Syntax

```
docsearch
docsearch expression
```

Description

`docsearch` opens the Help browser and displays the documentation home page. If the Help browser is already open, but not visible, then `docsearch` brings it to the foreground.

`docsearch expression` searches MathWorks documentation for pages with words that match the specified expression and highlights them. To clear highlighting, press the **Esc** key. The `docsearch` command does not search third-party or custom documentation.

Examples

Single Words

Find all documentation pages that contain the word *plot*.

```
docsearch plot
```

Multiple Words

Find documentation pages with the words *plot* and *tools*.

```
docsearch plot tools
```

Expand the search to include variations of the word *plot*, such as *plotting* or *plots*, using a wildcard character.

```
docsearch plot* tools
```

Narrow the search to pages that include an exact phrase by enclosing the phrase in quotation marks.

```
docsearch "plot tools"
```

Find pages with either word, but not necessarily both words, using the `OR` operator.

```
docsearch plot OR tools
```

Input Arguments

`expression` — Expression that defines search terms

string

Expression that defines search terms, specified as a string. Expressions can include:

- Quotation marks to specify exact phrases, such as `"plot tools"`.
- Boolean operator keywords in uppercase (listed here in order of precedence): `NOT`, `OR`, `AND`.
- Asterisk (`*`) wildcard characters, except at the beginning of a word or in an exact phrase. Searches require that at least two characters in the expression are *not* wildcard characters.

More About

Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.
- “Search Syntax and Tips”

Introduced before R2006a

dos

Execute DOS command and return output

Syntax

```
status = dos(command)
[status,cmdout] = dos(command)
[status,cmdout] = dos(command,'-echo')
```

Description

`status = dos(command)` executes the specified DOS command for Windows platforms, and waits for the command to finish execution before returning the exit status to the status variable.

`[status,cmdout] = dos(command)` additionally returns the output of the DOS command to cmdout. This syntax is most useful for DOS console commands that do not require user input, such as `dir`.

`[status,cmdout] = dos(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for DOS console commands that require user input and that run correctly in the MATLAB Command Window, such as `comp`.

Examples

Save DOS Command Exit Status

Issue a DOS command to create a new folder named `mynew` and save the exit status to a variable.

```
command = 'mkdir mynew';
status = dos(command)
```

```
status =
```

```
     0
```

The `status` of zero indicates that the `mynew` folder was created successfully.

Open and Run a Windows UI Command

Open Notepad and immediately return the exit status to MATLAB by appending an ampersand (`&`) to the `notepad` command.

```
status = dos('notepad &')
```

```
status =

     0
```

The `status` of zero indicates that Notepad successfully started.

Save Successful DOS Command Status and Output

Execute the DOS command, `dir`, and view the exit status and command output.

```
[status,cmdout] = dos('dir');
status, cmdout
```

```
status =

     0

cmdout =

 Volume in drive C is OSDisk
 Volume Serial Number is XXX-XXXX

 Directory of C:\my_MATLAB_files

04/10/2012  12:08 PM <DIR>          .
04/10/2012  12:08 PM <DIR>          ..
04/21/2011  09:24 AM               171 base.mat
02/08/2010  05:14 PM                73 baseball.dat
04/10/2012  12:08 PM               474 collatz.asv
04/10/2012  11:56 AM               480 collatz.m
.
.
.
```

When you issue a valid DOS command, `status` indicates success and `cmdout` contains the command output.

Save Unsuccessful DOS Command Status and Output

Attempt to execute a command called `foo`. Then, view the `status` and `results` output arguments.

```
[status,results] = dos('foo');
status, results
```

```
status =

     1

results =

'foo' is not recognized as an internal or external command,
operable program or batch file.
```

When you issue an invalid DOS command, `status` indicates failure and `results` contains the DOS error message.

Display DOS Command Output in MATLAB Command Window

Display command output and prompts in the Command Window as the command executes, and also assign the command output to the `results` variable.

```
[status,results] = dos('comp', '-echo');
```

```
Name of first file to compare: collatz.m
collatz.m
Name of second file to compare: collatz.asv
collatz.asv
Option: /A
/A
Option:

Comparing collatz.m and collatz.asv...
Files compare OK

Compare more files (Y/N) ? N
N
```

```
>>
```

Input Arguments

`command` — MS-DOS® command

string

MS-DOS command, specified as a string. The command can be a Windows UI program that opens a graphical user interface, or a DOS console command that you typically run in a DOS command window. The command executes in a DOS shell, which might not be the shell from which you launched MATLAB.

Example: `'dir'`

Output Arguments

`status` — Command exit status

0 | nonzero integer

Command exit status, returned as either `0` or a nonzero integer. When the command is successful, `status` is `0`. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (`&`), then `status` is the exit status upon command launch.
- If `command` does not include the ampersand character (`&`), then `status` is the exit status upon command completion.

`cmdout` — Output of operating system command

string

Output of the operating system command, returned as a string.

Limitations

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `dos` with a DOS `command` that relies on the current folder fails. MATLAB returns this error:

```
Error using dos
DOS commands may not be executed when the current directory is a UNC pathname
```

To work around this limitation, change the folder to a mapped drive before running `dos` or a function that calls `dos`.

More About

Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'notepad &'`). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

  Note: If `command` includes the trailing `&` character, then `cmdout` is empty.

Introduced before R2006a

dot

Dot product

Syntax

```
C = dot(A,B)
C = dot(A,B,dim)
```

Description

`C = dot(A,B)` returns the scalar dot product of `A` and `B`.

- If `A` and `B` are vectors, then they must have the same length.
- If `A` and `B` are matrices or multidimensional arrays, then they must have the same size. In this case, the `dot` function treats `A` and `B` as collections of vectors. The function calculates the dot product of corresponding vectors along the first array dimension whose size does not equal 1.

`C = dot(A,B,dim)` evaluates the dot product of `A` and `B` along dimension, `dim`. The `dim` input is a positive integer scalar.

Examples

Dot Product of Real Vectors

Create two simple, three-element vectors.

```
A = [4 -1 2];
B = [2 -2 -1];
```

Calculate the dot product of `A` and `B`.

```
C = dot(A,B)
```

```
C =
```

```
     8
```

The result is `8` since

$$C = \mathrm{A}(1) * \mathrm{B}(1) + \mathrm{A}(2) * \mathrm{B}(2) + \mathrm{A}(3) * \mathrm{B}(3)$$
$$C = 8 + 2 - 2 .$$

Dot Product of Complex Vectors

Create two complex vectors.

```
A = [1+i 1-i -1+i -1-i];
B = [3-4i 6-2i 1+2i 4+3i];
```

Calculate the dot product of `A` and `B`.

```
C = dot(A,B)
```

```
C =

   1.0000 - 5.0000i
```

The result is a complex scalar since `A` and `B` are complex. In general, the dot product of two complex vectors is also complex. An exception is when you take the dot product of a complex vector with itself.

Find the inner product of `A` with itself.

```
D = dot(A,A)
```

```
D =

     8
```

The result is a real scalar. The inner product of a vector with itself is related to the Euclidean length of the vector, `norm(A)`.

Dot Product of Matrices

Create two matrices.

```
A = [1 2 3;4 5 6;7 8 9];
```

```
B = [9 8 7;6 5 4;3 2 1];
```

Find the dot product of A and B.

```
C = dot(A,B)
```

```
C =

    54    57    54
```

The result, C, contains three separate dot products. dot treats the columns of A and B as vectors and calculates the dot product of corresponding columns. So, for example, C(1) = 54 is the dot product of A(:,1) with B(:,1).

Find the dot product of A and B, treating the *rows* as vectors.

```
D = dot(A,B,2)
```

```
D =

    46
    73
    46
```

In this case, D(1) = 46 is the dot product of A(1,:) with B(1,:).

Dot Product of Multidimensional Arrays

Create two multidimensional arrays.

```
A = cat(3,[1 1;1 1],[2 3;4 5],[6 7;8 9])
B = cat(3,[2 2;2 2],[10 11;12 13],[14 15; 16 17])
```

```
A(:,:,1) =

     1     1
     1     1

A(:,:,2) =

     2     3
     4     5
```

```
A(:,:,3) =

     6     7
     8     9

B(:,:,1) =

     2     2
     2     2

B(:,:,2) =

    10    11
    12    13

B(:,:,3) =

    14    15
    16    17
```

Calculate the dot product of `A` and `B` along the third dimension (`dim = 3`).

```
C = dot(A,B,3)
```

```
C =

   106   140
   178   220
```

The result, `C`, contains four separate dot products. The first dot product, `C(1,1) = 106`, is equal to the dot product of `A(1,1,:)` with `B(1,1,:)`.

Input Arguments

`A,B` — Input arrays

numeric arrays

Input arrays, specified as numeric arrays.

Data Types: `single | double`

Complex Number Support: Yes

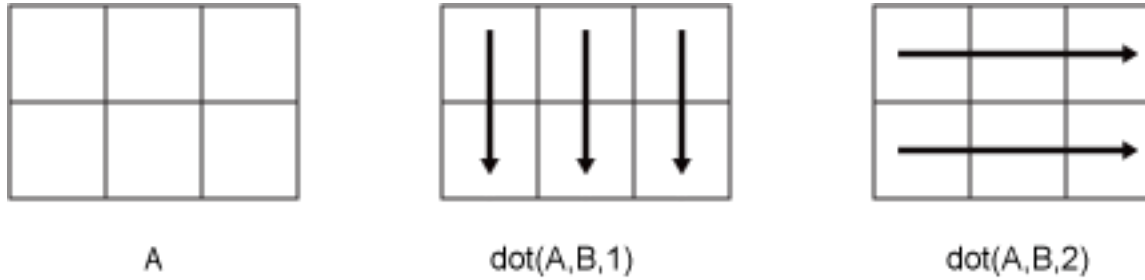
`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider two 2-D input arrays, `A` and `B`:

- `dot(A,B,1)` treats the columns of `A` and `B` as vectors and returns the dot products of corresponding columns.
- `dot(A,B,2)` treats the rows of `A` and `B` as vectors and returns the dot products of corresponding rows.



`dot` returns `conj(A).*B` if `dim` is greater than `ndims(A)`.

More About

Scalar Dot Product

The scalar dot product of two real vectors of length n is equal to

$$u \bullet v = \sum_{i=1}^{n} u_i v_i = u_1 v_1 + u_2 v_2 + \ldots + u_n v_n .$$

This relation is commutative for real vectors, such that `dot(u,v)` equals `dot(v,u)`. If the dot product is equal to zero, then u and v are perpendicular.

