (the default), $\partial f/\partial y$ is approximated by finite differences. Set the `Vectorized` property `'on'` if the ODE function is coded so that `odefun(T, [Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2),...]`. If $\partial f/\partial y$ is a sparse matrix, set the `JPattern` property to the sparsity pattern of $\partial f/\partial y$, i.e., a sparse matrix `S` with `S(i,j) = 1` if the `i`th component of $f(t,y)$ depends on the `j`th component of y, and 0 otherwise.

The solvers of the ODE suite can solve problems of the form $M(t,y)y' = f(t,y)$, with time- and state-dependent mass matrix M. (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable y and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to `'none'`.
- If the mass matrix depends weakly on y, set `MStateDependence` to `'weak'` (the default); otherwise, set it to `'strong'`. In either case, the function `MASS` is called with the two arguments (`t`,`y`).

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse $M(t,y)$.
- Supply the sparsity pattern of $\partial f/\partial y$ using the `JPattern` property or a sparse $\partial f/\partial y$ using the `Jacobian` property.
- For strongly state-dependent $M(t,y)$, set `MvPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the (`i`,`k`) component of $M(t,y)$ depends on component `j` of y, and `0` otherwise.

If the mass matrix M is singular, then $M(t,y)y' = f(t,y)$ is a system of differential algebraic equations. DAEs have solutions only when y_0 is consistent, that is, if there is a vector yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that `y0` is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to `'yes'`, `'no'`, or `'maybe'`. The default value of `'maybe'` causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and `y0` and `yp0` are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that M is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
`ode45`	Nonstiff	Medium	Most of the time. This should be the first solver you try.
`ode23`	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.
`ode113`	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.

Solver	Problem Type	Order of Accuracy	When to Use
`ode15s`	Stiff	Low to medium	If `ode45` is slow because the problem is stiff.
`ode23s`	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
`ode23t`	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
`ode23tb`	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-5628 for more details.

Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb

Examples

Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned} y_1' &= y_2 y_3 & y_1(0) &= 0 \\ y_2' &= -y_1 y_3 & y_2(0) &= 1 \\ y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1 \end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

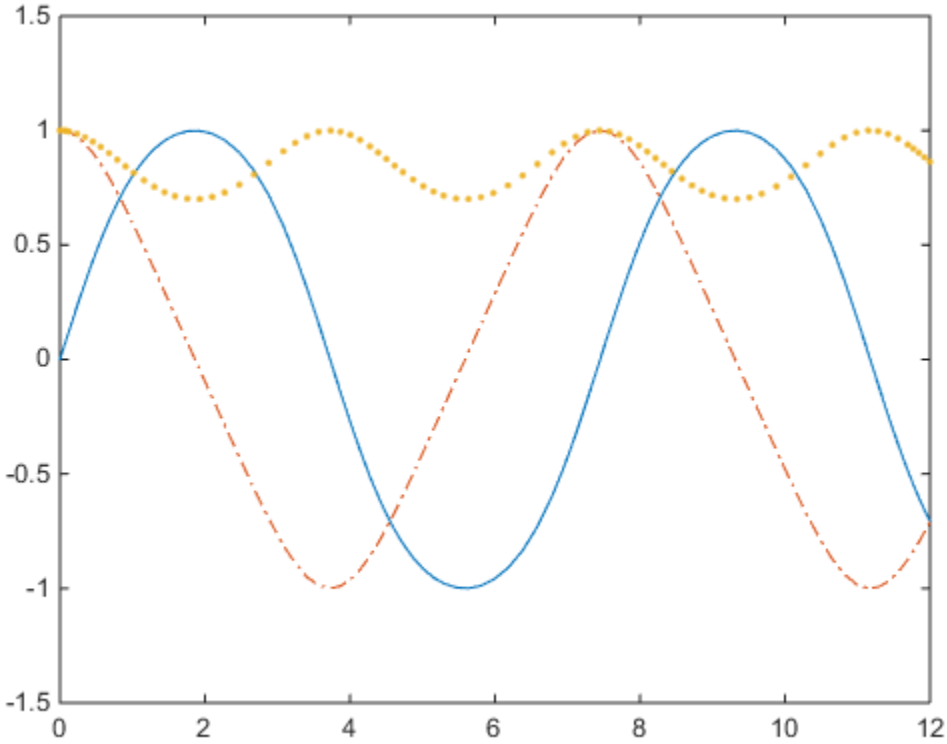
```
function dy = rigid(t,y)
dy = zeros(3,1);    % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time `0`.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array Y versus T shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```



Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$y_1' = y_2 \qquad y_1(0) = 2$$
$$y_2' = 1000(1 - y_1^2)y_2 - y_1 \qquad y_2(0) = 0$$

To simulate this system, create a function `vdp1000` containing the equations

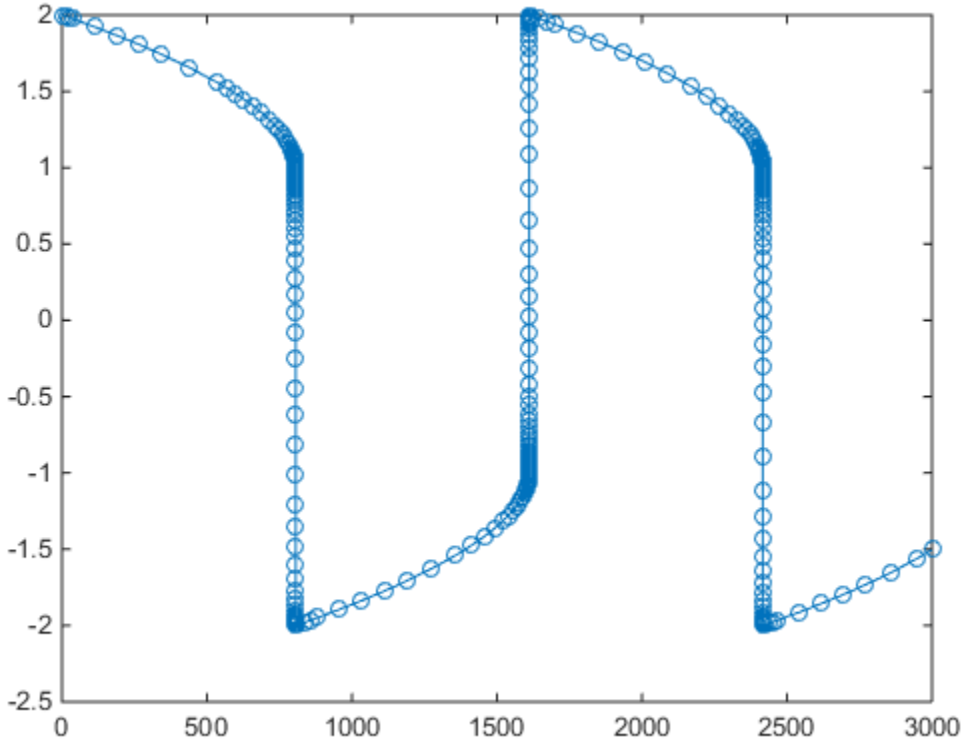
```
function dy = vdp1000(t,y)
dy = zeros(2,1);    % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances (`1e-3` and `1e-6`, respectively) and solve on a time interval of `[0 3000]` with initial condition vector `[2 0]` at time `0`.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-o')
```



Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

`y'(t) + f(t)y(t) = g(t)`
The initial condition is `y(1) = 1`, where the function `f(t)` is defined by the `n`-by-`1` vector `f` evaluated at times `ft`, and the function `g(t)` is defined by the `m`-by-`1` vector `g` evaluated at times `gt`.

First, define the time-dependent parameters `f(t)` and `g(t)` as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

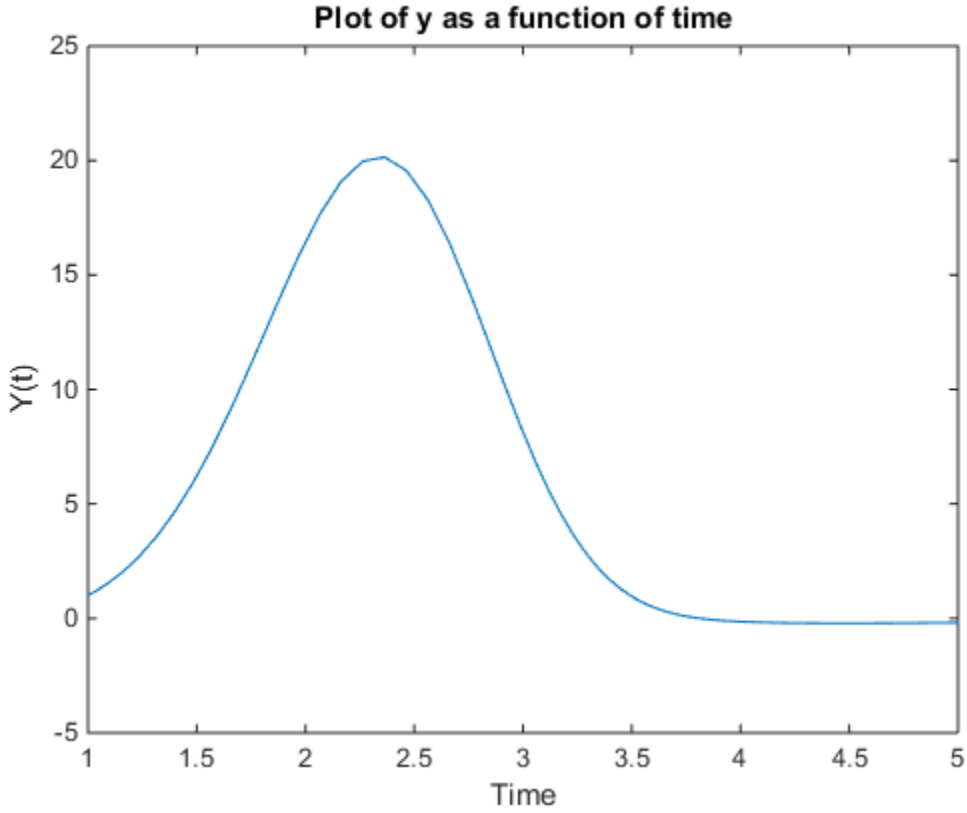
```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=1) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution `y(t)` as a function of time:

```
plot(T, Y);
title('Plot of y as a function of time');
xlabel('Time');
ylabel('Y(t)');
```



More About

Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing $y(t_n)$, it needs only the solution at the immediately preceding time point, $y(t_{n-1})$. In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

Introduced before R2006a

odeget

Ordinary differential equation options parameters

Syntax

```
o = odeget(options,'name')
o = odeget(options,'name',default)
```

Description

`o = odeget(options,'name')` extracts the value of the property specified by string `'name'` from integrator options structure `options`, returning an empty matrix if the property value is not specified in `options`. It is only necessary to type the leading characters that uniquely identify the property name. Case is ignored for property names.

`o = odeget(options,'name',default)` returns `o = default` if the named property is not specified in `options`.

The empty matrix `[]` is a valid `options` argument, and the syntax `odeget([],'name',default)` always returns `default`.

Examples

Having constructed an ODE options structure,

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-3 2e-3 3e-3]);
```

you can view these property settings with `odeget`.

```
odeget(options,'RelTol')
ans =

       1.0000e-04

odeget(options,'AbsTol')
ans =
```

```
    0.0010    0.0020    0.0030

odeget([],'RelTol',1e-3)
ans =

   1.0000e-03
```

odeset

Introduced before R2006a

odeset

Create or alter options structure for ordinary differential equation solvers

Syntax

```
options = odeset('name1',value1,'name2',value2,...)
options = odeset(oldopts,'name1',value1,...)
options = odeset(oldopts,newopts)
odeset
```

Description

The `odeset` function lets you adjust the integration parameters of the following ODE solvers.

For solving fully implicit differential equations:
`ode15i`

For solving initial value problems:
`ode23, ode45, ode113, ode15s, ode23s, ode23t, ode23tb`

See below for information about the integration parameters.

`options = odeset('name1',value1,'name2',value2,...)` creates an options structure that you can pass as an argument to any of the ODE solvers. In the resulting structure, `options`, the named properties have the specified values. For example, `'name1'` has the value `value1`. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify a property name. Case is ignored for property names.

`options = odeset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This sets `options` equal to the existing structure `oldopts`, overwrites any values in `oldopts` that are respecified using name/value pairs, and adds any new pairs to the structure. The modified structure is returned as an output argument.

`options = odeset(oldopts,newopts)` alters an existing options structure `oldopts` by combining it with a new options structure `newopts`. Any new options not equal to the empty matrix overwrite corresponding options in `oldopts`.

`odeset` with no input arguments displays all property names as well as their possible and default values.

ODE Properties

The following sections describe the properties that you can set using `odeset`. The available properties depend on the ODE solver you are using. There are several categories of properties:

Note This reference page describes the ODE properties for MATLAB, Version 7. The Version 5 properties are supported only for backward compatibility. For information on the Version 5 properties, type at the MATLAB command line: `more on, type odeset, more off`.

Error Control Properties

At each step, the solver estimates the local error `e` in the `i`th component of the solution. This error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.
`|e(i)| ≤ max(RelTol*abs(y(i)),AbsTol(i))`

For routine problems, the ODE solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require

tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For the absolute error tolerance, the scaling of the solution components is important: if `|y|` is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in `y`. You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component `y(i)` when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in `y(i)` so that you can accurately compute more interesting components.

The following table describes the error control properties. Further information on each property is given following the table.

Property	Value	Description
`RelTol`	Positive scalar {`1e-3`}	Relative error tolerance that applies to all components of the solution vector `y`.
`AbsTol`	Positive scalar or vector {`1e-6`}	Absolute error tolerances that apply to the individual components of the solution vector.
`NormControl`	`on` | {`off`}	Control error relative to norm of solution.

Description of Error Control Properties

`RelTol` — This tolerance is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components, except those smaller than thresholds `AbsTol(i)`.

The default, `1e-3`, corresponds to 0.1% accuracy.

`AbsTol` — `AbsTol(i)` is a threshold below which the value of the `i`th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero.

If `AbsTol` is a vector, the length of `AbsTol` must be the same as the length of the solution vector `y`. If `AbsTol` is a scalar, the value applies to all components of `y`.

`NormControl` — Set this property `on` to request that the solvers control the error in each integration step with `norm(e) <= max(RelTol*norm(y),AbsTol)`. By default the solvers use a more stringent componentwise error control.

Solver Output Properties

The following table lists the solver output properties that control the output that the solvers generate. Further information on each property is given following the table.

Property	Value	Description
`NonNegative`	Vector of integers	Specifies which components of the solution vector must be nonnegative. The default value is `[]`.
`OutputFcn`	Function handle	A function for the solver to call after every successful integration step.
`OutputSel`	Vector of indices	Specifies which components of the solution vector are to be passed to the output function.
`Refine`	Positive integer	Increases the number of output points by a factor of `Refine`.
`Stats`	`on` | {`off`}	Determines whether the solver should display statistics about its computations. By default, `Stats` is `off`.

Description of Solver Output Properties

`NonNegative` — The `NonNegative` property is not available in `ode23s`, `ode15i`. In `ode15s`, `ode23t`, and `ode23tb`, `NonNegative` is not available for problems where there is a mass matrix.

`OutputFcn` — To specify an output function, set `'OutputFcn'` to a function handle. For example,

```
options = odeset('OutputFcn',@myfun)
```

sets `'OutputFcn'` to `@myfun`, a handle to the function `myfun`. See the `function_handle` reference page for more information.

The output function must be of the form

```
status = myfun(t,y,flag)
```

“Parameterizing Functions” explains how to provide additional parameters to `myfun`, if necessary.

The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:

Flag	Description
`init`	The solver calls `myfun(tspan,y0,'init')` before beginning the integration to allow the output function to initialize. `tspan` and `y0` are the input arguments to the ODE solver.
`{[]}`	The solver calls `status = myfun(t,y,[])` after each integration step on which output is requested. `t` contains points where output was generated during the step, and `y` is the numerical solution at the points in `t`. If `t` is a vector, the `i`th column of `y` corresponds to the `i`th element of `t`. When `length(tspan) > 2` the output is produced at every point in `tspan`. When `length(tspan) = 2` the output is produced according to the `Refine` option. `myfun` must return a `status` output value of `0` or `1`. If `status = 1`, the solver halts integration. You can use this mechanism, for instance, to implement a **Stop** button.
`done`	The solver calls `myfun([],[],'done')` when integration is complete to allow the output function to perform any cleanup chores.

You can use these general purpose output functions or you can edit them to create your own. Type `help function` at the command line for more information.

- `odeplot` — Time series plotting (default when you call the solver with no output arguments and you have not specified an output function)
- `odephas2` — Two-dimensional phase plane plotting
- `odephas3` — Three-dimensional phase plane plotting
- `odeprint` — Print solution as it is computed

Note If you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history.

`OutputSel` — Use `OutputSel` to specify which components of the solution vector you want passed to the output function. For example, if you want to use the `odeplot` output

function, but you want to plot only the first and third components of the solution, you can do this using

```
options = ...
odeset('OutputFcn',@odeplot,'OutputSel',[1 3]);
```

By default, the solver passes all components of the solution to the output function.

`Refine` — If `Refine` is `1`, the solver returns solutions only at the end of each time step. If `Refine` is `n` >`1`, the solver subdivides each time step into `n` smaller intervals and returns solutions at each time point. `Refine` does not apply when `length(tspan)>2` or the ODE solver returns the solution as a structure.

Note In all the solvers, the default value of `Refine` is `1`. Within `ode45`, however, the default is `4` to compensate for the solver's large step sizes. To override this and see only the time steps chosen by `ode45`, set `Refine` to `1`.

The extra values produced for `Refine` are computed by means of continuous extension formulas. These are specialized formulas used by the ODE solvers to obtain accurate solutions between computed time steps without significant increase in computation time.

`Stats` — By default, `Stats` is `off`. If it is `on`, after solving the problem the solver displays

- Number of successful steps
- Number of failed attempts
- Number of times the ODE function was called to evaluate $f(t,y)$

Solvers based on implicit methods, including `ode23s`, `ode23t`, `ode15s`, and `ode15i`, also display

- Number of times that the partial derivatives matrix $\partial f/\partial x$ was formed
- Number of LU decompositions
- Number of solutions of linear systems

Step-Size Properties

The step-size properties specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step-size properties. Further information on each property is given following the table.

Property	Value	Description
`InitialStep`	Positive scalar	Suggested initial step size.
`MaxStep`	Positive scalar {`0.1*abs(t0-tf)`}	Upper bound on solver step size.

Description of Step-Size Properties

`InitialStep` — `InitialStep` sets an upper bound on the magnitude of the first step size the solver tries. If you do not set `InitialStep`, the initial step size is based on the slope of the solution at the initial time `tspan(1)`, and if the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable `InitialStep`.

`MaxStep` — If the differential equation has periodic coefficients or solutions, it might be a good idea to set `MaxStep` to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce `MaxStep` for any of the following purposes:

- To produce more output points. This can significantly slow down solution time. Instead, use `Refine` to compute additional outputs by continuous extension at very low cost.
- When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. See “Error Control Properties” on page 1-5634 for a description of the error tolerance properties.
- To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs,

break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbsTol`. Use `MaxStep` as a last resort.

Event Location Property

In some ODE problems the times of specific events are important, such as the time at which a ball hits the ground, or the time at which a spaceship returns to the earth. While solving a problem, the ODE solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property. Further information on each property is given following the table.

ODE Events Property

String	Value	Description
`Events`	Function handle	Handle to a function that includes one or more event functions.

Description of Event Location Properties

`Events` — The function is of the form

```
[value,isterminal,direction] = events(t,y)
```

`value`, `isterminal`, and `direction` are vectors for which the `i`th element corresponds to the `i`th event function:

- `value(i)` is the value of the `i`th event function.
- `isterminal(i)` = `1` if the integration is to terminate at a zero of this event function, otherwise, `0`.
- `direction(i) = 0` if all zeros are to be located (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing.

If you specify an events function and events are detected, the solver returns three additional outputs:

- `A` column vector of times at which events occur

- Solution values corresponding to these times
- Indices into the vector returned by the events function. The values indicate which event the solver detected.

If you call the solver as

```
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as `TE`, `YE`, and `IE` respectively. If you call the solver as

```
sol = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as `sol.xe`, `sol.ye`, and `sol.ie`, respectively.

For examples that use an event function, see "Event Location" and "Advanced Event Location" in the MATLAB Mathematics documentation.

Jacobian Matrix Properties

The stiff ODE solvers often execute faster if you provide additional information about the Jacobian matrix $\partial f/\partial y$, a matrix of partial derivatives of the function that defines the differential equations.

$$\frac{\partial f}{\partial y} = \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} & \cdots \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} & \cdots \\ \vdots & \vdots & \\ & & \end{bmatrix}$$

The Jacobian matrix properties pertain only to those solvers for stiff problems (`ode15s`, `ode23s`, `ode23t`, `ode23tb`, and `ode15i`) for which the Jacobian matrix $\partial f/\partial y$ can be critical to reliability and efficiency. If you do not provide a function to calculate the Jacobian, these solvers approximate the Jacobian numerically using finite differences. In this case, you might want to use the `Vectorized` or `JPattern` properties.

The following table describes the Jacobian matrix properties for all implicit solvers except `ode15i`. Further information on each property is given following the table. See Jacobian Properties for ode15i for `ode15i`-specific information.

Jacobian Properties for All Implicit Solvers Except ode15i

Property	Value	Description
`Jacobian`	Function handle | constant matrix	Matrix or function that evaluates the Jacobian.
`JPattern`	Sparse matrix of {0,1}	Generates a sparse Jacobian matrix numerically.
`Vectorized`	`on` | {`off`}	Allows the solver to reduce the number of function evaluations required.

Description of Jacobian Properties

`Jacobian` — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function `FJac`, where `FJac(t,y)` computes $\partial f/\partial y$, or to the constant value of $\partial f/\partial y$.

The Jacobian for the "van der Pol Equation (Stiff)", described in the MATLAB Mathematics documentation, can be coded as

```
function J = vdp1000jac(t,y)
J = [  0                    1
     (-2000*y(1)*y(2)-1)  (1000*(1-y(1)^2)) ];
```

`JPattern` — `JPattern` is a sparsity pattern with `1`s where there might be nonzero entries in the Jacobian.

Note If you specify `Jacobian`, the solver ignores any setting for `JPattern`.

Set this property to a sparse matrix S with $S(i,j) = 1$ if component i of $f(t,y)$ depends on component j of y, and 0 otherwise. The solver uses this sparsity pattern to generate a sparse Jacobian matrix numerically. If the Jacobian matrix is large and sparse, this can greatly accelerate execution. For an example using the `JPattern` property, see Example: Large, Stiff, Sparse Problem in the MATLAB Mathematics documentation.

`Vectorized` — The `Vectorized` property allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

Set `on` to inform the solver that you have coded the ODE function `F` so that `F(t,[y1 y2 ...])` returns `[F(t,y1) F(t,y2) ...]`. This allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

Note If you specify `Jacobian`, the solver ignores a setting of `'on'` for `'Vectorized'`.

With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. For example, you can vectorize the "van der Pol Equation (Stiff)", described in the MATLAB Mathematics documentation, by introducing colon notation into the subscripts and by using the array power (`.^`) and array multiplication (`.*`) operators.

```
function dydt = vdp1000(t,y)
dydt = [y(2,:); 1000*(1-y(1,:).^2).*y(2,:)-y(1,:)];
```

Note Vectorization of the ODE function used by the ODE solvers differs from the vectorization used by the boundary value problem (BVP) solver, `bvp4c`. For the ODE solvers, the ODE function is vectorized only with respect to the second argument, while `bvp4c` requires vectorization with respect to the first and second arguments.

The following table describes the Jacobian matrix properties for `ode15i`.

Jacobian Properties for ode15i

Property	Value	Description
`Jacobian`	Function handle | Cell array of constant values	Function that evaluates the Jacobian or a cell array of constant values.
`JPattern`	Sparse matrices of {0,1}	Generates a sparse Jacobian matrix numerically.
`Vectorized`	`on` | {`off`}	Vectorized ODE function

Description of Jacobian Properties for ode15i

`Jacobian` — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function

```
[dFdy,dFdp] = Fjac(t,y,yp)
```

or to a cell array of constant values [$\partial F/\partial y$,($\partial F/\partial y$)′].

`JPattern` — `JPattern` is a sparsity pattern with `1`'s where there might be nonzero entries in the Jacobian.

Set this property to `{dFdyPattern,dFdypPattern}`, the sparsity patterns of $\partial F/\partial y$ and $\partial F/\partial y'$, respectively.

`Vectorized` —

Set this property to `{yVect, ypVect}`. Setting `yVect` to `'on'` indicates that

```
F(t, [y1 y2 ...], yp)
```

returns

```
[F(t,y1,yp), F(t,y2,yp) ...]
```

Setting `ypVect` to `'on'` indicates that

```
F(t,y,[yp1 yp2 ...])
```

returns

```
[F(t,y,yp1) F(t,y,yp2) ...]
```

Mass Matrix and DAE Properties

This section describes mass matrix and differential-algebraic equation (DAE) properties, which apply to all the solvers except `ode15i`. These properties are not applicable to `ode15i` and their settings do not affect its behavior.

The solvers of the ODE suite can solve ODEs of the form

$$M(t,y)y' = f(t,y)$$

with a mass matrix $M(t,y)$ that can be sparse.

When $M(t,y)$ is nonsingular, the equation above is equivalent to $y' = M^{-1} f(t,y)$ and the ODE has a solution for any initial values y_0 at t_0. The more general form (Equation 1-3)

is convenient when you express a model naturally in terms of a mass matrix. For large, sparse $M(t,y)$, solving Equation 1-3 directly reduces the storage and run-time needed to solve the problem.

When $M(t,y)$ is singular, then $M(t,y)$ times $M(t,y)y' = f(t,y)$ is a DAE. A DAE has a solution only when y_0 is consistent; that is, there exists an initial slope yp_0 such that $M(t_0,y_0)yp_0 = f(t_0,y_0)$. If y_0 and yp_0 are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. For DAEs of index 1, solving an initial value problem with consistent initial conditions is much like solving an ODE.

The `ode15s` and `ode23t` solvers can solve DAEs of index 1. For examples of DAE problems, see Example: Differential-Algebraic Problem, in the MATLAB Mathematics documentation, and the examples amp1dae and hb1dae.

The following table describes the mass matrix and DAE properties. Further information on each property is given following the table.

Mass Matrix and DAE Properties (Solvers Other Than ode15i)

Property	Value	Description
`Mass`	Matrix | function handle	Mass matrix or a function that evaluates the mass matrix $M(t,y)$.
`MStateDependence`	`none | {weak} | strong`	Dependence of the mass matrix on y.
`MvPattern`	Sparse matrix	$\partial(M(t,y)v)/\partial y$ sparsity pattern.
`MassSingular`	`yes | no | {maybe}`	Indicates whether the mass matrix is singular.
`InitialSlope`	Vector {zero vector}	Vector representing the consistent initial slope yp_0.

Description of Mass Matrix and DAE Properties

`Mass` — For problems of the form $M(t)y' = f(t,y)$, set `'Mass'` to a mass matrix M.

For problems of the form $M(t)y' = f(t,y)$, set `'Mass'` to a function handle `@Mfun`, where `Mfun(t,y)` evaluates the mass matrix $M(t,y)$. The `ode23s` solver can only solve problems with a constant mass matrix M. When solving DAEs, using `ode15s` or `ode23t`, it is advantageous to formulate the problem so that M is a diagonal matrix (a semiexplicit DAE).

For example problems, see "Finite Element Discretization" in the MATLAB Mathematics documentation, or the examples `fem2ode` or `batonode`.

`MStateDependence` — Set this property to `none` for problems $M(t)y' = f(t, y)$. Both `weak` and `strong` indicate $M(t,y)$, but `weak` results in implicit solvers using approximations when solving algebraic equations.

`MvPattern` — Set this property to a sparse matrix S with $S(i,j) = 1$ if, for any k, the (i,k) component of $M(t,y)$ depends on component j of y, and 0 otherwise. For use with the `ode15s`, `ode23t`, and `ode23tb` solvers when `MStateDependence` is `strong`. See burgersode as an example.

`MassSingular` — Set this property to `no` if the mass matrix is not singular and you are using either the `ode15s` or `ode23t` solver. The default value of `maybe` causes the solver to test whether the problem is a DAE, by testing whether $M(t_0,y_0)$ is singular.

`InitialSlope` — Vector representing the consistent initial slope yp_0, where yp_0 satisfies $M(t_0, y_0) \cdot yp_0 = f(t_0, y_0)$. The default is the zero vector.

This property is for use with the `ode15s` and `ode23t` solvers when solving DAEs.

ode15s and ode15i-Specific Properties

`ode15s` is a variable-order solver for stiff problems. It is based on the numerical differentiation formulas (NDFs). The NDFs are generally more efficient than the closely related family of backward differentiation formulas (BDFs), also known as Gear's methods. The `ode15s` properties let you choose among these formulas, as well as specifying the maximum order for the formula used.

`ode15i` solves fully implicit differential equations of the form

$$f(t, y, y') = 0$$

using the variable order BDF method.

The following table describes the `ode15s` and `ode15i`-specific properties. Further information on each property is given following the table. Use `odeset` to set these properties.

ode15s and ode15i-Specific Properties

Property	Value	Description
`MaxOrder`	`1 | 2 | 3 | 4 | {5}`	Maximum order formula used to compute the solution.
`BDF` (`ode15s` only)	`on | {off}`	Specifies whether you want to use the BDFs instead of the default NDFs.

Description of ode15s and ode15i-Specific Properties

`MaxOrder` — Maximum order formula used to compute the solution.

`BDF` (`ode15s` only) — Set `BDF` `on` to have `ode15s` use the BDFs.

For both the NDFs and BDFs, the formulas of orders 1 and 2 are A-stable (the stability region includes the entire left half complex plane). The higher order formulas are not as stable, and the higher the order the worse the stability. There is a class of stiff problems (stiff oscillatory) that is solved more efficiently if `MaxOrder` is reduced (for example to `2`) so that only the most stable formulas are used.

Introduced before R2006a

odextend

Extend solution of initial value problem for ordinary differential equation

Syntax

```
solext = odextend(sol, odefun, tfinal)
solext = odextend(sol,[],tfinal)
solext = odextend(sol, odefun, tfinal, yinit)
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
solext = odextend(sol, odefun, tfinal, yinit, options)
```

Description

`solext = odextend(sol, odefun, tfinal)` extends the solution stored in `sol` to an interval with upper bound `tfinal` for the independent variable. Specify `odefun` as a function handle. Specify `sol` as an ODE solution structure created using an ODE solver. The lower bound for the independent variable in `solext` is the same as in `sol`. If you created `sol` with an ODE solver other than `ode15i`, the function `odefun` computes the right-hand side of the ODE equation, which is of the form $y' = f(t,y)$. If you created `sol` using `ode15i`, the function `odefun` computes the left-hand side of the ODE equation, which is of the form $f(t,y,y') = 0$.

"Parameterizing Functions" explains how to provide additional parameters to the function `odefun`, if necessary.

`odextend` extends the solution by integrating `odefun` from the upper bound for the independent variable in `sol` to `tfinal`, using the same ODE solver that created `sol`. By default, `odextend` uses

- The initial conditions `y = sol.y(:,end)` for the subsequent integration
- The same integration properties and additional input arguments the ODE solver originally used to compute `sol`. This information is stored as part of the solution structure `sol` and is subsequently passed to `solext`. Unless you want to change these values, you do not need to pass them to `odextend`.

`solext = odextend(sol,[],tfinal)` uses the same ODE function that the ODE solver uses to compute `sol` to extend the solution. It is not necessary to pass in `odefun` explicitly unless it differs from the original ODE function.

`solext = odextend(sol, odefun, tfinal, yinit)` uses the column vector `yinit` as new initial conditions for the subsequent integration, instead of the vector `sol.y(end)`.

Note `solext = odextend(sol, odefun, tfinal, [yinit, ypinit])` extends solutions obtained with `ode15i` by using the column vector `ypinit` to specify the initial derivative of the solution.

`solext = odextend(sol, odefun, tfinal, yinit, options)` uses the integration properties specified in `options` instead of the options the ODE solver originally used to compute `sol`. The new options are then stored within the structure `solext`. See `odeset` for details on setting `options` properties. Set `yinit = []` as a placeholder to specify the default initial conditions.

Examples

The following command

```
sol=ode45(@vdp1,[0 10],[2 0]);
```

uses `ode45` to solve the system `y' = vdp1(t,y)`, where `vdp1` is an example of an ODE function provided with MATLAB software, on the interval `[0 10]`. Then, the commands

```
sol=odextend(sol,@vdp1,20);
plot(sol.x,sol.y(1,:));
```

extend the solution to the interval `[0 20]` and plot the first component of the solution on `[0 20]`.

Introduced before R2006a

onCleanup

Cleanup tasks upon function completion

Syntax

```
cleanupObj = onCleanup(cleanupFun)
```

Description

`cleanupObj = onCleanup(cleanupFun)` creates an object that, when destroyed, executes the function cleanupFun. MATLAB implicitly clears all local variables at the termination of a function, whether by normal completion, or a forced exit, such as an error, or **Ctrl+C**.

If you reference or pass `cleanupObj` outside your function, then cleanupFun does not run when that function terminates. Instead, it runs whenever MATLAB destroys the object.

Examples

Close a Figure After Executing Function

Save the following code in `action.m` and type `action` in the Command Window.

```
function [] = action()
f = figure;
finishup = onCleanup(@() myCleanupFun(f));
disp('Display Figure')
end

function myCleanupFun(f)
close(f)
disp('Close Figure')
end
```

```
Display Figure
```

```
Close Figure
```

Switch Directories After Executing Function

Pass your own script to the `onCleanup` object so that it executes when MATLAB destroys the cleanup object.

Save the following code in `cleanup.m`.

```
cd(tempdir)
disp('You are now in the temporary folder')
```

Save the following code in `youraction.m` and type `youraction` in the Command Window.

```
function [] = youraction
 changeup = onCleanup(@cleanup);
 disp('Execute Code')
end
```

```
Execute Code
You are now in the temporary folder
```

Input Arguments

`cleanupFun` — Clean-up task

function handle

Clean-up task, specified as a handle to a function.

You can declare any number of `onCleanup` objects in a program file. However, if the clean-up tasks depend on the order of execution, then you should define only one object that calls a script or function, containing the relevant clean-up commands.

You should use an anonymous function handle to call your clean-up task. This allows you to pass arguments to your clean-up function.

Example: `@() fclose('file.m')`

Example: `@() user_script`

Example: `@() function(input)`

Data Types: `function_handle`

More About

Tips

- Avoid using nested functions during cleanup. MATLAB can clear variables used in nested functions before the clean-up function tries to read from them.
- If your program contains multiple cleanup objects, MATLAB does not guarantee the order that it destroys these objects.
- If the order of your cleanup functions matters, define one `onCleanup` object for all the tasks.

- "Clean Up When Functions Complete"
- "Object Lifecycle"
- "Function Handles"
- "What Are Anonymous Functions?"

`clear` | `clearvars` | `function_handle`

ones

Create array of all ones

Syntax

```
X = ones
X = ones(n)
X = ones(sz1,...,szN)
X = ones(sz)

X = ones(classname)
X = ones(n,classname)
X = ones(sz1,...,szN,classname)
X = ones(sz,classname)

X = ones('like',p)
X = ones(n,'like',p)
X = ones(sz1,...,szN,'like',p)
X = ones(sz,'like',p)
```

Description

`X = ones` returns the scalar `1`.

`X = ones(n)` returns an `n`-by-`n` matrix of ones.

`X = ones(sz1,...,szN)` returns an `sz1`-by-...-by-`szN` array of ones where `sz1,...,szN` indicates the size of each dimension. For example, `ones(2,3)` returns a 2-by-3 array of ones.

`X = ones(sz)` returns an array of ones where the size vector, `sz`, defines `size(X)`. For example, `ones([2,3])` returns a 2-by-3 array of ones.

`X = ones(classname)` returns a scalar `1` where the string, `classname`, specifies the data type. For example, `ones('int8')` returns a scalar, 8-bit integer `1`.

`X = ones(n,classname)` returns an `n`-by-`n` array of ones of data type `classname`.

`X = ones(sz1,...,szN,classname)` returns an `sz1`-by-...-by-`szN` array of ones of data type `classname`.

`X = ones(sz,classname)` returns an array of ones where the size vector, `sz`, defines `size(X)` and `classname` defines `class(X)`.

`X = ones('like',p)` returns a scalar `1` with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = ones(n,'like',p)` returns an `n`-by-`n` array of ones like `p`.

`X = ones(sz1,...,szN,'like',p)` returns an `sz1`-by-...-by-`szN` array of ones like `p`.

`X = ones(sz,'like',p)` returns an array of ones like `p` where the size vector, `sz`, defines `size(X)`.

Examples

Square Array of Ones

Create a 4-by-4 array of ones.

```
X = ones(4)
```

```
X =

     1     1     1     1
     1     1     1     1
     1     1     1     1
     1     1     1     1
```

3-D Array of Ones

Create a 2-by-3-by-4 array of ones.

```
X = ones(2,3,4);
```

```
size(X)
```

```
ans =
```

```
     2     3     4
```

Size Defined by Existing Array

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)
```

```
sz =

     3     2
```

Create an array of ones that is the same size as A

```
X = ones(sz)
```

```
X =

     1     1
     1     1
     1     1
```

Nondefault Numeric Data Type

Create a 1-by-3 vector of ones whose elements are 16-bit unsigned integers.

```
X = ones(1,3,'uint16'),
class(X)
```

```
X =

      1      1      1

ans =

uint16
```

Complex One

Create a scalar 1 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar 1 that is complex like p.

```
X = ones('like',p)
```

```
X =

   1.0000 + 0.0000i
```

Size and Numeric Data Type of Defined by Existing Array

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of ones that is the same size and data type as p.

```
X = ones(size(p),'like',p),
class(X)
```

```
X =

     1     1     1
     1     1     1

ans =

uint8
```

Input Arguments

n — Size of square matrix

integer value

Size of square matrix, specified as an integer value, defines the output as a square, n-by-n matrix of ones.

- If n is 0, then X is an empty matrix.
- If n is negative, then it is treated as 0.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz1,...,szN` — Size of each dimension

two or more integer values

Size of each dimension, specified as two or more integer values, defines `X` as a sz1-by...-by-szN array.

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- If any trailing dimensions greater than `2` have a size of `1`, then the output, `X`, does not include those dimensions.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Output size

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- If any trailing dimensions greater than `2` have a size of `1`, then the output, `X`, does not include those dimensions.

Example: `sz = [2,3,4]` defines `X` as a 2-by-3-by-4 array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`classname` — Output class

`'double'` (default) | `'single'` | `'int8'` | `'uint8'` | ...

Output class, specified as `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

Data Types: `char`

`p` — Prototype

numeric variable

Prototype, specified as a numeric variable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`complex` | `eye` | `false` | `rand` | `randn` | `size` | `zeros`

Introduced before R2006a

open

Open file in appropriate application

Syntax

```
open(name)
output = open(name)
```

Description

`open(name)` opens the specified file or variable in the appropriate application.

`output = open(name)` returns an empty `output` (`[]`) for most cases. If opening a MAT-file, `output` is a structure that contains the variables in the file. If opening a figure, `output` is a handle to that figure.

Input Arguments

`name`

Name of file or variable to open. If `name` does not include an extension, the `open` function:

1. Searches for a variable named `name`. If the variable exists, `open` opens it in the Variables editor.
2. Searches the MATLAB path for `name.mdl`, `name.slx`, or `name.m`. If `name.mdl` or `name.slx` exists, then `open` opens the model in Simulink. If only `name.m` exists, `open` opens the file in the MATLAB Editor.

If more than one file named `name` exists on the MATLAB path, the `open` function opens the file returned by `which(name)`.

The `open` function performs the following actions based on the file extension:

`.m`	Open in MATLAB Editor.

`.mat`	Return variables in structure *`st`* when called with the syntax: `st = open(name)`
`.fig`	Open figure in Handle Graphics.
`.mdl` or `.slx`	Open model in Simulink.
`.prj`	Open project in the MATLAB Compiler Deployment Tool.
`.doc*`	Open document in Microsoft Word.
`.exe`	Run executable file (only on Windows systems).
`.pdf`	Open document in Adobe® Acrobat®.
`.ppt*`	Open document in Microsoft PowerPoint.
`.xls*`	Start MATLAB Import Wizard.
`.htm` or `.html`	Open document in MATLAB browser.
`.url`	Open file in your default Web browser.

Examples

Open `Contents.m` in the MATLAB Editor by typing:

```
open Contents.m
```

Generally, MATLAB opens *`matlabroot`*`\toolbox\matlab\general\Contents.m`. However, if you have a file called `Contents.m` in a directory that is before `toolbox\matlab\general` on the MATLAB path, then `open` opens that file instead.

Open a file not on the MATLAB path by including the complete file specification:

```
open('D:\temp\data.mat')
```

If the file does not exist, MATLAB displays an error message.

Create a function called `opentxt` to handle files with extension `.txt`:

```
function opentxt(filename)

   fprintf('You have requested file: %s\n', filename);

   wh = which(filename);
```

```
    if exist(filename, 'file') == 2
      fprintf('Opening in MATLAB Editor: %s\n', filename);
      edit(filename);
    elseif ~isempty(wh)
      fprintf('Opening in MATLAB Editor: %s\n', wh);
      edit(wh);
    else
      warning('MATLAB:fileNotFound', ...
              'File was not found: %s', filename);
    end

end
```

Open the file `ngc6543a.txt` (a description of `ngc6543a.jpg`, located in *`matlabroot`*`\toolbox\matlab\demos`):

```
photo_text = 'ngc6543a.txt';
open(photo_text)
```

`open` calls your function with the following syntax:

```
opentxt(photo_text)
```

More About

Tips

The `open` function opens files based on their extension. You can extend the functionality of `open` by defining your own file handling function of the form `open`*`xxx`*, where *`xxx`* is a file extension. For example, if you create a function `openlog`, the `open` function calls `openlog` to process any files with the `.log` extension. The `open` function returns any single *`output`* defined by your function.

Introduced before R2006a

open

Class: VideoWriter

Open file for writing video data

Syntax

```
open(writerObj)
```

Description

`open(writerObj)` opens the file associated with writerObj for writing. When you open the file, all properties of the object become read only. `open` discards any existing contents of the file.

Input Arguments

`writerObj`

`VideoWriter` object created by the `VideoWriter` function.

Examples

Open a new AVI file:

```
myObj = VideoWriter('newfile.avi');
open(myObj);
```

See Also

`close` | `writeVideo` | `VideoWriter`

openfig

Open figure saved in FIG-file

Syntax

```
openfig(filename)
openfig(filename,copies)
openfig(___,visibility)

fig = openfig(___)
```

Description

`openfig(filename)` opens the figure saved in the MATLAB figure file (FIG-file) called `filename`.

`openfig(filename,copies)` specifies whether to open a new copy of the figure in the case that a copy is already open. If you do not want to create a new copy, set `copies` to `'reuse'`. The `'reuse'` option brings the existing figure to the front of the screen. To open a new copy of the figure regardless of whether a copy is already open, set `copies` to `'new'` . The `'new'` option is the default behavior.

`openfig(___,visibility)` specifies whether to open the figure in a visible or invisible state. To display the figure, set `visibility` to `'visible'`. If you do not want to display the figure, use the `'invisible'` setting. You can use this option with any of the input argument combinations in the previous syntaxes.

`fig = openfig(___)` returns the figure object. Set properties of the figure object to modify its appearance or behavior. For a list of properties, see Figure Properties.

Examples

Open Figure Saved in MATLAB Figure File

Create a surface plot and save the figure as a MATLAB figure file. Then, close the figure.

```
surf(peaks)
savefig('MySavedPlot.fig')
close(gcf)
```

Open the saved figure.

```
openfig('MySavedPlot.fig')
```

Open Invisible Figure in Visible State

Create a surface plot and make the figure invisible. Then, save the figure as a MATLAB figure file. Close the invisible figure.

```
surf(peaks)
set(gcf,'Visible','off')
savefig('MySavedPlot.fig')
close(gcf)
```

Open the saved figure and make it visible on the screen.

```
openfig('MySavedPlot.fig','visible')
```

Input Arguments

`filename` — File name of saved figure

string

File name of saved figure, specified as a string. You do not have to specify the full file path, as long as it is on your MATLAB path. Including `.fig` in the file name is optional.

Example: `openfig('MySavedFigure.fig')`

`copies` — Control for opening multiple copies of figure

`'new'` (default) | `'reuse'`

Control for opening multiple copies of the figure, specified as one of these values:

- `'new'` — Open a new copy of the figure, even if a copy already exists on the screen.
- `'reuse'` — Open a new copy of the figure only if one does not exist. If a copy exists, then bring the existing copy to the front of the screen. If the figure is off the screen, then `'reuse'` repositions the figure so that it is completely on the screen. This option helps provide compatibility with different screen sizes and resolutions by ensuring that the figure displays on screen.

Example: `openfig('MySavedFigure.fig','reuse')`

`visibility` — Figure visibility
`'visible' | 'invisible'`

Figure visibility, specified as one of these values:

- `'visible'` — Open the saved figure in a visible state. If the MATLAB figure file contains an invisible figure, then you can use this option to make the figure visible when it opens.
- `'invisible'` — Open the saved figure in an invisible state.

Example: `openfig('MySavedFigure.fig','invisible')`

Output Arguments

`fig` — Figure object
figure object

Figure object. Set properties of the figure to change the appearance or behavior of the opened figure. For a list of properties, see Figure Properties.

Limitations

- Do not use `openfig` to open FIG-files created with GUIDE. Use the `guide` function instead.

`open` | `saveas` | `savefig`

Introduced before R2006a

opengl

Control OpenGL rendering

Compatibility

The `autoselect`, `neverselect`, `advise`, `quiet`, `verbose`, and `DriverBugWorkaround` inputs have been removed in R2014b. For more information about the behavior of these syntaxes in previous releases, see opengl for R2014a.

Syntax

```
opengl info
d = opengl('data')

opengl software
opengl hardware

opengl('save','software')
opengl('save','hardware')
opengl('save','none')
```

Description

`opengl info` prints information about the OpenGL library on your system, such as the version, vendor, and graphics features that it supports. The returned fields might change in future releases as graphics features change. Using this command loads the OpenGL library.

`d = opengl('data')` returns the same data provided with `opengl info`, but stores it in a structure.

`opengl software` uses the software version of OpenGL built into MATLAB to render subsequent graphics. This command works only on Windows systems. To use software OpenGL on Linux systems, start MATLAB with the `-softwareopengl` flag. Macintosh systems do not support software OpenGL.

`opengl hardware` uses the version of OpenGL on your operating system to render subsequent graphics. Use this option if you have graphics hardware that supports hardware-accelerated OpenGL. This command works only on Windows systems. To use hardware OpenGL on Linux systems, start MATLAB with the `-nosoftwareopengl` flag.

`opengl('save','software')` sets your preferences so that future sessions of MATLAB on this computer use software OpenGL. This command does not affect the current session.

`opengl('save','hardware')` sets your preferences to the version of OpenGL on your operating system. This command does not affect the current session.

`opengl('save','none')` resets your preferences to the default values. This command does not affect the current session.

Examples

Display Information About OpenGL

Display information about the OpenGL library on your system, such as the vendor, the version, and the MATLAB graphics features that it supports. Also display whether MATLAB is using a hardware-accelerated implementation or a software implementation of OpenGL.

```
opengl info
```

```
                         Version: '3.3.0'
                          Vendor: 'NVIDIA Corporation'
                        Renderer: 'Quadro 400/PCIe/SSE2'
                  MaxTextureSize: 8192
                          Visual: 'Visual 0x07, (RGBA 32 bits (8 8 8 8), ...'
                        Software: 'false'
      SupportsGraphicsSmoothing: 1
  SupportsDepthPeelTransparency: 1
     SupportsAlignVertexCenters: 1
                     Extensions: {251x1 cell}
             MaxFrameBufferSize: 8192
```

Determine Graphics Hardware

Determine your graphics hardware by checking the `Vendor` and `Renderer` fields returned by the `opengl info` command.

```
opengl info
```

```
                          Version: '3.3.0'
                          Vendor: 'NVIDIA Corporation'
                        Renderer: 'Quadro 400/PCI/SSE2'
                 MaxTextureSize: 8192
                          Visual: 'Visual 0x07, (RGBA 32 bits (8 8 8 8), Z depth 24 b
                        Software: 'false'
       SupportsGraphicsSmoothing: 1
   SupportsDepthPeelTransparency: 1
      SupportsAlignVertexCenters: 1
                     Extensions: {235x1 cell}
             MaxFrameBufferSize: 8192
```

If you are using software OpenGL, then the name listed in the `Vendor` field is not your graphics hardware vendor. The line `Software: 'true'` indicates that you are using software OpenGL.

If you are using software OpenGL on Windows systems, determine your graphics hardware by closing all figures, switching to hardware OpenGL, and reissuing the `opengl info` command. Then, switch back to software OpenGL.

```
close all
opengl hardware
opengl info
opengl software
```

If you are using software OpenGL on Linux systems, determine your graphics hardware by starting MATLAB with the `-nosoftwareopengl` flag. Then, issue the `opengl info` command.

Mac OS X systems do not support software OpenGL, so the `Vendor` field always lists the name of your graphics hardware vendor.

Use Software OpenGL for Current Session

Switch to using software OpenGL to render graphics in the current session.

```
opengl software
```

This command works only on Windows systems.

Use Software OpenGL for Future Sessions

Set your preferences so that MATLAB uses software OpenGL to render graphics in all future sessions. This command does not affect the current session.

```
opengl('save','software')
```

More About

Tips

- By default, MATLAB uses your graphics hardware if it supports hardware-accelerated OpenGL. If it is not available or if you are using a virtual machine, a Linux VNC, or an unsupported graphics driver, then MATLAB uses software OpenGL instead. For more information on graphics renderers, see the figure `Renderer` property.
- For the best results with graphics, upgrade your graphics drivers to the latest version available. For more information, see "System Requirements for Graphics".

- "System Requirements for Graphics"
- "Resolving Low-Level Graphics Issues"

`matlablinux` | `matlabmac` | `matlabwindows`

Introduced before R2006a

openvar

Open workspace variable in Variables editor or other graphical editing tool

Syntax

```
openvar(varname)
```

Description

`openvar(varname)` opens the workspace variable named by the string, `varname`, in the Variables editor for graphical editing. Changes that you make to variables in the Variables editor occur in the workspace as soon as you enter them.

In some toolboxes, `openvar` opens a tool appropriate for viewing or editing objects indicated by `varname` instead of opening the Variables editor.

MATLAB does not impose any limitation on the size of a variable that you can open in the Variables editor. However, your operating system or the amount of physical memory installed on your computer can impose such limits.

Examples

Identify Outliers in a Linked Graph

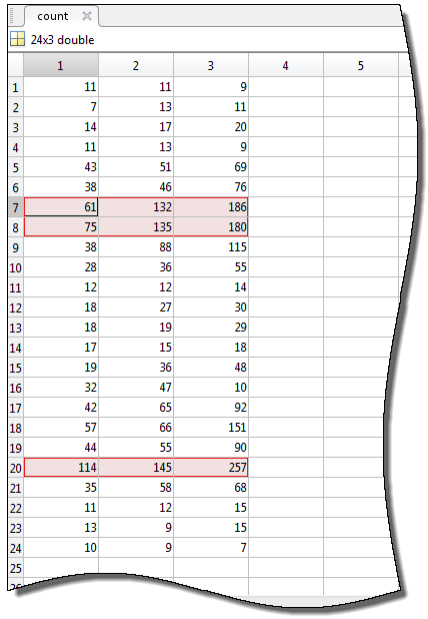
Use data brushing to identify observations in a vector or matrix that might warrant further analysis.

Make a scatter plot of data in the sample MAT-file `count.dat`, and open the variable `count` in the Variables editor.

```
load count.dat
scatter(count(:,1),count(:,2))
openvar('count')
```

Right-click a cell in the Variables editor and select **Brushing** > **Brushing On**. This turns on data brushing in the Variables editor.

Select the rows 7, 8, and 20. (Select noncontiguous rows by holding down the **Ctrl** key and clicking in each row.)



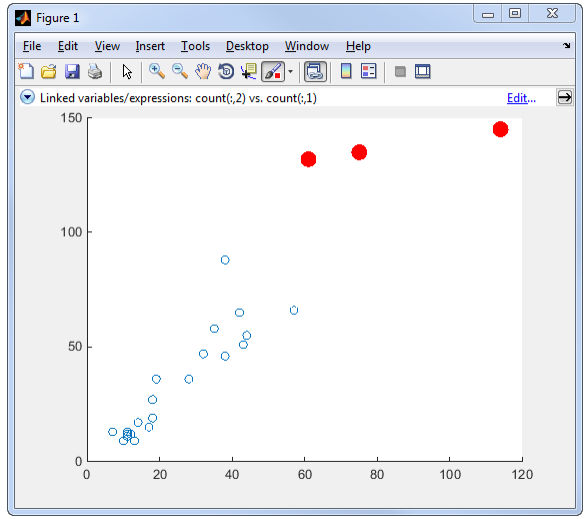
count

24x3 double

	1	2	3	4	5
1	11	11	9		
2	7	13	11		
3	14	17	20		
4	11	13	9		
5	43	51	69		
6	38	46	76		
7	61	132	186		
8	75	135	180		
9	38	88	115		
10	28	36	55		
11	12	12	14		
12	18	27	30		
13	18	19	29		
14	17	15	18		
15	19	36	48		
16	32	47	10		
17	42	65	92		
18	57	66	151		
19	44	55	90		
20	114	145	257		
21	35	58	68		
22	11	12	15		
23	13	9	15		
24	10	9	7		
25					

In the Figure window with the scatter plot, click **Brush/Select Data**  to enable data brushing, and **Link Plot**  to enable data linking.

The data observations you brushed in the Variables editor appear highlighted in the scatter plot.



As long as data linking is enabled in the figure, observations that you brush in the scatter plot are highlighted in the Variables editor. When a figure is not linked to its data sources, you can still brush its graphs and you can brush the same data in the Variables editor, but only the display that you brush responds by highlighting.

Input Arguments

`varname` — Variable name

string

Variable name, specified as a string. The named variable can be an array, character string, cell array, structure, or an object and its properties. If the named variable is a multidimensional array, then you can only view the array in the Variables editor, and not edit it.

Example: `'myVariable'`

Example: `'A'`

More About

Tips

- As an alternative to the `openvar` function, double-click a variable in the Workspace browser.

- "View, Edit, and Copy Variables"
- "Making Graphs Responsive with Data Linking"

Introduced before R2006a

optimget

Optimization options values

Syntax

```
val = optimget(options,'param')
val = optimget(options,'param',default)
```

Description

`val = optimget(options,'param')` returns the value of the specified parameter in the optimization options structure `options`. You need to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`val = optimget(options,'param',default)` returns `default` if the specified parameter is not defined in the optimization options structure `options`. Note that this form of the function is used primarily by other optimization functions.

Examples

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options`.

```
val = optimget(my_options,'Display')
```

This statement returns the value of the `Display` optimization options parameter in the structure called `my_options` (as in the previous example) except that if the `Display` parameter is not defined, it returns the value `'final'`.

```
optnew = optimget(my_options,'Display','final');
```

See Also

`optimset` | `fminbnd` | `fminsearch` | `fzero` | `lsqnonneg`

Introduced before R2006a

optimset

Create or edit optimization options structure

Syntax

```
options = optimset('param1',value1,'param2',value2,...)
optimset
options = optimset
options = optimset(optimfun)
options = optimset(oldopts,'param1',value1,...)
options = optimset(oldopts,newopts)
```

Description

The function `optimset` creates an `options` structure that you can pass as an input argument to the following four MATLAB optimization functions:

- `fminbnd`
- `fminsearch`
- `fzero`
- `lsqnonneg`

You can use the `options` structure to change the default parameters for these functions.

Note If you have an Optimization Toolbox license, you can also use `optimset` to create an expanded `options` structure containing additional options specifically designed for the functions provided in that toolbox. For more information about these additional options, see the reference page for the enhanced Optimization Toolbox `optimset` function.

`options = optimset('param1',value1,'param2',value2,...)` creates an optimization options structure called `options`, in which the specified parameters (`param`) have specified values. Any unspecified parameters are set to `[]` (parameters with value `[]` indicate to use the default value for that parameter when `options`

is passed to the optimization function). It is sufficient to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.

`optimset` with no input or output arguments displays a complete list of parameters with their valid values.

`options = optimset` (with no input arguments) creates an options structure `options` where all fields are set to `[]`.

`options = optimset(optimfun)` creates an options structure `options` with all parameter names and default values relevant to the optimization function `optimfun`.

`options = optimset(oldopts,'param1',value1,...)` creates a copy of `oldopts`, modifying the specified parameters with the specified values.

`options = optimset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any parameters in `newopts` with nonempty values overwrite the corresponding old parameters in `oldopts`.

Options

The following table lists the available options for the MATLAB optimization functions.

Option	Value	Description	Solvers
`Display`	`'off'` | `'iter'` | {`'final'`} | `'notify'`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration (not available for `lsqnonneg`); `'final'` displays just the final output; `'notify'` displays output only if the function does not converge.	`fminbnd`, `fminsearch`,`fzero`, `lsqnonneg`
`FunValChec`	{`'off'`} | `'on'`	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex` or `NaN`. `'off'` displays no error.	`fminbnd`, `fminsearch`,`fzero`

Option	Value	Description	Solvers
`MaxFunEval`	positive integer	Maximum number of function evaluations allowed.	`fminbnd`, `fminsearch`
`MaxIter`	positive integer	Maximum number of iterations allowed.	`fminbnd`, `fminsearch`
`OutputFcn`	function | {[ ]}	User-defined function that an optimization function calls at each iteration. See “Output Functions”.	`fminbnd`, `fminsearch`,`fzero`
`PlotFcns`	function | {[ ]}	User-defined or built-in plot function that an optimization function calls at each iteration. Built-in functions: • `@optimplotx` plots the current point • `@optimplotfval` plots the function value • `@optimplotfunccount` plots the function count (not available for `fzero`) See “Plot Functions”.	`fminbnd`, `fminsearch`,`fzero`
`TolFun`	positive scalar	Termination tolerance on the function value. See “Tolerances and Stopping Criteria”.	`fminsearch`
`TolX`	positive scalar	Termination tolerance on *x*, the current point. See “Tolerances and Stopping Criteria”.	`fminbnd`, `fminsearch`,`fzero`, `lsqnonneg`

Examples

This statement creates an optimization options structure called `options` in which the `Display` parameter is set to `'iter'` and the `TolFun` parameter is set to `1e-8`.

```
options = optimset('Display','iter','TolFun',1e-8)
```

This statement makes a copy of the options structure called `options`, changing the value of the `TolX` parameter and storing new values in `optnew`.

```
optnew = optimset(options,'TolX',1e-4);
```

This statement returns an optimization options structure that contains all the parameter names and default values relevant to the function `fminbnd`.

```
optimset('fminbnd')
```

`optimset` | `optimget` | `fminbnd` | `fminsearch` | `fzero` | `lsqnonneg`

Introduced before R2006a

or, |

Find logical OR

Syntax

```
A | B | ...
or(A, B)
```

Description

`A | B | ...` performs a logical OR of all input arrays `A`, `B`, etc., and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if any input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input `A` is a 3-by-5 matrix and input `B` is the number 1, then `B` is treated as if it were a 3-by-5 matrix of ones.

`or(A, B)` is called for the syntax `A | B` when either `A` or `B` is an object.

Note The symbols | and || perform different operations in a MATLAB application. The element-wise OR operator described here is |. The short-circuit OR operator is ||.

Examples

If matrix `A` is

```
    0.4235    0.5798         0    0.7942         0
    0.5155         0         0         0    0.8744
```

```
         0         0         0    0.4451    0.0150
    0.4329    0.6405    0.6808         0         0
```

and matrix `B` is

```
     0     1     0     1     0
     1     1     0     0     1
     0     0     0     1     0
     0     1     0     0     1
```

then

```
A | B
ans =
     1     1     0     1     0
     1     1     0     0     1
     0     0     0     1     1
     1     1     1     0     1
```

ordeig

Eigenvalues of quasitriangular matrices

Syntax

```
E = ordeig(T)
E = ordeig(AA,BB)
```

Description

`E = ordeig(T)` takes a quasitriangular Schur matrix `T`, typically produced by `schur`, and returns the vector `E` of eigenvalues in their order of appearance down the diagonal of T.

`E = ordeig(AA,BB)` takes a quasitriangular matrix pair `AA` and `BB`, typically produced by `qz`, and returns the generalized eigenvalues in their order of appearance down the diagonal of `AA-λ*BB`.

`ordeig` is an order-preserving version of `eig` for use with `ordschur` and `ordqz`. It is also faster than `eig` for quasitriangular matrices.

Examples

Example 1

```
T=diag([1 -1 3 -5 2]);
```

`ordeig(T)` returns the eigenvalues of `T` in the same order they appear on the diagonal.

```
ordeig(T)

ans =

     1
    -1
     3
```

```
    -5
     2
```

`eig(T)`, on the other hand, returns the eigenvalues in order of increasing magnitude.

```
eig(T)

ans =

    -5
    -1

Introduced before R2006a

orderfields

Order fields of structure array

Syntax

```
s = orderfields(s1)
s = orderfields(s1, s2)
s = orderfields(s1, c)
s = orderfields(s1, perm)
[s, perm] = orderfields(...)
```

Description

`s = orderfields(s1)` orders the fields in `s1` so that the new structure array `s` has field names in ASCII dictionary order.

`s = orderfields(s1, s2)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in `s2`. Structures `sl` and `s2` must have the same fields.

`s = orderfields(s1, c)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in the cell array of field name strings `c`. Structure `s1` and cell array `c` must contain the same field names.

`s = orderfields(s1, perm)` orders the fields in `s1` so that the new structure array `s` has fieldnames in the order specified by the indices in permutation vector `perm`.

If `s1` has `N` fieldnames, the elements of `perm` must be an arrangement of the numbers from `1` to `N`. This is particularly useful if you have more than one structure array that you would like to reorder in the same way.

`[s, perm] = orderfields(...)` returns a permutation vector representing the change in order performed on the fields of the structure array that results in `s`.

Examples

Create a structure `s`. Then create a new structure from `s`, but with the fields ordered alphabetically:

```
s = struct('b', 2, 'c', 3, 'a', 1)
s =
    b: 2
    c: 3
    a: 1

snew = orderfields(s)
snew =
    a: 1
    b: 2
    c: 3
```

Arrange the fields of `s` in the order specified by the second (cell array) argument of `orderfields`. Return the new structure in `snew` and the permutation vector used to create it in `perm`:

```
[snew, perm] = orderfields(s, {'b', 'a', 'c'})
snew =
    b: 2
    a: 1
    c: 3
perm =
     1
     3
     2
```

Now create a new structure, `s2`, having the same fieldnames as `s`. Reorder the fields using the permutation vector returned in the previous operation:

```
s2 = struct('b', 3, 'c', 7, 'a', 4)
s2 =
    b: 3
    c: 7
    a: 4

snew = orderfields(s2, perm)
snew =
    b: 3
    a: 4
```

```
    c: 7
```

More About

Tips

`orderfields` only orders top-level fields. It is not recursive.

ordqz

Reorder eigenvalues in QZ factorization

Syntax

```
[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)
[...] = ordqz(AA,BB,Q,Z,keyword)
[...] = ordqz(AA,BB,Q,Z,clusters)
```

Description

`[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)` reorders the QZ factorizations `Q*A*Z = AA` and `Q*B*Z = BB` produced by the `qz` function for a matrix pair `(A,B)`. It returns the reordered pair `(AAS,BBS)` and the cumulative orthogonal transformations `QS` and `ZS` such that `QS*A*ZS = AAS` and `QS*B*ZS = BBS`. In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular pair `(AAS,BBS)`, and the corresponding invariant subspace is spanned by the leading columns of `ZS`. The logical vector `select` specifies the selected cluster as `E(select)` where `E` is the vector of eigenvalues as they appear along the diagonal of `AA-λ*BB`.

Note To extract `E` from `AA` and `BB`, use `ordeig(BB)`, instead of `eig`. This ensures that the eigenvalues in `E` occur in the same order as they appear on the diagonal of `AA-λ*BB`.

`[...] = ordqz(AA,BB,Q,Z,keyword)` sets the selected cluster to include all eigenvalues in the region specified by `keyword`:

keyword	Selected Region
`'lhp'`	Left-half plane (`real(E) < 0`)
`'rhp'`	Right-half plane (`real(E) > 0`)
`'udi'`	Interior of unit disk (`abs(E) < 1`)
`'udo'`	Exterior of unit disk (`abs(E) > 1`)

`[...] = ordqz(AA,BB,Q,Z,clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices commensurate with `E = ordeig(AA,BB)`, such that all eigenvalues with the same `clusters` value form one cluster, `ordqz` sorts the specified clusters in descending order along the diagonal of `(AAS,BBS)`. The cluster with highest index appears in the upper left corner.

Introduced before R2006a

ordschur

Reorder eigenvalues in Schur factorization

Syntax

```
[US,TS] = ordschur(U,T,select)
[US,TS] = ordschur(U,T,keyword)
[US,TS] = ordschur(U,T,clusters)
```

Description

`[US,TS] = ordschur(U,T,select)` reorders the Schur factorization `X = U*T*U'` produced by the `schur` function and returns the reordered Schur matrix `TS` and the cumulative orthogonal transformation `US` such that `X = US*TS*US'`. In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular Schur matrix `TS`, and the corresponding invariant subspace is spanned by the leading columns of `US`. The logical vector `select` specifies the selected cluster as `E(select)` where `E` is the vector of eigenvalues as they appear along `T`'s diagonal.

Note To extract `E` from `T`, use `E = ordeig(T)`, instead of `eig`. This ensures that the eigenvalues in `E` occur in the same order as they appear on the diagonal of `TS`.

`[US,TS] = ordschur(U,T,keyword)` sets the selected cluster to include all eigenvalues in one of the following regions:

keyword	Selected Region
`'lhp'`	Left-half plane (`real(E) < 0`)
`'rhp'`	Right-half plane (`real(E) > 0`)
`'udi'`	Interior of unit disk (`abs(E) < 1`)
`'udo'`	Exterior of unit disk (`abs(E) > 1`)

`[US,TS] = ordschur(U,T,clusters)` reorders multiple clusters at once. Given a vector `clusters` of cluster indices, commensurate with `E = ordeig(T)`, and such that all eigenvalues with the same `clusters` value form one cluster, `ordschur` sorts the specified clusters in descending order along the diagonal of `TS`, the cluster with highest index appearing in the upper left corner.

orient

Hardcopy paper orientation

Alternatives

Use **File —> Print Preview** on the figure window menu to directly manipulate print layout, paper size, headers, fonts and other properties when printing figures. For details, see “Print Figure from File Menu” in the MATLAB Graphics documentation.

Syntax

```
orient
orient landscape
orient portrait
orient tall
orient(fig_handle)
orient(simulink_model)
orient(fig_handle,orientation)
orient(simulink_model,orientation)
```

Description

`orient` returns a string with the current paper orientation: `portrait`, `landscape`, or `tall`.

`orient landscape` sets the paper orientation of the current figure to full-page landscape, orienting the longest page dimension horizontally. The figure is centered on the page and scaled to fit the page with a 0.25 inch border.

`orient portrait` sets the paper orientation of the current figure to portrait, orienting the longest page dimension vertically. The `portrait` option returns the page orientation to the MATLAB default. (Note that the result of using the `portrait` option is affected by changes you make to figure properties. See the "Algorithm" section for more specific information.)

`orient tall` maps the current figure to the entire page in portrait orientation, leaving a 0.25 inch border.

`orient(fig_handle)` returns the current orientation of the specified figure.

`orient(simulink_model)` returns the current orientation of the Simulink model.

`orient(fig_handle,`*`orientation`*`)` sets the orientation for the specified figure to the specified orientation (`landscape`, `portrait`, or `tall`).

`orient(simulink_model,`*`orientation`*`)` sets the orientation for the Simulink model.

More About

Algorithms

`orient` sets the `PaperOrientation`, `PaperPosition`, and `PaperUnits` properties of the current figure. Subsequent print operations use these properties. The result of using the `portrait` option can be affected by default property values as follows:

- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the current values of `PaperOrientation` and `PaperPosition` to place the figure on the page.
- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the default figure `PaperPosition` with the x, y and width, height values reversed (i.e., [y,x,height,width]) to position the figure on the page.
- If the current figure `PaperType` is different from the default figure `PaperType`, then the `orient portrait` command uses the current figure `PaperPosition` with the x, y and width, height values reversed (i.e., [y,x,height,width]) to position the figure on the page.

Introduced before R2006a

orth

Orthonormal basis for range of matrix

Syntax

```
Q = orth(A)
```

Description

`Q = orth(A)` returns an orthonormal basis for the range of `A`. The columns of `Q` are vectors, which span the range of `A`. The number of columns in `Q` is equal to the rank of `A`.

Examples

Basis for Full Rank Matrix

Calculate and verify the orthonormal basis vectors for the range of a full rank matrix.

Define a matrix and find the rank.

```
A = [1 0 1;-1 -2 0; 0 1 -1];
r = rank(A)
```

```
r =

     3
```

Since `A` is a square matrix of full rank, the orthonormal basis calculated by `orth(A)` matches the matrix `U` calculated in the singular value decomposition, `[U,S] = svd(A,'econ')`. This is because the singular values of `A` are all nonzero.

Calculate the orthonormal basis for the range of `A` using `orth`.

```
Q = orth(A)
```

```
Q =
```

```
   -0.1200   -0.8097    0.5744
    0.9018    0.1531    0.4042
   -0.4153    0.5665    0.7118
```

The number of columns in `Q` is equal to `rank(A)`. Since `A` is of full rank, `Q` and `A` are the same size.

Verify that the basis, `Q`, is orthogonal and normalized within a reasonable error range.

```
E = norm(eye(r)-Q'*Q,'fro')
```

```
E =

   9.6228e-16
```

The error is on the order of `eps`.

Basis for Rank Deficient Matrix

Calculate and verify the orthonormal basis vectors for the range of a rank deficient matrix.

Define a singular matrix and find the rank.

```
A = [1 0 1; 0 1 0; 1 0 1];
r = rank(A)
```

```
r =

     2
```

Since `A` is rank deficient, the orthonormal basis calculated by `orth(A)` matches only the first `r = 2` columns of matrix `U` calculated in the singular value decomposition, `[U,S] = svd(A,'econ')`. This is because the singular values of `A` are *not* all nonzero.

Calculate the orthonormal basis for the range of `A` using `orth`.

```
Q = orth(A)
```

```
Q =

   -0.7071         0
         0    1.0000
   -0.7071         0
```

Since A is rank deficient, Q contains one fewer column than A.

Input Arguments

A — Input matrix

scalar | vector | matrix

Input matrix, specified as a scalar, vector, or matrix.

Data Types: single | double
Complex Number Support: Yes

More About

Range

The column space, or *range*, of a matrix A is the collection of all linear combinations of the columns of A. Any vector, b, that is a solution to the linear equation, A*x = b, is included in the range of A since you can also write it as a linear combination of the columns of A.

Rank

The rank of a matrix is equal to the dimension of the range.

Algorithms

orth is obtained from U in the singular value decomposition, [U,S] = svd(A,'econ'). If r = rank(A), the first r columns of U form an orthonormal basis for the range of A.

Introduced before R2006a

outerjoin

Outer join between two tables

Syntax

```
C = outerjoin(A,B)
C = outerjoin(A,B,Name,Value)
[C,ia,ib] = outerjoin(___)
```

Description

`C = outerjoin(A,B)` creates the table, `C`, as the outer join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The outer join includes the rows that match between `A` and `B`, and also unmatched rows from either `A` or `B`, all with respect to the key variables. `C` contains all variables from both `A` and `B`, including the key variables.

`C = outerjoin(A,B,Name,Value)` performs the outer-join operation with additional options specified by one or more Name,Value pair arguments.

`[C,ia,ib] = outerjoin(___)` also returns index vectors, ia and ib, indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

Examples

Outer-Join Operation of Tables with One Variable in Common

Create a table, `A`.

```
A = table([5;12;23;2;15;6],...
    {'cheerios';'pizza';'salmon';'oreos';'lobster';'pizza'},...
    'VariableNames',{'Age','FavoriteFood'},...
    'RowNames',{'Amy','Bobby','Holly','Harry','Marty','Sally'})
```

```
A =

              Age    FavoriteFood
              ___    ____________

    Amy        5     'cheerios'
    Bobby     12     'pizza'
    Holly     23     'salmon'
    Harry      2     'oreos'
    Marty     15     'lobster'
    Sally      6     'pizza'
```

Create a table, `B`, with one variable in common with `A`, called `FavoriteFood`.

```
B = table({'cheerios';'oreos';'pizza';'salmon';'cake'},...
    [110;160;140;367;243],...
    {'A-';'D';'B';'B';'C-'},...
    'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

```
B =

    FavoriteFood    Calories    NutritionGrade
    ____________    ________    ______________

    'cheerios'      110         'A-'
    'oreos'         160         'D'
    'pizza'         140         'B'
    'salmon'        367         'B'
    'cake'          243         'C-'
```

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`.

```
C = outerjoin(A,B)
```

```
C =

    Age    FavoriteFood_A    FavoriteFood_B    Calories    NutritionGrade
    ___    ______________    ______________    ________    ______________

    NaN    ''                'cake'            243         'C-'
      5    'cheerios'        'cheerios'        110         'A-'
     15    'lobster'         ''                NaN         ''
      2    'oreos'           'oreos'           160         'D'
     12    'pizza'           'pizza'           140         'B'
      6    'pizza'           'pizza'           140         'B'
```

```
    23    'salmon'          'salmon'          367          'B'
```

Table C contains a separate variable for the key variable from A, called FavoriteFood_A, and the key variable from B, called FavoriteFood_B.

Merge Key Variable Pair to Single Variable

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'}',[1 2 3 11 17]',...
    'VariableNames',{'Key1' 'Var1'})
```

```
A =

    Key1    Var1
    ____    ____

    'a'      1
    'b'      2
    'c'      3
    'e'     11
    'h'     17
```

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a','b','d','e'}',[4;5;6;7],...
    'VariableNames',{'Key1' 'Var2'})
```

```
B =

    Key1    Var2
    ____    ____

    'a'     4
    'b'     5
    'd'     6
    'e'     7
```

Use the outerjoin function to create a new table, C, with data from tables A and B. Merge the key values into a single variable in the output table, C.

```
C = outerjoin(A,B,'MergeKeys',true)
```

```
C =
```

```
    Key1    Var1    Var2
    ____    ____    ____

    'a'       1       4
    'b'       2       5
    'c'       3     NaN
    'd'     NaN       6
    'e'      11       7
    'h'      17     NaN
```

Variables in table C that came from A contain null values in the rows that have no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

Outer-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'}',[1 2 3 11 17]',...
    'VariableNames',{'Key1' 'Var1'})
```

```
A =

    Key1    Var1
    ____    ____

    'a'       1
    'b'       2
    'c'       3
    'e'      11
    'h'      17
```

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a','b','d','e'}',[4;5;6;7],...
    'VariableNames',{'Key1' 'Var2'})
```

```
B =

    Key1    Var2
    ____    ____
```

```
    'a'     4
    'b'     5
    'd'     6
    'e'     7
```

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Match up rows with common values in the key variable, `Key1`, but also retain rows whose key values don't have a match.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B)
```

```
C =

    Key1_A    Var1    Key1_B    Var2
    ______    ____    ______    ____

    'a'         1     'a'         4
    'b'         2     'b'         5
    'c'         3     ''        NaN
    ''        NaN     'd'         6
    'e'        11     'e'         7
    'h'        17     ''        NaN

ia =

     1
     2
     3
     0
     4
     5

ib =

     1
     2
     0
     3
     4
     0
```

The index vectors `ia` and `ib` contain zeros to indicate the rows in table `C` that do not correspond to rows in tables `A` or `B`, respectively.

Left Outer-Join Operation of Tables and Indices to Values

Create a table, `A`.

```
A = table({'a' 'b' 'c' 'e' 'h'}',[1 2 3 11 17]',...
    'VariableNames',{'Key1' 'Var1'})
```

```
A =

    Key1    Var1
    ____    ____

    'a'      1
    'b'      2
    'c'      3
    'e'     11
    'h'     17
```

Create a table, `B`, with common values in the variable `Key1` between tables `A` and `B`, but also containing rows with values of `Key1` not present in `A`.

```
B = table({'a','b','d','e'}',[4;5;6;7],...
    'VariableNames',{'Key1' 'Var2'})
```

```
B =

    Key1    Var2
    ____    ____

    'a'     4
    'b'     5
    'd'     6
    'e'     7
```

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Ignore rows in `B` whose key values do not match any rows in `A`.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B,'Type','left')
```

```
C =

    Key1_A    Var1    Key1_B    Var2
    ______    ____    ______    ____

    'a'        1      'a'         4
    'b'        2      'b'         5
    'c'        3      ''        NaN
    'e'       11      'e'         7
    'h'       17      ''        NaN

ia =

     1
     2
     3
     4
     5

ib =

     1
     2
     0
     4
     0
```

All values of `ia` are nonzero indicating that all rows in `C` have corresponding rows in `A`.

Input Arguments

`A,B` — Input tables

tables

Input tables, specified as tables.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Keys',2` uses the second variable in `A` and the second variable in `B` as key variables.

`'Keys'` — Variables to use as keys

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of `'Keys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the `'Keys'` name-value pair argument with the `'LeftKeys'` and `'RightKeys'` name-value pair arguments.

Example: `'Keys',[1 3]` uses the first and third variables in `A` and `B` as a key variables.

`'LeftKeys'` — Variables to use as keys in `A`

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in `A`, specified as the comma-separated pair consisting of `'LeftKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'LeftKeys'` name-value pair argument in conjunction with the `'RightKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must specify the same number of key variables. `outerjoin` pairs key values based on their order.

Example: `'LeftKeys',1` uses only the first variable in `A` as a key variable.

`'RightKeys'` — Variables to use as keys in `B`

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in `B`, specified as the comma-separated pair consisting of `'RightKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'RightKeys'` name-value pair argument in conjunction with the `'LeftKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must

specify the same number of key variables. `outerjoin` pairs key values based on their order.

Example: `'RightKeys',3` uses only the third variable in `B` as a key variable.

`'MergeKeys'` — Merge keys flag

`false` (default) | `true` | `0` | `1`

Merge keys flag, specified as the comma-separated pair consisting of `'MergeKeys'` and either `false`, `true`, `0` or `1`.

`false`	`outerjoin` includes two separate variables in the output table, `C`, for each key variable pair from tables `A` and `B`. This is the default behavior.
`true`	`outerjoin` includes a single variable in the output table, `C`, for each key variable pair from tables `A` and `B`. `outerjoin` creates the single variable by merging the key values from `A` and `B`, taking values from `A` where a corresponding row exists in `A`, and taking values from `B` otherwise. If you specify, `'MergeKeys',true`, then `outerjoin` includes all key variables in the output table, `C`, and overrides the inclusion or exclusion of key variables specified via the `'LeftVariables'` and `'RightVariables'` name-value pair arguments.

`'LeftVariables'` — Variables from `A` to include in `C`

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from `A` to include in `C`, specified as the comma-separated pair consisting of `'LeftVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use `'LeftVariables'` to include or exclude key variables as well as nonkey variables from the output, `C`.

By default, `outerjoin` includes all variables from `A`.

`'RightVariables'` — Variables from `B` to include in `C`

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from B to include in C, specified as the comma-separated pair consisting of 'RightVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'RightVariables' to include or exclude key variables as well as nonkey variables from the output, C.

By default, outerjoin includes all the variables from B.

'Type' — Type of outer join operation
'full' (default) | 'left' | 'right'

Type of outer-join operation, specified as the comma-separated pair consisting of 'Type' and either 'full', 'left', or 'right'.

- For a left outer join, C contains rows corresponding to key values in A that do not match any values in B, but not vice-versa.
- For a right outer join, C contains rows corresponding to key values in B that do not match any values in A, but not vice-versa.

By default, outerjoin does a full outer join and includes unmatched rows from both A and B.

Output Arguments

C — Outer join from A and B
table

Outer join from A and B, returned as a table. The output table, C, contains one row for each pair of rows in tables A and B that share the same combination of key values. If A and B contain variables with the same name, outerjoin adds a unique suffix to the corresponding variable names in C. Variables in C that came from A contain null values in those rows that had no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

In general, if there are m rows in table A and n rows in table B that all contain the same combination of values in the key variables, table C contains m*n rows for that combination. C also contains rows corresponding to key value combinations in one input table that do not match any row the other input table.

C contains the horizontal concatenation of A(ia,LeftVars) and B(ib,RightVars) sorted by the values in the key variables. By default, LeftVars consists of all the variables of A, and RightVars consists of all the from B. Otherwise, LefttVars consists of the variables specified by the 'LeftVariables' name-value pair argument, and RightVars consists of the variables specified by the 'RightVariables' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see Table Properties.

ia — Index to A

column vector

Index to A, returned as a column vector. Each element of ia identifies the row in table A that corresponds to that row in the output table, C. The vector ia contains zeros to indicate the rows in C that do not correspond to rows in A.

ib — Index to B

column vector

Index to B, returned as a column vector. Each element of ib identifies the row in table B that corresponds to that row in the output table, C. The vector ib contains zeros to indicate the rows in C that do not correspond to rows in B.

More About

Key Variable

Variable used to match and combine data between the input tables, A and B.

innerjoin | join

Introduced in R2013b

pack

Consolidate workspace memory

Syntax

```
pack
pack filename
pack('filename')
```

Description

`pack` frees up needed space by reorganizing information so that it only uses the minimum memory required. All variables from your base and global workspaces are preserved. Any persistent variables that are defined at the time are set to their default value (the empty matrix, `[]`).

The MATLAB software temporarily stores your workspace data in a file called `tp######.mat` (where `######` is a numeric value) that is located in your temporary folder. (You can use the command `dir(tempdir)` to see the files in this folder).

`pack filename` frees space in memory, temporarily storing workspace data in a file specified by `filename`. This file resides in your current working folder and, unless specified otherwise, has a `.mat` file extension.

`pack('filename')` is the function form of `pack`.

Examples

Change the current folder to one that is writable, run `pack`, and return to the previous folder.

```
cwd = pwd;
cd(tempdir);
pack
cd(cwd)
```

More About

Tips

You can only run `pack` from the MATLAB command line.

If you specify a `filename` argument, that file must reside in a folder for which you have write permission.

The `pack` function does not affect the amount of memory allocated to the MATLAB process. You must quit MATLAB to free up this memory.

Since MATLAB uses a heap method of memory management, extended MATLAB sessions may cause memory to become fragmented. When memory is fragmented, there may be plenty of free space, but not enough contiguous memory to store a new large variable.

If you get the `Out of memory` message from MATLAB, the `pack` function may find you some free memory without forcing you to delete variables.

The `pack` function frees space by

- Saving all variables in the base and global workspaces to a temporary file.
- Clearing all variables and functions from memory.
- Reloading the base and global workspace variables back from the temporary file and then deleting the file.

If you use `pack` and there is still not enough free memory to proceed, you must clear some variables. If you run out of memory often, you can allocate larger matrices earlier in the MATLAB session and use these system-specific tips:

- When running MATLAB on The Open Group UNIX platforms, ask your system manager to increase your swap space.
- On Microsoft Windows platforms, increase virtual memory using the Windows Control Panel.

To maintain persistent variables when you run pack, use `mlock` in the function.

`clear` | `memory`

Introduced before R2006a

padecoef

Padé approximation of time delays

Syntax

```
[num,den] = padecoef(T,N)
```

Description

`[num,den] = padecoef(T,N)` returns the `N`th-order Padé approximation of the continuous-time delay T in transfer function form. The row vectors `num` and `den` contain the numerator and denominator coefficients in descending powers of s. Both are `N`th-order polynomials.

Class support for input T:

`float: double, single`

Class Support

Input T support floating-point values of type `single` or `double`.

`pade`

pagesetupdlg

Page setup dialog box

Syntax

```
dlg = pagesetupdlg(fig)
```

Note: `pagesetupdlg` is no longer supported. Use `printpreview` instead.

Description

`dlg = pagesetupdlg(fig)` creates a dialog box from which a set of page layout properties for the figure window, `fig`, can be set.

`pagesetupdlg` implements the "Page Setup..." option in the **Figure File Menu**.

`pagesetupdlg` supports setting the layout for a single figure. `fig` must be a single figure handle, not a vector of figures or a Simulink diagram.

Introduced before R2006a

pan

Pan view of graph interactively

Syntax

```
pan on
pan xon
pan yon
pan off
pan
pan(figure_handle,...)
h = pan(figure_handle)
```

Description

`pan on` turns on mouse-based panning in the current figure.

`pan xon` turns on panning only in the *x* direction in the current figure.

`pan yon` turns on panning only in the *y* direction in the current figure.

`pan off` turns panning off in the current figure.

`pan` toggles the pan state in the current figure `on` or `off`.

`pan(figure_handle,...)` sets the pan state in the specified figure.

`h = pan(figure_handle)` returns the figure's pan *mode object* for the figure `figure_handle` for you to customize the mode's behavior.

Using Pan Mode Objects

Access the following properties of pan mode objects.

- *`Enable`* `'on'|'off'` — Specifies whether this figure mode is currently enabled on the figure
- *`Motion`* `'horizontal'|'vertical'|'both'` — The type of panning enabled for the figure

- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set

Pan Mode Callbacks

You can program the following callbacks for pan mode operations.

- `ButtonDownFilter <function_handle>` — Function to intercept `ButtonDown` events

  The application can inhibit the panning operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

  ```
  function [res] = myfunction(obj,event_obj)
  % obj          handle to the object clicked on
  % event_obj    event data (empty in this release)
  % res [output] a logical flag to determine whether the pan
  %              operation should take place(for 'res' set to 'false')
  %              or the 'ButtonDownFcn' property of the object should
  %              take precedence (when 'res' is 'true')
  ```

- `ActionPreCallback <function_handle>` — Function to execute before panning

  Set this callback to if you need to execute code when a pan operation begins. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

  ```
  function myfunction(obj,event_obj)
  % obj         handle to the figure that has been clicked on
  % event_obj   object containing struct of event data
  ```

  The event data struct has the following field:

`Axes`	The handle of the axes that is being panned

- `ActionPostCallback <function_handle>` — Function to execute after panning

  Set this callback if you need to execute code when a pan operation ends. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

  ```
  function myfunction(obj,event_obj)
  ```

```
% obj         handle to the figure that has been clicked on
% event_obj   object containing struct of event data
%             (same as the event data of the
%             'ActionPreCallback' callback)
```

Pan Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesPan(h,axes)` — Function querying permission to pan axes

  Calling the function `isAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a pan operation is permitted on the axes objects.
- `setAllowAxesPan(h,axes,flag)` — Function to set permission to pan axes

  Calling the function `setAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a pan operation on the axes objects.
- *`info`* `= getAxesPanMotion(h,axes)` — Function to get style of pan operations

  Calling the function `getAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, as input will return a character cell array of the same dimension as the axes handle vector, which indicates the type of pan operation for each axes. Possible values for the type of operation are `'horizontal'`, `'vertical'` or `'both'`.
- `setAxesPanMotion(h,axes,style)` — Function to set style of pan operations

  Calling the function `setAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of panning on each axes.

Examples

Example 1 — Entering Pan Mode

Plot a graph and turn on Pan mode:

```
plot(magic(10));
pan on
```

```
% pan on the plot
```

Example 2 — Constrained Pan

Constrain pan to *x*-axis using `set`:

```
plot(magic(10));
h = pan;
h.Motion = 'horizontal';
h.Enable = 'on';
% pan on the plot in the horizontal direction.
```

Example 3 — Constrained Pan in Subplots

Create four axes as subplots and give each one a different panning behavior:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = pan;
ax2 = subplot(2,2,2);
plot(rand(3));
setAllowAxesPan(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesPanMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesPanMotion(h,ax4,'vertical');
% pan on the plots.
```

Example 4 — Coding a ButtonDown Callback

Create a buttonDown callback for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
hLine.ButtonDownFcn = 'disp(''This executes'')';
hLine.Tag = 'DoNotIgnore';
h = pan;
h.ButtonDownFilter = @mycallback;
h.Enable = 'on';
```

```
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then
% return true.

% Indicate what the target is.
disp(['Clicked ' obj.Type ' object'])
objTag = obj.Tag;
if strcmpi(objTag,'DoNotIgnore')
   flag = true;
else
   flag = false;
end
```

Example 5 — Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-ButtonDown events for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Listen to pan events
plot(1:10);
h = pan;
h.ActionPreCallback = @myprecallback;
h.ActionPostCallback = @mypostcallback;
h.Enable = 'on';
%
function myprecallback(obj,evd)
disp('A pan is about to occur.');
%
function mypostcallback(obj,evd)
newLim = evd.Axes.XLim;
msgbox(sprintf('The new X-Limits are [%.2f,%.2f].',newLim));
```

Example 6 — Creating a Context Menu for Pan Mode

Coding a context menu that lets the user to switch to Zoom mode by right-clicking:

```
figure
plot(magic(10));
hCM = uicontextmenu;
hMenu = uimenu('Parent',hCM,'Label','Switch to zoom',...
```

```
        'Callback','zoom(gcbf,''on'')');
hPan = pan(gcf);
hPan.UIContextMenu = hCM;
pan('on')
```

You cannot add items to the built-in pan context menu, but you can replace it with your own.

Alternatives

Use the Pan tool  on the figure toolbar to enable and disable pan mode on a plot, or select **Pan** from the figure's **Tools** menu. For details, see "Panning — Shifting Your View of the Graph".

More About

Tips

You can create a pan mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

Note: Do not change figure callbacks within an interactive mode. While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a UI that updates a figure's callbacks, the UI should some keep track of which interactive mode is active, if any, before attempting to do this.

When you assign different pan behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

Introduced before R2006a

matlab.unittest.parameters

Summary of classes associated with MATLAB Unit Test parameters

Description

The `matlab.unittest.parameters` package consists of the following classes used in parameterized testing.

matlab.unittest.parameters.EmptyParameter
: Empty parameter implementation

matlab.unittest.parameters.ClassSetupParameter
: Specification of Class Setup Parameter

matlab.unittest.parameters.TestParameter
: Specification of Test Parameter

matlab.unittest.parameters.MethodSetupParameter
: Specification of Method Setup Parameter

See Also

`matlab.unittest.TestSuite.selectIf`

Related Examples

- “Create Basic Parameterized Test”
- “Create Advanced Parameterized Test”

matlab.unittest.parameters.EmptyParameter class

Package: matlab.unittest.parameters

Empty parameter implementation

Description

The `matlab.unittest.parameters.EmptyParameter` class is a `Parameter` implementation that provides no parameter information. There is no need for test authors to interact with this `Parameter` directly. This class provides an empty parameter instance to the `Parameterization` property of a nonparameterized test element.

Properties

`Property`

String indicating the name of the property that defines the Empty Parameter.

`Name`

String indicating the name that uniquely identifies a particular value for a Empty Parameter.

`Value`

Value of the Empty Parameter. The `Value` property holds the data that the Test Runner uses for parameterized testing.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

See Also

`matlab.unittest.TestCase`

Related Examples

Introduced in R2014a

matlab.unittest.parameters.ClassSetupParameter class

Package: matlab.unittest.parameters

Specification of Class Setup Parameter

Description

The `matlab.unittest.parameters.ClassSetupParameter` class holds information about a single value of a Class Setup Parameter.

Properties

`Property`

String indicating the name of the property that defines the Class Setup Parameter.

`Name`

String indicating the name that uniquely identifies a particular value for a Class Setup Parameter.

`Value`

Value of the Class Setup Parameter. The `Value` property holds the data that the Test Runner uses for parameterized testing.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

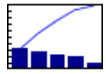
pareto

Pareto chart



Syntax

```
pareto(Y)
pareto(Y,names)
pareto(Y,X)
H = pareto(...)
```

Description

Pareto charts display the values in the vector `Y` as bars drawn in descending order. Values in `Y` must be nonnegative and not include `NaN`s. Only the first 95% of the cumulative distribution is displayed.

`pareto(Y)` labels each bar with its element index in `Y` and also plots a line displaying the cumulative sum of `Y`.

`pareto(Y,names)` labels each bar with the associated name in the string matrix or cell array `names`.

`pareto(Y,X)` labels each bar with the associated value from `X`.

`pareto(ax,..)` plots into the axes `ax` rather than the current axes, `gca`.

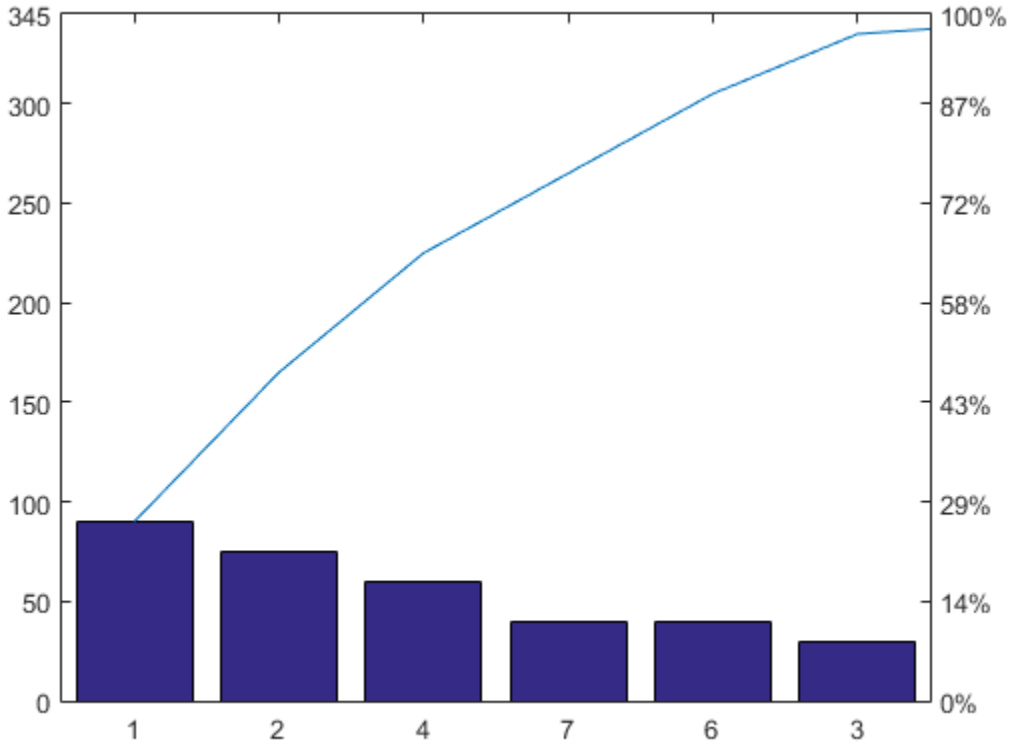
`H = pareto(...)` returns handles to the primitive line and bar series objects created.

Examples

Create Pareto Chart

Create a Pareto chart of vector `y`.

```
y = [90,75,30,60,5,40,40,5];
figure
pareto(y)
```



`pareto` displays the elements in `y` as bars in descending order and labels each bar with its index in `y`. Since `pareto` displays only the first 95% of the cumulative distribution, some elements in `y` are not displayed.

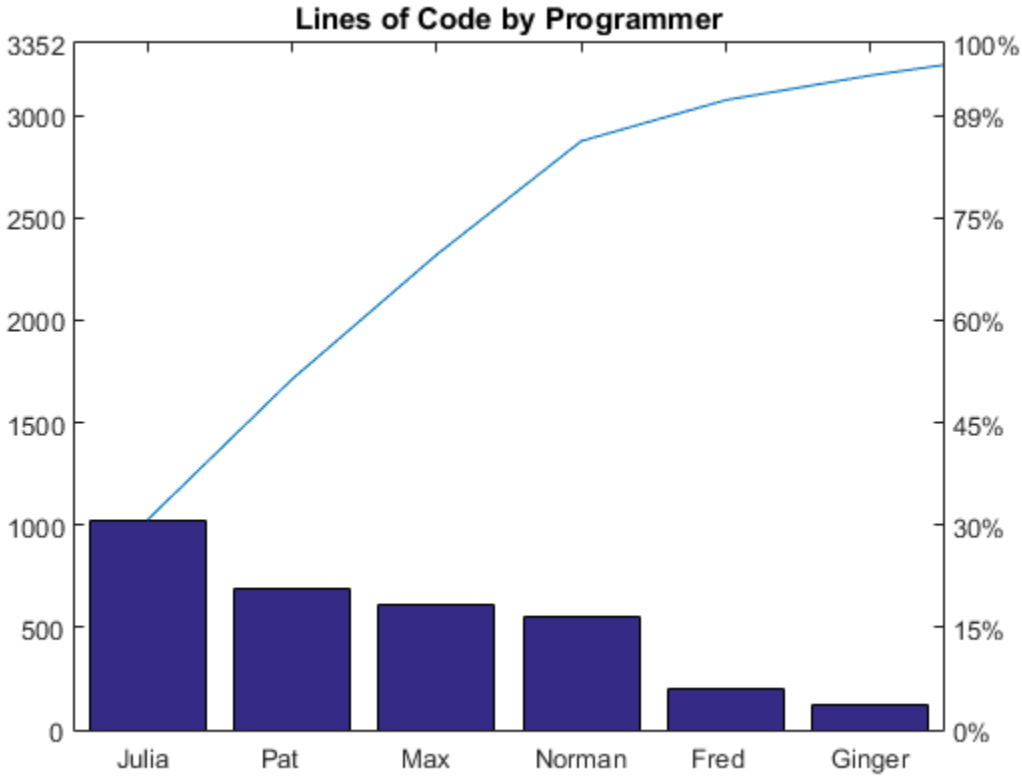
Label Bars in Pareto Chart

Examine the cumulative productivity of a group of programmers to see how normal its distribution is. Label each bar with the name of the programmer.

```
codelines = [200 120 555 608 1024 101 57 687];
```

```
coders = {'Fred','Ginger','Norman','Max','Julia','Wally','Heidi','Pat'};

figure
pareto(codelines, coders)
title('Lines of Code by Programmer')
```



More About

Tips

You cannot place datatips (use the Datacursor tool) on graphs created with `pareto`.

See Also

Introduced before R2006a

parfor

Parallel for loop

Syntax

```
parfor loopvar = initval:endval; statements; end
parfor (loopvar = initval:endval, M); statements; end
```

Description

`parfor loopvar = initval:endval; statements; end` executes a series of MATLAB statements for values of `loopvar` between `initval` and `endval`, inclusive, which specify a vector of increasing integer values. The loop runs in parallel when you have the Parallel Computing Toolbox or when you create a MEX function or standalone code with MATLAB Coder. Unlike a traditional `for`-loop, iterations are not executed in a guaranteed order.

`parfor (loopvar = initval:endval, M); statements; end` executes statements in a loop using a maximum of `M` workers or threads, where `M` is a nonnegative integer.

Examples

Perform three large eigenvalue computations using three workers or cores with Parallel Computing Toolbox software:

```
parpool(3)
parfor i=1:3, c(:,i) = eig(rand(1000)); end
```

More About

Tips

- If you have Parallel Computing Toolbox software, see the function reference pages for `parfor` and `parpool` for additional information.

- If you have MATLAB Coder software, see the `parfor` function reference page for additional information.

See Also

`for`

parse

Class: inputParser

Parse function inputs

Syntax

```
parse(p,argList)
```

Description

`parse(p,argList)` parses and validates the inputs in `arglist`.

Input Arguments

`p`

Object of class `inputParser`.

`argList`

Comma separated list of inputs to parse and validate for your custom function. The class of each input depends upon your function definition.

Examples

Input Parsing

Parse and validate required and optional function inputs.

Create a custom function with required and optional inputs in the file `findArea.m`.

```
function a = findArea(width,varargin)
   p = inputParser;
   defaultHeight = 1;
```

```
defaultUnits = 'inches';
defaultShape = 'rectangle';
expectedShapes = {'square','rectangle','parallelogram'};

addRequired(p,'width',@isnumeric);
addOptional(p,'height',defaultHeight,@isnumeric);
addParameter(p,'units',defaultUnits);
addParameter(p,'shape',defaultShape,...
             @(x) any(validatestring(x,expectedShapes)));

parse(p,width,varargin{:});
a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```
Error using findArea (line 14)
The value of 'width' is invalid. It must satisfy the function: isnumeric.
```

Specify an unsupported value for `shape`:

```
findArea(4,'shape','circle')
```

```
Error using findArea (line 14)
The value of 'shape' is invalid. Expected input to match one of these strings:

square, rectangle, parallelogram

The input, ''circle'', did not match any of the valid strings.
```

See Also

`addOptional` | `addParameter` | `addRequired` | `inputParser`

parseSoapResponse

Convert response string from SOAP (Simple Object Access Protocol) server into MATLAB types

Compatibility

`parseSoapResponse` will be removed in a future release. Use `matlab.wsdl.createWSDLClient` instead.

Syntax

```
data = parseSoapResponse(response)
```

Description

`data = parseSoapResponse(response)` extracts data from SOAP server `response` and converts to MATLAB types.

Examples

Retrieve Book Information from Library Database

This example assumes the library is on a local intranet and does not use an actual endpoint; therefore, you cannot run it.

Retrieve the name of the author of a book titled “In the Fall.” The relative path of the library service is `urn:LibraryCatalog`. To get the author's name, use the `getAuthor` function, which takes the book name as the input value. The `getAuthor` parameter is `nameToLookUp`. The XML data type for title is `{http://www.w3.org/2001/XMLSchema}string`. The SOAP message style is `rpc` by default.

Create the SOAP message.

```
message = createSoapMessage(...
```

```
  'urn:LibraryCatalog',...
  'getAuthor',...
  {'In the Fall'},...
  {'nameToLookUp'},...
  {'{http://www.w3.org/2001/XMLSchema}string'})

message =

[#document: null]
```

This response does not necessarily indicate that the message is valid, although certain input problems produce error messages.

Send the message to the server for processing, and get the author's name back. The server endpoint is `http://test/soap/services/LibraryCatalog`. The server method is `urn:LibraryCatalog#getAuthor`.

```
response = callSoapService(...
  'http://test/soap/services/LibraryCatalog',...
  'urn:LibraryCatalog#getAuthor',...
  message)

<?xml version="1.0" encoding="utf-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<getAuthorResponse xmlns="urn:LibraryCatalog">
<ns1:getAuthorReturn xmlns:ns1="http://latestversion.soap.test">
Kate Alvin
</ns1:getAuthorReturn>
</getAuthorResponse>
</soapenv:Body>
</soapenv:Envelope>
```

MATLAB returns the message in a single line, displayed here on separate lines for legibility.

Extract the author's name.

```
author = parseSoapResponse(response)

author = Kate Alvin
```

MATLAB automatically converted the XML string data type to `char`.

Input Arguments

`response` — Data from SOAP server

string

Data from SOAP server, specified as a string. response is the output from the `callSoapService` function.

Output Arguments

`data` — Output of SOAP service call

cell array of any valid MATLAB type

Output of SOAP service call, returned as a cell array of any valid MATLAB type. For information about data, see the documentation for the SOAP service used in the `callSoapService` function.

Introduced before R2006a

pascal

Pascal matrix

Syntax

```
A = pascal(n)
A = pascal(n,1)
A = pascal(n,2)
```

Description

`A = pascal(n)` returns a "Pascal's Matrix" on page 1-5740 of order `n`: a symmetric positive definite matrix with integer entries taken from Pascal's triangle. The inverse of `A` has integer entries.

`A = pascal(n,1)` returns the lower triangular Cholesky factor (up to the signs of the columns) of the Pascal matrix. It is *involutary*, that is, it is its own inverse.

`A = pascal(n,2)` returns a transposed and permuted version of `pascal(n,1)`. `A` is a cube root of the identity matrix.

Examples

`pascal(4)` returns

```
1     1     1     1
1     2     3     4
1     3     6    10
1     4    10    20
```

`A = pascal(3,2)` produces

```
A =
     1     1     1
    -2    -1     0
     1     0     0
```

More About

Pascal's Matrix

Pascal's triangle is a triangle formed by rows of numbers. The first row has entry `1`. Each succeeding row is formed by adding adjacent entries of the previous row, substituting a `0` where there is no adjacent entry. Pascal's matrix is generated by selecting the portion of Pascal's triangle that corresponds to the specified matrix dimensions, as outlined in the graphic. The matrix outlined corresponds to the MATLAB command `pascal(4)`.

Introduced before R2006a

patch

Create one or more filled polygons

Syntax

```
patch(X,Y,C)
patch(X,Y,Z,C)
patch(FV)
patch(X,Y,C,'PropertyName',propertyvalue...)
patch('PropertyName',propertyvalue,...)
handle = patch(...)
```

Properties

For a list of properties, see Patch Properties.

Description

`patch(X,Y,C)` adds a filled 2-D patch object to the current axes. A patch object is one or more polygons defined by the coordinates of its vertices. The elements of `X` and `Y` specify the vertices of a polygon . If `X` and `Y` are `m`-by-`n` matrices, MATLAB draws `n` polygons with `m` vertices. `C` determines the color of the patch. For more information on color input requirements, see “Coloring Patches” on page 1-5746.

MATLAB does not require each face to have the same number of vertices. In cases where they do not, pad the end of the `Faces` matrix with `NaNs`. To define a patch with faces that do not close, add one or more `NaNs` to the row in the `Vertices` matrix that defines the vertex you do not want connected.

See “Introduction to Patch Objects” for more information on using patch objects.

`patch(X,Y,Z,C)` creates a patch in 3-D coordinates. If the coordinate data does not define closed polygons, `patch` closes the polygons. The data can define concave or intersecting polygons. However, if the edges of an individual patch face intersect themselves, the resulting face might be only partly filled. In that case, it is better to divide the face into smaller polygons.

`patch(FV)` creates a patch using structure `FV`, which contains the fields `vertices`, `faces`, and optionally `facevertexcdata`. These fields correspond to the `Vertices`, `Faces`, and `FaceVertexCData` patch properties. Specifying only unique vertices and their connection matrix can reduce the size of the data for patches having many faces. For an example of how to specify patches with this method, see "Specifying Patch Object Shapes" on page 1-5743.

`patch(X,Y,C,'PropertyName',propertyvalue...)` follows the `X`, `Y`, `(Z)`, and `C` arguments with property name/property value pairs to specify additional patch properties. For a description of the properties, see Patch Properties. You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

`patch('PropertyName',propertyvalue,...)` specifies all properties using property name/property value pairs. This form lets you omit the color specification because MATLAB uses the default face color and edge color unless you explicitly assign a value to the `FaceColor` and `EdgeColor` properties. This form also lets you specify the patch using the `Faces` and `Vertices` properties instead of *x*-, *y*-, and *z*-coordinates. See "Specifying Patch Object Shapes" on page 1-5743 for more information.

`handle = patch(...)` returns the handle of the patch object it creates.

Unlike high-level area creation functions, such as `fill` or `area`, `patch` does not check the settings of the figure and axes `NextPlot` properties. It simply adds the patch object to the current axes.

Examples

Define a Square Patch

Create a square patch with red face color and black edges using x- and y-coordinates:

```
x = [0 1 1 0];
y = [0 0 1 1];
patch(x,y,'red')
```

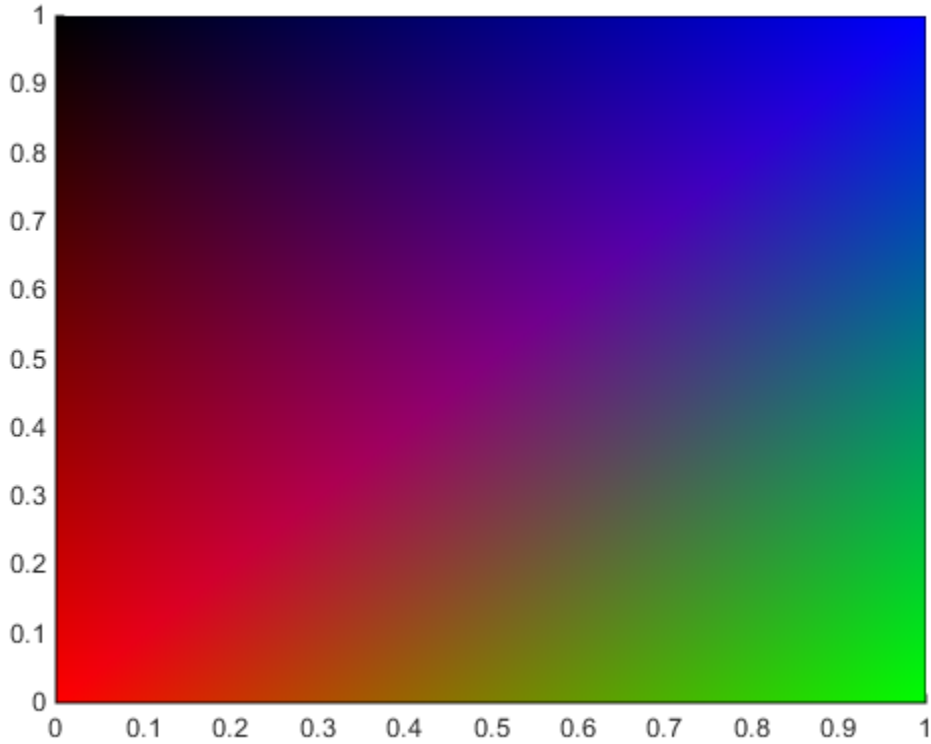
Create a square patch with red face color and black edges using vertices and faces:

```
vert = [0 0;1 0;1 1;0 1]; % x and y vertex coordinates
fac = [1 2 3 4]; % vertices to connect to make square
```

```
patch('Faces',fac,'Vertices',vert,'FaceColor','red')
```

Specify colors for each vertex and interpolate the face color:

```
fvc = [1 0 0;0 1 0;0 0 1;0 0 0];
patch('Faces',fac,'Vertices',vert,...
'FaceVertexCData',fvc,'FaceColor','interp')
```



Specifying Patch Object Shapes

The next two examples create a patch object using two methods:

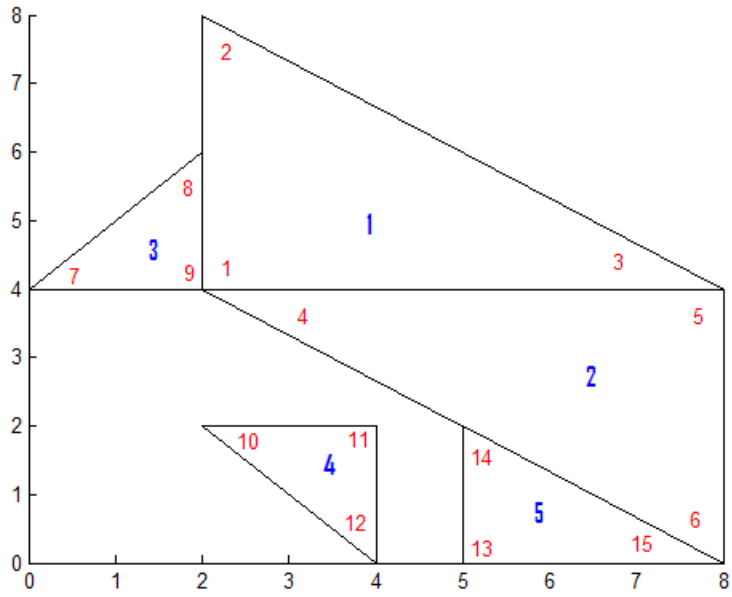
- Specifying *x*-, *y*-, and *z*-coordinates and color data (`XData`, `YData`, `ZData`, and `CData` properties)

- Specifying vertices, the connection matrix, and color data (`Vertices`, `Faces`, and `FaceVertexCData` properties)

Create five triangular faces, each having three vertices, by specifying the *x*-, *y*-, and *z*-coordinates of each vertex:

```
xdata = [2 2 0 2 5;
         2 8 2 4 5;
         8 8 2 4 8];
ydata = [4 4 4 2 0;
         8 4 6 2 2;
         4 0 4 0 0];
zdata = ones(3,5);

% Red numbers denote the vertex indices.
% For this example:
% xindices = [1 4 7 10 13;
%             2 5 8 11 14;
%             3 6 9 12 15];
% Blue numbers denote the face numbers.
patch(xdata,ydata,zdata,'w')
```

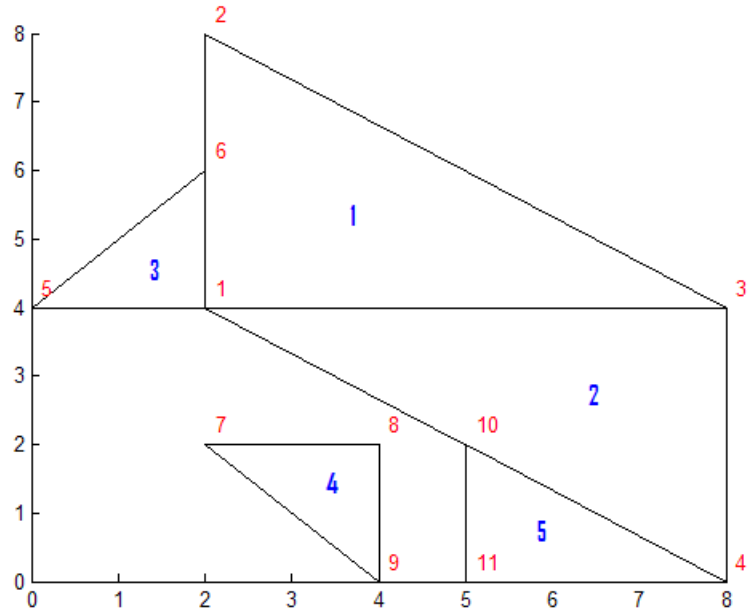


Create the five triangular faces, specifying faces and vertices:

```
% The Vertices property contains the coordinates of each
% unique vertex defining the patch. The Faces property
% specifies how to connect these vertices to form each
% face of the patch. More than one face may
% use a given vertex.
% For this example, five triangles have 11 total vertices,
% instead of 15. Each row contains
% the x- and y-coordinates
% of each vertex.
verts = [2 4; ...
        2 8; ...
        8 4; ...
        8 0; ...
        0 4; ...
        2 6; ...
        2 2; ...
        4 2; ...
        4 0; ...
        5 2; ...
        5 0 ];

% There are five faces, defined by connecting the
% vertices in the order indicated.
faces = [ ...
        1  2  3; ...
        1  3  4; ...
        5  6  1; ...
        7  8  9; ...
        11 10 4 ];

% Create the patch by specifying the Faces, Vertices,
% and FaceVertexCData properties as well as the
% FaceColor property. Red numbers denote the vertex
% numbers, as defined in faces. Blue indicate face numbers.
p = patch('Faces',faces,'Vertices',verts,'FaceColor','w');
```



```
% Using the previous values for verts and faces, you can
% create the same patch object using a structure:
patchinfo.Vertices = verts;
patchinfo.Faces = faces;
patchinfo.FaceColor = 'w';

patch(patchinfo);
```

Coloring Patches

There are many ways to customize your patch objects using colors. The appropriate input depends on:

- Whether you want to change the edge colors
- How you specified the patch faces:
  - Using face/vertex values
  - Using *x*-, *y*-, and *z*-coordinates

The following sections present the various options available.

Specifying Edge Colors

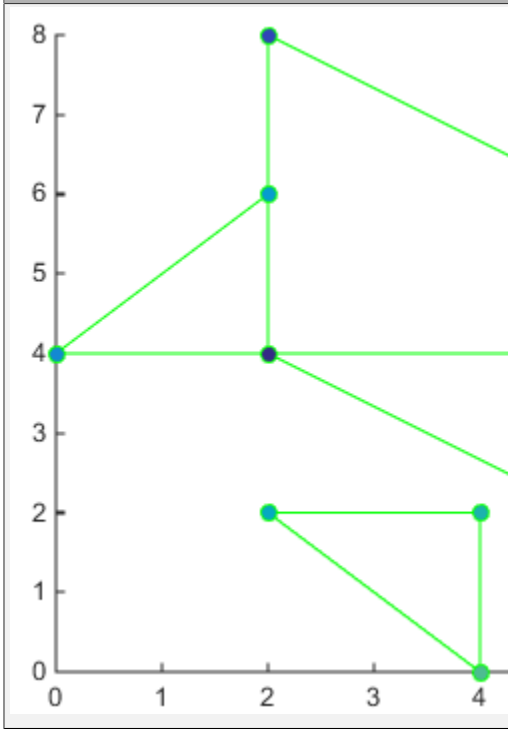
The following options apply to the edge colors of your patch object. The settings are independent of the face colors, but the colors themselves depend on the colors specified at each vertex. Markers show the color at each vertex. Specify the colors using the `EdgeColor` property. Explore the options using the Sample Code in the following table. Create a base patch object with this code:

```
xdata = [2     2     0     2     5;
         2     8     2     4     5;
         8     8     2     4     8];
ydata = [4     4     4     2     0;
         8     4     6     2     2;
         4     0     4     0     0];
cdata = [15     0     4     6    10;
         1     2     5     7     9;
         2     3     0     8     3];
p = patch(xdata,ydata,cdata,'Marker','o',...
          'MarkerFaceColor','flat',...
          'FaceColor','none')
```

For more detailed information on how the `EdgeColor` property works, see thePatch Properties property page.

Desired Look	EdgeColor Value	Sample Code
All edges have the same color, around all faces. This option does not rely on the `FaceColor` value.	MATLAB color specifier.`EdgeColor`	`set(p,'EdgeColor','g')`

Desired Look	EdgeColor Value	Sample Code
		



Desired Look	EdgeColor Value	Sample Code
Each edge corresponds to the color of the vertex that precedes the edge, with one color per edge. This option requires that the `FaceColor` property be `flat` or `interp`. By default, if you specify `CData` when creating the patch object, its `FaceColor` property is `interp`. 	`'flat'`	`set(p,'EdgeColor','flat',...` `'LineWidth',3)`

Desired Look	EdgeColor Value	Sample Code
Each edge corresponds to the vertex colors, interpolated between vertices. This option requires that the `FaceColor` property be `flat` or `interp`. By default, if you specify `CData` when creating the patch object, its `FaceColor` property is `interp`. 	`'interp'`	`set(p,'EdgeColor','interp')`

Desired Look	EdgeColor Value	Sample Code
Edges have no color. This option does not rely on the `FaceColor` value. If set, markers retain vertex colors. 	`'none'`	`set(p,'EdgeColor','none')`

Specifying Face Colors Using Face/Vertex Input Matrices

The following options apply to the face colors of your patch object when you specify the faces using face/vertex input matrices. To explore the options, start with a base patch object:

```
% For this example, there are five triangles (m = 5)
% sharing eleven unique vertices (k = 11).
verts = [2 4; ...
         2 8; ...
         8 4; ...
         8 0; ...
```

```
          0 4; ...
          2 6; ...
          2 2; ...
          4 2; ...
          4 0; ...
          5 2; ...
          5 0 ];
faces = [1  2  3; ...
         1  3  4; ...
         5  6  1; ...
         7  8  9; ...
         11 10 4];
p = patch('Faces',faces,'Vertices',verts,'FaceColor','b');
```

For more information on the relevant properties, see `FaceColor`, `FaceVertexCData`, and `CDataMapping`.

Desired Look	Parameter Values	Sample Code

All faces have the same color.
  	
	• `FaceColor`
	• `FaceVertexCData`: `[]` (no input)
	An empty array is the default value, and `patch` ignores any input until you set `FaceColor` to `'flat'` or `'interp'`.
	• Color source: truecolor
	• `CDataMapping`: `'direct'` or `'scaled'`.
	`'scaled'` is the default value, but neither affects the outcome.
		`set(p,'FaceColor','r')`
		or
		`set(p,'FaceColor',[1 0 0])`

Desired Look	Parameter Values	Sample Code

Each face has a single, unique color, indexed from a selected section of the colormap.
  	
	• `FaceColor`: `'flat'`
	• `FaceVertexCData`: `m`-by-1 matrix of index values
	• Color source: A selected portion of the `colormap`
	• `CDataMapping`: `'scaled'`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 60]';`
		`set(p,'FaceColor','flat',...`
		`'FaceVertexCData',cdata,...`
		`'CDataMapping','scaled')`

Desired Look	Parameter Values	Sample Code

Each face has a single, unique color, indexed from the whole colormap.
  	
	• `FaceColor`: `'flat'`
	• `FaceVertexCData`: m-by-1 matrix of index values
	• Color source: `colormap`
	• `CDataMapping`: `'direct'`
	
	`'scaled'` is the default value when you input `CData` values. If you want to change the axes `CLim` property, but want your patch object to index the entire colormap, use `'CDataMapping','dire`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 60]';`
		`set(p,'FaceColor','flat',...`
		`'FaceVertexCData',cdata,...`
		`'CDataMapping','direct')`

Desired Look	Parameter Values	Sample Code

Each face has a single, unique color, determined by truecolor value input.
  	
	• `FaceColor`: `'flat'`
	• `FaceVertexCData`: `m`-by-3 matrix of truecolor values, from 0 to 1
	• Color source: truecolor
	• `CDataMapping`: `'direct'` or `'scaled'`.
	`'scaled'` is the default value, but neither affects the outcome.
		`clear cdata`
		`cdata = [0 0 1 0 0.8;`
		`0 1 0 0 0.8;`
		`1 0 1 0 0.8]';`
		`set(p,'FaceColor','flat',...`
		`'FaceVertexCData',cdata)`

Desired Look	Parameter Values	Sample Code

Each unique vertex has a single, unique color, indexed from a selected section of the colormap. Faces each have a single, unique color, but edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'flat'`
	• `FaceVertexCData`: k-by-1 matrix of index values
	• Color source: A selected portion of the `colormap`
	• `CDataMapping`: `'scaled'`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 ...`
		`60 12 23 40 13 26 24]';`
		`set(p,'FaceColor','flat',...`
		`'FaceVertexCData',cdata,...`
		`'EdgeColor','flat',...`
		`'LineWidth',5,...`
		`'CDataMapping','scaled')`

Desired Look	Parameter Values	Sample Code

Each unique vertex has a single, unique color, indexed from the whole colormap. Faces each have a single, unique color, but edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'flat'`
	• `FaceVertexCData`: k-by-1 matrix of index values
	• Color source: `colormap`
	• `CDataMapping`: `'direct'`
	`'scaled'` is the default value when you input `CData` values. If you want to change the axes `CLim` property, but want your patch object to index the entire colormap, use `'CDataMapping','dire`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 ...`
		`60 12 23 40 13 26 24]';`
		`set(p,'FaceColor','flat',...`
		`'FaceVertexCData',cdata,...`
		`'CDataMapping','direct',...`
		`'EdgeColor','flat',...`
		`'LineWidth',5)`

Desired Look	Parameter Values	Sample Code

Each unique vertex has a single, unique color, determined by truecolor value input. Faces each have a single, unique color, but edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'flat'`
	• `FaceVertexCData`: k-by-3 matrix of truecolor values, from 0 to 1
	• Color source: truecolor
	• `CDataMapping`: `'direct'` or `'scaled'`.
	`'scaled'` is the default value, but neither affects the outcome.
		`clear cdata`
		`cdata = [0 0 1;`
		`0 1 0;`
		`0 1 1;`
		`1 0 0;`
		`1 0 1;`
		`1 1 0;`
		`0 0 0;`
		`0.2 0.2 0.2;`
		`0.4 0.4 0.4;`
		`0.6 0.6 0.6;`
		`0.8 0.8 0.8];`
		`set(p,'FaceColor','flat',...`
		`'FaceVertexCData',cdata,...`
		`'EdgeColor','interp',...`
		`'LineWidth',5)`

Desired Look	Parameter Values	Sample Code

Each unique vertex has a single, unique color, indexed from a selected section of the colormap. Edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'interp'`
	• `FaceVertexCData`: k-by-1 matrix of index values
	• Color source: A selected portion of the `colormap`
	• `CDataMapping`: `'scaled'`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 ...`
		`60 12 23 40 13 26 24]';`
		`set(p,'FaceColor','interp',...`
		`'FaceVertexCData',cdata,...`
		`'EdgeColor','flat',...`
		`'LineWidth',5,...`
		`'CDataMapping','scaled')`

Desired Look	Parameter Values	Sample Code

Each unique vertex has a single, unique color, indexed from the whole colormap. Edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'interp'`
	• `FaceVertexCData`: k-by-1 matrix of index values
	• Color source: `colormap`
	• `CDataMapping`: `'direct'`
	`'scaled'` is the default value when you input `CData` values. If you want to change the axes `CLim` property, but want your patch object to index the entire colormap, use `'CDataMapping','dire`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 ...`
		`60 12 23 40 13 26 24]';`
		`set(p,'FaceColor','interp',...`
		`'FaceVertexCData',cdata,...`
		`'CDataMapping','direct',...`
		`'EdgeColor','flat',...`
		`'LineWidth',5)`

Desired Look	Parameter Values	Sample Code

Each unique vertex has a single, unique color, determined by truecolor value input. Edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'interp'`
	• `FaceVertexCData`: k-by-3 matrix of truecolor values, from 0 to 1
	• Color source: truecolor
	• `CDataMapping`: `'direct'` or `'scaled'`.
	`'scaled'` is the default value, but neither affects the outcome.
		`clear cdata`
		`cdata = [0 0 1;`
		`0 1 0;`
		`0 1 1;`
		`1 0 0;`
		`1 0 1;`
		`1 1 0;`
		`0 0 0;`
		`0.2 0.2 0.2;`
		`0.4 0.4 0.4;`
		`0.6 0.6 0.6;`
		`0.8 0.8 0.8];`
		`set(p,'FaceColor','interp',...`
		`'FaceVertexCData',cdata,...`
		`'EdgeColor','interp',...`
		`'LineWidth',5)`

Specifying Face Colors Using x-, y-, and z-Coordinate Input

The following options apply to the face colors of your patch object when you specify the faces using *x*-, *y*-, and *z*-coordinates. To explore the options, start with a base patch object:

```
% For this example, there are five (m=5) triangles (n=3).
% The total number of vertices is mxn, or k = 15.
xdata = [2 2 0 2 5;
         2 8 2 4 5;
         8 8 2 4 8];
```

```
ydata = [4 4 4 2 0;
         8 4 6 2 2;
         4 0 4 0 0];
zdata = ones(3,5);
p = patch(xdata,ydata,zdata,'b')
```

For more information on the relevant properties, see `FaceColor`, `CData`, and `CDataMapping`.

Desired Look	Parameter Values	Sample Code

All faces have the same color.
  	
	• `FaceColor`: `ColorSpec`
	• `CData`: `[]` (no input)
	• Color source: truecolor
	• `CDataMapping`: `'direct'` or `'scaled'`.
	
	`'scaled'` is the default value, but neither affects the outcome.
		`set(p,'FaceColor','r')`
		
		or
		
		`set(p,'FaceColor',[1 0 0])`

Each face has a single, unique color, indexed from a selected section of the colormap.	• `FaceColor`: `'flat'`
	• `CData`: m-by-1 matrix of index values
	• Color source: A selected portion of the `colormap`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 60];`
		`set(p,'FaceColor','flat',...`
		`'CData',cdata,...`
		`'CDataMapping','scaled')`

Desired Look	Parameter Values	Sample Code
	• `CDataMapping: 'scaled'`	

Desired Look	Parameter Values	Sample Code

Each face has a single, unique color, indexed from the whole colormap.
  	
	• `FaceColor`: `'flat'`
	• `CData`: `m`-by-1 matrix of index values
	• Color source: `colormap`
	• `CDataMapping`: `'direct'`
	
	`'scaled'` is the default value when you input `CData` values. If you want to change the axes `CLim` property, but want your patch object to index the entire colormap, use `'CDataMapping','dire`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 60];`

		`'LineWidth',5)`

Desired Look	Parameter Values	Sample Code

Each vertex has a single, unique color, determined by truecolor value input. Faces each have a single, unique color, but edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'flat'`
	• `CData`: `m`-by-`n`-by-3 matrix of truecolor values, from 0 to 1
	• Color source: truecolor
	• `CDataMapping`: `'direct'` or `'scaled'`.
	`'scaled'` is the default value, but neither affects the outcome.
		`clear cdata`
		`cdata(:,:,1) = [0 0 1 0 0.8;`
		`0 0 1 0.2 0.6;`
		`0 1 0 0.4 1];`
		
		`cdata(:,:,2) = [0 0 0 0 0.8;`
		`1 1 1 0.2 0.6;`
		`1 0 0 0.4 0];`
		
		`cdata(:,:,3) = [1 1 1 0 0.8;`
		`0 1 0 0.2 0.6;`
		`1 0 1 0.4 0];`
		`set(p,'FaceColor','flat',...`
		`'CData',cdata,...`
		`'EdgeColor','interp',...`
		`'LineWidth',5)`

Desired Look	Parameter Values	Sample Code

Each vertex has a single, unique color, indexed from a selected section of the colormap. Edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'interp'`
	• `CData`: `m`-by-`n` matrix of index values
	• Color source: A selected portion of the `colormap`
	• `CDataMapping`: `'scaled'`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 60;`
		`12 23 40 13 26;`
		`24 8 1 65 42];`
		`set(p,'FaceColor','interp',...`
		`'CData',cdata,...`
		`'EdgeColor','flat',...`
		`'LineWidth',5,...`
		`'CDataMapping','scaled')`

Desired Look	Parameter Values	Sample Code

Each vertex has a single, unique color, indexed from the whole colormap. Edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'interp'`
	• `CData`: `m`-by-`n` matrix of index values
	• Color source: `colormap`
	• `CDataMapping`: `'direct'`
	
	`'scaled'` is the default value when you input `CData` values. If you want to change the axes `CLim` property, but want your patch object to index the entire colormap, use `'CDataMapping','dire`
		`clear cdata`
		`set(gca,'CLim',[0 40])`
		`cdata = [15 30 25 2 60;`
		`12 23 40 13 26;`
		`24 8 1 65 42];`
		`set(p,'FaceColor','interp',...`
		`'CData',cdata,...`
		`'CDataMapping','direct',...`
		`'EdgeColor','flat',...`
		`'LineWidth',5)`

Desired Look	Parameter Values	Sample Code

Each vertex has a single, unique color, determined by truecolor value input. Edges may have `'flat'` or `'interp'` color.
 	• `FaceColor`: `'interp'`
	• `CData`: `m`-by-`n`-by-3 matrix of truecolor values, from 0 to 1
	• Color source: truecolor
	• `CDataMapping`: `'direct'` or `'scaled'`.
	`'scaled'` is the default value, but neither affects the outcome.
		`clear cdata`
		`cdata(:,:,1) = [0.8 0.1 0.2`
		`  0.9 0.3 1;`
		`  0.1 0.5 0.9;`
		`  0.9 1 0.5;`
		`  0.6 0.9 0.8];`
		
		`cdata(:,:,2) =[0.1 0.6 0.7;`
		`  0.4 0.1 0.7;`
		`  0.9 0.8 0.3;`
		`  0.7 0.9 0.6;`
		`  0.9 0.6 0.1];`
		
		`cdata(:,:,3) =[0.7 0.8 0.4;`
		`  0.1 0.6 0.3;`
		`  0.2 0.3 0.7;`
		`  0.0 0.9 0.7;`
		`  0.0 0.0 0.1];`
		`set(p,'FaceColor','interp',...`
		`'CData',cdata,...`
		`'EdgeColor','interp',...`
		`'LineWidth',5)`

Introduced before R2006a

Patch Properties

Control patch appearance and behavior

Patch properties control the appearance and behavior of patch objects. By changing property values, you can modify certain aspects of the patch.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = patch;
c = h.CData;
h.CDataMapping = 'scaled';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Faces

`FaceColor` — Face color

`[0 0 0]` (default) | `'none'` | `'flat'` | `'interp'` | RGB triplet or color string

Face color, specified as one of these values:

- `'none'` — Do not draw the faces.
- `'flat'` — Uniform face colors. Use the CData values. The color data at the first vertex determines the color for the entire face. You must first specify `CData` or `FaceVertexCData` as an array containing one value per face.
- `'interp'` — Vary the color across each face. Use a bilinear interpolation of the CData values at each vertex. You must first specify `CData` or `FaceVertexCData` as an array containing one value per vertex.
- RGB triplet or color string — Same color for all of the faces.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`

Long Name	Short Name	RGB Triplet
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

`FaceAlpha` — Face transparency

1 (default) | scalar in range `[0,1]` | `'flat'` | `'interp'`

Face transparency, specified as one of these values:

- Scalar in range `[0,1]` — Use the same transparency value for all of the faces. A value of `1` is fully opaque and `0` is completely transparent.
- `'flat'` — Use uniform transparency across each face. The alpha data at the first vertex determines the transparency for the entire face. You must first specify the `FaceVertexAlphaData` property as an array containing one alpha value per face.
- `'interp'` — Vary the transparency across each face. Bilinear interpolation of the `AlphaData` values at each vertex determines the transparency values. You must first specify the FaceVertexAlphaData property as an array containing one alpha value per vertex.

`FaceLighting` — Effect of light objects on faces

`'flat'` (default) | `'gouraud'` | `'none'`

Effect of light objects on faces, specified as one of these values:

- `'flat'` — Apply light uniformly across the faces. Use this value to view faceted objects.
- `'gouraud'` — Vary the light across the faces. Calculate the light at the vertices and then linearly interpolate the light across the faces. Use this value to view curved surfaces.
- `'none'` — Do not apply light from light objects to the faces.

Note: The `'phong'` value has been removed. Use `'gouraud'` instead.

`BackFaceLighting` — Face lighting when normals point away from camera

`'reverslit'` (default) | `'unlit'` | `'lit'`

Face lighting when the vertex normals point away from camera, specified as one of these values:

- `'reverslit'` — Light the face as if the vertex normal pointed towards the camera.
- `'unlit'` — Do not light the face.
- `'lit'` — Light the face according to the vertex normal.

Use this property to discriminate between the internal and external surfaces of an object. For an example, see “Back Face Lighting”.

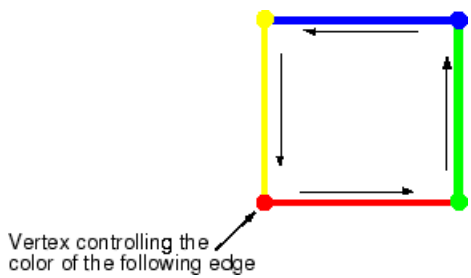
Edges

`EdgeColor` — Edge color of the patch faces

`[0 0 0]` (default) | `'none'` | `'flat'` | `'interp'` | RGB triplet or color string

Color of the edges of the patch faces, specified as one of these values:

- `'none'` — Do not draw edges.
- `'flat'` — Use the color of each vertex to set the color of the edge that follows it. This means that the edge coloring is dependent on the order in which you specify the vertices:



- `'interp'` — Linearly interpolate the `CData` or `FaceVertexCData` values at the vertices determines the edge color.
- RGB triplet or a color string — Use the same color for all edges.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

`[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'flat'`

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	
`':'`	Dotted line	
`'-.'`	Dash-dotted line	
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`EdgeAlpha` — Transparency of patch face edges

`1` (default) | scalar value in range `[0,1]` | `'flat'` | `'interp'`

Transparency of patch face edges, specified as one of these values:

- Scalar value in range `[0,1]` — Use the same transparency value for all of the edges.. A value of `1` is fully opaque and `0` is completely transparent.
- `'flat'` — Uniform transparency along each edge. Before you set EdgeAlpha to `'flat'`, you must first define FaceVertexAlphaData as an array containing one alpha value per face. The alpha data of each vertex controls the transparency of the edge that follows it.
- `'interp'` — Very the transparency along edge segment. Before you set EdgeAlpha to `'interp'`, you must first define FaceVertexAlphaData as an array containing one alpha value per vertex. Linear interpolation of the alpha data at each vertex determines the transparency of the edge connecting those vertices.

`EdgeLighting` — Effect of light objects on edges

`'none'` (default) | `'flat'` | `'gouraud'`

Effect of light objects on edges, specified as one of these values:

- `'flat'` — Apply light uniformly across the each edges.
- `'none'` — Do not apply lights from light objects to the edges.
- `'gouraud'` — Calculate the light at the vertices, and then linearly interpolate across the edges.

Note: The `'phong'` value has been removed. Use `'gouraud'` instead.

`AlignVertexCenters` — Sharp vertical and horizontal lines

`'off'` (default) | `'on'`

Sharp vertical and horizontal lines, specified as `'off'` or `'on'`.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the patch object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | `'flat'` | RGB triplet or color string

Marker outline color, specified as specified as one of these values:

- `'auto'` — Use the same color as the EdgeColor property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- `'flat'` — Use the CData value at the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | `'flat'` | RGB triplet or color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which allows the background to show through.

- `'auto'` — Use the same color as the `Color` property for the axes.
- `'flat'` — Use the CData value of the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

This property affects only the circle, square, diamond, pentagram, hexagram, and the four triangle marker types.

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Example:

`MarkerSize` — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

Face and Vertex Normals

`FaceNormals` — Face normal vectors

m-by-n-by-3 array (default) | array of normal vectors

Face normal vectors, specified as an array of normal vectors with one normal vector one per patch face. Define one normal per patch face, as determined by the size of the Faces property value. Face normals determine the orientation of each patch face. This data is used for lighting calculations.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the patch generates this data when the axes contains light objects. The patch computes face normals using Newell's method.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`VertextNormals` — Vertex normal vectors

m-by-n-by-3 array (default) | array of normal vectors

Vertex normal vectors, specified as an array of normal vectors with one normal vector one per patch vertex. Define one normal per patch vertex, as determined by the size of the Vertices property value. Vertex normals determine the shape and orientation of the patch. This data is used for lighting calculations.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the patch generates this data when the axes contains light objects.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FaceNormalsMode` — Selection mode for `FaceNormals`

`'auto'` (default) | `'manual'`

Selection mode for `FaceNormals`, specified as one of these values:

- `'auto'` — The `patch` function calculates face normals when you add a light to the scene.
- `'manual'` — Use the face normal data specified by the FaceNormals property. Assigning values to the FaceNormals property sets FaceNormalsMode to `'manual'`.

`VertexNormalsMode` — Selection mode for `VertexNormals`

`'auto'` (default) | `'manual'`

Selection mode for `VertexNormals`, specified as one of these values:

- `'auto'` — The `patch` function calculates vertex normals when you add a light to the scene.

- `'manual'` — Use the vertex normal data specified by the VertexNormals property. Assigning values to the VertexNormals property sets VertexNormalsMode to `'manual'`.

Ambient Lighting

`AmbientStrength` — Strength of ambient light

`0.3` (default) | scalar in range `[0,1]`

Strength of ambient light, specified as a scalar value in the range `[0,1]`. Ambient light is a nondirectional light that illuminates the entire scene. There must be at least one visible light object in the axes for the ambient light to be visible.

The `AmbientLightColor` property for the axes sets the color of the ambient light. The color is the same for all objects in the axes.

Example: `0.5`

Data Types: `double`

`DiffuseStrength` — Strength of diffuse light

`0.6` (default) | scalar in range `[0,1]`

Strength of diffuse light, specified as a scalar value in the range `[0,1]`. Diffuse light is the nonspecular reflectance from light objects in the axes.

Example: `0.3`

Data Types: `double`

`SpecularStrength` — Strength of specular reflection

`0.9` (default) | scalar in range `[0,1]`

Strength of specular reflection, specified as a scalar value in the range `[0,1]`. Specular reflections are the bright spots on the surface from light objects in the axes.

Example: `0.3`

Data Types: `double`

`SpecularColorReflectance` — Color of specular reflections

`1` (default) | scalar between `0` and `1` inclusive

Color of specular reflections, specified as a scalar between `0` and `1` inclusive.

- `0` — The color of the specular reflection depends on both the color of the object from which it reflects and the color of the light source.
- `1` — The color of the specular reflection depends only on the color or the light source (that is, the light object `Color` property).

The contributions from the light source color and the patch color to the specular reflection color vary linearly for values between `0` and `1`.

Example: `0.5`

Data Types: `single | double`

`SpecularExponent` — Expansiveness of specular reflection

`10` (default) | scalar value greater than `0`

Expansiveness of specular reflection, specified as a scalar value greater than `0`. SpecularExponent controls the size of the specular reflection spot. Greater values produce less specular reflection.

Most materials have exponents in the range of `5` to `20`.

Example: `17`

Data Types: `double`

Color and Transparency Mapping

`FaceVertexAlphaData` — Face and vertex transparency data

`[ ]` (default) | single transparency value | column vector of transparency values

Face and vertex transparency data, specified in one of these forms:

- A single transparency value, which applies the same transparency to the entire patch. The FaceAlpha property must be set to `'flat'`.
- An m-by-1 array (where m is the number of rows in the Faces property), which specifies one transparency value per face. The FaceAlpha property must be set to `'flat'`.
- An m-by-1 array (where m is the number of rows in the Vertices property), which specifies one transparency value per vertex. The FaceAlpha property must be set to `'interp'`.

The AlphaDataMapping property determines how MATLAB interprets the FaceVertexAlphaData property values.

`AlphaDataMapping` — Transparency mapping method

`'scaled'` (default) | `'direct'` | `'none'`

Transparency mapping method, specified as one of these values:

- `'none'` — Clamps the elements of FaceVertexAlphaData to the region between `0` and `1`. A value of `1` or greater means completely opaque, a value of `0` or less means completely transparent, and a value between `0` and `1` means semitransparent.
- `'scaled'` — Transforms the FaceVertexAlphaData to span the portion of the figure alphamap indicated by the axes `ALim` property, linearly mapping data values to alpha values.
- `'direct'` — Uses the FaceVertexAlphaData as indices directly into the figure alphamap, which is determined by the figure `Alphamap` property. Values with a decimal portion are fixed to the nearest lower integer. MATLAB maps values less than 1 to the first value in the alphamap and values greater than `length(alphamap)` to the last value in the alphamap. If FaceVertexAlphaData is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the alphamap).

`FaceVertexCData` — Face and vertex colors

`[ ]` (default) | single color for entire patch | one color per face | one color per vertex

Face and vertex colors, specified as a single color for the entire patch, one color per face, or one color per vertex for interpolated face color.

If you want to use indexed colors, then specify FaceVertexCData in one of these forms:

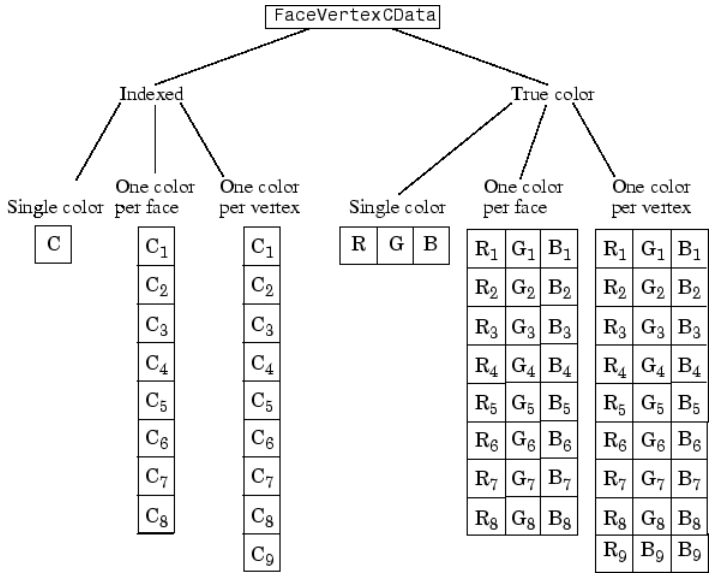
- For one color for the entire patch, use a single value.
- For one color per face, use an m-by-1 column vector, where m is the number of rows in the Faces property.
- For interpolated face color, use an m-by–1 column vector where m is the number of rows in the Vertices property.

If you want to use true colors, then specify FaceVertexCData in one of these forms:

- For one color for the entire patch, use a three-element row vector defining an RGB triplet.

- For one color per face, use an m-by-3 array of RBG triplets, where m is the number of rows in the Faces property.
- For interpolated face color, use an m-by-3 array, where m is the number of rows in the Vertices property.

The following diagram illustrates the various forms of the FaceVertexCData property for a patch having eight faces and nine vertices. The CDataMapping property determines how MATLAB interprets the FaceVertexCData property when you specify indexed colors.



`CData` — Patch color data

single color for entire patch | one color per face | one color per vertex

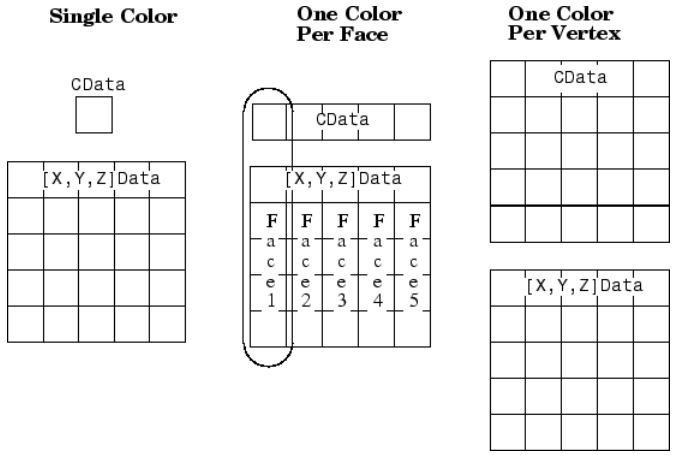
Patch color data, specified as a single color for the entire patch, one color per face, or one color per vertex.

The way the `patch` function interprets CData depends on the type of data supplied. Specify `CData` in one of these forms:

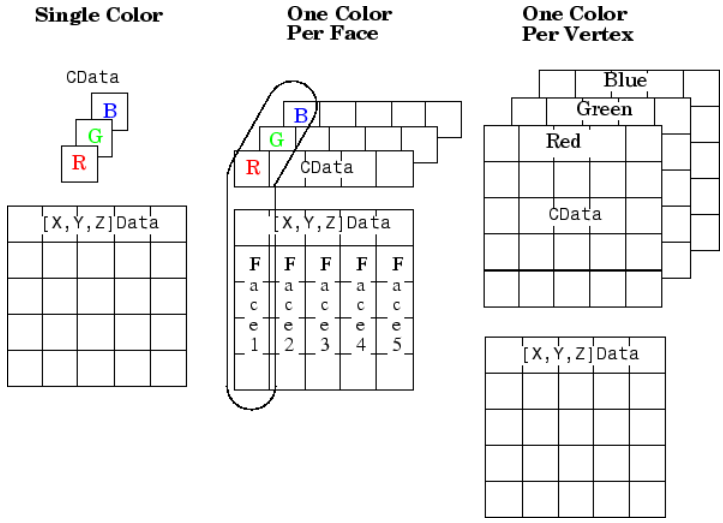
- Numeric values that are scaled to map linearly into the current colormap.
- Integer values that are used directly as indices into the current colormap.
- Arrays of RGB triplets. RGB triplets are not mapped into the current colormap, but interpreted as the colors defined.

The following diagrams illustrate the dimensions of `CData` with respect to the arrays in the `XData`, `YData`, and `ZData` properties.

These diagrams illustrates the use of indexed color.



These diagrams illustrates the use of true color. True color requires either a single RGB triplet or an array of RGB triplets.



If CData contains NaNs, then `patch` does not color the faces.

An alternative method for defining patches uses the `Faces`, `Vertices`, and `FaceVertexCData` properties.

Example: `[1,0,0]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CDataMapping` — Direct or scaled color data mapping

`'scaled'` (default) | `'direct'`

Direct or scaled color data mapping, specified as `'scaled'` (the default) or `'direct'`. The `CData` and FaceVertexCData properties contains color data. If you use true color specification for CData or FaceVertexCData, then this property has no effect.

- `'direct'` — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of `1` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
  - If the values are of type `uint8`, `uint16`, `uint32`, `uint64` , `int8`, `int16`, `int32`, or `int64`, then values of `0` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
  - If the values are of type `logical`, then values of `0` map to the first color in the colormap and values of `1` map to the second color in the colormap.
- `'scaled'` — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

Data

`XData` — x-coordinates of the patch vertices

vector | matrix

The *x*-coordinates of the patch vertices, specified as a vector or a matrix. If XData is a matrix, then each column represents the *x*-coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`YData` — y-coordinates of the patch vertices

vector | matrix

The *y*-coordinates defining the patch, specified as a vector or a matrix. If YData is a matrix, then each column represents the *y*-coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ZData` — z-coordinates of the patch vertices

vector | matrix

The *z*-coordinates of the patch vertices, specified as a vector or a matrix. If ZData is a matrix, then each column represents the *z*-coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

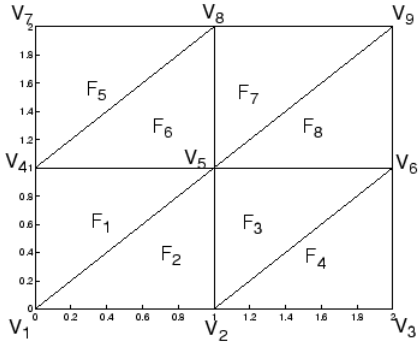
`Faces` — Vertex connection defining each face

vector | matrix

Vertex connection defining each face, specified as a vector or a matrix defining the vertices in the Vertices property that are to be connected to form each face. The Faces and Vertices properties provide an alternative way to specify a patch that can be more efficient than using XData, YData, and ZData coordinates in most cases.

Each row in the faces array designates the connections for a single face, and the number of elements in that row that are not `NaN` defines the number of vertices for that face. Therefore, an m-by-n Faces array defines m faces with up to n vertices each.

For example, consider the following patch. It is composed of eight triangular faces defined by nine vertices. The corresponding Faces and Vertices properties are shown to the right of the patch. Note how some faces share vertices with other faces. For example, the fifth vertex (`V5`) is used six times, once each by faces one, two, three, six, seven, and eight. Without sharing vertices, this same patch requires `24` vertex definitions.



Faces property

F1	V1	V4	V5
F2	V1	V5	V2
F3	V2	V5	V6

V2	X2	Y2	Z2
V3	X3	Y3	Z3
V4	X4	Y4	Z4
V5	X5	Y5	Z5
V6	X6	Y6	Z6
V7	X7	Y7	Z7
V8	X8	Y8	Z8
V9	X9	Y9	Z9

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Vertices` — Vertex coordinates

vector | matrix

Vertex coordinates, specified as a vector or a matrix defining the (*x*,*y*,*z*) coordinates of each vertex. The Faces and Vertices properties provide an alternative way to specify a patch that can be more efficient than using XData, YData, and ZData coordinates in most cases. See the `Faces` property for a description of how the vertex data is used.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Visibility

`Visible` — Visibility of patch

`'on'` (default) | `'off'`

Visibility of patch, specified as one of these values:

- `'on'` — Display the patch.
- `'off'` — Hide the patch without deleting it. You still can access the properties of an invisible patch object.

`Clipping` — Clipping of patch to axes limits

`'on'` (default) | `'off'`

Clipping of patch to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the patch that are outside the axes limits.
- `'off'` — Display the entire patch, even if parts of it appear outside the axes limits. Parts of the patch might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the patch that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the

printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'patch'`

Type of graphics object, returned as `'patch'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — User-specified tag

`''` (default) | string

Tag to associate with the patch, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with patch

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the patch object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the patch.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the patch object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the patch from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the patch object in the legend as one entry (default).
   - `'off'` — Do not include the patch object in the legend.
   - `'children'` — Include only children of the patch object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of patch

axes object | group object | transform object

Parent of patch, specified as an axes, group, or transform object.

`Children` — Children of patch

empty `GraphicsPlaceholder` array

The patch has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of patch object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The patch object handle is always visible.
- `'off'` — The patch object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The patch object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the patch at the command-line, but allows callback functions to access it.

If the patch object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the patch. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the patch. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the patch when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the patch.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected
`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks
`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the patch that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the patch responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'` and you can click a part of the patch that has no color. The HitTest property determines if the patch responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the patch passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

`HitTest` — Response to captured mouse clicks
`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the patch. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the patch that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the patch object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the patch is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.

  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the patch tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the patch. Setting the `CreateFcn` property on an existing patch has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during patch creation. MATLAB executes the callback after creating the patch and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function. You also can access the patch object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the patch. MATLAB executes the callback before destroying the patch so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The patch object — You can access properties of the patch object from within the callback function. You also can access the patch object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of patch

`'off'` (default) | `'on'`

Deletion status of patch, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the patch begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the patch no longer exists.

Check the value of the BeingDeleted property to verify that the patch is not about to be deleted before querying or modifying it.

path

View or change search path

Alternatives

As an alternative to the `path` function, use the Set Path dialog box.

Syntax

```
path
path('newpath')
path(path,'newpath')
path('newpath',path)
p = path
```

Description

`path` displays the MATLAB search path, which is stored in `pathdef.m`.

`path('newpath')` changes the search path to `newpath`, where `newpath` is a string array of folders.

`path(path,'newpath')` adds the `newpath` folder to the end of the search path. If `newpath` is already on the search path, then `path(path,'newpath')` moves `newpath` to the end of the search path.

`path('newpath',path)` adds the `newpath` folder to the top of the search path. If `newpath` is already on the search path, then `path('newpath',path)` moves `newpath` to the top of the search path. To add multiple folders in one statement, instead use `addpath`.

`p = path` returns the search path to string variable `p`.

Examples

Display the search path:

```
path
```

MATLAB returns, for example

```
MATLABPATH

 H:\My Documents\MATLAB
 C:\Program Files\MATLAB\R2ONnn\toolbox\matlab\general
 C:\Program Files\MATLAB\R2ONnn\toolbox\matlab\ops
 C:\Program Files\MATLAB\R2ONnn\toolbox\matlab\lang
 C:\Program Files\MATLAB\R2ONnn\toolbox\matlab\elmat
 C:\Program Files\MATLAB\R2ONnn\toolbox\matlab\elfun
...
```

`R2ONnn` represents the folder for the MATLAB release, for example, `R2009b`.

Add a new folder to the search path on Microsoft Windows platforms:

```
path(path,'c:/tools/goodstuff')
```

Add a new folder to the search path on UNIX[3] platforms:

```
path(path,'/home/tools/goodstuff')
```

Temporarily add the folder `my_files` to the search path, run `my_function` in `my_files`, then restore the previous search path:

```
p = path
path(p,'my_files')
my_function
path(p)
```

Introduced before R2006a

path2rc

Save current search path to `pathdef.m` file

Syntax

```
path2rc
```

Description

`path2rc` runs `savepath`. The `savepath` function is replacing `path2rc`. Use `savepath` instead of `path2rc` and replace instances of `path2rc` with `savepath`.

Introduced before R2006a

pathsep

Search path separator for current platform

Syntax

```
c = pathsep
```

Description

`c = pathsep` returns the search path separator character for this platform. The search path separator is the character that separates path names in the `pathdef.m` file, as returned by the `path` function. The character is a semicolon (`;`). For versions of MATLAB software earlier than version 7.7 (R2008b), the character on UNIX[4] platforms was a colon (`:`). Use `pathsep` to work programmatically with the content of the search path file.

pathtool

Open Set Path dialog box to view and change search path

Syntax

```
pathtool
```

Description

`pathtool` opens the Set Path dialog box, a graphical user interface you use to view and modify the MATLAB search path.

Introduced before R2006a

pause

Halt execution temporarily

Syntax

```
pause
pause(n)
pause on
pause off
pause query
state = pause('query')
oldstate = pause(newstate)
```

Description

`pause`, by itself, causes the currently executing function to stop and wait for you to press any key before continuing. Pausing must be enabled for this to take effect. (See `pause on`, below). `pause` without arguments also blocks execution of Simulink models, but not repainting of them.

`pause(n)` pauses execution for `n` seconds before continuing, where `n` is any nonnegative real number. Pausing must be enabled for this to take effect.

Typing `pause(inf)` puts you into an infinite loop. To return to the MATLAB prompt, type **Ctrl+C**.

`pause on` enables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. Pausing remains enabled until you enter `pause off` in your function or at the command line.

`pause off` disables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. This allows normally interactive scripts to run unattended. Pausing remains disabled until you enter `pause on` in your function or at the command line, or start a new MATLAB session.

`pause query` displays `'on'` if pausing is currently enabled. Otherwise, it displays `'off'`.

`state = pause('query')` returns `'on'` in character array `state` if pausing is currently enabled. Otherwise, the value of `state` is `'off'`.

`oldstate = pause(newstate)`, enables or disables pausing, depending on the `'on'` or `'off'` value in `newstate`, and returns the former setting (also either `'on'` or `'off'`) in character array `oldstate`.

More About

Tips

The accuracy of `pause` is subject to the scheduling resolution of the operating system you are using, and also to other system activity. It cannot be guaranteed with 100% confidence. Asking for finer resolutions shows higher relative error.

While MATLAB is paused, the following continue to execute:

- Repainting of figure windows, Simulink block diagrams, and Java windows
- HG callbacks from figure windows
- Event handling from Java windows

`keyboard` | `input` | `drawnow`

Introduced before R2006a

pbaspect

Set or query plot box aspect ratio

Syntax

```
pbaspect
pbaspect([aspect_ratio])
pbaspect('mode')
pbaspect('auto')
pbaspect('manual')
pbaspect(axes_handle,...)
```

Description

The plot box aspect ratio determines the relative size of the *x*-, *y*-, and *z*-axes.

`pbaspect` with no arguments returns the plot box aspect ratio of the current axes.

`pbaspect([aspect_ratio])` sets the plot box aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the *x*-, *y*-, and *z*-axes size. For example, a value of `[1 1 1]` (the default) means the plot box is a cube (although with stretch-to-fill enabled, it may not appear as a cube). See Tips.

`pbaspect('mode')` returns the current value of the plot box aspect ratio mode, which can be either `auto` (the default) or `manual`. See Remarks.

`pbaspect('auto')` sets the plot box aspect ratio mode to `auto`.

`pbaspect('manual')` sets the plot box aspect ratio mode to `manual`.

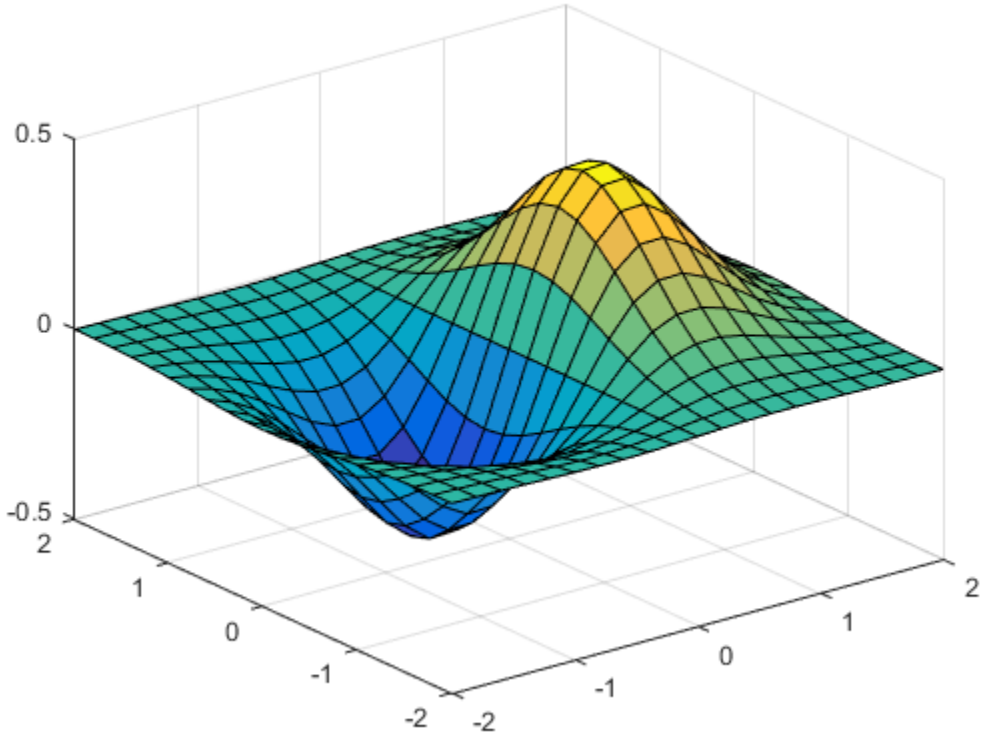
`pbaspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. If you do not specify an axes handle, `pbaspect` operates on the current axes.

Examples

Query Plot Box Aspect Ratio

Plot the function $z = xe^{(-x^2-y^2)}$ over the range $-2 \le x \le 2$ and $-2 \le y \le 2$.

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
```



Query the plot box aspect ratio to show that the plot box is square.

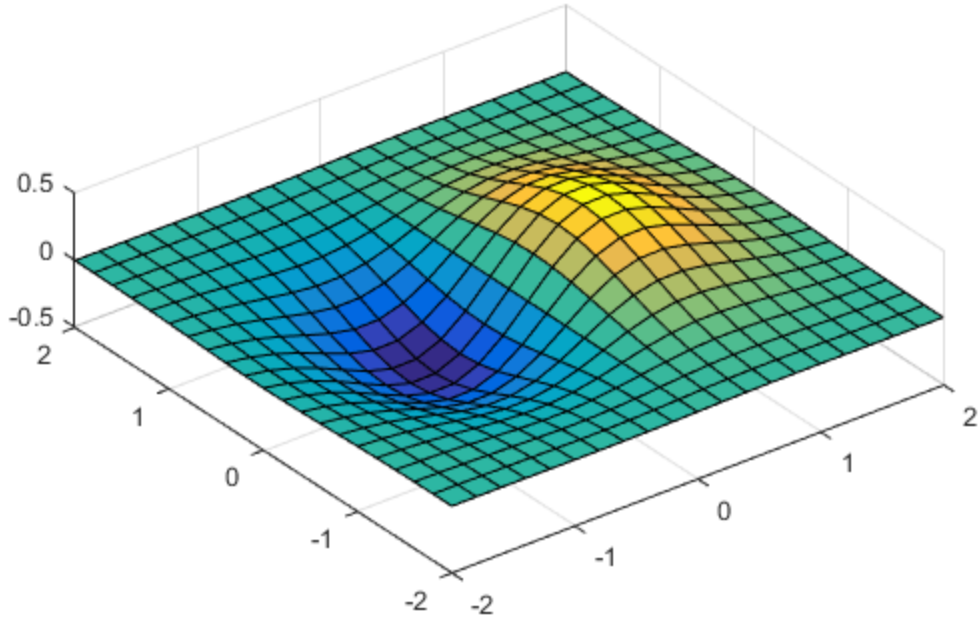
```
plotboxaspect = pbaspect
```

```
plotboxaspect =

    1.0000    0.9419    0.8518
```

Change the data aspect ratio.

```
daspect([1,1,1])
```



Query the plot box aspect ratio to show how it changes to accommodate the specified data aspect ratio.