For complex vectors, the dot product involves a complex conjugate. This ensures that the inner product of any vector with itself is real and positive definite.

$$u \bullet v = \sum_{i=1}^{n} \overline{u}_i v_i .$$

Unlike the relation for real vectors, the complex relation is not commutative, so `dot(u,v)` equals `conj(dot(v,u))`.

Algorithms

- When inputs `A` and `B` are real or complex vectors, the `dot` function treats them as column vectors and `dot(A,B)` is the same as `sum(conj(A).*B)`.
- When the inputs are matrices or multidimensional arrays, the `dim` argument determines which dimension the `sum` function operates on. In this case, `dot(A,B)` is the same as `sum(conj(A).*B,dim)`.

`conj` | `cross` | `sum`

Introduced before R2006a

double

Convert to double precision

Syntax

```
double(x)
```

Description

`double(x)` returns the double-precision value for `X`. If `X` is already a double-precision array, `double` has no effect.

More About

Tips

The `double` function can be overloaded for any object when it makes sense to convert it to a double-precision value.

- "Floating-Point Numbers"

See Also

`cast` | `single` | `str2double` | `typecast`

Introduced before R2006a

dragrect

Drag rectangles with mouse

Syntax

```
[finalrect] = dragrect(initialrect)
[finalrect] = dragrect(initialrect,stepsize)
```

Description

`[finalrect] = dragrect(initialrect)` tracks one or more rectangles anywhere on the screen. The n-by-4 matrix `initialrect` defines the rectangles. Each row of `initialrect` must contain the initial rectangle position as `[left bottom width height]` values. `dragrect` returns the final position of the rectangles in `finalrect`.

`[finalrect] = dragrect(initialrect,stepsize)` moves the rectangles in increments of `stepsize`. The lower left corner of the first rectangle is constrained to a grid of size equal to `stepsize` starting at the lower left corner of the figure, and all other rectangles maintain their original offset from the first rectangle.

`[finalrect] = dragrect(...)` returns the final positions of the rectangles when the mouse button is released. The default step size is `1`.

Examples

Drag a rectangle that is 50 pixels wide and 100 pixels in height.

```
waitforbuttonpress
point1 = get(gcf,'CurrentPoint') % button down detected
rect = [point1(1,1) point1(1,2) 50 100]
[r2] = dragrect(rect)
```

More About

Tips

`dragrect` returns immediately if a mouse button is not currently pressed. Use `dragrect` in a `ButtonDownFcn`, or from the command line in conjunction with `waitforbuttonpress`, to ensure that the mouse button is down when `dragrect` is called. `dragrect` returns when you release the mouse button.

If the drag ends over a figure window, the positions of the rectangles are returned in that figure's coordinate system. If the drag ends over a part of the screen not contained within a figure window, the rectangles are returned in the coordinate system of the figure over which the drag began.

Note: You cannot use normalized figure units with `dragrect`.

`rbbox` | `waitforbuttonpress`

Introduced before R2006a

drawnow

Update figures and process callbacks

Syntax

```
drawnow
drawnow limitrate
drawnow nocallbacks
drawnow limitrate nocallbacks

drawnow update
drawnow expose
```

Description

`drawnow` updates figures and processes any pending callbacks. Use this command if you modify graphics objects and want to see the updates on the screen immediately.

`drawnow limitrate` limits the number of updates to 20 frames per second. If it has been fewer than 50 milliseconds since the last update, or if the graphics renderer is busy with the previous change, then `drawnow` discards the new updates. Use this command if you are updating graphics objects in a loop and do not need to see every update on the screen. Skipping updates can create faster animations. Pending callbacks are processed, so you can interact with figures during animations.

`drawnow nocallbacks` defers callbacks, such as mouse clicks, until the next full `drawnow` command. Use this option if you want to prevent callbacks from interrupting your code. For more information, see “Actions Equivalent to drawnow” on page 1-2248.

`drawnow limitrate nocallbacks` limits the number of updates to 20 frames per second, skips updates if the renderer is busy, and defers callbacks.

`drawnow update` skips updates if the renderer is busy and defers callbacks.

Note: This syntax is not recommended. Use the `limitrate` option instead.

`drawnow expose` updates figures, but defers callbacks.

Note: This syntax is not recommended. Use the `nocallbacks` option instead.

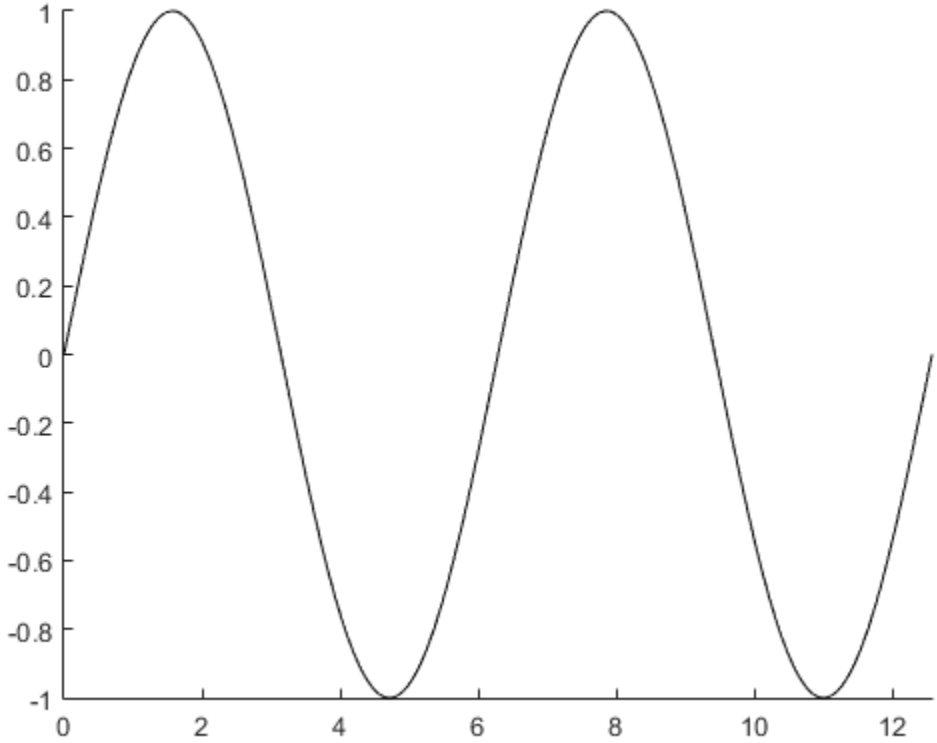
Examples

Create Animation of Streaming Data

Create an animation of a line growing as it accumulates 2,000 data points. Use `drawnow` to display the changes on the screen after each iteration through the loop.

```
h = animatedline;
axis([0 4*pi -1 1])
x = linspace(0,4*pi,2000);

for k = 1:length(x)
    y = sin(x(k));
    addpoints(h,x(k),y);
    drawnow
end
```



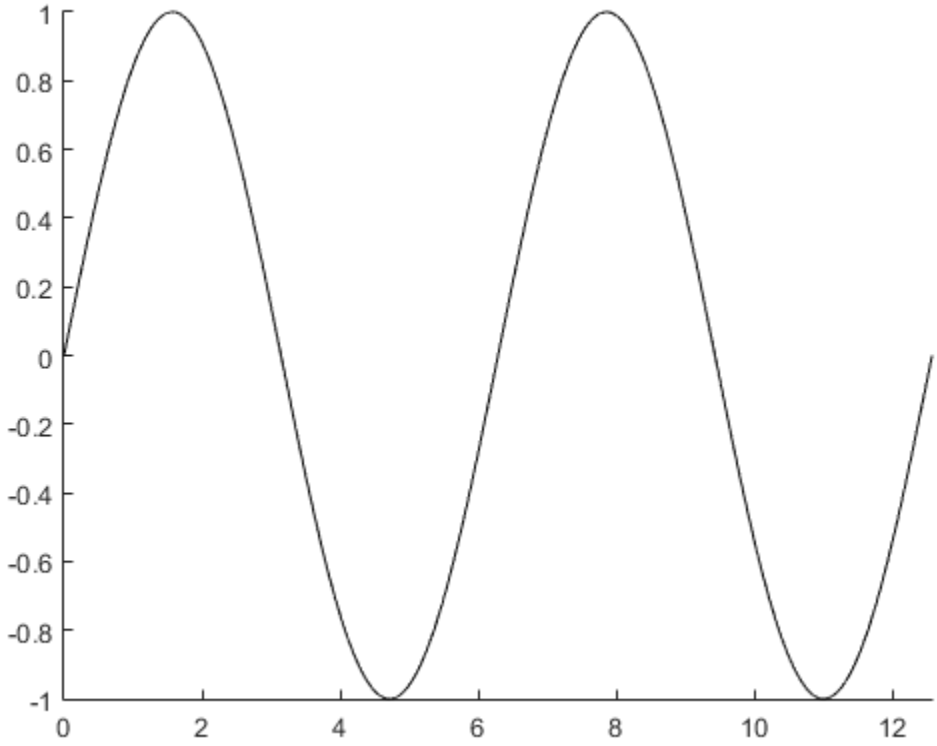
Skip Updates for Faster Animation

Create an animation of a line growing as it accumulates 10,000 points. Since there are 10,000 points, drawing each update on the screen is slow. Create a faster, smooth animation by limiting the number of updates using `drawnow limitrate`. Then, display the final updates on the screen by calling `drawnow` after the loop ends.

```
h = animatedline;
axis([0 4*pi -1 1])
x = linspace(0,4*pi,10000);

for k = 1:length(x)
    y = sin(x(k));
    addpoints(h,x(k),y);
```

```
    drawnow limitrate
end
drawnow
```

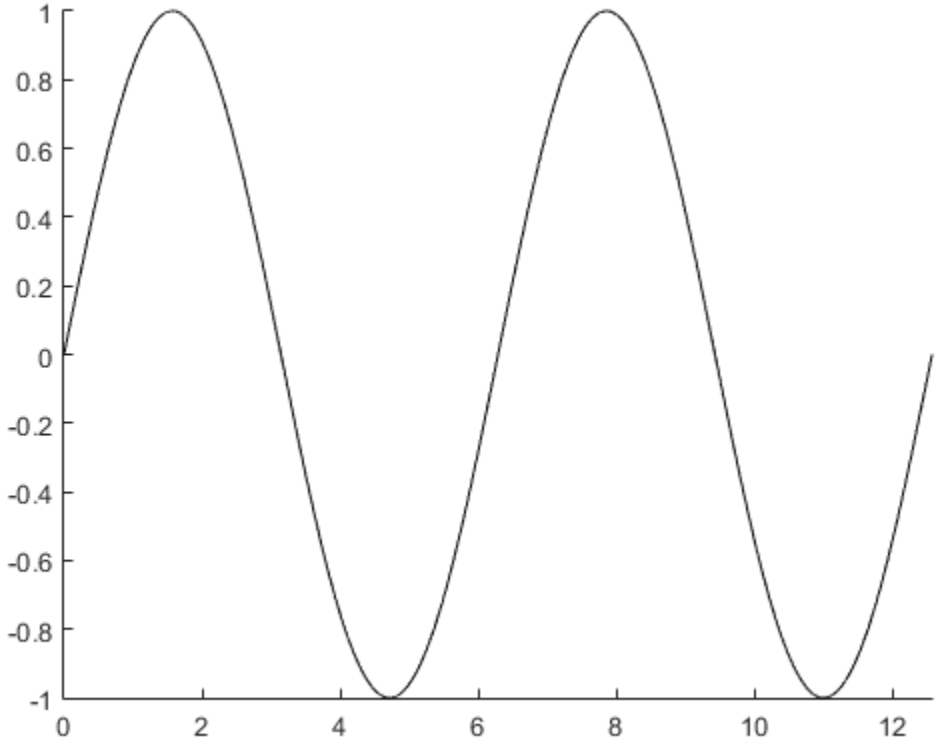


Precompute Data, Then Create Animation

Compute all the data before the animation loop.

```
h = animatedline;
axis([0 4*pi -1 1])
x = linspace(0,4*pi,10000);
y = sin(x);
```

```
for k = 1:length(x)
    addpoints(h,x(k),y(k));
    drawnow limitrate
end
drawnow
```



If you have long computations, precomputing the data can improve perfomance. Precomputing minimizes the computation time by letting the computation run without

interruptions. Additionally, it helps ensure a smooth animation by focusing on only graphics code in the animation loop.

More About

Actions Equivalent to drawnow

These actions are equivalent to calling a full `drawnow` command:

- Returning to the MATLAB prompt.
- Using the `figure`, `getframe`, `input`, `pause`, and `keyboard` functions.
- Using functions that wait for user input, such as `waitforbuttonpress`, `waitfor`, or `ginput`.

Tips

- The `nocallbacks` option always adds interrupting callbacks to the queue. If you want to discard interrupting callbacks, then use the `Interruptible` and `BusyAction` properties instead.

See Also

`pause` | `refreshdata` | `waitfor`

Introduced before R2006a

dsearchn

N-D nearest point search

Syntax

```
k = dsearchn(X,T,XI)
k = dsearchn(X,T,XI,outval)
k = dsearchn(X,XI)
[k,d] = dsearchn(X,...)
```

Description

`k = dsearchn(X,T,XI)` returns the indices `k` of the closest points in `X` for each point in `XI`. `X` is an `m`-by-`n` matrix representing `m` points in n-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in n-dimensional space. `T` is a `numt`-by-`n+1` matrix, a triangulation of the data `X` generated by `delaunayn`. The output `k` is a column vector of length `p`.

`k = dsearchn(X,T,XI,outval)` returns the indices `k` of the closest points in `X` for each point in `XI`, unless a point is outside the convex hull. If `XI(J,:)` is outside the convex hull, then `K(J)` is assigned `outval`, a scalar double. `Inf` is often used for `outval`. If `outval` is `[]`, then `k` is the same as in the case `k = dsearchn(X,T,XI)`.

`k = dsearchn(X,XI)` performs the search without using a triangulation. With large `X` and small `XI`, this approach is faster and uses much less memory.

`[k,d] = dsearchn(X,...)` also returns the distances `d` to the closest points. `d` is a column vector of length `p`.

More About

Algorithms

`dsearchn` is based on Qhull [1]. For information about Qhull, see http://www.qhull.org/. For copyright information, see http://www.qhull.org/COPYING.txt.

`delaunayTriangulation`

Introduced before R2006a

duration

Create duration array from numeric values

The `duration` function creates an array that represents elapsed time in units of fixed length, such as hours, minutes, and seconds. You also can create elapsed times in terms of fixed-length (24-hour) days and fixed-length (365.2425-day long) years.

Syntax

```
D = duration(H,MI,S)
D = duration(H,MI,S,MS)
D = duration(X)

D = duration( ___ ,'Format',displayFormat)
```

Description

`D = duration(H,MI,S)` creates a duration array from numeric arrays containing the number of hours, minutes, and seconds specified by `H`, `MI`, and `S`, respectively.

`D = duration(H,MI,S,MS)` creates a duration array from numeric arrays containing the number of hours, minutes, second, and milliseconds specified by `H`, `MI`, `S`, and `MS`, respectively.

`D = duration(X)` creates a column vector of durations from a numeric matrix.

`D = duration( ___ ,'Format',displayFormat)` additionally specifies the format in which `D` displays. You can use this syntax with any of the arguments from the previous syntaxes.

Examples

Create Duration Array with Default Format

```
D = duration(1,30:33,0)
```

```
D =

   01:30:00    01:31:00    01:32:00    01:33:00
```

Create Duration Array and Specify Format

Create a `duration` array from a matrix and display the values in units of fractional hours.

```
X = magic(3);
D = duration(X,'Format','h')
```

```
D =

   8.0183 hrs
   3.0853 hrs
   4.1506 hrs
```

Input Arguments

`H,MI,S` — Hour, minute, and second arrays

scalar | vector | matrix | multidimensional array

Hour, minute, and second arrays specified as a scalar, vector, matrix or multidimensional array. These arrays must be the same size, or any one can be a scalar.

Example: `12,45,07.451`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`H,MI,S,MS` — Hour, minute, second, and millisecond arrays

scalar | vector | matrix | multidimensional array

Hour, minute, second, and millisecond arrays, each specified as a scalar, vector, matrix or multidimensional array. The arrays must be the same size, or any one can be a scalar.

Example: `12,45,30,35`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

X — Input matrix

matrix

Input matrix, specified in the form `[H,M,S]`.

Example: `[1,30,0]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

displayFormat — Display format of D

`'hh:mm:ss'` (default) | string

Display format of `D`, the duration array, specified as a string. The `displayFormat` value does not change the duration values in `D`, only their display.

To display a duration as a single number that includes a fractional part (for example, 1.234 hours), specify one of the following strings.

Value of `displayFormat`	Description
`'y'`	Number of exact fixed-length years. A fixed-length year is equal to 365.2425 days.
`'d'`	Number of exact fixed-length days. A fixed-length day is equal to 24 hours.
`'h'`	Number of hours
`'m'`	Number of minutes
`'s'`	Number of seconds

To display a duration in the form of a digital timer, specify one of the strings:

- `'dd:hh:mm:ss'`
- `'hh:mm:ss'`
- `'mm:ss'`
- `'hh:mm'`

In addition, you can display up to nine fractional second digits by appending up to nine `S` characters. For example, `'hh:mm:ss.SSS'` displays the milliseconds of a duration value to three digits.

Data Types: `char`

Output Arguments

`D` — Output duration

`duration` array

Output duration, returned as a `duration` array.

You can change the display format of a duration by modifying the `Format` property. For example, to display the duration, `D`, as a number of minutes, type:

```
D.Format = 'm'
```

More About

- "Represent Dates and Times in MATLAB"

See Also

`calendarDuration`

Introduced in R2014b

dynamicprops

Abstract class used to derive handle class with dynamic properties

Syntax

```
classdef myclass < dynamicprops
```

Description

`classdef myclass < dynamicprops` makes *`myclass`* a subclass of the `dynamicprops` class, which is a subclass of the `handle` class.

Use the `dynamicprops` class to derive classes that can define dynamic properties (instance properties), which are associated with a specific objects, but have no effect on the objects class definition. Dynamic properties are useful for attaching temporary data to one or more objects.

dynamicprops Methods

This class defines one method `addprop` and, as a subclass of the `handle` class, inherits all the `handle` class methods.

- `addprop` — adds the named property to the specified handle objects. See "Dynamic Properties — Adding Properties to an Instance" for more information.

See Also

`handle`

echo

Display statements during function execution

Syntax

```
echo on
echo off
echo
echo fcnname on
echo fcnname off
echo fcnname
echo on all
echo off all
```

Description

The `echo` command controls the display (or *echoing*) of statements in a function during their execution. Normally, statements in a function file are not displayed on the screen during execution. Command echoing is useful for debugging or for demonstrations, allowing the commands to be viewed as they execute.

The `echo` command behaves in a slightly different manner for script files and function files. For script files, the use of `echo` is simple; echoing can be either `on` or `off`, in which case any script used is affected.

`echo on` turns on the echoing of commands in all script files.

`echo off` turns off the echoing of commands in all script files.

`echo` toggles the echo state.

When you turn on echoing for a script or function file, each line in the file is displayed as it is executed. Since this results in inefficient execution, use `echo` only for debugging.

`echo fcnname on` turns on echoing of the named function file.

`echo fcnname off` turns off echoing of the named function file.

`echo` *`fcnname`* toggles the echo state of the named function file.

`echo on all` sets echoing on for all function files.

`echo off all` sets echoing off for all function files.

More About

Tips

- To avoid confusing syntax, do not use `on` or `off` as a function name.

`function`

Introduced before R2006a

echodemo

Run example script step-by-step in Command Window

Syntax

```
echodemo filename
echodemo(filename,index)
```

Description

`echodemo filename` runs the script specified by `filename` step-by-step in the Command Window. The file must contain sections defined with two percent signs (`%%`) to enable pausing after each step. At each step, you can click links in the Command Window to proceed or stop. If the Command Window is not large enough to show the links, scroll up to see them.

Caution If variables in your base workspace have the same name as variables that the example file creates, the example could overwrite your data. Preserve your data by saving it to a MAT-file before running the example.

`echodemo(filename,index)` starts with the section number specified by `index`. If the example relies on results of previous steps, using this syntax can produce errors or unexpected results.