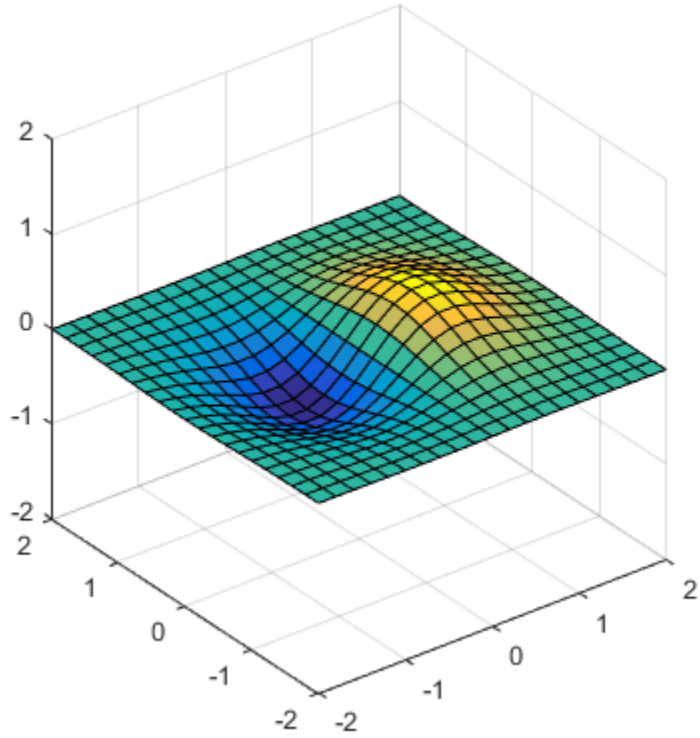
```
plotboxaspect = pbaspect
```

```
plotboxaspect =

     4     4     1
```

Make the plot box square again by changing the plot box aspect ratio to `[1,1,1]`.

```
pbaspect([1,1,1])
```



More About

Tips

`pbaspect` sets or queries values of the axes object `PlotBoxAspectRatio` and `PlotBoxAspectRatioMode` properties.

When the plot box aspect ratio mode is `auto`, the MATLAB software sets the ratio to `[1 1 1]`, but may change it to accommodate manual settings of the data aspect ratio, camera view angle, or axis limits. See the axes `DataAspectRatio` property for a table listing the interactions between various properties.

Setting a value for the plot box aspect ratio or setting the plot box aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the plot box aspect ratio to its current value,

```
pbaspect(pbaspect)
```

can cause a change in the way the graphs look. See the Remarks section of the `axes` reference description, “Axes Aspect Ratio Properties” in the 3-D Visualization manual, and “Setting Aspect Ratio” in the MATLAB Graphics manual for a discussion of stretch-to-fill.

- Setting Aspect Ratio

Introduced before R2006a

pcg

Preconditioned conjugate gradients method

Syntax

```
x = pcg(A,b)
pcg(A,b,tol)
pcg(A,b,tol,maxit)
pcg(A,b,tol,maxit,M)
pcg(A,b,tol,maxit,M1,M2)
pcg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = pcg(A,b,...)
[x,flag,relres] = pcg(A,b,...)
[x,flag,relres,iter] = pcg(A,b,...)
[x,flag,relres,iter,resvec] = pcg(A,b,...)
```

Description

`x = pcg(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be symmetric and positive definite, and should also be large and sparse. The column vector `b` must have length `n`. You also can specify `A` to be a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `pcg` converges, a message to that effect is displayed. If `pcg` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`pcg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `pcg` uses the default, `1e-6`.

`pcg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `pcg` uses the default, `min(n,20)`.

`pcg(A,b,tol,maxit,M)` and `pcg(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `pcg` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`pcg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `pcg` uses the default, an all-zero vector.

`[x,flag] = pcg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`pcg` converged to the desired tolerance `tol` within `maxit` iterations.
1	`pcg` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`pcg` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `pcg` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = pcg(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = pcg(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = pcg(A,b,...)` also returns a vector of the residual norms at each iteration including `norm(b-A*x0)`.

Examples

Using pcg with Large Matrices

This example shows how to use pcg with a matrix input and with a function handle.

```
n1 = 21;
A = gallery('moler',n1);
b1 = sum(A,2);
tol = 1e-6;
maxit = 15;
M1 = spdiags((1:n1)',0,n1,n1);
[x1,flag1,rr1,iter1,rv1] = pcg(A,b1,tol,maxit,M1);
```

Alternatively, you can use the following function in place of the matrix A:

```
function y = applyMoler(x)
y = x;
y(end-1:-1:1) = y(end-1:-1:1) - cumsum(y(end:-1:2));
y(2:end) = y(2:end) - cumsum(y(1:end-1));
```

By using this function, you can solve larger systems more efficiently as there is no need to store the entire matrix A:

```
n2 = 21;
b2 = applyMoler(ones(n2,1));
tol = 1e-6;
maxit = 15;
M2 = spdiags((1:n2)',0,n2,n2);
[x2,flag2,rr2,iter2,rv2] = pcg(@applyMoler,b2,tol,maxit,M2);
```

Using pcg with a Preconditioner

This example demonstrates how to use a preconditioner matrix with pcg.

Create an input matrix and try to solve the system with pcg.

```
A = delsq(numgrid('S',100));
b = ones(size(A,1),1);
[x0,fl0,rr0,it0,rv0] = pcg(A,b,1e-8,100);
```

fl0 is 1 because pcg does not converge to the requested tolerance of 1e-8 within the requested maximum 100 iterations. A preconditioner can make the system converge more quickly.

Use ichol with only one input argument to construct an incomplete Cholesky factorization with zero fill.

```
L = ichol(A);
```

```
[x1,fl1,rr1,it1,rv1] = pcg(A,b,1e-8,100,L,L');
```

`fl1` is `0` because `pcg` drives the relative residual to `9.8e-09` (the value of `rr1`) which is less than the requested tolerance of `1e-8` at the seventy-seventh iteration (the value of `it1`) when preconditioned by the zero-fill incomplete Cholesky factorization. `rv1(1) = norm(b)` and `rv1(78) = norm(b-A*x1)`.

The previous matrix represents the discretization of the Laplacian on a 100x100 grid with Dirichlet boundary conditions. This means that a modified incomplete Cholesky preconditioner might perform even better.

Use the `michol` option to create a modified incomplete Cholesky preconditioner.

```
L = ichol(A,struct('michol','on'));
[x2,fl2,rr2,it2,rv2] = pcg(A,b,1e-8,100,L,L');
```

In this case you attain convergence in only forty-seven iterations.

You can see how the preconditioners affect the rate of convergence of `pcg` by plotting each of the residual histories starting from the initial estimate (iterate number `0`).

```
figure;
semilogy(0:it0,rv0/norm(b),'b.');
hold on;
semilogy(0:it1,rv1/norm(b),'r.');
semilogy(0:it2,rv2/norm(b),'k.');
legend('No Preconditioner','IC(0)','MIC(0)');
xlabel('iteration number');
ylabel('relative residual');
hold off;
```

pchip

Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)

Syntax

```
yi = pchip(x,y,xi)
pp = pchip(x,y)
```

Description

`yi = pchip(x,y,xi)` returns vector `yi` containing elements corresponding to the elements of `xi` and determined by piecewise cubic interpolation within vectors `x` and `y`. The vector `x` specifies the points at which the data `y` is given, so `x` and `y` must have the same length. If `y` is a matrix or array, then the values in the last dimension, `y(:,...,:,j)`, are taken as the values to match with `x`. In that case, the last dimension of `y` must be the same length as `x`. If `y` has `n` dimensions, then output `yi` is of size `[size(y,1) size(y,2) ... size(y,n-1) length(xi)]`. For example, if `y` is a matrix, then `yi` is of size `[size(y,1) length(xi)]`.

`pp = pchip(x,y)` returns a piecewise polynomial structure for use by `ppval`. `x` can be a row or column vector. `y` is a row or column vector of the same length as `x`, or a matrix with `length(x)` columns.

`pchip` finds values of an underlying interpolating function $P(x)$ at intermediate points, such that:

- On each subinterval $x_k \le x \le x_{k+1}$, $P(x)$ is the cubic Hermite interpolant to the given values and certain slopes at the two endpoints.
- $P(x)$ interpolates y, i.e., $P(x_j) = y_j$, and the first derivative $\frac{dP}{dx}$ is continuous. The second derivative $\frac{d^2P}{dx^2}$ is probably not continuous; there may be jumps at the x_j.

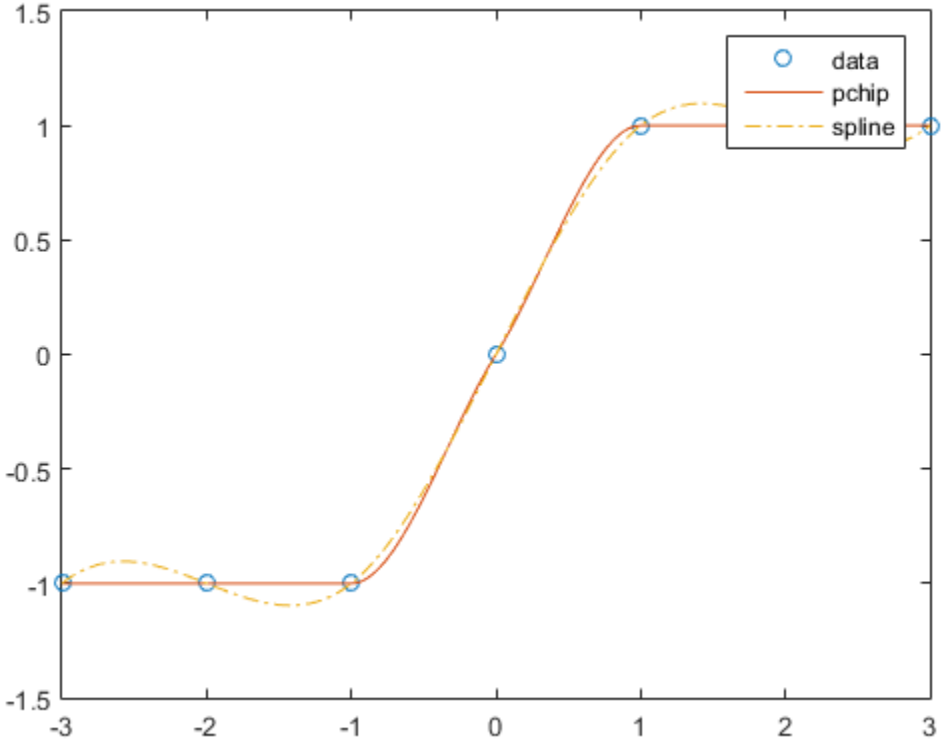
- The slopes at the x_j are chosen in such a way that $P(x)$ preserves the shape of the data and respects monotonicity. This means that, on intervals where the data are monotonic, so is $P(x)$; at points where the data has a local extremum, so does $P(x)$.

Note If y is a matrix, $P(x)$ satisfies the above for each column of y.

Examples

Data Interpolation Using `spline` and `pchip`

```
x = -3:3;
y = [-1 -1 -1 0 1 1 1];
t = -3:.01:3;
p = pchip(x,y,t);
s = spline(x,y,t);
plot(x,y,'o',t,p,'-',t,s,'-.')
legend('data','pchip','spline',4)
```



More About

Tips

`spline` constructs $S(x)$ in almost the same way `pchip` constructs $P(x)$. However, `spline` chooses the slopes at the x_j differently, namely to make even $S''(x)$ continuous. This has the following effects:

- `spline` produces a smoother result, i.e. $S''(x)$ is continuous.

- `spline` produces a more accurate result if the data consists of values of a smooth function.
- `pchip` has no overshoots and less oscillation if the data are not smooth.
- `pchip` is less expensive to set up.
- The two are equally expensive to evaluate.

pcode

Create protected function file

Syntax

```
pcode(fun)
pcode(fun1,...,funN)
pcode(fun,'-inplace')
```

Description

`pcode(fun)` obfuscates the code in `fun.m` and produces a file called `fun.p`, known as a P-file. If `fun` is a folder, then all the script or function files in that folder are obfuscated in P-files. MATLAB creates the P-files in the current folder. The original `.m` file or folder can be anywhere on the search path.

`pcode(fun1,...,funN)` creates `N` P-files from the listed files. If any inputs are folders, then MATLAB creates a P-file for every `.m` file the folders contain.

`pcode(fun,'-inplace')` creates P-files in the same folder as the script or function files.

Note: The `pcode` function *obfuscates* your `.m` files, it does not *encrypt* them. While the content in a `.p` file is difficult to understand, it should not be considered secure. It is not recommended that you P-code files to protect your intellectual property.

Input Arguments

`fun`

MATLAB file or directory containing MATLAB files. If `fun` resides within a package and/or class folder, then `pcode` creates the same package and/or class structure to house the resulting P-files.

An input argument with no file extension and that is not a folder must be a function in the MATLAB path or in the current folder.

When using wild cards `*`, `pcode` ignores all files with extensions other than `.m`.

Default:

Examples

P-Coding Multiple Files

Convert selected files from the `sparfun` folder into P-files.

Create a temporary folder and define an existing path to `.m` files.

```
tmp = tempname;
mkdir(tmp)
cd(tmp)
fun = fullfile(matlabroot,'toolbox','matlab','sparfun','spr*.m');
```

Create the P-files.

```
pcode(fun)
dir(tmp)
```

```
.           ..          sprand.p     sprandn.p    sprandsym.p  sprank.p
```

The temporary folder now contains encoded P-files.

P-Coding Files That Belong to a Package and/or Class

Generate P-files from input files that are part of a package and/or class. This example uses an existing MATLAB example class.

Define `funclass` as an existing a class folder that contains `.m` files.

```
funclass = fullfile(docroot, 'techdoc', 'matlab_oop', ...
    'examples', '@BankAccount')
dir(funclass)
```

```
funclass =

C:\Program Files\MATLAB\R2013a\help\techdoc\matlab_oop\examples\@BankAccount
```

```
.            ..           BankAccount.m
```

Create a temporary folder. This folder has no package or class structure at this time.

```
tmp = tempname;
mkdir(tmp);
cd(tmp);
dir(tmp)
```

```
.            ..
```

Create a P-file for every `.m` file in the path `funclass`. Because the input files are part of a package and/or class, MATLAB creates a folder structure so that the output file belongs to the same package and/or class.

```
pcode(funclass)
dir(tmp)
```

```
.            ..            @BankAccount
```

You see that the P-file resides in the same folder structure.

```
dir('@BankAccount')
```

```
.            ..            BankAccount.p
```

P-Coding In Place

Generate P-files in the same folder as the input files using the option `inplace`

Copy several MATLAB files to a temporary folder.

```
fun = fullfile(matlabroot,'toolbox','matlab','sparfun','spr*.m');
tmp = tempname;
mkdir(tmp);
copyfile(fun,tmp)
dir(tmp)
```

```
.          ..          sprand.m     sprandn.m    sprandsym.m  sprank.m
```

Create P-files in the same folder as the original `.m` files.

```
pcode(tmp,'-inplace')
dir(tmp)
```

```
.            sprand.m     sprandn.m    sprandsym.m  sprank.m
```

```
..          sprand.p     sprandn.p    sprandsym.p  sprank.p
```

More About

Tips

- The `pcode` algorithm was redesigned in MATLAB 7.5 (Release R2007b). You can run older P-files in any current version of MATLAB; however, upcoming releases will not run P-files created before version 7.5. Files generated in 7.5, or later versions, cannot run in MATLAB 7.4 or earlier.
- When obfuscating all files in a folder, `pcode` does not obfuscate any files within subfolders.
- A P-file takes precedence over the corresponding `.m` file for execution, even after modifications to the `.m` file.
- MATLAB does not display any of the help comments that might be in the original `.m` file.

pcolor

Pseudocolor (checkerboard) plot

Syntax

```
pcolor(C)
pcolor(X,Y,C)
pcolor(axes_handles,...)
h = pcolor(...)
```

Description

A pseudocolor plot is a rectangular array of cells with colors determined by `C`. MATLAB creates a pseudocolor plot using each set of four adjacent points in `C` to define a surface rectangle (i.e., cell).

The default `shading` is `faceted`, which colors each cell with a single color. The last row and column of `C` are not used in this case. With `shading interp`, each cell is colored by bilinear interpolation of the colors at its four vertices, using all elements of `C`.

The minimum and maximum elements of `C` are assigned the first and last colors in the colormap. Colors for the remaining elements in `C` are determined by a linear mapping from value to colormap element.

`pcolor(C)` draws a pseudocolor plot. The elements of `C` are linearly mapped to an index into the current colormap. The mapping from `C` to the current colormap is defined by `colormap` and `caxis`.

`pcolor(X,Y,C)` draws a pseudocolor plot of the elements of `C` at the locations specified by `X` and `Y`. The plot is a logically rectangular, two-dimensional grid with vertices at the points `[X(i,j), Y(i,j)]`. `X` and `Y` are vectors or matrices that specify the spacing of the grid lines. If `X` and `Y` are vectors, `X` corresponds to the columns of `C` and `Y` corresponds to the rows. If `X` and `Y` are matrices, they must be the same size as `C`.

`pcolor(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

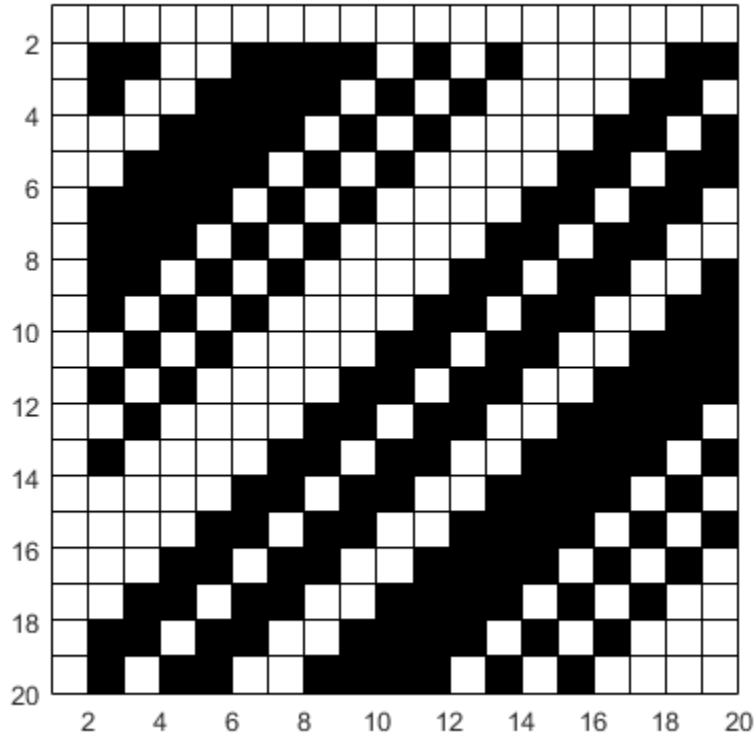
`h = pcolor(...)` returns a handle to a `surface` graphics object.

Examples

Pseudocolor Plot of Hadamard Matrix

A Hadamard matrix has elements that are `+1` and `-1`. A colormap with only two entries is appropriate when displaying a pseudocolor plot of this matrix.

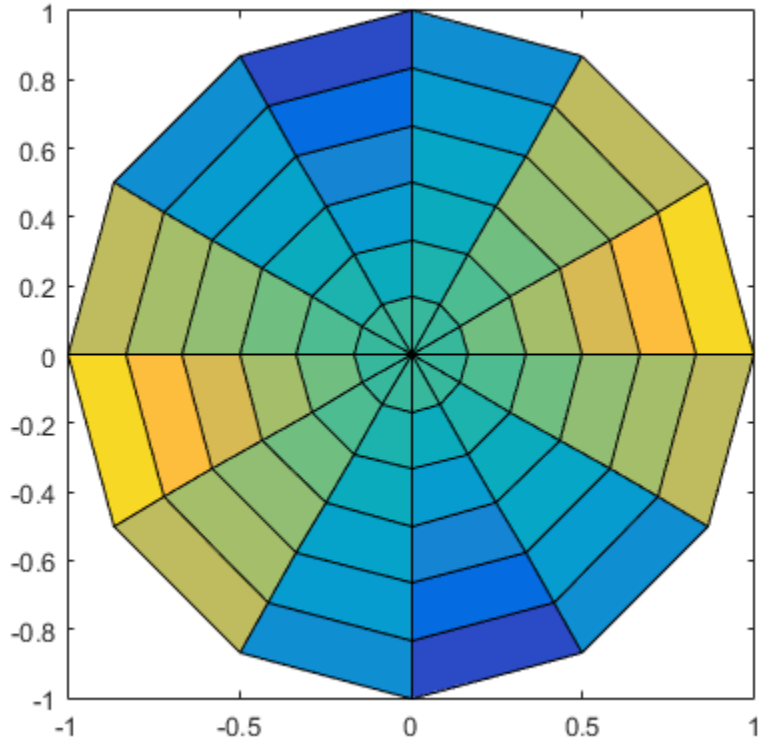
```
pcolor(hadamard(20))
colormap(gray(2))
axis ij
axis square
```



Polar Coordinate System

A simple color wheel illustrates a polar coordinate system.

```
n = 6;
r = (0:n)'/n;
theta = pi*(-n:n)/n;
X = r*cos(theta);
Y = r*sin(theta);
C = r*cos(2*theta);
pcolor(X,Y,C)
axis equal tight
```



More About

Tips

A pseudocolor plot is a flat surface plot viewed from above. `pcolor(X,Y,C)` is the same as viewing `surf(X,Y,zeros(size(X)),C)` using `view([0 90])`.

When you use `shading faceted` or `shading flat`, the constant color of each cell is the color associated with the corner having the smallest *x*-*y* coordinates. Therefore, `C(i,j)` determines the color of the cell in the *i*th row and *j*th column. The last row and column of `C` are not used.

When you use `shading interp`, each cell's color results from a bilinear interpolation of the colors at its four vertices, and all elements of `C` are used.

Algorithms

Use the `pcolor`, `image`, or `imagesc` function to display image data. Each function displays a rectangular array of cells and uses `C` to determine the colors.

- `pcolor(C)` uses the values in `C` to define the vertex colors by scaling the values to map to the full range of the colormap. The size of `C` determines the number of vertices. `pcolor` determines the cell colors using the colors defined at the cell vertices.
- `image(C)` uses `C` to define the cell colors by mapping the values directly into the colormap. The size of `C` determines the number of cells.
- `imagesc(C)` uses `C` to define the cell colors by scaling the values to map to the full range of the colormap. The size of `C` determines the number of cells.

`pcolor(X,Y,C)` can produce parametric grids, which is not possible with `image` or `imagesc`.

pdepe

Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D

Syntax

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
[sol,tsol,sole,te,ie] =
pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
```

Arguments

`m`	A parameter corresponding to the symmetry of the problem. `m` can be slab = `0`, cylindrical = `1`, or spherical = `2`.
`pdefun`	A handle to a function that defines the components of the PDE.
`icfun`	A handle to a function that defines the initial conditions.
`bcfun`	A handle to a function that defines the boundary conditions.
`xmesh`	A vector [`x0`, `x1`, ..., `xn`] specifying the points at which a numerical solution is requested for every value in `tspan`. The elements of `xmesh` must satisfy `x0 < x1 < ... < xn`. The length of `xmesh` must be >= `3`.
`tspan`	A vector [`t0`, `t1`, ..., `tf`] specifying the points at which a solution is requested for every value in `xmesh`. The elements of `tspan` must satisfy `t0 < t1 < ... < tf`. The length of `tspan` must be >= `3`.
`options`	Some options of the underlying ODE solver are available in `pdepe`: `RelTol`, `AbsTol`, `NormControl`, `InitialStep`, `MaxStep`, and `Events`. In most cases, default values for these options provide satisfactory solutions. See `odeset` for details.

Description

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)` solves initial-boundary value problems for systems of parabolic and elliptic PDEs in the one space variable x and time

t. `pdefun`, `icfun`, and `bcfun` are function handles. See the `function_handle` reference page for more information. The ordinary differential equations (ODEs) resulting from discretization in space are integrated to obtain approximate solutions at times specified in `tspan`. The `pdepe` function returns values of the solution on a mesh provided in `xmesh`.

"Parameterizing Functions" explains how to provide additional parameters to the functions `pdefun`, `icfun`, or `bcfun`, if necessary.

`pdepe` solves PDEs of the form:

$$c\left(x,t,u,\frac{\partial u}{\partial x}\right)\frac{\partial u}{\partial t}=x^{-m}\frac{\partial}{\partial x}\left(x^{m}f\left(x,t,u,\frac{\partial u}{\partial x}\right)\right)+s\left(x,t,u,\frac{\partial u}{\partial x}\right)$$

The PDEs hold for $t_0 \le t \le t_f$ and $a \le x \le b$. The interval $[a,b]$ must be finite. m can be 0, 1, or 2, corresponding to slab, cylindrical, or spherical symmetry, respectively. If $m > 0$, then a must be ≥ 0.

In Equation 1-4, $f\,(x,t,u,\partial u/\partial x)$ is a flux term and $s\,(x,t,u,\partial u/\partial x)$ is a source term. The coupling of the partial derivatives with respect to time is restricted to multiplication by a diagonal matrix $c\,(x,t,u,\partial u/\partial x)$. The diagonal elements of this matrix are either identically zero or positive. An element that is identically zero corresponds to an elliptic equation and otherwise to a parabolic equation. There must be at least one parabolic equation. An element of c that corresponds to a parabolic equation can vanish at isolated values of x if those values of x are mesh points. Discontinuities in c and/or s due to material interfaces are permitted provided that a mesh point is placed at each interface.

For $t = t_0$ and all x, the solution components satisfy initial conditions of the form

$$u(x,t_0)=u_0(x)$$

For all t and either $x = a$ or $x = b$, the solution components satisfy a boundary condition of the form

$$p(x,t,u)+q(x,t)f\left(x,t,u,\frac{\partial u}{\partial x}\right)=0$$

Elements of q are either identically zero or never zero. Note that the boundary conditions are expressed in terms of the flux f rather than $\partial u/\partial x$. Also, of the two coefficients, only p can depend on u.

In the call `sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)`:

- `m` corresponds to m.
- `xmesh(1)` and `xmesh(end)` correspond to a and b.
- `tspan(1)` and `tspan(end)` correspond to t_0 and t_f.
- `pdefun` computes the terms c, f, and s (Equation 1-4). It has the form

  ```
  [c,f,s] = pdefun(x,t,u,dudx)
  ```

  The input arguments are scalars `x` and `t` and vectors `u` and `dudx` that approximate the solution u and its partial derivative with respect to x, respectively. `c`, `f`, and `s` are column vectors. `c` stores the diagonal elements of the matrix c (Equation 1-4).
- `icfun` evaluates the initial conditions. It has the form

  ```
  u = icfun(x)
  ```

  When called with an argument `x`, `icfun` evaluates and returns the initial values of the solution components at `x` in the column vector `u`.
- `bcfun` evaluates the terms p and q of the boundary conditions (Equation 1-6). It has the form

  ```
  [pl,ql,pr,qr] = bcfun(xl,ul,xr,ur,t)
  ```

  `ul` is the approximate solution at the left boundary `xl` = a and `ur` is the approximate solution at the right boundary `xr` = b. `pl` and `ql` are column vectors corresponding to p and q evaluated at `xl`, similarly `pr` and `qr` correspond to `xr`. When $m > 0$ and $a = 0$, boundedness of the solution near $x = 0$ requires that the flux f vanish at $a = 0$. `pdepe` imposes this boundary condition automatically and it ignores values returned in `pl` and `ql`.

`pdepe` returns the solution as a multidimensional array `sol`. u_i = `ui` = `sol(:,:,i)` is an approximation to the `i`th component of the solution vector u. The element `ui(j,k)` = `sol(j,k,i)` approximates u_i at (t,x) = (`tspan(j)`,`xmesh(k)`).

`ui = sol(j,:,i)` approximates component `i` of the solution at time `tspan(j)` and mesh points `xmesh(:)`. Use `pdeval` to compute the approximation and its partial derivative $\partial u_i/\partial x$ at points not included in `xmesh`. See `pdeval` for details.

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)` solves as above with default integration parameters replaced by values in `options`, an argument created

with the odeset function. Only some of the options of the underlying ODE solver are available in pdepe: RelTol, AbsTol, NormControl, InitialStep, and MaxStep. The defaults obtained by leaving off the input argument options will generally be satisfactory. See odeset for details.

[sol,tsol,sole,te,ie] = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options) with the 'Events' property in options set to a function handle Events, solves as above while also finding where event functions g(t,u(x,t))are zero. For each function you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Three column vectors are returned by events: [value,isterminal,direction] = events(m,t,xmesh,umesh). xmesh contains the spatial mesh and umesh is the solution at the mesh points. Use pdeval to evaluate the solution between mesh points. For the I-th event function, value(i) is the value of the function, ISTERMINAL(I) = 1 if the integration is to terminate at a zero of this event function and 0 otherwise. direction(i) = 0 if all zeros are to be computed (the default), +1 if only zeros where the event function is increasing, and -1 if only zeros where the event function is decreasing. Output tsol is a column vector of times specified in tspan, prior to first terminal event. SOL(j,:,:) is the solution at T(j). TE is a vector of times at which events occur. SOLE(j,:,:) is the solution at TE(j) and indices in vector IE specify which event occurred.

If UI = SOL(j,:,i) approximates component i of the solution at time TSPAN(j) and mesh points XMESH, pdeval evaluates the approximation and its partial derivative $\partial u_i/\partial x$ at the array of points XOUT and returns them in UOUT and DUOUTDX: [UOUT,DUOUTDX] = PDEVAL(M,XMESH,UI,XOUT)

Note: The partial derivative $\partial u_i/\partial x$ is evaluated here rather than the flux. The flux is continuous, but at a material interface the partial derivative may have a jump.

Examples

Example 1. This example illustrates the straightforward formulation, computation, and plotting of the solution of a single PDE.

$$\pi^2 \frac{\partial u}{\partial t} = \frac{\partial}{\partial x}\left(\frac{\partial u}{\partial x}\right)$$

This equation holds on an interval $0 \le x \le 1$ for times $t \ge 0$.

The PDE satisfies the initial condition

$$u(x,0) = \sin \pi x$$

and boundary conditions

$$u(0,t) \equiv 0$$
$$\pi e^{-t} + \frac{\partial u}{\partial x}(1,t) = 0$$

It is convenient to use local functions to place all the functions required by `pdepe` in a single function.

```
function pdex1

m = 0;
x = linspace(0,1,20);
t = linspace(0,2,5);

sol = pdepe(m,@pdex1pde,@pdex1ic,@pdex1bc,x,t);
% Extract the first solution component as u.
u = sol(:,:,1);

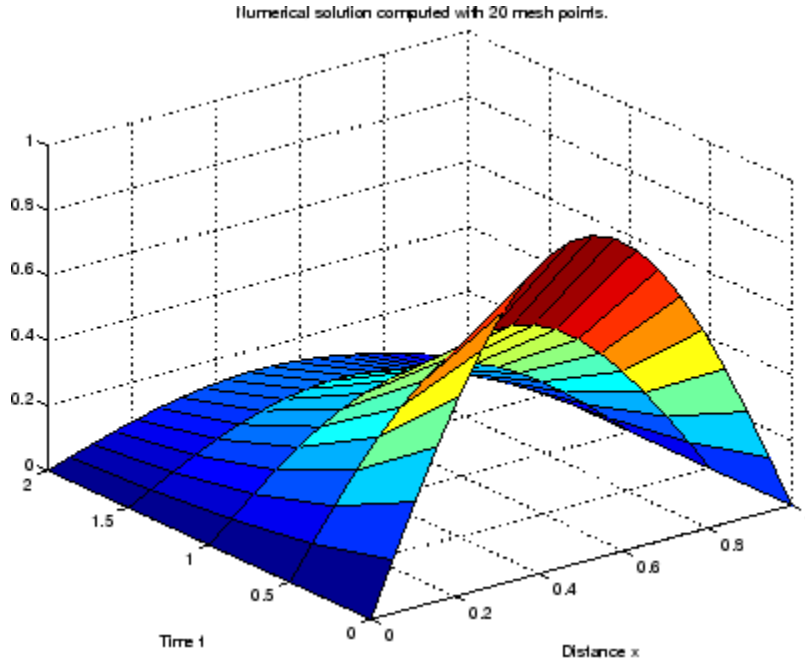
% A surface plot is often a good way to study a solution.
surf(x,t,u)
title('Numerical solution computed with 20 mesh points.')
xlabel('Distance x')
ylabel('Time t')

% A solution profile can also be illuminating.
figure
plot(x,u(end,:))
title('Solution at t = 2')
xlabel('Distance x')
ylabel('u(x,2)')
% --------------------------------------------------------------
function [c,f,s] = pdex1pde(x,t,u,DuDx)
c = pi^2;
f = DuDx;
```

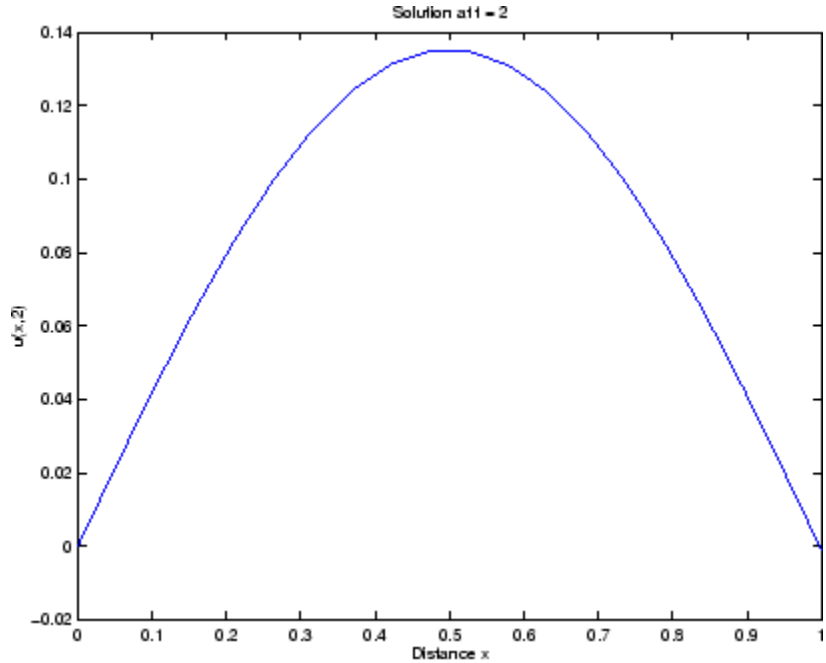
```
s = 0;
% --------------------------------------------------------------
function u0 = pdex1ic(x)
u0 = sin(pi*x);
% --------------------------------------------------------------
function [pl,ql,pr,qr] = pdex1bc(xl,ul,xr,ur,t)
pl = ul;
ql = 0;
pr = pi * exp(-t);
qr = 1;
```

In this example, the PDE, initial condition, and boundary conditions are coded in local functions `pdex1pde`, `pdex1ic`, and `pdex1bc`.

The surface plot shows the behavior of the solution.



The following plot shows the solution profile at the final value of `t` (i.e., `t = 2`).



Example 2. This example illustrates the solution of a system of PDEs. The problem has boundary layers at both ends of the interval. The solution changes rapidly for small t.

The PDEs are

$$\frac{\partial u_1}{\partial t} = 0.024\frac{\partial^2 u_1}{\partial x^2} - F(u_1 - u_2)$$
$$\frac{\partial u_2}{\partial t} = 0.170\frac{\partial^2 u_2}{\partial x^2} + F(u_1 - u_2)$$

where $F(y) = \exp(5.73y) - \exp(-11.46y)$.

This equation holds on an interval $0 \le x \le 1$ for times $t \ge 0$.

The PDE satisfies the initial conditions

$$u_1(x,0) \equiv 1$$
$$u_2(x,0) \equiv 0$$

and boundary conditions

$$\frac{\partial u_1}{\partial x}(0,t) \equiv 0$$
$$u_2(0,t) \equiv 0$$
$$u_1(1,t) \equiv 1$$
$$\frac{\partial u_2}{\partial x}(1,t) \equiv 0$$

In the form expected by `pdepe`, the equations are

$$\begin{bmatrix}1\\1\end{bmatrix} .* \frac{\partial}{\partial t}\begin{bmatrix}u_1\\u_2\end{bmatrix} = \frac{\partial}{\partial x}\begin{bmatrix}0.024(\partial u_1/\partial x)\\0.170(\partial u_2/\partial x)\end{bmatrix} + \begin{bmatrix}-F(u_1-u_2)\\F(u_1-u_2)\end{bmatrix}$$

The boundary conditions on the partial derivatives of u have to be written in terms of the flux. In the form expected by `pdepe`, the left boundary condition is

$$\begin{bmatrix}0\\u_2\end{bmatrix} + \begin{bmatrix}1\\0\end{bmatrix} .* \begin{bmatrix}0.024(\partial u_1/\partial x)\\0.170(\partial u_2/\partial x)\end{bmatrix} = \begin{bmatrix}0\\0\end{bmatrix}$$

and the right boundary condition is

$$\begin{bmatrix}u_1-1\\0\end{bmatrix} + \begin{bmatrix}0\\1\end{bmatrix} .* \begin{bmatrix}0.024(\partial u_1/\partial x)\\0.170(\partial u_2/\partial x)\end{bmatrix} = \begin{bmatrix}0\\0\end{bmatrix}$$

The solution changes rapidly for small t. The program selects the step size in time to resolve this sharp change, but to see this behavior in the plots, the example must select the output times accordingly. There are boundary layers in the solution at both ends of [0,1], so the example places mesh points near `0` and `1` to resolve these sharp changes. Often some experimentation is needed to select a mesh that reveals the behavior of the solution.

```
function pdex4
```

```
m = 0;
x = [0 0.005 0.01 0.05 0.1 0.2 0.5 0.7 0.9 0.95 0.99 0.995 1];
t = [0 0.005 0.01 0.05 0.1 0.5 1 1.5 2];

sol = pdepe(m,@pdex4pde,@pdex4ic,@pdex4bc,x,t);
u1 = sol(:,:,1);
u2 = sol(:,:,2);

figure
surf(x,t,u1)
title('u1(x,t)')
xlabel('Distance x')
ylabel('Time t')

figure
surf(x,t,u2)
title('u2(x,t)')
xlabel('Distance x')
ylabel('Time t')
% --------------------------------------------------------------
function [c,f,s] = pdex4pde(x,t,u,DuDx)
c = [1; 1];
f = [0.024; 0.17] .* DuDx;
y = u(1) - u(2);
F = exp(5.73*y)-exp(-11.47*y);
s = [-F; F];
% --------------------------------------------------------------
function u0 = pdex4ic(x);
u0 = [1; 0];
% --------------------------------------------------------------
function [pl,ql,pr,qr] = pdex4bc(xl,ul,xr,ur,t)
pl = [0; ul(2)];
ql = [1; 0];
pr = [ur(1)-1; 0];
qr = [0; 1];
```

In this example, the PDEs, initial conditions, and boundary conditions are coded in local functions `pdex4pde`, `pdex4ic`, and `pdex4bc`.

The surface plots show the behavior of the solution components.

More About

Tips

- The arrays `xmesh` and `tspan` play different roles in `pdepe`.

  `tspan` – The `pdepe` function performs the time integration with an ODE solver that selects both the time step and formula dynamically. The elements of `tspan` merely specify where you want answers and the cost depends weakly on the length of `tspan`.

  `xmesh` – Second order approximations to the solution are made on the mesh specified in `xmesh`. Generally, it is best to use closely spaced mesh points where the solution changes rapidly. `pdepe` does *not* select the mesh in x automatically. You must provide an appropriate fixed mesh in `xmesh`. The cost depends strongly on the length of `xmesh`. When $m > 0$, it is not necessary to use a fine mesh near $x = 0$ to account for the coordinate singularity.

- The time integration is done with `ode15s`. `pdepe` exploits the capabilities of `ode15s` for solving the differential-algebraic equations that arise when Equation 1-4 contains elliptic equations, and for handling Jacobians with a specified sparsity pattern.
- After discretization, elliptic equations give rise to algebraic equations. If the elements of the initial conditions vector that correspond to elliptic equations are not "consistent" with the discretization, `pdepe` tries to adjust them before beginning the time integration. For this reason, the solution returned for the initial time may have a discretization error comparable to that at any other time. If the mesh is sufficiently fine, `pdepe` can find consistent initial conditions close to the given ones. If `pdepe` displays a message that it has difficulty finding consistent initial conditions, try refining the mesh.

  No adjustment is necessary for elements of the initial conditions vector that correspond to parabolic equations.

`function_handle` | `pdeval` | `ode15s` | `odeset` | `odeget`

Introduced before R2006a

pdeval

Evaluate numerical solution of PDE using output of pdepe

Syntax

```
[uout,duoutdx] = pdeval(m,x,ui,xout)
```

Arguments

`m`	Symmetry of the problem: slab = `0`, cylindrical = `1`, spherical = `2`. This is the first input argument used in the call to `pdepe`.
`x`	A vector [`x0`, `x1`, ..., `xn`] specifying the points at which the elements of `ui` were computed. This is the same vector with which `pdepe` was called.
`ui`	A vector `sol(j,:,i)` that approximates component `i` of the solution at time t_f and mesh points `xmesh`, where `sol` is the solution returned by `pdepe`.
`xout`	A vector of points from the interval [`x0`,`xn`] at which the interpolated solution is requested.

Description

`[uout,duoutdx] = pdeval(m,x,ui,xout)` approximates the solution u_i and its partial derivative $\partial u_i/\partial x$ at points from the interval [`x0`,`xn`]. The `pdeval` function returns the computed values in `uout` and `duoutdx`, respectively.

Note `pdeval` evaluates the partial derivative $\partial u_i/\partial x$ rather than the flux f. Although the flux is continuous, the partial derivative may have a jump at a material interface.

`pdepe`

Introduced before R2006a

peaks

Example function of two variables

Syntax

```
Z = peaks;
Z = peaks(n);
Z = peaks(V);
Z = peaks(X,Y);
peaks(...)
[X,Y,Z] = peaks(...);
```

Description

`peaks` is a function of two variables, obtained by translating and scaling Gaussian distributions, which is useful for demonstrating `mesh`, `surf`, `pcolor`, `contour`, and so on.

`Z = peaks;` returns a 49-by-49 matrix.

`Z = peaks(n);` returns an `n`-by-`n` matrix.

`Z = peaks(V);` returns an `n`-by-`n` matrix, where `n = length(V)`.

`Z = peaks(X,Y);` evaluates `peaks` at the given `X` and `Y` (which must be the same size) and returns a matrix the same size.

`peaks(...)` (with no output argument) plots the peaks function with `surf`. Use any of the input argument combinations in the previous syntaxes.

`[X,Y,Z] = peaks(...);` returns two additional matrices, `X` and `Y`, for parametric plots, for example, `surf(X,Y,Z,del2(Z))`. If not given as input, the underlying matrices `X` and `Y` are

```
[X,Y] = meshgrid(V,V)
```

where V is a given vector, or V is a vector of length n with elements equally spaced from -3 to 3. If no input argument is given, the default n is 49.

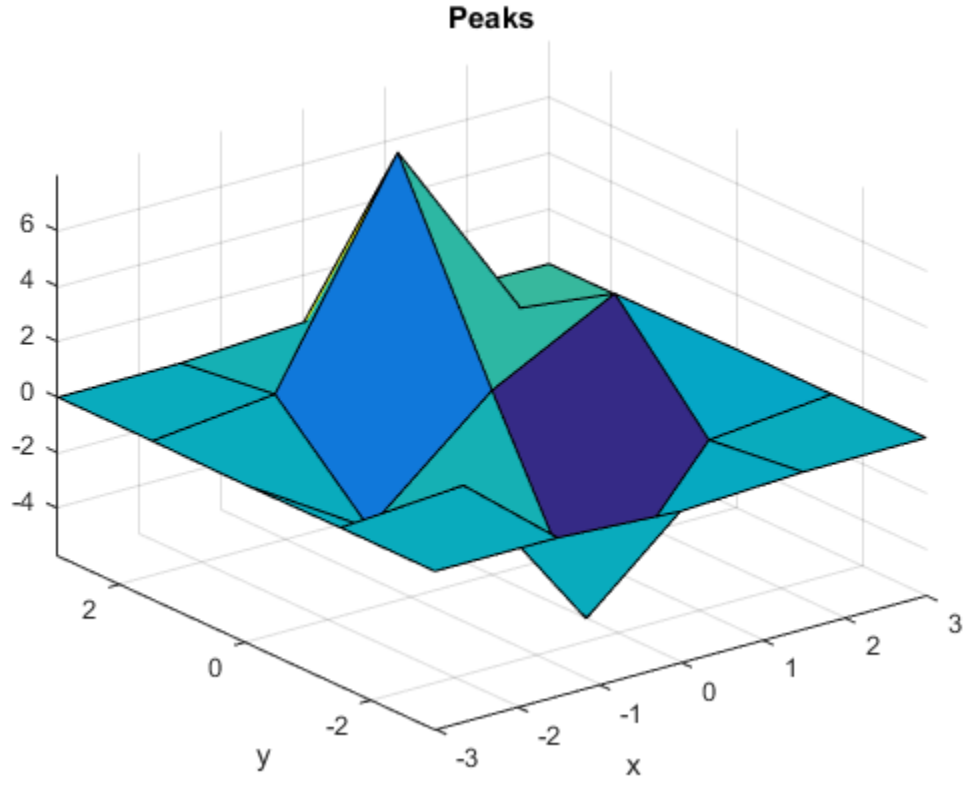
Examples

Peaks Surface

Create a 5-by-5 matrix of peaks and display the surface.

```
figure
peaks(5);
```

```
z =  3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
   - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
   - 1/3*exp(-(x+1).^2 - y.^2)
```



See Also

`meshgrid` | `surf`

Introduced before R2006a

perl

Call Perl script using appropriate operating system executable

Syntax

```
perl('perlfile')
perl('perlfile',arg1,arg2,...)
result = perl(...)
[result, status] = perl(...)
```

Description

`perl('perlfile')` calls the Perl script `perlfile`, using the appropriate operating system Perl executable. Perl is included with the MATLAB software on Microsoft Windows systems, and thus MATLAB users can run user-created MATLAB functions containing the `perl` function. On Linux and Macintosh systems, MATLAB calls the Perl interpreter available with the operating system.

`perl('perlfile',arg1,arg2,...)` calls the Perl script `perlfile`, using the appropriate operating system Perl executable, and passes the arguments `arg1`, `arg2`, and so on, to `perlfile`.

`result = perl(...)` returns the results of attempted Perl call to `result`.

`[result, status] = perl(...)` returns the results of attempted Perl call to `result` and its exit status to `status`.

It is sometimes beneficial to use Perl scripts instead of MATLAB code. The `perl` function allows you to run those scripts from MATLAB. Specific examples where you might choose to use a Perl script include:

- Perl script already exists
- Perl script preprocesses data quickly, formatting it in a way more easily read by MATLAB
- Perl has features not supported by MATLAB

Examples

Given the Perl script, `hello.pl`:

```
$input = $ARGV[0];
print "Hello $input.";
```

At the MATLAB command line, type:

```
perl('hello.pl','World')
```

```
ans =
Hello World.
```

`dos` | `regexp` | `system` | `unix` | `!` (exclamation point)

Introduced before R2006a

perms

All possible permutations

Syntax

```
P = perms(v)
```

Description

`P = perms(v)` returns a matrix containing all permutations of the elements of vector `v` in reverse lexicographic order. Each row of `P` contains a different permutation of the n elements in `v`. Matrix `P` has the same data type as `v`, and it has $n!$ rows and n columns.

Examples

All Permutations of Double Integers

```
v = [2 4 6];
P = perms(v)
```

```
P =

     6     4     2
     6     2     4
     4     6     2
     4     2     6
     2     4     6
     2     6     4
```

All Permutations of Unsigned Integers

```
v = uint16([1023 4095 65535]);
P = perms(v)
```

```
P =

  65535   4095   1023
  65535   1023   4095
```

```
   4095  65535   1023
   4095   1023  65535
   1023   4095  65535
   1023  65535   4095
```

All Permutations of Complex Numbers

```
v = [1+1i 2+1i 3+1i];
P = perms(v)
```

```
P =

   3.0000 + 1.0000i   2.0000 + 1.0000i   1.0000 + 1.0000i
   3.0000 + 1.0000i   1.0000 + 1.0000i   2.0000 + 1.0000i
   2.0000 + 1.0000i   3.0000 + 1.0000i   1.0000 + 1.0000i
   2.0000 + 1.0000i   1.0000 + 1.0000i   3.0000 + 1.0000i
   1.0000 + 1.0000i   2.0000 + 1.0000i   3.0000 + 1.0000i
   1.0000 + 1.0000i   3.0000 + 1.0000i   2.0000 + 1.0000i
```

Input Arguments

v — Set of items

vector of numeric, `logical`, or `char` values

Set of items, specified as a vector of numeric, `logical`, or `char` values.

Example: `[1 2 3 4]`

Example: `[1+1i 2+1i 3+1i 4+1i]`

Example: `int16([1 2 3 4])`

Example: `['abcd']`

Example: `[true false true false]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

Limitations

`perms(v)` is practical when `length(v)` is less than about 10.

See Also

`nchoosek` | `permute` | `randperm`

Introduced before R2006a

permute

Rearrange dimensions of N-D array

Syntax

```
B = permute(A,order)
```

Description

`B = permute(A,order)` rearranges the dimensions of `A` so that they are in the order specified by the vector `order`. `B` has the same values of `A` but the order of the subscripts needed to access any particular element is rearranged as specified by `order`. All the elements of `order` must be unique, real, positive, integer values.

Examples

Given any matrix `A`, the statement

```
permute(A,[2 1])
```

is the same as `A.'`.

For example:

```
A = [1 2; 3 4]; permute(A,[2 1])
ans =
     1     3
     2     4
```

The following code permutes a three-dimensional array:

```
X = rand(12,13,14);
Y = permute(X,[2 3 1]);
size(Y)
ans =
    13    14    12
```

More About

Tips

`permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

See Also

`ipermute` | `fliplr` | `flipud` | `circshift` | `reshape` | `shiftdim`

Introduced before R2006a

persistent

Define persistent variable

Syntax

```
persistent X Y Z
```

Description

`persistent X Y Z` defines `X`, `Y`, and `Z` as variables that are local to the function in which they are declared; yet their values are retained in memory between calls to the function. Persistent variables are similar to global variables because the MATLAB software creates permanent storage for both. They differ from global variables in that persistent variables are known only to the function in which they are declared. This prevents persistent variables from being changed by other functions or from the MATLAB command line.

Whenever you clear or modify a function that is in memory, MATLAB also clears all persistent variables declared by that function. To keep a function in memory until MATLAB quits, use `mlock`.

If the persistent variable does not exist the first time you issue the `persistent` statement, it is initialized to the empty matrix.

It is an error to declare a variable persistent if a variable with the same name exists in the current workspace. MATLAB also errors if you declare any of a function's input or output arguments as persistent within that same function. For example, the following persistent declaration is invalid:

```
function myfun(argA, argB, argC)
persistent argB
```

Examples

This function writes a large array to a spreadsheet file and then reads several rows from the same file. Because you only need to write the array to the spreadsheet one time, the

program tests whether an array can be read from the file and, if so, does not waste time in repeating that task. By defining the `dblArray` variable as persistent, you can easily check whether the array has been read from the spreadsheet file.

Here is the `arrayToXLS` function:

```
function arrayToXLS(A, xlsfile, x1, x2)
persistent dblArray;

if isempty(dblArray)
    disp 'Writing spreadsheet file ...'
    xlswrite(xlsfile, A);
end

disp 'Reading array from spreadsheet ...'
dblArray = xlsread(xlsfile, 'Sheet1', [x1 ':' x2])
fprintf('\n');
```

Run the function three times and observe the time elapsed for each run. The second and third run take approximately one tenth the time of the first run in which the function must create the spreadsheet:

```
largeArray = rand(4000, 200);

tic,  arrayToXLS(largeArray, 'myTest.xls','E254', 'J256'),  toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
    0.0982    0.3783    0.1264    0.7880    0.1902    0.5811
    0.2251    0.2704    0.5682    0.7271    0.8028    0.2834
    0.6453    0.5568    0.8254    0.4961    0.9096    0.5402

Elapsed time is 8.990525 seconds.

tic,  arrayToXLS(largeArray, 'myTest.xls','E257', 'J258'),  toc
Reading array from spreadsheet ...
dblArray =
    0.4620    0.3781    0.6386    0.5930    0.0946    0.4865
    0.1605    0.1251    0.8709    0.5188    0.6702    0.2138

Elapsed time is 0.912534 seconds.
```

```
tic,  arrayToXLS(largeArray, 'myTest.xls','E259', 'J262'),  toc
Reading array from spreadsheet ...
dblArray =
    0.7015    0.6588    0.4023    0.0359    0.4512    0.6097
    0.1308    0.6441    0.0431    0.6396    0.7481    0.8688
    0.8278    0.2686    0.5475    0.8550    0.5896    0.1080
    0.9437    0.1671    0.0505    0.1203    0.2461    0.7306

Elapsed time is 0.928843 seconds.
```

Now clear the `arrayToXLS` function from memory and observe that running it takes much longer again:

```
clear functions

tic,  arrayToXLS(largeArray, 'myTest.xls','E263', 'J264'),  toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
    0.6292    0.7788    0.0732    0.6481    0.9299    0.8631
    0.7700    0.5181    0.9805    0.5092    0.8658    0.4070

Elapsed time is 7.603461 seconds.
```

More About

Tips

There is no function form of the `persistent` command (i.e., you cannot use parentheses and quote the variable names).

See Also

`global` | `clear` | `mislocked` | `mlock` | `munlock` | `isempty`

Introduced before R2006a

pi

Ratio of circle's circumference to its diameter

Syntax

```
pi
```

Description

`pi` returns the floating-point number nearest the value of π. The expressions `4*atan(1)` and `imag(log(-1))` provide the same value.

Examples

Find the sine of π:

```
sin(pi)
```

returns

```
ans =

   1.2246e-16
```

The expression `sin(pi)` is not exactly zero because `pi` is not exactly π.

Introduced before R2006a

pie

Pie chart

Syntax

```
pie(X)
pie(X,explode)
pie(X,labels)
pie(X,explode,labels)

pie(ax, ___ )

p = pie( ___ )
```

Description

`pie(X)` draws a pie chart using the data in `X`. Each slice of the pie chart represents an element in `X`.

- If `sum(X) ≤ 1`, then the values in `X` directly specify the areas of the pie slices. `pie` draws only a partial pie if `sum(X) < 1`.
- If `sum(X) > 1`, then `pie` normalizes the values by `X/sum(X)` to determine the area of each slice of the pie.
- If `X` is of data type `categorical`, the slices correspond to categories. The area of each slice is the number of elements in the category divided by the number of elements in `X`.

`pie(X,explode)` offsets slices from the pie. `explode` is a vector or matrix of zeros and nonzeros that correspond to `X`. The `pie` function offsets slices for the nonzero elements only in `explode`.

If `X` is of data type `categorical`, then `explode` can be a vector of zeros and nonzeros corresponding to categories, or a cell array of the names of categories to offset.

`pie(X,labels)` specifies text labels for the slices. The number of labels must equal the number of slices. `X` must be numeric.

`pie(X,explode,labels)` specifies text labels for the slices. The number of labels must equal the number of slices.

`pie(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

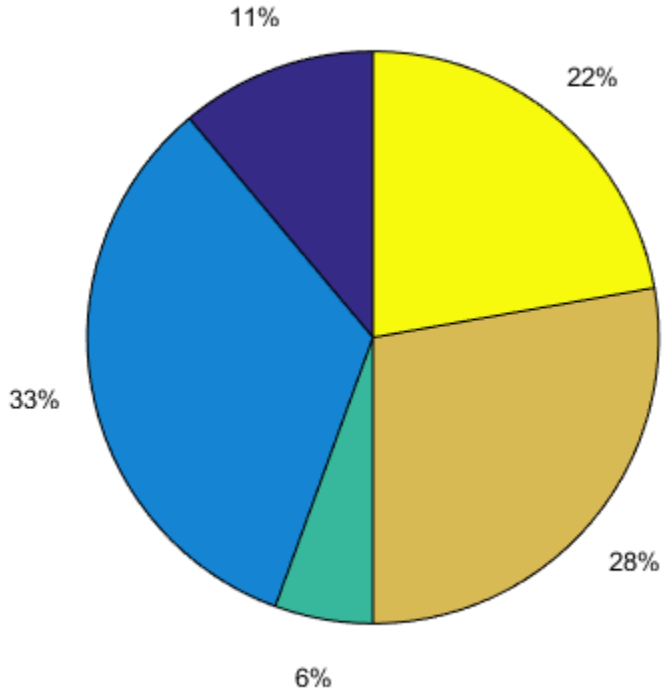
`p = pie( ___ )` returns a vector of patch and text graphics objects. The input can be any of the input argument combinations in the previous syntaxes.

Examples

Create Pie Chart with Offset Slices

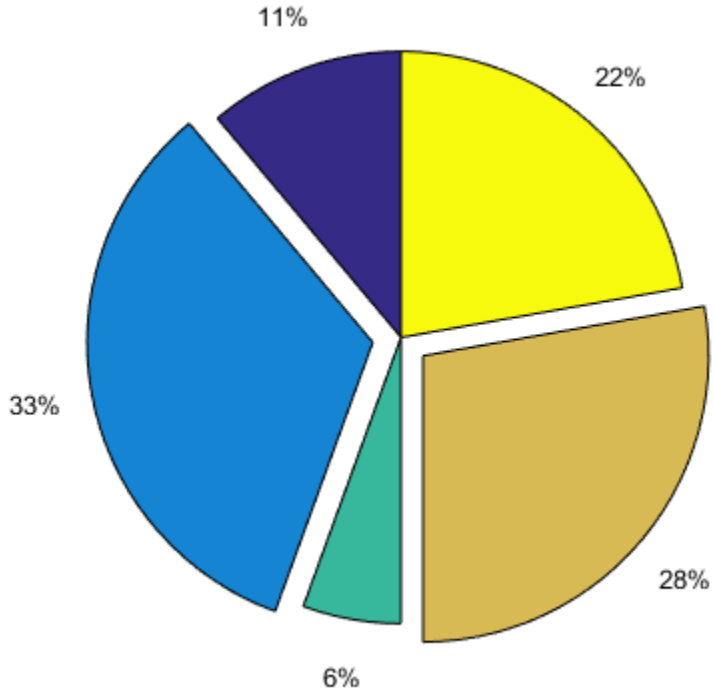
Create a pie chart of vector `X`.

```
X = [1 3 0.5 2.5 2];
pie(X)
```



Offset the second and fourth pie slices by setting the corresponding `explode` elements to 1.

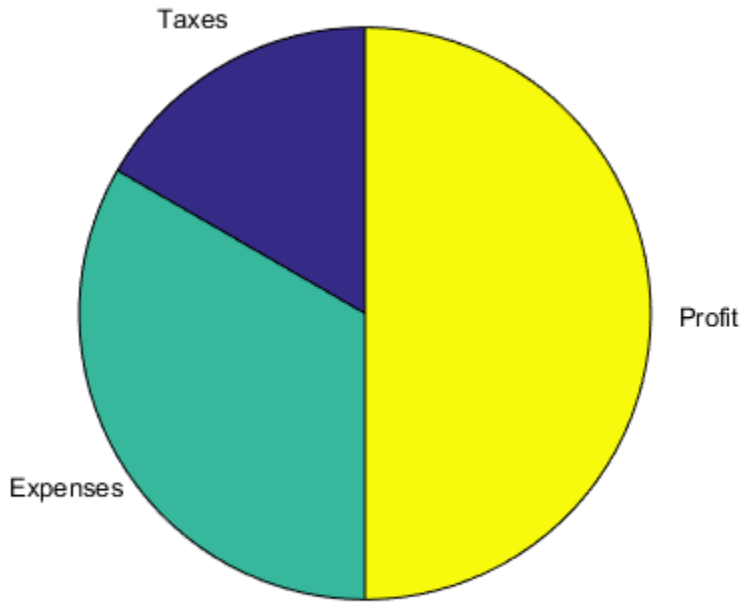
```
explode = [0 1 0 1 0];
pie(X,explode)
```



Specify Text Labels for Pie Chart

Create a pie chart of vector `X` and label the slices.

```
X = 1:3;
labels = {'Taxes','Expenses','Profit'};
pie(X,labels)
```



Modify Text Label for Pie Chart

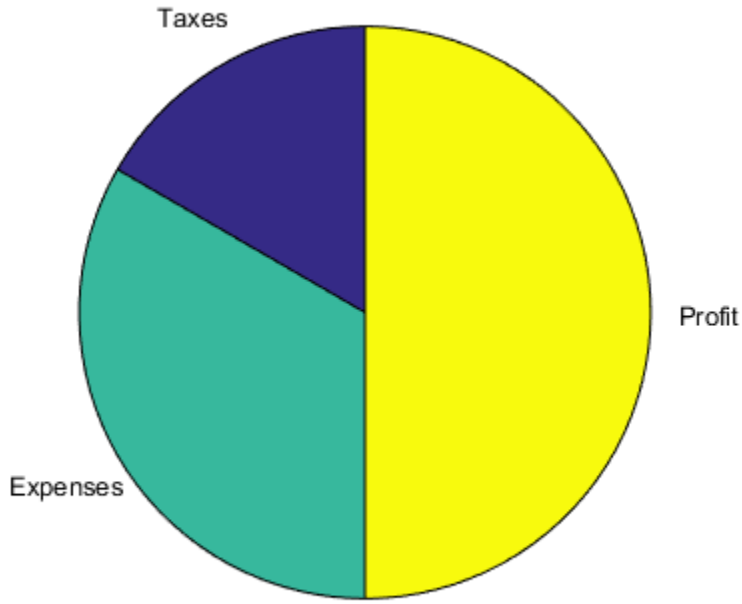
Create a labeled pie chart, and then modify the color and font size of the text labels.

```
X = 1:3;
labels = {'Taxes','Expenses','Profit'};
p = pie(X,labels)
```

```
p =

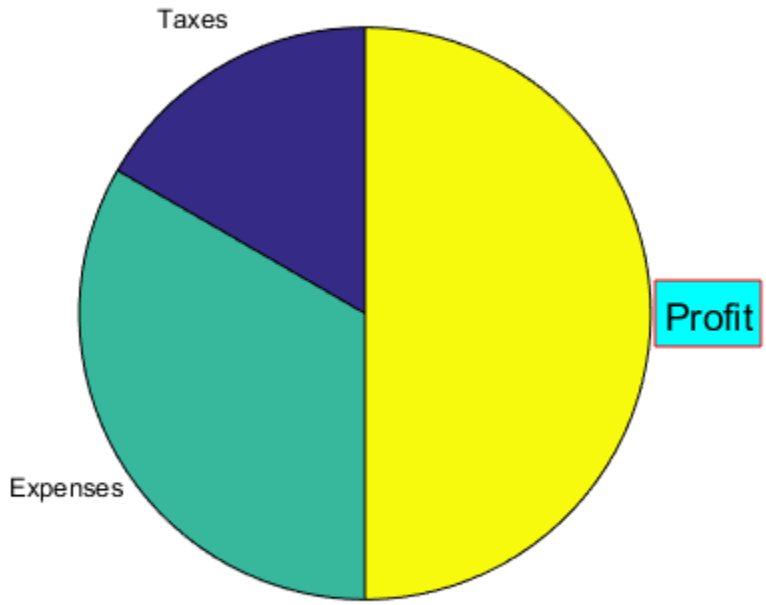
  1x6 graphics array:

    Patch    Text     Patch    Text     Patch    Text
```



Get the text object for the label 'Profit'. Change its color and font size. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

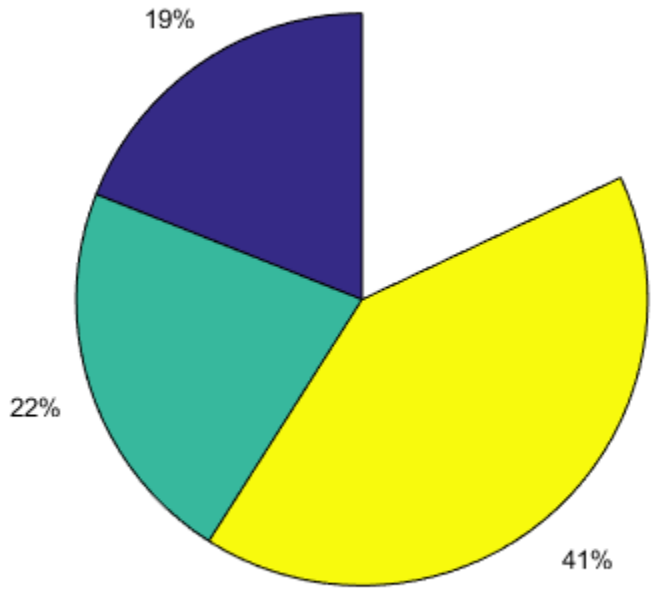
```
t = p(6);
t.BackgroundColor = 'cyan';
t.EdgeColor = 'red';
t.FontSize = 14;
```



Plot Partial Pie Chart

Create a pie chart of vector `X` where the sum of the elements is less than 1.

```
X = [0.19 0.22 0.41];
pie(X)
```



`pie` draws a partial pie because the sum of the elements is less than 1.

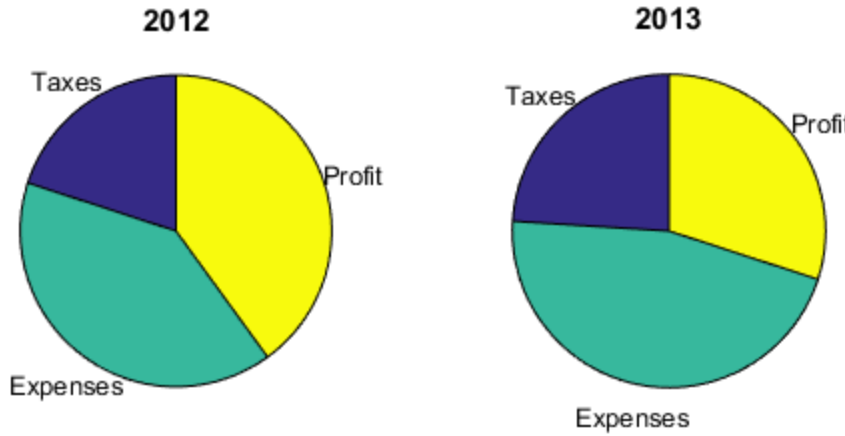
Plot Multiple Pie Charts

Create two vectors of data and plot and label each one in its own pie chart.

```
X = [0.2 0.4 0.4];
labels = {'Taxes','Expenses','Profit'};
ax1 = subplot(1,2,1);
pie(ax1,X,labels)
title(ax1,'2012');

Y = [0.24 0.46 0.3];
ax2 = subplot(1,2,2);
```

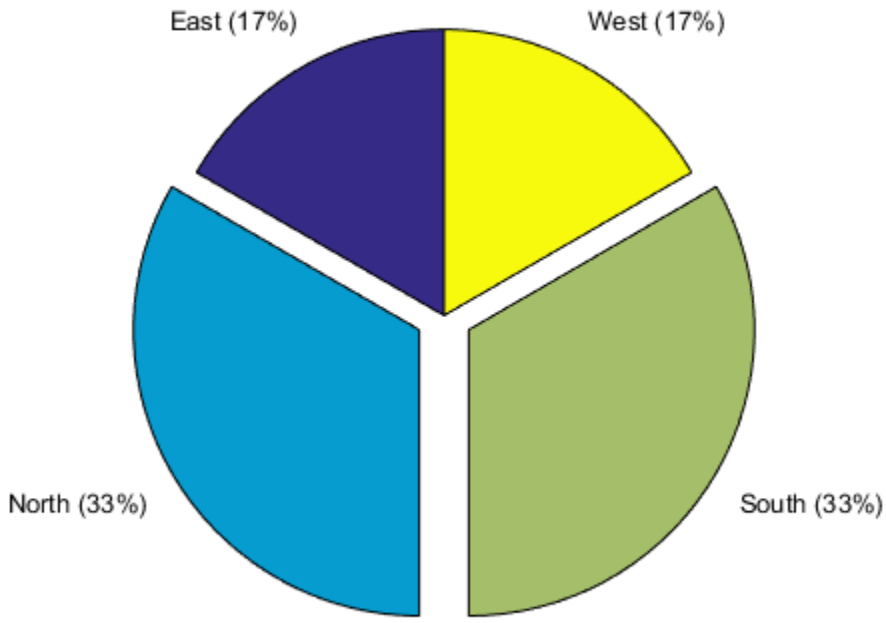
```
pie(ax2,Y,labels)
title(ax2,'2013');
```



Plot Categorical Pie Chart with Offsets

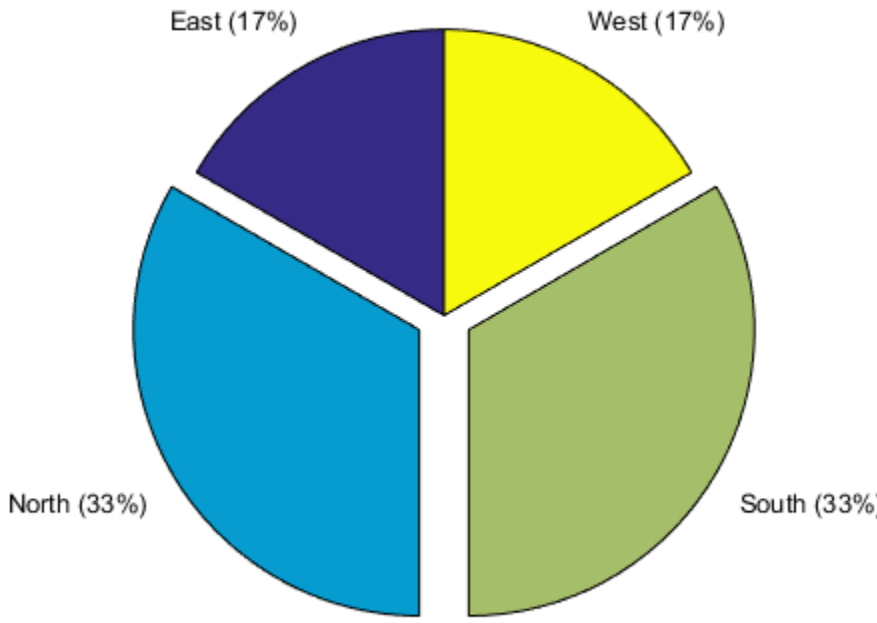
Plot a categorical pie chart with offset slices corresponding to categories.

```
X = categorical({'North','South','North','East','South','West'});
explode = {'North','South'};
pie(X,explode)
```



Now, use a logical vector to offset the same slices.

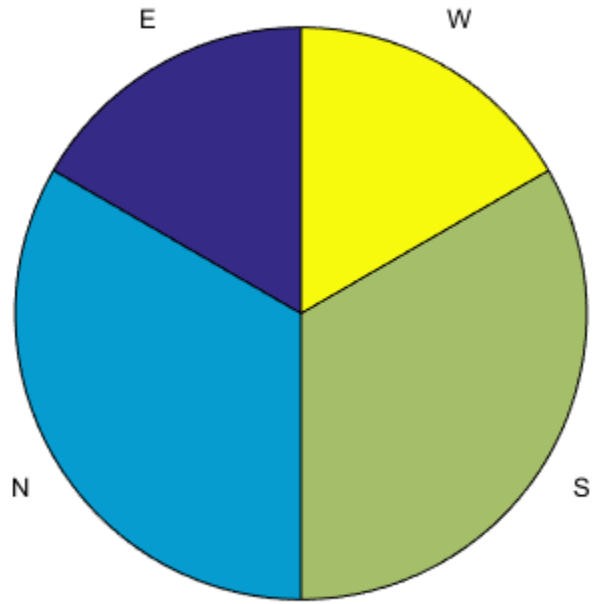
```
explode = [0 1 1 0];
pie(X,explode)
```



Plot Categorical Pie Chart with Labels

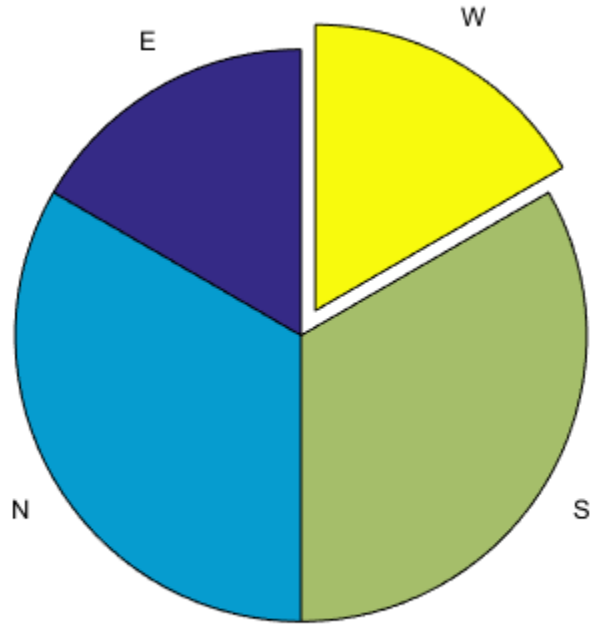
Plot a categorical pie chart without any offset slices and label the slices. When `X` is of data type `categorical` you must specify the input argument `explode`. To specify labels without any offset slices, specify `explode` as an empty cell array, and `labels` as the labels.

```
X = categorical({'North','South','North','East','South','West'});
explode = {};
labels = {'E','N','S','W'};
pie(X,explode,labels)
```



Now, offset a slice and label all slices.

```
X = categorical({'North','South','North','East','South','West'});
explode = {'West'};
labels = {'E','N','S','W'};
pie(X,explode,labels)
```



- “Offset Pie Slice with Greatest Contribution”
- “Label Pie Chart With Text and Percentages”

Input Arguments

X — Input array

vector or matrix

Input vector or matrix.

- If `X` is numeric, then all values in `X` must be finite. `pie` ignores nonpositive values.

- If `X` is categorical, then `pie` ignores undefined elements.

Data Types: `double|logical|categorical`

`explode` — Offset slices
vector or matrix

Offset slices, specified as a vector or matrix.

- If `X` is numeric, then `explode` must be a logical or numeric vector or matrix of zeros and nonzeros that correspond to `X`. A true (nonzero) value offsets the corresponding slice from the center of the pie chart, so that `X(i,j)` is offset from the center if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.
- If `X` is categorical, then `explode` can be a cell array of strings that are category names. `pie` offsets slices corresponding to categories in `explode`.
- If `X` is categorical, then `explode` also can be a logical or numeric vector with elements that correspond to each category in `X`. The `pie` function offsets slices corresponding to true (nonzero) in category order.

`labels` — Text labels
cell array of strings

Text labels for slices, specified as a cell array of strings.

`ax` — Axes
axes object

Axes object. Use `ax` to plot the pie chart in a specific axes instead of the current axes (`gca`).

Output Arguments

`p` — Patch and text objects
vector

Patch and text objects, returned as a vector.

See Also
`pie3`

Introduced before R2006a

pie3

3-D pie chart

Syntax

```
pie3(X)
pie3(X,explode)
pie3(...,labels)
pie3(axes_handle,...)
h = pie3(...)
```

Description

`pie3(X)` draws a three-dimensional pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

- If `sum(X) ≤ 1`, then the values in `X` directly specify the area of the pie slices. `pie3` draws only a partial pie if `sum(X) < 1`.
- If the sum of the elements in `X` is greater than one, then `pie3` normalizes the values by `X/sum(X)` to determine the area of each slice of the pie.

`pie3(X,explode)` specifies whether to offset a slice from the center of the pie chart. `X(i,j)` is offset from the center of the pie chart if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie3(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`.

`pie3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

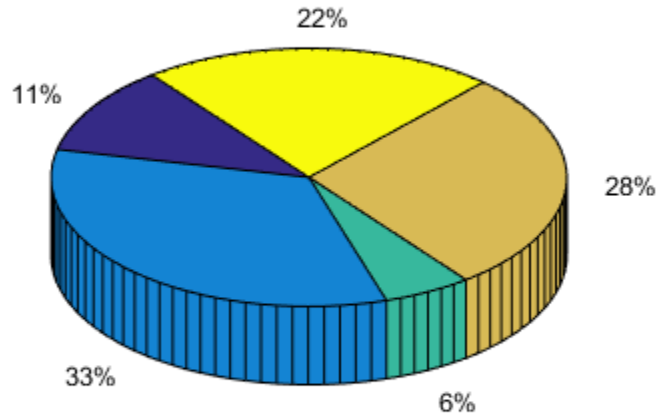
`h = pie3(...)` returns a vector of handles to patch, surface, and text graphics objects.

Examples

Create 3-D Pie Chart

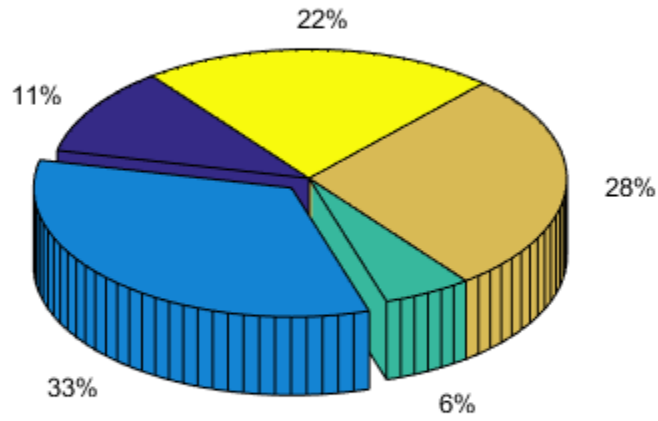
Create a 3-D pie chart of vector `x`.

```
x = [1,3,0.5,2.5,2];
figure
pie3(x)
```



To offset the second pie slice, set the corresponding `explode` element to 1.

```
explode = [0,1,0,0,0];
figure
pie3(x,explode)
```



Specify Text Labels for 3-D Pie Chart

Create a 3-D pie chart and specify the text labels.

```
x = 1:3;
labels = {'Taxes','Expenses','Profit'};

figure
```

```
pie3(x,labels)
```

`pie`

Introduced before R2006a

pinv

Moore-Penrose pseudoinverse of matrix

Syntax

```
B = pinv(A)
B = pinv(A,tol)
```

Definitions

The Moore-Penrose pseudoinverse is a matrix `B` of the same dimensions as `A'` satisfying four conditions:

```
A*B*A = A
B*A*B = B
A*B is Hermitian
B*A is Hermitian
```

The computation is based on `svd(A)` and any singular values less than `tol` are treated as zero.

Description

`B = pinv(A)` returns the Moore-Penrose pseudoinverse of `A`.

`B = pinv(A,tol)` returns the Moore-Penrose pseudoinverse and overrides the default tolerance, `max(size(A))*norm(A)*eps`.

Examples

If `A` is square and not singular, then `pinv(A)` is an expensive way to compute `inv(A)`. If `A` is not square, or is square and singular, then `inv(A)` does not exist. In these cases, `pinv(A)` has some of, but not all, the properties of `inv(A)`.

If A has more rows than columns and is not of full rank, then the overdetermined least squares problem

```
minimize norm(A*x-b)
```

does not have a unique solution. Two of the infinitely many solutions are

```
x = pinv(A)*b
```

and

```
y = A\b
```

These two are distinguished by the facts that `norm(x)` is smaller than the norm of any other solution and that `y` has the fewest possible nonzero components.

For example, the matrix generated by

```
A = magic(8); A = A(:,1:6)
```

is an 8-by-6 matrix that happens to have `rank(A) = 3`.

```
A =
    64     2     3    61    60     6
     9    55    54    12    13    51
    17    47    46    20    21    43
    40    26    27    37    36    30
    32    34    35    29    28    38
    41    23    22    44    45    19
    49    15    14    52    53    11
     8    58    59     5     4    62
```

The right-hand side is `b = 260*ones(8,1)`,

```
b =
     260
     260
     260
     260
     260
     260
     260
     260
```

The scale factor 260 is the 8-by-8 magic sum. With all eight columns, one solution to `A*x = b` would be a vector of all 1's. With only six columns, the equations are still consistent,

so a solution exists, but it is not all 1's. Since the matrix is rank deficient, there are infinitely many solutions. Two of them are

```
x = pinv(A)*b
```

which is

```
x =
    1.1538
    1.4615
    1.3846
    1.3846
    1.4615
    1.1538
```

and

```
y = A\b
```

which produces this result.