Examples

Run Example Script in Command Window

Run the Loma Prieta Earthquake example.

```
echodemo quake
```

Start Script from Specified Section

Start the Loma Prieta Earthquake example from the third section.

```
filename = 'quake';
index = 3;
echodemo(filename,index)
```

This code errors because the example requires variables created in earlier sections.

Input Arguments

`filename` — Script file name

string

Script file name, specified as a string.

When you use the function syntax for `echodemo` and specify its inputs within parentheses, enclose the `filename` input in single quotes.

`index` — Section index

scalar integer

Section index, specified as a scalar integer.

The link text in the Command Window shows the current section number, `n`, and the total number of sections, `m`, as `n/m`.

More About

Tips

- Only use `echodemo` to display scripts, not functions. `echodemo` can run any script that you can execute, but only scripts with sections pause between steps.

`demo` | `doc` | `publish`

Introduced before R2006a

edgeAttachments

Class: TriRep

(Will be removed) Simplices attached to specified edges

Note: `edgeAttachments(TriRep)` will be removed in a future release. Use `edgeAttachments(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
SI = edgeAttachments(TR, V1, V2)
SI = edgeAttachments(TR, EDGE)
```

Description

`SI = edgeAttachments(TR, V1, V2)` returns the simplices `SI` attached to the edges specified by `(V1, V2)`. `(V1, V2)` represents the start and end vertices of the edges to be queried.

`SI = edgeAttachments(TR, EDGE)` specifies edges in matrix format.

Input Arguments

`TR`	Triangulation representation.
`V1,V2`	Column vectors of vertex indices into the array of points representing the vertex coordinates.
`EDGE`	Matrix specifying edge start and end points. `EDGE` is of size `m`-by-2, `m` being the number of edges to query.

Output Arguments

`SI`	Vector cell array of indices into the triangulation matrix. `SI` is a cell array because the number of simplices associated with each edge can vary.

Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

Examples

Example 1

Load a 3-D triangulation to compute the tetrahedra attached to an edge.

```
load tetmesh
trep = TriRep(tet, X);
v1 = [15 21]';
v2 = [936 716]';
t1 = edgeAttachments(trep, v1, v2);
```

You can also specify the input as edges.

```
e = [v1 v2];
t2 = edgeAttachments(trep, e);
isequal(t1,t2);
```

Example 2

Create a triangulation with `DelaunayTri`.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Query the triangles attached to edge (1,5).

```
t = edgeAttachments(dt, 1,5);
```

```
t{:};
```

triangulation | edges | delaunayTriangulation

edges

Class: TriRep

(Will be removed) Triangulation edges

Note: `edges(TriRep)` will be removed in a future release. Use `edges(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
E = edges(TR)
```

Description

`E = edges(TR)` returns the edges in the triangulation in an `n`-by-2 matrix. `n` is the number of edges. The vertices of the edges index into `TR.X`, the array of points representing the vertex coordinates.

Input Arguments

`TR`	Triangulation representation.

Output Arguments

`E`	Edge matrix.

Examples

Example 1

Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Return all edges.

```
e = edges(trep);
```

Example 2

Query a 2-D `DelaunayTri`-generated triangulation.

```
X = rand(10,2);
dt = DelaunayTri(X);
e = edges(dt);
```

See Also

`triangulation` | `edgeAttachments` | `delaunayTriangulation`

edit

Edit or create file

Syntax

```
edit
edit file
edit file1 ... fileN
```

Description

`edit` opens a new file called `Untitled` in the Editor. MATLAB does not automatically save `Untitled`.

`edit file` opens the specified file in the Editor. If file does not already exist, MATLAB asks if you want to create it. file can include a partial path, complete path, relative path, or no path. If `file` includes a partial path or no path, `edit` will look for the file on the search path. You must have write permission to the path to create file, otherwise, MATLAB ignores the argument.

You must specify the extension to open `.mat` and `.mdl` files. MATLAB cannot directly edit binary files, such as `.p` and `.mex` files.

`edit file1 ... fileN` opens each file, `file1 ... fileN`, in the Editor.

Examples

Open a New File

```
edit
```

A new file titled `Untitled` opens in the MATLAB Editor (or default editor). `Untitled` does not appear in your Current Folder.

Create a New File

```
mkdir tests
edit tests/new_script.m
```

A dialog box appears, asking if you want to create `new_script.m`. If you select **Yes**, MATLAB creates and opens `tests/new_script.m`.

Open Files

```
edit file1 file2 file3 file4
```

MATLAB sequentially creates and opens the files: `file1`, `file2`, `file3`, and `file4` in sequence.

Input Arguments

`file` — Name of file

string

Name of file, specified as a string. If file specifies a path that contains a nonexistent folder, MATLAB throws an error. Specify multiple files on the same line by separating filenames with a space.

If `file` is overloaded (that is, appears in multiple folders on the search path), then include a partial path to edit the correct page, such as

```
edit folderName/file
```

If you do not specify the extension, then `edit` opens a file with the specified name and a `.m` extension.

```
edit name
```

If the file is part of a class or package, then either specify the path and extension, or separate the components of the name with periods, such as:

```
edit className.name
edit packageName.name
edit packageName.className.name
edit packageName.name
```

Data Types: `char`

`open` | `type`

Introduced before R2006a

eig

Eigenvalues and eigenvectors

Syntax

```
e = eig(A)
[V,D] = eig(A)
[V,D,W] = eig(A)

e = eig(A,B)
[V,D] = eig(A,B)
[V,D,W] = eig(A,B)

[___] = eig(A,balanceOption)
[___] = eig(A,B,algorithm)

[___] = eig(___,eigvalOption)
```

Description

`e = eig(A)` returns a column vector containing the eigenvalues of square matrix `A`.

`[V,D] = eig(A)` returns diagonal matrix `D` of eigenvalues and matrix `V` whose columns are the corresponding right eigenvectors, so that `A*V = V*D`.

`[V,D,W] = eig(A)` also returns full matrix `W` whose columns are the corresponding left eigenvectors, so that `W'*A = D*W'`.

The eigenvalue problem is to determine the solution to the equation $Av = \lambda v$, where A is an `n`-by-`n` matrix, v is a column vector of length `n`, and λ is a scalar. The values of λ that satisfy the equation are the eigenvalues. The corresponding values of v that satisfy the equation are the right eigenvectors. The left eigenvectors, w, satisfy the equation $w'A = \lambda w'$.

`e = eig(A,B)` returns a column vector containing the generalized eigenvalues of square matrices `A` and `B`.

`[V,D] = eig(A,B)` returns diagonal matrix `D` of generalized eigenvalues and full matrix `V` whose columns are the corresponding right eigenvectors, so that `A*V = B*V*D`.

`[V,D,W] = eig(A,B)` also returns full matrix `W` whose columns are the corresponding left eigenvectors, so that `W'*A = D*W'*B`.

The generalized eigenvalue problem is to determine the solution to the equation $Av = \lambda Bv$, where A and B are `n`-by-`n` matrices, v is a column vector of length `n`, and λ is a scalar. The values of λ that satisfy the equation are the generalized eigenvalues. The corresponding values of v are the generalized right eigenvectors. The left eigenvectors, w, satisfy the equation $w'A = \lambda w'B$.

`[ ___ ] = eig(A,balanceOption)`, where `balanceOption` is `'nobalance'`, disables the preliminary balancing step in the algorithm. The default for `balanceOption` is `'balance'`, which enables balancing. The `eig` function can return any of the output arguments in previous syntaxes.

`[ ___ ] = eig(A,B,algorithm)`, where `algorithm` is `'chol'`, uses the Cholesky factorization of `B` to compute the generalized eigenvalues. The default for `algorithm` depends on the properties of `A` and `B`, but is generally `'qz'`, which uses the QZ algorithm.

If `A` is Hermitian and `B` is Hermitian positive definite, then the default for `algorithm` is `'chol'`.

`[ ___ ] = eig( ___ ,eigvalOption)` returns the eigenvalues in the form specified by `eigvalOption` using any of the input or output arguments in previous syntaxes. Specify `eigvalOption` as `'vector'` to return the eigenvalues in a column vector or as `'matrix'` to return the eigenvalues in a diagonal matrix.

Examples

Eigenvalues of Matrix

Use `gallery` to create a symmetric positive definite matrix.

```
A = gallery('lehmer',4)
```

```
A =
```

```
    1.0000    0.5000    0.3333    0.2500
    0.5000    1.0000    0.6667    0.5000
    0.3333    0.6667    1.0000    0.7500
    0.2500    0.5000    0.7500    1.0000
```

Calculate the eigenvalues of `A`. The result is a column vector.

```
e = eig(A)
```

```
e =

    0.2078
    0.4078
    0.8482
    2.5362
```

Alternatively, use `eigvalOption` to return the eigenvalues in a diagonal matrix.

```
D = eig(A,'matrix')
```

```
D =

    0.2078         0         0         0
         0    0.4078         0         0
         0         0    0.8482         0
         0         0         0    2.5362
```

Eigenvalues and Eigenvectors of Matrix

Use `gallery` to create a circulant matrix.

```
A = gallery('circul',3)
```

```
A =

     1     2     3
     3     1     2
     2     3     1
```

Calculate the eigenvalues and right eigenvectors of `A`.

```
[V,D] = eig(A)
```

```
V =
```

```
  -0.5774 + 0.0000i   0.2887 - 0.5000i   0.2887 + 0.5000i
  -0.5774 + 0.0000i  -0.5774 + 0.0000i  -0.5774 + 0.0000i
  -0.5774 + 0.0000i   0.2887 + 0.5000i   0.2887 - 0.5000i

D =

   6.0000 + 0.0000i   0.0000 + 0.0000i   0.0000 + 0.0000i
   0.0000 + 0.0000i  -1.5000 + 0.8660i   0.0000 + 0.0000i
   0.0000 + 0.0000i   0.0000 + 0.0000i  -1.5000 - 0.8660i
```

Verify that the results satisfy `A*V = V*D`.

```
A*V - V*D

ans =

   1.0e-14 *

  -0.2665 + 0.0000i  -0.0444 + 0.0222i  -0.0444 - 0.0222i
   0.0888 + 0.0000i   0.0111 + 0.0777i   0.0111 - 0.0777i
  -0.0444 + 0.0000i  -0.0111 + 0.0833i  -0.0111 - 0.0833i
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since `eig` performs the decomposition using floating-point computations, then `A*V` can, at best, approach `V*D`. In other words, `A*V - V*D` is close to, but not exactly, `0`.

Eigenvalues of a Matrix Whose Elements Differ Dramatically in Scale

```
A = [ 3.0     -2.0      -0.9     2*eps;
     -2.0      4.0       1.0    -eps;
     -eps/4    eps/2    -1.0     0;
     -0.5     -0.5       0.1     1.0];
```

Calculate the eigenvalues and right eigenvectors using the default (balancing) behavior.

```
[VB,DB] = eig(A)

VB =

    0.6153   -0.4176   -0.0000   -0.1437
   -0.7881   -0.3261   -0.0000    0.1264
   -0.0000   -0.0000   -0.0000   -0.9196
    0.0189    0.8481    1.0000    0.3432
```

```
DB =

    5.5616         0         0         0
         0    1.4384         0         0
         0         0    1.0000         0
         0         0         0   -1.0000
```

Verify that the results satisfy `A*VB = VB*DB`.

```
A*VB - VB*DB

ans =

    0.0000    0.0000   -0.0000    0.0000
         0   -0.0000    0.0000   -0.0000
    0.0000   -0.0000    0.0000    0.0000
         0    0.0000    0.0000    0.6031
```

This result does not satisfy `A*VB = VB*DB`. Ideally, the eigenvalue decomposition satisfies this relationship. Since `eig` performs the decomposition using floating-point computations, then `A*V` can, at best, approach `V*D`. In other words, `A*V - V*D` is close to, but not exactly, `0`.

Now, try calculating the eigenvalues and right eigenvectors without the balancing step.

```
[VN,DN] = eig(A,'nobalance')

VN =

    0.6153   -0.4176   -0.0000   -0.1528
   -0.7881   -0.3261         0    0.1345
   -0.0000   -0.0000   -0.0000   -0.9781
    0.0189    0.8481   -1.0000    0.0443

DN =

    5.5616         0         0         0
         0    1.4384         0         0
         0         0    1.0000         0
         0         0         0   -1.0000
```

Verify that the results satisfy `A*VN = VN*DN`.

```
A*VN - VN*DN
```

```
ans =

   1.0e-14 *

   -0.1776   -0.0111   -0.0559   -0.0167
    0.3553    0.1055    0.0336   -0.0194
    0.0017    0.0002    0.0007         0
    0.0264   -0.0222    0.0222    0.0097
```

`A*VN - VN*DN` is much closer to `0`, so the `'nobalance'` option produces more accurate results in this case.

Left Eigenvectors

Create a 3-by-3 matrix.

```
A = [1 7 3; 2 9 12; 5 22 7];
```

Calculate the right eigenvectors, `V`, the eigenvalues, `D`, and the left eigenvectors, `W`.

```
[V,D,W] = eig(A)
```

```
V =

   -0.2610   -0.9734    0.1891
   -0.5870    0.2281   -0.5816
   -0.7663   -0.0198    0.7912

D =

   25.5548         0         0
         0   -0.5789         0
         0         0   -7.9759

W =

   -0.1791   -0.9587   -0.1881
   -0.8127    0.0649   -0.7477
   -0.5545    0.2768    0.6368
```

Verify that the results satisfy `W'*A = D*W'`.

```
W'*A - D*W'
```

```
ans =

   1.0e-13 *

   -0.0444   -0.1066   -0.0888
   -0.0011    0.0442    0.0333
         0    0.0266    0.0178
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since `eig` performs the decomposition using floating-point computations, then `W'*A` can, at best, approach `D*W'`. In other words, `W'*A - D*W'` is close to, but not exactly, `0`.

Eigenvalues of Nondiagonalizable (Defective) Matrix

Create a 3-by-3 matrix.

```
A = [3 1 0; 0 3 1; 0 0 3];
```

Calculate the eigenvalues and right eigenvectors of `A`.

```
[V,D] = eig(A)
```

```
V =

    1.0000   -1.0000    1.0000
         0    0.0000   -0.0000
         0         0    0.0000

D =

     3     0     0
     0     3     0
     0     0     3
```

`A` has repeated eigenvalues and the eigenvectors are not independent. This means that `A` is not diagonalizable and is, therefore, defective.

Verify that `V` and `D` satisfy the equation, `A*V = V*D`, even though `A` is defective.

```
A*V - V*D
```

```
ans =

   1.0e-15 *
```

```
         0    0.8882   -0.8882
         0         0    0.0000
         0         0         0
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since `eig` performs the decomposition using floating-point computations, then `A*V` can, at best, approach `V*D`. In other words, `A*V - V*D` is close to, but not exactly, `0`.

Generalized Eigenvalues

Create two matrices, `A` and `B`, then solve the generalized eigenvalue problem for the eigenvalues and right eigenvectors of the pair `(A,B)`.

```
A = [1/sqrt(2) 0; 0 1];
B = [0 1; -1/sqrt(2) 0];
[V,D]=eig(A,B)
```

```
V =

   1.0000 + 0.0000i   1.0000 + 0.0000i
   0.0000 - 0.7071i   0.0000 + 0.7071i

D =

   0.0000 + 1.0000i   0.0000 + 0.0000i
   0.0000 + 0.0000i   0.0000 - 1.0000i
```

Verify that the results satisfy `A*V = B*V*D`.

```
A*V - B*V*D
```

```
ans =

     0     0
     0     0
```

The residual error `A*V - B*V*D` is exactly zero.

Generalized Eigenvalues Using QZ Algorithm for Badly Conditioned Matrices

Create a badly conditioned symmetric matrix containing values close to machine precision.

```
format long e
```

```
A = diag([10^-16, 10^-15])

A =

     1.000000000000000e-16                         0
                         0     1.000000000000000e-15
```

Calculate the generalized eigenvalues and a set of right eigenvectors using the default algorithm. In this case, the default algorithm is `'chol'`.

```
[V1,D1] = eig(A,A)

V1 =

     1.000000000000000e+08                         0
                         0     3.162277660168380e+07

D1 =

     9.999999999999999e-01                         0
                         0     1.000000000000000e+00
```

Now, calculate the generalized eigenvalues and a set of right eigenvectors using the `'qz'` algorithm.

```
[V2,D2] = eig(A,A,'qz')

V2 =

     1     0
     0     1

D2 =

     1     0
     0     1
```

Check how well the `'chol'` result satisfies `A*V1 = A*V1*D1`.

```
format short
A*V1 - A*V1*D1

ans =
```

```
   1.0e-23 *

    0.1654         0
         0   -0.6617
```

Now, check how well the `'qz'` result satisfies `A*V2 = A*V2*D2`.

```
A*V2 - A*V2*D2

ans =

     0     0
     0     0
```

When both matrices are symmetric, `eig` uses the `'chol'` algorithm by default. In this case, the QZ algorithm returns more accurate results.

Generalized Eigenvalues Where One Matrix is Singular

Create a 2-by-2 identity matrix, `A`, and a singular matrix, `B`.

```
A = eye(2);
B = [3 6; 4 8];
```

Try to calculate the generalized eigenvalues of the matrix, $B^{-1}A$.

```
[V,D] = eig(B\A)

Warning: Matrix is singular to working precision.
Error using eig
Input to EIG must not contain NaN or Inf.
```

Now calculate the generalized eigenvalues and right eigenvectors by passing both matrices to the `eig` function.

```
[V,D] = eig(A,B)

V =

   -0.7500   -1.0000
   -1.0000    0.5000

D =
```

```
    0.0909         0
         0       Inf
```

It is better to pass both matrices separately, and let `eig` choose the best algorithm to solve the problem. In this case, `eig(A,B)` returned a set of eigenvectors and at least one real eigenvalue, even though `B` is not invertible.

Verify $Av = \lambda Bv$ for the first eigenvalue and the first eigenvector.