```
Warning: Rank deficient, rank = 3  tol =   1.8829e-013.
y =
    4.0000
    5.0000
         0
         0
         0
   -1.0000
```

Both of these are exact solutions in the sense that `norm(A*x-b)` and `norm(A*y-b)` are on the order of roundoff error. The solution `x` is special because

```
norm(x) = 3.2817
```

is smaller than the norm of any other solution, including

```
norm(y) = 6.4807
```

On the other hand, the solution `y` is special because it has only three nonzero components.

Introduced before R2006a

planerot

Givens plane rotation

Syntax

```
[G,y] = planerot(x)
```

Description

`[G,y] = planerot(x)` where `x` is a 2-component column vector, returns a 2-by-2 orthogonal matrix G so that `y = G*x` has `y(2) = 0`.

Examples

```
x = [3 4];
[G,y] = planerot(x')

G  =
    0.6000    0.8000
   -0.8000    0.6000

y =
     5
     0
```

Introduced before R2006a

play

Play audio from `audioplayer` object

Syntax

```
play(playerObj)
play(playerObj,start)
play(playerObj,[start,stop])
```

Description

`play(playerObj)` plays the audio associated with `audioplayer` object `playerObj` from beginning to end.

`play(playerObj,start)` plays audio from the sample indicated by `start` to the end.

`play(playerObj,[start,stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

Examples

Play with and without Blocking

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y,chirpData.Fs);

gongData = load('gong.mat');
gongObj = audioplayer(gongData.y,gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
```

```
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

play(playerObj,start);
```

Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

play(playerObj,[start,stop]);
```

See Also

How To

- "Play Audio"

play

Play audio from `audiorecorder` object

Syntax

```
player = play(recObj)
player = play(recObj, start)
player = play(recObj, [start stop])
```

Description

`player = play(recObj)` plays the audio associated with `audiorecorder` object `recObj` from beginning to end, and returns an `audioplayer` object.

`player = play(recObj, start)` plays audio from the sample indicated by `start` to the end.

`player = play(recObj, [start stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

Examples

Record 5 seconds of your speech with a microphone, and play it back. Display the properties of the `audioplayer` object.

```
myVoice = audiorecorder;

disp('Start speaking.');
recordblocking(myVoice, 5);
disp('End of recording. Playing back ...');

playerObj = play(myVoice);

disp('Properties of playerObj:');
get(playerObj)
```

Play back only the first 3 seconds of the speech recorded in the previous example:

```
play(myVoice, [1 myVoice.SampleRate*3]);
```

See Also

audioplayer | audiorecorder

playblocking

Play audio from `audioplayer` object, holding control until playback completes

Syntax

```
playblocking(playerObj)
playblocking(playerObj,start)
playblocking(playerObj,[start,stop])
```

Description

`playblocking(playerObj)` plays the audio associated with `audioplayer` object `playerObj` from beginning to end. `playblocking` does not return control until playback completes.

`playblocking(playerObj,start)` plays audio from the sample indicated by `start` to the end.

`playblocking(playerObj,[start,stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

Examples

Play with and without Blocking

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y,chirpData.Fs);

gongData = load('gong.mat');
gongObj = audioplayer(gongData.y,gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

playblocking(playerObj,start);
beep;
```

Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

playblocking(playerObj,[start,stop]);
beep;
```

How To

- "Play Audio"

plot

2-D line plot

Syntax

```
plot(X,Y)
plot(X,Y,LineSpec)
plot(X1,Y1,...,Xn,Yn)
plot(X1,Y1,LineSpec1,...,Xn,Yn,LineSpecn)

plot(Y)
plot(Y,LineSpec)

plot( ___ ,Name,Value)
plot(ax, ___ )

h = plot( ___ )
```

Description

`plot(X,Y)` creates a 2-D line plot of the data in `Y` versus the corresponding values in `X`.

- If `X` and `Y` are both vectors, then they must have equal length. The `plot` function plots `Y` versus `X`.
- If `X` and `Y` are both matrices, then they must have equal size. The `plot` function plots columns of `Y` versus columns of `X`.
- If one of `X` or `Y` is a vector and the other is a matrix, then the matrix must have dimensions such that one of its dimensions equals the vector length. If the number of matrix rows equals the vector length, then the `plot` function plots each matrix column versus the vector. If the number of matrix columns equals the vector length, then the function plots each matrix row versus the vector. If the matrix is square, then the function plots each column versus the vector.
- If one of `X` or `Y` is a scalar and the other is either a scalar or a vector, then the `plot` function plots discrete points. However, to see the points you must specify a marker symbol, for example, `plot(X,Y,'o')`.

`plot(X,Y,LineSpec)` sets the line style, marker symbol, and color.

`plot(X1,Y1,...,Xn,Yn)` plots multiple `X`, `Y` pairs using the same axes for all lines.

`plot(X1,Y1,LineSpec1,...,Xn,Yn,LineSpecn)` sets the line style, marker type, and color for each line. You can mix `X`, `Y`, `LineSpec` triplets with `X`, `Y` pairs. For example, `plot(X1,Y1,X2,Y2,LineSpec2,X3,Y3)`.

`plot(Y)` creates a 2-D line plot of the data in `Y` versus the index of each value.

- If `Y` is a vector, then the *x*-axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then the `plot` function plots the columns of `Y` versus their row number. The *x*-axis scale ranges from 1 to the number of rows in `Y`.
- If `Y` is complex, then the `plot` function plots the imaginary part of `Y` versus the real part of `Y`, such that `plot(Y)` is equivalent to `plot(real(Y),imag(Y))`.

`plot(Y,LineSpec)` sets the line style, marker symbol, and color.

`plot( ___ ,Name,Value)` specifies line properties using one or more `Name,Value` pair arguments. Use this option with any of the input argument combinations in the previous syntaxes. `Name,Value` pair settings apply to all the lines plotted. You cannot specify different `Name,Value` pairs for each line using this syntax.

`plot(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option, `ax` can precede any of the input combinations in the previous syntaxes.

`h = plot( ___ )` returns a column vector of chart line objects. Use `h` to modify a specific chart lines after it is created.

Examples

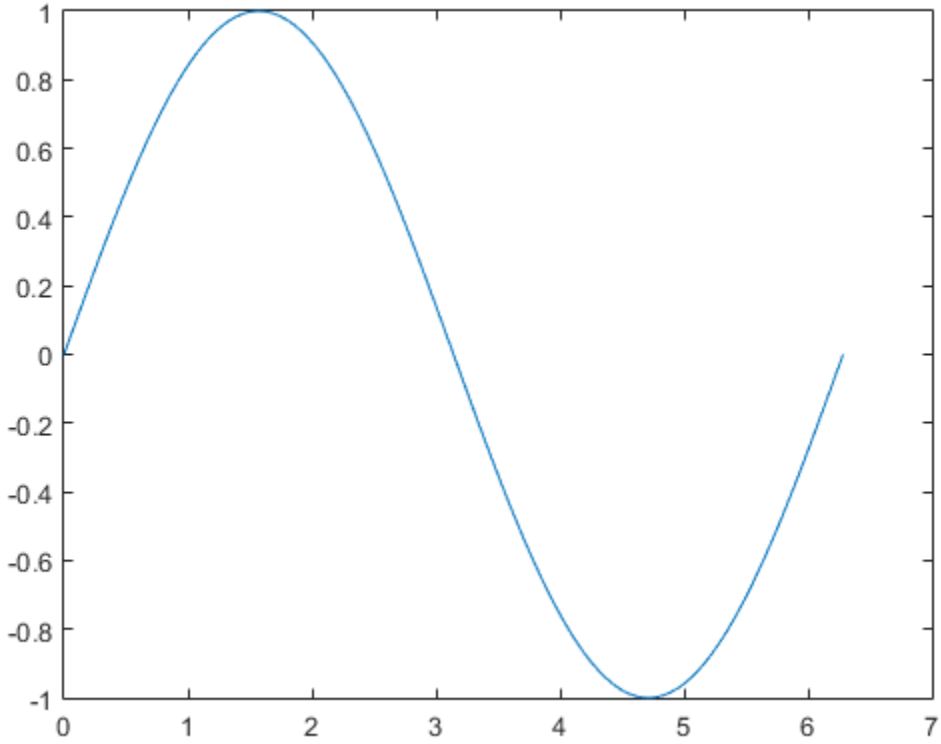
Create Line Plot

Define `x` as a vector of linearly spaced values between 0 and 2π. Use an increment of $\pi/100$ between the values. Define `y` as sine values of `x`.

```
x = 0:pi/100:2*pi;
y = sin(x);
```

Create a line plot of the data.

```
figure % opens new figure window
plot(x,y)
```

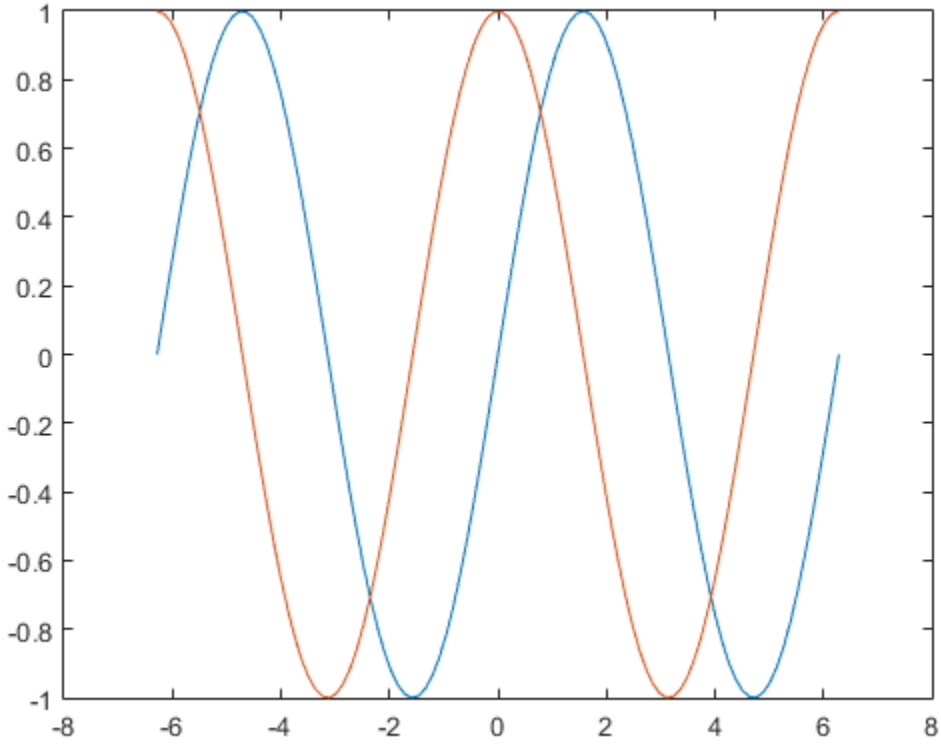


Plot Multiple Lines

Define `x` as 100 linearly spaced values between -2π and 2π. Define `y1` and `y2` as sine and cosine values of `x`. Create a line plot of both sets of data.

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,x,y2)
```



Create Line Plot From Matrix

Define `Y` as the 4-by-4 matrix returned by the `magic` function.

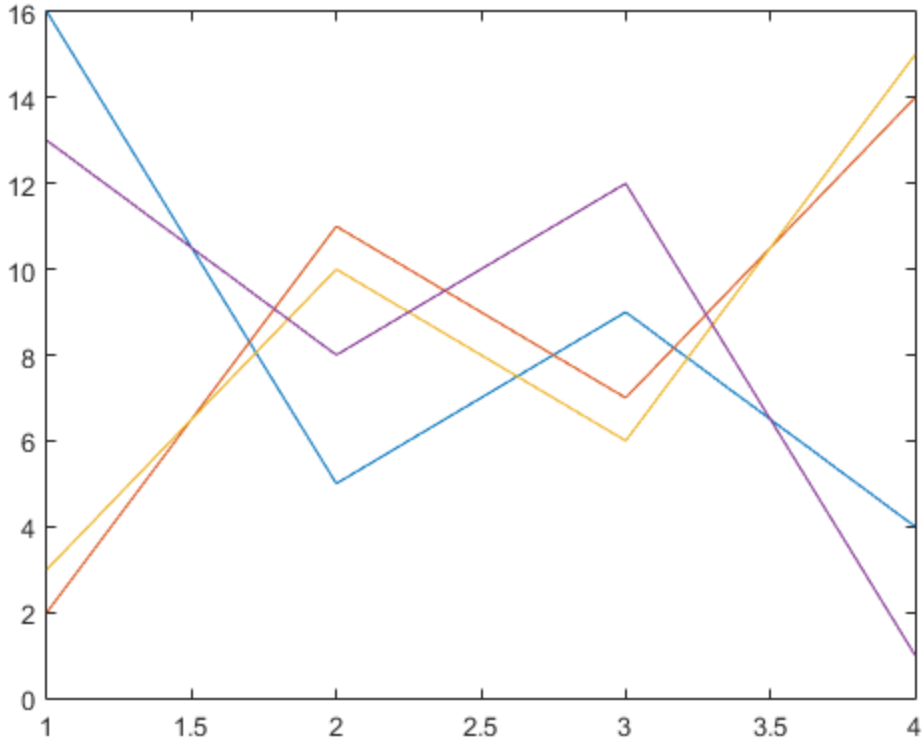
```
Y = magic(4)
```

```
Y =

    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Create a 2-D line plot of `Y`. MATLAB® plots each matrix column as a separate line.

```
figure
plot(Y)
```



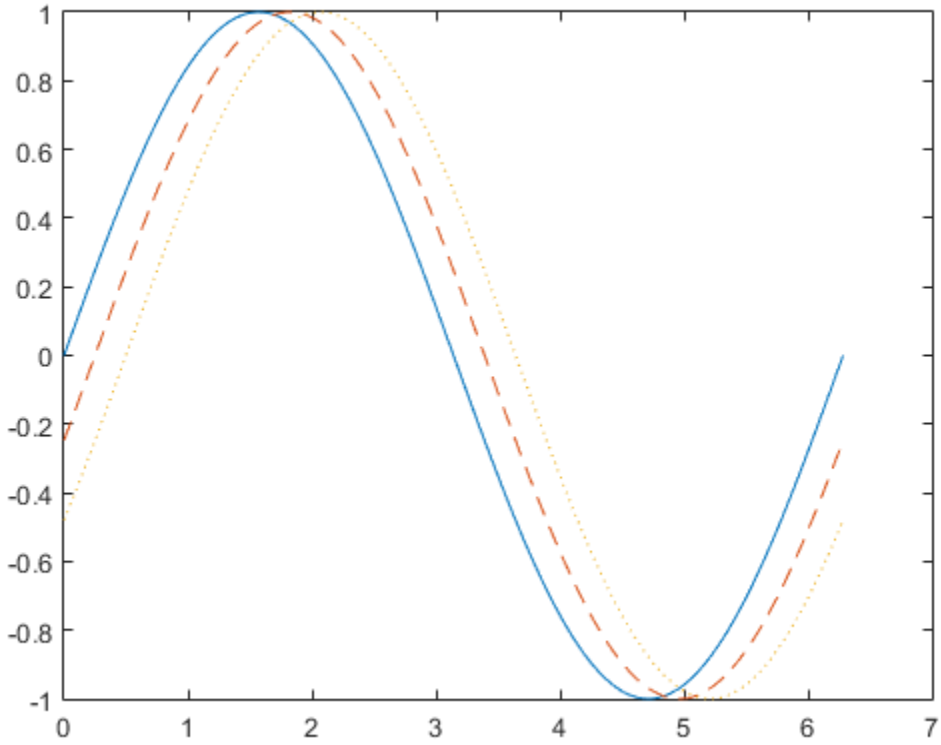
Specify Line Style

Plot three sine curves with a small phase shift between each line. Use the default line style for the first line. Specify a dashed line style for the second line and a dotted line style for the third line.

```
x = 0:pi/100:2*pi;
y1 = sin(x);
y2 = sin(x-0.25);
```

```
y3 = sin(x-0.5);

figure
plot(x,y1,x,y2,'--',x,y3,':')
```



MATLAB® cycles the line color through the default color order.

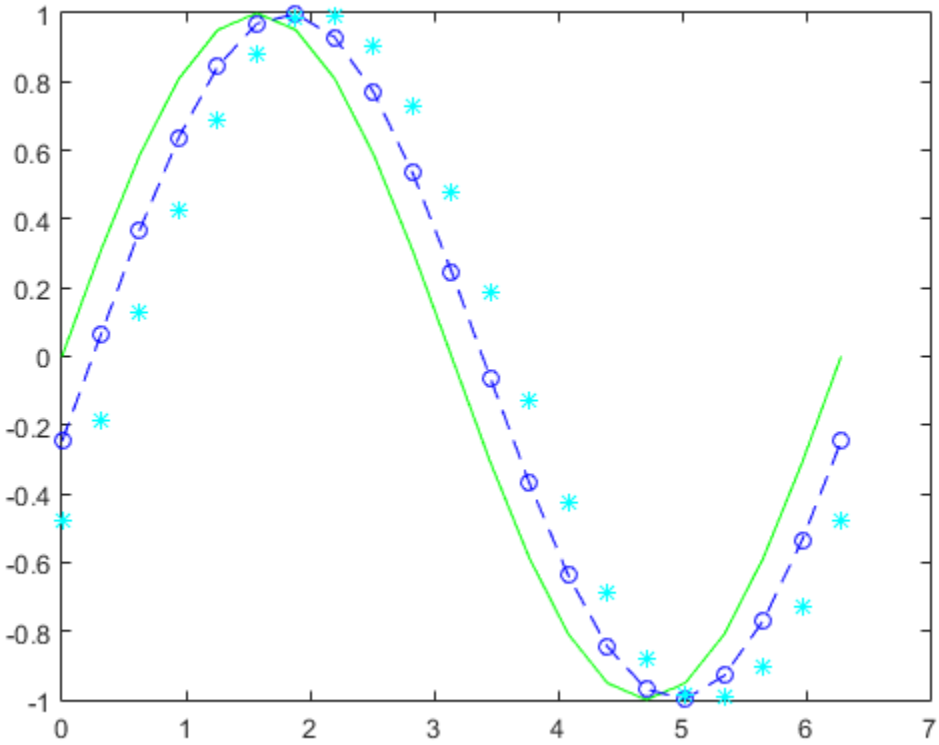
Specify Line Style, Color, and Marker

Plot three sine curves with a small phase shift between each line. Use a green line with no markers for the first sine curve. Use a blue dashed line with circle markers for the second sine curve. Use only cyan star markers for the third sine curve.

```
x = 0:pi/10:2*pi;
```

```
y1 = sin(x);
y2 = sin(x-0.25);
y3 = sin(x-0.5);

figure
plot(x,y1,'g',x,y2,'b--o',x,y3,'c*')
```

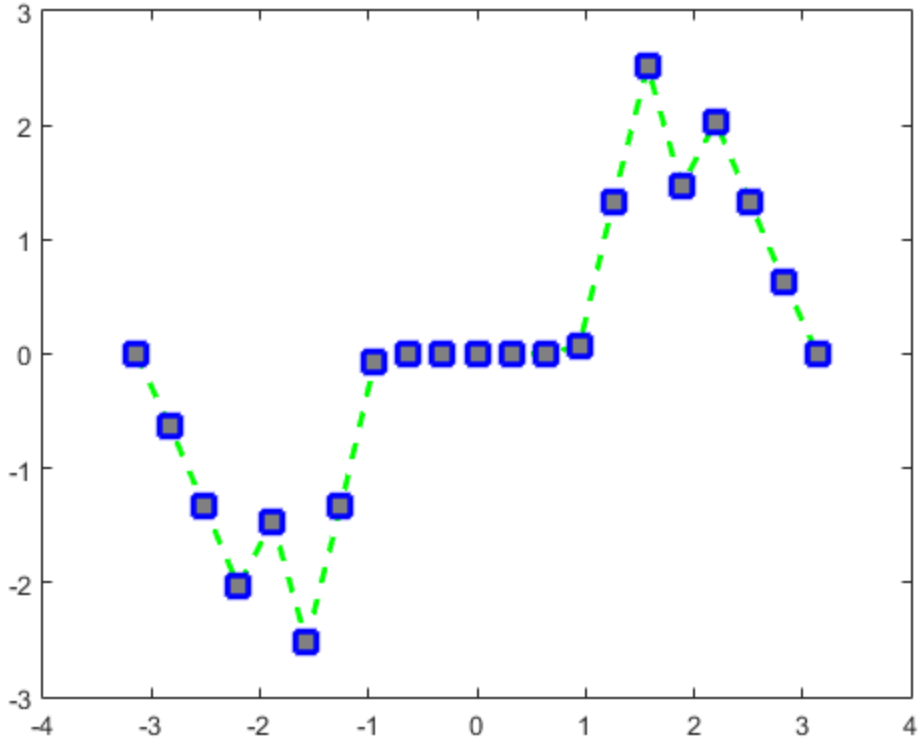


Specify Line Width, Marker Size, and Marker Color

Create a line plot and use the `LineSpec` option to specify a dashed green line with square markers. Use `Name,Value` pairs to specify the line width, marker size, and marker colors. Set the marker edge color to blue and set the marker face color using an RGB color value.

```
x = -pi:pi/10:pi;
y = tan(sin(x)) - sin(tan(x));

figure
plot(x,y,'--gs',...
    'LineWidth',2,...
    'MarkerSize',10,...
    'MarkerEdgeColor','b',...
    'MarkerFaceColor',[0.5,0.5,0.5])
```



Add Title and Axis Labels

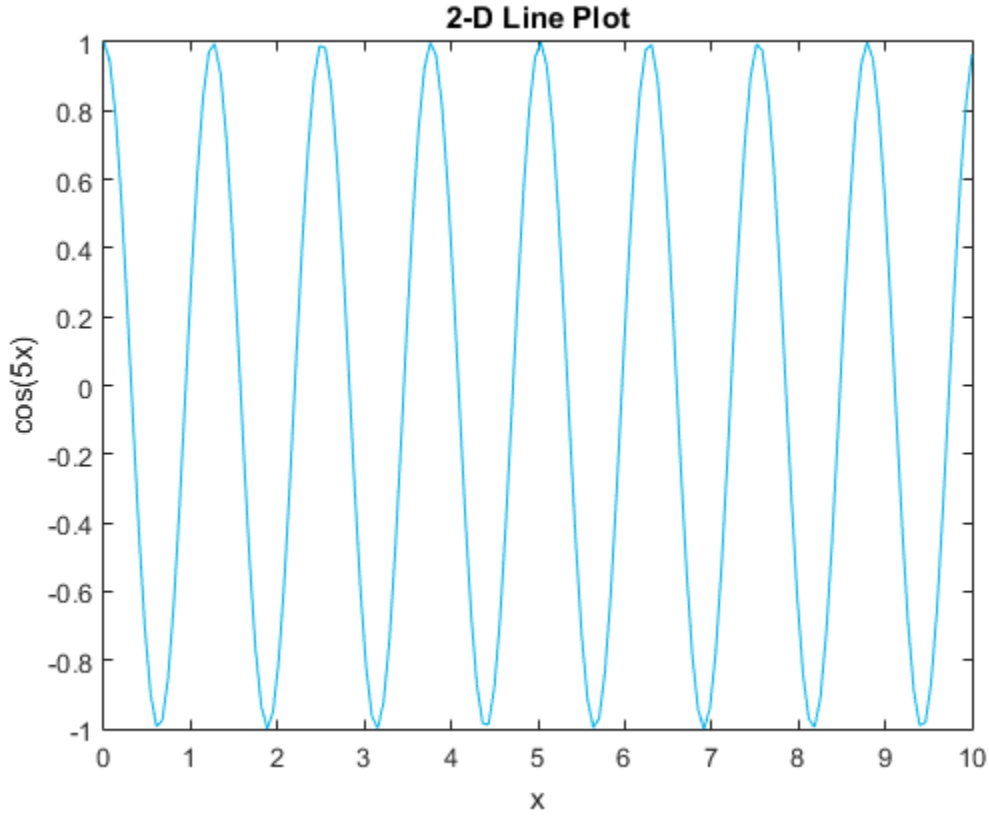
Use the `linspace` function to define `x` as a vector of 150 values between 0 and 10. Define `y` as cosine values of `x`.

```
x = linspace(0,10,150);
y = cos(5*x);
```

Create a 2-D line plot of the cosine curve. Change the line color to a shade of blue-green using an RGB color value. Add a title and axis labels to the graph using the `title`, `xlabel`, and `ylabel` functions.

```
figure
plot(x,y,'Color',[0,0.7,0.9])

title('2-D Line Plot')
xlabel('x')
ylabel('cos(5x)')
```

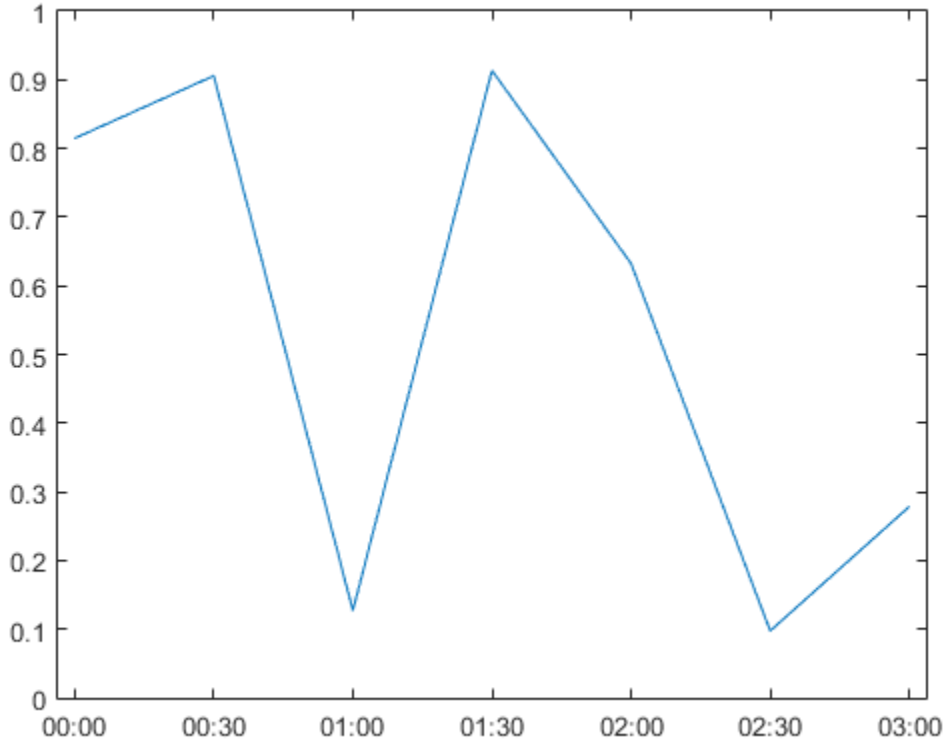


Plot Durations and Specify Tick Format

Define `t` as seven linearly spaced `duration` values between 0 and 3 minutes. Plot random data and specify the format of the `duration` tick marks using the `'DurationTickFormat'` name-value pair argument.

```
t = 0:seconds(30):minutes(3);
y = rand(1,7);

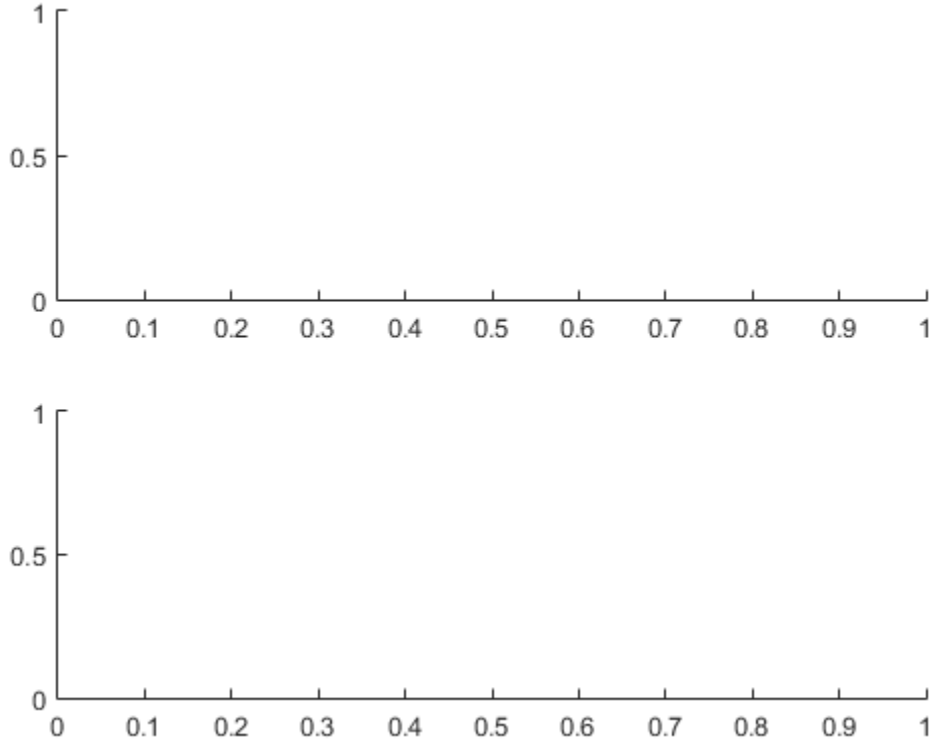
plot(t,y,'DurationTickFormat','mm:ss')
```



Specify Axes for Line Plot

Create a figure with two subplots and return the handle to each subplot axes, `ax1` and `ax1`.

```
figure % new figure
ax1 = subplot(2,1,1); % top subplot
ax2 = subplot(2,1,2); % bottom subplot
```

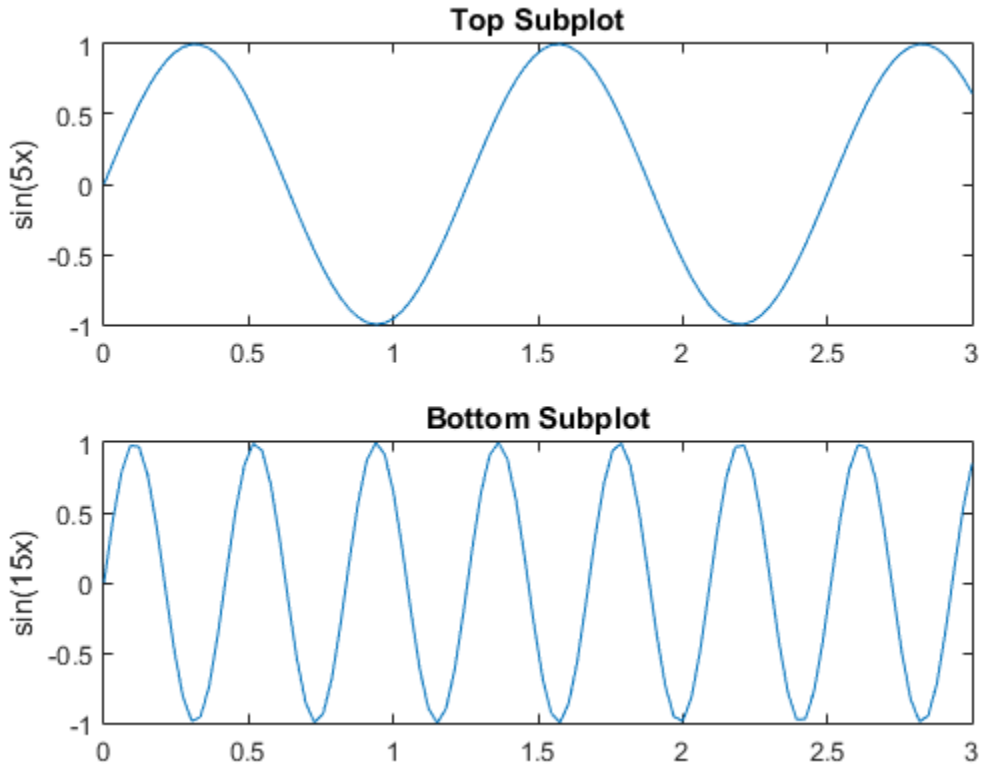


Create a 2-D line plot in each axes by referring to the axes handles. Add a title and *y*-axis label to each axes by passing the axes handles to the `title` and `ylabel` functions.

```
x = linspace(0,3);
y1 = sin(5*x);
y2 = sin(15*x);

plot(ax1,x,y1)
title(ax1,'Top Subplot')
ylabel(ax1,'sin(5x)')

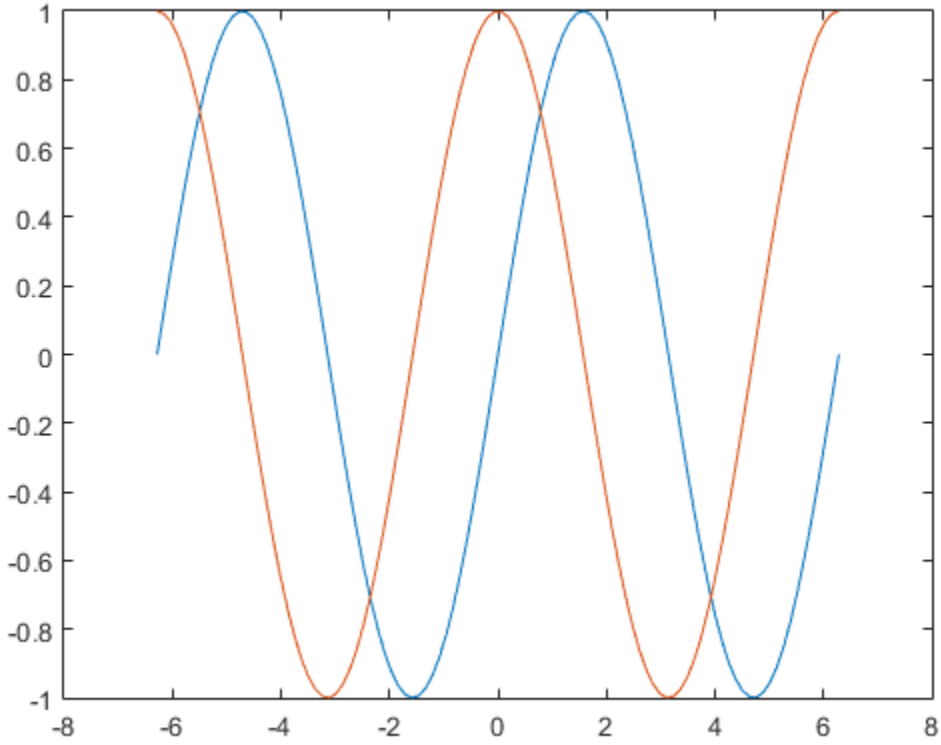
plot(ax2,x,y2)
title(ax2,'Bottom Subplot')
ylabel(ax2,'sin(15x)')
```



Modify Lines After Creation

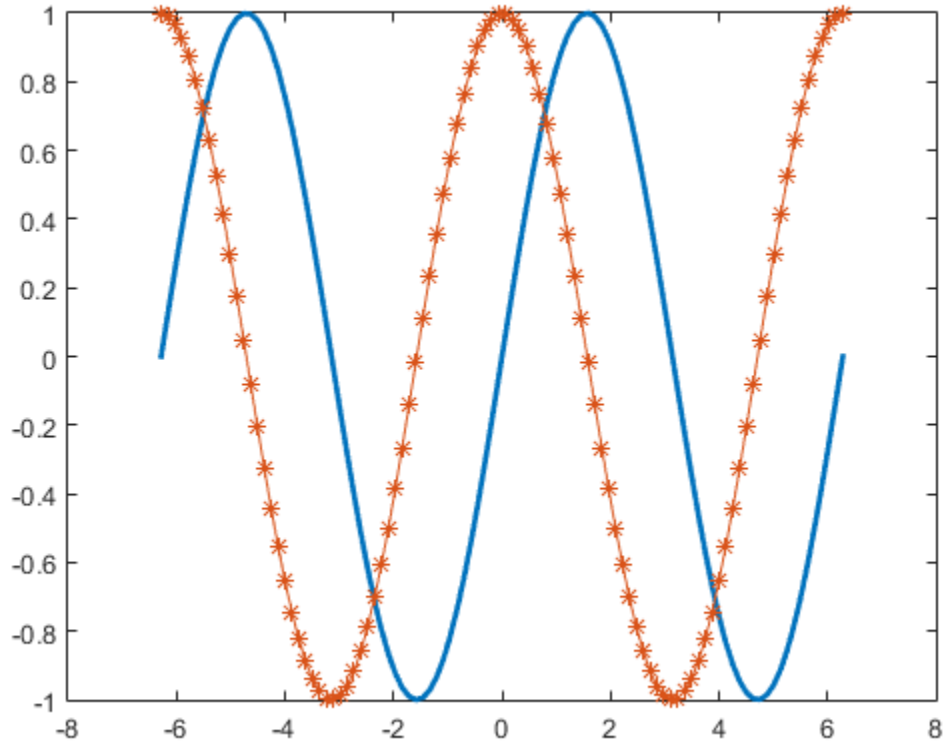
Define `x` as 100 linearly spaced values between -2π and 2π. Define `y1` and `y2` as sine and cosine values of `x`. Create a line plot of both sets of data and return the two chart lines in `p`.

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);
p = plot(x,y1,x,y2);
```



Change the line width of the first line to 2. Add star markers to the second line. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
p(1).LineWidth = 2;
p(2).Marker = '*';
```

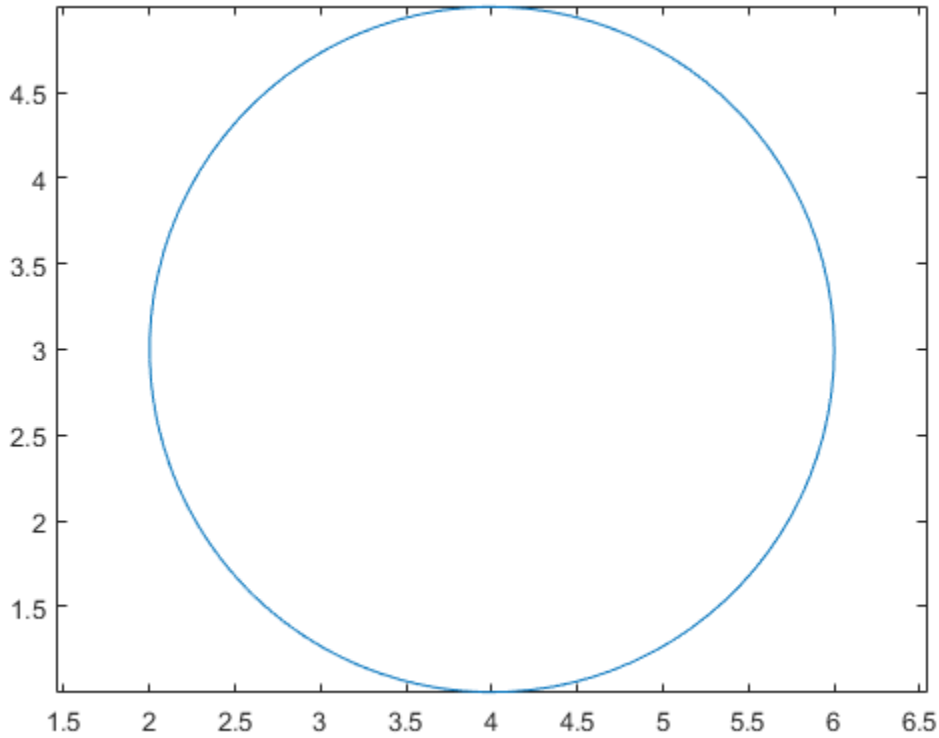


Plot Circle

Plot a circle centered at the point (4,3) with a radius equal to 2. Use `axis equal` to use equal data units along each coordinate direction.

```
r = 2;
xc = 4;
yc = 3;

theta = linspace(0,2*pi);
x = r*cos(theta) + xc;
y = r*sin(theta) + yc;
plot(x,y)
axis equal
```



Input Arguments

Y — y values

scalar | vector | matrix

y values, specified as a scalar, a vector, or a matrix. Y can be a numeric array, logical array, datetime array, or duration array. To plot against specific *x* values you must also specify X.

X — x values

scalar | vector | matrix

x values, specified as a scalar, a vector, or a matrix. `X` can be a numeric array, logical array, datetime array, or duration array.

`LineSpec` — Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. The elements of the string can appear in any order, and you can omit one or more options from the string specifier. If you omit the line style and specify the marker character, then the plot shows only the marker and no line.

If `Y` is a matrix and you specify a color with `LineSpec`, then all the lines use the specified color. If you specify a marker type or line style and do not specify a color, then the lines cycle through the color order.

Example: `'--or'` is a red dashed line with circle markers

Specifier	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line

Specifier	Marker
`o`	Circle
`+`	Plus sign
`*`	Asterisk
`.`	Point
`x`	Cross
`s`	Square
`d`	Diamond
`^`	Upward-pointing triangle
`v`	Downward-pointing triangle
`>`	Right-pointing triangle
`<`	Left-pointing triangle

Specifier	Marker
p	Pentagram
h	Hexagram

Specifier	Color
y	yellow
m	magenta
c	cyan
r	red
g	green
b	blue
w	white
k	black

`ax` — Axes object

axes object

Axes object. If you do not specify an axes, then the `plot` function uses the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

The chart line properties listed here are only a subset. For a complete list, see Chart Line Properties.

Example: `'Marker','o','MarkerFaceColor','red'`

`'Color'` — Line color

`[0 0.4470 0.7410]` (default) | RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string, or `'none'`. If you specify the `Color` as `'none'`, then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`'DatetimeTickFormat'` — Format for `datetime` tick labels

string

Format for `datetime` tick labels, specified as the comma-separated pair consisting of `'DatetimeTickFormat'` and a string. Use the letters `A-Z` and `a-z` to construct a custom string value. These letters correspond to the Unicode Locale Data Markup Language (LDML) standard for dates. You can include non-ASCII letter characters such as a hyphen, space, or colon to separate the fields.

If you do not specify a value for `'DatetimeTickFormat'`, then `plot` automatically optimizes and updates the tick labels based on the axis limits.

Example: `'DatetimeTickFormat','eeee, MMMM d, yyyy HH:mm:ss'` displays a date and time such as `Saturday, April 19, 2014 21:41:06`.

The following table shows several common display formats and examples of the formatted output for the date, Saturday, April 19, 2014 at 9:41:06 PM in New York City.

Value of `DatetimeTickFormat`	Example
`'yyyy-MM-dd'`	2014-04-19

Value of `DatetimeTickFormat`	Example
`'dd/MM/yyyy'`	`19/04/2014`
`'dd.MM.yyyy'`	`19.04.2014`
`'yyyy# MM# dd#'`	`2014# 04# 19#`
`'MMMM d, yyyy'`	`April 19, 2014`
`'eeee, MMMM d, yyyy HH:mm:ss'`	`Saturday, April 19, 2014 21:41:06`
`'MMMM d, yyyy HH:mm:ss Z'`	`April 19, 2014 21:41:06 -0400`

For a complete list of valid letter identifiers, see the `Format` property for datetime arrays.

`DatetimeTickFormat` is not a chart line property. You must set the tick format using the name-value pair argument when creating a plot.

`'DurationTickFormat'` — Format for `duration` tick labels

string

Format for `duration` tick labels, specified as the comma-separated pair consisting of `'DurationTickFormat'` and a string.

If you do not specify a value for `'DurationTickFormat'`, then `plot` automatically optimizes and updates the tick labels based on the axis limits.

To display a duration as a single number that includes a fractional part, for example, 1.234 hours, specify one of the following strings.

Value of `DurationTickFormat`	Description
`'y'`	Number of exact fixed-length years. A fixed-length year is equal to 365.2425 days.
`'d'`	Number of exact fixed-length days. A fixed-length day is equal to 24 hours.
`'h'`	Number of hours
`'m'`	Number of minutes
`'s'`	Number of seconds

Example: `'DurationTickFormat','h'` displays duration values in terms of fixed-length days.

To display a duration in the form of a digital timer, specify one of the following strings.

- `'dd:hh:mm:ss'`
- `'hh:mm:ss'`
- `'mm:ss'`
- `'hh:mm'`

In addition, you can display up to nine fractional second digits by appending up to nine `S` characters.

Example: `'DurationTickFormat','hh:mm:ss.SSS'` displays the milliseconds of a duration value to three digits.

`DurationTickFormat` is not a chart line property. You must set the tick format using the name-value pair argument when creating a plot.

`'LineStyle'` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	
`':'`	Dotted line	
`'-.'`	Dash-dotted line	
`'none'`	No line	No line

`'LineWidth'` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`'Marker'` — Marker symbol

`'none'` (default) | string

Marker symbol, specified as one of the marker strings in this table. By default, a chart line does not have markers. Add markers at each data point along the line by specifying a marker symbol.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'Marker','+'`

Example: `'Marker','diamond'`

`'MarkerEdgeColor'` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

'MarkerFaceColor' — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

'MarkerSize' — Marker size
6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

Output Arguments

h — One or more chart line objects
scalar | vector

One or more chart line objects, returned as a scalar or a vector. These are unique identifiers, which you can use to query and modify properties of a specific chart line.

More About

Tips

- Use NaN and Inf values to create breaks in the lines. For example, this code plots the first two elements, skips the third element, and draws another line using the last two elements:

  ```
  plot([1,2,NaN,4,5])
  ```

- plot uses colors and line styles based on the ColorOrder and LineStyleOrder properties of the axes. plot cycles through the colors with the first line style. Then, it cycles through the colors again with each additional line style.

You can change the default colors and line styles by setting default values for the `ColorOrder` and `LineStyleOrder` properties. For example, to set the default line styles to a solid line with asterisk markers, a dotted line, and circle markers with no line, use this command:

```
set(groot,'defaultAxesLineStyleOrder',{'-*',':','o'})
```

For more information about setting defaults, see “Default Property Values”.

Properties

Chart Line Properties

Introduced before R2006a

plot3

3-D line plot

Syntax

```
plot3(X1,Y1,Z1,...)
plot3(X1,Y1,Z1,LineSpec,...)
plot3(...,'PropertyName',PropertyValue,...)
plot3(axes_handle,...)
h = plot3(...)
```

Description

The `plot3` function displays a three-dimensional plot of a set of data points.

`plot3(X1,Y1,Z1,...)`, where `X1`, `Y1`, `Z1` are vectors or matrices, plots one or more lines in three-dimensional space through the points whose coordinates are the elements of `X1`, `Y1`, and `Z1`.

`plot3(X1,Y1,Z1,LineSpec,...)` creates and displays all lines defined by the `Xn,Yn,Zn,LineSpec` quads, where `LineSpec` is a line specification that determines line style, marker symbol, and color of the plotted lines.

`plot3(...,'PropertyName',PropertyValue,...)` sets line properties to the specified property values for all the charting lines created by `plot3`. See Chart Line Properties for a description of the properties you can set.

`plot3(axes_handle,...)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle` can precede any of the input combinations in the previous syntaxes.

`h = plot3(...)` returns a column vector of charting line handles, with one handle per object.

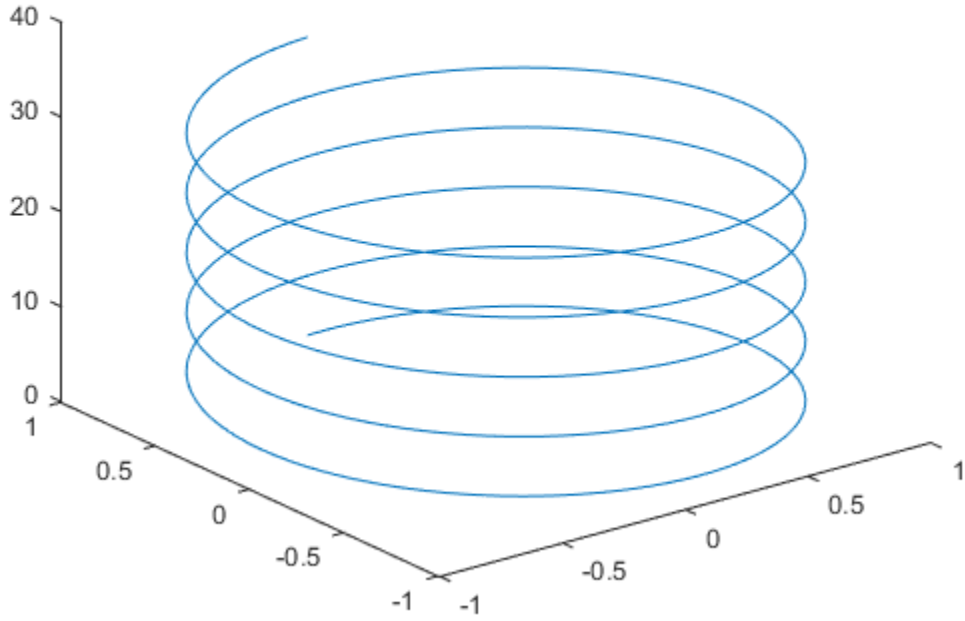
Examples

Plot 3-D Helix

Define `t` as values between 0 and 10π. Define `st` and `ct` as vectors of sine and cosine values. Plot a 3-D helix.

```
t = 0:pi/50:10*pi;
st = sin(t);
ct = cos(t);

figure
plot3(st,ct,t)
```



More About

Tips

If one or more of `X1`, `Y1`, `Z1` is a vector, the vectors are plotted versus the rows or columns of the matrix, depending whether the vectors' lengths equal the number of rows or the number of columns.

You can mix `Xn,Yn,Zn` triples with `Xn,Yn,Zn,`*`LineSpec`* quads, for example,

```
plot3(X1,Y1,Z1,X2,Y2,Z2,LineSpec,X3,Y3,Z3)
```

See `LineSpec` and `plot` for information on line types and markers.

Properties

Chart Line Properties

Introduced before R2006a

plotbrowser

Show or hide figure **Plot Browser**

Syntax

```
plotbrowser('on')
plotbrowser('off')
plotbrowser
plotbrowser(figure_handle,...)
```

Description

`plotbrowser('on')` displays the Plot Browser on the current figure.

`plotbrowser('off')` hides the Plot Browser on the current figure.

`plotbrowser` toggles the visibility of the Plot Browser on the current figure. You can use `plotbrowser('toggle')` instead for the same functionality.

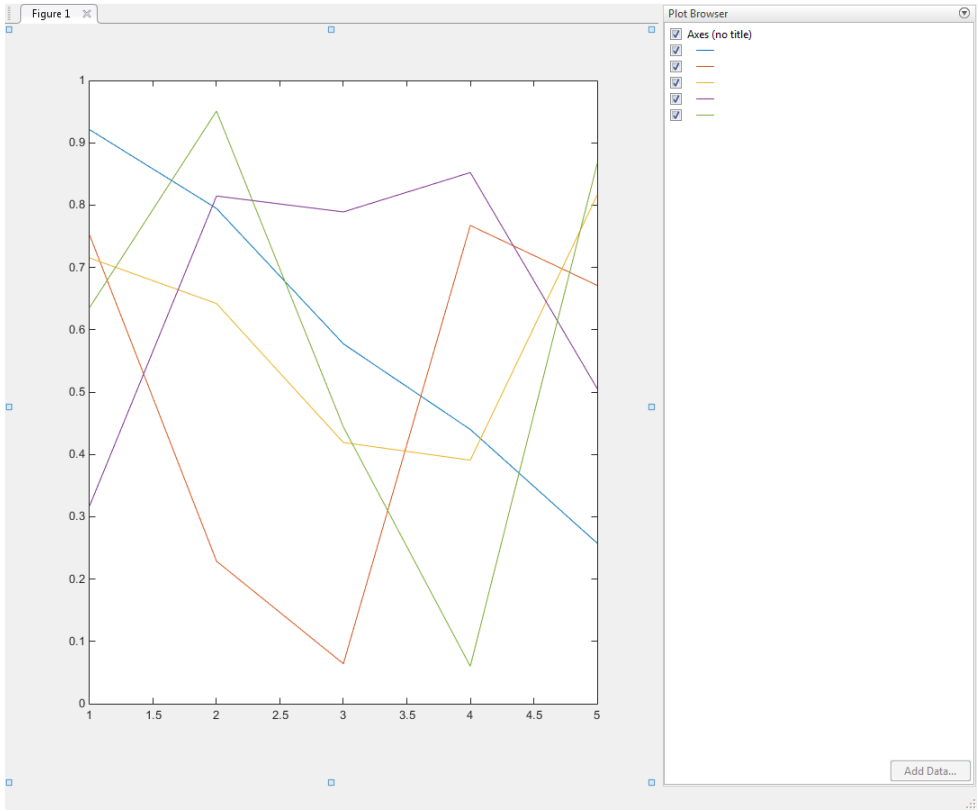
`plotbrowser(figure_handle,...)` shows or hides the Plot Browser on the figure specified by `figure_handle`.

Examples

Open Plot Browser

Plot a 5-by-5 matrix of random numbers. Then, open the plot browser.

```
plot(rand(5))
plotbrowser('on')
```



Alternatives

To collectively enable Plotting Tools, use the large Plotting Tool icon on the figure toolbar. To collectively disable the Plotting Tools, use the smaller icon. Open or close the **Plot Browser** tool from the figure's **View** menu.

More About

Tips

If you call `plotbrowser` in a MATLAB program and subsequent lines depend on the Plot Browser being fully initialized, follow it by `drawnow` to ensure complete initialization.

See Also

`plottools` | `figurepalette` | `propertyeditor`

Introduced before R2006a

plotedit

Interactively edit and annotate plots

Syntax

```
plotedit on
plotedit off
plotedit
plotedit(h)
plotedit(state)
plotedit(h,state)
```

Description

`plotedit on` starts plot edit mode for the current figure, allowing you to use a graphical interface to annotate and edit plots easily. In plot edit mode, you can label axes, change line styles, and add text, line, and arrow annotations.

`plotedit off` ends plot mode for the current figure.

`plotedit` toggles the plot edit mode for the current figure.

`plotedit(h)` toggles the plot edit mode for the figure specified by figure handle `h`.

`plotedit(state)` specifies the `plotedit` state for the current figure. Values for `state` can be as shown.

Value for state	Description
`'on'`	Starts plot edit mode
`'off'`	Ends plot edit mode
`'showtoolsmenu'`	Displays the **Tools** menu in the menu bar
`'hidetoolsmenu'`	Removes the **Tools** menu from the menu bar

Note `'hidetoolsmenu'` is intended for UI developers who do not want the **Tools** menu to appear in applications that use the figure window.

`plotedit(h,state)` specifies the `plotedit` `state` for figure handle `h`.

Examples

Start plot edit mode for figure 2.

```
plotedit(2)
```

End plot edit mode for figure 2.

```
plotedit(2, 'off')
```

Hide the **Tools** menu for the current figure:

```
plotedit('hidetoolsmenu')
```

plotmatrix

Scatter plot matrix

Syntax

```
plotmatrix(X,Y)
plotmatrix(X)
plotmatrix(___,LineSpec)

[H,AX,BigAx,P,PAx] = plotmatrix(___)
```

Description

`plotmatrix(X,Y)` creates a matrix of subaxes containing scatter plots of the columns of `X` against the columns of `Y`. If `X` is *p*-by-*n* and `Y` is *p*-by-*m*, then `plotmatrix` produces an *n*-by-*m* matrix of subaxes.

`plotmatrix(X)` is the same as `plotmatrix(X,X)` except that the subaxes along the diagonal are replaced with histogram plots of the data in the corresponding column of `X`. For example, the subaxes along the diagonal in the *i*th column is replaced by `hist(X(:,i))`.

`plotmatrix(___,LineSpec)` specifies the line style, marker symbol, and color for the scatter plots. The option `LineSpec` can be preceded by any of the input argument combinations in the previous syntaxes.

`[H,AX,BigAx,P,PAx] = plotmatrix(___)` returns handles to the graphic objects created as follows:

- `H` – Matrix of handles to the line objects used to create the scatter plots
- `AX` – Matrix of handles to the individual subaxes
- `BigAx` – Handle to the big axes that frames the subaxes
- `P` – Vector of handles for the patch objects that create the histogram plots
- `PAx` – Vector of handles to the invisible histogram axes

`BigAx` is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command will center text with respect to the big axes.

Examples

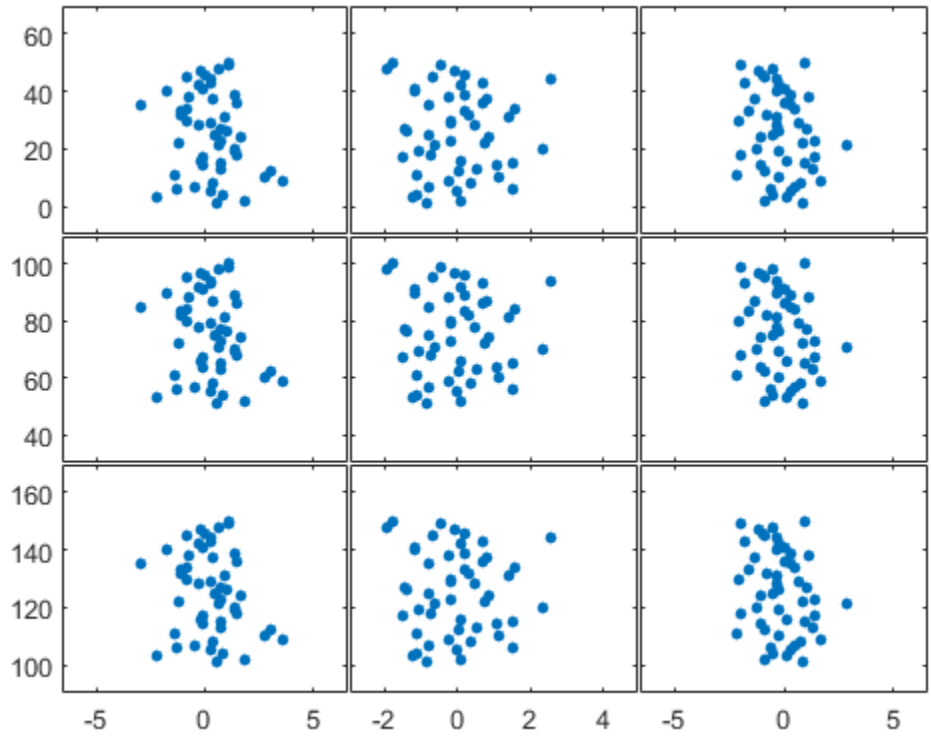
Create Scatter Plot Matrix with Two Matrix Inputs

Initialize the random-number generator to make the output of `randn` repeatable. Define `X` as a matrix of normally distributed pseudorandom data and `Y` as a matrix of integer values.

```
rng default
X = randn(50,3);
Y = reshape(1:150,50,3);
```

Create a scatter plot matrix of the columns of `X` against the columns of `Y`.

```
figure
plotmatrix(X,Y)
```



The subplot in the ith row, jth column of the figure is a scatter plot of the ith column of `Y` against the jth column of `X`.

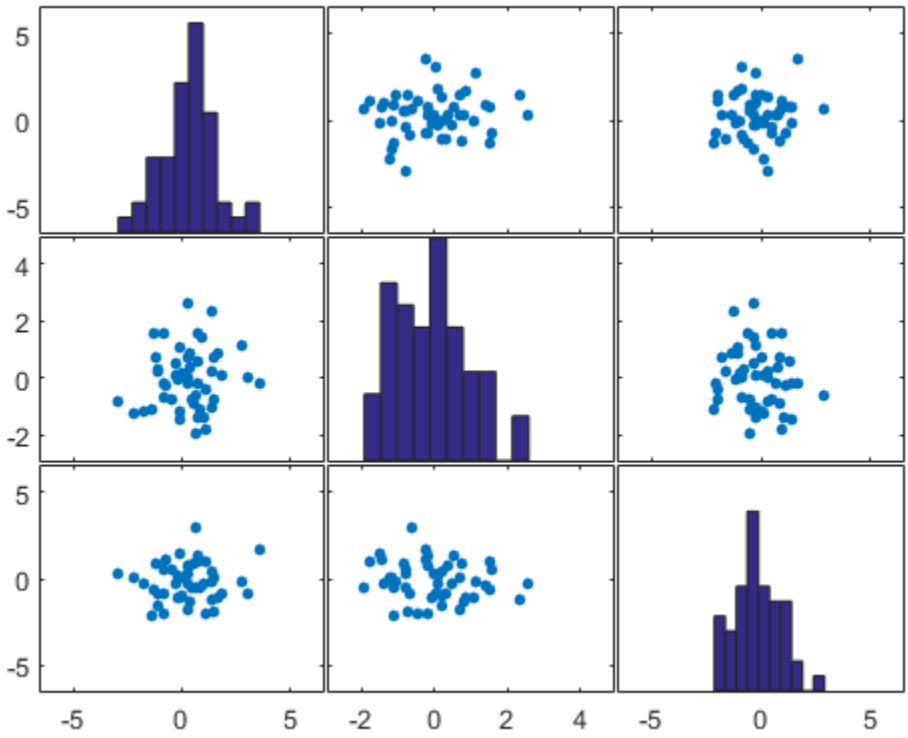
Create Scatter Plot Matrix with One Matrix Input

Initialize the random-number generator to make the output of `randn` repeatable and generate a matrix of normally distributed pseudorandom data

```
rng default
X = randn(50,3);
```

Create a scatter plot matrix.

```
figure
plotmatrix(X)
```



The subplot in the ith row, jth column of the matrix is a scatter plot of the ith column of `X` against the jth column of `X`. Along the diagonal, `plotmatrix` creates a histogram plot of each column of `X`.

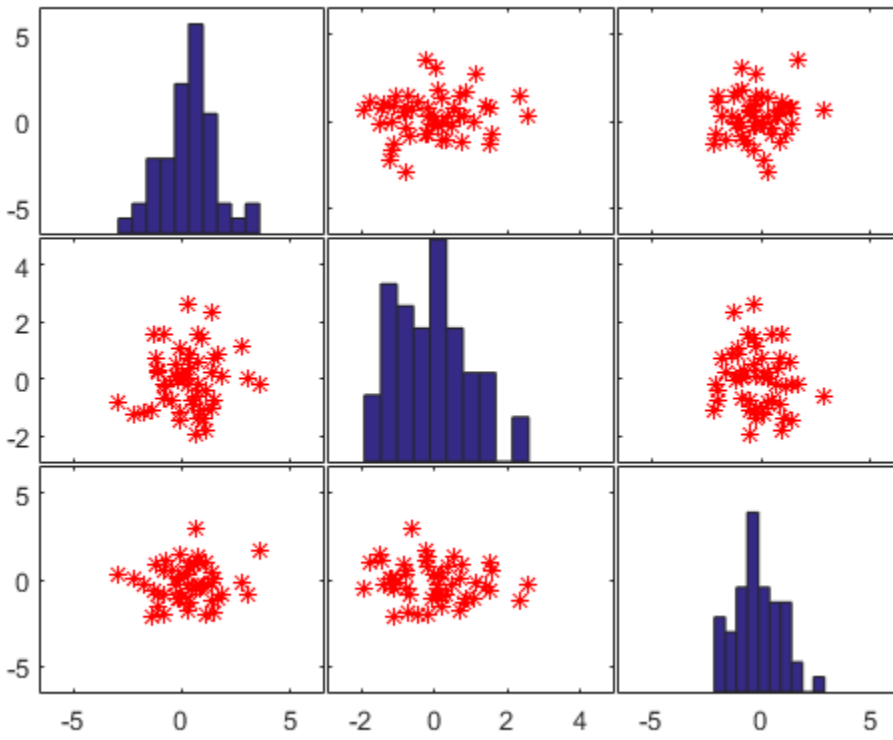
Specify Marker Type and Color

Initialize the random-number generator to make the output of `randn` repeatable. Generate a matrix of normally distributed pseudorandom data.

```
rng(0,'twister');
X = randn(50,3);
```

Create a scatter plot matrix and specify the marker type and the color for the scatter plots.

```
figure
plotmatrix(X,'*r')
```

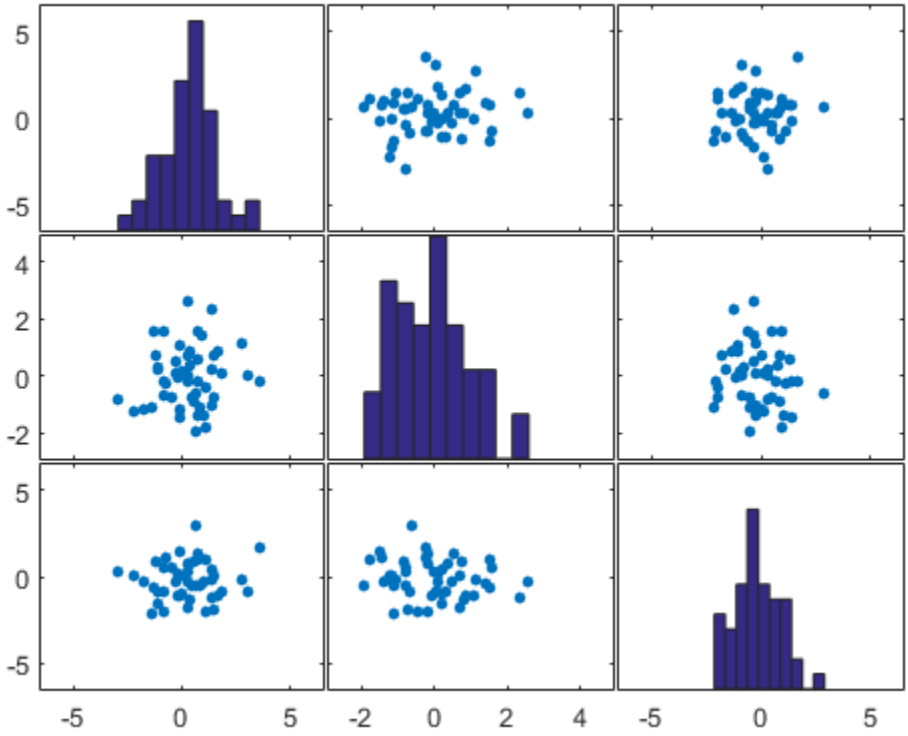


The `LineSpec` option sets properties for the scatter plots. To set properties for the histogram plots, use the patch object handles.

Set Plotmatrix Properties after Creation

Create a scatter plot matrix of random data.

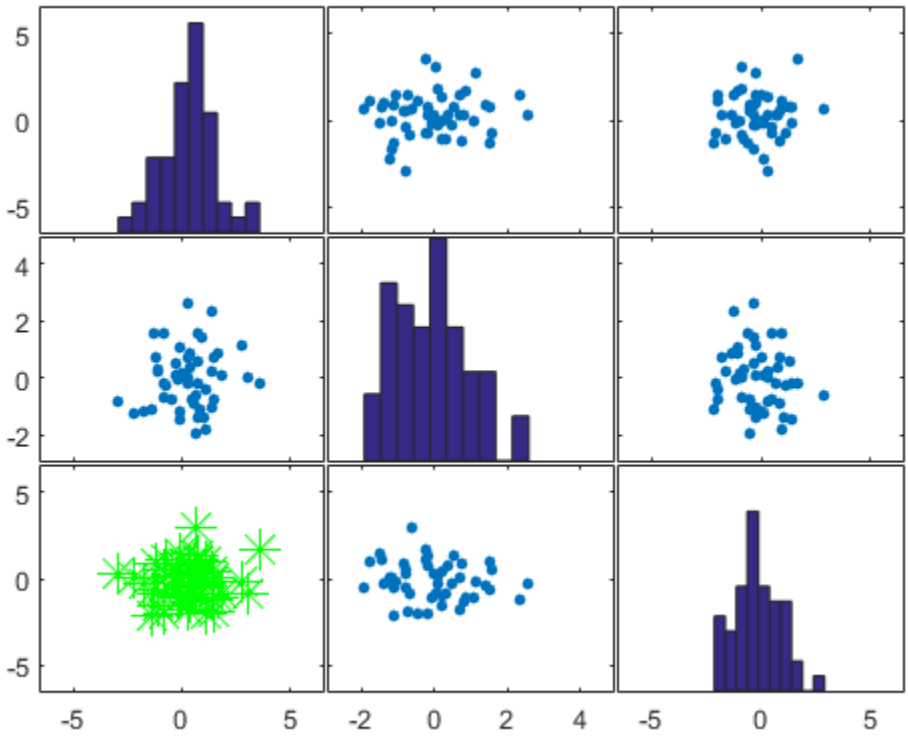
```
rng default
X = randn(50,3);
[H,AX,BigAx,P,PAx] = plotmatrix(X);
```



To set properties for the scatter plots, use `H`. To set properties for the histograms, use `P`. To set axes properties, use `AX`, `BigAx`, and `PAx`. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

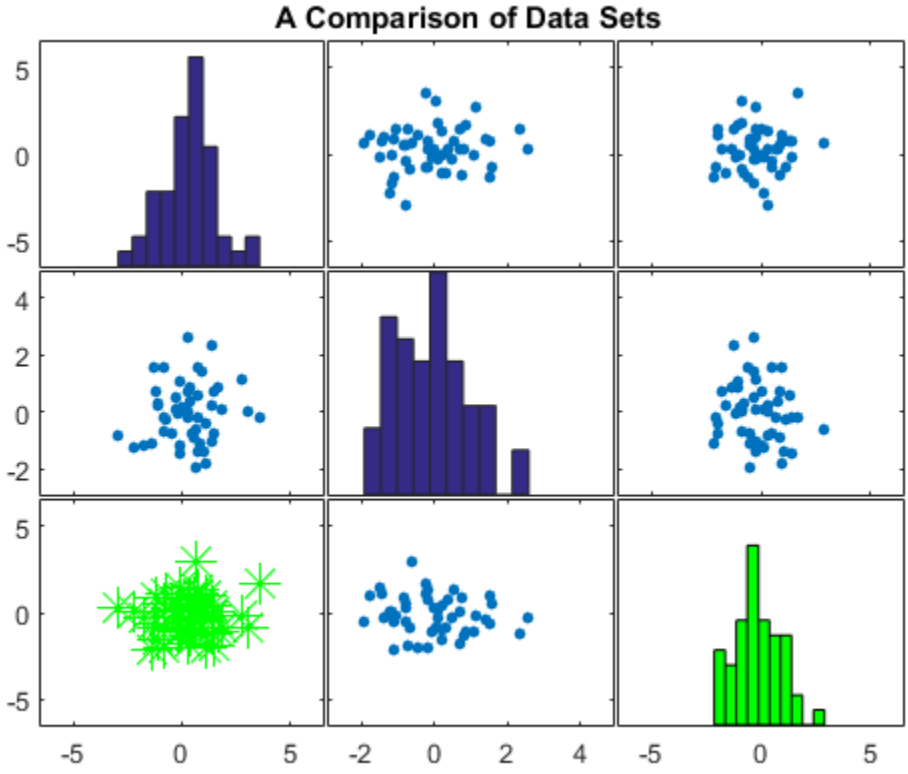
Set the color and marker type for the scatter plot in the lower left corner.

```
H(3).Color = 'g';
H(3).Marker = '*';
```



Set the color for the histogram plot in the lower right corner. Use the `title` command to title the figure.

```
P(3).EdgeColor = 'k';
P(3).FaceColor = 'g';
title(BigAx,'A Comparison of Data Sets')
```



Input Arguments

X — Data to display

matrix

Data to display, specified as a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Y — Data to plot against X

matrix

Data to plot against `X`, specified as a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`LineSpec` — Line style, marker symbol, and color for scatter plots

string

Line style, marker symbol, and color for the scatter plots, specified as a string. For more information on line style, marker symbol, and color options see `LineSpec`.

Example: `':*r'`

Data Types: `char`

Output Arguments

`H` — Line object handles

matrix

Line object handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific line object. The line objects are used to create the scatter plots.

`AX` — Subaxes handles

matrix

Subaxes handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific subaxes.

`BigAx` — Big axes handle

scalar

Big axes handle, returned as a scalar. This is a unique identifier, which you can use to query and modify properties of the big axes. `BigAx` is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command will center text with respect to the big axes.

`P` — Patch object handles

vector | []

Patch object handles, returned as a vector or `[]`. If histogram plots are created, then `P` is returned as a vector of patch object handles for the histogram plots. These are unique

identifiers, which you can use to query and modify the properties of a specific patch object. If no histogram plots are created, then `P` is returned as empty brackets.

`PAx` — Handle to invisible histogram axes

vector | []

Handle to invisible histogram axes, returned as a vector or `[ ]`. If histogram plots are created, then `PAx` is returned as a vector of histogram axes handles. These are unique identifiers, which you can use to query and modify the properties of a specific axes, such as the axes scale. If no histogram plots are created, then `PAx` is returned as empty brackets.

See Also

`scatter` | `scatter3`

Introduced before R2006a

plottools

Show or hide plot tools

Syntax

```
plottools('on')
plottools('off')
plottools
plottools(figure_handle,...)
plottools(...,'tool')
```

Description

`plottools('on')` displays the Figure Palette, Plot Browser, and Property Editor on the current figure, configured as you last used them.

`plottools('off')` hides the Figure Palette, Plot Browser, and Property Editor on the current figure.

`plottools` with no arguments, is the same as `plottools('on')`

`plottools(figure_handle,...)` displays or hides the plot tools on the specified figure instead of on the current figure.

`plottools(...,'tool')` operates on the specified tool only. *`tool`* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

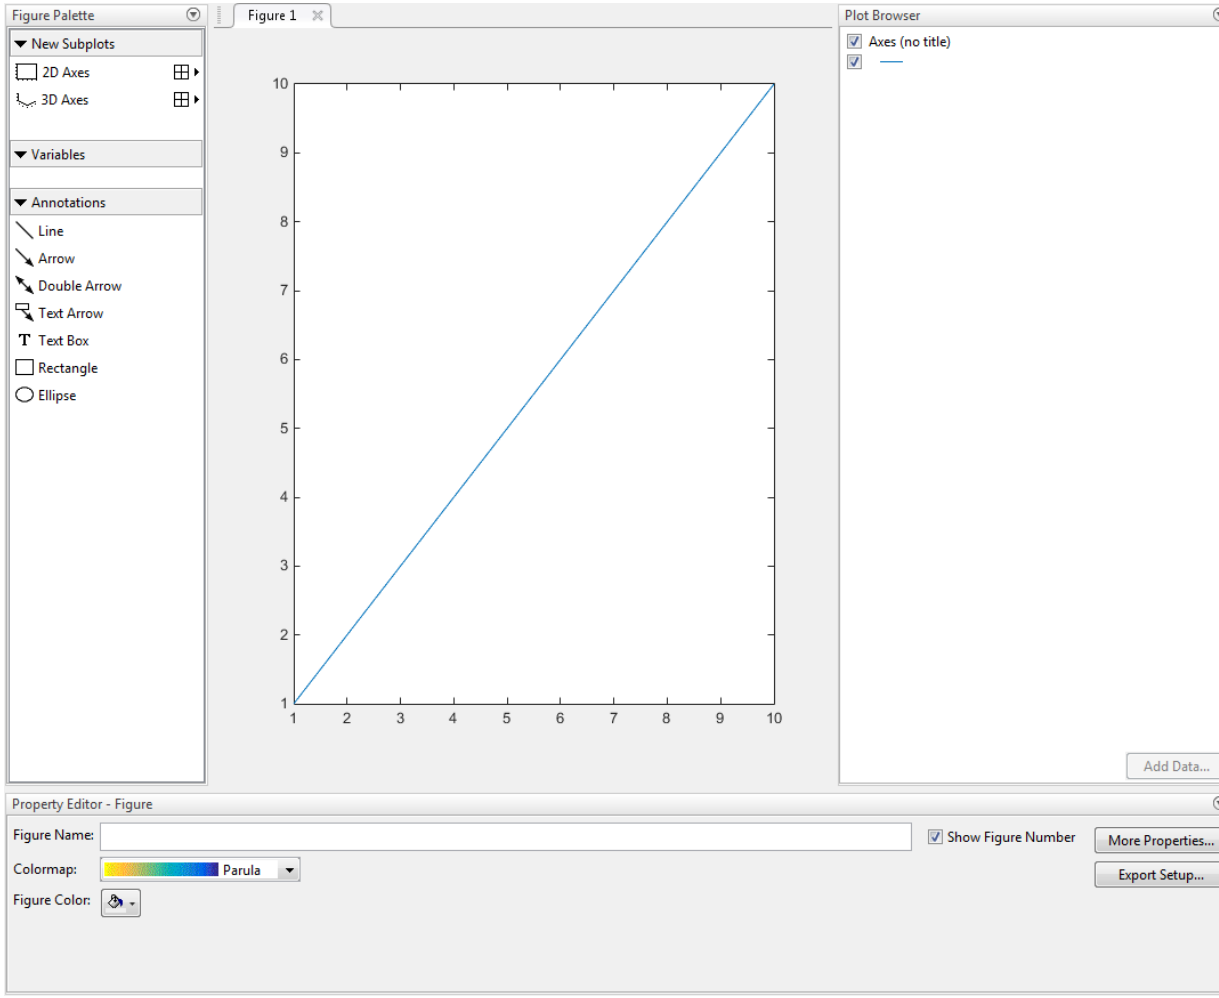
Note: The first time you open the plotting tools, all three of them appear, grouped around the current figure as shown above. If you close, move, or undock any of the tools, MATLAB remembers the configuration you left them in and restores it when you invoke the tools for subsequent figures, both within and across MATLAB sessions.

Examples

Open Plot Tools

Create a line plot and open the plot tools.