```
eigval = D(1,1);
eigvec = V(:,1);
A*eigvec - eigval*B*eigvec
```

```
ans =

   1.0e-15 *

    0.1110
    0.2220
```

Ideally, the eigenvalue decomposition satisfies the relationship. Since the decomposition is performed using floating-point computations, then `A*eigvec` can, at best, approach `eigval*B*eigvec`, as it does in this case.

Input Arguments

A — Input matrix

square matrix

Input matrix, specified as a real or complex square matrix.

Data Types: `double` | `single`
Complex Number Support: Yes

B — Generalized eigenvalue problem input matrix

square matrix

Generalized eigenvalue problem input matrix, specified as a square matrix of real or complex values. `B` must be the same size as `A`.

Data Types: `double` | `single`

Complex Number Support: Yes

`balanceOption` — Balance option

`'balance'` (default) | `'nobalance'`

Balance option, specified as one of two strings: `'balance'`, which enables a preliminary balancing step, or `'nobalance'` which disables it. In most cases, the balancing step improves the conditioning of `A` to produce more accurate results. However, there are cases in which balancing produces incorrect results. Specify `'nobalance'` when `A` contains values whose scale differs dramatically. For example, if `A` contains nonzero integers, as well as very small (near zero) values, then the balancing step might scale the small values to make them as significant as the integers and produce inaccurate results.

`'balance'` is the default behavior. For more information about balancing, see `balance`.

Data Types: `char`

`algorithm` — Generalized eigenvalue algorithm

`'chol'` | `'qz'`

Generalized eigenvalue algorithm, specified as `'chol'` or `'qz'`, which selects the algorithm to use for calculating the generalized eigenvalues of a pair.

algorithm	Description
`'chol'`	Computes the generalized eigenvalues of `A` and `B` using the Cholesky factorization of `B`.
`'qz'`	Uses the QZ algorithm, also known as the generalized Schur decomposition. This algorithm ignores the symmetry of `A` and `B`.

In general, the two algorithms return the same result. The QZ algorithm can be more stable for certain problems, such as those involving badly conditioned matrices.

When you omit the `algorithm` argument, the `eig` function selects an algorithm based on the properties of `A` and `B`. It uses the `'chol'` algorithm for symmetric (Hermitian) `A` and symmetric (Hermitian) positive definite `B`. Otherwise, it uses the `'qz'` algorithm.

Regardless of the algorithm you specify, the `eig` function always uses the QZ algorithm when `A` or `B` are not symmetric.

`eigvalOption` — Eigenvalue option

`'vector' | 'matrix'`

Eigenvalue option, specified as `'vector'` or `'matrix'`. This option allows you to specify whether the eigenvalues are returned in a column vector or a diagonal matrix. The default behavior varies according to the number of outputs specified:

- If you specify one output, such as `e = eig(A)`, then the eigenvalues are returned as a column vector by default.
- If you specify two or three outputs, such as `[V,D] = eig(A)`, then the eigenvalues are returned as a diagonal matrix, `D`, by default.

Example: `D = eig(A,'matrix')` returns a diagonal matrix of eigenvalues with the one output syntax.

Data Types: `char`

Output Arguments

`e` — Eigenvalues (returned as vector)

column vector

Eigenvalues, returned as a column vector containing the eigenvalues (or generalized eigenvalues of a pair) with multiplicity.

- When `A` is real and symmetric or complex Hermitian, the values of `e` that satisfy $Av = \lambda v$ are real.
- When `A` is real and skew-symmetric or skew-Hermitian, the values of `e` that satisfy $Av = \lambda v$ are purely imaginary or zero.

`V` — Right eigenvectors

square matrix

Right eigenvectors, returned as a square matrix whose columns are the right eigenvectors of `A` or generalized right eigenvectors of the pair, `(A,B)`. The form and normalization of `V` depends on the combination of input arguments:

- `[V,D] = eig(A)` returns matrix `V`, whose columns are the right eigenvectors of `A` such that `A*V = V*D`. The eigenvectors in `V` are normalized so that the 2-norm of each is 1.

If A is real symmetric, then the right eigenvectors, V, are orthonormal.

- `[V,D] = eig(A,'nobalance')` also returns matrix V. However, the 2-norm of each eigenvector is not necessarily 1.
- `[V,D] = eig(A,B)` and `[V,D] = eig(A,B,algorithm)` returns V as a matrix whose columns are the generalized right eigenvectors that satisfy `A*V = B*V*D`. The 2-norm of each eigenvector is not necessarily 1. In this case, D contains the generalized eigenvalues of the pair, `(A,B)`, along the main diagonal.

  If A is symmetric and B is symmetric positive definite, then the eigenvectors in V are normalized so that the B-norm of each is 1.

D — Eigenvalues (returned as matrix)

diagonal matrix

Eigenvalues, returned as a diagonal matrix with the eigenvalues of A on the main diagonal or the eigenvalues of the pair, `(A,B)`, with multiplicity, on the main diagonal.

- When A is real and symmetric or complex Hermitian, the values of D that satisfy $Av = \lambda v$ are real.
- When A is real and skew-symmetric or skew-Hermitian, the values of D that satisfy $Av = \lambda v$ are purely imaginary or zero.

W — Left eigenvectors

square matrix

Left eigenvectors, returned as a square matrix whose columns are the left eigenvectors of A or generalized left eigenvectors of the pair, `(A,B)`. The form and normalization of W depends on the combination of input arguments:

- `[V,D,W] = eig(A)` returns matrix W, whose columns are the left eigenvectors of A such that `W'*A = D*W'`. The eigenvectors in W are normalized so that the 2-norm of each is 1. If A is symmetric, then W is the same as V.
- `[V,D,W] = eig(A,'nobalance')` also returns matrix W. However, the 2-norm of each eigenvector is not necessarily 1.
- `[V,D,W] = eig(A,B)` and `[V,D,W] = eig(A,B,algorithm)` returns W as a matrix whose columns are the generalized left eigenvectors that satisfy `W'*A = D*W'*B`. The 2-norm of each eigenvector is not necessarily 1. In this case, D contains the generalized eigenvalues of the pair, `(A,B)`, along the main diagonal.

If A and B are symmetric, then W is the same as V.

More About

Tips

- The eig function can calculate the eigenvalues of sparse matrices that are real and symmetric. To calculate the eigenvectors of a sparse matrix, or to calculate the eigenvalues of a sparse matrix that is not real and symmetric, use the eigs function.

balance | condeig | eigs | hess | qz | schur

Introduced before R2006a

eigs

Largest eigenvalues and eigenvectors of matrix

Syntax

```
d = eigs(A)
[V,D] = eigs(A)
[V,D,flag] = eigs(A)
eigs(A,B)
eigs(A,k)
eigs(A,B,k)
eigs(A,k,sigma)
eigs(A,B,k,sigma)
eigs(A,K,sigma,opts)
eigs(A,B,k,sigma,opts)
eigs(Afun,n,...)
```

Description

`d = eigs(A)` returns a vector of `A`'s six largest magnitude eigenvalues. `A` must be a square matrix. `A` should be large and sparse, though `eigs` will work on full matrices as well. See "Tips" on page 1-2291 below.

`[V,D] = eigs(A)` returns a diagonal matrix `D` of `A`'s six largest magnitude eigenvalues and a matrix `V` whose columns are the corresponding eigenvectors.

`[V,D,flag] = eigs(A)` also returns a convergence flag. If `flag` is `0` then all the eigenvalues converged; otherwise not all converged.

`eigs(A,B)` solves the generalized eigenvalue problem `A*V == B*V*D`. `B` must be the same size as `A`. `eigs(A,[],...)` indicates the standard eigenvalue problem `A*V == V*D`.

`eigs(A,k)` and `eigs(A,B,k)` return the `k` largest magnitude eigenvalues.

`eigs(A,k,sigma)` and `eigs(A,B,k,sigma)` return `k` eigenvalues based on *`sigma`*, which can take any of the following values:

scalar (real or complex, including 0)	The eigenvalues closest to *sigma*. If A is a function, Afun must return Y = (A-sigma*B)\x (i.e., Y = A\x when *sigma* = 0).
'lm'	Largest magnitude (default).
'sm'	Smallest magnitude. Same as *sigma* = 0. If A is a function, Afun must return Y = A\x.

For real symmetric A and symmetric positive-definite B, the following are also options:

'la'	Largest algebraic
'sa'	Smallest algebraic
'be'	Both ends (one more from high end if k is odd)

For nonsymmetric and complex problems, the following are also options:

'lr'	Largest real part
'sr'	Smallest real part
'li'	Largest imaginary part
'si'	Smallest imaginary part

Note The syntax eigs(A,k,...) is not valid when A is scalar. To pass a value for k, you must specify B as the second argument and k as the third (eigs(A,B,k,...)). If necessary, you can set B equal to [], the default.

eigs(A,K,*sigma*,opts) and eigs(A,B,k,*sigma*,opts) specify an options structure. Default values are shown in brackets ({}).

Parameter	Description	Values
opts.issym	1 if A or A-*sigma**B represented by Afun is symmetric, 0 otherwise.	[{0} | 1]
opts.isreal	1 if A or A-*sigma**B represented by Afun is real, 0 otherwise.	[0 | {1}]
opts.tol	Convergence: Ritz estimate residual <= tol*norm(A).	[scalar | {eps}]
opts.maxit	Maximum number of iterations.	[integer | {300}]
opts.p	Number of Lanczos basis vectors.	[integer | {2*k}]

Parameter	Description	Values
	`p >= 2k` (`p >= 2k+1` real nonsymmetric) advised. `p` must satisfy `k < p <= n` for real symmetric, `k+1 < p <= n` otherwise. Note: If you do not specify a `p` value, the default algorithm uses at least 20 Lanczos vectors.	
`opts.v0`	Starting vector.	[`n`-by-1 vector | {randomly generated by `rand`}]
`opts.disp`	Diagnostic information display level.	`[{0} | 1 | 2]`
`opts.cholB`	`1` if `B` is really its Cholesky factor `chol(B)`, `0` otherwise.	`[{0} | 1]`
`opts.permB`	Permutation vector `permB` if sparse `B` is really `chol(B(permB,permB))`.	`[permB | {1:n}]`

`eigs(Afun,n,...)` accepts a function handle, `Afun`, instead of the matrix `A`.

`y = Afun(x)` should return:

`A*x`	if *`sigma`* is not specified, or is a string other than `'sm'`
`A\x`	if *`sigma`* is `0` or `'sm'`
`(A-sigma*I)\x`	if *`sigma`* is a nonzero scalar (standard eigenvalue problem). `I` is an identity matrix of the same size as `A`.
`(A-sigma*B)\x`	if *`sigma`* is a nonzero scalar (generalized eigenvalue problem)

"Parameterizing Functions" explains how to provide additional parameters to the function `Afun`, if necessary.

The matrix `A`, `A-`*`sigma`*`*I` or `A-`*`sigma`*`*B` represented by `Afun` is assumed to be real and nonsymmetric unless specified otherwise by `opts.isreal` and `opts.issym`. In all the `eigs` syntaxes, `eigs(A,...)` can be replaced by `eigs(Afun,n,...)`.

Examples

Smallest Eigenvalues of Sparse Matrix

```
A = delsq(numgrid('C',15));
d1 = eigs(A,5,'sm')
```

returns

```
d1 =
    0.5520
    0.4787
    0.3469
    0.2676
    0.1334
```

Smallest Eigenvalues of Function-Generated Sparse Matrix

This example replaces the matrix `A` in example 1 with a handle to a function `dnRk`. The example is contained in file `run_eigs` that

- Calls `eigs` with the function handle `@dnRk` as its first argument.
- Contains `dnRk` as a nested function, so that all variables in `run_eigs` are available to `dnRk`.

The following shows the code for `run_eigs`:

```
function d2 = run_eigs
n = 139;
opts.issym = 1;
R = 'C';
k = 15;
d2 = eigs(@dnRk,n,5,'sm',opts);