```
plot(1:10);
plottools('on')
```



Alternatives

Click the larger **Plotting Tools** icon on the figure toolbar to collectively enable plotting tools, and the smaller icon to collectively disable them. Individually select

the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Customize Graph Using Plot Tools”.

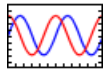
See Also

`figurepalette` | `plotbrowser` | `propertyeditor`

Introduced before R2006a

plotyy

2-D line plots with y-axes on both left and right side



Syntax

```
plotyy(X1,Y1,X2,Y2)
plotyy(X1,Y1,X2,Y2,function)
plotyy(X1,Y1,X2,Y2,'function1','function2')
[AX,H1,H2] = plotyy(...)
```

Description

`plotyy(X1,Y1,X2,Y2)` plots `Y1` versus `X1` with *y*-axis labeling on the left and plots `Y2` versus `X2` with *y*-axis labeling on the right.

`plotyy(X1,Y1,X2,Y2,function)` uses the specified plotting function to produce the graph.

`function` can be either a function handle or a string specifying `plot`, `semilogx`, `semilogy`, `loglog`, `stem`, or any MATLAB function that accepts the syntax

```
h = function(x,y)
```

For example,

```
plotyy(x1,y1,x2,y2,@loglog) % function handle
plotyy(x1,y1,x2,y2,'loglog') % string
```

Function handles enable you to access user-defined local functions and can provide other advantages. See @ for more information on using function handles.

`plotyy(X1,Y1,X2,Y2,'function1','function2')` uses `function1(X1,Y1)` to plot the data for the left axis and `function2(X2,Y2)` to plot the data for the right axis.

`[AX,H1,H2] = plotyy(...)` returns the handles of the two axes created in `AX` and the handles of the graphics objects from each plot in `H1` and `H2`. `AX(1)` is the left axes and `AX(2)` is the right axes.

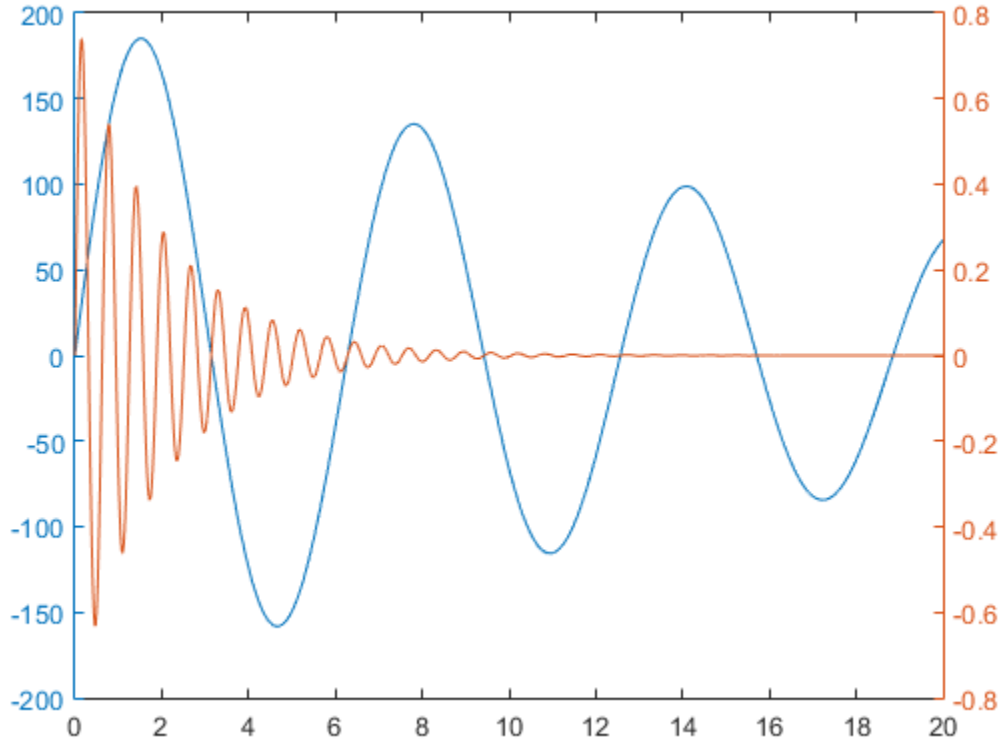
Examples

Plot Two Data Sets with Different y-Axes

Plot two data sets on one graph using two *y*-axes.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure % new figure
plotyy(x,y1,x,y2)
```



Add Title and Axis Labels

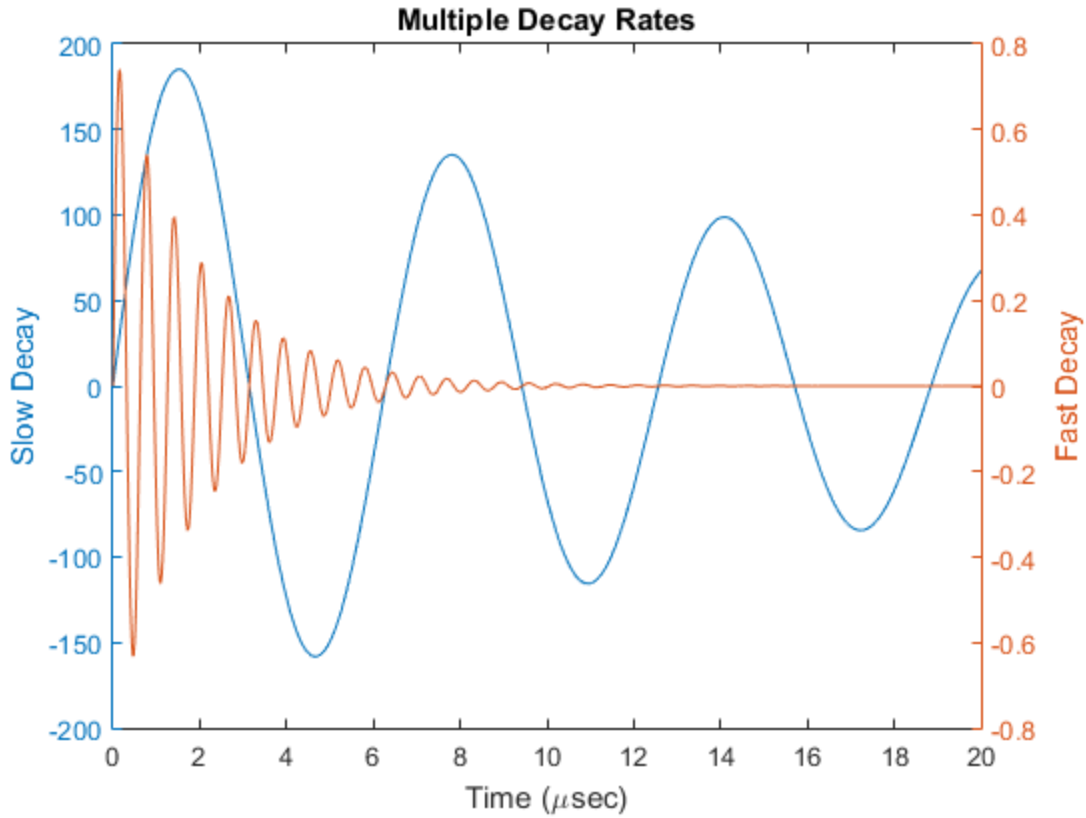
Plot two data sets using a graph with two *y*-axes. Add a title and axis labels.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure % new figure
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);

title('Multiple Decay Rates')
xlabel('Time (\musec)')
```

```
ylabel(hAx(1),'Slow Decay') % left y-axis
ylabel(hAx(2),'Fast Decay') % right y-axis
```

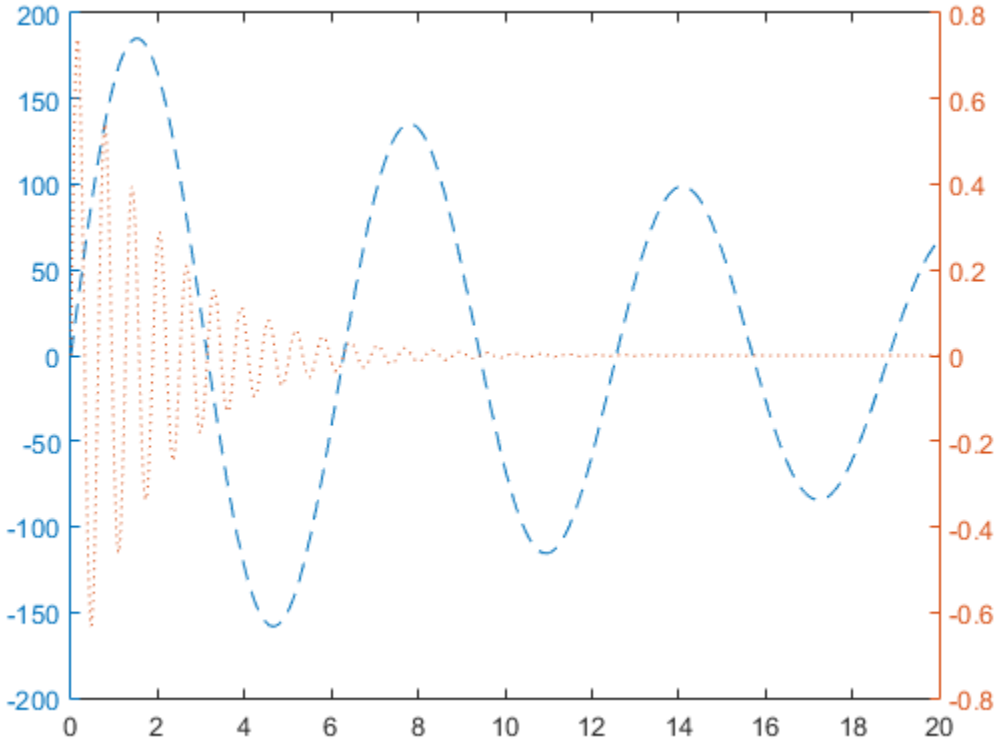


Change Line Styles

Plot two data sets using a graph with two *y*-axes. Change the line styles. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);
hLine1.LineStyle = '--';
hLine2.LineStyle = ':';
```



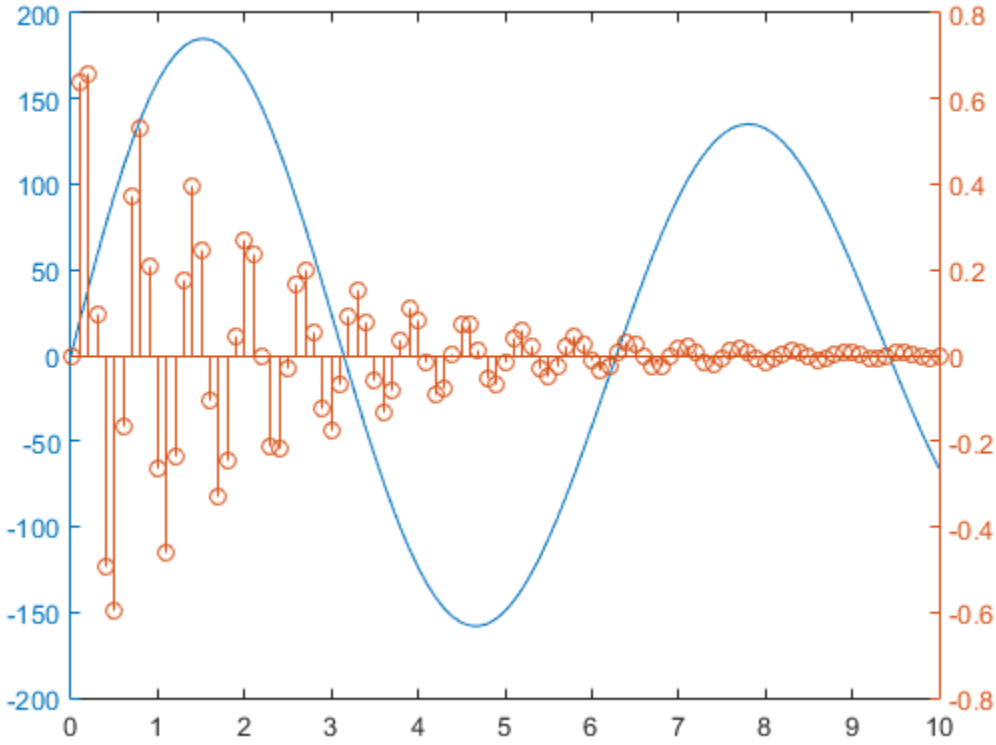
Combine Different Types of Plots

Plot two data sets using a graph with two y-axes. Use a line plot for the data associated with the left *y*-axes. Use a stem plot for the data associated with the right *y*-axes.

```
x = 0:0.1:10;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure
```

```
plotyy(x,y1,x,y2,'plot','stem')
```



Use Right y-Axis for Two Data Sets

Plot three data sets using a graph with two *y*-axes. Plot one set of data associated with the left *y*-axis. Plot two sets of data associated with the right *y*-axis by using two-column matrices.

```
x = linspace(0,10);
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
y3 = 0.2*exp(-0.5*x).*sin(10*x);

figure
```

```
[hAx,hLine1,hLine2] = plotyy(x,y1,[x',x'],[y2',y3']);
```

matlab.unittest.plugins

Summary of classes in MATLAB Plugins Interface

Description

Plugins customize a `TestRunner` object. The `matlab.unittest.plugins` package consists of the following customized MATLAB plugins.

matlab.unittest.plugins.CodeCoveragePlugin	Plugin that produces a code coverage report
matlab.unittest.plugins.DiagnosticsValidationPlugin	Plugin to help validate diagnostic code
matlab.unittest.plugins.FailureDiagnosticsPlugin	Plugin to show diagnostics on failure
matlab.unittest.plugins.LoggingPlugin	Plugin to report diagnostic messages
matlab.unittest.plugins.OutputStream	Interface that determines where to send text output
matlab.unittest.plugins.StopOnFailuresPlugin	Plugin to debug test failures
matlab.unittest.plugins.TAPPlugin	Plugin that produces Test Anything Protocol stream
matlab.unittest.plugins.ToFile	Output stream to write text output to file
matlab.unittest.plugins.ToStandardOutput	Output stream to display text information to screen
matlab.unittest.plugins.TestRunnerPlugin	Plugin interface for extending TestRunner
matlab.unittest.plugins.TestRunProgressPlugin	Plugin that reports test run progress

Related Examples

- “Add Plugin to Test Runner”
- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”
- “Write Plugin to Save Diagnostic Details”

matlab.unittest.plugins.CodeCoveragePlugin class

Package: matlab.unittest.plugins

Plugin that produces a code coverage report

Description

Add the `CodeCoveragePlugin` to the `TestRunner` to produce a line coverage report for MATLAB source code. The testing framework runs the tests, and the resulting coverage report indicates the executed lines of code. The coverage report is based on source code located in one or more folders or packages.

The `CodeCoveragePlugin` uses the MATLAB profiler to determine which lines of code the tests execute. The tests and source code should not interact with the profiler. Prior to running a suite of tests, the plugin clears any data collected by the profiler.

Construction

`matlab.unittest.plugins.CodeCoveragePlugin.forFolder(folder)` creates a plugin that produces a code coverage report for one or more folders. The plugin reports on the source code inside `folder`.

`matlab.unittest.plugins.CodeCoveragePlugin.forPackage(package)` creates a plugin that produces a code coverage report for one or more packages. The plugin reports on the source code contained in `package`.

Input Arguments

`folder` — Location(s) of folder containing source code

string | cell array of strings

Location(s) of folder containing source code, specified as a string or cell array of strings. `folder` is the absolute or relative path to one or more folders. If you specify multiple folders, MATLAB opens a profile coverage report for each folder.

Example: `'C:\projects\myproj'`

Example: `pwd`

Example: `{'C:\projects\myprojA','myprojB'}`

`package` — Name(s) of package containing source code

string | cell array of strings

Name(s) of package containing source code, specified as a string or cell array of strings. If you specify multiple packages, MATLAB opens a profile coverage report for each package.

Example: `'myproject.controller'`

Example: `{'myprojA','myprojB'}`

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Generate Code Coverage Report

In an new file, `quadraticSolver.m`, in your working folder, create the following function.

```
function roots = quadraticSolver(a,b,c)
% quadraticSolver returns solutions to the
% quadratic equation a*x^2 + b*x + c = 0.

checkInputs

roots(1) = (-b + sqrt(b^2 - 4*a*c)) / (2*a);
roots(2) = (-b - sqrt(b^2 - 4*a*c)) / (2*a);

    function checkInputs
        if ~isa(a,'numeric') || ~isa(b,'numeric') || ~isa(c,'numeric')
            error('quadraticSolver:InputMustBeNumeric', ...
                'Coefficients must be numeric.')
        end
```

```
    end
end
```

Create a test for the quadratic solver. In a `tests` subfolder, create `SolverTest.m` containing the following test class.

```
classdef SolverTest < matlab.unittest.TestCase
    % SolverTest tests solutions to the quadratic equation
    % a*x^2 + b*x + c = 0

    methods (Test)
        function testRealSolution(testCase)
            actSolution = quadraticSolver(1,-3,2);
            expSolution = [2,1];
            testCase.verifyEqual(actSolution,expSolution)
        end
        function testImaginarySolution(testCase)
            actSolution = quadraticSolver(1,2,10);
            expSolution = [-1+3i, -1-3i];
            testCase.verifyEqual(actSolution,expSolution)
        end
    end

end
```

At the command prompt, create a test suite from the `tests` folder.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.CodeCoveragePlugin

suite = TestSuite.fromFolder('tests');
```

Create a test runner.

```
runner = TestRunner.withTextOutput;
```

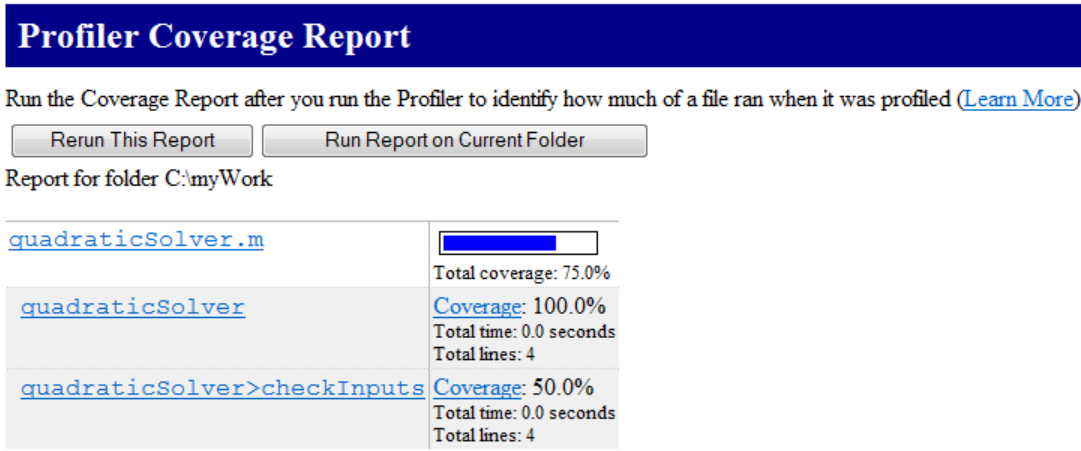
Add `CodeCoveragePlugin` to the runner and run the tests. Specify that the source code folder is your current working folder. If you have other source code files in your current working folder, they will show up in the coverage report.

```
runner.addPlugin(CodeCoveragePlugin.forFolder(pwd))
result = runner.run(suite);
```

```
Running SolverTest
```

```
..
Done SolverTest
__________
```

MATLAB opens a Profiler Coverage Report for the quadratic solver function.



The `checkinputs` nested function does not have complete code coverage. Since the tests in `SolverTest.m` do not pass nonnumeric input to `quadraticSolver`, MATLAB does not exercise the code that throws an error if the inputs are not numeric. To address the missing coverage, add a test method to test the error condition.

See Also

`matlab.unittest.plugins.TestRunnerPlugin` | `profile`

Introduced in R2014b

matlab.unittest.plugins.DiagnosticsValidationPlugin class

Package: matlab.unittest.plugins

Plugin to help validate diagnostic code

Description

The `DiagnosticsValidationPlugin` creates a plugin to help validate diagnostic code.

Add the `DiagnosticsValidationPlugin` to the `TestRunner` to confirm that user-supplied diagnostics execute correctly. This plugin is useful because typically tests do not encounter failure conditions. A failure can result in unexercised diagnostic code. If a programming error exists in this diagnostic code, the error is not evident unless the test fails. However, at this point in the testing process, the diagnostics for the failure condition are lost due to the error in the diagnostic code.

Use this plugin to unconditionally evaluate the diagnostics supplied by the test writer, regardless of whether the test results in a passing or failing condition. This approach helps you to confirm that all of the diagnostic code is free from programming errors.

The diagnostic analysis can reduce the test performance and can result in very verbose text output. Be aware of these impacts before using this plugin for routine testing.

Construction

`matlab.unittest.plugins.DiagnosticsValidationPlugin` creates a plugin to help validate diagnostic code.

`matlab.unittest.plugins.DiagnosticsValidationPlugin(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the default `ToStandardOutput` stream.

Input Arguments

`stream`

Location where the plugin directs text output, specified as an `OutputStream`.

Default: `ToStandardOutput`

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Add Plugin to TestRunner

In your working folder, create a file, `ExampleTest.m`, containing the following test class. In this example, the `testThree` method has an intentional error. The method should use a function handle to the `dir` function as a `FunctionHandleDiagnostic`, but `dir` is misspelled.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)
            % test code
        end
        function testTwo(testCase)
            % test code
        end
        function testThree(testCase)
            % The following should use @dir as a function handle,
            % but there is a typo
            testCase.verifyEqual('myfile','myfile', @dri)
        end
    end
end
```

All of the tests in `ExampleTest.m` result in a passing condition, but there is an error in the diagnostic.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.DiagnosticsValidationPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withTextOutput;
```

Run the tests.

```
result1 = runner.run(suite);
```

```
Running ExampleTest
...
Done ExampleTest
__________
```

No diagnostic output is displayed because all the tests passed. The testing framework does not encounter the bug in the `FunctionHandleDiagnostic` of `testThree`.

Add `DiagnosticValidationPlugin` to the runner and run the tests.

```
runner.addPlugin(DiagnosticsValidationPlugin)
result2 = runner.run(suite);
```

```
Running ExampleTest
..
------------------------------
Validation of Test Diagnostic:
------------------------------
Error occurred while capturing diagnostics:
Error using evalc
Undefined function or variable 'dri'.

Error in ExampleTest/testThree (line 12)
            testCase.verifyEqual('myfile','myfile', @dri);

.
Done ExampleTest
__________
```

The framework executes the diagnostic provided by the `FunctionHandleDiagnostic`, even though none of the tests fails. Without this plugin, the test framework only encounters the bug if the test fails.

`matlab.unittest.diagnostics` | `matlab.unittest.plugins` | `OutputStream` | `ToStandardOutput`

matlab.unittest.plugins.FailureDiagnosticsPlugin class

Package: matlab.unittest.plugins

Plugin to show diagnostics on failure

Description

The `FailureDiagnosticsPlugin` creates a plugin to show diagnostics upon encountering a test failure. Add it to the `TestRunner` to output test failure diagnostics to the Command Window. This plugin is used by default when you construct a test runner using `TestRunner.withTextOutput`.

Construction

`matlab.unittest.plugins.FailureDiagnosticsPlugin` creates a plugin to show diagnostics upon encountering a test failure.

`matlab.unittest.plugins.FailureDiagnosticsPlugin(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the `ToStandardOutput` stream.

Input Arguments

`stream`

Location where the plugin directs text output, specified as an `OutputStream`.

Default: `ToStandardOutput`

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Add Plugin to TestRunner

In your working folder, create a file, `ExampleTest.m`, containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testPathAdd(testCase)
            % test code
        end
        function testOne(testCase)  % Test fails
            testCase.verifyEqual(5, 4, 'Testing 5==4')
        end
         function testTwo(testCase)  % Test passes
             testCase.verifyEqual(5, 5, 'Testing 5==5')
        end
    end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure.
The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.FailureDiagnosticsPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Run the tests.

```
result1 = runner.run(suite);
```

No output is displayed, but `result1` contains information about the failed test.

Add `FailureDiagnosticsPlugin` to the runner and run the tests.

```
runner.addPlugin(FailureDiagnosticsPlugin)
result2 = runner.run(suite);
```

```
================================================================================
Verification failed in ExampleTest/testOne.

`matlab.unittest.diagnostics` | `matlab.unittest.plugins` | `OutputStream` | `ToStandardOutput`

Introduced in R2013a

matlab.unittest.plugins.LoggingPlugin class

Package: matlab.unittest.plugins

Plugin to report diagnostic messages

Description

The `LoggingPlugin` creates a plugin to report diagnostic messages that are created by the `log` method of a `TestCase` or `Fixture`.

Construction

Instantiate a `LoggingPlugin` using one of its static methods.

Use the `withVerbosity` static method to configure a plugin to respond to messages of a particular verbosity. Also, the `withVerbosity` method accepts a number of name/value pairs to configure the format for reporting logged messages.

Properties

`Description` — Logged diagnostic message description

`'Diagnostic logged'` (default) | string

Logged diagnostic message description, specified as a string. The value of this property is printed alongside each logged diagnostic message. `Description` is read only, and its value is set during construction.

`HideLevel` — Indicator to display verbosity level

`false` (default) | `true`

Indicator to display the verbosity level alongside each logged diagnostic, specified as `false` (`logical(0)`) or `true` (`logical(1)`). By default, this property is `false` and the test framework displays the verbosity level. `HideLevel` is read only, and its value is set during construction.

`HideTimestamp` — Indicator to display timestamp

`false` (default) | `true`

Indicator to display the timestamp from when the test framework generates the logged message alongside each logged diagnostic, specified as `false` (`logical(0)`) or `true` (`logical(1)`). By default, this property is `false` and the test framework displays the timestamp. `HideTimestamp` is read only, and its value is set during construction.

`NumStackFrames` — Number of stack frames to display

`0` (default) | integer value | `Inf`

Number of stack frames to display after each logged diagnostic message, specified as an integer value. By default, this property is `0`, and the test framework does not display stack information. If `NumStackFrames` is `Inf`, the test framework displays all available stack frames. `NumStackFrames` is read only, and its value is set during construction.

`Verbosity` — Verbosity levels supported by plugin instance

array of `matlab.unittest.Verbosity` instances

Verbosity levels supported by plugin instance, specified as an array of `matlab.unittest.Verbosity` instances. The plugin reacts to diagnostics that are logged at a verbosity level listed in this array. `Verbosity` is read only, and its value is set during construction.

Methods

withVerbosity	Construct LoggingPlugin for messages of specified verbosity

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

See Also

`matlab.unittest.Verbosity` | `matlab.unittest.fixtures.Fixture.log` | `matlab.unittest.TestCase.log`

Introduced in R2014b

matlab.unittest.plugins.LoggingPlugin.withVerbosity

Class: matlab.unittest.plugins.LoggingPlugin
Package: matlab.unittest.plugins

Construct LoggingPlugin for messages of specified verbosity

Syntax

```
matlab.unittest.plugins.LoggingPlugin.withVerbosity(v)
matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,stream)
matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,Name,Value)
```

Description

`matlab.unittest.plugins.LoggingPlugin.withVerbosity(v)` constructs a `LoggingPlugin` for messages of the specified verbosity.

`matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,stream)` redirects the text output to the output stream.

`matlab.unittest.plugins.LoggingPlugin.withVerbosity(v,Name,Value)` includes additional options specified by one or more Name,Value pair arguments.

Input Arguments

v — Verbosity levels supported by plugin instance

`1 | 2 | 3 | 4 | matlab.unittest.Verbosity` enumeration

Verbosity levels supported by the plugin instance, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The plugin reacts to diagnostics that are logged at this level and lower. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	`matlab.unittest.Verbosity.Ter`	minimal amount of information

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
2	`matlab.unittest.Verbosity.Con`	typical amount of information
3	`matlab.unittest.Verbosity.Det`	supplemental amount of information
4	`matlab.unittest.Verbosity.Ver`	surplus of information

`stream` — Location where plugin directs text output
`ToStandardOutput` instance (default) | `OutputStream` instance

Location where the plugin directs text output, specified as an `OutputStream` instance. By default, the plugin uses the `OutputStream` subclass `ToStandardOutput` as the stream.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Description'` — Logged diagnostic message description
`'Diagnostic logged'` (default) | string

Logged diagnostic message description, specified as a string. This value is printed alongside each logged diagnostic message. If the value is an empty string, the test framework does not display a description.

`'ExcludingLowerLevels'` — Indicator to display messages logged at levels lower than the verbosity level
`false` (default) | `true`

Indicator to display messages logged at levels lower than the verbosity level, v, specified as `false` or `true` (`logical(0)` or `logical(1)`). By default, the value is `false` and the plugin reacts to all messages logged at level v or lower. If the value is `true`, the plugin reacts only to messages logged at level `v`.

`'HideLevel'` — Indicator to display verbosity level
`false` (default) | `true`

Indicator to display the verbosity level alongside each logged diagnostic, specified as `false` or `true` (`logical(0)` or `logical(1)`). By default, the value is `false` and the test framework displays the verbosity level.

`'HideTimestamp'` — Indicator to display timestamp

`false` (default) | `true`

Indicator to display the timestamp from when the test framework generates the logged message alongside each logged diagnostic, specified as `false` or `true` (`logical(0)` or `logical(1)`). By default, the value is `false` and the test framework displays the timestamp.

`'NumStackFrames'` — Number of stack frames to display

`0` (default) | integer value | `Inf`

Number of stack frames to display after each logged diagnostic message, specified as an integer value. By default, the value is `0`, and the test framework does not display stack information. If `NumStackFrames` is `Inf`, the test framework displays all available stack frames.

Examples

Create Logging Plugin

Create a function-based test in a file, `sampleLogTest.m`, in your working folder.

```
function tests = sampleLogTest
tests = functiontests(localfunctions);

function svdTest(testCase)
import matlab.unittest.Verbosity

log(testCase,'Generating matrix.');
m = rand(1000);

log(testCase,1,'About to call SVD.');
[U,S,V] = svd(m);

log(testCase,Verbosity.Terse,'SVD finished.');

verifyEqual(testCase,U*S*V',m,'AbsTol',1e-6)
```

At the command prompt, run the test.

```
results = run(sampleLogTest);
```

```
Running sampleLogTest
   [Terse] Diagnostic logged (2014-04-14T14:20:59): About to call SVD.
   [Terse] Diagnostic logged (2014-04-14T14:20:59): SVD finished.
.
Done sampleLogTest
__________
```

The default runner reports the diagnostics at level 1 (`Terse`).

Create a test runner to report the diagnostics at levels 1 and 2, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(2);
runner.addPlugin(p);

results = runner.run(sampleLogTest);
```

```
 [Concise] Diagnostic logged (2014-04-14T14:28:14): Generating matrix.
   [Terse] Diagnostic logged (2014-04-14T14:28:14): About to call SVD.
   [Terse] Diagnostic logged (2014-04-14T14:28:15): SVD finished.
```

Configure Logged Message Output

Create the following class In a file in your current working folder, `ExampleLogTest.m`.

```
classdef ExampleLogTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)  % Test fails
            log(testCase,3,'Starting Test')
            log(testCase,'Testing 5==4')
            testCase.verifyEqual(5,4)
            log(testCase,4,'Test Complete')
        end
        function testTwo(testCase)  % Test passes
            log(testCase,matlab.unittest.Verbosity.Detailed,'Starting Test')
            log(testCase,'Testing 5==5')
            testCase.verifyEqual(5,5)
            log(testCase,matlab.unittest.Verbosity.Verbose,'Test Complete')
```

```
        end
    end
end
```

The log messages in `testTwo` uses `Verbosity` enumerations instead of the corresponding integers.

At the command prompt, create the test suite and a runner at verbosity level 4, and then run the test.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin
suite   = TestSuite.fromClass(?ExampleLogTest);

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(4);
runner.addPlugin(p);

results = runner.run(suite);
```

```
[Detailed] Diagnostic logged (2014-04-14T15:24:03): Starting Test
 [Concise] Diagnostic logged (2014-04-14T15:24:03): Testing 5==4
 [Verbose] Diagnostic logged (2014-04-14T15:24:03): Test Complete
[Detailed] Diagnostic logged (2014-04-14T15:24:03): Starting Test
 [Concise] Diagnostic logged (2014-04-14T15:24:03): Testing 5==5
 [Verbose] Diagnostic logged (2014-04-14T15:24:03): Test Complete
```

Create a new plugin to direct the output to a file, `myOutput.log`, and rerun the tests.

```
import matlab.unittest.plugins.ToFile
outFile = 'myOutput.log';

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(4,ToFile(outFile));
runner.addPlugin(p);

results = runner.run(suite);
```

Observe the contents in the file created by the plugin.

```
disp(fileread(outFile))
```

```
[Detailed] Diagnostic logged (2014-04-14T15:27:44): Starting Test
 [Concise] Diagnostic logged (2014-04-14T15:27:44): Testing 5==4
```

```
 [Verbose] Diagnostic logged (2014-04-14T15:27:44): Test Complete
[Detailed] Diagnostic logged (2014-04-14T15:27:44): Starting Test
 [Concise] Diagnostic logged (2014-04-14T15:27:44): Testing 5==5
 [Verbose] Diagnostic logged (2014-04-14T15:27:44): Test Complete
```

Create a new plugin that does not display level 4 messages. Do not display the verbosity level or timestamp. Rerun the tests.

```
runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(matlab.unittest.Verbosity.Detailed,...
    'HideLevel',true,'HideTimestamp',true);
runner.addPlugin(p);

results = runner.run(suite);
```

```
Diagnostic logged: Starting Test
Diagnostic logged: Testing 5==4
Diagnostic logged: Starting Test
Diagnostic logged: Testing 5==5
```

See Also

`matlab.unittest.plugins.OutputStream` | `matlab.unittest.plugins.ToStandardOutput` | `matlab.unittest.Verbosity` | `matlab.unittest.fixtures.Fixture.log` | `matlab.unittest.TestCase.log`

Introduced in R2014b

matlab.unittest.plugins.OutputStream class

Package: matlab.unittest.plugins

Interface that determines where to send text output

Description

The `OutputStream` interface is an abstract interface class that you can use as a base class to specify where plugins direct their text output. To create a custom output stream, implement a `print` method that correctly handles the formatted text information the testing framework passes to it. Many text-oriented plugins accept an `OutputStream` to redirect the text they produce in a configurable manner.

Methods

print	Print string to output stream

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Custom Output Stream

In a file in your working directory, create a new output stream class in the file `ToFigure.m`. This class allows plugin output to be redirected to a figure.

```
classdef ToFigure < matlab.unittest.plugins.OutputStream

    properties(SetAccess=private)
```

```
    Figure
end
properties(Access=private)
    ListBox
end
```

This class uses two properties. `Figure` is the figure that receives and displays the output. `ListBox` is a handle to the list box that displays the text.

In the same file, add the following `methods` block.

```
methods
    function print(stream,formatSpec,varargin)
        % Create the figure
        if isempty(stream.Figure) || ~ishghandle(stream.Figure)
            stream.createFigure
        end
        newStr = sprintf(formatSpec,varargin{:});
        oldStr = strjoin(stream.ListBox.String', '\n');

        % Create the full string
        fullStr = [oldStr,newStr];
        fullStrCell = strsplit(fullStr,'\n','CollapseDelimiters',false);

        % Set the string and selection
        stream.ListBox.String = fullStrCell';
        stream.ListBox.Value = numel(fullStrCell);
        drawnow
    end
end
```

You must implement the `print` method for any subclass of `OutputStream`. In this example, the method creates a new figure (if necessary), formats the incoming text, and then adds it to the output stream.

In the same file, add the following `methods` block containing a helper function to create the figure.

```
methods(Access=private)
    function createFigure(stream)
        stream.Figure = figure(...
            'Name',         'Unit Test Output', ...
            'WindowStyle',  'docked');
```

```
            stream.ListBox = uicontrol( ...
                'Parent',       stream.Figure, ...
                'Style',        'listbox', ...
                'String',       {}, ...
                'Units',        'normalized', ...
                'Position',     [.05 .05 .9 .9], ...
                'Max',          2, ...
                'FontName',     'Monospaced', ...
                'FontSize',      13);
        end
    end
end
```

In an new file in your working folder, create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)  % Test fails
            testCase.verifyEqual(5, 4, 'Testing 5==4' );
        end
        function testTwo(testCase)  % Test passes
            testCase.verifyEqual(5, 5, 'Testing 5==5' );
        end
        function testThree(testCase)
            % test code
        end
    end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure.
The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.DiagnosticsValidationPlugin

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `DiagnosticsValidationPlugin` that explicitly specifies that its output should go to a figure via the `ToFigure` output stream.

```
plugin = DiagnosticsValidationPlugin(ToFigure);
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

```
Running ExampleTest

================================================================================
Verification failed in ExampleTest/testOne.

    ----------------
    Test Diagnostic:
    ----------------
    Testing 5==4

    ---------------------
    Framework Diagnostic:
    ---------------------
    verifyEqual failed.

                1        5         4           1        0.25

    Actual Value:
             5
    Expected Value:
             4

    ------------------
    Stack Information:
    ------------------
    In C:\work\ExampleTest.m (ExampleTest.testOne) at 4
================================================================================
...
Done ExampleTest
__________
```

```
Failure Summary:

     Name                 Failed  Incomplete  Reason(s)
    ================================================================
     ExampleTest/testOne    X                 Failed by verification.
```

Only the test failures produce output to the screen. By default, `TestRunner.withTextOutput` uses a `FailureDiagnosticsPlugin` to display output on the screen.

In addition to the default text output being displayed on the screen, the `DiagnosticsValidationPlugin` output is directed to a docked figure. The figure shows the following text.

```
------------------------------
Validation of Test Diagnostic:
------------------------------
Testing 5==4
------------------------------
Validation of Test Diagnostic:
------------------------------
Testing 5==5
```

The `DiagnosticsValidationPlugin` displays the diagnostic information regardless of whether the tests encounter failure conditions.

`matlab.unittest.plugins.OutputStream` | `fprintf` | `matlab.unittest.plugins`

Introduced in R2014a

print

Class: matlab.unittest.plugins.OutputStream
Package: matlab.unittest.plugins

Print string to output stream

Syntax

```
print(stream,formatSpec,A1,...,An)
```

Description

`print(stream,formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec`, and sends the result to the output stream, `stream`. Assign `formatSpec` and `A1,...,An` using the same interface that you use for `sprintf` and `fprintf`.

Input Arguments

`stream`

Output stream, specified as an instance of the `OutputStream` class

`formatSpec`

Format of text in output stream, specified as a string. For information on the construction of `formatSpec` string, see the input argument entry on the `fprintf` or `sprint` reference pages.

`A`

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

See Also

`fprintf` | `sprintf`

Introduced in R2014a

matlab.unittest.plugins.StopOnFailuresPlugin class

Package: matlab.unittest.plugins

Plugin to debug test failures

Description

The `StopOnFailuresPlugin` class provides a plugin to help debug test failures. Adding `StopOnFailuresPlugin` to the test runner pauses execution of a test if it encounters a qualification failure or uncaught error and puts MATLAB into debug mode.

If `StopOnFailuresPlugin` encounters a qualification failure or uncaught error in a test, you can use MATLAB debugging commands, such as `dpbup`, `dbstep`, `dbcont`, and `dbquit`, to investigate the cause of the test failure.

If `StopOnFailuresPlugin` encounters an uncaught error in a test, you cannot use `dbup` to shift context to the source of the error because the error disrupts the stack.

Construction

`matlab.unittest.plugins.StopOnFailuresPlugin` creates a plugin to debug test failures.

`matlab.unittest.plugins.StopOnFailuresPlugin('IncludingAssumptionFailures', tf)` indicates whether to react to assumption failures. By default, `StopOnFailuresPlugin` reacts to only uncaught errors and verification, assertion, and fatal assertion qualification errors. However, when `'IncludingAssumptionFailures'` is set to `true`, the plugin also reacts to assumption failures.

Input Arguments

`tf` — Indicator to react to assumption failures

FALSE (default) | TRUE

Indicator to react to assumption failures, specified as logical `false` or `true`. When this value is `true`, the test runner reacts to assumption failures. When the value is `false`, the plugin ignores assumption failures.

Properties

`IncludeAssumptionFailures`

When this property value is `true`, the instance reacts to assumption failures. When the value is `false`, the instance ignores assumption failures. The `IncludeAssumptionFailures` property is `false` by default. To specify the property as `true`, use the `InlcudingAssumptionFailures` input when you construct the instance.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Add Plugin to TestRunner

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)  % Test fails
            act = 3.1416;
            exp = pi;
            testCase.verifyEqual(act, exp)
        end
        function testTwo(testCase)  % Test does not complete
            testCase.assumeEqual(5, 4)
        end
    end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and a test runner.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.StopOnFailuresPlugin
```

```
suite = TestSuite.fromClass(?ExampleTest);
runner = TestRunner.withTextOutput;
```

Run the tests.

```
result = runner.run(suite);
```

```
Running ExampleTest

================================================================================
Verification failed in ExampleTest/testOne.

`dbcont` | `dbquit` | `dbstep` | `dbup` | `matlab.unittest.plugins`

matlab.unittest.plugins.TAPPlugin class

Package: matlab.unittest.plugins

Plugin that produces Test Anything Protocol stream

Description

The `TAPPlugin` creates a plugin that produces a Test Anything Protocol (TAP) stream. Using this plugin, you can integrate MATLAB Unit Test results into third-party systems that recognize the TAP protocol. For example, you can integrate test results with continuous integration systems like Jenkins™ or TeamCity®.

Construction

`matlab.unittest.plugins.TAPPlugin.producingOriginalFormat` creates a plugin that produces output in the form of the original TAP format (version 12). By default, the plugin displays the output to the screen. In this case, other output sent to the screen can invalidate the TAP stream. To avoid this, redirect the output to a different output stream, such as the `ToFile` stream.

`matlab.unittest.plugins.TAPPlugin.producingOriginalFormat(stream)` redirects all the text output to the output stream, `stream`. If you do not specify the output stream, the plugin uses the `ToStandardOutput` stream.

Input Arguments

`stream`

Location where the plugin directs text output, specified as an `OutputStream`.

Default: `ToStandardOutput`

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create TAP Plugin

In an new file in your working folder, create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)  % Test fails
            testCase.verifyEqual(5, 4, 'Testing 5==4')
        end
        function testTwo(testCase)  % Test passes
            testCase.verifyEqual(5, 5, 'Testing 5==5')
        end
        function testThree(testCase)
            % test code
        end
    end
end
```

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.TAPPlugin
import matlab.unittest.plugins.ToFile

suite   = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window using the default plugin.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file `MyTapOutput.tap`.

```
tapFile = 'MyTAPOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(tapFile));
```

Add the plugin to the TestRunner and run the suite.

```
runner.addPlugin(plugin)
```

```
result = runner.run(suite);

Running ExampleTest

External Web Sites

- Jenkins
- TeamCity
- testanything.org

Introduced in R2014a

matlab.unittest.plugins.ToFile class

Package: matlab.unittest.plugins
Superclasses: matlab.unittest.plugins.OutputStream

Output stream to write text output to file

Description

The `ToFile` class creates an output stream that writes text output to a file. Whenever text prints to this stream, the output stream opens the file, appends the text, and closes the file.

Construction

`matlab.unittest.plugins.ToFile(fname)` creates an `OutputStream` that writes text output to the file, `fname`.

Input Arguments

`fname`

Name of file to write the output text, specified as a string. If `fname` exists, the text from the stream is appended to the file.

Properties

`Filename`

Name of file to redirect text output from the plugin, specified in the input argument, `fname`.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Direct TAPPlugin Output Text to Separate File

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)  % Test fails
            testCase.verifyEqual(5, 4, 'Testing 5==4')
        end
        function testTwo(testCase)  % Test passes
            testCase.verifyEqual(5, 5, 'Testing 5==5')
        end
        function testThree(testCase)
            % test code
        end
    end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure.
The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.TAPPlugin
import matlab.unittest.plugins.ToFile

suite   = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file, `MyTapOutput.tap`.

```
filename = 'MyTapOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(filename));
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

```
Running ExampleTest

```

Only the test failures produce output to the screen. By default, `TestRunner.withTextOutput` uses a `FailureDiagnosticsPlugin` to display output on the screen.

Observe contents in the file created by the plugin.

```
disp(fileread(filename))
```

```
1..3
not ok 1 - ExampleTest/testOne
ok 2 - ExampleTest/testTwo
ok 3 - ExampleTest/testThree
```

See Also

`matlab.unittest.plugins.OutputStream` | `fopen` | `fprintf` | `matlab.unittest.plugins`

Introduced in R2014a

matlab.unittest.plugins.ToStandardOutput class

Package: matlab.unittest.plugins
Superclasses: matlab.unittest.plugins.OutputStream

Output stream to display text information to screen

Description

The `ToStandardOutput` class creates an output stream to display text output to the screen. Many plugins that accept an output stream use `ToStandardOutput` as their default stream.

Construction

`matlab.unittest.plugins.ToStandardOutput` creates an `OutputStream` that prints text output to the screen.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Direct Plugin Output Text to Standard Output

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)  % Test fails
            testCase.verifyEqual(5, 4, 'Testing 5==4')
        end
```

```
        function testTwo(testCase)  % Test passes
            testCase.verifyEqual(5, 5, 'Testing 5==5')
        end
        function testThree(testCase)
            % test code
        end
    end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
import matlab.unittest.plugins.FailureDiagnosticsPlugin
import matlab.unittest.plugins.ToStandardOutput

suite   = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Create a `FailureDiagnosticsPlugin` that explicitly specifies that its output should go to the screen.

```
plugin = FailureDiagnosticsPlugin(ToStandardOutput);
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin)
result = runner.run(suite);
```

```
================================================================================

```

Only the test failures produce output to the screen.

See Also

`matlab.unittest.plugins.OutputStream` | `fprintf` | `matlab.unittest.plugins`

Introduced in R2014a

matlab.unittest.plugins.TestRunnerPlugin class

Package: matlab.unittest.plugins

Plugin interface for extending TestRunner

Description

The `TestRunnerPlugin` interface enables extension of the `matlab.unittest.TestRunner`. To customize a test run, create a subclass of `TestRunnerPlugin` and override select methods. `TestRunnerPlugin` provides you with a default implementation, so override only methods necessary to achieve your required customization. Every method you implement must invoke its corresponding superclass method, passing along the same instance of `pluginData` that it receives.

To run tests with this extension, add the custom `TestRunnerPlugin` to the `TestRunner` using the `addPlugin` method of `TestRunner`.

Methods

runTestSuite	Extend running of TestSuite array
createSharedTestFixture	Extend creation of shared test fixture instances
setupSharedTestFixture	Extend setting up shared test fixture
runTestClass	Extend running of TestSuite array from same class or function
createTestClassInstance	Extend creation of class-level TestCase instances
setupTestClass	Extend setting up test class

runTest	Extend running of single TestSuite element
createTestMethodInstance	Extend creation of method-level TestCase instances
setupTestMethod	Extend setting up of test method
runTestMethod	Extend running of single Test method
teardownTestMethod	Extend tearing down of test method
teardownTestClass	Extend tearing down of test class
teardownSharedTestFixture	Extend tearing down shared test fixture

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Related Examples

- "Write Plugins to Extend TestRunner"
- "Create Custom Plugin"

Introduced in R2014a

runTestSuite

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend running of TestSuite array

Syntax

```
runTestSuite(plugin,pluginData)
```

Description

`runTestSuite(plugin,pluginData)` extends the running of the original `TestSuite` array that the test framework hands to the `TestRunner`.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test suite information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement runTestSuite Method

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
    methods (Access = protected)
        function runTestSuite(plugin, pluginData)
```

```
            % Introspect into pluginData to get TestSuite size
            suiteSize = numel(pluginData.TestSuite);
            fprintf('### Running a total of %d tests\n', suiteSize)

            % Invoke the super class method
            runTestSuite@matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData)
        end
    end
end
```

`matlab.unittest.TestRunner` |
`matlab.unittest.plugins.plugindata.TestSuiteRunPluginData` |
`matlab.unittest.TestResult`

Introduced in R2014a

createSharedTestFixture

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend creation of shared test fixture instances

Syntax

```
f = createSharedTestFixture(plugin,pluginData)
```

Description

`f = createSharedTestFixture(plugin,pluginData)` extends the creation of shared test fixtures and returns the modified `Fixture` instance, `f`. The testing framework uses the fixture instance to customize running tests that use shared fixtures. The testing framework evaluates this method within the scope of the `runTestSuite` method of the `TestRunnerPlugin` for each shared test fixture it needs to set up. A typical implementation of this method is to add listeners to various events originating from the shared test fixture instance. Since the `Fixture` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createSharedTestFixture` method.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Shared test fixture creation information, specified as an instance of `matlab.unittest.plugins.plugindata.PluginData`. The test framework uses this information to introspect into the test content.

Examples

Extend Creation of Shared Test Fixture Instances

Extend the running of tests to count the number of shared test fixture assertion failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

    properties (SetAccess = private)
        FixtureAssertionFailureData = {};
    end

    methods (Access = protected)
        function fixture = createSharedTestFixture(plugin, pluginData)
            % Invoke the super class method
            fixture = createSharedTestFixture@...
                matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

            % Get the fixture name
            fixtureName = pluginData.Name;

            % Add a listener to fixture assertion failures
            % and capture the qualification failure information
            fixture.addlistener('AssertionFailed', @(~,evd) ...
                plugin.captureFixtureAssertionFailureData(evd, fixtureName))
        end
    end

    methods (Access = private)
        function captureFixtureAssertionFailureData(plugin, eventData, fixtureName)
            plugin.FixtureAssertionFailureData{end+1} = struct(...
                'FixtureName', fixtureName, ...
                'ActualValue', eventData.ActualValue, ...
                'Constraint' , eventData.Constraint, ...
                'Stack'      , eventData.Stack);
        end
    end
end
```

setupSharedTestFixture

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend setting up shared test fixture

Syntax

```
setupSharedTestFixture(plugin,pluginData)
```

Description

`setupSharedTestFixture(plugin,pluginData)` extends the setting up of a shared test fixture. This method defines how the `TestRunner` performs shared fixture setup. The test framework evaluates this method one time for each shared test fixture, within the scope of the `runTestSuite` method of the `TestRunnerPlugin`.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Shared test fixture setup information, specified as an instance of `matlab.unittest.plugins.plugindata.SharedTestFixturePluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement setupSharedTestFixture Method

Display the shared test fixture name at setup time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

    methods (Access = protected)
        function setupSharedTestFixture(plugin, pluginData)
            fprintf('### Setting up: %s\n', pluginData.Name)
            setupSharedTestFixture@matlab.unittest.plugins.TestRunnerPlugin...
                (plugin, pluginData);
        end
    end
end
```

Introduced in R2014a

runTestClass

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend running of TestSuite array from same class or function

Syntax

```
runTestClass(plugin,pluginData)
```

Description

`runTestClass(plugin,pluginData)` extends the running of tests that belong to the same test class, function, or script. This method applies to a subset of the full `TestSuite` being run by the `TestRunner`. The test framework evaluates this method within the scope of the `runTestSuite` method of the `TestRunnerPlugin`. It evaluates this method between setting up and tearing down the shared test fixture (`setupSharedTestFixture` and `teardownSharedTestFixture`). Provided the test framework completes shared test fixture setup, it invokes this method one time per test class.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test suite information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

Examples

Extend runTestClass method

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
    methods (Access = protected)
        function runTestClass(plugin, pluginData)
            fprintf('### Running test class: %s\n', pluginData.Name)

            runTestClass@matlab.unittest.plugins.TestRunnerPlugin(...
                plugin, pluginData);
        end
    end
end
```

createTestClassInstance

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend creation of class-level TestCase instances

Syntax

```
tc = createTestClassInstance(plugin,pluginData)
```

Description

`tc = createTestClassInstance(plugin,pluginData)` extends the creation of class-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework uses the `TestCase` instance to customize running tests that belong to the same test class. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the class level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createTestClassInstance` method. For each class, the test framework passes the instance to any method with the `TestClassSetup` or `TestClassTeardown` attribute.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Class-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.plugindata.PluginData`. The test framework uses this information to introspect into the test content.

Examples

Extend Creation of Class-Level TestCase Instances

Extend the running of tests to count the number of class-level assumption failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

    properties (SetAccess = private)
        TestClassAssumptionFailureData = {};
    end

    methods (Access = protected)
        function testCase = createTestClassInstance(plugin,pluginData)
            % Invoke super class method
            testCase = createTestClassInstance@...
                matlab.unittest.plugins.TestRunnerPlugin(plugin,pluginData);

            % Get the test class name
            instanceName = pluginData.Name;

            % Add a listener to capture assumption failures
            testCase.addlistener('AssumptionFailed', @(~,evd) ...
                plugin.captureClassLevelAssumptionFailureData(evd,instanceName))
        end
    end

    methods (Access = private)
        function captureClassLevelAssumptionFailureData(plugin,eventData,instanceName)
            plugin.TestClassAssumptionFailureData{end+1} = struct(...
                'InstanceName', instanceName, ...
                'ActualValue'   , eventData.ActualValue, ...
                'Constraint'    , eventData.Constraint, ...
                'Stack'         , eventData.Stack);
        end
    end
end
```

setupTestClass

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend setting up test class

Syntax

```
setupTestClass(plugin,pluginData)
```

Description

`setupTestClass(plugin,pluginData)` extends the setting up of a test class. This method defines how the `TestRunner` performs test class setup. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. If the test class contains properties with the `ClassSetupParameter` attribute, the test framework evaluates the `setupTestClass` method as many times as the class setup parameterization dictates.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test class setup information, specified as an instance of `matlab.unittest.plugins.plugindata.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement setupTestClass Method

Display the test class name at setup time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

    methods (Access = protected)
        function setupTestClass(plugin, pluginData)
            fprintf('### Setting up: %s\n', pluginData.Name)
            setupTestClass@matlab.unittest.plugins.TestRunnerPlugin...
                (plugin, pluginData);
        end
    end
end
```

Introduced in R2014a

runTest

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend running of single TestSuite element

Syntax

```
runTest(plugin,pluginData)
```

Description

`runTest(plugin,pluginData)` extends the running of a single `TestSuite` element. This method allows the test author to override the method that runs a scalar test element in the `TestSuite` array, including the creation of the `TestCase`, and the `TestMethodSetup` and `TestMethodTeardown` routines. Provided the test framework completes all fixture setup, it invokes this method one time per test element.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test element information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

Examples

Extend runTest method

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
    methods (Access = protected)
        function runTest(plugin, pluginData)
            fprintf('### Running test: %s\n', pluginData.Name)
            runTest@matlab.unittest.plugins.TestRunnerPlugin(...
                plugin, pluginData);
        end
    end
end
```

createTestMethodInstance

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend creation of method-level TestCase instances

Syntax

```
tc = createTestMethodInstance(plugin,pluginData)
```

Description

`tc = createTestMethodInstance(plugin,pluginData)` extends the creation of method-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the method level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createTestMethodInstance` method. The test framework creates instances for every element of the `matlab.unittest.Test` array and passes each instance to its corresponding `Test` methods and to any method with the `TestMethodSetup` or `TestMethodTeardown` attribute.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Method-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.plugindata.PluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement createMethodInstance Method

Add a listener to listen for assumption failures. Use the helper function, `captureMethodLevelAssumptionFailureData`, to populate the `TestMethodAssumptionFailureData` property.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

    properties (SetAccess = private)
        TestMethodAssumptionFailureData = {};
    end

    methods (Access = protected)
        function testCase = createTestMethodInstance(plugin, pluginData)
            testCase = createTestMethodInstance@...
                matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

            instanceName = pluginData.Name;
            testCase.addlistener('AssumptionFailed', @(~,evd) ...
                plugin.captureMethodLevelAssumptionFailureData(evd,instanceName))
        end
    end

    methods (Access = private)
        function captureMethodLevelAssumptionFailureData(...
                plugin, eventData, instanceName)
            plugin.TestMethodAssumptionFailureData{end+1} = struct(...
                'InstanceName', instanceName, ...
                'ActualValue'     , eventData.ActualValue, ...
                'Constraint'      , eventData.Constraint, ...
                'Stack'           , eventData.Stack);
        end
    end

end
```

Introduced in R2014a

setupTestMethod

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend setting up of test method

Syntax

```
setupTestMethod(plugin,pluginData)
```

Description

`setupTestMethod(plugin,pluginData)` extends the setting up of a test method. This method defines how the `TestRunner` performs test method setup for the single test suite element. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test method setup information, specified as an instance of `matlab.unittest.plugins.plugindata.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement setupTestMethod

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
```

```
    methods (Access = protected)
        function setupTestMethod(plugin, pluginData)
            fprintf('### Setting up: %s\n', pluginData.Name)
            setupTestMethod@matlab.unittest.plugins.TestRunnerPlugin...
                (plugin, pluginData);
        end
    end
end
```

runTestMethod

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend running of single Test method

Syntax

```
runTestMethod(plugin,pluginData)
```

Description

`runTestMethod(plugin,pluginData)` extends the running of a single `Test` method. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`. It evaluates this method between setting up and tearing down the scalar `TestSuite` element (`setupTestMethod` and `teardownTestMethod`).

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test method information, specified as an instance of `matlab.unittest.plugins.plugindata.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

Examples

Extend runTestMethod method

Print the time taken to evaluate the test method.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
    methods (Access = protected)
        function runTestMethod(plugin, pluginData)
            tic

            runTestMethod@matlab.unittest.plugins.TestRunnerPlugin(...
                plugin, pluginData);

            fprintf('### %s ran in %f seconds excluding fixture time.',...
                pluginData.Name, toc)
        end
    end
end
```

teardownTestMethod

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend tearing down of test method

Syntax

```
teardownTestMethod(plugin,pluginData)
```

Description

`teardownTestMethod(plugin,pluginData)` extends the tearing down of a test method. This method defines how the `TestRunner` performs test method teardown for the single test suite element. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test method teardown information, specified as an instance of `matlab.unittest.plugins.plugindata.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement teardownTestMethod Method

Display the test method name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
    methods (Access = protected)
        function teardownTestMethod(plugin, pluginData)
            fprintf('### Tearing down: %s\n', pluginData.Name)
            teardownTestMethod@matlab.unittest.plugins.TestRunnerPlugin...
                (plugin, pluginData);
        end
    end
end
```

teardownTestClass

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend tearing down of test class

Syntax

```
teardownTestClass(plugin,pluginData)
```

Description

`teardownTestClass(plugin,pluginData)` extends the tearing down of a test class. This method defines how the `TestRunner` performs test class teardown. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. If the test class contains properties with the `ClassSetupParameter` attribute, the test framework evaluates the `teardownTestClass` method as many times as the class setup parameterization dictates.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Test class teardown information, specified as an instance of `matlab.unittest.plugins.plugindata.ImplicitFixturePluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement teardownTestClass Method

Display the test class name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

    methods (Access = protected)
        function teardownTestClass(plugin, pluginData)
            fprintf('### Tearing down: %s\n', pluginData.Name)
            teardownTestClass@matlab.unittest.plugins.TestRunnerPlugin...
                (plugin, pluginData);
        end
    end
end
```

teardownSharedTestFixture

Class: matlab.unittest.plugins.TestRunnerPlugin
Package: matlab.unittest.plugins

Extend tearing down shared test fixture

Syntax

```
teardownSharedTestFixture(plugin,pluginData)
```

Description

`teardownSharedTestFixture(plugin,pluginData)` extends the tearing down of a shared test fixture. This method defines how the `TestRunner` performs shared fixture teardown. The test framework evaluates this method one time for each shared test fixture, within the scope of the `runTestSuite` method of the `TestRunnerPlugin`.

Input Arguments

`plugin`

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

`pluginData`

Shared test fixture teardown information, specified as an instance of `matlab.unittest.plugins.plugindata.SharedTestFixturePluginData`. The test framework uses this information to introspect into the test content.

Examples

Implement teardownSharedTestFixture Method

Display the shared test fixture name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

    methods (Access = protected)
        function teardownSharedTestFixture(plugin, pluginData)
            fprintf('### Setting up: %s\n', pluginData.Name)
            teardownSharedTestFixturee@matlab.unittest.plugins.TestRunnerPlugin...
                (plugin, pluginData);
        end
    end
end
```

Introduced in R2014a

matlab.unittest.plugins.TestRunProgressPlugin class

Package: matlab.unittest.plugins

Plugin that reports test run progress

Description

The `TestRunProgressPlugin` creates a plugin that reports on test run progress.

Construction

`matlab.unittest.plugins.TestRunProgressPlugin.withVerbosity(v)` constructs a `TestRunProgressPlugin` for the specified verbosity.

`matlab.unittest.plugins.TestRunProgressPlugin.withVerbosity(v, stream)` redirects the text output to the output stream.

Input Arguments

v — Verbosity level

`1 | 2 | 3 | 4 | matlab.unittest.Verbosity` enumeration

Verbosity level, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	`matlab.unittest.Verbosity.Ter`	Minimal amount of information
2	`matlab.unittest.Verbosity.Con`	Typical amount of information
3	`matlab.unittest.Verbosity.Det`	Supplemental amount of information
4	`matlab.unittest.Verbosity.Ver`	Surplus of information

`stream` — Location where plugin directs text output

`ToStandardOutput` instance (default) | `OutputStream` instance

Location where the plugin directs text output, specified as an `OutputStream` instance. By default, the plugin uses the `OutputStream` subclass `ToStandardOutput` as the stream.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Test Run Progress Plugin

Create a function-based test called `cylinderPlotTest` in a file in your working folder.

```
function tests = cylinderPlotTest
tests = functiontests(localfunctions);
end

function setupOnce(testCase)
testCase.TestData.Figure = figure;
addTeardown(testCase,@close,testCase.TestData.Figure)
end

function setup(testCase)
testCase.TestData.Axes = axes('Parent',testCase.TestData.Figure);
addTeardown(testCase,@clf,testCase.TestData.Figure)
cylinder(testCase.TestData.Axes,10)
end

function testXLim(testCase)
xlim = testCase.TestData.Axes.XLim;
verifyLessThanOrEqual(testCase,xlim(1),-10,'Minimum x-limit too large')
verifyGreaterThanOrEqual(testCase,xlim(2),10,'Maximum x-limit too small')
end
```

```
function zdataTest(testCase)
s = findobj(testCase.TestData.Axes,'Type','surface');
verifyEqual(testCase,min(s.ZData(:)),0,'Min cylinder value is incorrect')
verifyEqual(testCase,max(s.ZData(:)),1,'Max cylinder value is incorrect')
end
```

At the command prompt, run the test.

```
results = run(cylinderPlotTest);
```

```
Running cylinderPlotTest
..
Done cylinderPlotTest
__________
```

By default, the test runner uses verbosity level 2.

Create a test runner to report the diagnostics at level 1, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.TestRunProgressPlugin

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(1);
runner.addPlugin(p);

results = runner.run(cylinderPlotTest);
```

```
..
```

Create a test runner to report the diagnostics at level 4, and rerun the test.

```
runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(4);
runner.addPlugin(p);

results = runner.run(cylinderPlotTest);
```

```
 Running cylinderPlotTest
  Setting up cylinderPlotTest
    Evaluating TestClassSetup: setupOnce
  Done setting up cylinderPlotTest in 0.067649 seconds
   Running cylinderPlotTest/testXLim
    Evaluating TestMethodSetup: setup
    Evaluating Test: testXLim
    Evaluating TestMethodTeardown: teardown
```

```
    Evaluating addTeardown function: clf
   Done cylinderPlotTest/testXLim in 0.053834 seconds
   Running cylinderPlotTest/zdataTest
    Evaluating TestMethodSetup: setup
    Evaluating Test: zdataTest
    Evaluating TestMethodTeardown: teardown
    Evaluating addTeardown function: clf
   Done cylinderPlotTest/zdataTest in 0.037715 seconds
  Tearing down cylinderPlotTest
    Evaluating TestClassTeardown: teardownOnce
    Evaluating addTeardown function: close
  Done tearing down cylinderPlotTest in 0.022783 seconds
 Done cylinderPlotTest in 0.18198 seconds
```

Configure Progress Message Output

Create a class named `ExampleProgressTest` in a file in your current working folder.

```
classdef ExampleProgressTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)  % Test fails
            testCase.verifyEqual(5,4)
        end
        function testTwo(testCase)  % Test passes
            testCase.verifyEqual(5,5)
        end
    end
end
```

At the command prompt, create the test suite and a runner at verbosity level 3, and then run the test.

```
import matlab.unittest.TestSuite
import matlab.unittest.TestRunner
import matlab.unittest.plugins.TestRunProgressPlugin

suite = TestSuite.fromClass(?ExampleProgressTest);

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(3);
runner.addPlugin(p);
results = runner.run(suite);
```

```
 Running ExampleProgressTest
```

```
  Setting up ExampleProgressTest
  Done setting up ExampleProgressTest in 0 seconds
   Running ExampleProgressTest/testOne
   Done ExampleProgressTest/testOne in 0.0049988 seconds
   Running ExampleProgressTest/testTwo
   Done ExampleProgressTest/testTwo in 0.0044541 seconds
  Tearing down ExampleProgressTest
  Done tearing down ExampleProgressTest in 0 seconds
 Done ExampleProgressTest in 0.0094529 seconds
__________
```

Create a new plugin to direct the output to a file named `myOutput.log`, and rerun the tests.

```
import matlab.unittest.plugins.ToFile
outFile = 'myOutput.log';

runner = TestRunner.withNoPlugins;
p = TestRunProgressPlugin.withVerbosity(3,ToFile(outFile));
runner.addPlugin(p);

results = runner.run(suite);
```

Observe the contents of the file created by the plugin.

```
disp(fileread(outFile))
```

```
 Running ExampleProgressTest
  Setting up ExampleProgressTest
  Done setting up ExampleProgressTest in 0 seconds
   Running ExampleProgressTest/testOne
   Done ExampleProgressTest/testOne in 0.0050172 seconds
   Running ExampleProgressTest/testTwo
   Done ExampleProgressTest/testTwo in 0.0049449 seconds
  Tearing down ExampleProgressTest
  Done tearing down ExampleProgressTest in 0 seconds
 Done ExampleProgressTest in 0.009962 seconds
__________
```

Introduced in R2014b

matlab.unittest.plugins.plugindata

Summary of classes in MATLAB Plugin Data Interface

Description

The `plugindata` classes store information about test content for use by the plugins and plugin methods. The `TestRunner` passes instances of these classes to various plugin methods. The `matlab.unittest.plugins.plugindata` package consists of the following MATLAB plugin data classes.

matlab.unittest.plugins.plugindata.ImplicitFixturePluginData	Plugin data containing test setup and teardown information
matlab.unittest.plugins.plugindata.PluginData	Data object passed to TestRunnerPlugin methods

See Also

`matlab.unittest.plugins` | `TestRunnerPlugin`

matlab.unittest.plugins.plugindata.ImplicitFixturePluginData class

Package: matlab.unittest.plugins.plugindata

Plugin data containing test setup and teardown information

Description

The `ImplicitFixturePluginData` class defines the data the `TestRunner` passes to plugin methods related to setting up and tearing down tests. The `TestRunner` creates this class, so there is no need for test plugin authors to construct this class directly.

Properties

`Name` — Label of test content test runner sets up or tears down

string

Label of test content test runner sets up or tears down, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name` programmatically to introspect into the content.

Data Types: `char`

See Also

`TestRunnerPlugin` | `TestRunnerPlugin.setupTestClass` | `TestRunnerPlugin.setupTestMethod` | `TestRunnerPlugin.teardownTestClass` | `TestRunnerPlugin.teardownTestMethod`

Introduced in R2015a

matlab.unittest.plugins.plugindata.PluginData class

Package: matlab.unittest.plugins.plugindata

Data object passed to TestRunnerPlugin methods

Description

The `PluginData` class defines the data the `TestRunner` passes to various plugin methods. It is created by the `TestRunner`, so there is no need for test plugin authors to construct this class directly.

Properties

`Name`

Label of test content executed by the test runner within the scope of a plugin method, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name`programmatically to introspect into the content.

See Also

`TestRunnerPlugin`

Introduced in R2014a

matlab.unittest.plugins.plugindata.SharedTestFixturePluginDa class

Package: matlab.unittest.plugins.plugindata

Plugin data containing shared test fixture information

Description

The `SharedTestFixturePluginData` defines the data the `TestRunner` passes to plugin methods related to shared test fixtures. The `TestRunner` creates this, so there is no need for test plugin authors to construct this class directly.

Properties

`Name`

Label of shared test fixture, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name`programmatically to introspect into the content.

`Description`

Description of action performed during setup and teardown of a shared text fixture, represented as a string

See Also

`matlab.unittest.fixtures.Fixture` | `TestRunnerPlugin`

Introduced in R2014a

matlab.unittest.plugins.plugindata.TestSuiteRunPluginData class

Package: matlab.unittest.plugins.plugindata

Plugin data containing selected test information

Description

The `TestSuiteRunPluginData` defines the data the `TestRunner` passes to plugin methods related to running tests from the suite. The `TestRunner` creates this, so there is no need for test plugin authors to construct this class directly.

Properties

`Name`

Name corresponding to the portion of the test suite the runner executes within a plugin method, represented as a string. Use the `Name` property for informational, labeling, and display purposes. Do not use `Name`programmatically to introspect into the content.

`TestSuite`

Select test methods, represented as a `matlab.unittest.TestSuite` instance

`TestResult`

Results from running select test methods listed in `TestSuite`, represented as a `matlab.unittest.TestResult` array

Introduced in R2014a

plus, +

Addition

Syntax

```
C = A + B
C = plus(A,B)
```

Description

`C = A + B` adds arrays `A` and `B` and returns the result in `C`.

`C = plus(A,B)` is an alternate way to execute `A + B`, but is rarely used. It enables operator overloading for classes.

Examples

Add Scalar to Array

Create an array, `A`, and add a scalar value to it.

```
A = [0 1; 1 0];
C = A + 2
```

```
C =

     2     3
     3     2
```

The scalar value is added to each entry of `A`.

Add Two Arrays

Create two arrays, `A` and `B`, and add them together.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
```

```
C = A + B

C =

     6     9
     4     5
```

The elements of A are added to the corresponding elements of B.

Input Arguments

A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. A can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.
Complex Number Support: Yes

B — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. B can be a numeric array, logical array, character array, datetime array, duration array, or calendar duration array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.

If one input is a datetime array, duration array, or calendar duration array, then numeric values in the other input are treated as a number of 24-hour days.
Complex Number Support: Yes

pointLocation

Class: DelaunayTri

(Will be removed) Simplex containing specified location

Note: `pointLocation(DelaunayTri)` will be removed in a future release. Use `pointLocation(triangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
SI = pointLocation(DT,QX)
SI = pointLocation(DT,QX,QY)
SI = pointLocation(DT,QX,QY,QZ)
[SI, BC] = pointLocation(DT,...)
```

Description

`SI = pointLocation(DT,QX)` returns the indices `SI` of the enclosing simplex (triangle/tetrahedron) for each query point location in `QX`. The enclosing simplex for point `QX(k,:)` is `SI(k)`. `pointLocation` returns `NaN` for all points outside the convex hull.

`SI = pointLocation(DT,QX,QY)` and `SI = pointLocation(DT,QX,QY,QZ)` allow the query point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`[SI, BC] = pointLocation(DT,...)` returns the barycentric coordinates `BC`.

Input Arguments

`DT`	Delaunay triangulation.

`QX`	Matrix of size `mpts`-by-`ndim`, `mpts` being the number of query points.

Output Arguments

`SI`	Column vector of length `mpts` containing the indices of the enclosing simplex for each query point. `mpts` is the number of query points.
`BC`	`BC` is a `mpts`-by-`ndim` matrix, each row `BC(i,:)` represents the barycentric coordinates of `QX(i,:)` with respect to the enclosing simplex `SI(i)`.

Examples

Example 1

Create a 2-D Delaunay triangulation:

```
X = rand(10,2);
dt = DelaunayTri(X);
```

Find the triangles that contain specified query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
triids = pointLocation(dt, qrypts)
```

Example 2

Create a 3-D Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
z = rand(10,1);
dt = DelaunayTri(x,y,z);
```

Find the triangles that contain specified query points and evaluate the barycentric coordinates:

```
qrypts = [0.25 0.25 0.25; 0.5 0.5 0.5];
```

```
[tetids, bcs] = pointLocation(dt, qrypts)
```

pol2cart

Transform polar or cylindrical coordinates to Cartesian

Syntax

```
[X,Y] = pol2cart(THETA,RHO)
[X,Y,Z] = pol2cart(THETA,RHO,Z)
```

Description

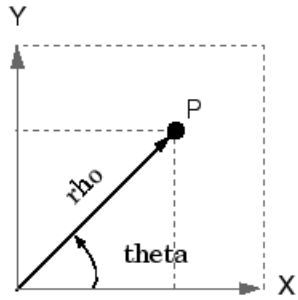
`[X,Y] = pol2cart(THETA,RHO)` transforms the polar coordinate data stored in corresponding elements of `THETA` and `RHO` to two-dimensional Cartesian, or *xy*, coordinates. The arrays `THETA` and `RHO` must be the same size (or either can be scalar). The values in `THETA` must be in radians.

`[X,Y,Z] = pol2cart(THETA,RHO,Z)` transforms the cylindrical coordinate data stored in corresponding elements of `THETA`, `RHO`, and `Z` to three-dimensional Cartesian, or *xyz* coordinates. The arrays `THETA`, `RHO`, and `Z` must be the same size (or any can be scalar). The values in `THETA` must be in radians.

More About

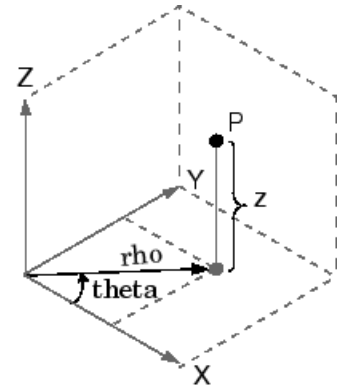
Algorithms

The mapping from polar and cylindrical coordinates to Cartesian coordinates is:



Polar to Cartesian Mapping

```
x = rho*cos(theta)
y = rho*sin(theta)
```



Polar to Cartesian Mapping

```
x = rho*cos(theta)
y = rho*sin(theta)
      z = z
```

See Also

`cart2pol` | `cart2sph` | `sph2cart`

Introduced before R2006a

polar

Polar coordinate plot

Syntax

```
polar(theta,rho)
polar(theta,rho,LineSpec)
polar(axes_handle,...)
h = polar(...)
```

Description

The `polar` function accepts polar coordinates, plots them in a Cartesian plane, and draws the polar grid on the plane.

`polar(theta,rho)` creates a polar coordinate plot of the angle `theta` versus the radius `rho`. `theta` is the angle from the *x*-axis to the radius vector specified in radians; `rho` is the length of the radius vector specified in dataspace units.

`polar(theta,rho,LineSpec)` `LineSpec` specifies the line type, plot symbol, and color for the lines drawn in the polar plot.

`polar(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = polar(...)` returns the handle of a line object in `h`.

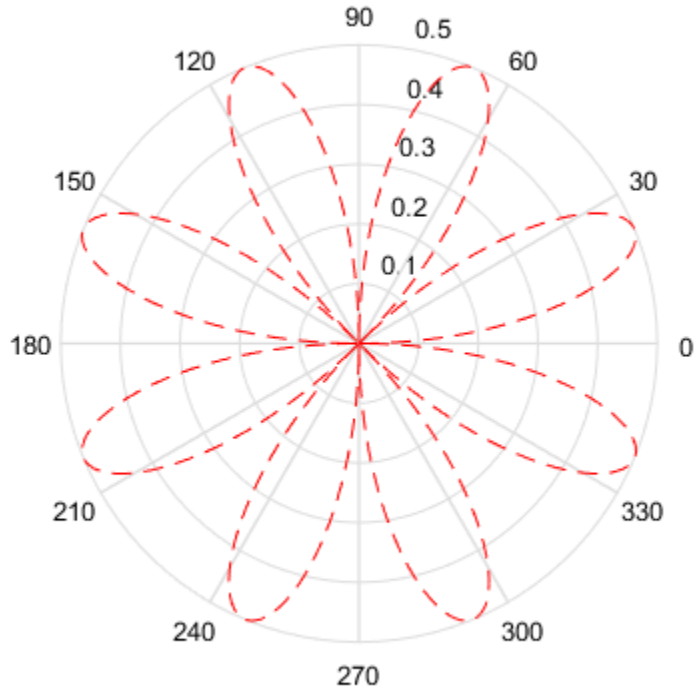
Examples

Simple Polar Plot

Create a simple polar plot using a dashed red line.

```
theta = 0:0.01:2*pi;
rho = sin(2*theta).*cos(2*theta);

figure
polar(theta,rho,'--r')
```



More About

Tips

Negative `r` values reflect through the origin, rotating by `pi` (since `(theta,r)` transforms to `(r*cos(theta), r*sin(theta))`). If you want different behavior, you can

manipulate `r` prior to plotting. For example, you can make `r` equal to `max(0,r)` or `abs(r)`.

Introduced before R2006a

poly

Polynomial with specified roots

Syntax

```
p = poly(A)
p = poly(r)
```

Description

`p = poly(A)` where `A` is an `n`-by-`n` matrix returns an `n+1` element row vector whose elements are the coefficients of the characteristic polynomial, $\det(\lambda I - A)$. The coefficients are ordered in descending powers: if a vector `c` has `n+1` components, the polynomial it represents is $c_1\lambda^n + c_2\lambda^{n-1} + \ldots + c_n\lambda + c_{n+1}$

`p = poly(r)` where `r` is a vector returns a row vector whose elements are the coefficients of the polynomial whose roots are the elements of `r`.

Examples

MATLAB displays polynomials as row vectors containing the coefficients ordered by descending powers. The characteristic equation of the matrix

```
A =

    1    2    3
    4    5    6
    7    8    0
```

is returned in a row vector by `poly`:

```
p = poly(A)

p =
    1    -6    -72    -27
```

The roots of this polynomial (eigenvalues of matrix A) are returned in a column vector by roots:

```
r = roots(p)

r =

    12.1229
    -5.7345
    -0.3884
```

More About

Tips

Note the relationship of this command to

```
r = roots(p)
```

which returns a column vector whose elements are the roots of the polynomial specified by the coefficients row vector p. For vectors, roots and poly are inverse functions of each other, up to ordering, scaling, and roundoff error.

Algorithms

The algorithms employed for poly and roots illustrate an interesting aspect of the modern approach to eigenvalue computation. poly(A) generates the characteristic polynomial of A, and roots(poly(A)) finds the roots of that polynomial, which are the eigenvalues of A. But both poly and roots use eig, which is based on similarity transformations. The classical approach, which characterizes eigenvalues as roots of the characteristic polynomial, is actually reversed.

If A is an n-by-n matrix, poly(A) produces the coefficients c(1) through c(n+1), with c(1) = 1, in

$$\det(\lambda I - A) = c_1\lambda^n + \ldots + c_n\lambda + c_{n+1}$$

The algorithm is

```
z = eig(A);
c = zeros(n+1,1); c(1) = 1;
```

```
for j = 1:n
    c(2:j+1) = c(2:j+1)-z(j)*c(1:j);
end
```

This recursion is easily derived by expanding the product.

$$(\lambda - \lambda_1)(\lambda - \lambda_2)\ldots(\lambda - \lambda_n)$$

It is possible to prove that `poly(A)` produces the coefficients in the characteristic polynomial of a matrix within roundoff error of `A`. This is true even if the eigenvalues of `A` are badly conditioned. The traditional algorithms for obtaining the characteristic polynomial, which do not use the eigenvalues, do not have such satisfactory numerical properties.

Introduced before R2006a

polyarea

Area of polygon

Syntax

```
A = polyarea(X,Y)
A = polyarea(X,Y,dim)
```

Description

`A = polyarea(X,Y)` returns the area of the polygon specified by the vertices in the vectors `X` and `Y`.

If `X` and `Y` are matrices of the same size, then `polyarea` returns the area of polygons defined by the columns `X` and `Y`.

If `X` and `Y` are multidimensional arrays, `polyarea` returns the area of the polygons in the first nonsingleton dimension of `X` and `Y`.

`A = polyarea(X,Y,dim)` operates along the dimension specified by scalar `dim`.

Examples

Find Area of Polygon

```
L = linspace(0,2.*pi,9);
xv = 1.2*cos(L)';
yv = 1.2*sin(L)';

xv = [xv ; xv(1)];
yv = [yv ; yv(1)];

A = polyarea(xv,yv)
```

```
A =
```

```
    4.0729
```

```
plot(xv,yv);
title(['Area = ' num2str(A)])
axis image
```

Introduced before R2006a

polyder

Polynomial derivative

Syntax

```
k = polyder(p)
k = polyder(a,b)
[q,d] = polyder(b,a)
```

Description

The `polyder` function calculates the derivative of polynomials, polynomial products, and polynomial quotients. The operands `a`, `b`, and `p` are vectors whose elements are the coefficients of a polynomial in descending powers.

`k = polyder(p)` returns the derivative of the polynomial `p`.

`k = polyder(a,b)` returns the derivative of the product of the polynomials `a` and `b`.

`[q,d] = polyder(b,a)` returns the numerator `q` and denominator `d` of the derivative of the polynomial quotient `b/a`.

Examples

The derivative of the product

$$\left(3x^2+6x+9\right)\left(x^2+2x\right)$$

is obtained with

```
a = [3 6 9];
b = [1 2 0];
k = polyder(a,b)
k =
    12    36    42    18
```

This result represents the polynomial

$$12x^3 + 36x^2 + 42x + 18$$

conv | deconv

Introduced before R2006a

polyeig

Polynomial eigenvalue problem

Syntax

```
[X,e] = polyeig(A0,A1,...Ap)
e = polyeig(A0,A1,..,Ap)
[X, e, s] = polyeig(A0,A1,..,AP)
```

Description

`[X,e] = polyeig(A0,A1,...Ap)` solves the polynomial eigenvalue problem of degree `p`

$$\left(A_0 + \lambda A_1 + \ldots + \lambda^P A_p\right)x = 0$$

where polynomial degree `p` is a non-negative integer, and `A0,A1,...Ap` are input matrices of order `n`. The output consists of a matrix `X` of size `n`-by-`n*p` whose columns are the eigenvectors, and a vector `e` of length `n*p` containing the eigenvalues.

If `lambda` is the `j`th eigenvalue in `e`, and `x` is the `j`th column of eigenvectors in `X`, then `(A0 + lambda*A1 + ... + lambda^p*Ap)*x` is approximately `0`.

`e = polyeig(A0,A1,..,Ap)` is a vector of length `n*p` whose elements are the eigenvalues of the polynomial eigenvalue problem.

`[X, e, s] = polyeig(A0,A1,..,AP)` also returns a vector `s` of length `p*n` containing condition numbers for the eigenvalues. At least one of `A0` and `AP` must be nonsingular. Large condition numbers imply that the problem is close to a problem with multiple eigenvalues.

More About

Tips

Based on the values of `p` and `n`, `polyeig` handles several special cases:

- `p = 0`, or `polyeig(A)` is the standard eigenvalue problem: `eig(A)`.
- `p = 1`, or `polyeig(A,B)` is the generalized eigenvalue problem: `eig(A,-B)`.
- `n = 1`, or `polyeig(a0,a1,...,ap)` for scalars `a0,a1,...,ap` is the standard polynomial problem: `roots([ap ... a1 a0])`.

If both `A0` and `Ap` are singular the problem is potentially ill-posed. Theoretically, the solutions might not exist or might not be unique. Computationally, the computed solutions might be inaccurate. If one, but not both, of `A0` and `Ap` is singular, the problem is well posed, but some of the eigenvalues might be zero or infinite.

Note that scaling `A0,A1,..,Ap` to have `norm(Ai)` roughly equal 1 may increase the accuracy of `polyeig`. In general, however, this cannot be achieved. (See Tisseur [3] for more detail.)

Algorithms

The `polyeig` function uses the QZ factorization to find intermediate results in the computation of generalized eigenvalues. It uses these intermediate results to determine if the eigenvalues are well-determined. See the descriptions of `eig` and `qz` for more on this.

Introduced before R2006a

polyfit

Polynomial curve fitting

Syntax

```
p = polyfit(x,y,n)
[p,S] = polyfit(x,y,n)
[p,S,mu] = polyfit(x,y,n)
```

Description

`p = polyfit(x,y,n)` returns the coefficients for a polynomial `p(x)` of degree `n` that is a best fit (in a least-squares sense) for the data in `y`. The coefficients in `p` are in descending powers, and the length of `p` is `n+1`

$$p(x) = p_1 x^n + p_2 x^{n-1} + ... + p_n x + p_{n+1}.$$

`[p,S] = polyfit(x,y,n)` also returns a structure `S` that can be used as an input to `polyval` to obtain error estimates.