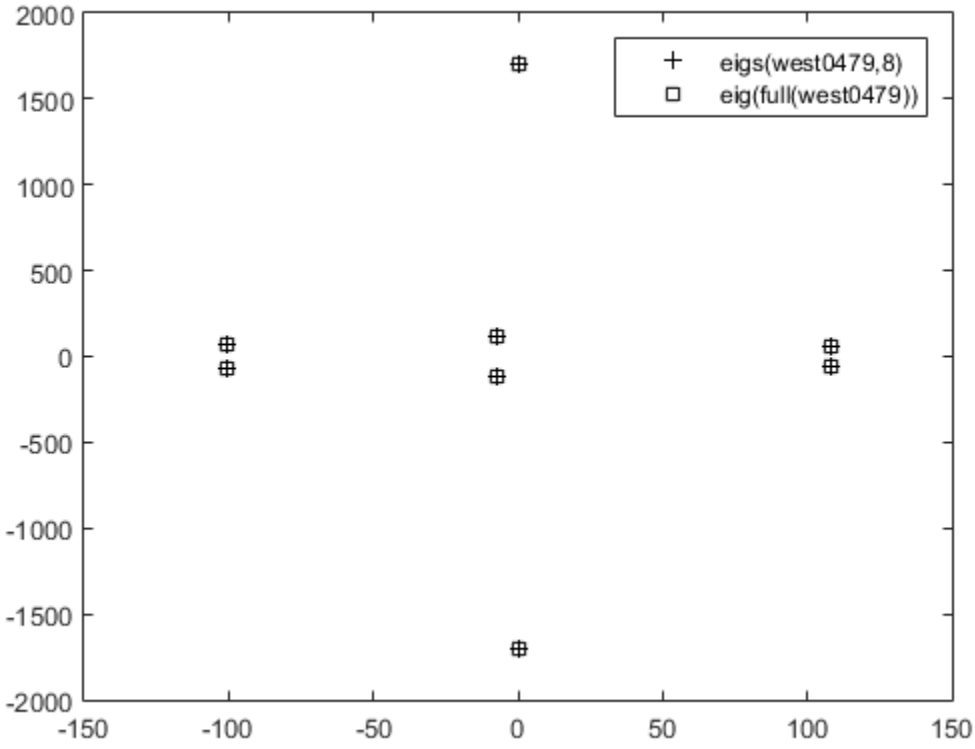
    function y = dnRk(x)
        y = (delsq(numgrid(R,k))) \ x;
    end
end
```

Largest Eigenvalue Pairs of Sparse Matrix

west0479 is a real-valued 479-by-479 sparse matrix with both real and complex pairs of conjugate eigenvalues. `eig` computes all 479 eigenvalues. `eigs` easily picks out the largest magnitude eigenvalues.

This plot shows the 8 largest magnitude eigenvalues of west0479 as computed by `eig` and `eigs`.

```
load west0479
d = eig(full(west0479));
dlm = eigs(west0479,8);
[dum,ind] = sort(abs(d));
plot(dlm,'k+')
hold on
plot(d(ind(end-7:end)),'ks')
hold off
legend('eigs(west0479,8)','eig(full(west0479))')
```



Repeated Eigenvalues of Symmetric Positive Definite Sparse Matrix

`A = delsq(numgrid('C',30))` is a symmetric positive definite matrix of size 632 with eigenvalues reasonably well-distributed in the interval (0 8), but with 18 eigenvalues repeated at 4.

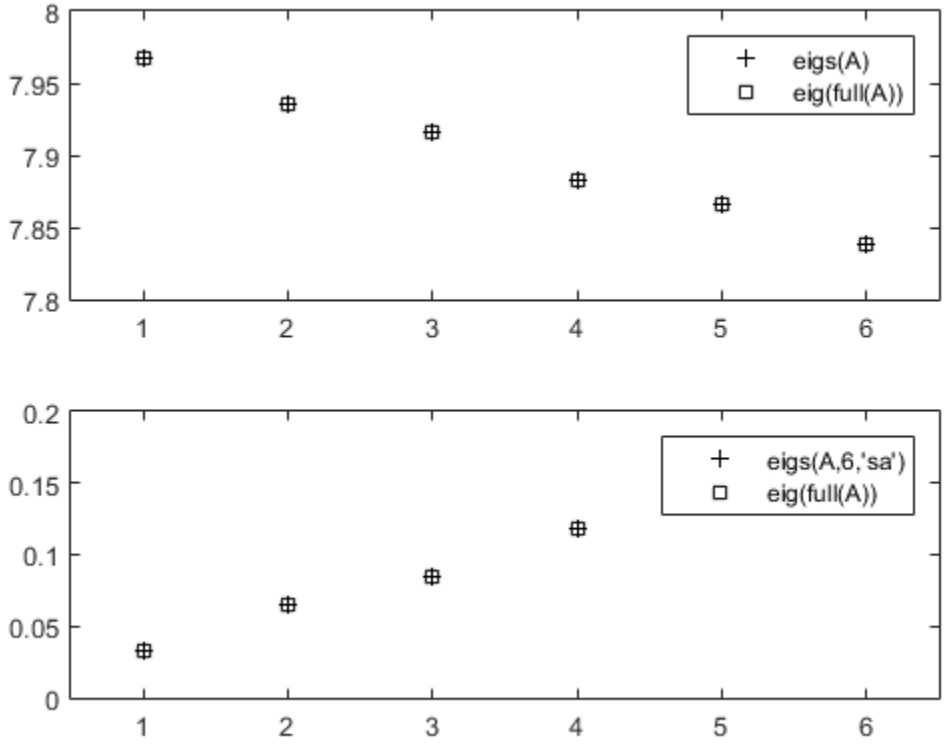
Use the `eig` function to compute all 632 eigenvalues, and the `eigs` function to compute the six largest and smallest magnitude eigenvalues.

```
A = delsq(numgrid('C',30));
d = sort(eig(full(A)));
dlm = eigs(A);
dsm = eigs(A,6,'sa');
```

Plot the results from `eig` and `eigs` for the six largest and smallest magnitude eigenvalues.

```
subplot(2,1,1)
plot(dlm,'k+')
hold on
plot(d(end:-1:end-5),'ks')
hold off
legend('eigs(A)','eig(full(A))',3)
xlim([0.5 6.5])

subplot(2,1,2)
plot(dsm,'k+')
hold on
plot(d(1:6),'ks')
hold off
legend('eigs(A,6,''sa'')','eig(full(A))',2)
xlim([0.5 6.5])
```



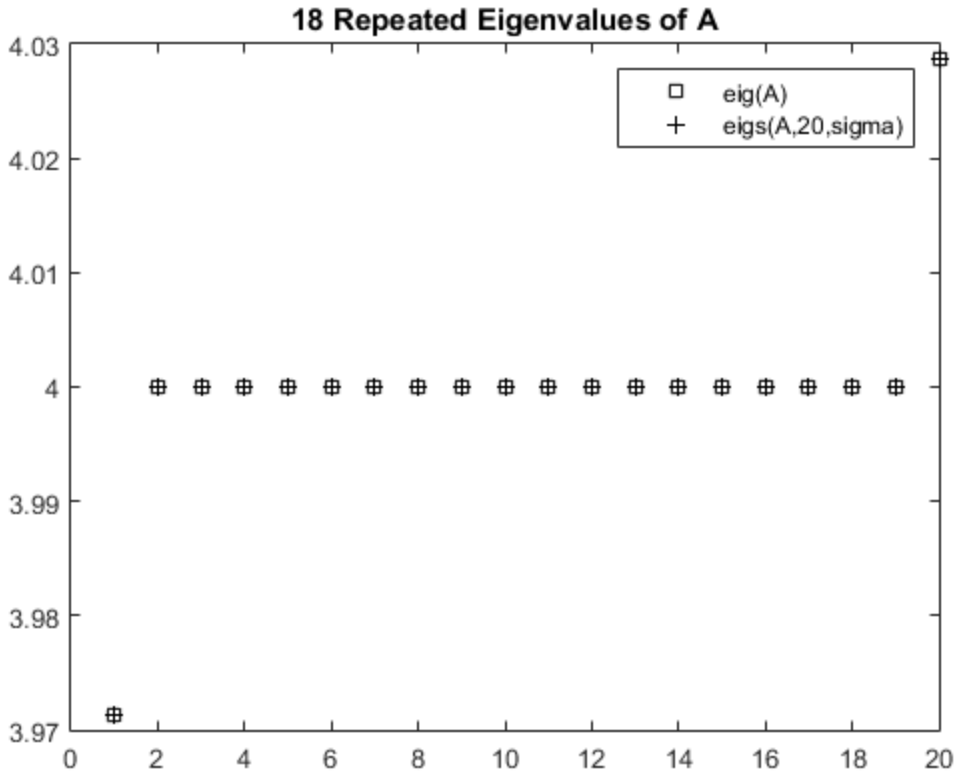
The repeated eigenvalue at 4 must be handled more carefully. The call `eigs(A,20,4.0)` to compute 20 eigenvalues near 4.0 tries to find eigenvalues of `A - 4.0*I`. This involves divisions of the form `1/(lambda - 4.0)`, where lambda is an estimate of an eigenvalue of `A`. As lambda gets closer to 4.0, `eigs` fails. We must use `sigma` near but not equal to 4 to find those eigenvalues.

```
sigma = 4 - 1e-6;
D = sort(eigs(A,20,sigma));
```

The plot below shows the 20 eigenvalues closest to 4 that were computed by `eig`, along with the 20 eigenvalues closest to 4 - 1e-6 that were computed by `eigs`.

```
figure(2)
plot(d(307:326),'ks')
```

```
hold on
plot(D,'k+')
hold off
legend('eig(A)','eigs(A,20,sigma)')
title('18 Repeated Eigenvalues of A')
```



More About

Tips

- `d = eigs(A,k)` is not a substitute for

  `d = eig(full(A))`

```
d = sort(d)
d = d(end-k+1:end)
```

but is most appropriate for large sparse matrices. If the problem fits into memory, it may be quicker to use `eig(full(A))`.

- Unless you provide a start vector with `opts.v0`, the default start vector is generated by `rand`, possibly leading to different iterations each run, and perhaps even different convergence behavior. In order to control this, specify your start vector via `opts.v0`.
- `eigs` does not always return sorted eigenvalues and eigenvectors. Use `sort` to explicitly sort the output eigenvalues and eigenvectors in cases where their order is important.

ellipj

Jacobi elliptic functions

Syntax

```
[SN,CN,DN] = ellipj(U,M)
[SN,CN,DN] = ellipj(U,M,tol)
```

Description

`[SN,CN,DN] = ellipj(U,M)` returns the Jacobi elliptic functions SN, CN, and DN evaluated for corresponding elements of argument U and parameter M. Inputs U and M must be the same size, or either U or M must be scalar.

`[SN,CN,DN] = ellipj(U,M,tol)` computes the Jacobi elliptic functions to accuracy `tol`. The default value of tol is `eps`. Increase tol for a less accurate but more quickly computed answer.

Examples

Find the Jacobi Elliptic Functions

Find the Jacobi elliptic functions for `U = 0.5` and `M = 0.25`.