`[p,S,mu] = polyfit(x,y,n)` also returns `mu`, which is a two-element vector with centering and scaling values. `mu(1)` is `mean(x)`, and `mu(2)` is `std(x)`. Using these values, `polyfit` centers `x` at zero and scales it to have unit standard deviation

$$\hat{x} = \frac{x - \bar{x}}{\sigma_x}.$$

This centering and scaling transformation improves the numerical properties of both the polynomial and the fitting algorithm.

Examples

Fit Polynomial to Trigonometric Function

Generate 10 points equally spaced along a sine curve in the interval `[0,4*pi]`.

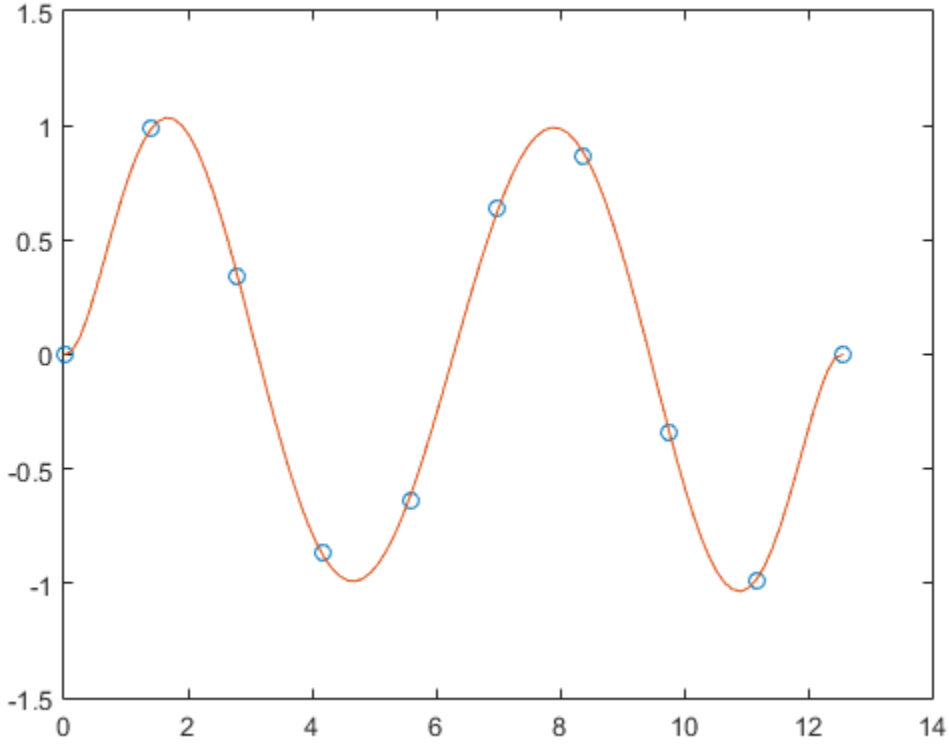
```
x = linspace(0,4*pi,10);
y = sin(x);
```

Use `polyfit` to fit a 7th-degree polynomial to the points.

```
p = polyfit(x,y,7);
```

Evaluate the polynomial on a finer grid and plot the results.

```
x1 = linspace(0,4*pi);
y1 = polyval(p,x1);
figure
plot(x,y,'o')
hold on
plot(x1,y1)
hold off
```



Fit Polynomial to Set of Points

Create a vector of 5 equally spaced points in the interval `[0,1]`, and evaluate $y(x) = (1+x)^{-1}$ at those points.

```
x = linspace(0,1,5);
y = 1./(1+x);
```

Fit a polynomial of degree 4 to the 5 points. In general, for `n` points, you can fit a polynomial of degree `n-1` to exactly pass through the points.

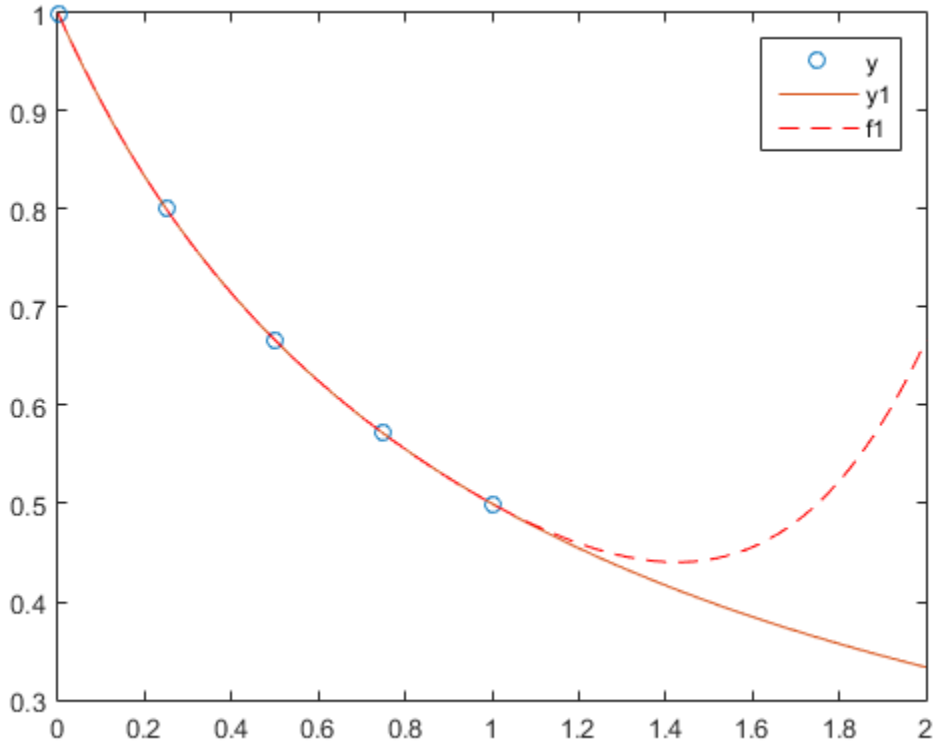
```
p = polyfit(x,y,4);
```

Evaluate the original function and the polynomial fit on a finer grid of points between 0 and 2.

```
x1 = linspace(0,2);
y1 = 1./(1+x1);
f1 = polyval(p,x1);
```

Plot the function values and the polynomial fit in the wider interval `[0,2]`, with the points used to obtain the polynomial fit highlighted as circles. The polynomial fit is good in the original `[0,1]` interval, but quickly diverges from the fitted function outside of that interval.

```
figure
plot(x,y,'o')
hold on
plot(x1,y1)
plot(x1,f1,'r--')
legend('y','y1','f1')
```



Fit Polynomial to Error Function

First generate a vector of `x` points, equally spaced in the interval `[0,2.5]`, and then evaluate `erf(x)` at those points.

```
x = (0:0.1:2.5)';
y = erf(x);
```

Determine the coefficients of the approximating polynomial of degree 6.

```
p = polyfit(x,y,6)
```

```
p =
```

```
    0.0084   -0.0983    0.4217   -0.7435    0.1471    1.1064    0.0004
```

To see how good the fit is, evaluate the polynomial at the data points and generate a table showing the data, fit, and error.

```
f = polyval(p,x);
T = table(x,y,f,y-f,'VariableNames',{'X','Y','Fit','FitError'})
```

```
T =

     X         Y          Fit          FitError

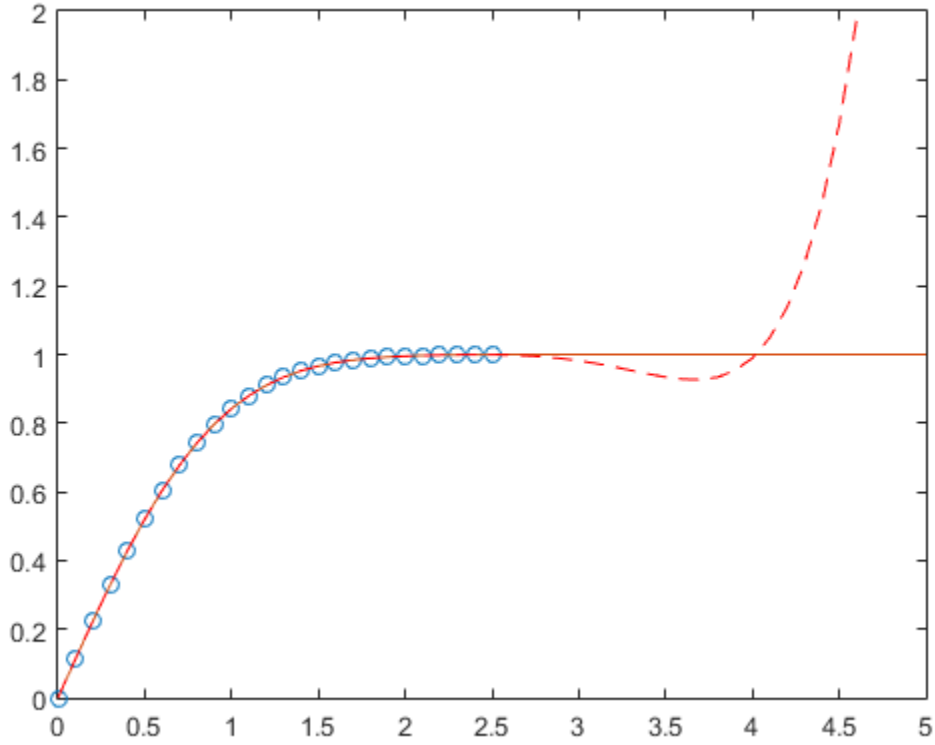
```

In this interval, the interpolated values and the actual values agree fairly closely. Create a plot to show how outside this interval, the extrapolated values quickly diverge from the actual data.

```
x1 = (0:0.1:5)';
y1 = erf(x1);
f1 = polyval(p,x1);
figure
plot(x,y,'o')
hold on
plot(x1,y1,'-')
plot(x1,f1,'r--')
axis([0  5  0  2])
hold off
```



Use Centering and Scaling to Improve Numerical Properties

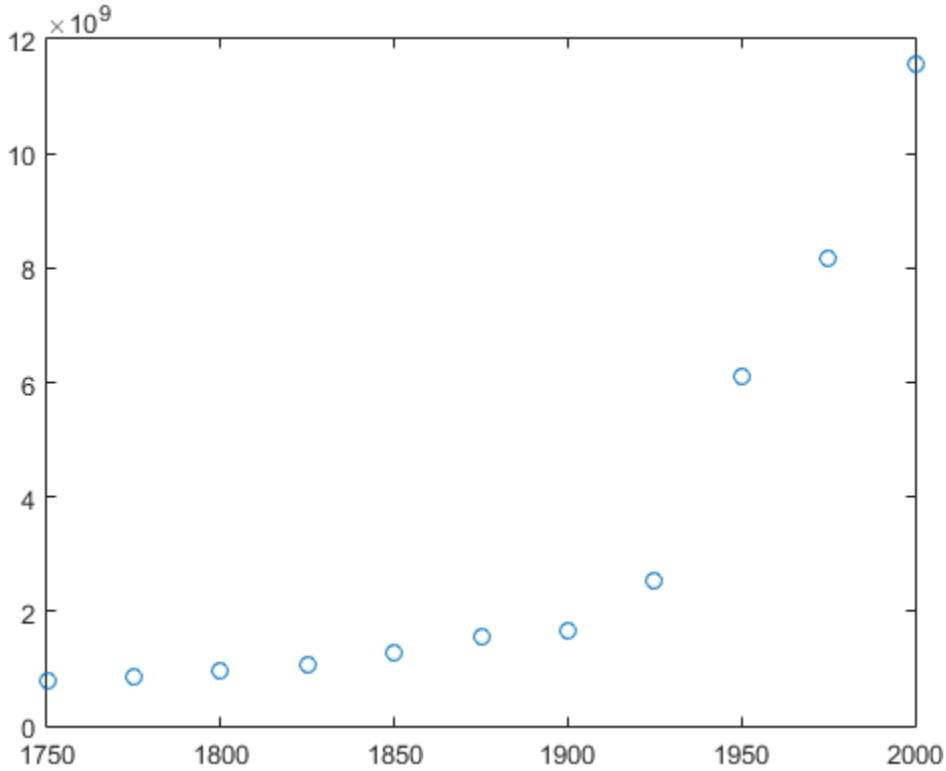
Create a table of population data for the years 1750 - 2000 and plot the data points.

```
year = (1750:25:2000)';
pop = 1e6*[791 856 978 1050 1262 1544 1650 2532 6122 8170 11560]';
T = table(year, pop)
plot(year,pop,'o')
```

```
T =

    year       pop
    ____    _________
```

```
1750      7.91e+08
1775      8.56e+08
1800      9.78e+08
1825       1.05e+09
1850     1.262e+09
1875     1.544e+09
1900      1.65e+09
1925     2.532e+09
1950     6.122e+09
1975      8.17e+09
2000     1.156e+10
```

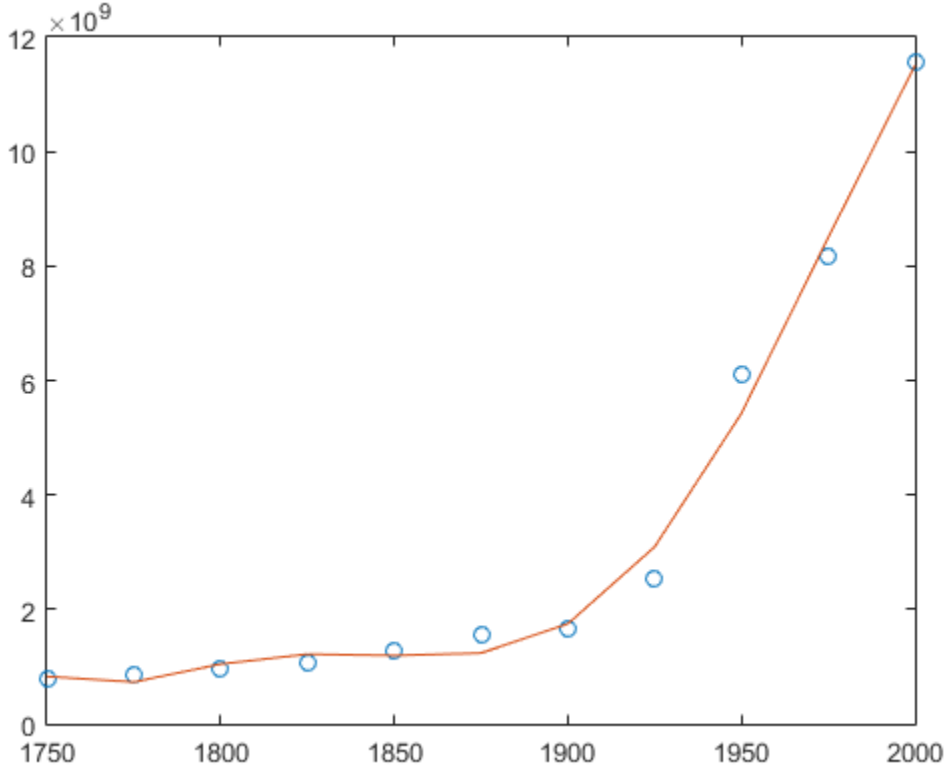


Use `polyfit` with three outputs to fit a 5th-degree polynomial using centering and scaling, which improves the numerical properties of the problem. `polyfit` centers the data in `year` at 0 and scales it to have a standard deviation of 1, which avoids an ill-conditioned Vandermonde matrix in the fit calculation.

```
[p,~,mu] = polyfit(T.year, T.pop, 5);
```

Use `polyval` with four inputs to evaluate `p` with the scaled years, `(year-mu(1))/mu(2)`. Plot the results against the original years.

```
f = polyval(p,year,[],mu);
hold on
plot(year,f)
hold off
```



Input Arguments

x — Query points

vector

Query points, specified as a vector. The points in `x` correspond to the fitted function values contained in `y`.

Warning messages result when `x` has repeated (or nearly repeated) points or if `x` might need centering and scaling.

Data Types: `single` | `double`

Complex Number Support: Yes

y — Fitted values at query points

vector

Fitted values at query points, specified as a vector. The values in `y` correspond to the query points contained in `x`.

Data Types: `single | double`
Complex Number Support: Yes

n — Degree of polynomial fit

positive integer scalar

Degree of polynomial fit, specified as a positive integer scalar. `n` specifies the polynomial power of the left-most coefficient in `p`.

A warning message results if `n` is greater than or equal to `length(x)`.

Output Arguments

p — Least-squares fit polynomial coefficients

vector

Least-squares fit polynomial coefficients, returned as a vector. `p` has length `n+1` and contains the polynomial coefficients in descending powers with the highest power being `n`.

Use `polyval` to evaluate `p` at query points.

S — Error estimation structure

structure

Error estimation structure. This optional output structure is primarily used as an input to the `polyval` function to obtain error estimates. `S` contains the following fields:

Field	Description
`R`	Triangular factor from a QR decomposition of the Vandermonde matrix of `x`
`df`	Degrees of freedom

Field	Description
`normr`	Norm of the residuals

If the data in `y` is random, then an estimate of the covariance matrix of `p` is `(Rinv*Rinv')*normr^2/df`, where `Rinv` is the inverse of `R`.

If the errors in the data in `y` are independent and normal with constant variance, then `[y,delta] = polyval(...)` produces error bounds that contain at least 50% of the predictions. That is, `y ± delta` contains at least 50% of the predictions of future observations at `x`.

`mu` — Centering and scaling values

two element vector

Centering and scaling values, returned as a two element vector. `mu(1)` is `mean(x)`, and `mu(2)` is `std(x)`. These values center the query points in `x` at zero with unit standard deviation.

Use `mu` as the fourth input to `polyval` to evaluate `p` at the scaled points, `(x - mu(1))/mu(2)`.

Limitations

- In problems with many points, increasing the degree of the polynomial fit using `polyfit` does not always result in a better fit. High-order polynomials can be oscillatory between the data points, leading to a *poorer* fit to the data. In those cases, you might use a low-order polynomial fit (which tends to be smoother between points) or a different technique, depending on the problem.
- Polynomials are unbounded, oscillatory functions by nature. Therefore, they are not well-suited to extrapolating bounded data or monotonic (increasing or decreasing) data.

More About

Algorithms

`polyfit` uses `x` to form Vandermonde matrix `V` with `n+1` columns, resulting in the linear system

$$\begin{pmatrix} x_1^{n+1} & x_1^n & \cdots & 1 \\ x_2^{n+1} & x_2^n & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ x_n^{n+1} & x_n^n & \cdots & 1 \end{pmatrix} \begin{pmatrix} p_1 \\ p_2 \\ \vdots \\ p_n \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix},$$

which `polyfit` solves with `p = V\y`. Since the columns in the Vandermonde matrix are powers of the vector `x`, the condition number of `V` is often large for high-order fits, resulting in a singular coefficient matrix. In those cases centering and scaling can improve the numerical properties of the system to produce a more reliable fit.

- "Programmatic Fitting"

`cov` | `lscov` | `poly` | `polyder` | `polyint` | `polyval` | `roots`

Introduced before R2006a

polyint

Integrate polynomial analytically

Syntax

```
polyint(p,k)
polyint(p)
```

Description

`polyint(p,k)` returns a polynomial representing the integral of polynomial `p`, using a scalar constant of integration `k`. Specify `p` and `k` as type `double` or `single`.

`polyint(p)` assumes a constant of integration `k=0`.

See Also

`polyder` | `polyval` | `polyvalm` | `polyfit`

Introduced before R2006a

polyval

Polynomial evaluation

Syntax

```
y = polyval(p,x)
[y,delta] = polyval(p,x,S)
y = polyval(p,x,[],mu)
[y,delta] = polyval(p,x,S,mu)
```

Description

`y = polyval(p,x)` returns the value of a polynomial of degree `n` evaluated at `x`. The input argument `p` is a vector of length `n+1` whose elements are the coefficients in descending powers of the polynomial to be evaluated.

$y = p_1x^n + p_2x^{n-1} + \ldots + p_nx + p_{n+1}$

`x` can be a matrix or a vector. In either case, `polyval` evaluates `p` at each element of `x`.

`[y,delta] = polyval(p,x,S)` uses the optional output structure `S` generated by `polyfit` to generate error estimates `delta`. `delta` is an estimate of the standard deviation of the error in predicting a future observation at `x` by `p(x)`. If the coefficients in `p` are least squares estimates computed by `polyfit`, and the errors in the data input to `polyfit` are independent, normal, and have constant variance, then `y±delta` contains at least 50% of the predictions of future observations at `x`.

`y = polyval(p,x,[],mu)` or `[y,delta] = polyval(p,x,S,mu)` use $\hat{x} = (x - \mu_1)/\mu_2$ in place of `x`. In this equation, $\mu_1 = \text{mean}(x)$ and $\mu_2 = \text{std}(x)$. The centering and scaling parameters `mu` = [μ_1,μ_2] are optional output computed by `polyfit`.

Examples

The polynomial $p(x) = 3x^2 + 2x + 1$ is evaluated at $x = 5$, 7, and 9 with

```
p = [3 2 1];
polyval(p,[5 7 9])
```

which results in

```
ans =

    86   162   262
```

For another example, see `polyfit`.

More About

Tips

The `polyvalm(p,x)` function, with `x` a matrix, evaluates the polynomial in a matrix sense. See `polyvalm` for more information.

See Also

`polyfit` | `polyvalm` | `polyder` | `polyint`

Introduced before R2006a

polyvalm

Matrix polynomial evaluation

Syntax

```
Y = polyvalm(p,X)
```

Description

`Y = polyvalm(p,X)` evaluates a polynomial in a matrix sense. This is the same as substituting matrix `X` in the polynomial `p`.

Polynomial `p` is a vector whose elements are the coefficients of a polynomial in descending powers, and `X` must be a square matrix.

Examples

The Pascal matrices are formed from Pascal's triangle of binomial coefficients. Here is the Pascal matrix of order 4.

```
X = pascal(4)
X =
     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    20
```

Its characteristic polynomial can be generated with the `poly` function.

```
 p = poly(X)
 p =
     1    -29     72    -29     1
```

This represents the polynomial $x^4 - 29x^3 + 72x^2 - 29x + 1$.

Pascal matrices have the curious property that the vector of coefficients of the characteristic polynomial is palindromic; it is the same forward and backward.

Evaluating this polynomial at each element is not very interesting.

```
polyval(p,X)
ans =
   16      16      16      16
   16      15    -140    -563
   16    -140   -2549  -12089
   16    -563  -12089  -43779
```

But evaluating it in a matrix sense is interesting.

```
polyvalm(p,X)
ans =
   0    0    0    0
   0    0    0    0
   0    0    0    0
   0    0    0    0
```

The result is the zero matrix. This is an instance of the Cayley-Hamilton theorem: a matrix satisfies its own characteristic equation.

`polyfit` | `polyval`

Introduced before R2006a

posixtime

Convert MATLAB datetime to POSIX time

Syntax

```
p = posixtime(t)
```

Description

`p = posixtime(t)` returns the POSIX® time equivalent to the datetime values in `t`. The POSIX time is the number of seconds (including fractional seconds) elapsed since 00:00:00 1-Jan-1970 UTC, ignoring leap seconds. `p` is a `double` array.

Examples

Convert Datetime Array to POSIX Time

Create a `datetime` array. Then, convert the dates to the equivalent POSIX® time.

```
t = datetime('now') + calmonths(1:3)
```

```
t =

   23-Mar-2015 10:12:07   23-Apr-2015 10:12:07   23-May-2015 10:12:07
```

```
format longG
p = posixtime(t)
```

```
p =

            1427105527.525            1429783927.525            1432375927.525
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

See Also

`datenum` | `datetime` | `exceltime` | `juliandate` | `yyyymmdd`

Introduced in R2014b

pow2

Base 2 power and scale floating-point numbers

Syntax

```
X = pow2(Y)
X = pow2(F,E)
```

Description

`X = pow2(Y)` returns an array `X` whose elements are 2 raised to the power `Y`.

`X = pow2(F,E)` computes $x = f * 2^e$ for corresponding elements of `F` and `E`. The result is computed quickly by simply adding `E` to the floating-point exponent of `F`. Arguments `F` and `E` are real and integer arrays, respectively.

Examples

For IEEE arithmetic, the statement `X = pow2(F,E)` yields the values:

```
F          E         X
1/2        1         1
pi/4       2         pi
-3/4       2         -3
1/2        -51       eps
1-eps/2    1024      realmax
1/2        -1021     realmin
```

More About

Tips

This function corresponds to the ANSI C function `ldexp()` and the IEEE floating-point standard function `scalbn()`.

`exp` | `hex2num` | `log2` | `mpower` | `power` | `realmax` | `realmin`

Introduced before R2006a

power, .^

Element-wise power

Syntax

```
C = A.^B
C = power(A,B)
```

Description

`C = A.^B` raises each element of `A` to the corresponding power in `B`.

`C = power(A,B)` is an alternate way to execute `A.^B`, but is rarely used. It enables operator overloading for classes.

Examples

Square Each Element of Vector

Create a vector, `A`, and square each element.

```
A = 1:5;
C = A.^2
```

```
C =

     1     4     9    16    25
```

Find Inverse of Each Matrix Element

Create a matrix, `A`, and take the inverse of each element.

```
A = [1 2 3; 4 5 6; 7 8 9];
C = A.^-1
```

```
C =
```

```
    1.0000    0.5000    0.3333
    0.2500    0.2000    0.1667
    0.1429    0.1250    0.1111
```

An inversion of the elements is not equal to the inverse of the matrix, which is instead written `A^-1` or `inv(A)`.

Find Roots of Number

Calculate the roots of `-1` to the `1/3` power.

```
A = -1;
B = 1/3;
C = A.^B
```

```
C =

   0.5000 + 0.8660i
```

For negative base `A` and noninteger `B`, if `abs(B)` is less than `1`, the `power` function returns the complex roots of `A`.

Use the `nthroot` function to obtain the real roots.

```
C = nthroot(A,3)
```

```
C =

    -1
```

Input Arguments

A — Base

scalar | vector | matrix | multidimensional array

Base, specified as a scalar, vector, matrix, or multidimensional array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

B — Exponent

scalar | vector | matrix | multidimensional array

Exponent, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

`mpower` | `nthroot` | `realpow`

Introduced before R2006a

ppval

Evaluate piecewise polynomial

Syntax

```
v = ppval(pp,xx)
```

Description

`v = ppval(pp,xx)` returns the value of the piecewise polynomial *f*, contained in `pp`, at the entries of `xx`. You can construct `pp` using the functions `pchip`, `spline`, or the spline utility `mkpp`.

`v` is obtained by replacing each entry of `xx` by the value of *f* there. If *f* is scalar-valued, `v` is of the same size as `xx`. `xx` may be N-dimensional.

If `pp` was constructed by `pchip`, `spline`, or `mkpp` using the orientation of non-scalar function values specified for those functions, then:

If `f` is `[D1,..,Dr]`-valued, and `xx` is a vector of length `N`, then `V` has size `[D1,...,Dr, N]`, with `V(:,...,:,J)` the value of `f` at `xx(J)`.

If `f` is `[D1,..,Dr]`-valued, and `xx` has size `[N1,...,Ns]`, then `V` has size `[D1,...,Dr, N1,...,Ns]`, with `V(:,...,:, J1,...,Js)` the value of `f` at `xx(J1,...,Js)`.

Examples

Compare the result of integrating *cos*(*x*) between 0 and 10 to the result of integrating a piece-wise polynomial approximation of the same function.

```
a = 0; b = 10;
int1 = integral(@cos,a,b)

int1 =
   -0.5440
```

Create a piece-wise polynomial approximation of *cos*(*x*) and integrate over the same interval.

```
x = a:b;
y = cos(x);
pp = spline(x,y);
int2 = integral(@(x)ppval(pp,x),a,b)

int2 =
   -0.5485
```

See Also

`mkpp` | `spline` | `unmkpp`

Introduced before R2006a

prefdir

Folder containing preferences, history, and layout files

Syntax

```
prefdir
folder = prefdir
folder = prefdir(1)
```

Description

`prefdir` returns the folder that contains

- Preferences for MATLAB and related products (`matlab.prf`)
- Command history file (`History.xml`)
- MATLAB shortcuts (`shortcuts_2.xml`)
- MATLAB desktop layout files (`MATLABDesktop.xml` and `Your_Saved_LayoutMATLABLayout.xml`)
- Other related files

`folder = prefdir` assigns to `folder` the name of the folder containing preferences and related files.

`folder = prefdir(1)` creates a folder for preferences and related files if one does not exist. If the folder does exist, the name is assigned to `folder`.

Examples

View the location of the preferences folder:

```
prefdir
```

Make the preferences folder become the current folder:

```
cd(prefdir)
```

```
% Then, view the files for customizing MathWorks products:
dir
```

On Windows platforms, go directly to the preferences folder in Microsoft Windows Explorer

```
winopen(prefdir)
```

More About

Tips

- You must have write access to the preferences folder. Otherwise, MATLAB generates an error in the Command Window when you try to change preferences. This can happen if the folder is hidden, for example: `myname/.matlab/R2009a`.
- "Preferences Folder and Files MATLAB Uses When Multiple MATLAB Releases Are Installed"

See Also

`preferences` | `getpref` | `setpref`

Introduced before R2006a

preferences

Open Preferences dialog box

Syntax

```
preferences
```

Description

`preferences` displays the Preferences dialog box, from which you can make changes to options for MATLAB and related products.

More About

- "Preferences"

`prefdir`

Introduced before R2006a

primes

Prime numbers less than or equal to input value

Syntax

```
p = primes(n)
```

Description

`p = primes(n)` returns a row vector containing all the prime numbers less than or equal to `n`. The data type of `p` is the same as that of `n`.

Examples

Primes Less Than or Equal to 25

```
p = primes(25)
```

```
p =

    2     3     5     7    11    13    17    19    23
```

Primes Less Than or Equal to an Unsigned Integer

```
n = uint16(12);
p = primes(n)
```

```
p =

    2     3     5     7    11
```

Input Arguments

n — Input value

scalar, real integer value

Input value, specified as a scalar that is a real integer value.

Example: `10`

Example: `int16(32)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

See Also

`factor` | `isprime`

Introduced before R2006a

print

Print figure or save to specific file format

Syntax

```
print(filename,formattype)
print(filename,formattype,formatoptions)

print
print(printer)
print(driver)
print(printer,driver)

print('-clipboard',clipboardformat)

print(resolution, ___ )
print(renderer, ___ )
print('-noui', ___ )
print(fig, ___ )

cdata = print('-RGBImage');
```

Description

`print(filename,formattype)` saves the current figure to a file using the specified file format. If the file name does not include an extension, then `print` appends the appropriate one.

`print(filename,formattype,formatoptions)` specifies additional options that are available for some formats.

`print` prints the current figure to the default printer.

`print(printer)` specifies the printer. Specify the printer as a string containing the printer name preceded by `-P`, for example, `'-Pmy printer'`. The printer must be setup on your system.

`print(driver)` specifies the driver for the temporary file that `print` generates and sends to the printer. Specify a driver if you want to ensure that the printed output is either black and white or color.

`print(printer,driver)` specifies the printer and the driver.

`print('-clipboard',clipboardformat)` copies the current figure to the clipboard using the specified format. You can paste the copied figure into other applications.

`print(resolution, ___ )` uses the specified resolution. Specify the resolution as a string containing an integer value preceded by `-r`, for example, `'-r200'`. Use this option with any of the input arguments from the previous syntaxes.

`print(renderer, ___ )` uses the specified renderer. Specify the renderer as either `'-painters'` or `'-opengl'`.

`print('-noui', ___ )` excludes user interface controls, such as push buttons and sliders, from the saved or printed output. It does not exclude user interface objects that can contain an axes, such as a uitab or uipanel.

`print(fig, ___ )` saves or prints the figure or Simulink block diagram specified by `fig` instead of the current figure.

`cdata = print('-RGBImage');` returns the RGB image data for the current figure. This option differs from screen captures in that all printing features apply to the output. You can additionally specify the resolution, renderer, '-noui', and fig options with this syntax. However, you cannot specify a Simulink block diagram.

Examples

Print Paper Copy of Figure

Create a bar chart and print it to your system default printer. If you do not specify the figure to print, then `print` uses the current figure.

```
bar(1:10)
print
```

Copy Figure to Clipboard

Create a plot and copy it to the system clipboard.

```
plot(1:10)
print('-clipboard','-dmeta')
```

You can paste the copied plot into other applications.

Save Figure as Image File

Create a plot and save it as a PNG image file.

```
bar(1:10)
print('BarPlot','-dpng')
```

`print` saves the plot as `BarPlot.png`.

Save Figure as Vector Graphics File

Create a plot and save it as an Encapsulated PostScript file.

```
bar(1:10)
print('BarPlot','-depsc')
```

`print` saves the plot as `BarPlot.eps`.

Add TIFF Preview to EPS File

Save the current figure as an Encapsulated PostScript File and add a TIFF preview.

```
surf(peaks)
print('SurfacePlot','-depsc','-tiff')
```

Specify Figure to Save

Save a specific figure by passing its object variable to `print`.

```
fig = figure;
plot(1:10)
print(fig,'MySavedPlot','-dpng')
```

Alternatively, refer to a figure using the value of its `Number` property, which is the integer value that displays in the figure window title bar. For example, save the figure with `Figure 2` displayed in the title bar. Precede the integer value by `-f`.

```
figure(2);
plot(1:10)
```

```
print('-f2','MySavedPlot','-dpng')
```

Save Figure at Screen Size and Resolution

Save a surface plot to a PNG file. Set the `PaperPositionMode` property for the figure to `'auto'` so that it saves at the size displayed on the screen. Use `'-r0'` to save it with screen resolution.

```
surf(peaks)
set(gcf,'PaperPositionMode','auto')
print('PeaksSurface','-dpng','-r0')
```

Save Figure Without Saving UIControls

Create a figure with a push button that clears the axes. Save the figure to a JPEG file without saving the push button.

```
surf(peaks)
uicontrol('Style','pushbutton','String','Clear',...
    'Position',[20 20 50 20],'Callback','cla');
print('SurfacePlot','-djpeg','-noui')
```

Return RGB Image Data for Figure

Return the RGB image data for a figure.

```
surf(peaks)
cdata = print('-RGBImage');
```

Display the image data at full resolution using `imshow`.

```
figure
imshow(cdata)
```

Input Arguments

`filename` — File name

string

File name, specified as a string containing the desired file name and path.

Example: `'My Saved Chart'`

Example: `'Folder\My Saved Chart'`

The maximum file name length, including the path, is operating system and file format specific. Typically, the file name should be no more than 126 characters, or if you include the path, then no more than 128 characters.

`formattype` — File format
`'-djpeg' | '-dpng' | '-dtiff' | '-dpdf' | '-deps' | ...`

File format, specified as one of the options in these tables.

Bitmap Image File

Bitmap images contain a pixel-based representation of the figure. The size of the generated file depends on the figure and the format used. Bitmap images are widely used by Web browsers and other applications that display graphics. However, they do not scale well and you cannot modify individual graphics objects, such as lines and text, in other graphics applications.

This table lists the supported bitmap image formats.

Option	Bitmap Image Format	Corresponding File Extension
`'jpeg'`	JPEG 24-bit	`.jpg`
`'png'`	PNG 24-bit	`.png`
`'tiff'`	TIFF 24-bit (compressed)	`.tif`
`'tiffn'`	TIFF 24-bit (not compressed)	`.tif`
`'meta'`	Enhanced metafile (Windows only)	`.emf`
`'bmpmono'`	BMP Monochrome	`.bmp`
`'bmp'`	BMP 24-bit	`.bmp`
`'bmp16m'`	BMP 24-bit	`.bmp`
`'bmp256'`	BMP 8-bit (256 color, uses a fixed colormap)	`.bmp`
`'hdf'`	HDF 24-bit	`.hdf`
`'pbm'`	PBM (plain format) 1-bit	`.pbm`

Option	Bitmap Image Format	Corresponding File Extension
'pbmraw'	PBM (raw format) 1-bit	.pbm
'pcxmono'	PCX 1-bit	.pcx
'pcx24b'	PCX 24-bit color (three 8-bit planes)	.pcx
'pcx256'	PCX 8-bit newer color (256 color)	.pcx
'pcx16'	PCX older color (EGA/VGA 16-color)	.pcx
'pgm'	PGM (plain format)	.pgm
'pgmraw'	PGM (raw format)	.pgm
'ppm'	PPM (plain format)	.ppm
'ppmraw'	PPM (raw format)	.ppm

Vector Graphics File

Vector graphics files store commands that redraw the figure. This type of format scales well, but can result in a large file. Additionally, it might not produce the correct 3-D arrangement of objects in certain cases. Some applications support extensive editing of vector graphics formats. However, some applications do not support editing beyond resizing the graphic. In general, you should try to make all the necessary changes while your figure is still in MATLAB.

If you set the `Renderer` property for the figure, then `print` uses that renderer when generating output. Otherwise, `print` chooses the appropriate renderer. Typically, `print` uses the Painters renderer when generating vector graphics files. For some complex figures, `print` uses the OpenGL renderer instead. If it uses the OpenGL renderer, then the vector graphics file contains an embedded image, which might limit the extent to which you can edit the image in other applications. To ensure that `print` uses the Painters renderer, set the `Renderer` property for the figure to `'painters'` or specify `'-painters'` as an input argument to `print`.

Note: The default figure renderer is OpenGL. If the figure renderer differs from the renderer used when generating output, some details of the saved figure can differ from

the figure on the display. If necessary, you can make the displayed figure and the saved figure use the same renderer. Set the `Renderer` property for the figure or specify the renderer input argument to the `print` function.

This table lists the supported vector graphics formats.

Option	Vector Graphics Format	Corresponding File Extension
`'pdf'`	Full page Portable Document Format (PDF) color	`.pdf`
`'eps'`	Encapsulated PostScript (EPS) Level 3 black and white	`.eps`
`'epsc'`	Encapsulated PostScript (EPS) Level 3 color	`.eps`
`'eps2'`	Encapsulated PostScript (EPS) Level 2 black and white	`.eps`
`'epsc2'`	Encapsulated PostScript (EPS) Level 2 color	`.eps`
`'meta'`	Enhanced Metafile (Windows only)	`.emf`
`'svg'`	SVG (scalable vector graphics)	`.svg`
`'ps'`	Full-page PostScript (PS) Level 3 black and white	`.ps`
`'psc'`	Full-page PostScript (PS) Level 3 color	`.ps`
`'ps2'`	Full-page PostScript (PS) Level 2 black and white	`.ps`
`'psc2'`	Full-page PostScript (PS) Level 2 color	`.ps`

Note: Only PDF and PS formats use the `PaperOrientation` property of the figure and the `left` and `bottom` elements of the `PaperPosition` property. Other formats ignore these values.

`formatoptions` — Additional formatting options

`'-tiff' | '-loose' | '-cmyk' | '-append'`

Additional formatting options supported by some file formats, specified as one or more of these values:

- `'-tiff'` — Include a TIFF preview. EPS files only.
- `'-loose'` — Use a loose bounding box. EPS and PS files only.
- `'-cmyk'` — Use CMYK colors instead of RGB colors. EPS and PS files only.
- `'-append'` — Append the figure to an existing PS file. PS files only.

Example: `print('my file','-deps','-tiff','loose')` saves the current figure to the file `my file.eps` using a loose bounding box and includes a TIFF preview.

`printer` — Printer name

string containing `-P` and printer name

Printer name, specified as a string containing `-P` and printer name.

Example: `'-Pmy local printer'`

To view a list of available printers, use this command:

```
[~,printers] = findprinters
```

If you do not specify a printer, then `print` uses the system default printer. If you want to set up a new printer or select a different default printer, use the operating system printer management utilities. Restart MATLAB if you do not see a printer that is already setup.

`driver` — Printer driver

`'-dwin' | '-dwinc' | '-dps' | '-dpsc' | '-dps2' | '-dpsc2'`

Printer driver, specified as `'-dwin'`, `'-dwinc'`, `'-dps'`, `'-dpsc'`, `'-dps2'`, or `'-dpsc2'`. If you do not specify a driver, then `print` relies on your operating system to choose the driver.

The option you use depends on your system, for example:

System	Driver	Output
Windows	`'-dwin'`	Black and white
	`'-dwinc'`	Color
Linux or Mac OS X	`'-dps'` or `'-dps2'`	Black and white
	`'-dpsc'` or `'-dpsc2'`	Color

`clipboardformat` — Format copied to clipboard

`-dmeta | -dbitmap | -dpdf`

Format copied to clipboard, specified as one of these options:

- `'-dmeta'` — Enhanced metafile (Windows only)
- `'-dbitmap'` — Bitmap image (Windows and Mac OS X)
- `'-dpdf'` — PDF file (Windows and Mac OS X)

`resolution` — Resolution

string containing `-r` and integer

Resolution, specified as a string containing `-r` and an integer value indicating the resolution in dots per inch. For example, `'-r300'` sets the output resolution to 300 dots per inch. To specify screen resolution, use `'-r0'`.

In general, using a higher resolution value yields higher quality output, but at the cost of higher memory use and larger output files. The higher the resolution setting, the longer it takes to render your figure. By default, the resolution is 90 dpi for Simulink models and 150 dpi for figures. For typical laser-printer output, the default resolution of 150 dpi for figures is normally adequate. However, if you are preparing figures for high-quality printing, such as a textbook or color brochures, you might want to use 200 or 300 dpi. The resolution can be limited by the printer's capabilities.

Specifying the resolution is useful if you want to scale a bitmap image or a vector graphics file that contains an embedded image. At ordinary magnification, the effect is subtle. The effect is most apparent when viewing the output at a higher magnification or when printed.

`renderer` — Graphics renderer

`'-opengl' | '-painters'`

Graphics renderer, specified as `'-opengl'` or `'-painters'`.

- `'-opengl'` — OpenGL renderer. Use this renderer when saving bitmap images. OpenGL produces a bitmap image even with vector formats, which might limit the extent to which you can edit the image in other applications.
- `'-painters'` — Painters renderer. Use this renderer when saving vector graphics files. If you save to a vector graphics file and if the figure `RendererMode` property is set to `'auto'`, then `print` automatically attempts to use the Painters renderer. If you want to ensure that your output format is a true vector graphics file, then specify the Painters renderer. For example:

  ```
  print('-painters','-deps','myVectorFile')
  ```

Note: In some cases, saving a file with the `'-painters'` option can cause longer rendering times and, in rare cases, might not accurately arrange graphics objects in 3-D views. Additionally, the Painters renderer cannot print or save lines thinner than 1 pixel.

If you do not specify the renderer, then `print` automatically uses the appropriate renderer to produce the output format that you request. However, if you set the `Renderer` property for the figure, then `print` uses that renderer when generating output.

`fig` — Figure or Simulink block diagram

figure object | Simulink block diagram

Figure object or Simulink block diagram. You can refer to a figure using either its object variable name or using the figure number preceded by `-f`. For example, `-f2` refers to the figure with a `Number` property value of `2`. When specifying a Simulink block diagram, precede the model name with `-s`. Specify the current model using `'-s'`.

Output Arguments

`cdata` — Image data

n-by-m-by-3 array

Image data, returned as an n-by-m-by-3 array.

Limitations

- `print` does not support capturing ActiveX controls.
- Starting MATLAB in no display mode on Linux or using the `-noFigureWindows` startup option on any platform has these limitations for `print`:
  - Does not print or save uicontrols.
  - Always uses the painters renderer, even if you specify the `'-opengl'` option.

More About

Tips

- You can set properties of the figure to control some printing and saving parameters. This table lists properties of the figure related to printing and saving.

Figure Property	Description
`PaperPosition`	Size of the printed or saved figure. If printing to a printer or a full-page output format, then this property also determines the figure location on the page.
`PaperPositionMode`	Specifies whether to use the `PaperPosition` property or the size of the figure on the screen to set the size of the printed or saved figure.
`InvertHardcopy`	Specifies whether to use the current background color of the figure or to change the background color to white when printing or saving the figure.
`PaperOrientation`	Figure orientation on printed page.
`PaperType`	Standard printer paper size.
`PaperSize`	Custom width and height of printer paper.
`PaperUnits`	Units for the `PaperSize` and `PaperPosition` properties.

- The `print` function returns a warning message when you print a figure that has a callback defined for the `SizeChangedFcn` property. To avoid the warning, set the `PaperPositionMode` property for the figure to `'auto'`.

`getframe` | `saveas` | `savefig`

Introduced before R2006a

printopt

Configure printer defaults

Syntax

```
[pcmd,dev] = printopt
```

Description

`[pcmd,dev] = printopt` returns strings containing the current system-dependent printing command and output device. `printopt` is a file used by `print` to produce the hard-copy output. You can edit the file `printopt.m` to set your default printer type and destination.

`pcmd` and `dev` are platform-dependent strings. `pcmd` contains the command that `print` uses to send a file to the printer. `dev` contains the printer driver or graphics format option for the `print` command. Their defaults are platform dependent.

Platform	Print Command	Driver or Format
Mac and UNIX	`lpr -r`	`-dps2`
Windows	COPY /B %s LPT1:	`-dwin`

See Also

`printdlg` | `print`

Introduced before R2006a

printdlg

Open figure Print dialog box

Note: The `-crossplatform` and `-setup` input arguments have been removed in R2014b. They no longer have any effect.

Syntax

```
printdlg
printdlg(fig)
```

Description

`printdlg` prints the current figure.

`printdlg(fig)` creates a modal dialog box from which you can print the figure window identified by the handle `fig`. Uimenus do not print.

More About

Tips

If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see the printer which is already setup.

See Also

`print` | `printopt` | `printpreview`

Introduced before R2006a

printpreview

Open figure Print Preview dialog box

Syntax

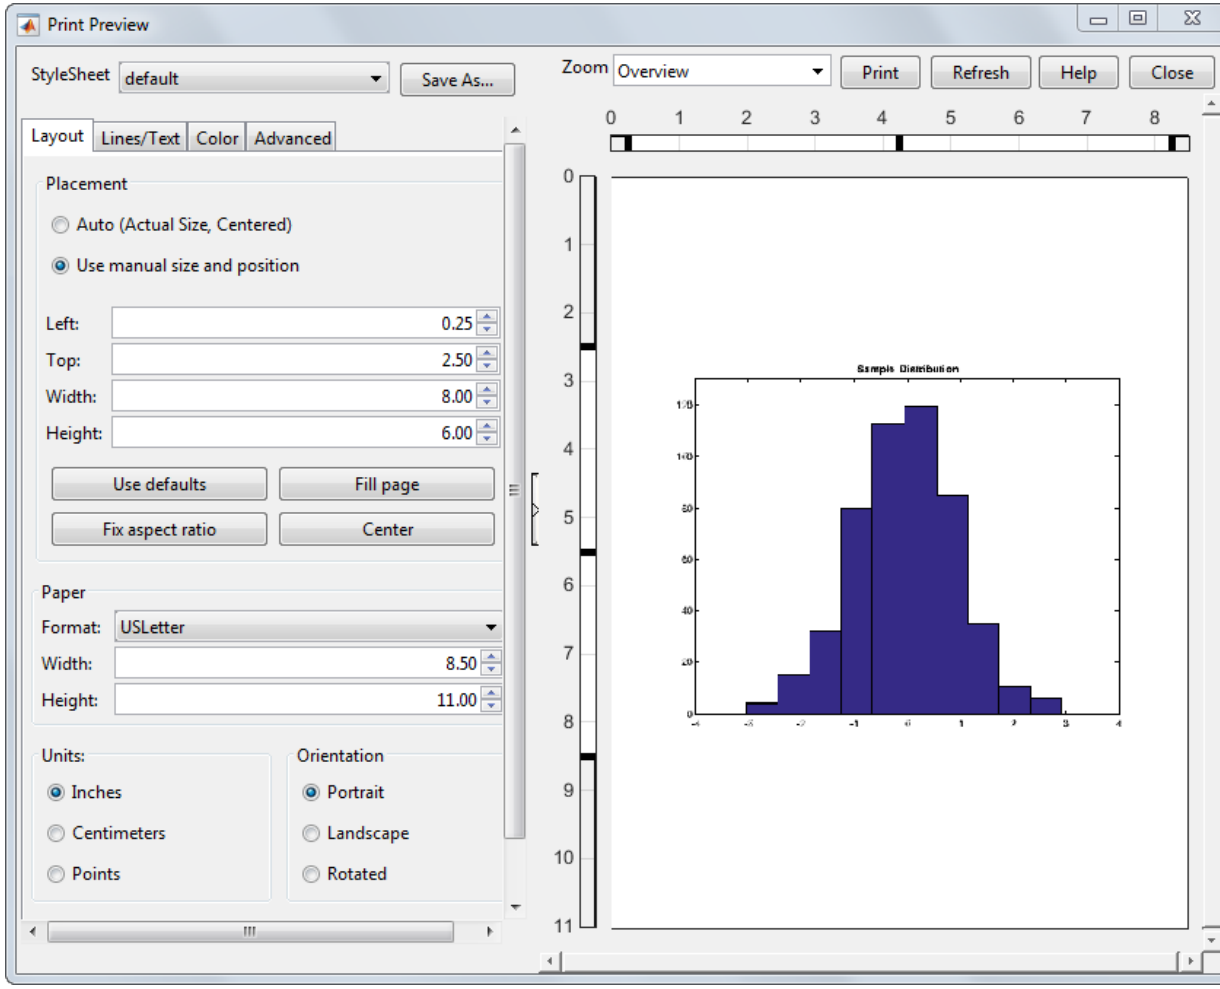
```
printpreview
printpreview(f)
```

Description

`printpreview` displays a dialog box showing the figure in the currently active figure window as it will print. A scaled version of the figure displays in the right-hand pane of the dialog box.

`printpreview(f)` displays a dialog box showing the figure having the handle `f` as it will print.

Use the Print Preview dialog box, shown below, to control the layout and appearance of figures before sending them to a printer or print file. Controls are grouped into four tabbed panes: **Layout**, **Lines/Text**, **Color**, and **Advanced**.



Right Pane Controls

You can position and scale plots on the printed page using the rulers in the right-hand pane of the Print Preview dialog. Use the outer ruler handlebars to change margins. Moving them changes plot proportions. Use the center ruler handlebars to change the position of the plot on the page. Plot proportions do not change, but you can move portions of the plot off the paper. The buttons on that pane let you refresh the plot, close the dialog (preserving all current settings), print the page immediately, or obtain context-

sensitive help. Use the **Zoom** box and scroll bars to view and position page elements more precisely.

The Layout Tab

Use the **Layout** tab, shown above, to control the paper format and placement of the plot on printed pages. The following table summarizes the **Layout** options:

Group	Option	Description
Placement	**Auto**	Let MATLAB decide placement of plot on page*
	Use manual...	Specify position parameters for plot on page*
	Top, Left, Width, Height	Standard position parameters in current units
	Use defaults	Revert to default position
	Fill page	Expand figure to fill printable area (see note below)
	Fix aspect ratio	Correct height/width ratio
	Center	Center plot on printed page
Paper	**Format**	U.S. and ISO® sheet size selector
	Width, Height	Sheet size in current units
Units	**Inches**	Use inches as units for dimensions and positions
	Centimeters	Use centimeters as units for dimensions and positions
	Points	Use points as units for dimensions and positions
Orientation	**Portrait**	Upright paper orientation
	Landscape	Sideways paper orientation
	Rotated	Currently the same as **Landscape**

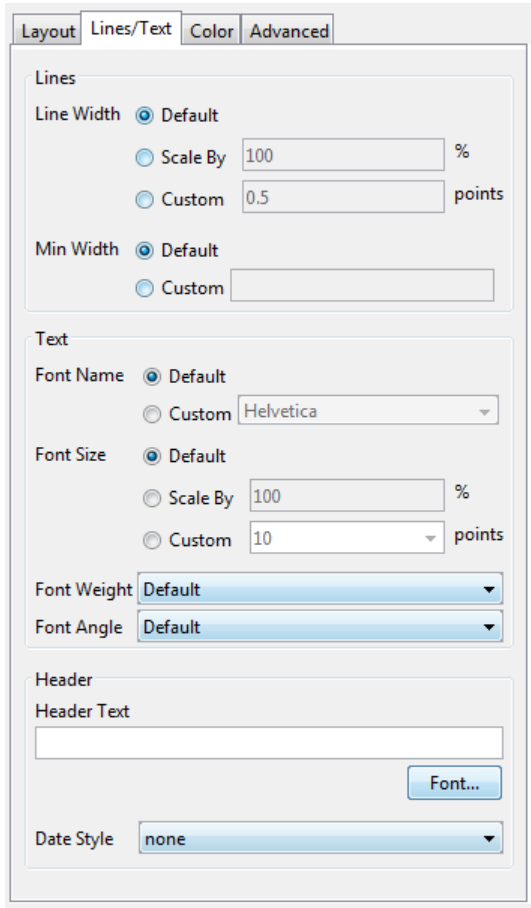
* Selecting **Auto** in the Placement group sets the figure `PaperPositionMode` to `'auto'` and disables the controls in that panel. Selecting **Use manual size and position** sets the figure `PaperPositionMode` to `'manual'` and enables the controls. If you set

`PaperPositionMode` programmatically, the print preview Placement controls respond accordingly.

Note: Selecting the **Fill page** option changes the `PaperPosition` property to fill the page, allowing objects in normalized units to expand to fill the space. If an object within the figure has an absolute size, for example a table, it can overflow the page when objects with normalized units expand. To avoid having objects fall off the page, do not use **Fill page** under such circumstances.

The Lines/Text Tab

Use the **Lines/Text** tab, shown below, to control the line weights, font characteristics, and headers for printed pages. The following table summarizes the **Lines/Text** options:

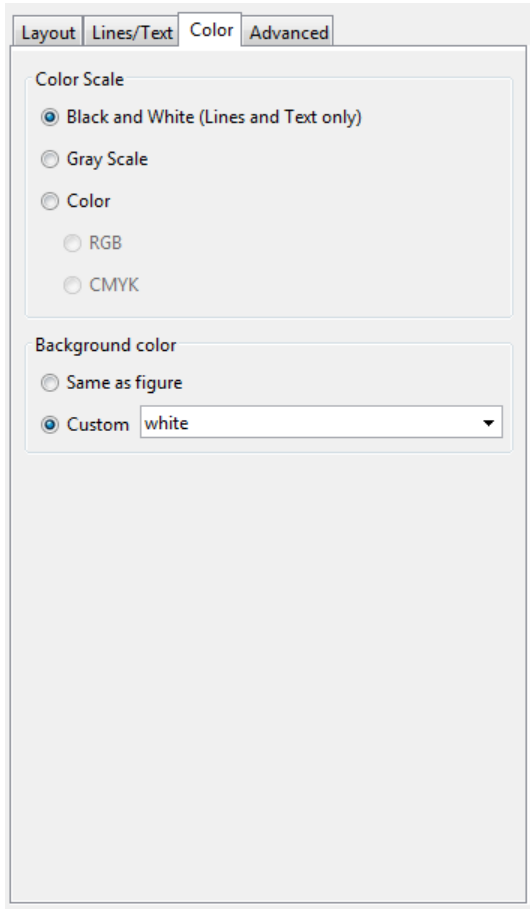


Group	Option	Description
Lines	**Line Width**	Scale all lines by a percentage from 0 upward (100 being no change), print lines at a specified point size, or default line widths used on the plot
	Min Width	Smallest line width (in points) to use when printing; defaults to 0.5 point
Text	**Font Name**	Select a system font for all text on plot, or default to fonts currently used on the plot

Group	Option	Description
	Font Size	Scale all text by a percentage from 0 upward (100 being no change), print text at a specified point size, or default to this used on the plot
	Font Weight	Select `Normal` ... `Bold` font styling for all text from drop-down menu or default to the font weights used on the plot
	Font Angle	Select `Normal`, `Italic` or `Oblique` font styling for all text from drop-down menu or default to the font angles used on the plot
Header	**Header Text**	Type the text to appear on the header at the upper left of printed pages, or leave blank for no header
	Date Style	Select a date format to have today's date appear at the upper left of printed pages, or `none` for no date

The Color Tab

Use the **Color** tab, shown below, to control how colors are printed for lines and backgrounds. The following table summarizes the **Color** options:

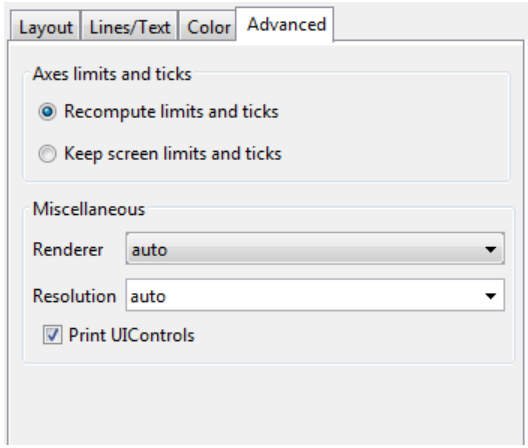


Group	Option	Description
Color Scale	**Black and White**	Select to print lines and text in black and white, but use color for patches and other objects
	Gray Scale	Convert colors to shades of gray on printed pages
	Color	Print everything in color, matching colors on plot; select `RGB` (default) or `CMYK` color model for printing

Group	Option	Description
Background Color	**Same as figure**	Print the figure's background color as it is
	Custom	Select a color name, or type a colorspec for the background; `white` (default) implies no background color, even on colored paper.

The Advanced Tab

Use the **Advanced** tab, shown below, to control finer details of printing, such as limits and ticks, renderer, resolution, and the printing of UIControls. The following table summarizes the **Advanced** options:



Group	Option	Description
Axes limits and ticks	**Recompute limits and ticks**	Redraw *x*- and *y*-axes ticks and limits based on printed plot size (default)
	Keep limits and ticks	Use the *x*- and *y*-axes ticks and limits shown on the plot when printing the previewed figure
Miscellaneous	**Renderer**	Select a rendering algorithm for printing: `painters`, `opengl`, or `auto` (default)

Group	Option	Description
	Resolution	Select resolution to print at in dots per inch: `150`, `300`, `600`, or `auto` (default), or type in any other positive value
	Print UIControls	Print all visible UIControls in the figure (default), or uncheck to exclude them from being printed

Alternatives

Use **File > Print Preview** on the figure window menu to access the Print Preview dialog box, described below. For details, see "Print Figure from File Menu".

`print`

Introduced before R2006a

prod

Product of array elements

Syntax

```
B = prod(A)
B = prod(A,dim)
B = prod( ___ ,type)
```

Description

`B = prod(A)` returns the product of the array elements of `A`.

- If `A` is a vector, then `prod(A)` returns the product of the elements.
- If `A` is a nonempty matrix, then `prod(A)` treats the columns of `A` as vectors and returns a row vector of the products of each column.
- If `A` is an empty 0-by-0 matrix, `prod(A)` returns `1`.
- If `A` is a multidimensional array, then `prod(A)` acts along the first nonsingleton dimension and returns an array of products. The size of this dimension reduces to `1` while the sizes of all other dimensions remain the same.

`prod` computes and returns `B` as `single` when the input, `A`, is `single`. For all other numeric and logical data types, `prod` computes and returns `B` as `double`.

`B = prod(A,dim)` returns the products along dimension `dim`. For example, if `A` is a matrix, `prod(A,2)` is a column vector containing the products of each row.

`B = prod( ___ ,type)` returns an array in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be `'double'`, `'native'`, or `'default'`.

Examples

Product of Elements in Each Column

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

```
A =

     1     4     7
     2     5     8
     3     6     9
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =

     6   120   504
```

The length of the first dimension is `1`, and the length of the second dimension matches `size(A,2)`.

Logical Input with Double Output

Create an array of logical values.

```
A = [true false; true true]
```

```
A =

     1     0
     1     1
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =

     1     0
```

The output is `double`.

```
class(B)
```

```
ans =
```

```
double
```

Product of Elements in Each Row

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

```
A =

     1     4     7
     2     5     8
     3     6     9
```

Find the product of the elements in each row and reduce the length of the second dimension to 1.

```
dim = 2;
B = prod(A,dim)
```

```
B =

    28
    80
   162
```

The length of the first dimension matches `size(A,1)`, and the length of the second dimension is 1.

Product of Elements in Each Plane

Create a 3-by-3-by-2 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9];
A(:,:,2)=[10:3:16;11:3:17;12:3:18]
```

```
A(:,:,1) =

     1     4     7
     2     5     8
     3     6     9

A(:,:,2) =
```

```
    10    13    16
    11    14    17
    12    15    18
```

Find the product of each element in the first plane with its corresponding element in the second plane.

```
dim = 3;
B = prod(A,dim)
```

```
B =

    10    52   112
    22    70   136
    36    90   162
```

The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is `1`.

Single-Precision Input Treated as Double

Create a 3-by-3 array of single-precision values.

```
A = single([1200 1500 1800; 1300 1600 1900; 1400 1700 2000])
```

```
A =

        1200        1500        1800
        1300        1600        1900
        1400        1700        2000
```

Find the product of the elements in each row by multiplying in double precision.

```
B = prod(A,2,'double')
```

```
B =

   1.0e+09 *

    3.2400
    3.9520
    4.7600
```

The output is double precision.

```
class(B)
```

```
ans =

double
```

Integer Data Type for Input and Output

Create a 3-by-3 array of 8-bit unsigned integers.

```
A = uint8([1:3:7;2:3:8;3:3:9])
```

```
A =

    1    4    7
    2    5    8
    3    6    9
```

Find the product of the elements in each column natively in `uint8`.

```
B = prod(A,'native')
```

```
B =

    6  120  255
```

The result is an array of 8-bit unsigned integers.

```
class(B)
```

```
ans =

uint8
```

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

`dim` — Dimension to operate along

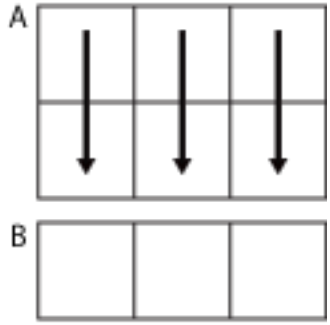
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(B,dim)` is `1`, while the sizes of all other dimensions remain the same.

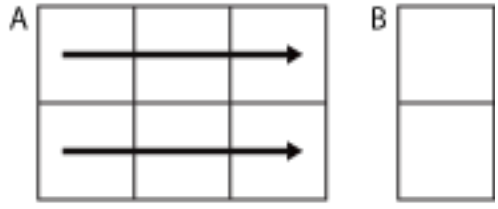
Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `prod(A,1)` returns a row vector containing the product of the elements in each column.



prod(A,1)

- If `dim = 2`, then `prod(A,2)` returns a column vector containing the product of the elements in each row.



prod(A,2)

`prod` returns `A` when `dim` is greater than `ndims(A)`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`type` — Output class

`'default'` (default) | `'double'` | `'native'`

Output class, specified as `'default'`, `'double'`, or `'native'`, and which defines the data type of the output, `B`.

`type`	Output data type
`'default'`	`double`, unless the input data type is `single`. In which case, the output data type is `single`.
`'double'`	`double`
`'native'`	same data type as the input array, `A`

Data Types: `char`

Output Arguments

`B` — Product array

scalar | vector | matrix | multidimensional array

Product array, returned as a scalar, vector, matrix, or multidimensional array.

The class of `B` is as follows:

- If the `type` argument specifies `'default'` or is not used
  - and the input is not `single`, then the output is `double`.
  - and the input is `single`, then the output is `single`.
- If the `type` argument specifies `'double'`, then the output is `double` regardless of the input data type.
- If the `type` argument specifies `'native'`, then the output is the same data type as the input.

More About

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to `1`.

For example:

- If `X` is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of `X`.

Introduced before R2006a

profile

Profile execution time for function

Syntax

```
profile on
profile -history
profile -nohistory
profile -history -historysize integer
profile -timer clock
profile -history -historysize integer -timer clock
profile off
profile resume
profile clear
profile viewer
S = profile('status')
stats = profile('info')
```

Description

The `profile` function helps you debug and optimize MATLAB code files by tracking their execution time. For each MATLAB function, MATLAB local function, or MEX-function in the file, `profile` records information about execution time, number of calls, parent functions, child functions, code line hit count, and code line execution time. Some people use `profile` simply to see the child functions; see also `matlab.codetools.requiredFilesAndProducts` for that purpose. To open the Profiler graphical user interface, use the `profile viewer` syntax. By default, Profiler time is CPU time. The total time reported by the Profiler is not the same as the time reported using the `tic` and `toc` functions or the time you would observe using a stopwatch.

Note: If your system uses Intel multi-core chips, you may want to restrict the active number of CPUs to 1 for the most accurate and efficient profiling. See "Multi-Core Processors — Setting for Most Accurate Profiling on Windows Systems" or "Multi-Core

Processors — Setting for Most Accurate Profiling on Linux Systems" for details on how to do this.

`profile on` starts the Profiler, clearing previously recorded profile statistics. Note the following:

- You can specify all, none, or a subset, of the `–history`, `–historysize` and `–timer` options with the `profile on` syntax.
- You can specify options in any order, including before or after `on`.
- If the Profiler is currently on and you specify `profile` with one of the options, MATLAB software returns an error message and the option has no effect. For example, if you specify `profile –timer real`, MATLAB returns the following error: `The profiler has already been started. TIMER cannot be changed.`
- To change options, first specify `profile off`, and then specify `profile on` or `profile resume` with new options.

`profile -history` records the exact sequence of function calls. The `profile` function records, by default, up to 1,000,000 function entry and exit events. For more than 1,000,000 events, `profile` continues to record other profile statistics, but not the sequence of calls. To change the number of function entry and exit events that the `profile` function records, use the `–historysize` option. By default, the `history` option is not enabled.

`profile -nohistory` disables further recording of the history (exact sequence of function calls). Use the `-nohistory` option after having previously set the `-history` option. All other profiling statistics continue to be collected.

`profile -history -historysize` *`integer`* specifies the number of function entry and exit events to record. By default, `historysize` is set to 1,000,000.

`profile -timer` *`clock`* specifies the type of time to use. Valid values for *`clock`* are:

- `'cpu'` — The Profiler uses computer time (the default).
- `'real'` — The Profiler uses wall-clock time.

For example, `cpu` time for the `pause` function is typically small, but `real` time accounts for the actual time paused, and therefore would be larger.

`profile -history -historysize integer -timer clock` specifies all of the options. Any order is acceptable, as is a subset.

`profile off` stops the Profiler.

`profile resume` restarts the Profiler without clearing previously recorded statistics.

`profile clear` clears the statistics recorded by `profile`.

`profile viewer` stops the Profiler and displays the results in the Profiler window. For more information, see Profiling for Improving Performance in the Desktop Tools and Development Environment documentation.

`S = profile('status')` returns a structure containing information about the current status of the Profiler. The table lists the fields in the order that they appear in the structure.

Field	Values	Default Value
`ProfilerStatus`	`'on'` or `'off'`	off
`DetailLevel`	`'mmex'`	'mmex'
`Timer`	`'cpu'` or `'real'`	'cpu'
`HistoryTracking`	`'on'` or `'off'`	'off'
`HistorySize`	integer	1000000

`stats = profile('info')` stops the Profiler and displays a structure containing the results. Use this function to access the data generated by `profile`. The table lists the fields in the order that they appear in the structure.

Field	Description
`FunctionTable`	Structure array containing statistics about each function called
`FunctionHistory`	Array containing function call history
`ClockPrecision`	Precision of the `profile` function's time measurement
`ClockSpeed`	Estimated clock speed of the CPU
`Name`	Name of the profiler

The `FunctionTable` field is an array of structures, where each structure contains information about one of the functions or local functions called during execution. The following table lists these fields in the order that they appear in the structure.

Field	Description
`CompleteName`	Full path to `FunctionName`, including local functions
`FunctionName`	Function name; includes local functions
`FileName`	Full path to `FunctionName`, with file extension, excluding local functions
`Type`	MATLAB functions, MEX-functions, and many other types of functions including MATLAB local functions, nested functions, and anonymous functions
`NumCalls`	Number of times the function was called
`TotalTime`	Total time spent in the function and its child functions
`TotalRecursiveTime`	No longer used.
`Children`	`FunctionTable` indices to child functions
`Parents`	`FunctionTable` indices to parent functions
`ExecutedLines`	Array containing line-by-line details for the function being profiled. Column 1: Number of the line that executed. If a line was not executed, it does not appear in this matrix. Column 2: Number of times the line was executed Column 3: Total time spent on that line. Note: The sum of Column 3 entries does not necessarily add up to the function's `TotalTime`.
`IsRecursive`	`BOOLEAN` value: Logical `1` (true) if recursive, otherwise logical `0` (false)
`PartialData`	`BOOLEAN` value: Logical `1` (true) if function was modified during profiling, for example by being edited or cleared. In that event, data was collected only up until the point when the function was modified.

Examples

Profile, View Results, and Save Profile Data as HTML

This example profiles the MATLAB `magic` command and then displays the results in the Profiler window. The example then retrieves the profile data on which the HTML display is based and uses the `profsave` command to save the profile data in HTML form.

```
profile on
plot(magic(35))
profile viewer
p = profile('info');
profsave(p,'profile_results')
```

Profile, Save Profile Data to a MAT-File, and View Results

Another way to save profile data is to store it in a MAT-file. This example stores the profile data in a MAT-file, clears the profile data from memory, and then loads the profile data from the MAT-file. This example also shows a way to bring the reloaded profile data into the Profiler graphical interface as live profile data, not as a static HTML page.

```
p = profile('info');
save myprofiledata p
clear p
load myprofiledata
profview(0,p)
```

Profile and Show Results Including History

This example illustrates an effective way to view the results of profiling when the `history` option is enabled. The history data describes the sequence of functions entered and exited during execution. The `profile` command returns history data in the `FunctionHistory` field of the structure it returns. The history data is a 2-by-`n` array. The first row contains Boolean values, where `0` means entrance into a function and `1` means exit from a function. The second row identifies the function being entered or exited by its index in the `FunctionTable` field. This example reads the history data and displays it in the MATLAB Command Window.

```
profile on -history
plot(magic(4));
p = profile('info');
```

```
for n = 1:size(p.FunctionHistory,2)
 if p.FunctionHistory(1,n)==0
        str = 'entering function: ';
 else
        str = 'exiting function: ';
 end
 disp([str p.FunctionTable(p.FunctionHistory(2,n)).FunctionName])
end
```

`matlab.codetools.requiredFilesAndProducts` | `mlint` | `profsave`

Introduced before R2006a

profsave

Save profile report in HTML format

Syntax

```
profsave
profsave(profinfo)
profsave(profinfo,dirname)
```

Description

`profsave` executes the `profile('info')` function and saves the results in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of the structure returned by `profile`. By default, `profsave` stores the HTML files in a subfolder of the current folder named `profile_results`.

`profsave(profinfo)` saves the profiling results, `profinfo`, in HTML format. `profinfo` is a structure of profiling information returned by the `profile('info')` function.

`profsave(profinfo,dirname)` saves the profiling results, `profinfo`, in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of `profinfo` and stores them in the folder specified by `dirname`.

Examples

Run `profile` and save the results.

```
profile on
plot(magic(5))
profile off
profsave(profile('info'),'myprofile_results')
```

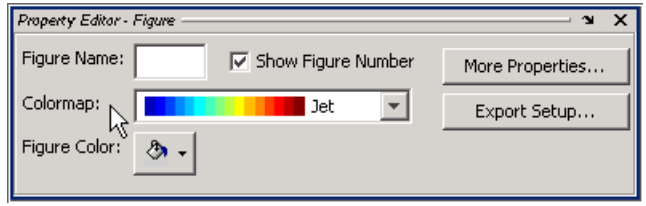
`profile`

Introduced before R2006a

propedit

Open Property Editor



Syntax

```
propedit
propedit(handle_list)
```

Description

`propedit` starts the Property Editor, a graphical user interface to the properties of graphics objects. If no current figure exists, `propedit` will create one.

`propedit(handle_list)` edits the properties for the object (or objects) in `handle_list`.

Starting the Property Editor enables plot editing mode for the figure.

See Also

`inspect` | `plotedit` | `propertyeditor`

Introduced before R2006a

propedit (COM)

Open built-in property page for control

Syntax

```
propedit(h)
```

Description

`propedit(h)` requests the control to display its built-in property page. Note that some controls do not have a built-in property page. For those controls, this command fails.

COM functions are available on Microsoft Windows systems only.

See Also

`get (COM)` | `inspect`

Introduced before R2006a

properties

Class property names

Syntax

```
properties('classname')
properties(obj)
p = properties(...)
```

Description

`properties('classname')` displays the names of the public properties for the MATLAB class named by `classname`. The `properties` function also displays inherited properties.

`properties(obj)` `obj` can be either a scalar object or an array of objects. When `obj` is scalar, `properties` also returns dynamic properties. See “Dynamic Properties — Adding Properties to an Instance” for information on using dynamic properties.

`p = properties(...)` returns the property names in a cell array of strings.

Definitions

A property is public when its `GetAccess` attribute value is `public` and its `Hidden` attribute value is `false` (default values for these attributes). See “Property Attributes” for a complete list of attributes.

`properties` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

Examples

Retrieve the names of the public properties of class `memmapfile` and store the result in a cell array of strings:

```
p = properties('memmapfile');
p
ans =

    'writable'
    'offset'
    'format'
    'repeat'
    'filename'
```

Construct an instance of the `MException` class and get its properties names:

```
me = MException('Msg:ID','MsgText');
properties(me)
Properties for class MException:

    identifier
    message
    cause
    stack
```

See Also

`fieldnames` | `events` | `methods`

propertyeditor

Show or hide **Property Editor**

Syntax

```
propertyeditor('on')
propertyeditor('off')
propertyeditor
propertyeditor(figure_handle,...)
```

Description

`propertyeditor('on')` displays the Property Editor tool on the current figure.

`propertyeditor('off')` hides the Property Editor on the current figure.

`propertyeditor` toggles the visibility of the Property Editor on the current figure. You can also use `propertyeditor('toggle')`instead for the same functionality.

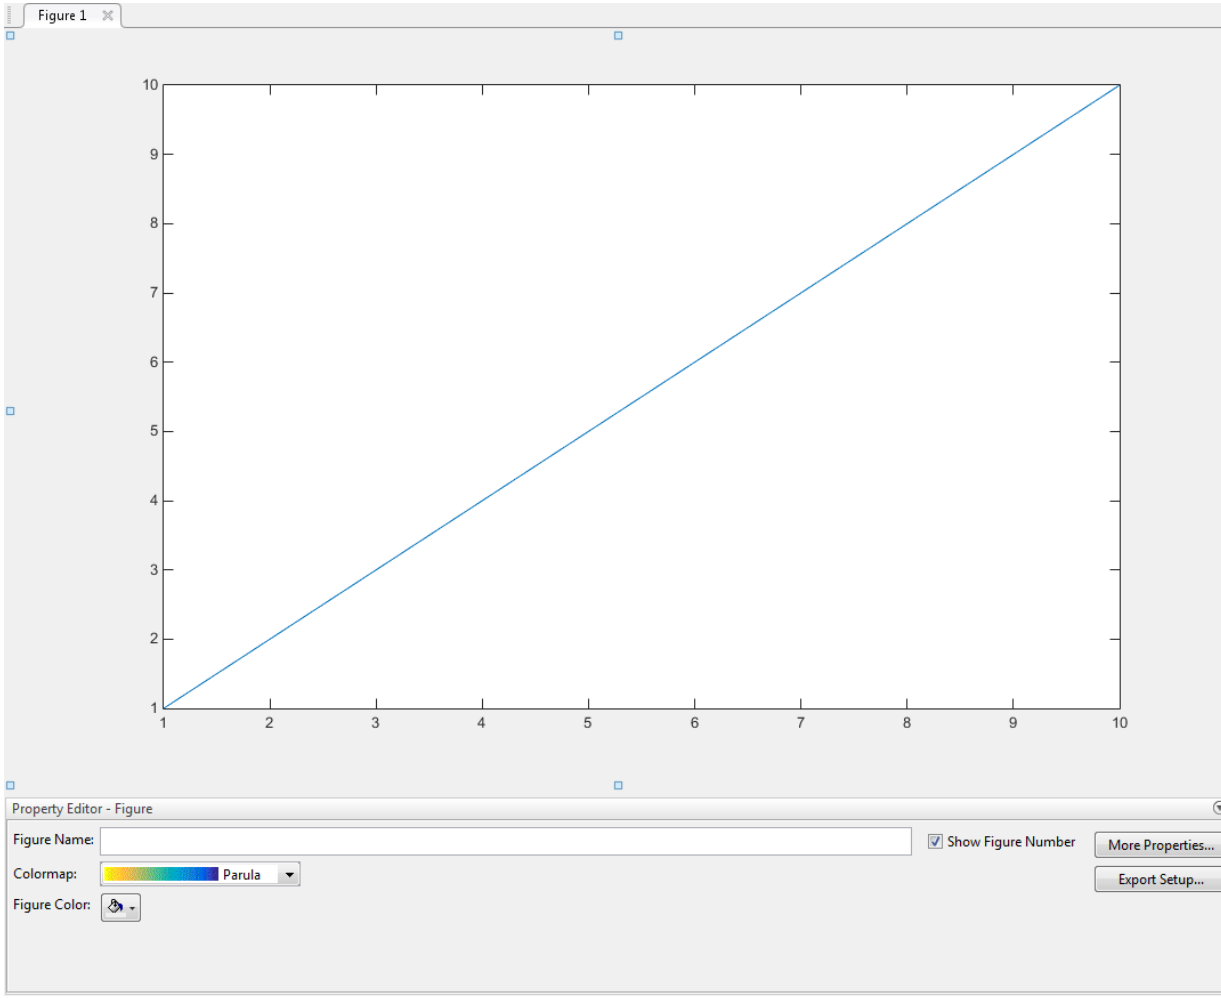
`propertyeditor(figure_handle,...)` displays or hides the Property Editor on the figure specified by `figure_handle`.

Examples

Open Property Editor

Create a simple plot and open the property editor.

```
plot(1:10)
propertyeditor
```



Alternatives

To collectively enable Plotting Tools, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the Plotting Tools, use the smaller icon  . Open or close

the **Property Editor** tool from the figure's **View** menu. For details, see “Customize Objects in Graph”.

More About

Tips

If you call `propertyeditor` in a MATLAB program and subsequent lines depend on the Property Editor being fully initialized, follow it by `drawnow` to ensure complete initialization.

matlab.mixin.util.PropertyGroup class

Package: matlab.mixin.util

Custom property list for object display

Description

Use the `PropertyGroup` class to create custom property display lists for class derived from `matlab.mixin.CustomDisplay`.

Construction

`P = matlab.mixin.util.PropertyGroup(propertyList)` constructs a property group with the supplied propertyList.

`P = matlab.mixin.util.PropertyGroup(propertyList,title)` displays title above the list of properties.

Input Arguments

`propertyList`

The propertyList is either a cell array of property names, or a scalar `struct` with property name-value pairs.

`title`

Text to display above properties.

Properties

`NumProperties`

The number of properties in the `PropertyList`.

Attributes:

Dependent	true
GetAccess	public
GetObservable	true
SetAccess	private
Transient	true

PropertyList

The list of properties to display, stored as a scalar struct or a cell array of strings.

Attributes:

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

Title

An optional Title for the PropertyGroup.

Attributes:

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Introduced in R2013b

psi

Psi (polygamma) function

Syntax

```
Y = psi(X)
Y = psi(k,X)
```

Description

`Y = psi(X)` evaluates the ψ function for each element of array `X`. `X` must be real and nonnegative. The ψ function, also known as the digamma function, is the logarithmic derivative of the gamma function

$$\begin{aligned}\psi(x) &= \text{digamma}(x) \\ &= \frac{d(\log(\Gamma(x)))}{dx} \\ &= \frac{d(\Gamma(x))/dx}{\Gamma(x)}\end{aligned}$$

`Y = psi(k,X)` evaluates the `k`th derivative of ψ at the elements of `X`. `psi(0,X)` is the digamma function, `psi(1,X)` is the trigamma function, `psi(2,X)` is the tetragamma function, etc.

Examples

Example 1

Use the `psi` function to calculate Euler's constant, γ.

```
format long
-psi(1)
ans =
   0.57721566490153
```

```
-psi(0,1)
ans =
   0.57721566490153
```

Example 2

The trigamma function of 2, `psi(1,2)`, is the same as $(\pi^2/6) - 1$.

```
format long
psi(1,2)
ans =
   0.64493406684823

pi^2/6 - 1
ans =
   0.64493406684823
```

`gamma` | `gammainc` | `gammaln`

Introduced before R2006a

publish

Generate view of MATLAB file in specified format

Syntax

```
publish(file)
publish(file,format)

publish(file,Name,Value)
publish(file,options)

my_doc = publish(file, ___ )
```

Description

`publish(file)` generates a view of a MATLAB file in HTML format for sharing your code. For example, `publish('myfile.m')` executes the code in `myfile.m` using the base workspace and saves the formatted code and results in `/html/myfile.html`. The `html` subfolder is relative to the `file` folder.

When MATLAB publishes a file, it can delete existing files from the output folder that start with the same name as `file`.

`publish(file,format)` generates a view of a MATLAB file in the specified file format. The resulting files save to the `html` subfolder for all file formats.

`publish(file,Name,Value)` generates a view of the MATLAB file, `file`, with options specified by one or more name-value pair arguments.

`publish(file,options)` uses the options structure to customize the output, which is useful when you want to preconfigure and save your options for repeated use. The options structure fields and values correspond to names and values of name-value pair arguments, respectively.

`my_doc = publish(file, ___ )` generates a view of the MATLAB file `file`, and returns a string indicating the path of the resulting output file. It can include any of the input arguments in previous syntaxes.

Examples

Generate HTML View of MATLAB Script

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file, `fourier_demo2.m`, to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Generate an HTML view of the MATLAB file.

```
 publish('fourier_demo2.m');
```

The `publish` command executes the code for each cell in `fourier_demo2.m`, and saves the file to `/html/fourier_demo2.html`.

View the HTML file.

```
web('html/fourier_demo2.html')
```

Generate View of MATLAB Script in Microsoft Word Format

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the file in Microsoft Word format.

```
publish('fourier_demo2.m','doc');
```

View the published output.

```
winopen('html/fourier_demo2.doc')
```

Publish MATLAB Script Using Name-Value Pairs to Customize Output

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script. Use name-value pair arguments to include window decorations in the published output.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the example MATLAB file to HTML format.

```
publish('fourier_demo2.m', 'figureSnapMethod', 'entireFigureWindow')
```

The `'figureSnapMethod','entireFigureWindow'` name-value pair argument specifies to include the window decorations in the figures, and to match the figure background color to the screen color.

View the published output.

```
web('html/fourier_demo2.html')
```

Customize `publish` Output Using Options Structure

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use a structure to customize the published output.

Specifying options as a structure is useful when you want to preconfigure and save your options for repeated use.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Define options to customize the published output as a structure, `options_doc_nocode`.

```
options_doc_nocode.format = 'doc';
options_doc_nocode.showCode = false;
```

Publish the file, specifying the options structure.

```
publish('fourier_demo2.m',options_doc_nocode);
```

Save File Path of Published Script to Variable

Generate an HTML view of a MATLAB script, and save the path of the published HTML file to a variable.

This example assumes that the current folder is `C:\my_MATLAB_files`.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the MATLAB file, and save the path of the resulting published HTML file to an output variable.

```
mydoc = publish('fourier_demo2.m')
```

```
mydoc =

C:\my_MATLAB_files\html\fourier_demo2.html
```

Input Arguments

`file` — MATLAB file

string

Full or partial path of the MATLAB file for which you want to generate a presentation view, specified as a string.

Example: `'myfile.m'`

`format` — Output format of published file

`'html'` (default) | `'doc'` | `'latex'` | `'ppt'` | `'xml'` | `'pdf'`

Output format of published MATLAB file, specified as one of the following string values.

Output Format	String Value
Hypertext Markup Language	`'html'` (default)
Microsoft Word	`'doc'`
LaTeX	`'latex'`
Microsoft PowerPoint	`'ppt'`
Extensible Markup Language	`'xml'`
Portable Document Format	`'pdf'`

Example: `publish('myfile.m','ppt');`

`options` — Options for published output

MATLAB structure

Options for published output, specified as a structure. Use the options structure instead of name-value pair arguments when you want to reuse the same configuration for publishing multiple MATLAB code files.

The options structure field and values correspond to names and values of the name-value pair arguments, respectively.

For example, to specify the PDF output format and the output folder `C:\myPublishedOutput`, use:

```
options = struct('format','pdf','outputDir','C:\myPublishedOutput')
```

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'format','latex','showCode',false` specifies LaTeX output file format and excludes the code from the output.

Output Options

`'format'` — Published output file format

`'html'` (default) | `'doc'` | `'latex'` | `'ppt'` | `'xml'` | `'pdf'`

Published output file format, specified as the comma-separated pair consisting of `'format'` and one of the following string values.

Output Format	String Value
Hypertext Markup Language	`'html'` (default)
Microsoft Word	`'doc'`
LaTeX	`'latex'`

Output Format	String Value
Microsoft PowerPoint	`'ppt'`
Extensible Markup Language	`'xml'`
Portable Document Format	`'pdf'`

`'outputDir'` — Output folder

`''` (default) | full path

Output folder to which the published document is saved, specified as the comma-separated pair consisting of `'outputDir'` and the full path. You must specify the full path as a string, for example `'C:\myPublishedOutput'`.

The default value, `''`, specifies the `html` subfolder of the current folder.

`'stylesheet'` — Extensible Stylesheet language (XSL) file

`''` (default) | full path to XSL file name

Extensible Stylesheet Language (XSL) file to use when publishing MATLAB code to HTML, XML, or LaTeX format, specified as the comma-separated pair consisting of `'stylesheet'` and the full path to the XSL file. The full path must be a string, for example, `'C:\myStylesheet\stylesheet.xsl'`

The default value, `''`, specifies the MATLAB default style sheet.

Figure Options

`'createThumbnail'` — Thumbnail image creation

`true` (default) | `false`

Thumbnail image creation for the published document, specified as the comma-separated pair consisting of `'createThumbnail'` and either `true` or `false`. You can use this thumbnail to represent your file in HTML pages.

`'figureSnapMethod'` — Published figure window appearance

`'entireGUIWindow'` (default) | `'print'` | `'getframe'` | `'entireFigureWindow'`

Appearance of published figure windows, including window decorations and background color, specified as the comma-separated pair consisting of `'figureSnapMethod'` and one of the following string values.

String Value	Window Decorations		Background Color	
	GUIs	Figures	GUIs	Figures
'entireGUIWindow' (default)	Included	Excluded	Matches screen	White
'print'	Excluded	Excluded	White	White
'getframe'	Excluded	Excluded	Matches screen	Matches screen
'entireFigureWindow'	Included	Included	Matches screen	Matches screen

'imageFormat' — Published image file format

'png' | 'epsc2' | 'jpg' | ...

Published image file format, specified as the comma-separated pair consisting of 'imageFormat' and one of the following string values.

'format' Value	Valid 'imageFormat' Value	Default 'imageFormat' Value
'doc'	Any image format that your installed version of Microsoft Office can import, including 'png' , 'jpg', 'bmp', and 'tiff'. If the 'figureSnapMethod' is 'print', then you can also specify 'eps', 'epsc', 'eps2', 'ill', 'meta', and 'pdf'.	'png'
'html'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'
'latex'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'epsc2', except when 'figureSnapMethod' is any one of the following: • 'getframe' • 'entireFigureWindow'

		• `'entireGUIWindow'` and the snapped window is a GUI window In these cases the default is `'png'`
`'pdf'`	`'bmp'` or `'jpg'`.	`'bmp'`
`'ppt'`	Any format that your installed version of Microsoft Office can import, including `'png'`, `'jpg'`, `'bmp'`, and `'tiff'`.	`'png'`
`'xml'`	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	`'png'`

`'maxHeight'` — Maximum height of published images

`[]` (default) | positive integer value

Maximum height of published images that the code generates, specified as the comma-separated pair consisting of `'maxHeight'` and one of the following values:

- `[]` (default)—Unrestricted height. This value is always used when the `'format'` value is `'pdf'`.
- Positive integer value that specifies the image height in pixels.

`'maxWidth'` — Maximum width of published images

`''` (default) | positive integer value

Maximum width of an image that the code generates, specified as the comma-separated pair consisting of `'maxWidth'` and one of the following values:

- `[]` (default)—Unrestricted width. This value is always used when the `'format'` value is `'pdf'`.
- Positive integer value that specifies the image width in pixels.

`'useNewFigure'` — Create new figure

`true` (default) | `false`

A logical value that determines if MATLAB creates a new Figure window for figures that the code generates, specified as the comma-separated pair consisting of `'useNewFigure'` and one of the following:

- `true` (default)—If the code generates a figure, then MATLAB creates a Figure window with a white background, and at the default size before publishing.
- `false`—MATLAB does not create a figure window.

  This value enables you to use a figure with different properties for publishing. For example, open a Figure window, change the size and background color, and then publish your code. Figures in your published document use the characteristics of the figure you opened before publishing.

Code Options

`'evalCode'` — Option to run code

`true` (default) | `false`

Option to evaluate code and include the MATLAB output in the published view, specified as a logical value.

`'catchError'` — Error handling during publishing

`true` (default) | `false`

Error handling during publishing, specified as the comma-separated pair consisting of `'catchError'` and one of the following logical values:

- `true` (default)—MATLAB continues publishing and includes the error in the published file.
- `false`—MATLAB displays the error at the command line and does not produce a published file.

`'codeToEvaluate'` — Additional code to evaluate during publishing

string

Additional code to evaluate during publishing, specified as the comma-separated pair consisting of `'codeToEvaluate'` and the string with the corresponding code. Use this option to specify code that does not appear in the MATLAB file, for example to set the value of an input argument for a function being published.

If this option is unspecified, MATLAB evaluates only the code in the MATLAB file you are publishing.

`'maxOutputLines'` — Maximum number of lines

`Inf` (default) | nonnegative integer value

Maximum number of lines in MATLAB output per cell evaluated during publishing, specified as the comma-separated pair consisting of `'maxOutputLines'` and one of the following values:

- `Inf` (default)—MATLAB includes all output lines in the published output.
- Nonnegative integer—MATLAB truncates the number of lines in the output at the number of lines you specify.

`'showCode'` — Option to include code in published file

`true` (default) | `false`

Option to include code in published file, specified as the comma-separated pair consisting of `'showCode'` and a logical value.

More About

Window Decorations

Window decorations include window title bar, toolbar, menu bar, and window border.

Syntax Highlighting

Syntax highlighting colors various elements in code to help you identify these elements while reading or editing code. By default, keywords are blue, strings are purple, and unterminated strings are maroon.

MATLAB does not preserve syntax highlighting when you set `'format'` to `'latex'` or `'ppt'`.

Tips

- If `'format` is `'html'`, MATLAB includes the code being published at the end of the published HTML file as comments, even when you set the `'showCode'` option to `false`. Because MATLAB includes the code as comments, this code does not display

in a Web browser. This enables you to use the `grabcode` function to extract the MATLAB code from an HTML file, even when the file does not display the code.

- "Publishing MATLAB Code"
- "Publishing Markup"

Introduced before R2006a

PutCharArray

Store character array in Automation server

Syntax

IDL Method Signature

```
PutCharArray([in] BSTR varname, [in] BSTR workspace,
    [in] BSTR string)
```

Microsoft Visual Basic Client

```
PutCharArray(varname As String, workspace As String,
    string As String)
```

MATLAB Client

```
PutCharArray(h,'varname','workspace','string')
```

Description

`PutCharArray(h,'varname','workspace','string')` stores the character array in `string` in the specified `workspace` of the server attached to handle `h`, assigning to it the variable `varname`. The values for *`workspace`* are `base` or `global`. The function name is case-sensitive.

Examples

Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab As Object
```

```
Try
    Matlab = GetObject(, "matlab.application")
Catch e As Exception
    Matlab = CreateObject("matlab.application")
End Try
MsgBox("MATLAB window created; now open it...")
```

Open the MATLAB window, then click **Ok**.

```
Matlab.PutCharArray("str", "base", _
       "He jests at scars that never felt a wound.")
MsgBox("In MATLAB, type" & vbCrLf _
  & "str")
```

In the MATLAB window type `str`; MATLAB displays:

```
str =
He jests at scars that never felt a wound.
```

Click **Ok**.

```
MsgBox("closing MATLAB window...")
```

Click **Ok** to close and terminate MATLAB.

```
Matlab.Quit()
```

More About

Tips

The character array specified in the `string` argument can have any dimensions. However, `PutCharArray` changes the dimensions to a 1–by-n column-wise representation, where n is the number of characters in the array. Executing the following commands in MATLAB illustrates this behavior:

```
h = actxserver('matlab.application');
chArr = ['abc'; 'def'; 'ghk']
chArr =
abc
def
ghk
```

```
PutCharArray(h,'Foo','base',chArr)
tstArr = GetCharArray(h,'Foo','base')
tstArr =
adgbehcfk
```

See Also

GetCharArray | PutWorkspaceData | GetWorkspaceData | Execute

Introduced before R2006a

PutFullMatrix

Matrix in Automation server workspace

Syntax

IDL Method Signature

```
PutFullMatrix([in] BSTR varname, [in] BSTR workspace,
[in] SAFEARRAY(double) xreal, [in] SAFEARRAY(double) ximag)
```

Microsoft Visual Basic Client

```
PutFullMatrix([in] varname As String, [in] workspace As String,
[in] xreal As Double, [in] ximag As Double)
```

MATLAB Client

```
PutFullMatrix(h,'varname','workspace',xreal,ximag)
```

Description

`PutFullMatrix(h,'varname','workspace',xreal,ximag)` stores a matrix in the specified *`workspace`* of the server attached to handle `h` and assigns it to variable `varname`. Use `xreal` and `ximag` for the real and imaginary parts of the matrix. The matrix cannot be a scalar, an empty array, or have more than two dimensions. The values for *`workspace`* are `base` or `global`.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the `variant` data type instead of `safearray`, which VBScript does not support.

Examples

This example uses a Visual Basic .NET client to write a matrix to the base workspace of the server:

```
Dim MatLab As Object
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim ZReal(4, 4) As Double
Dim ZImag(4, 4) As Double
Dim i, j As Integer

For i = 0 To 4
   For j = 0 To 4
   XReal(i, j) = Rnd() * 6
   XImag(i, j) = 0
   Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("M","base",XReal,XImag)
MatLab.GetFullMatrix("M","base",ZReal,ZImag)
```

Use a Visual Basic .NET client to write a matrix to the global workspace of the server:

```
Dim MatLab As Object
Dim XReal(1,2) As Double
Dim XImag(1,2) As Double
Dim result As String
Dim i,j As Integer

For i = 0 To 1
 For j = 0 To 2
  XReal(i,j) = (j * 2 + 1) + i
  XImag(i,j) = 1
 Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("X","global",XReal,XImag)
result = Matlab.Execute("whos global")
MsgBox(result)
```

Introduced before R2006a

PutWorkspaceData

Data in Automation server workspace

Syntax

IDL Method Signature

```
PutWorkspaceData([in] BSTR varname, [in] BSTR workspace,
[in] VARIANT data)
```

Microsoft Visual Basic Client

```
PutWorkspaceData(varname As String, workspace As String,
data As Object)
```

MATLAB Client

```
PutWorkspaceData(h,'varname','workspace',data)
```

Description

`PutWorkspaceData(h,'varname','workspace',data)` stores `data` in the *`workspace`* of the server attached to handle `h` and assigns it to `varname`. The values for *`workspace`* are `base` or `global`.

Use `PutWorkspaceData` to pass numeric and character array data respectively to the server. Do *not* use `PutWorkspaceData` on sparse arrays, structures, or function handles. Use the `Execute` method for these data types.

The `GetWorkspaceData` and `PutWorkspaceData` functions pass numeric data as a `variant` data type. These functions are especially useful for VBScript clients as VBScript does not support the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`.

Examples

Create an array in a Visual Basic .NET client and put it in the base workspace of the MATLAB Automation server:

1. Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application:

```
Dim Matlab As Object
Dim data(6) As Double
Dim i As Integer
MatLab = CreateObject("matlab.application")
For i = 0 To 6
   data(i)  = i * 15
Next i
MatLab.PutWorkspaceData("A","base",data)
MsgBox("In MATLAB, type" & vbCrLf & "A")
```

2. Open the MATLAB window and type `A`. MATLAB displays:

```
A =
     0    15    30    45    60    75    90
```

3. Click **Ok** to close and terminate MATLAB.

See Also

`GetWorkspaceData` | `PutFullMatrix` | `PutCharArray` | `Execute`

Introduced before R2006a

pwd

Identify current folder

Syntax

```
pwd
currentFolder = pwd
```

Description

`pwd` displays the MATLAB current folder.

`currentFolder = pwd` returns the current folder as a string to `currentFolder`.

Alternatives

- Use the Current Folder toolbar.

See Also

`cd` | `dir`

Introduced before R2006a

pyargs

Create keyword argument for Python function

Syntax

```
kwa = pyargs(argKey,argValue)
```

Description

`kwa = pyargs(argKey,argValue)` creates a `pyargs` keyword argument to pass to a Python function.

Examples

Use Keyword Argument to Modify the Display of Calendar Month

Create a calendar.

```
cal = py.calendar.TextCalendar;
```

Display calendar for December, 2014.

```
formatmonth(cal,int32(2014),int32(12))
```

```
ans =

  Python str with no properties.

       December 2014
Mo Tu We Th Fr Sa Su
 1  2  3  4  5  6  7
 8  9 10 11 12 13 14
15 16 17 18 19 20 21
22 23 24 25 26 27 28
29 30 31
```

Read the function signature from the Python documentation for the `calendar.TextCalendar.formatmonth` function.

```
py.help('calendar.TextCalendar.formatmonth')
```

```
Help on method formatmonth in calendar.TextCalendar:

calendar.TextCalendar.formatmonth = formatmonth(self, theyear, themonth, w=0, l=0) unbo
    Return a month's calendar string (multi-line).
```

Arguments `w` and `l` are optional, with default values of `0`.

Read the function signature in MATLAB.

```
methods(cal,'-full')
```

```
lhs formatmonth(self, theyear, themonth, w, l, pyargs)
```

Search the output for the `formatmonth` function signature. You can use the `pyargs` argument instead of the optional `w` and `l` arguments.

Change the line spacing, `l`, using a `pyargs` argument.

```
formatmonth(cal,int32(2014),int32(12),pyargs('l',int32(2)))
```

```
ans =

  Python str with no properties.

       December 2014

Mo Tu We Th Fr Sa Su

 1  2  3  4  5  6  7

 8  9 10 11 12 13 14

15 16 17 18 19 20 21

22 23 24 25 26 27 28

29 30 31
```

Input Arguments

`argKey,argValue` — Python function arguments

keyword and value arguments

Python function keyword arguments specified as one or more comma-separated pairs of argKey,argValue arguments. `argKey` is the Python function key name and is a string. `argValue` is the argument value, represented by any type. Use the function argument list to identify `argKey` and `argValue`. You can specify several key and value pair arguments in any order as `argKey1,argValue1,...,argKeyN,argValueN`.

Example: `'length',int32(2)`

Introduced in R2014b

matlab.exception.PyException class

Package: matlab.exception

Capture error information for Python exception

Description

Process information from a `matlab.exception.PyException` object to handle Python errors thrown from Python methods called from MATLAB. This class is derived from `MException`.

Construction

`e = matlab.exception.PyException(msgID,errMsg,excObj)` constructs instance e of `matlab.exception.PyException` class.

Input Arguments

`msgID` — Message identifier
string

Message identifier, specified as a string.

`errMsg` — Error message
string

Error message, specified as a string.

`excObj` — Exception object
`pythonclass`

Exception object, specified as the `pythonclass` that caused the exception.

Output Arguments

`e` — Exception object
exception object

Instance of `matlab.exception.PyException` class

Properties

`ExceptionObject` — Object

exception object

Python exception object that caused the error.

Tips

- Typically, you do not construct a `matlab.exception.PyException` object explicitly. MATLAB automatically constructs a `PyException` object whenever Python throws an exception. The `PyException` object wraps the original Python exception.

Examples

Catch Python Exception

Generate a Python exception and display information.

```
try
  py.list('x','y',1)
catch e
  e.message
  if(isa(e,''))
    e.ExceptionObject
  end
end
```

```
ans =

Python Error: list() takes at most 1 argument (3 given)
```

When MATLAB displays a message containing the text `Python Error`, refer to your Python documentation for more information.

Introduced in R2014b

pyversion

Change default version of Python interpreter

Syntax

```
pyversion
[version, executable, isloaded] = pyversion

___ = pyversion version
___ = pyversion executable
```

Description

`pyversion` displays details about the current Python version.

`[version, executable, isloaded] = pyversion` returns Python version information.

`___ = pyversion version` changes the default Python version on Microsoft Windows platforms. The setting is persistent across MATLAB sessions.

You cannot change the version after MATLAB loads Python. To change the version if Python is loaded already, restart MATLAB, and then call `pyversion`.

`___ = pyversion executable` specifies full path to Python executable. Use on any platform or for repackaged CPython implementation downloads.

Examples

Display Python Version

```
pyversion
```

```
       version: '2.7'
    executable: 'C:\Python27\python.exe'
       library: 'C:\windows\system32\python27.dll'
```

```
           home: 'C:\Python27'
      isloaded: 0
```

Use Python Version 2.7

```
[v, e, isloaded] = pyversion;
if isloaded
    disp('To change the Python version, restart MATLAB, then call pyversion.')
else
    pyversion 2.7
end
```

Input Arguments

`version` — Python version number

string

Python version number, specified as a string. Version must contain the major and minor version numbers separated by a period. Windows platform only.

`pyversion` looks for the version in the Windows registry. If you download from `www.python.org/downloads`, the installation automatically adds the version to the registry. If you download the Python application from a different source, either add it to the registry, or use the `pyversion(executable)` syntax to change the version.

Example: `3.3`

`executable` — Name of existing Python executable file

string

Name of an existing Python executable file, specified as a string. This argument must contain the name of the Python executable file and it can contain the full path.

Example: `C:\Python33\python.exe`

Output Arguments

`version` — Python version number

string

Python version number, specified as a string.

`executable` — Name of Python executable file

string

Name of Python executable file, specified as a string.

`isloaded` — Indicates if specified version is loaded

logical

Indicates if specified version is loaded, specified as logical. MATLAB loads Python when you type a `py.` command.

If MATLAB cannot load Python, isloaded is `0` and MATLAB displays “Undefined variable "py" or function "py.command"” when you type a `py.` command.

Limitations

- Do not use `pyversion` to set the version in a MATLAB function containing Python commands. MATLAB loads the Python interpreter when it processes a Python command in the function before it executes the `pyversion` function.

Introduced in R2014b

qmr

Quasi-minimal residual method

Syntax

```
x = qmr(A,b)
qmr(A,b,tol)
qmr(A,b,tol,maxit)
qmr(A,b,tol,maxit,M)
qmr(A,b,tol,maxit,M1,M2)
qmr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = qmr(A,b,...)
[x,flag,relres] = qmr(A,b,...)
[x,flag,relres,iter] = qmr(A,b,...)
[x,flag,relres,iter,resvec] = qmr(A,b,...)
```

Description

`x = qmr(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. You can specify `A` as a function handle, `afun`, such that `afun(x,'notransp')` returns `A*x` and `afun(x,'transp')` returns `A'*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `qmr` converges, a message to that effect is displayed. If `qmr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`qmr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `qmr` uses the default, `1e-6`.

`qmr(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `qmr` uses the default, `min(n,20)`.

`qmr(A,b,tol,maxit,M)` and `qmr(A,b,tol,maxit,M1,M2)` use preconditioners `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `qmr` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x,'notransp')` returns `M\x` and `mfun(x,'transp')` returns `M'\x`.

`qmr(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `qmr` uses the default, an all zero vector.

`[x,flag] = qmr(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`qmr` converged to the desired tolerance `tol` within `maxit` iterations.
1	`qmr` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	The method stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `qmr` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = qmr(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = qmr(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = qmr(A,b,...)` also returns a vector of the residual norms at each iteration, including `norm(b-A*x0)`.

Examples

Using qmr with a Matrix Input

This example shows how to use `qmr` with a matrix input. The code:

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8; maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = qmr(A,b,tol,maxit,M1,M2);
```

displays the message:

```
qmr converged at iteration 9 to a solution...
with relative residual
5.6e-009
```

Using qmr with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_qmr` that

- Calls `qmr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_qmr` are available to `afun`.

The following shows the code for `run_qmr`:

```
function x1 = run_qmr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = qmr(@afun,b,tol,maxit,M1,M2);

    function y = afun(x,transp_flag)
       if strcmp(transp_flag,'transp')      % y = A'*x
          y = 4 * x;
          y(1:n-1) = y(1:n-1) - 2 * x(2:n);
          y(2:n) = y(2:n) - x(1:n-1);
```

```
        elseif strcmp(transp_flag,'notransp') % y = A*x
           y = 4 * x;
           y(2:n) = y(2:n) - 2 * x(1:n-1);
           y(1:n-1) = y(1:n-1) - x(2:n);
        end
    end
end
```

When you enter

```
x1=run_qmr;
```

MATLAB software displays the message

```
qmr converged at iteration 9 to a solution with relative residual
5.6e-009
```

Using qmr with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

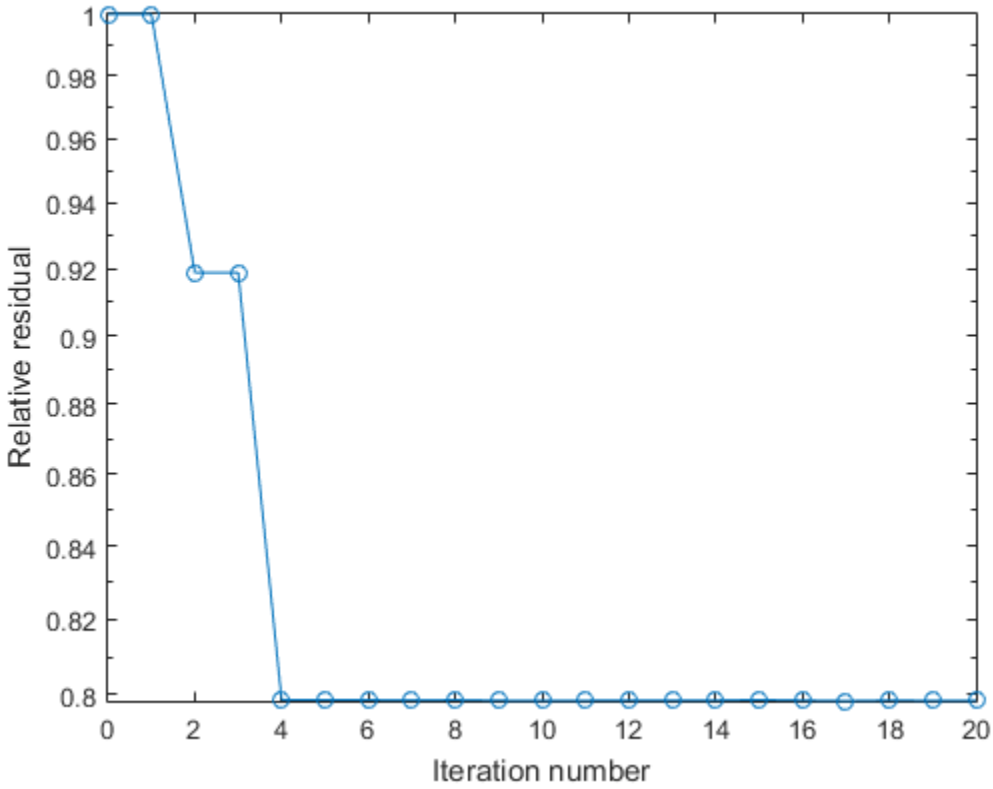
Use `qmr` to find a solution at the requested tolerance and number of iterations.

```
[x0,fl0,rr0,it0,rv0] = qmr(A,b,tol,maxit);
```

`fl0` is 1 because `qmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

Plot the behavior of `qmr`.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

```
Error using ilu
```

```
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = qmr(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `qmr` drives the relative residual to `4.1410e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

You can follow the progress of `qmr` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

Introduced before R2006a

qr

Orthogonal-triangular decomposition

Syntax

```
[Q,R] = qr(A)
[Q,R] = qr(A,0)
[Q,R,E] = qr(A)
[Q,R,E] = qr(A,'matrix')
[Q,R,e] = qr(A,'vector')
[Q,R,e] = qr(A,0)
X = qr(A)
X = qr(A,0)
R = qr(A)
R = qr(A,0)
[C,R] = qr(A,B)
[C,R,E] = qr(A,B)
[C,R,E] = qr(A,B,'matrix')
[C,R,e] = qr(A,B,'vector')
[C,R] = qr(A,B,0)
[C,R,e] = qr(A,B,0)
```

Description

`[Q,R] = qr(A)`, where `A` is `m`-by-`n`, produces an `m`-by-`n` upper triangular matrix `R` and an `m`-by-`m` unitary matrix `Q` so that `A = Q*R`.

`[Q,R] = qr(A,0)` produces the economy-size decomposition. If `m > n`, only the first `n` columns of `Q` and the first `n` rows of `R` are computed. If `m<=n`, this is the same as `[Q,R] = qr(A)`.

If A is full:

`[Q,R,E] = qr(A)` or `[Q,R,E] = qr(A,'matrix')` produces unitary `Q`, upper triangular `R` and a permutation matrix `E` so that `A*E = Q*R`. The column permutation `E` is chosen so that `abs(diag(R))` is decreasing.

`[Q,R,e] = qr(A,'vector')` returns the permutation information as a vector instead of a matrix. That is, `e` is a row vector such that `A(:,e) = Q*R`.

`[Q,R,e] = qr(A,0)` produces an economy-size decomposition in which `e` is a permutation vector, so that `A(:,e) = Q*R`.

`X = qr(A)` and `X = qr(A,0)` return a matrix `X` such that `triu(X)` is the upper triangular factor `R`.

If A is sparse:

`R = qr(A)` computes a `Q`-less `QR` decomposition and returns the upper triangular factor `R`. Note that `R = chol(A'*A)`. Since `Q` is often nearly full, this is preferred to `[Q,R] = QR(A)`.

`R = qr(A,0)` produces economy-size `R`. If `m>n`, `R` has only `n` rows. If `m<=n`, this is the same as `R = qr(A)`.

`[Q,R,E] = qr(A)` or `[Q,R,E] = qr(A,'matrix')` produces unitary `Q`, upper triangular `R` and a permutation matrix `E` so that `A*E = Q*R`. The column permutation `E` is chosen to reduce fill-in in R.

`[Q,R,e] = qr(A,'vector')` returns the permutation information as a vector instead of a matrix. That is, `e` is a row vector such that `A(:,e) = Q*R`.

`[Q,R,e] = qr(A,0)` produces an economy-size decomposition in which `e` is a permutation vector, so that `A(:,e) = Q*R`.

`[C,R] = qr(A,B)`, where `B` has as many rows as `A`, returns `C = Q'*B`. The least-squares solution to `A*X = B` is `X = R\C`.

`[C,R,E] = qr(A,B)` or `[C,R,E] = qr(A,B,'matrix')`, also returns a fill-reducing ordering. The least-squares solution to `A*X = B` is `X = E*(R\C)`.

`[C,R,e] = qr(A,B,'vector')` returns the permutation information as a vector instead of a matrix. That is, the least-squares solution to `A*X = B` is `X(e,:) = R\C`.

`[C,R] = qr(A,B,0)` produces economy-size results. If `m>n`, `C` and `R` have only `n` rows. If `m<=n`, this is the same as `[C,R] = qr(A,B)`.

`[C,R,e] = qr(A,B,0)` additionally produces a fill-reducing permutation vector `e`. In this case, the least-squares solution to `A*X = B` is `X(e,:) = R\C`.

Examples

Find the least squares approximate solution to `A*x = b` with the `Q`-less `QR` decomposition and one step of iterative refinement:

```
if issparse(A), R = qr(A);
else R = triu(qr(A)); end
x = R\(R'\(A'*b));
r = b - A*x;
err = R\(R'\(A'*r));
x = x + err;
```

See Also

`lu` | `chol` | `null` | `orth` | `qrdelete` | `qrinsert` | `qrupdate`

Introduced before R2006a

qrdelete

Remove column or row from QR factorization

Syntax

```
[Q1,R1] = qrdelete(Q,R,j)
[Q1,R1] = qrdelete(Q,R,j,'col')
[Q1,R1] = qrdelete(Q,R,j,'row')
```

Description

`[Q1,R1] = qrdelete(Q,R,j)` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the column `A(:,j)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

`[Q1,R1] = qrdelete(Q,R,j,'col')` is the same as `qrdelete(Q,R,j)`.

`[Q1,R1] = qrdelete(Q,R,j,'row')` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the row `A(j,:)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
[Q1,R1] = qrdelete(Q,R,j,'row');

Q1 =
    0.5274   -0.5197   -0.6697   -0.0578
    0.7135    0.6911    0.0158    0.1142

`planerot` | `qr` | `qrinsert`

Introduced before R2006a

qrinsert

Insert column or row into QR factorization

Syntax

```
[Q1,R1] = qrinsert(Q,R,j,x)
[Q1,R1] = qrinsert(Q,R,j,x,'col')
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

Description

`[Q1,R1] = qrinsert(Q,R,j,x)` returns the QR factorization of the matrix `A1`, where `A1` is `A = Q*R` with the column `x` inserted before `A(:,j)`. If `A` has `n` columns and `j = n+1`, then `x` is inserted after the last column of `A`.

`[Q1,R1] = qrinsert(Q,R,j,x,'col')` is the same as `qrinsert(Q,R,j,x)`.

`[Q1,R1] = qrinsert(Q,R,j,x,'row')` returns the QR factorization of the matrix `A1`, where `A1` is `A = Q*R` with an extra row, `x`, inserted before `A(j,:)`.

Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
x = 1:5;
[Q1,R1] = qrinsert(Q,R,j,x,'row')

Q1 =
    0.5231    0.5039   -0.6750    0.1205    0.0411    0.0225
    0.7078   -0.6966    0.0190   -0.0788    0.0833   -0.0150

`planerot` | `qr` | `qrdelete`

Introduced before R2006a

qrupdate

Rank 1 update to QR factorization

Syntax

```
[Q1,R1] = qrupdate(Q,R,u,v)
```

Description

`[Q1,R1] = qrupdate(Q,R,u,v)` when `[Q,R] = qr(A)` is the original QR factorization of `A`, returns the QR factorization of `A + u*v'`, where `u` and `v` are column vectors of appropriate lengths.

Examples

The matrix

```
mu = sqrt(eps)

mu =

   1.4901e-08

A = [ones(1,4); mu*eye(4)];
```

is a well-known example in least squares that indicates the dangers of forming `A'*A`. Instead, we work with the QR factorization – orthonormal Q and upper triangular R.

```
 [Q,R] = qr(A);
```

As we expect, `R` is upper triangular.

```
R =

   -1.0000   -1.0000   -1.0000   -1.0000
         0    0.0000    0.0000    0.0000
         0         0    0.0000    0.0000
```

```
         0         0         0    0.0000
         0         0         0         0
```

In this case, the upper triangular entries of `R`, excluding the first row, are on the order of `sqrt(eps)`.

Consider the update vectors

```
 u = [-1 0 0 0 0]'; v = ones(4,1);
```

Instead of computing the rather trivial QR factorization of this rank one update to `A` from scratch with

```
[QT,RT] = qr(A + u*v')

QT =

     0     0     0     0     1
    -1     0     0     0     0
     0    -1     0     0     0
     0     0    -1     0     0
     0     0     0    -1     0

RT =

  1.0e-007 *

   -0.1490         0         0         0
         0   -0.1490         0         0
         0         0   -0.1490         0
         0         0         0   -0.1490
         0         0         0         0
```

we may use `qrupdate`.

```
[Q1,R1] = qrupdate(Q,R,u,v)

Q1 =

   -0.0000   -0.0000   -0.0000   -0.0000    1.0000
    1.0000   -0.0000   -0.0000   -0.0000    0.0000
    0.0000    1.0000   -0.0000   -0.0000    0.0000
    0.0000    0.0000    1.0000   -0.0000    0.0000
   -0.0000   -0.0000   -0.0000    1.0000    0.0000
```

```
R1 =

   1.0e-007 *
    0.1490    0.0000    0.0000    0.0000
         0    0.1490    0.0000    0.0000
         0         0    0.1490    0.0000
         0         0         0    0.1490
         0         0         0         0
```

Note that both factorizations are correct, even though they are different.

More About

Tips

`qrupdate` works only for full matrices.

Algorithms

`qrupdate` uses the algorithm in section 12.5.1 of the third edition of *Matrix Computations* by Golub and van Loan. `qrupdate` is useful since, if we take `N = max(m,n)`, then computing the new QR factorization from scratch is roughly an $O(N^3)$ algorithm, while simply updating the existing factors in this way is an $O(N^2)$ algorithm.

See Also

`cholupdate` | `qr`

Introduced before R2006a

quad

Numerically evaluate integral, adaptive Simpson quadrature

Compatibility

`quad` will be removed in a future release. Use `integral` instead.

Syntax

```
q = quad(fun,a,b)
q = quad(fun,a,b,tol)
q = quad(fun,a,b,tol,trace)
[q,fcnt] = quad(...)
```

Description

Quadrature is a numerical method used to find the area under the graph of a function, that is, to compute a definite integral.

$$q = \int_a^b f(x)dx$$

`q = quad(fun,a,b)` tries to approximate the integral of function `fun` from `a` to `b` to within an error of `1e-6` using recursive adaptive Simpson quadrature. `fun` is a function handle. Limits `a` and `b` must be finite. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, the integrand evaluated at each element of `x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`q = quad(fun,a,b,tol)` uses an absolute error tolerance `tol` instead of the default which is `1.0e-6`. Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results. In MATLAB version 5.3 and earlier, the `quad` function used a less reliable algorithm and a default relative tolerance of `1.0e-3`.

`q = quad(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q]` during the recursion.

`[q,fcnt] = quad(...)` returns the number of function evaluations.

The function `quadl` may be more efficient with high accuracies and smooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a,Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or $|x-c|^p$ for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

Examples

To compute the integral

$$\int_0^2 \frac{1}{x^3 - 2x - 5} dx,$$

write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Then pass `@myfun`, a function handle to `myfun`, to `quad`, along with the limits of integration, `0` to `2`:

```
Q = quad(@myfun,0,2)

Q =

   -0.4605
```

Alternatively, you can pass the integrand to `quad` as an anonymous function handle `F`:

```
F = @(x)1./(x.^3-2*x-5);
Q = quad(F,0,2);
```

Diagnostics

`quad` may issue one of the following warnings:

`'Minimum step size reached'` indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

`'Maximum function count exceeded'` indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

`'Infinite or Not-a-Number function value encountered'` indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

`quad2d` | `dblquad` | `quadgk` | `quadl` | `quadv` | `trapz` | `triplequad` | `function_handle` | `integral` | `integral2` | `integral3`

Introduced before R2006a

quad2d

Numerically evaluate double integral, tiled method

Syntax

```
q = quad2d(fun,a,b,c,d)
[q,errbnd] = quad2d(...)
q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)
```

Description

`q = quad2d(fun,a,b,c,d)` approximates the integral of `fun(x,y)` over the planar region $a \le x \le b$ and $c(x) \le y \le d(x)$. `fun` is a function handle, `c` and `d` may each be a scalar or a function handle.

All input functions must be vectorized. The function `Z=fun(X,Y)` must accept 2-D matrices `X` and `Y` of the same size and return a matrix `Z` of corresponding values. The functions `ymin=c(X)` and `ymax=d(X)` must accept matrices and return matrices of the same size with corresponding values.

`[q,errbnd] = quad2d(...)`. `errbnd` is an approximate upper bound on the absolute error, `|Q - I|`, where `I` denotes the exact value of the integral.

`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)` performs the integration as above with specified values of optional parameters:

`AbsTol`	absolute error tolerance
`RelTol`	relative error tolerance

`quad2d` attempts to satisfy `ERRBND <= max(AbsTol,RelTol*|Q|)`. This is absolute error control when `|Q|` is sufficiently small and relative error control when `|Q|` is larger. A default tolerance value is used when a tolerance is not specified. The default value of `AbsTol` is 1e-5. The default value of `RelTol` is `100*eps(class(Q))`. This is also the minimum value of `RelTol`. Smaller `RelTol` values are automatically increased to the default value.

`MaxFunEvals`	Maximum allowed number of evaluations of `fun` reached.

The `MaxFunEvals` parameter limits the number of vectorized calls to `fun`. The default is 2000.

`FailurePlot`	Generate a plot if `MaxFunEvals` is reached.

Setting `FailurePlot` to `true` generates a graphical representation of the regions needing further refinement when `MaxFunEvals` is reached. No plot is generated if the integration succeeds before reaching `MaxFunEvals`. These (generally) 4-sided regions are mapped to rectangles internally. Clusters of small regions indicate the areas of difficulty. The default is `false`.

`Singular`	Problem may have boundary singularities

With `Singular` set to `true`, `quad2d` will employ transformations to weaken boundary singularities for better performance. The default is `true`. Setting `Singular` to `false` will turn these transformations off, which may provide a performance benefit on some smooth problems.

Examples

Example 1

Integrate $y\sin(x)+x\cos(y)$ over $\pi \le x \le 2\pi$, $0 \le y \le \pi$. The true value of the integral is $-\pi^2$.

```
Q = quad2d(@(x,y) y.*sin(x)+x.*cos(y),pi,2*pi,0,pi)
```

Example 2

Integrate $[(x+y)^{1/2}(1+x+y)^2]^{-1}$ over the triangle $0 \le x \le 1$ and $0 \le y \le 1-x$. The integrand is infinite at (0,0). The true value of the integral is $\pi/4 - 1/2$.

```
fun = @(x,y) 1./(sqrt(x + y) .* (1 + x + y).^2 )
```

In Cartesian coordinates:

```
ymax = @(x) 1 - x;
Q = quad2d(fun,0,1,0,ymax)
```

In polar coordinates:

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
rmax = @(theta) 1./(sin(theta) + cos(theta));
Q = quad2d(polarfun,0,pi/2,0,rmax)
```

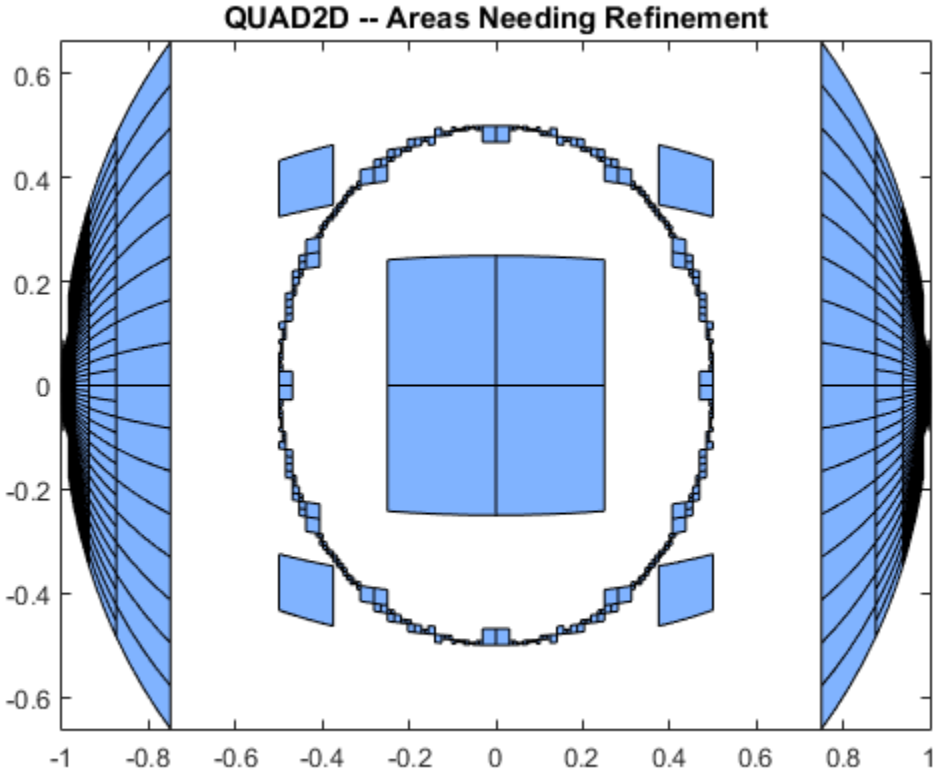
Limitations

`quad2d` begins by mapping the region of integration to a rectangle. Consequently, it may have trouble integrating over a region that does not have four sides or has a side that cannot be mapped smoothly to a straight line. If the integration is unsuccessful, some helpful tactics are leaving `Singular` set to its default value of `true`, changing between Cartesian and polar coordinates, or breaking the region of integration into pieces and adding the results of integration over the pieces.

For instance:

```
fun = @(x,y)abs(x.^2 + y.^2 - 0.25);
c = @(x)-sqrt(1 - x.^2);
d = @(x)sqrt(1 - x.^2);
quad2d(fun,-1,1,c,d,'AbsTol',1e-8,...
    'FailurePlot',true,'Singular',false);
```

```
Warning: Reached the maximum number of function evaluations (2000). The result
fails the global error test.
```

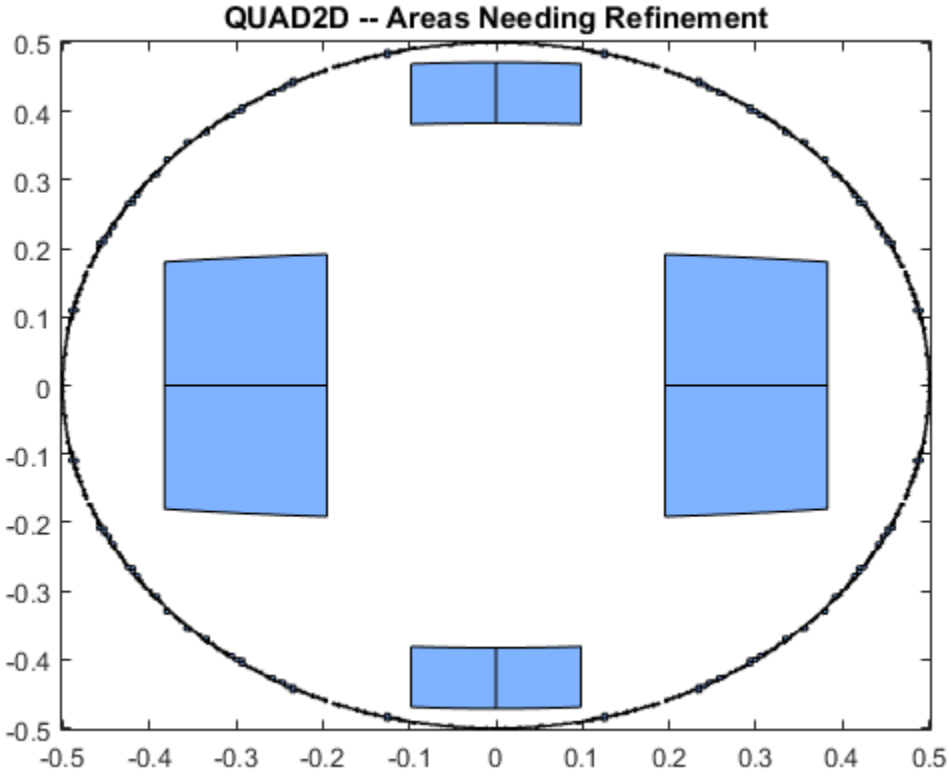


The failure plot shows two areas of difficulty, near the points `(-1,0)` and `(1,0)` and near the circle $x^2 + y^2 = 0.25$.

Changing the value of `Singular` to `true` will cope with the geometric singularities at `(-1,0)` and `(1,0)`. The larger shaded areas may need refinement but are probably not areas of difficulty.

```
Q = quad2d(fun,-1,1,c,d,'AbsTol',1e-8, ...
     'FailurePlot',true,'Singular',true);
```

```
Warning: Reached the maximum number of function evaluations (2000). The result
passes the global error test.
```



From here you can take advantage of symmetry:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-8,...
     'Singular',true,'FailurePlot',true)
```

```
Q =

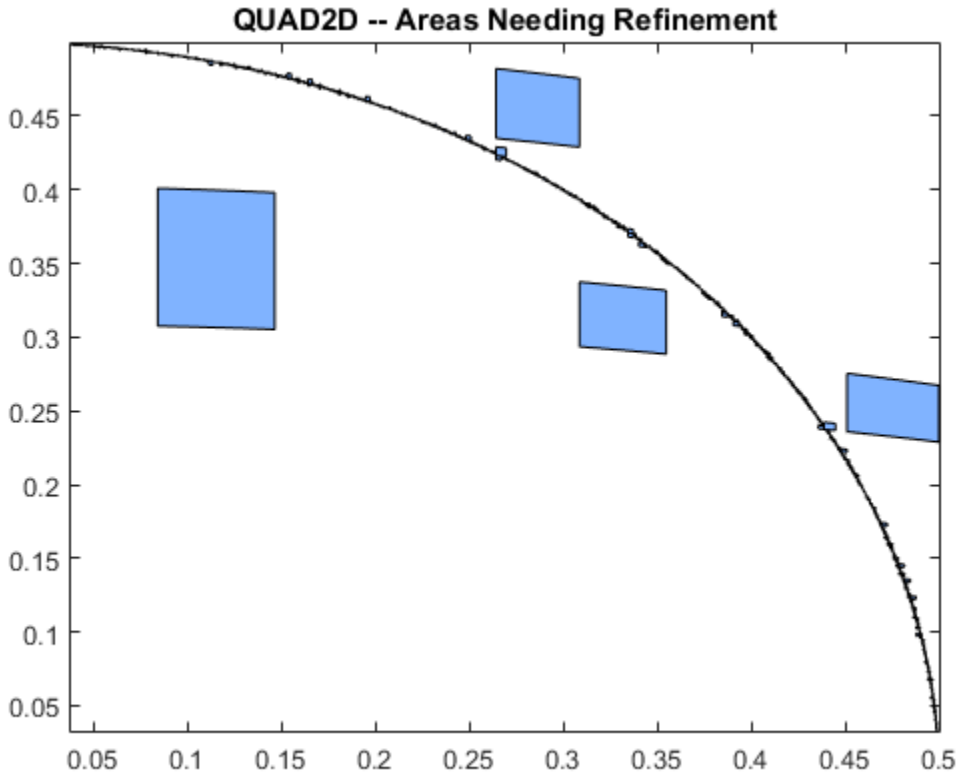
    0.9817
```

However, the code is still working very hard near the singularity. It may not be able to provide higher accuracy:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-10,...
```

```
    'Singular',true,'FailurePlot',true);
```

```
Warning: Reached the maximum number of function evaluations (2000). The result
passes the global error test.
```



At higher accuracy, a change in coordinates may work better.

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
Q = 4*quad2d(polarfun,0,pi/2,0,1,'AbsTol',1e-10);
```

It is best to put the singularity on the boundary by splitting the region of integration into two parts:

```
Q1 = 4*quad2d(polarfun,0,pi/2,0,0.5,'AbsTol',5e-11);
```

```
Q2 = 4*quad2d(polarfun,0,pi/2,0.5,1,'AbsTol',5e-11);
Q = Q1 + Q2;
```

`dblquad` | `quad` | `quadl` | `quadv` | `quadgk` | `triplequad` | `function_handle` | `integral` | `integral2` | `integral3`

quadgk

Numerically evaluate integral, adaptive Gauss-Kronrod quadrature

Syntax

```
q = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b)
[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)
```

Description

`q = quadgk(fun,a,b)` attempts to approximate the integral of a scalar-valued function `fun` from `a` to `b` using high-order global adaptive quadrature and default error tolerances. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, where `y` is the integrand evaluated at each element of `x`. `fun` must be a function handle. Limits `a` and `b` can be `-Inf` or `Inf`. If both are finite, they can be complex. If at least one is complex, the integral is approximated over a straight line path from `a` to `b` in the complex plane.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`[q,errbnd] = quadgk(fun,a,b)` returns an approximate upper bound on the absolute error, `|Q - I|`, where `I` denotes the exact value of the integral.

`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)` performs the integration with specified values of optional parameters. The available parameters are

Parameter	Description	
`'AbsTol'`	Absolute error tolerance. The default value of `'AbsTol'` is `1.e-10` (double), `1.e-5` (single).	`quadgk` attempts to satisfy `errbnd <= max(AbsTol,RelTol*|Q|)`. This is absolute error control when `|Q|` is sufficiently small and relative error control when `|Q|` is larger. For pure absolute error control use `'AbsTol'`
`'RelTol'`	Relative error tolerance.	

Parameter	Description	
	The default value of `'RelTol'` is `1.e-6` (double), `1.e-4` (single).	`> 0` and `'RelTol'= 0`. For pure relative error control use `'AbsTol' = 0`. Except when using pure absolute error control, the minimum relative tolerance is `'RelTol' >= 100*eps(class(Q))`.
`'Waypoints'`	Vector of integration waypoints.	If `fun(x)` has discontinuities in the interval of integration, the locations should be supplied as a `Waypoints` vector. When `a`, `b`, and the waypoints are all real, only the waypoints between `a` and `b` are used, and they are used in sorted order. Note that waypoints are not intended for singularities in `fun(x)`. Singular points should be handled by making them endpoints of separate integrations and adding the results. If `a`, `b`, or any entry of the waypoints vector is complex, the integration is performed over a sequence of straight line paths in the complex plane, from `a` to the first waypoint, from the first waypoint to the second, and so forth, and finally from the last waypoint to `b`.

Parameter	Description	
`'MaxIntervalCount'`	Maximum number of intervals allowed. The default value is `650`.	The `'MaxIntervalCount'` parameter limits the number of intervals that `quadgk` uses at any one time after the first iteration. A warning is issued if `quadgk` returns early because of this limit. Routinely increasing this value is not recommended, but it may be appropriate when `errbnd` is small enough that the desired accuracy has nearly been achieved.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a,Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or $|x-c|^p$ for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

Examples

Integrand with a singularity at an integration end point

Write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = exp(x).*log(x);
```

Then pass `@myfun`, a function handle to `myfun`, to `quadgk`, along with the limits of integration, `0` to `1`:

```
q = quadgk(@myfun,0,1)

q =

   -1.3179
```

Alternatively, you can pass the integrand to `quadgk` as an anonymous function handle `F`:

```
f = (@(x)exp(x).*log(x));
q = quadgk(f,0,1);
```

Oscillatory integrand on a semi-infinite interval

Integrate over a semi-infinite interval with specified tolerances, and return the approximate error bound:

```
f = @(x)x.^5.*exp(-x).*sin(x);
[q,errbnd] = quadgk(f,0,inf,'RelTol',1e-8,'AbsTol',1e-12)

q =

  -15.0000

errbnd =

  9.4386e-009
```

Contour integration around a pole

Use `Waypoints` to integrate around a pole using a piecewise linear contour:

```
f = @(z)1./(2*z - 1);
```

```
q = quadgk(f,-1-i,-1-i,'Waypoints',[1-i,1+i,-1+i])

q =

   0.0000 + 3.1416i
```

Diagnostics

`quadgk` may issue one of the following warnings:

`'Minimum step size reached'` indicates that interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

`'Reached the limit on the maximum number of intervals in use'` indicates that the integration was terminated before meeting the tolerance requirements and that continuing the integration would require more than `MaxIntervalCount` subintervals. The integral may not exist, or it may be difficult to approximate numerically. Increasing `MaxIntervalCount` usually does not help unless the tolerance requirements were nearly met when the integration was previously terminated.

`'Infinite or Not-a-Number function value encountered'` indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

More About

Algorithms

`quadgk` implements adaptive quadrature based on a Gauss-Kronrod pair (15^{th} and 7^{th} order formulas).

quadl

Numerically evaluate integral, adaptive Lobatto quadrature

Compatibility

`quadl` will be removed in a future release. Use `integral` instead.

Syntax

```
q = quadl(fun,a,b)
q = quadl(fun,a,b,tol)
quadl(fun,a,b,tol,trace)
[q,fcnt] = quadl(...)
```

Description

`q = quadl(fun,a,b)` approximates the integral of function `fun` from `a` to `b`, to within an error of 10^{-6} using recursive adaptive Lobatto quadrature. `fun` is a function handle. It accepts a vector `x` and returns a vector `y`, the function `fun` evaluated at each element of `x`. Limits `a` and `b` must be finite.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`q = quadl(fun,a,b,tol)` uses an absolute error tolerance of `tol` instead of the default, which is `1.0e-6`. Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results.

`quadl(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a q]` during the recursion.

`[q,fcnt] = quadl(...)` returns the number of function evaluations.

Use array operators `.*`, `./` and `.^` in the definition of `fun` so that it can be evaluated with a vector argument.

The function quad might be more efficient with low accuracies or nonsmooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The quad function might be most efficient for low accuracies with nonsmooth integrands.
- The quadl function might be more efficient than quad at higher accuracies with smooth integrands.
- The quadgk function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The quadv function vectorizes quad for an array-valued fun.
- If the interval is infinite, [a,Inf), then for the integral of fun(x) to exist, fun(x) must decay as x approaches infinity, and quadgk requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but quadgk can be used if fun(x) decays fast enough.
- The quadgk function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint c like log|x-c| or $|x-c|^p$ for p >= -1/2. If the function is singular at points inside (a,b), write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with quadgk, and add the results.

Examples

Pass the function handle, @myfun, to quadl:

```
Q = quadl(@myfun,0,2);
```

where the function myfun.m is:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Pass anonymous function handle F to quadl:

```
F = @(x) 1./(x.^3-2*x-5);
Q = quadl(F,0,2);
```

Diagnostics

`quadl` might issue one of the following warnings:

`'Minimum step size reached'` indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

`'Maximum function count exceeded'` indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

`'Infinite or Not-a-Number function value encountered'` indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

More About

Algorithms

`quadl` implements a high order method using an adaptive Gauss/Lobatto quadrature rule.

quadv

Vectorized quadrature

Compatibility

`quadv` will be removed in a future release. Use `integral` with the `'ArrayValued'` option instead.

Syntax

```
Q = quadv(fun,a,b)
Q = quadv(fun,a,b,tol)
Q = quadv(fun,a,b,tol,trace)
[Q,fcnt] = quadv(...)
```

Description

`Q = quadv(fun,a,b)` approximates the integral of the complex array-valued function `fun` from `a` to `b` to within an error of `1.e-6` using recursive adaptive Simpson quadrature. `fun` is a function handle. The function `Y = fun(x)` should accept a scalar argument `x` and return an array result `Y`, whose components are the integrands evaluated at `x`. Limits `a` and `b` must be finite.

"Parameterizing Functions" explains how to provide addition parameters to the function `fun`, if necessary.

`Q = quadv(fun,a,b,tol)` uses the absolute error tolerance `tol` for all the integrals instead of the default, which is `1.e-6`.

Note The same tolerance is used for all components, so the results obtained with `quadv` are usually not the same as those obtained with `quad` on the individual components.

`Q = quadv(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q(1)]` during the recursion.

`[Q,fcnt] = quadv(...)` returns the number of function evaluations.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite, `[a,Inf)`, then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like `log|x-c|` or $|x-c|^p$ for `p >= -1/2`. If the function is singular at points inside `(a,b)`, write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

Examples

For the parameterized array-valued function `myarrayfun`, defined by

```
function Y = myarrayfun(x,n)
Y = 1./((1:n)+x);
```

the following command integrates `myarrayfun`, for the parameter value n = 10 between a = 0 and b = 1:

```
Qv = quadv(@(x)myarrayfun(x,10),0,1);
```

The resulting array `Qv` has 10 elements estimating `Q(k) = log((k+1)./(k))`, for `k = 1:10`.

The entries in `Qv` are slightly different than if you compute the integrals using `quad` in a loop:

```
for k = 1:10
 Qs(k) = quadv(@(x)myscalarfun(x,k),0,1);
end
```

where `myscalarfun` is:

```
function y = myscalarfun(x,k)
y = 1./(k+x);
```

matlab.unittest.qualifications

Summary of classes in MATLAB Qualifications Interface

Description

Qualifications are methods for testing values and responding to failures. Qualification failures might or might not correspond to a test failure, and they might or might not continue execution in the test when one is encountered. To determine which qualification to use, see “Types of Qualifications”.

matlab.unittest.qualifications.Assertable	Qualification to validate preconditions of a test
matlab.unittest.qualifications.Assumable	Qualification to filter test content
matlab.unittest.qualifications.FatalAssertable	Qualification to abort test execution
matlab.unittest.qualifications.Verifiable	Qualification to produce soft-failure conditions

The package contains the following event data classes:

matlab.unittest.qualifications.ExceptionEventData	Event data for ExceptionThrown event listeners
matlab.unittest.qualifications.QualificationEventData	Event data for qualification event listeners

The package contains the following exception handling classes:

matlab.unittest.qualifications.AssertionFailedException	Exception used for assertion failures

matlab.unittest.qualifications.AssumptionFailedException
Exception used for assumption failures

matlab.unittest.qualifications.FatalAssertionFailedException
Exception used for fatal assertion failures

matlab.unittest.qualifications.Assertable class

Package: matlab.unittest.qualifications

Qualification to validate preconditions of a test

Description

The `Assertable` class provides a qualification to validate preconditions of a test. Apart from actions performed for failures, the `Assertable` class works the same as other `matlab.unittest` qualifications.

Upon an assertion failure, the `Assertable` class throws an `AssertionFailedException` to inform the testing framework of the failure. This is most useful when a failure at the assertion point renders the rest of the current test method invalid, yet does not prevent proper execution of other test methods. Often, you use assertions to ensure that preconditions of the current test are not violated or that fixtures are set up correctly. Make sure the test content is “Exception Safe” on page 1-6212. If you cannot make the fixture teardown exception safe or if you cannot recover it after failure, use fatal assertions instead.

Use assertions to allow remaining test methods to receive coverage when preconditions are violated in a test and all fixture states are restorable. Assertions also reduce the noise level of failures by not performing later verifications that fail due the precondition failures. In the event of a failure, however, the test framework marks the full content of the test method that failed as incomplete. Therefore, if the failure does not affect the preconditions of the test or cause problems with fixture setup or teardown, use verifications, which give the added information that the full test content was run.

Methods

assertClass	Assert exact class of specified value
assertEmpty	Assert value is empty
assertEqual	Assert value is equal to specified value

assertError	Assert function throws specified exception
assertFail	Produce unconditional assertion failure
assertFalse	Assert value is false
assertGreaterThan	Assert value is greater than specified value
assertGreaterThanOrEqual	Assert value is greater than or equal to specified value
assertInstanceOf	Assert value is object of specified type
assertLength	Assert value has specified length
assertLessThan	Assert value is less than specified value
assertLessThanOrEqual	Assert value is less than or equal to specified value
assertMatches	Assert string matches specified regular expression
assertNotEmpty	Assert value is not empty
assertNotEqual	Assert value is not equal to specified value
assertNotSameHandle	Assert value is not handle to specified instance
assertNumElements	Assert value has specified element count
assertReturnsTrue	Assert function returns true when evaluated

assertSameHandle	Assert two values are handles to same instance
assertSize	Assert value has specified size
assertSubstring	Assert string contains specified string
assertThat	Assert that value meets specified constraint
assertTrue	Assert value is true
assertWarning	Assert function issues specified warning
assertWarningFree	Assert function issues no warnings

Events

`AssertionFailed`	Triggered upon failing assertion. A `QualificationEventData` object is passed to listener callback functions.
`AssertionPassed`	Triggered upon passing assertion. A `QualificationEventData` object is passed to listener callback functions.

Definitions

Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
close(f);
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.assertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assertEqual`.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
testCase.addTeardown(@close, f);
```

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test for Preconditions Using Assertions

Use assertable qualifications to test for preconditions. This example will create a test case to write a polynomial to a MAT-file.

Create `DocPolynomSaveLoadTest` Test Case. Refer to the following `DocPolynomSaveLoadTest` test case in the subsequent steps in this example. The steps highlight specific code in the `testSaveLoad` function; the code statements are not intended to be executed outside the context of the class definition file.

DocPolynomSaveLoadTest Class Definition File

```
classdef DocPolynomSaveLoadTest < matlab.unittest.TestCase

    methods (TestClassSetup)
```

```
        function addDocPolynomClassToPath(testCase)
            origPath = path;
            testCase.addTeardown(@path, origPath);
            addpath(fullfile(matlabroot, ...
                'help', 'techdoc', 'matlab_oop', 'examples'));
        end
    end

    methods (Test)
        function testSaveLoad(testCase)

            import matlab.unittest.diagnostics.Diagnostic;

            %% Phase 1: Setup
            % Create a temporary working folder
            tempFolder = tempname;
            [success, message] = mkdir(tempFolder);
            testCase.assertTrue(success, ...
                Diagnostic.join('Could not create temporary folder.',...
                message));
            testCase.addTeardown(@() testCase.cleanUpTemporaryFolder(...
                tempFolder));

            % Change to the temporay folder and register the
            % teardown, which restores the original folder
            origFolder = pwd;
            testCase.addTeardown(@cd, origFolder);
            cd(tempFolder);

            %% Phase 2: Exercise
            % Save the instance to a mat file.
            p = DocPolynom([1, 0, 1]);
            save('DocPolynomFile', 'p');

            % Validate Precondition. Save resulted in valid .mat file
            testCase.assertEqual(exist('DocPolynomFile.mat','file'),...
                2, Diagnostic.join(...
                'mat file was not saved correctly.',@() dir(pwd)));

            loaded = load('DocPolynomFile');

            %% Phase 3: Verify
            testCase.verifyEqual(loaded.p, p,...
```

```
                'Loaded polynom did not equal original polynom.');

            %% Phase 4: Teardown
            % Done inline via calls to addTeardown at the points
            % at which the state was changed.

        end
    end

    methods(Access=private)
        function cleanUpTemporaryFolder(testCase,tempFolder)
            % Clean up the temporary folder and fatally assert
            % that it was correctly cleaned up.

            import matlab.unittest.diagnostics.Diagnostic;

            [success, message] = rmdir(tempFolder, 's');
            testCase.fatalAssertTrue(success, ...
                Diagnostic.join('Could not remove temporary folder.',...
                message));
        end
    end

end
```

To execute the MATLAB commands in "Run DocPolynomSaveLoadTest Test Case", add the `DocPolynomSaveLoadTest.m` file to a folder on your MATLAB path.

The `testSaveLoad` function consists of the following phases:

- Phase 1: Setup — Create and verify precondition code.
- Phase 2: Exercise — Create a `DocPolynom` object and save it to a MAT-file.
- Phase 3: Verify — Test that object was successfully saved.
- Phase 4: Teardown — Execute teardown code.

Define phase 1 precondition. For this test, use a temporary folder for creating a `DocPolynom` object. The precondition for continuing with this test is that the following commands execute successfully.

```
tempFolder = tempname;
[success, message] = mkdir(tempFolder);
```

Test the results of the `mkdir` function. Use the `assertTrue` method to test the `mkdir` success argument for errors. If an assertion occurs, the remainder of the `testSaveLoad` test method is invalid, and the test is marked `Incomplete`.

```
testCase.assertTrue(success, ...
    Diagnostic.join('Could not create the temporary folder.', ...
        message))
```

If the `mkdir` function fails, MATLAB displays the diagnostic message, `Could not create the temporary folder`, as well as the contents of the `mkdir` message argument.

Add teardown fixture code. Creating a temporary folder is setup code, which requires a corresponding call to the `rmdir` function to restore MATLAB to the original state. Use the `addTeardown` method to ensure the teardown code executes even when an exception is thrown in the middle of the test method. This makes the test Exception Safe.

```
testCase.addTeardown(@() testCase.cleanUpTemporaryFolder(tempFolder))
```

Place teardown code in the helper function. Although the `addTeardown` statement occurs in the same code block as the `mkdir` setup statement, the `cleanUpTemporaryFolder` code is executed in phase 4 of the test method.

In the `DocPolynomSaveLoadTest` test case, the helper function, `cleanUpTemporaryFolder`, executes the `rmdir` function.

Define the precondition for creating valid MAT-File. A precondition for verifying that the `DocPolynom` object was correctly saved and loaded is that the MAT-file, `DocPolynomFile.mat`, was successfully created. The following code in the `Phase 2: Exercise` block tests this condition. If an assertion occurs, the remainder of the `testSaveLoad` test method is invalid, and the test is marked `Failed` and `Incomplete`.

```
 testCase.assertEqual(exist('DocPolynomFile.mat','file'), 2, ...
     Diagnostic.join('The mat file was not saved correctly.', ...
     @() dir(pwd)))
```

If the file was not created, MATLAB displays the diagnostic message, `The mat file was not saved correctly`, as well as the contents of the temporary folder.

Run `DocPolynomSaveLoadTest` Test Case.

```
tc = DocPolynomSaveLoadTest;
run(tc);
```

```
Running DocPolynomSaveLoadTest
.
Done DocPolynomSaveLoadTest
__________
```

More About

- "Types of Qualifications"

Introduced in R2013a

assertClass

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert exact class of specified value

Syntax

```
assertClass(assertable,actual,className)
assertClass(assertable,actual,metaClass)
assertClass( ___ ,diagnostic)
```

Description

`assertClass(assertable,actual,className)` asserts that actual is a MATLAB value whose class is the class specified by className.

`assertClass(assertable,actual,metaClass)` asserts that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass. The instance must be an exact class match. See `assertInstanceOf` to assert inclusion in a class hierarchy.

`assertClass( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- The method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsOfClass;
  assertable.assertThat(actual, IsOfClass(className));
  assertable.assertThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyClass`, and replace calls to `verifyClass` with `assertClass`.

See Also

`assertInstanceOf` | `assertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assertEmpty

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is empty

Syntax

```
assertEmpty(assertable,actual)
assertEmpty(assertable,actual,diagnostic)
```

Description

`assertEmpty(assertable,actual)` asserts that actual is an empty MATLAB value.

`assertEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assertable.assertThat(actual, IsEmpty());
  ```

  This method is a convenience method. There exists more functionality when using the `IsEmpty` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyEmpty`, and replace calls to `verifyEmpty` with `assertEmpty`.

See Also

`assertNotEmpty` | `assertThat` | `isempty`

More About

- "Types of Qualifications"

Introduced in R2013a

assertEqual

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is equal to specified value

Syntax

```
assertEqual(assertable,actual,expected)
assertEqual( ___ ,Name,Value)
assertEqual( ___ ,diagnostic)
```

Description

`assertEqual(assertable,actual,expected)` asserts that actual is strictly equal to expected.

`assertEqual( ___ ,Name,Value)` asserts equality with additional options specified by one or more Name,Value pair arguments.

`assertEqual( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
```

```
    'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expected`

Expected value.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'AbsTol'`

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

Default:

`'RelTol'`

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied, `abs(expected-actual) <= relTol.*abs(expected)` must be true.

Default:

Examples

See examples for `verifyEqual`, and replace calls to `verifyEqual` with `assertEqual`.

See Also

`assertNotEqual` | `assertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assertError

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert function throws specified exception

Syntax

```
assertError(assertable,actual,identifier)
assertError(assertable,actual,metaClass)
assertError( ___ ,diagnostic)
```

Description

`assertError(assertable,actual,identifier)` asserts that actual is a function handle that throws an exception with an error identifier that is equal to identifier.

`assertError(assertable,actual,metaClass)` asserts that actual is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in metaClass. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assertError( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  assertable.assertThat(actual, Throws(identifier));
  assertable.assertThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via `assertThat`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`identifier`

Error identifier, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyError`, and replace calls to `verifyError` with `assertError`.

See Also

`MException` | `assertThat` | `assertWarning` | `error`

More About

- "Types of Qualifications"

Introduced in R2013a

assertFail

Produce unconditional assertion failure

Syntax

```
assertFail(assertable)
assertFail(assertable,diagnostic)
```

Description

`assertFail(assertable)` produces an unconditional assertion failure when encountered.

`assertFail(assertable,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Tips

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Examples

See examples for `verifyFail`, and replace calls to `verifyFail` with `assertFail`.

More About

- "Types of Qualifications"

Introduced in R2013a

assertFalse

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is false

Syntax

```
assertFalse(assertable,actual)
assertFalse(assertable,actual,diagnostic)
```

Description

`assertFalse(assertable,actual)` asserts that actual is a scalar logical with the value of false.

`assertFalse(assertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  assertable.assertThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via `assertThat`.
- Unlike `assertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assertTrue`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

For examples, see `verifyFalse`, and replace calls to `verifyFalse` with `assertFalse`.

See Also

`assertThat` | `assertTrue`

- "Types of Qualifications"

Introduced in R2013a

assertGreaterThan

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is greater than specified value

Syntax

```
assertGreaterThan(assertable,actual,floor)
assertGreaterThan(assertable,actual,floor,diagnostic)
```

Description

`assertGreaterThan(assertable,actual,floor)` asserts that all elements of actual are greater than all the elements of floor.

`assertGreaterThan(assertable,actual,floor,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThan;
  assertable.assertThat(actual, IsGreaterThan(floor));
  ```

  There exists more functionality when using the `IsGreaterThan` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as floor unless either one is scalar, at which point scalar expansion occurs.

`floor`

Minimum value, exclusive.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyGreaterThan`, and replace calls to `verifyGreaterThan` with `assertGreaterThan`.

- "Types of Qualifications"

Introduced in R2013a

assertGreaterThanOrEqual

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is greater than or equal to specified value

Syntax

```
assertGreaterThanOrEqual(assertable,actual,floor)
assertGreaterThanOrEqual(assertable,actual,floor,diagnostic)
```

Description

`assertGreaterThanOrEqual(assertable,actual,floor)` asserts that all elements of actual are greater than or equal to all the elements of floor.

`assertGreaterThanOrEqual(assertable,actual,floor,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  assertable.assertThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. assertInstanceOf

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is object of specified type

Syntax

```
assertInstanceOf(assertable,actual,className)
assertInstanceOf(assertable,actual,metaClass)
assertInstanceOf( ___ ,diagnostic)
```

Description

`assertInstanceOf(assertable,actual,className)` asserts that actual is a MATLAB value whose class is the class specified by className.

`assertInstanceOf(assertable,actual,metaClass)` asserts that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass.

`assertInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  assertable.assertThat(actual, IsInstanceOf(className));
  assertable.assertThat(actual, IsInstanceOf(metaClass));
  ```

  There exists more functionality when using the `IsInstanceOf` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test

methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyInstanceOf`, and replace calls to `verifyInstanceOf` with `assertInstanceOf`.

More About

- "Types of Qualifications"

Introduced in R2013a

assertLength

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value has specified length

Syntax

```
assertLength(assertable,actual,expectedLength)
assertLength(assertable,actual,expectedLength,diagnostic)
```

Description

`assertLength(assertable,actual,expectedLength)` that actual is a MATLAB array whose length is expectedLength.

`assertLength(assertable,actual,expectedLength,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasLength;
  assertable.assertThat(actual, HasLength(expectedLength));
  ```

  There exists more functionality when using the `HasLength` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedLength`

The length of an array is defined as the largest dimension of that array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyLength`, and replace calls to `verifyLength` with `assertLength`.

assertLessThan

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is less than specified value

Syntax

```
assertLessThan(assertable,actual,ceiling)
assertLessThan(assertable,actual,ceiling,diagnostic)
```

Description

`assertLessThan(assertable,actual,ceiling)` asserts that all elements of actual are less than all the elements of ceiling.

`assertLessThan(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  assertable.assertThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. assertLessThanOrEqual

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is less than or equal to specified value

Syntax

```
assertLessThanOrEqual(assertable,actual,ceiling)
assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)
```

Description

`assertLessThanOrEqual(assertable,actual,ceiling)` asserts that all elements of actual are less than or equal to all the elements of ceiling.

`assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThanOrEqualTo;
  assertable.assertThat(actual, IsLessThanOrEqualTo(ceiling));
  ```

  There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as ceiling unless either one is scalar, at which point scalar expansion occurs.

Default:

`ceiling`

Maximum value.

Default:

`diagnostic`

assertMatches

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert string matches specified regular expression

Syntax

```
assertMatches(assertable,actual,expression)
assertMatches(assertable,actual,expression,diagnostic)
```

Description

`assertMatches(assertable,actual,expression)` asserts that actual is a string that matches the regular expression defined by expression.

`assertMatches(assertable,actual,expression,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  assertable.assertThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expression`

The value to match, specified as a regular expression.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyMatches`, and replace calls to `verifyMatches` with `assertMatches`.

See Also

`assertSubstring` | `assertThat` | `regexp`

More About

- "Types of Qualifications"

Introduced in R2013a

assertNotEmpty

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is not empty

Syntax

```
assertNotEmpty(assertable,actual)
assertNotEmpty(assertable,actual,diagnostic)
```

Description

`assertNotEmpty(assertable,actual)` asserts that actual is a non-empty MATLAB value.

`assertNotEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assertable.assertThat(actual, ~IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotEmpty`, and replace calls to `verifyNotEmpty` with `assertNotEmpty`.

See Also

`assertEmpty` | `assertThat` | `isempty`

More About

- "Types of Qualifications"

Introduced in R2013a

assertNotEqual

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is not equal to specified value

Syntax

```
assertNotEqual(assertable,actual,notExpected)
assertNotEqual(assertable,actual,notExpected,diagnostic)
```

Description

`assertNotEqual(assertable,actual,notExpected)` asserts that actual is not equal to notExpected.

`assertNotEqual(assertable,actual,notExpected,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEqualTo;
  assertable.assertThat(actual, ~IsEqualTo(notExpected));
  ```

  There exists more functionality when using the `IsEqualTo` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`notExpected`

Value to compare.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotEqual`, and replace calls to `verifyNotEqual` with `assertNotEqual`.

See Also

`assertEqual` | `assertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assertNotSameHandle

Class: matlab.unittest.TestCase
Package: matlab.unittest

Assert value is not handle to specified instance

Syntax

```
assertNotSameHandle(assertable,actual,notExpectedHandle)
assertNotSameHandle(assertable,actual,notExpectedHandle,diagnostic)
```

Description

`assertNotSameHandle(assertable,actual,notExpectedHandle)` asserts that actual is a different size and/or does not contain the same instances as the notExpectedHandle handle array.

`assertNotSameHandle(assertable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assertable.assertThat(actual, ~IsSameHandleAs(notExpectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`notExpectedHandle`

The handle array to compare.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotSameHandle`, and replace calls to `verifyNotSameHandle` with `assertNotSameHandle`.

See Also

`assertSameHandle` | `assertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assertNumElements

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value has specified element count

Syntax

```
assertNumElements(assertable,actual,expectedElementCount)
assertNumElements(assertable,actual,expectedElementCount,diagnostic)
```

Description

`assertNumElements(assertable,actual,expectedElementCount)` asserts that actual is a MATLAB array with expectedElementCount number of elements.

`assertNumElements(assertable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasElementCount;
  assertable.assertThat(actual, HasElementCount(expectedElementCount));
  ```

  There exists more functionality when using the `HasElementCount` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedElementCount`

The expected number of elements in the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNumElements`, and replace calls to `verifyNumElements` with `assertNumElements`.

More About

- "Types of Qualifications"

Introduced in R2013a

assertReturnsTrue

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert function returns true when evaluated

Syntax

```
assertReturnsTrue(assertable,actual)
assertReturnsTrue(assertable,actual,diagnostic)
```

Description

`assertReturnsTrue(assertable,actual)` asserts that actual is a function handle that returns a scalar logical whose value is true.

`assertReturnsTrue(assertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assertTrue`.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  assertable.assertThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test

methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyReturnsTrue`, and replace calls to `verifyReturnsTrue` with `assertReturnsTrue`.

See Also

`assertThat` | `assertTrue`

More About

- "Types of Qualifications"

Introduced in R2013a

assertSameHandle

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert two values are handles to same instance

Syntax

```
assertSameHandle(assertable,actual,expectedHandle)
assertSameHandle(assertable,actual,expectedHandle,diagnostic)
```

Description

`assertSameHandle(assertable,actual,expectedHandle)` asserts that actual is the same size and contains the same instances as the expectedHandle handle array.

`assertSameHandle(assertable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assertable.assertThat(actual, IsSameHandleAs(expectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedHandle`

The expected handle array.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySameHandle`, and replace calls to `verifySameHandle` with `assertSameHandle`.

See Also

- "Types of Qualifications"

Introduced in R2013a

assertSize

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value has specified size

Syntax

```
assertSize(assertable,actual,expectedSize)
assertSize(assertable,actual,expectedSize,diagnostic)
```

Description

`assertSize(assertable,actual,expectedSize)` asserts that actual is a MATLAB array whose size is expectedSize.

`assertSize(assertable,actual,expectedSize,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasSize;
  assertable.assertThat(actual, HasSize(expectedSize));
  ```

  There exists more functionality when using the `HasSize` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedSize`

The expected sizes of each dimension the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySize`, and replace calls to `verifySize` with `assertSize`.

`assertLength` | `assertNumElements` | `assertThat` | `size`

More About

- "Types of Qualifications"

Introduced in R2013a

assertSubstring

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert string contains specified string

Syntax

```
assertSubstring(assertable,actual,substring)
assertSubstring(assertable,actual,substring,diagnostic)
```

Description

`assertSubstring(assertable,actual,substring)` asserts that actual is a string that contains substring.

`assertSubstring(assertable,actual,substring,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ContainsSubstring;
  assertable.assertThat(actual, ContainsSubstring(substring));
  ```

  There exists more functionality when using the `ContainsSubstring` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`substring`

The value to match, specified as a string.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySubstring`, and replace calls to `verifySubstring` with `assertSubstring`.

See Also

`assertMatches` | `assertThat` | `strfind`

More About

- "Types of Qualifications"

Introduced in R2013a

assertThat

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert that value meets specified constraint

Syntax

```
assertThat(assertable,actual,constraint)
assertThat(assertable,actual,constraint,diagnostic)
```

Description

`assertThat(assertable,actual,constraint)` asserts that actual is a value that satisfies the constraint provided.

If the constraint is not satisfied, an assertion failure is produced utilizing only the framework diagnostic generated by the constraint.

`assertThat(assertable,actual,constraint,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

When using this signature, both the diagnostic information contained within diagnostic is used in addition to the diagnostic information provided by the constraint.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`constraint`

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyThat`, and replace calls to `verifyThat` with `assertThat`.

Tips

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

More About

- "Types of Qualifications"

Introduced in R2013a

assertTrue

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert value is true

Syntax

```
assertTrue(assertable,actual)
assertTrue(assertable,actual,diagnostic)
```

Description

`assertTrue(assertable,actual)` asserts that actual is a scalar logical with the value of true.

`assertTrue(assertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and non-zero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  assertable.assertThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via `assertThat`.

  Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally

less performant but can provide slightly better diagnostic information is the use of `assertReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyTrue`, and replace calls to `verifyTrue` with `assertTrue`.

See Also

`assertFalse` | `assertReturnsTrue` | `assertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assertWarning

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert function issues specified warning

Syntax

```
assertWarning(assertable,actual,warningID)
assertWarning(assertable,actual,warningID,diagnostic)
[output1,...,outputN] = assertWarning( ___ )
```

Description

`assertWarning(assertable,actual,warningID)` asserts that actual issues a warning with the identifier warningID.

`assertWarning(assertable,actual,warningID,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`[output1,...,outputN] = assertWarning( ___ )` also returns the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  assertable.assertThat(actual, IssuesWarnings({warningID}));
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`warningID`

Warning ID, specified as a string.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Output Arguments

`output1,...,outputN`

Output arguments, 1 through n (if any), from actual, returned as any type. The argument type is specified by the actual argument list.

Examples

See examples for `verifyWarning`, and replace calls to `verifyWarning` with `assertWarning`.

See Also

`assertError` | `assertThat` | `assertWarningFree` | `warning`

More About

- "Types of Qualifications"

Introduced in R2013a

assertWarningFree

Class: matlab.unittest.qualifications.Assertable
Package: matlab.unittest.qualifications

Assert function issues no warnings

Syntax

```
assertWarningFree(assertable,actual)
assertWarningFree(assertable,actual,diagnostic)
[output1,...,outputN] = assertWarningFree( ___ )
```

Description

`assertWarningFree(assertable,actual)` asserts that actual is a function handle that issues no warnings.

`assertWarningFree(assertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`[output1,...,outputN] = assertWarningFree( ___ )` also returns the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  assertable.assertThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assertThat`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`assertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Output Arguments

`output1,...,outputN`

Output arguments, 1 through n (if any), from actual, returned as any type. The argument type is specified by the actual argument list.

Examples

See examples for `verifyWarningFree`, and replace calls to `verifyWarningFree` with `assertWarningFree`.

See Also

More About

- "Types of Qualifications"

Introduced in R2013a

matlab.unittest.qualifications.AssertionFailedException class

Package: matlab.unittest.qualifications

Exception used for assertion failures

Description

The `AssertionFailedException` class provides an exception used for assertion failures. This class is used exclusively by the `Assertable` qualification type.

See Also

`MException` | `Assertable`

matlab.unittest.qualifications.Assumable class

Package: matlab.unittest.qualifications

Qualification to filter test content

Description

The `Assumable` class provides a qualification to filter test content. Apart from actions performed in the event of failures, the `Assumable` class works the same as other `matlab.unittest` qualifications.

Upon an assumption failure, the `Assumable` class informs the testing framework of the failure by throwing an `AssumptionFailedException`. The test framework then marks the test content as filtered and continues testing. Often, assumptions are used to ensure that the test is run only when certain preconditions are met. However, running the test without satisfying the preconditions does not produce a test failure. Ensure that the test content is "Exception Safe" on page 1-6297. If the failure condition is meant to produce a test failure, use assertions or verifications instead of assumptions.

The attributes specified in the `TestCase` method definition determine which tests are filtered. The following behavior occurs when the test framework encounters an assumption failure inside of a `TestCase` method:

- If you define the `TestCase` method using the `Test` attribute, the framework marks the entire method as filtered and runs subsequent test methods.
- If you define the `TestCase` method using the `TestMethodSetup` or `TestMethodTeardown` attributes, the test framework marks the method to run for that instance as filtered.
- If you define the `TestCase` method using the `TestClassSetup` or `TestClassTeardown` attributes, the test framework filters the entire `TestCase` class.

Filtering test content using assumptions does not produce test failures. Therefore, dead test code can result. Avoid this by monitoring filtered tests.

Methods

assumeClass	Assume exact class of specified value
assumeEmpty	Assume value is empty
assumeEqual	Assume value is equal to specified value
assumeError	Assume function throws specified exception
assumeFail	Produce unconditional assumption failure
assumeFalse	Assume value is false
assumeGreaterThan	Assume value is greater than specified value
assumeGreaterThanOrEqual	Assume value is greater than or equal to specified value
assumeInstanceOf	Assume value is object of specified type
assumeLength	Assume value has specified length
assumeLessThan	Assume value is less than specified value
assumeLessThanOrEqual	Assume value is less than or equal to specified value
assumeMatches	Assume string matches specified regular expression
assumeNotEmpty	Assume value is not empty

assumeNotEqual	Assume value is not equal to specified value
assumeNotSameHandle	Assume value is not handle to specified instance
assumeNumElements	Assume value has specified element count
assumeReturnsTrue	Assume function returns true when evaluated
assumeSameHandle	Assume two values are handles to same instance
assumeSize	Assume value has specified size
assumeSubstring	Assume string contains specified string
assumeThat	Assume value meets specified constraint
assumeTrue	Assume value is true
assumeWarning	Assume function issues specified warning
assumeWarningFree	Assume function issues no warnings

Events

`AssumptionFailed`	Triggered upon failing assumption. A `QualificationEventData` object is passed to listener callback functions.
`AssumptionPassed`	Triggered upon passing assumption. A `QualificationEventData` object is passed to listener callback functions.

Definitions

Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assumeEqual(actual, expected)
close(f)
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f)
testCase.assumeEqual(actual, expected)
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assumeEqual`.

```
% Not exception safe
f = figure;
testCase.assumeEqual(actual, expected)
testCase.addTeardown(@close, f)
```

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Write TestClassSetup Method Using Assumptions

Assumptions assure that a test runs only when certain preconditions are satisfied and when such an event should not produce a test failure. When an assumption failure occurs, the test is marked as filtered.

Create `IsSupportedTest` test case. Refer to the following `IsSupportedTest` test case in the subsequent steps in this example, which highlight specific functions in the file.

IsSupportedTest Class Definition File

```
classdef IsSupportedTest < matlab.unittest.TestCase
    methods(TestClassSetup)
        function TestPlatform(testcase)
            testcase.assumeFalse(ispc,...
                'Do not run any of these tests on Windows.')
        end
    end
    methods(Test)
        function test1(testcase)
            % write test code here
        end
    end
end
```

To execute the MATLAB commands in this example, add the `IsSupportedTest.m` file to a folder on your MATLAB path.

Write Test to Verify Platform. All tests in this test case must run on UNIX platforms only. The `TestPlatform` function uses the `assumeFalse` method to test if MATLAB is running on a Windows platform. If it is, the test fails.

```
function TestPlatform(testcase)
    testcase.assumeFalse(ispc,...
        'Do not run any of these tests on Windows.')
end
```

Make `TestPlatform` a `TestClassSetup` Test. To make the `TestPlatform` test a precondition, add it inside the `methods (TestClassSetup)` block.

Run the test case. Create a test case object and run the tests on a Windows platform.

```
tc = IsSupportedTest;
res = tc.run;

Running IsSupportedTest

================================================================================
All tests in IsSupportedTest were filtered.
    Test Diagnostic: Do not run any of these tests on Windows.
    Details
================================================================================

Done IsSupportedTest
__________

Failure Summary:

More About

- "Types of Qualifications"
- "Dynamically Filtered Tests"

Introduced in R2013a

assumeClass

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume exact class of specified value

Syntax

```
assumeClass(assumable,actual,className)
assumeClass(assumable,actual,metaClass)
assumeClass( ___ ,diagnostic)
```

Description

`assumeClass(assumable,actual,className)` assumes that actual is a MATLAB value whose class is the class specified by className.

`assumeClass(assumable,actual,metaClass)` assumes that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass. The instance must be an exact class match. See `assumeInstanceOf` to assume inclusion in a class hierarchy.

`assumeClass( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- The method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsOfClass;
  assumable.assumeThat(actual, IsOfClass(className));
  assumable.assumeThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyClass`, and replace calls to `verifyClass` with `assumeClass`.

`assumeInstanceOf` | `assumeThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeEmpty

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is empty

Syntax

```
assumeEmpty(assumable,actual)
assumeEmpty(assumable,actual,diagnostic)
```

Description

`assumeEmpty(assumable,actual)` assumes that actual is an empty MATLAB value.

`assumeEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assumable.assumeThat(actual, IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not

require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyEmpty`, and replace calls to `verifyEmpty` with `assumeEmpty`.

See Also

`assumeNotEmpty` | `assumeThat` | `isempty`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeEqual

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is equal to specified value

Syntax

```
assumeEqual(assumable,actual,expected)
assumeEqual( ___ ,Name,Value)
assumeEqual( ___ ,diagnostic)
```

Description

`assumeEqual(assumable,actual,expected)` assumes that actual is strictly equal to expected.

`assumeEqual( ___ ,Name,Value)` assumes equality with additional options specified by one or more Name,Value pair arguments.

`assumeEqual( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
```

```
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expected`

Expected value.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'AbsTol'`

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

Default:

`'RelTol'`

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied, `abs(expected-actual) <= relTol.*abs(expected)` must be true.

Default:

Examples

See examples for `verifyEqual`, and replace calls to `verifyEqual` with `assumeEqual`.

See Also

`assumeNotEqual` | `assumeThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeError

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume function throws specified exception

Syntax

```
assumeError(assumable,actual,identifier)
assumeError(assumable,actual,metaClass)
assumeError( ___ ,diagnostic)
```

Description

`assumeError(assumable,actual,identifier)` assumes that actual is a function handle that throws an exception with an error identifier that is equal to identifier.

`assumeError(assumable,actual,metaClass)` assumes that actual is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in metaClass. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assumeError( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  assumable.assumeThat(actual, Throws(identifier));
  assumable.assumeThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via `assumeThat`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`identifier`

Error identifier, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyError`, and replace calls to `verifyError` with `assumeError`.

See Also

`MException` | `assumeThat` | `assumeWarning` | `error`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeFail

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Produce unconditional assumption failure

Syntax

```
assumeFail(assumable)
assumeFail(assumable,diagnostic)
```

Description

`assumeFail(assumable)` produces an unconditional assumption failure when encountered.

`assumeFail(assumable,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Tips

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Examples

See examples for `verifyFail`, and replace calls to `verifyFail` with `assumeFail`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeFalse

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is false

Syntax

```
assumeFalse(assumable,actual)
assumeFalse(assumable,actual,diagnostic)
```

Description

`assumeFalse(assumable,actual)` assumes that actual is a scalar logical with the value of false.

`assumeFalse(assumable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  assumable.assumeThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via `assumeThat`.
- Unlike `assumeTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assumeTrue`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

For examples, see `verifyFalse`, and replace calls to `verifyFalse` with `assumeFalse`.

See Also

`assumeThat` | `assumeTrue`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeGreaterThan

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is greater than specified value

Syntax

```
assumeGreaterThan(assumable,actual,floor)
assumeGreaterThan(assumable,actual,floor,diagnostic)
```

Description

`assumeGreaterThan(assumable,actual,floor)` assumes that all elements of actual are greater than all the elements of floor.

`assumeGreaterThan(assumable,actual,floor,diagnostic)` also displays the diagnostic information in diagnostic upon a failure

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThan;
  assumable.assumeThat(actual, IsGreaterThan(floor));
  ```

  There exists more functionality when using the `IsGreaterThan` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as floor unless either one is scalar, at which point scalar expansion occurs.

`floor`

Minimum value, exclusive.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyGreaterThan`, and replace calls to `verifyGreaterThan` with `assumeGreaterThan`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeGreaterThanOrEqual

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is greater than or equal to specified value

Syntax

```
assumeGreaterThanOrEqual(assumable,actual,floor)
assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)
```

Description

`assumeGreaterThanOrEqual(assumable,actual,floor)` assumes that all elements of actual are greater than or equal to all the elements of floor.

`assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  assumable.assumeThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as floor unless either one is scalar, at which point scalar expansion occurs.

`floor`

Minimum value.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyGreaterThanOrEqual`, and replace calls to `verifyGreaterThanOrEqual` with `assumeGreaterThanOrEqual`.

See Also

`matlab.unittest.constraints.IsGreaterThanOrEqualTo` | `matlab.unittest.diagnostics.Diagnostic` | `assumeGreaterThan` | `assumeLessThan` | `assumeLessThanOrEqual` | `assumeThat` | `ge`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeInstanceOf

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is object of specified type

Syntax

```
assumeInstanceOf(assumable,actual,className)
assumeInstanceOf(assumable,actual,metaClass)
assumeInstanceOf( ___ ,diagnostic)
```

Description

`assumeInstanceOf(assumable,actual,className)` assumes that actual is a MATLAB value whose class is the class specified by className.

`assumeInstanceOf(assumable,actual,metaClass)` assumes that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass.

`assumeInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsInstanceOf;
  assumable.assumeThat(actual, IsInstanceOf(className));
  assumable.assumeThat(actual, IsInstanceOf(metaClass));
  ```

  There exists more functionality when using the `IsInstanceOf` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyInstanceOf`, and replace calls to `verifyInstanceOf` with `assumeInstanceOf`.

See Also

`assumeClass` | `assumeThat` | `isa`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeLength

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value has specified length

Syntax

```
assumeLength(assumable,actual,expectedLength)
assumeLength(assumable,actual,expectedLength,diagnostic)
```

Description

`assumeLength(assumable,actual,expectedLength)` assumes that actual is a MATLAB array whose length is expectedLength.

`assumeLength(assumable,actual,expectedLength,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasLength;
  assumable.assumeThat(actual, HasLength(expectedLength));
  ```

  There exists more functionality when using the `HasLength` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedLength`

The length of an array is defined as the largest dimension of that array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyLength`, and replace calls to `verifyLength` with `assumeLength`.

See Also

`assumeNumElements` | `assumeSize` | `assumeThat` | `length`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeLessThan

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is less than specified value

Syntax

```
assumeLessThan(assumable,actual,ceiling)
assumeLessThan(assumable,actual,ceiling,diagnostic)
```

Description

`assumeLessThan(assumable,actual,ceiling)` assumes that all elements of actual are less than all the elements of ceiling.

`assumeLessThan(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  assumable.assumeThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as ceiling unless either one is scalar, at which point scalar expansion occurs.

Default:

`ceiling`

Maximum value, exclusive.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyLessThan`, and replace calls to LessThan with `assumeLessThan`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeLessThanOrEqual

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is less than or equal to specified value

Syntax

```
assumeLessThanOrEqual(assumable,actual,ceiling)
assumeLessThanOrEqual(assumable,actual,ceiling,diagnostic)
```

Description

`assumeLessThanOrEqual(assumable,actual,ceiling)` assumes that all elements of actual are less than or equal to all the elements of ceiling.

`assumeLessThanOrEqual(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThanOrEqualTo;
  assumable.assumeThat(actual, IsLessThanOrEqualTo(ceiling));
  ```

  There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as ceiling unless either one is scalar, at which point scalar expansion occurs.

Default:

`ceiling`

Maximum value.

Default:

`diagnostic`

assumeMatches

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume string matches specified regular expression

Syntax

```
assumeMatches(assumable,actual,expression)
assumeMatches(assumable,actual,expression,diagnostic)
```

Description

`assumeMatches(assumable,actual,expression)` assumes that actual is a string that matches the regular expression defined by expression.

`assumeMatches(assumable,actual,expression,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  assumable.assumeThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The string to test.

Default:

`expression`

The value to match, specified as a regular expression.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyMatches`, and replace calls to `verifyMatches` with `assumeMatches`.

- "Types of Qualifications"

Introduced in R2013a

assumeNotEmpty

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is not empty

Syntax

```
assumeNotEmpty(assumable,actual)
assumeNotEmpty(assumable,actual,diagnostic)
```

Description

`assumeNotEmpty(assumable,actual)` assumes that actual is a non-empty MATLAB value.

`assumeNotEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  assumable.assumeThat(actual, ~IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotEmpty`, and replace calls to `verifyNotEmpty` with `assumeNotEmpty`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeNotEqual

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is not equal to specified value

Syntax

```
assumeNotEqual(assumable,actual,notExpected)
assumeNotEqual(assumable,actual,notExpected,diagnostic)
```

Description

`assumeNotEqual(assumable,actual,notExpected)` assumes that actual is not equal to notExpected.

`assumeNotEqual(assumable,actual,notExpected,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEqualTo;
  assumable.assumeThat(actual, ~IsEqualTo(notExpected));
  ```

  There exists more functionality when using the `IsEqualTo` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`notExpected`

Value to compare.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotEqual`, and replace calls to `verifyNotEqual` with `assumeNotEqual`.

See Also

`assumeEqual` | `assumeThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeNotSameHandle

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is not handle to specified instance

Syntax

```
assumeNotSameHandle(assumable,actual,notExpectedHandle)
assumeNotSameHandle(assumable,actual,notExpectedHandle,diagnostic)
```

Description

`assumeNotSameHandle(assumable,actual,notExpectedHandle)` assumes that actual is a different size and/or does not contain the same instances as the notExpectedHandle handle array.

`assumeNotSameHandle(assumable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assumable.assumeThat(actual, ~IsSameHandleAs(notExpectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`notExpectedHandle`

The handle array to compare.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotSameHandle`, and replace calls to `verifyNotSameHandle` with `assumeNotSameHandle`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeNumElements

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value has specified element count

Syntax

```
assumeNumElements(assumable,actual,expectedElementCount)
assumeNumElements(assumable,actual,expectedElementCount,diagnostic)
```

Description

`assumeNumElements(assumable,actual,expectedElementCount)` assumes that actual is a MATLAB array with expectedElementCount number of elements.

`assumeNumElements(assumable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasElementCount;
  assumable.assumeThat(actual, HasElementCount(expectedElementCount));
  ```

  There exists more functionality when using the `HasElementCount` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedElementCount`

The expected number of elements in the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNumElements`, and replace calls to `verifyNumElements` with `assumeNumElements`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeReturnsTrue

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume function returns true when evaluated

Syntax

```
assumeReturnsTrue(assumable,actual)
assumeReturnsTrue(assumable,actual,diagnostic)
```

Description

`assumeReturnsTrue(assumable,actual)` assumes that actual is a function handle that returns a scalar logical whose value is true.

`assumeReturnsTrue(assumable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assumeTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assumeTrue`.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  assumable.assumeThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyReturnsTrue`, and replace calls to `verifyReturnsTrue` with `assumeReturnsTrue`.

See Also

`assumeThat` | `assumeTrue`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeSameHandle

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume two values are handles to same instance

Syntax

```
assumeSameHandle(assumable,actual,expectedHandle)
assumeSameHandle(assumable,actual,expectedHandle,diagnostic)
```

Description

`assumeSameHandle(assumable,actual,expectedHandle)` assumes that actual is the same size and contains the same instances as the expectedHandle handle array.

`assumeSameHandle(assumable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  assumable.assumeThat(actual, IsSameHandleAs(expectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications

are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedHandle`

The expected handle array.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySameHandle`, and replace calls to `verifySameHandle` with `assumeSameHandle`.

See Also

`handle` | `assumeNotSameHandle` | `assumeThat`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeSize

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value has specified size

Syntax

```
assumeSize(assumable,actual,expectedSize)
assumeSize(assumable,actual,expectedSize,diagnostic)
```

Description

`assumeSize(assumable,actual,expectedSize)` assumes that actual is a MATLAB array whose size is expectedSize.

`assumeSize(assumable,actual,expectedSize,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasSize;
  assumable.assumeThat(actual, HasSize(expectedSize));
  ```

  There exists more functionality when using the `HasSize` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedSize`

The expected sizes of each dimension the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySize`, and replace calls to `verifySize` with `assumeSize`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeSubstring

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume string contains specified string

Syntax

```
assumeSubstring(assumable,actual,substring)
assumeSubstring(assumable,actual,substring,diagnostic)
```

Description

`assumeSubstring(assumable,actual,substring)` assumes that actual is a string that contains substring.

`assumeSubstring(assumable,actual,substring,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ContainsSubstring;
  assumable.assumeThat(actual, ContainsSubstring(substring));
  ```

  There exists more functionality when using the `ContainsSubstring` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs

to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`substring`

The value to match, specified as a string.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySubstring`, and replace calls to `verifySubstring` with `assumeSubstring`.

`assumeMatches` | `assumeThat` | `strfind`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeThat

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value meets specified constraint

Syntax

```
assumeThat(assumable,actual,constraint)
assumeThat(assumable,actual,constraint,diagnostic)
```

Description

`assumeThat(assumable,actual,constraint)` assumes that actual is a value that satisfies the constraint provided.

If the constraint is not satisfied, an assumption failure is produced utilizing only the framework diagnostic generated by the constraint.

`assumeThat(assumable,actual,constraint,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

When using this signature, both the diagnostic information contained within diagnostic is used in addition to the diagnostic information provided by the constraint.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`constraint`

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Tips

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Examples

See examples for `verifyThat`, and replace calls to `verifyThat` with `assumeThat`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeTrue

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume value is true

Syntax

```
assumeTrue(assumable,actual)
assumeTrue(assumable,actual,diagnostic)
```

Description

`assumeTrue(assumable,actual)` assumes that actual is a scalar logical with the value of true.

`assumeTrue(assumable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  assumable.assumeThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via `assumeThat`.

  Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered

to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `assumeReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyTrue`, and replace calls to `verifyTrue` with `assumeTrue`.

More About

- "Types of Qualifications"

Introduced in R2013a

assumeWarning

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume function issues specified warning

Syntax

```
assumeWarning(assumable,actual,warningID)
assumeWarning(assumable,actual,warningID,diagnostic)
[output1,...,outputN] = assumeWarning( ___ )
```

Description

`assumeWarning(assumable,actual,warningID)` assumes that actual issues a warning with the identifier warningID.

`assumeWarning(assumable,actual,warningID,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`[output1,...,outputN] = assumeWarning( ___ )` also return the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  assumable.assumeThat(actual, IssuesWarnings({warningID}));
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`warningID`

Warning ID, specified as a string.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Output Arguments

`output1,...,outputN`

Output arguments, 1 through n (if any), from actual, returned as any type. The argument type is specified by the actual argument list.

Examples

See examples for `verifyWarning`, and replace calls to `verifyWarning` with `assumeWarning`.

See Also

`assumeError` | `assumeThat` | `assumeWarningFree` | `warning`

More About

- "Types of Qualifications"

Introduced in R2013a

assumeWarningFree

Class: matlab.unittest.qualifications.Assumable
Package: matlab.unittest.qualifications

Assume function issues no warnings

Syntax

```
assumeWarningFree(assumable,actual)
assumeWarningFree(assumable,actual,diagnostic)
[output1,...,outputN] = assumeWarningFree( ___ )
```

Description

`assumeWarningFree(assumable,actual)` assumes that actual is a function handle that issues no warnings.

`assumeWarningFree(assumable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`[output1,...,outputN] = assumeWarningFree( ___ )` also returns the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  assumable.assumeThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assumeThat`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. Alternatively,

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`assumable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Output Arguments

`output1,...,outputN`

Output arguments, 1 through n (if any), from actual, returned as any type. The argument type is specified by the actual argument list.

Examples

See examples for `verifyWarningFree`, and replace calls to `verifyWarningFree` with `assumeWarningFree`.

More About

- "Types of Qualifications"

Introduced in R2013a

matlab.unittest.qualifications.AssumptionFailedException class

Package: matlab.unittest.qualifications

Exception used for assumption failures

Description

The `AssumptionFailedException` class provides an exception used for assumption failures. This class is used exclusively by the `Assumable` qualification type.

See Also

`MException` | `Assumable`

matlab.unittest.qualifications.ExceptionEventData class

Package: matlab.unittest.qualifications

Event data for ExceptionThrown event listeners

Description

The `ExceptionEventData` class holds event data for `ExceptionThrown` event listeners. `ExceptionThrown` event listeners are callback functions that you register with the testing framework to listen for the `TestRunner` to encounter an error during execution of test content. Typically, authors of custom plugins use this class. Only the test framework constructs this class directly.

Properties

`Exception`

Unexpected exception caught by `TestRunner` during its execution of test content

See Also

`matlab.unittest.TestRunner` | `matlab.unittest.plugins.TestRunnerPlugin` | `MException`

Introduced in R2014a

matlab.unittest.qualifications.FatalAssertable class

Package: matlab.unittest.qualifications

Qualification to abort test execution

Description

The `FatalAssertable` class provides a qualification to abort test execution. Apart from actions performed for failures, the `FatalAssertable` class works the same as `matlab.unittest` qualifications.

Upon a fatal assertion failure, the `FatalAssertable` class informs the testing framework of the failure by throwing a `FatalAssertionFailedException`. The test running framework then displays diagnostic information for the failure and aborts the entire test session. This is useful when the software under test contains so many errors that it does not make sense to continue the test session. Also, you can use fatal assertions in fixture teardown to guarantee the fixture state is restored correctly. If it is not restored, the full testing session will aborts and indicates to restart MATLAB before you resume testing. This allows later tests to run in a consistent MATLAB state. If you can recover the fixture teardown and make it "Exception Safe" on page 1-6381 for failures, use assertions instead.

Fatal assertions prevent false test failures due to the failure of a fundamental test. They also prevent false test failures when a prior test failed to restore test fixtures. If the test framework cannot properly tear down fixtures, restart MATLAB to ensure testing can resume in a clean state.

Methods

fatalAssertClass	Fatally assert exact class of specified value
fatalAssertEmpty	Fatally assert value is empty
fatalAssertEqual	Fatally assert value is equal to specified value

fatalAssertError	Fatally assert function throws specified exception
fatalAssertFail	Produce unconditional fatal assertion failure
fatalAssertFalse	Fatally assert value is false
fatalAssertGreaterThanOrEqual	Fatally assert value is greater than or equal to specified value
fatalAssertInstanceOf	Fatally assert value is object of specified type
fatalAssertLength	Fatally assert value has specified length
fatalAssertLessThan	Fatally assert value is less than specified value
fatalAssertLessThanOrEqual	Fatally assert value is less than or equal to specified value
fatalAssertMatches	Fatally assert string matches specified regular expression
fatalAssertNotEmpty	Fatally assert value is not empty
fatalAssertNotEqual	Fatally assert value is not equal to specified value
fatalAssertNotSameHandle	Fatally assert value is not handle to specified instance

fatalAssertNumElements	Fatally assert value has specified element count
fatalAssertReturnsTrue	Fatally assert function returns true when evaluated
fatalAssertSameHandle	Fatally assert two values are handles to same instance
fatalAssertSize	Fatally assert value has specified size
fatalAssertSubstring	Fatally assert string contains specified string
fatalAssertThat	Fatally assert value meets specified constraint
fatalAssertTrue	Fatally assert value is true
fatalAssertWarning	Fatally assert function issues specified warning
fatalAssertWarningFree	Fatally assert function issues no warnings

Events

`FatalAssertionFailed`	Triggered upon failing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.
`FatalAssertionPassed`	Triggered upon passing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.

Definitions

Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.fatalAssertEqual(actual, expected)
close(f)
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f)
testCase.fatalAssertEqual(actual, expected)
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `fatalAssertEqual`.

```
% Not exception safe
f = figure;
testCase.fatalAssertEqual(actual, expected);
testCase.addTeardown(@close, f)
```

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Write Helper Function Using Fatal Assertions

A fatal assertion renders the remainder of the current test method invalid because the state is unrecoverable. A *helper function* is a function in the `TestCase` class but not located within any of the `methods` block statement. Execution of these functions is not controlled by the `matlab.unittest` framework.

Add the `DocPolynomSaveLoadTest.m` file to a folder on your MATLAB path. Refer to the helper function, `cleanUpTemporaryFolder`, in the `DocPolynomSaveLoadTest` test case.

DocPolynomSaveLoadTest Class Definition File

```
classdef DocPolynomSaveLoadTest < matlab.unittest.TestCase

    methods (TestClassSetup)
        function addDocPolynomClassToPath(testCase)
            origPath = path;
            testCase.addTeardown(@path, origPath);
            addpath(fullfile(matlabroot, ...
                'help', 'techdoc', 'matlab_oop', 'examples'));
        end
    end

    methods (Test)
        function testSaveLoad(testCase)

            import matlab.unittest.diagnostics.Diagnostic;

            %% Phase 1: Setup
            % Create a temporary working folder
            tempFolder = tempname;
            [success, message] = mkdir(tempFolder);
            testCase.assertTrue(success, ...
                Diagnostic.join('Could not create temporary folder.',...
                message));
            testCase.addTeardown(@() testCase.cleanUpTemporaryFolder(...
                tempFolder));

            % Change to the temporay folder and register the
            % teardown, which restores the original folder
            origFolder = pwd;
```

```
            testCase.addTeardown(@cd, origFolder);
            cd(tempFolder);

            %% Phase 2: Exercise
            % Save the instance to a mat file.
            p = DocPolynom([1, 0, 1]);
            save('DocPolynomFile', 'p');

            % Validate Precondition. Save resulted in valid .mat file
            testCase.assertEqual(exist('DocPolynomFile.mat','file'),...
                2, Diagnostic.join(...
                'mat file was not saved correctly.',@() dir(pwd)));

            loaded = load('DocPolynomFile');

            %% Phase 3: Verify
            testCase.verifyEqual(loaded.p, p,...
                'Loaded polynom did not equal original polynom.');

            %% Phase 4: Teardown
            % Done inline via calls to addTeardown at the points
            % at which the state was changed.

        end
    end

    methods(Access=private)
        function cleanUpTemporaryFolder(testCase,tempFolder)
            % Clean up the temporary folder and fatally assert
            % that it was correctly cleaned up.

            import matlab.unittest.diagnostics.Diagnostic;

            [success, message] = rmdir(tempFolder, 's');
            testCase.fatalAssertTrue(success, ...
                Diagnostic.join('Could not remove temporary folder.',...
                message));
        end
    end

end
```

Make the `cleanUpTemporaryFolder` function a helper function by placing it inside a separate `methods` block.

```
methods(Access=private)
    function cleanUpTemporaryFolder(testCase, tempFolder)
        % code
    end
end
```

Use the `fatalAssertTrue` method to test the `rmdir` success argument for errors. If a fatal assertion occurs, the test run is aborted.

```
function cleanUpTemporaryFolder(testCase, tempFolder)

    import matlab.unittest.diagnostics.Diagnostic

    [success, message] = rmdir(tempFolder, 's');
    testCase.fatalAssertTrue(success, ...
        Diagnostic.join('Could not remove the temporary folder.',...
        message))
end
```

If the `rmdir` function fails, then this test has failed to restore the state of MATLAB and the machine at initial startup. Aborting prevents subsequent tests to fail because MATLAB is left in an unexpected state by this test.

- "Types of Qualifications"

Introduced in R2013a

fatalAssertClass

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert exact class of specified value

Syntax

```
fatalAssertClass(fatalAssertable,actual,className)
fatalAssertClass(fatalAssertable,actual,metaClass)
fatalAssertClass( ___ ,diagnostic)
```

Description

`fatalAssertClass(fatalAssertable,actual,className)` fatally asserts that actual is a MATLAB value whose class is the class specified by className.

`fatalAssertClass(fatalAssertable,actual,metaClass)` fatally asserts that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass.

`fatalAssertClass( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- The method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsOfClass;
  fatalAssertable.fatalAssertThat(actual, IsOfClass(className));
  fatalAssertable.fatalAssertThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is

no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyClass`, and replace calls to `verifyClass` with `fatalAssertClass`.

`fatalAssertInstanceOf` | `fatalAssertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertEmpty

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is empty

Syntax

```
fatalAssertEmpty(fatalAssertable,actual)
fatalAssertEmpty(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertEmpty(fatalAssertable,actual)` fatally asserts that actual is an empty MATLAB value.

`fatalAssertEmpty(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  fatalAssertable.fatalAssertThat(actual, IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyEmpty`, and replace calls to `verifyEmpty` with `fatalAssertEmpty`.

`fatalAssertNotEmpty` | `fatalAssertThat` | `isempty`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertEqual

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is equal to specified value

Syntax

```
fatalAssertEqual(fatalAssertable,actual,expected)
fatalAssertEqual( ___ ,Name,Value)
fatalAssertEqual( ___ ,diagnostic)
```

Description

`fatalAssertEqual(fatalAssertable,actual,expected)` fatally asserts that actual is strictly equal to expected .

`fatalAssertEqual( ___ ,Name,Value)` fatally asserts equality with additional options specified by one or more Name,Value pair arguments.

`fatalAssertEqual( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
fatalAassertable.fatalAssertThat(actual, IsEqualTo(expected, ...
```

```
    'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expected`

Expected value.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'AbsTol'`

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

Default:

`'RelTol'`

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied, `abs(expected-actual) <= relTol.*abs(expected)` must be true.

Default:

Examples

See examples for `verifyEqual`, and replace calls to `verifyEqual` with `fatalAssertEqual`.

See Also

`fatalAssertNotEqual` | `fatalAssertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertError

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert function throws specified exception

Syntax

```
fatalAssertError(fatalAssertable,actual,identifier)
fatalAssertError(fatalAssertable,actual,metaClass)
fatalAssertError( ___ ,diagnostic)
```

Description

`fatalAssertError(fatalAssertable,actual,identifier)` fatally asserts that actual is a function handle that throws an exception with an error identifier that is equal to identifier.

`fatalAssertError(fatalAssertable,actual,metaClass)` fatally asserts that actual is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in metaClass. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class..

`fatalAssertError( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  fatalAssertable.fatalAssertThat(actual, Throws(identifier));
  fatalAssertable.fatalAssertThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`identifier`

Error identifier, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyError`, and replace calls to `verifyError` with `fatalAssertError`.

See Also

`MException` | `error` | `fatalAssertThat` | `fatalAssertWarning`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertFail

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Produce unconditional fatal assertion failure

Syntax

```
fatalAssertFail(fatalAssertable)
fatalAssertFail(fatalAssertable,diagnostic)
```

Description

`fatalAssertFail(fatalAssertable)` produces an unconditional fatal assertion failure when encountered.

`fatalAssertFail(fatalAssertable,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Tips

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Examples

See examples for `verifyFail`, and replace calls to `verifyFail` with `fatalAssertFail`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertFalse

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is false

Syntax

```
fatalAssertFalse(fatalAssertable,actual)
fatalAssertFalse(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertFalse(fatalAssertable,actual)` fatally asserts that actual is a scalar logical with the value of false.

`fatalAssertFalse(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  fatalAssertable.fatalAssertThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via `fatalAssertThat`.
- Unlike `fatalAssertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `fatalAssertTrue`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyFalse`, and replace calls to `verifyFalse` with `fatalAssertFalse`.

`fatalAssertThat` | `fatalAssertTrue`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertGreaterThan

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is greater than specified value

Syntax

```
fatalAssertGreaterThan(fatalAssertable,actual,floor)
fatalAssertGreaterThan(fatalAssertable,actual,floor,diagnostic)
```

Description

`fatalAssertGreaterThan(fatalAssertable,actual,floor)` fatally asserts that all elements of actual are greater than all the elements of floor.

`fatalAssertGreaterThan(fatalAssertable,actual,floor,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  matlab.unittest.constraints.IsGreaterThan;
  fatalAssertable.fatalAssertThat(actual, IsGreaterThan(floor));
  ```

  There exists more functionality when using the `IsGreaterThan` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as floor unless either one is scalar, at which point scalar expansion occurs.

`floor`

Minimum value, exclusive.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Default:

Examples

See examples for `verifyGreaterThan`, and replace calls to `verifyGreaterThan` with `fatalAssertGreaterThan`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertGreaterThanOrEqual

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is greater than or equal to specified value

Syntax

```
fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor)
fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor,
diagnostic)
```

Description

`fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor)` fatally asserts that all elements of actual are greater than or equal to all the elements of floor.

`fatalAssertGreaterThanOrEqual(fatalAssertable,actual,floor, diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  fatalAssertable.fatalAssertThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as floor unless either one is scalar, at which point scalar expansion occurs.

`floor`

Minimum value.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertInstanceOf

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is object of specified type

Syntax

```
fatalAssertInstanceOf(fatalAssertable,actual,className)
fatalAssertInstanceOf(fatalAssertable,actual,metaClass)
fatalAssertInstanceOf( ___ ,diagnostic)
```

Description

`fatalAssertInstanceOf(fatalAssertable,actual,className)` fatally asserts that actual is a MATLAB value whose class is the class specified by className.

`fatalAssertInstanceOf(fatalAssertable,actual,metaClass)` fatally asserts that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass.

`fatalAssertInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsInstanceOf;
  fatalAssertable.fatalAssertThat(actual, IsInstanceOf(className));
  fatalAssertable.fatalAssertThat(actual, IsInstanceOf(metaClass));
  ```

  There exists more functionality when using the `IsInstanceOf` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is

no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyInstanceOf`, and replace calls to `verifyInstanceOf` with `fatalAssertInstanceOf`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertLength

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value has specified length

Syntax

```
fatalAssertLength(fatalAssertable,actual,expectedLength)
fatalAssertLength(fatalAssertable,actual,expectedLength,diagnostic)
```

Description

`fatalAssertLength(fatalAssertable,actual,expectedLength)` fatally asserts that actual is a MATLAB array whose length is expectedLength.

`fatalAssertLength(fatalAssertable,actual,expectedLength,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasLength;
  fatalAssertable.fatalAssertThat(actual, HasLength(expectedLength));
  ```

  There exists more functionality when using the `HasLength` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedLength`

The length of an array is defined as the largest dimension of that array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyLength`, and replace calls to `verifyLength` with `fatalAssertLength`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertLessThan

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is less than specified value

Syntax

```
fatalAssertLessThan(fatalAssertable,actual,ceiling)
fatalAssertLessThan(fatalAssertable,actual,ceiling,diagnostic)
```

Description

`fatalAssertLessThan(fatalAssertable,actual,ceiling)` fatally asserts that all elements of actual are less than all the elements of ceiling.

`fatalAssertLessThan(fatalAssertable,actual,ceiling,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  assertable.assertThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via `assertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as ceiling unless either one is scalar, at which point scalar expansion occurs.

Default:

`ceiling`

Maximum value, exclusive.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyLessThan`, and replace calls to `verifyLessThan` with `fatalAssertLessThan`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertLessThanOrEqual

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is less than or equal to specified value

Syntax

```
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling,
diagnostic)
```

Description

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)` fatally asserts that all elements of actual are less than or equal to all the elements of ceiling.

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling, diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThanOrEqualTo;
  fatalAssertable.fatalAssertThat(actual, IsLessThanOrEqualTo(ceiling));
  ```

  There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as ceiling unless either one is scalar, at which point scalar expansion occurs.

Default:

`actual`

The value to test.

Default:

`ceiling`

Maximum value.

fatalAssertMatches

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert string matches specified regular expression

Syntax

```
fatalAssertMatches(fatalAssertable,actual,expression)
fatalAssertMatches(fatalAssertable,actual,expression,diagnostic)
```

Description

`fatalAssertMatches(fatalAssertable,actual,expression)` fatally asserts that actual is a string that matches the regular expression defined by expression.

`fatalAssertMatches(fatalAssertable,actual,expression,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  fatalAssertable.fatalAssertThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expression`

The value to match, specified as a regular expression.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyMatches`, and replace calls to `verifyMatches` with `fatalAssertMatches`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertNotEmpty

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is not empty

Syntax

```
fatalAssertNotEmpty(fatalAssertable,actual)
fatalAssertNotEmpty(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertNotEmpty(fatalAssertable,actual)` fatally asserts that actual is a non-empty MATLAB value.

`fatalAssertNotEmpty(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  fatalAssertable.fatalAssertThat(actual, ~IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotEmpty`, and replace calls to `verifyNotEmpty` with `fatalAssertNotEmpty`.

fatalAssertNotEqual

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is not equal to specified value

Syntax

```
fatalAssertNotEqual(fatalAssertable,actual,notExpected)
fatalAssertNotEqual(fatalAssertable,actual,notExpected,diagnostic)
```

Description

`fatalAssertNotEqual(fatalAssertable,actual,notExpected)` fatally asserts that actual is not equal to notExpected.

`fatalAssertNotEqual(fatalAssertable,actual,notExpected,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEqualTo;
  fatalAssertable.fatalAssertThat(actual, ~IsEqualTo(notExpected));
  ```

  There exists more functionality when using the `IsEqualTo` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertNotSameHandle

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is not handle to specified instance

Syntax

```
fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle)
fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle,
diagnostic)
```

Description

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle)` fatally asserts that actual is a different size and/or does not contain the same instances as the notExpectedHandle handle array.

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle, diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  fatalAssertable.fatalAssertThat(actual, ~IsSameHandleAs(notExpectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`notExpectedHandle`

The handle array to compare.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNotSameHandle`, and replace calls to `verifyNotSameHandle` with `fatalAssertNotSameHandle`.

`fatalAssertSameHandle` | `fatalAssertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertNumElements

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value has specified element count

Syntax

```
fatalAssertNumElements(fatalAssertable,actual,expectedElementCount)
fatalAssertNumElements(fatalAssertable,actual,expectedElementCount,
diagnostic)
```

Description

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount)` fatally asserts that actual is a MATLAB array with expectedElementCount number of elements.

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount, diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasElementCount;
  fatalAssertable.fatalAssertThat(actual, HasElementCount(expectedElementCount));
  ```

  There exists more functionality when using the `HasElementCount` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedElementCount`

The expected number of elements in the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyNumElements`, and replace calls to `verifyNumElements` with `fatalAssertNumElements`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertReturnsTrue

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert function returns true when evaluated

Syntax

```
fatalAssertReturnsTrue(fatalAssertable,actual)
fatalAssertReturnsTrue(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertReturnsTrue(fatalAssertable,actual)` fatally asserts that actual is a function handle that returns a scalar logical whose value is true.

`fatalAssertReturnsTrue(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `fatalAssertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `fatalAssertTrue`.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  fatalAssertable.fatalAssertThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is

no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyReturnsTrue`, and replace calls to `verifyReturnsTrue` with `fatalAssertReturnsTrue`.

`fatalAssertThat` | `fatalAssertTrue`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertSameHandle

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert two values are handles to same instance

Syntax

```
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle,
diagnostic)
```

Description

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)` fatally asserts that actual is the same size and contains the same instances as the expectedHandle handle array.

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle, diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  fatalAssertable.fatalAssertThat(actual, IsSameHandleAs(expectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedHandle`

The expected handle array.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySameHandle`, and replace calls to `verifySameHandle` with `fatalAssertSameHandle`.

See Also

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertSize

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value has specified size

Syntax

```
fatalAssertSize(fatalAssertable,actual,expectedSize)
fatalAssertSize(fatalAssertable,actual,expectedSize,diagnostic)
```

Description

`fatalAssertSize(fatalAssertable,actual,expectedSize)` fatally asserts that actual is a MATLAB array whose size is expectedSize.

`fatalAssertSize(fatalAssertable,actual,expectedSize,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasSize;
  fatalAssertable.fatalAssertThat(actual, HasSize(expectedSize));
  ```

  There exists more functionality when using the `HasSize` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedSize`

The expected sizes of each dimension the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySize`, and replace calls to `verifySize` with `fatalAssertSize`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertSubstring

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert string contains specified string

Syntax

```
fatalAssertSubstring(fatalAssertable,actual,substring)
fatalAssertSubstring(fatalAssertable,actual,substring,diagnostic)
```

Description

`fatalAssertSubstring(fatalAssertable,actual,substring)` fatally asserts that actual is a string that contains substring.

`fatalAssertSubstring(fatalAssertable,actual,substring,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ContainsSubstring;
  fatalAssertable.fatalAssertThat(actual,...
  ContainsSubstring(substring));
  ```

  There exists more functionality when using the `ContainsSubstring` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution

of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`substring`

The value to match, specified as a string.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifySubstring`, and replace calls to `verifySubstring` with `fatalAssertSubstring`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertThat

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value meets specified constraint

Syntax

```
fatalAssertThat(fatalAssertable,actual,constraint)
fatalAssertThat(fatalAssertable,actual,constraint,diagnostic)
```

Description

`fatalAssertThat(fatalAssertable,actual,constraint)` fatally asserts that actual is a value that satisfies the constraint provided.

If the constraint is not satisfied, a fatal assertion failure is produced utilizing only the framework diagnostic generated by the constraint.

`fatalAssertThat(fatalAssertable,actual,constraint,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

When using this signature, both the diagnostic information contained within diagnostic is used in addition to the diagnostic information provided by the constraint.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`constraint`

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Tips

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Examples

See examples for `verifyThat`, and replace calls to `verifyThat` with `fatalAssertThat`.

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertTrue

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert value is true

Syntax

```
fatalAssertTrue(fatalAssertable,actual)
fatalAssertTrue(fatalAssertable,actual,diagnostic)
```

Description

`fatalAssertTrue(fatalAssertable,actual)` fatally asserts that actual is a scalar logical with the value of true.

`fatalAssertTrue(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  fatalAssertable.fatalAssertThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via `fatalAssertThat`.

  However, this method is optimized for performance and does not construct a new `IsTrue` constraint for each call. Sometimes such use can come at the expense of less

diagnostic information. Use the `fatalAssertReturnsTrue` method for a similar approach which may provide better diagnostic information.

- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

See examples for `verifyTrue`, and replace calls to `verifyTrue` with `fatalAssertTrue`.

`fatalAssertFalse` | `fatalAssertReturnsTrue` | `fatalAssertThat`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertWarning

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert function issues specified warning

Syntax

```
fatalAssertWarning(fatalAssertable,actual,warningID)
fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)
[output1,...,outputN] = fatalAssertWarning( ___ )
```

Description

`fatalAssertWarning(fatalAssertable,actual,warningID)` fatally asserts that actual issues a warning with the identifier warningID.

`fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`[output1,...,outputN] = fatalAssertWarning( ___ )` also returns the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  fatalAssertable.fatalAssertThat(actual, IssuesWarnings({warningID}));
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture

teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.
- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`warningID`

Warning ID, specified as a string.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Output Arguments

`output1,...,outputN`

Output arguments, 1 through n (if any), from actual, returned as any type. The argument type is specified by the actual argument list.

Examples

See examples for `verifyWarning`, and replace calls to `verifyWarning` with `fatalAssertWarning`.

See Also

`fatalAssertError` | `fatalAssertThat` | `fatalAssertWarningFree` | `warning`

More About

- "Types of Qualifications"

Introduced in R2013a

fatalAssertWarningFree

Class: matlab.unittest.qualifications.FatalAssertable
Package: matlab.unittest.qualifications

Fatally assert function issues no warnings

Syntax

```
fatalAssertWarningFree(fatalAssertable,actual)
fatalAssertWarningFree(fatalAssertable,actual,diagnostic)
[output1,...,outputN] = fatalAssertWarningFree( ___ )
```

Description

`fatalAssertWarningFree(fatalAssertable,actual)` fatally asserts that actual is a function handle that issues no warnings.

`fatalAssertWarningFree(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`[output1,...,outputN] = fatalAssertWarningFree( ___ )` also returns the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  fatalAssertable.fatalAssertThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via `fatalAssertThat`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture

teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. Alternatively,

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. For more information, see `matlab.unittest.qualifications.Verifiable`.

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

Input Arguments

`fatalAssertable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Output Arguments

`output1,...,outputN`

Output arguments, 1 through n (if any), from actual, returned as any type. The argument type is specified by the actual argument list.

Examples

See examples for `verifyWarningFree`, and replace calls to `verifyWarningFree` with `fatalAssertWarningFree`.

More About

- "Types of Qualifications"

Introduced in R2013a

matlab.unittest.qualifications.FatalAssertionFailedException class

Package: matlab.unittest.qualifications

Exception used for fatal assertion failures

Description

The `FatalAssertionFailedException` class provides an exception used for fatal assertion failures. This class is used exclusively by the `FatalAssertable` qualification type.

See Also

`MException` | `FatalAssertable`

matlab.unittest.qualifications.QualificationEventData class

Package: matlab.unittest.qualifications

Event data for qualification event listeners

Description

The `QualificationEventData` class holds event data for qualification event listeners. Qualification event listeners are callback functions that you register with the testing framework to listen for passing and/or failing qualifications. Qualifications can be assertions, fatal assertions, assumptions, or verifications performed on test content. The corresponding qualification classes define these events. Typically, authors of custom plugins use this class. Only the test framework constructs this class directly.

Properties

`ActualValue`

Value tested to satisfy the qualification logic of the `Constraint`

`Constraint`

Instance of `matlab.unittest.constraints.Constraint` used for the qualification

When you use a qualification method on a `TestCase` or `Fixture` object, the `Constraint` property contains the underlying constraint used for the qualification. For example, if you use the `verifyEqual` method, the underlying constraint is the `IsEqualTo` constraint. Therefore, if you invoke the constraint's `getDiagnosticFor` method, the diagnostic result can appear different than what the test framework displays.

`TestDiagnostic`

Diagnostic specified in the qualification, represented as a string, function handle, or instance of the `Diagnostic` class

`TestDiagnosticResult`

Result of diagnostic specified in the qualification, represented as a cell array of strings

`FrameworkDiagnosticResult`

Result of diagnostic from constraint used for the qualification, represented as a cell array of strings

`Stack`

Function call stack leading up to the qualification event, represented as a structure array

`matlab.unittest.qualifications.Assertable` | `matlab.unittest.qualifications.Assumable` | `matlab.unittest.qualifications.FatalAssertable` | `matlab.unittest.qualifications.Verifiable` | `matlab.unittest.fixtures.Fixture`

Introduced in R2014a

matlab.unittest.qualifications.Verifiable class

Package: matlab.unittest.qualifications

Qualification to produce soft-failure conditions

Description

The `Verifiable` class provides a qualification to produce soft-failure conditions. Apart from actions performed for failures, the `Verifiable` class works the same as other `matlab.unittest` qualifications.

Upon a verification failure, the `Verifiable` class informs the testing framework of the failure, including all diagnostic information associated with the failure, but continues to execute the currently running test without throwing an `MException`. This is most useful when a failure at the verification point is not fatal to the remaining test content. Often, you use verifications as the primary verification of a Four-Phase Test. Use other qualification types, such as assertions, fatal assertions, and assumptions, to test for violation of preconditions or incorrect test setup.

Since verifications do not throw `MExecptions`, all test content runs to completion even when verification failures occur. This helps you understand how close a piece of software is to meeting the test suite requirements. Qualification types that throw exceptions do not provide this insight, since once an exception is thrown an arbitrary amount of code remains that is not reached or exercised. Verifications also provide more testing coverage in failure conditions. However, when you overuse verifications, they can produce excess noise for a single failure condition. If a failure condition will cause later qualification points to also fail, use assertions or fatal assertions instead.

Methods

verifyClass	Verify exact class of specified value
verifyEmpty	Verify value is empty
verifyEqual	Verify value is equal to specified value

verifyError	Verify function throws specified exception
verifyFail	Produce unconditional verification failure
verifyFalse	Verify value is false
verifyGreaterThan	Verify value is greater than specified value
verifyGreaterThanOrEqual	Verify value is greater than or equal to specified value
verifyInstanceOf	Verify value is object of specified type
verifyLength	Verify value has specified length
verifyLessThan	Verify value is less than specified value
verifyLessThanOrEqual	Verify value is less than or equal to specified value
verifyMatches	Verify string matches specified regular expression
verifyNotEmpty	Verify value is not empty
verifyNotEqual	Verify value is not equal to specified value
verifyNotSameHandle	Verify value is not handle to specified instance
verifyNumElements	Verify value has specified element count
verifyReturnsTrue	Verify function returns true when evaluated

verifySameHandle	Verify two values are handles to same instance
verifySize	Verify value has specified size
verifySubstring	Verify string contains specified string
verifyThat	Verify value meets given constraint
verifyTrue	Verify value is true
verifyWarning	Verify function issues specified warning
verifyWarningFree	Verify function issues no warnings

Events

`VerificationFailed`	Triggered upon failing verification. A `QualificationEventData` object is passed to listener callback functions.
`VerificationPassed`	Triggered upon passing verification. A `QualificationEventData` object is passed to listener callback functions.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Write Test Methods Using Verifications

Verifications produce and record failures without throwing an exception, meaning the currently running test runs to completion. This example creates a test case to verify arithmetic operations on objects of the `DocPolynom` example class.

Create the `DocPolynomTest` Test Case. Refer to the following `DocPolynomTest` test case in the subsequent steps in this example, which highlight specific functions in the file.

DocPolynomTest Class Definition File

```
classdef DocPolynomTest < matlab.unittest.TestCase
    % Tests the DocPolynom class.

   properties
      msgEqn = 'Equation under test: ';
   end

   methods (TestClassSetup)
        function addDocPolynomClassToPath(testCase)
            testCase.addTeardown(@path,addpath(fullfile(matlabroot,...
                'help', 'techdoc', 'matlab_oop', 'examples')))
        end
    end

    methods (Test)
        function testConstructor(testCase)
            p = DocPolynom([1, 0, 1]);
            testCase.verifyClass(p, ?DocPolynom)
        end

        function testAddition(testCase)
            p1 = DocPolynom([1, 0, 1]);
            p2 = DocPolynom([5, 2]);

            actual = p1 + p2;
            expected = DocPolynom([1, 5, 3]);

            msg = [testCase.msgEqn,...
                '(x^2 + 1) + (5*x + 2) = x^2 + 5*x + 3'];
```

```
            testCase.verifyEqual(actual, expected, msg)
        end

        function testMultiplication(testCase)
            p1 = DocPolynom([1, 0, 3]);
            p2 = DocPolynom([5, 2]);

            actual = p1 * p2;
            expected = DocPolynom([5, 2, 15, 6]);

            msg = [testCase.msgEqn,...
                '(x^2 + 3) * (5*x + 2) = 5*x^3 + 2*x^2 + 15*x + 6'];
            testCase.verifyEqual(actual, expected, msg)
        end

    end
end
```

To execute the MATLAB commands in this example, add the `DocPolynomTest.m` file to a folder on your MATLAB path.

Write Test to Verify Constructor. Create a function, `testConstructor`, using the `verifyClass` method to test the `DocPolynom` class constructor.

```
function testConstructor(testCase)
    p = DocPolynom([1, 0, 1]);
    testCase.verifyClass(p, ?DocPolynom)
end
```

Write Tests to Verify Operations. In the `testAddition` function, use the `verifyEqual` method to test the equation `(x^2 + 1) + (5*x + 2) = x^2 + 5*x + 3`. The `verifyEqual` method includes this equation in the diagnostic argument.

```
function testAddition(testCase)
    p1 = DocPolynom([1, 0, 1]);
    p2 = DocPolynom([5, 2]);

    actual = p1 + p2;
    expected = DocPolynom([1, 5, 3]);

    msg = [testCase.msgEqn,...
        '(x^2 + 1) + (5*x + 2) = x^2 + 5*x + 3'];
    testCase.verifyEqual(actual, expected, msg)
end
```

The function, `testMultiplication`, tests multiplication operations.

Run the tests in the `DocPolynomTest` test case.

```
tc = DocPolynomTest;
ts = matlab.unittest.TestSuite.fromClass(?DocPolynomTest);
res = run(ts);
```

```
Running DocPolynomTest
...
Done DocPolynomTest
__________
```

All tests passed.

- "Types of Qualifications"

External Web Sites

- Four-Phase Test

Introduced in R2013a

verifyClass

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify exact class of specified value

Syntax

```
verifyClass(verifiable,actual,className)
verifyClass(verifiable,actual,metaClass)
verifyClass( ___ ,diagnostic)
```

Description

`verifyClass(verifiable,actual,className)` verifies that actual is a MATLAB value whose class is the class specified by className.

`verifyClass(verifiable,actual,metaClass)` verifies that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass. The instance must be an exact class match. Use `verifyInstanceOf` to verify inclusion in a class hierarchy.

`verifyClass( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- The method is functionally equivalent to the following methods:

  ```
  import matlab.unittest.constraints.IsOfClass;
  verifiable.verifyThat(actual, IsOfClass(className));
  verifiable.verifyThat(actual, IsOfClass(metaClass));
  ```

  There exists more functionality when using the `IsOfClass` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test a Class

These interactive tests verify the class of the number, 5.

Create a `TestCase` object and the value to test.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
actvalue = 5;
```

Verify class of `actvalue` is `double`.

```
verifyClass(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify class of `actvalue` is `char`.

```
verifyClass(testCase, actvalue, 'char');
```

```
Interactive verification failed.
```

```
----------------------
Framework Diagnostic:
----------------------
verifyClass failed.
--> The value's class is incorrect.

    Actual Class:
        double
    Expected Class:
        char

Actual Value:
         5
```

Test fails.

Test a Function Handle

These interactive tests verify function handles, specified as a meta.class instance, `?function_handle`.

Create a `TestCase` object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a function handle.

```
fh = @sin;
verifyClass(testCase, fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
verifyClass(testCase, fh, ?function_handle);
```

```
Interactive verification failed.

----------------------
Framework Diagnostic:
----------------------
verifyClass failed.
--> The value's class is incorrect.
```

```
    Actual Class:
        char
    Expected Class:
        function_handle

Actual Value:
    sin
```

Test fails.

Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, `BaseExample`.

```
classdef BaseExample
end
```

Create a derived class, `DerivedExample`.

```
classdef DerivedExample < BaseExample
end
```

Verify the classes are not equal.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyClass(testCase, DerivedExample(), ?BaseExample);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyClass failed.
--> The value's class is incorrect.

    Actual Class:
        DerivedExample
    Expected Class:
        BaseExample

Actual Value:
      DerivedExample with no properties.
```

Test fails.

Test Class of Output Value

Use `verifyClass` to test the `add5` function returns a `double` value.

Function for unit testing:

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.')
end
res = x + 5;
end
```

`TestCase` class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double')
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric')
        end
    end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m')
```

```
result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
__________
```

Introduced in R2013a

verifyEmpty

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is empty

Syntax

```
verifyEmpty(verifiable,actual)
verifyEmpty( ___ ,diagnostic)
```

Description

`verifyEmpty(verifiable,actual)` verifies that actual is an empty MATLAB value.

`verifyEmpty( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  verifiable.verifyThat(actual, IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures

result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.

- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test for Empty Strings

Create a `TestCase` object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifyEmpty(testCase, '');
```

```
Interactive verification passed.
```

Test for Empty Arrays

An array with any zero dimension is empty.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEmpty(testCase, ones(2, 5, 0, 3));
```

```
Interactive verification passed.
```

```
verifyEmpty(testCase, [2 3], 'Array is not empty.');
```

```
Interactive verification failed.

----------------
Test Diagnostic:
----------------
Array is not empty.

---------------------
Framework Diagnostic:
---------------------
verifyEmpty failed.
--> The value must be empty.
--> The value has a size of [1  2].

Actual Value:
         2     3
```

Test failed.

Test for Empty Cell Arrays

Test empty cell array, `{}`.

```
matlab.unittest.TestCase.forInteractiveUse;
verifyEmpty(testCase, {}, 'Cell array is not empty.');

Interactive verification passed.
```

A cell array of empty arrays is not empty.

```
verifyEmpty(testCase, {[], [], []}, 'Cell array is not empty.');

Interactive verification failed.

----------------
Test Diagnostic:
----------------
Cell array is not empty.

---------------------
Framework Diagnostic:
---------------------
verifyEmpty failed.
--> The value must be empty.
--> The value has a size of [1  3].

Actual Value:
        []    []    []
```

Test failed.

Test for Empty Test Suite

Test for empty object, `emptyTestSuite`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
emptyTestSuite = matlab.unittest.TestSuite.empty;
verifyEmpty(testCase, emptyTestSuite);

Interactive verification passed.
```

More About

- "Types of Qualifications"

Introduced in R2013a

verifyEqual

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is equal to specified value

Syntax

```
verifyEqual(verifiable,actual,expected)
verifyEqual( ___ ,Name,Value)
verifyEqual( ___ ,diagnostic)
```

Description

`verifyEqual(verifiable,actual,expected)` verifies that actual is strictly equal to expected.

`verifyEqual( ___ ,Name,Value)` verifies equality with additional options specified by one or more Name,Value pair arguments.

`verifyEqual( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure

Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
verifiable.verifyThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
```

```
    'Within', RelativeTolerance(reltol)));

import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
verifiable.verifyThat(actual, IsEqualTo(expected, ...
    'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expected`

Expected value.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'AbsTol'`

Absolute tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For an absolute tolerance to be satisfied, `abs(expected-actual) <= absTol` must be true.

Default:

`'RelTol'`

Relative tolerance, specified as a numeric array. The tolerance is applied only to values of the same data type. The value can be a scalar or array the same size as the actual and expected values.

For a relative tolerance to be satisfied, `abs(expected-actual) <= relTol.*abs(expected)` must be true.

Default:

Examples

Comparing Numeric Values

Numeric values are equivalent if they are of the same class with equivalent size, complexity, and sparsity.

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

A value is equal to itself.

```
verifyEqual(testCase, 5, 5);
```

```
Interactive verification passed.
```

Values must have equal sizes.

```
verifyEqual(testCase, [5 5], 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
--> Sizes do not match.

    Actual double size:
              1     2
    Expected double size:
```

```
             1     1

Actual Value:
         5     5
Expected Value:
         5
```

Test failed.

Test Classes

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEqual(testCase, int8(5), int16(5));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
--> Classes do not match.

    Actual Class:
        int8
    Expected Class:
        int16

Actual Value:
        5
Expected Value:
         5
```

Test failed.

Test Cell Arrays

Each element of a cell array must be equal in value, class, and size.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});
```

```
Interactive verification passed.
```

Test Numeric Tolerances

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifyEqual(testCase, 4.95, 5);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
--> The values are not equal using "isequaln".
--> Failure table:
            Index    Actual    Expected           Error               RelativeError
            _____    ______    ________    ___________________    ____________________

            1        4.95      5           -0.0499999999999998    -0.00999999999999996

Actual Value:
       4.950000000000000
Expected Value:
         5
```

Test failed.

```
verifyEqual(testCase, 1.5, 2, 'AbsTol', 1)

Interactive verification passed.

verifyEqual(testCase, 1.5, 2, 'RelTol', 0.1, ...
    'Difference between actual and expected exceeds relative tolerance')

Interactive verification failed.

----------------
Test Diagnostic:
----------------
Difference between actual and expected exceeds relative tolerance

---------------------
Framework Diagnostic:
---------------------
verifyEqual failed.
--> The values are not equal using "isequaln".
--> The error was not within relative tolerance.
--> Failure table:
            Index    Actual    Expected    Error    RelativeError    RelativeTolerance
            _____    ______    ________    _____    _____________    _________________
```

```
           1        1.5        2           -0.5      -0.25            0.1

Actual Value:
       1.500000000000000
Expected Value:
         2
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyError

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify function throws specified exception

Syntax

```
verifyError(verifiable,actual,identifier)
verifyError(verifiable,actual,metaClass)
verifyError( ___ ,diagnostic)
```

Description

`verifyError(verifiable,actual,identifier)` verifies that actual is a function handle that throws an exception with an error identifier that is equal to identifier.

`verifyError(verifiable,actual,metaClass)` verifies that actual is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in metaClass. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`verifyError( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Throws;
  verifiable.verifyThat(actual, Throws(identifier));
  verifiable.verifyThat(actual, Throws(metaClass));
  ```

  There exists more functionality when using the `Throws` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`identifier`

Error identifier, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test for Error IDs

```
testCase = matlab.unittest.TestCase.forInteractiveUse;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%
verifyError(testCase, @() error('SOME:error:id','Error!'), 'SOME:error:id');
verifyError(testCase, @testCase.assertFail, ...
    ?matlab.unittest.qualifications.AssertionFailedException);

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%
verifyError(testCase, 5, 'some:id', '5 is not a function handle');
verifyError(testCase, @testCase.verifyFail, ...
    ?matlab.unittest.qualifications.AssertionFailedException, ...
    'Verifications dont throw exceptions.');
verifyError(testCase, @() error('SOME:id'), 'OTHER:id', 'Wrong id');
verifyError(testCase, @() error('whoops'), ...
    ?matlab.unittest.qualifications.AssertionFailedException, ...
```

```
    'Wrong type of exception thrown');
```

Test Error Condition

Create `testNonNumericInput` to test if function throws expected error message, `add5:InputMustBeNumeric`, for unexpected condition, input is `char`.

Function for unit testing:

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.')
end
res = x + 5;
end
```

`TestCase` class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double')
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric')
        end
    end
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m')
```

```
result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
__________
```

More About

- "Types of Qualifications"

Introduced in R2013a

verifyFail

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Produce unconditional verification failure

Syntax

```
verifyFail(verifiable)
verifyFail(verifiable,diagnostic)
```

Description

`verifyFail(verifiable)` produces an unconditional verification failure when encountered.

`verifyFail(verifiable,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Tips

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Examples

Test for Failure Condition

An example of where this method may be used is in a callback function that should not be executed in a given scenario. A test can confirm this does not occur by unconditionally performing a failure if the code path is reached.

Create a handle class, `MyHandle`, with a `SomethingHappened` event.

```
classdef MyHandle < handle
    events
        SomethingHappened
    end
```

```
end
```

Create a file, `ListenerTest`, on your MATLAB path that contains the following `TestCase` class.

```
classdef ListenerTest < matlab.unittest.TestCase
    methods(Test)
        function testDisabledListeners(testCase)
            h = MyHandle;

            % Add a listener to a test helper method
            listener = h.addlistener('SomethingHappened', ...
                @testCase.shouldNotGetCalled);

            % Passing scenario (code path is not reached)
            %%%%%%%%%%%%%%%%%%%%%
            % Disabled listener should not invoke callbacks
            listener.Enabled = false;
            h.notify('SomethingHappened');

            % Failing scenario (code path is reached)
            %%%%%%%%%%%%%%%%%%%%%
            % Enabled listener invoke callback and fail
            listener.Enabled = true;
            h.notify('SomethingHappened');
        end
    end

    methods
        function shouldNotGetCalled(testCase, ~, ~)
            % A test helper callback method that should not execute
            testCase.verifyFail('This listener callback should not have executed');
        end
    end

end
```

From the command prompt, run the test.

```
run(ListenerTest);
```

```
Running ListenerTest

================================================================================
Verification failed in ListenerTest/testDisabledListeners.
```

```
    ----------------
    Test Diagnostic:
    ----------------
    This listener callback should not have executed

More About

- "Types of Qualifications"

Introduced in R2013a

verifyFalse

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is false

Syntax

```
verifyFalse(verifiable,actual)
verifyFalse( ___ ,diagnostic)
```

Description

`verifyFalse(verifiable,actual)` verifies that actual is a scalar logical with the value of false.

`verifyFalse( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsFalse;
  verifiable.verifyThat(actual, IsFalse());
  ```

  There exists more functionality when using the `IsFalse` constraint directly via `verifyThat`.
- Unlike `verifyTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `verifyTrue`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test MATLAB Logical Functions

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test `true`.

```
verifyFalse(testCase, true);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must evaluate to "false".

Actual Value:
         1
```

Test failed.

Test `false`.

```
verifyFalse(testCase, false);
```

```
Interactive verification passed.
```

Test the Value 0

The number `0` is a `double` value, not a logical value.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifyFalse(testCase, 0);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must be logical. It is of type "double".

Actual Value:
         0
```

Test failed.

Test Array of Logical Values

To be false, the value must be scalar.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyFalse(testCase, [false false false]);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         0     0     0
```

Test failed.

Test an array of mixed logical values.

```
verifyFalse(testCase, [false true false], ...
    'A mixed array of logicals is not the one false value');

Interactive verification failed.

---------------
Test Diagnostic:
---------------
```

```
A mixed array of logicals is not the one false value

---------------------
Framework Diagnostic:
---------------------
verifyFalse failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         0     1     0
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyGreaterThan

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is greater than specified value

Syntax

```
verifyGreaterThan(verifiable,actual,floor)
verifyGreaterThan( ___ ,diagnostic)
```

Description

`verifyGreaterThan(verifiable,actual,floor)` verifies that all elements of actual are greater than all the elements of floor.

`verifyGreaterThan( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  matlab.unittest.constraints.IsGreaterThan;
  verifiable.verifyThat(actual, IsGreaterThan(floor));
  ```

  There exists more functionality when using the `IsGreaterThan` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as floor unless either one is scalar, at which point scalar expansion occurs.

`floor`

Minimum value, exclusive.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify `3` is greater than `2`.

```
verifyGreaterThan(testCase, 3, 2);
```

```
Interactive verification passed.
```

Test if `5` is greater than `9`.

```
verifyGreaterThan(testCase, 5, 9);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThan failed.
--> The value must be greater than the minimum value.

Actual Value:
         5
Minimum Value (Exclusive):
         9
```

Test failed.

Compare an Array to a Scalar

Test if each element is greater than the FLOOR value, `2`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThan(testCase, [5 6 7], 2);

Interactive verification passed.
```

Test if value `5` is greater than each element in the FLOOR array, `[1 2 3]`.

```
verifyGreaterThan(testCase, 5, [1 2 3]);

Interactive verification passed.
```

Test if each element in the matrix is greater than the FLOOR value, `4`.

```
verifyGreaterThan(testCase, [1 2 3; 4 5 6], 4);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThan failed.
--> Each element must be greater than the minimum value.

    Failing Indices:
              1     2     3     5

Actual Value:
         1     2     3
         4     5     6
Minimum Value (Exclusive):
         4
```

Test failed.

Compare Arrays

Test if each element is greater than each corresponding element of the FLOOR array, `[4 -9 0]`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThan(testCase, [5 -3 2], [4 -9 0]);

Interactive verification passed.
```

Compare an array to itself.

```
verifyGreaterThan(testCase, eye(2), eye(2));

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThan failed.
--> Each element must be greater than each corresponding element of the minimum value a

    Failing Indices:
              1     2     3     4

Actual Value:
         1     0
         0     1
Minimum Value (Exclusive):
         1     0
         0     1
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyGreaterThanOrEqual

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is greater than or equal to specified value

Syntax

```
verifyGreaterThanOrEqual(verifiable,actual,floor)
verifyGreaterThanOrEqual( ___ ,diagnostic)
```

Description

`verifyGreaterThanOrEqual(verifiable,actual,floor)` that all elements of actual are greater than or equal to all the elements of floor.

`verifyGreaterThanOrEqual( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
  verifiable.verifyThat(actual, IsGreaterThanOrEqualTo(floor));
  ```

  There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as floor unless either one is scalar, at which point scalar expansion occurs.

`floor`

Minimum value.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify `3` is greater than `2`.

```
verifyGreaterThanOrEqual(testCase, 3, 2);
```

```
Interactive verification passed.
```

Verify `3` is greater than or equal to `3`.

```
verifyGreaterThanOrEqual(testCase, 3, 3);
```

```
Interactive verification passed.
```

Test if `5` is greater than `9`.

```
verifyGreaterThanOrEqual(testCase, 5, 9);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThanOrEqual failed.
--> The value must be greater than or equal to the minimum value.

Actual Value:
         5
Minimum Value (Inclusive):
         9
```

Test failed.

Compare an Array to a Scalar

Test if each element is greater than or equal to the FLOOR value, `2`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThanOrEqual(testCase, [5 2 7], 2);
```

```
Interactive verification passed.
```

Test if each element in the matrix is greater than or equal to the FLOOR value, `4`.

```
verifyGreaterThanOrEqual(testCase, [1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyGreaterThanOrEqual failed.
--> Each element must be greater than or equal to the minimum value.

    Failing Indices:
              1     3     5

Actual Value:
         1     2     3
         4     5     6
Minimum Value (Inclusive):
         4
```

Compare Arrays

Test if each element is greater than or equal to each corresponding element of the FLOOR array, `[4 -3 0]`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThanOrEqual(testCase, [5 -3 2], [4 -3 0]);
```

```
Interactive verification passed.
```

Compare an array to itself.

```
verifyGreaterThanOrEqual(testCase, eye(2), eye(2));
```

```
Interactive verification passed.
```

More About

- "Types of Qualifications"

Introduced in R2013a

verifyInstanceOf

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is object of specified type

Syntax

```
verifyInstanceOf(verifiable,actual,className)
verifyInstanceOf(verifiable,actual,metaClass)
verifyInstanceOf( ___ ,diagnostic)
```

Description

`verifyInstanceOf(verifiable,actual,className)` verifies that actual is a MATLAB value whose class is the class specified by className.

`verifyInstanceOf(verifiable,actual,metaClass)` verifies that actual is a MATLAB value whose class is the class specified by the `meta.class` instance metaClass.

`verifyInstanceOf( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsInstanceOf;
  verifiable.verifyThat(actual, IsInstanceOf(className));
  verifiable.verifyThat(actual, IsInstanceOf(metaClass));
  ```

  There exists more functionality when using the `IsInstanceOf` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to

completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`className`

Name of class, specified as a string.

Default:

`metaClass`

An instance of `meta.class`.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test a Class

These interactive tests verify the class of the number, 5.

Create a `TestCase` object and the value to test.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
actvalue = 5;
```

Verify `actvalue` is an instance of class `double`.

```
verifyInstanceOf(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify if `actvalue` is an instance of `char`.

```
verifyInstanceOf(testCase, 5, 'char');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
```

```
---------------------
verifyInstanceOf failed.
--> The value must be an instance of the expected type.

    Actual Class:
        double
    Expected Type:
        char

Actual Value:
         5
```

Test failed.

Test a Function Handle

These tests verify function handles, specified as a meta.class instance, `?function_handle`.

Create a function handle.

```
fh = @sin;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyInstanceOf(testCase, fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
verifyInstanceOf(testCase, fh, ?function_handle);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyInstanceOf failed.
--> The value must be an instance of the expected type.

    Actual Class:
        char
    Expected Type:
        function_handle
```

```
Actual Value:
    sin
```

Test failed.

Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, `BaseExample`.

```
classdef BaseExample
end
```

Create a derived class, `DerivedExample`.

```
classdef DerivedExample < BaseExample
end
```

Verify `DerivedExample` is an instance of `BaseExample`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
testCase.verifyInstanceOf(DerivedExample(), ?BaseExample);
```

```
Interactive verification passed.
```

Verify `BaseExample` is not an instance of `DerivedExample`.

```
testCase.verifyInstanceOf(BaseExample(), ?DerivedExample);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyInstanceOf failed.
--> The value must be an instance of the expected type.

    Actual Class:
        BaseExample
    Expected Type:
        DerivedExample

Actual Value:
      BaseExample with no properties.
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyLength

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value has specified length

Syntax

```
verifyLength(verifiable,actual,expectedLength)
verifyLength( ___ ,diagnostic)
```

Description

`verifyLength(verifiable,actual,expectedLength)` verifies that actual is a MATLAB array whose length is expectedLength.

`verifyLength( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasLength;
  verifiable.verifyThat(actual, HasLength(expectedLength));
  ```

  There exists more functionality when using the `HasLength` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedLength`

The length of an array is defined as the largest dimension of that array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test Array Lengths

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify length of array is the expected value, 5.

```
verifyLength(testCase, ones(2, 5, 3), 5, 'User diagnostic');
```

```
Interactive verification passed.
```

Length of array is not the expected value, 3.

```
verifyLength(testCase, [2 3], 3);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLength failed.
--> The array has an incorrect length.

    Actual Length:
                2
    Expected Length:
                3

Actual Array:
         2     3
```

Test failed.

The length of a 2x3 array is 3.

```
verifyLength(testCase, [1 2 3; 4 5 6], 3);
```

```
Interactive verification passed.
```

Verify the length of a 2x3 array is not the number of elements, 6.

```
verifyLength(testCase, [1 2 3; 4 5 6], 6);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLength failed.
--> The array has an incorrect length.

    Actual Length:
             3
    Expected Length:
             6

Actual Array:
         1     2     3
         4     5     6
```

Test failed.

```
verifyLength(testCase, eye(2), 4);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLength failed.
--> The array has an incorrect length.

    Actual Length:
             2
    Expected Length:
             4

Actual Array:
```

```
     1     0
     0     1
```

Test Cell Array Lengths

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLength(testCase, {'somestring', 'someotherstring'}, 2);
```

```
Interactive verification passed.
```

More About

- "Types of Qualifications"

Introduced in R2013a

verifyLessThan

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is less than specified value

Syntax

```
verifyLessThan(verifiable,actual,ceiling)
verifyLessThan( ___ ,diagnostic)
```

Description

`verifyLessThan(verifiable,actual,ceiling)` verifies that all elements of actual are less than all the elements of ceiling.

`verifyLessThan( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsLessThan;
  verifiable.verifyThat(actual, IsLessThan(ceiling));
  ```

  There exists more functionality when using the `IsLessThan` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test. actual must be the same size as ceiling unless either one is scalar, at which point scalar expansion occurs.

Default:

`ceiling`

Maximum value, exclusive.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify `2` is less than `3`.

```
verifyLessThan(testCase, 2, 3);
```

```
Interactive verification passed.
```

Test if `9` is less than `5`.

```
verifyLessThan(testCase, 9, 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLessThan failed.
--> The value must be less than the maximum value.

Actual Value:
         9
Maximum Value (Exclusive):
         5
```

Test failed.

Compare an Array to a Scalar

Test if each element is less than the CEILING value, `9`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThan(testCase, [5 6 7], 9);

Interactive verification passed.
```

Test if each element in the matrix is less than the CEILING value, `4`.

```
verifyLessThan(testCase, [1 2 3; 4 5 6], 4);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyLessThan failed.
--> Each element must be less than the maximum value.

    Failing Indices:
              2     4     6

Actual Value:
         1     2     3
         4     5     6
Maximum Value (Exclusive):
         4
```

Test failed.

Compare Arrays

Test if each element is less than each corresponding element of the CEILING array, `[7 -1 8]`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThan(testCase, [5 -3 2], [7 -1 8]);

Interactive verification passed.
```

Compare an array to itself.

```
verifyLessThan(testCase, eye(2), eye(2));

Interactive verification failed.

---------------------
```

```
Framework Diagnostic:
---------------------
verifyLessThan failed.
--> Each element must be less than each corresponding element of the maximum value arra

    Failing Indices:
              1     2     3     4

Actual Value:
         1     0
         0     1
Maximum Value (Exclusive):
         1     0
         0     1
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyMatches

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify string matches specified regular expression

Syntax

```
verifyMatches(verifiable,actual,expression)
verifyMatches( ___ ,diagnostic)
```

Description

`verifyMatches(verifiable,actual,expression)` that actual is a string that matches the regular expression defined by expression.

`verifyMatches( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.Matches;
  verifiable.verifyThat(actual, Matches(expression));
  ```

  There exists more functionality when using the `Matches` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The string to test.

Default:

`expression`

The value to match, specified as a regular expression.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test for String Matches

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify that strings matches a regular expression.

```
verifyMatches(testCase, 'Some String', 'Some [Ss]tring', ...
    'My result should have matched the expression');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another string', '(Some |An)other');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another 3 strings', '^Another \d+ strings?$');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, '3 more strings', '\d+ strings?');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyMatches failed.
--> The string did not match the regular expression.

Actual String:
    3 more strings
Regular Expression:
    \d+ strings?
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyNotEmpty

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is not empty

Syntax

```
verifyNotEmpty(verifiable,actual)
verifyNotEmpty( ___ ,diagnostic)
```

Description

`verifyNotEmpty(verifiable,actual)` verifies that actual is a non-empty MATLAB value.

`verifyNotEmpty( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEmpty;
  verifiable.verifyThat(actual, ~IsEmpty());
  ```

  There exists more functionality when using the `IsEmpty` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test for Non-Empty Strings

Create a `TestCase` object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifyNotEmpty(testCase, '');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [0  0].

Actual Value:
         ''
```

Test failed.

Test for Non-Empty Arrays

An array with any zero dimension is empty.

Test array `[2 3]`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, [2 3]);
```

```
Interactive verification passed.
```

Test array with a zero dimension.

```
verifyNotEmpty(testCase, ones(2, 5, 0, 3));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEmpty failed.
```

```
--> The value must not be empty.
--> The value has a size of [2  5  0  3].

Actual Value:
       Empty array: 2-by-5-by-0-by-3
```

Test failed.

Test for Non-Empty Cell Arrays

A cell array of empty arrays is not empty.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, {[], [], []}, '');
```

```
Interactive verification passed.
```

Test for Non-Empty Test Suite

Test an empty object, `emptyTestSuite`.

```
emptyTestSuite = matlab.unittest.TestSuite.empty;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, emptyTestSuite);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [0  0].

Actual Value:
      0x0 TestCase array with no properties.
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyNotEqual

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is not equal to specified value

Syntax

```
verifyNotEqual(verifiable,actual,notExpected)
verifyNotEqual( ___ ,diagnostic)
```

Description

`verifyNotEqual(verifiable,actual,notExpected)` verifies that actual is not equal to notExpected.

`verifyNotEqual( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsEqualTo;
  verifiable.verifyThat(actual, ~IsEqualTo(notExpected));
  ```

  There exists more functionality when using the `IsEqualTo` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`notExpected`

Value to compare.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Compare Numeric Values