```
[s,c,d] = ellipj(0.5,0.25)
```

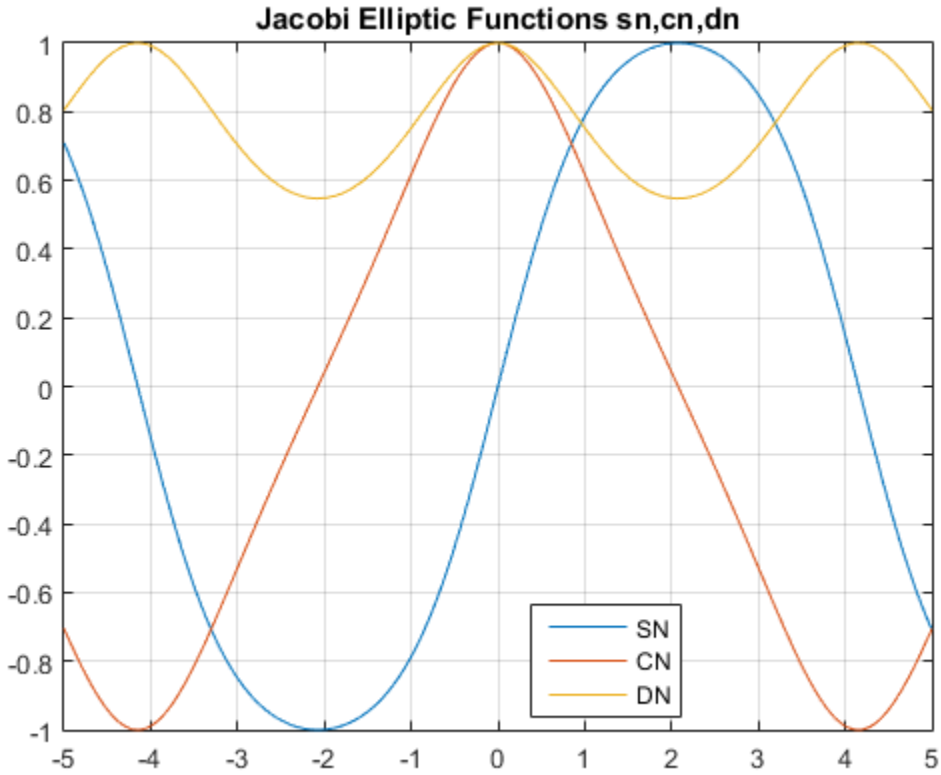
```
s =
    0.4751
c =
    0.8799
d =
    0.9714
```

Plot the Jacobi Elliptic Functions

Plot the Jacobi elliptic functions for `-5≤U≤5` and `M = 0.7`.

```
M = 0.7;
```

```
U = -5:0.01:5;
[S,C,D] = ellipj(U,M);
plot(U,S,U,C,U,D);
legend('SN','CN','DN','Location','best')
grid on
title('Jacobi Elliptic Functions sn,cn,dn')
```

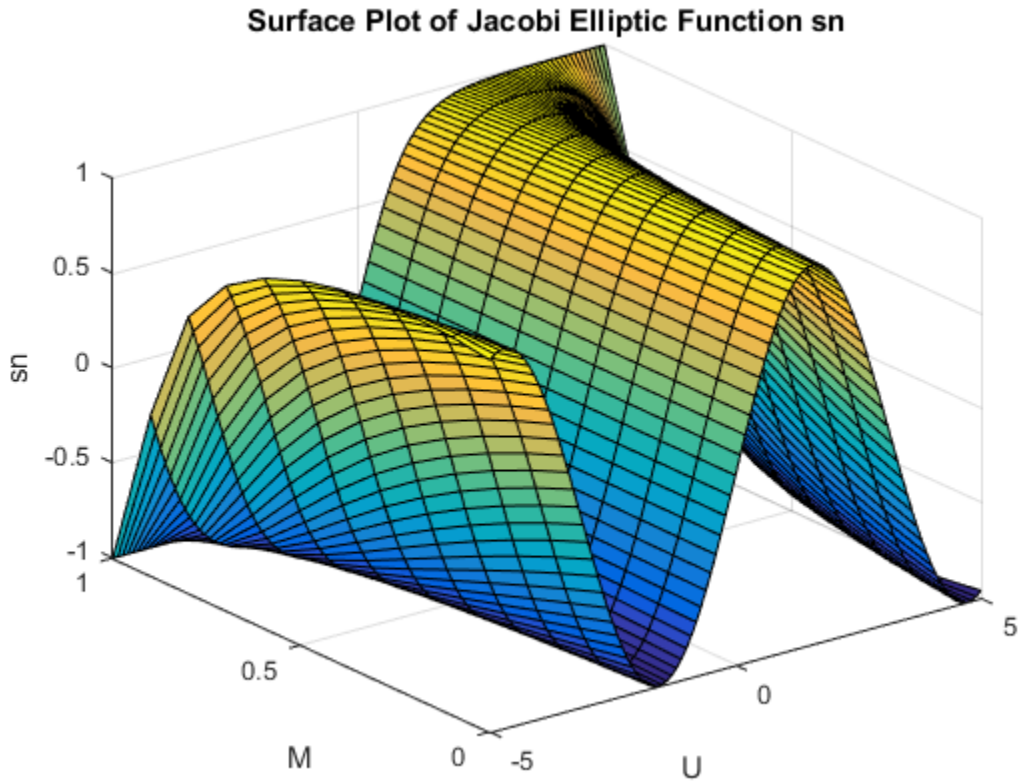


Generate a Surface Plot of the Jacobi Elliptic sn Function

Generate a surface plot of the Jacobi elliptic sn function for the allowed range of `M` and `-5≤U≤5`.

```
[M,U] = meshgrid(0:0.1:1,-5:0.1:5);
S = ellipj(U,M);
```

```
surf(U,M,S)
xlabel('U')
ylabel('M')
zlabel('sn')
title('Surface Plot of Jacobi Elliptic Function sn')
```



Faster Calculations of Jacobi Elliptic Integrals by Changing Tolerance

The default value of `tol` is `eps`. Find the run time with the default value for arbitrary `M` using `tic` and `toc`. Increase `tol` by a factor of 1000 and find the run time. Compare the run times.

```
tic
ellipj(0.253,0.937)
```

```
toc
tic
ellipj(0.253,0.937,eps*1000)
toc

ans =

    0.2479

Elapsed time is 0.048734 seconds.

ans =

    0.2479

Elapsed time is 0.007390 seconds.
```

`ellipj` runs significantly faster when tolerance is significantly increased.

Input Arguments

`U` — Floating-point input

number | vector | matrix | multidimensional array

Floating-point input, specified as a floating-point number, vector, matrix, or multidimensional array. `U` is limited to real values. If U is nonscalar, M must be a scalar or a nonscalar of the same size as U.

Data Types: `single` | `double`

`M` — Floating-point input

number | vector | matrix | multidimensional array

Floating-point input, specified as a floating-point number, vector, matrix, or multidimensional array. M can take values $0 \le m \le 1$. If M is a nonscalar, U must be a scalar or a nonscalar of the same size as M. Map other values of `M` into this range using the transformations described in [1], equations 16.10 and 16.11.

Data Types: `single` | `double`

`tol` — Accuracy of result

eps (default) | nonnegative real number

Accuracy of result, specified as a nonnegative real number. The default value is `eps`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `function_handle`

Output Arguments

SN — Jacobi elliptic function sn

floating-point number | floating-point vector | floating-point matrix | floating-point multidimensional array

Jacobi elliptic function sn, returned as a floating-point number, vector, matrix, or multidimensional array.

CN — Jacobi elliptic function cn

floating-point number | floating-point vector | floating-point matrix | floating-point multidimensional array

Jacobi elliptic function cn, returned as a floating-point number, vector, matrix, or multidimensional array.

DN — Jacobi elliptic function dn

floating-point number | floating-point vector | floating-point matrix | floating-point multidimensional array

Jacobi elliptic function dn, returned as a floating-point number, vector, matrix, or multidimensional array.

More About

Jacobi Elliptic Functions

The Jacobi elliptic functions are defined in terms of the integral

$$u = \int_0^{\phi} \frac{d\theta}{\sqrt{1 - m\sin^2\theta}}.$$

Then

$$sn(u) = \sin\phi,\ cn(u) = \cos\phi,\ dn(u) = \sqrt{1 - m\sin^2\phi}.$$

Some definitions of the elliptic functions use the elliptical modulus k or modular angle a instead of the parameter m. They are related by

$$k^2 = m = \sin^2 a.$$

The Jacobi elliptic functions obey many mathematical identities. For a good sample, see [1].

Algorithms

`ellipj` computes the Jacobi elliptic functions using the method of the arithmetic-geometric mean of [1]. It starts with the triplet of numbers

$$a_0 = 1,\ b_0 = \sqrt{1-m},\ c_0 = \sqrt{m}.$$

`ellipj` computes successive iterations using

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1})$$
$$b_i = (a_{i-1}b_{i-1})^{\frac{1}{2}}$$
$$c_i = \frac{1}{2}(a_{i-1} - b_{i-1}).$$

Next, it calculates the amplitudes in radians using

$$\sin(2\phi_{n-1} - \phi_n) = \frac{c_n}{a_n}\sin(\phi_n),$$

being careful to unwrap the phases correctly. The Jacobian elliptic functions are then simply

$$sn(u) = \sin\phi_0$$
$$cn(u) = \cos\phi_0$$
$$dn(u) = \sqrt{1 - m\cdot sn(u)^2}.$$

```

`ellipke` runs significantly faster when tolerance is significantly increased.

Input Arguments

`M` — Floating-point input

number | vector | matrix | multidimensional array

Floating-point input, specified as a floating-point number, vector, matrix, or multidimensional array. M is limited to values $0 \le m \le 1$.

Data Types: `single` | `double`

`tol` — Accuracy of result

eps (default) | nonnegative real number

Accuracy of result, specified as a nonnegative real number. The default value is `eps`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

Output Arguments

`K` — Complete elliptic integral of first kind

floating-point number | floating-point vector | floating-point matrix | floating-point multidimensional array

Complete elliptic integral of the first kind, specified as a floating-point number, vector, matrix, or multidimensional array.

E — Complete elliptic integral of second kind

floating-point number | floating-point vector | floating-point matrix | floating-point multidimensional array

Complete elliptic integral of the second kind, specified as a floating-point number, vector, matrix, or multidimensional array.

More About

Complete Elliptic Integrals of the First and Second Kind

The complete elliptic integral of the first kind is

$$[K(m)] = \int_0^1 [(1-t^2)(1-mt^2)]^{-\frac{1}{2}} dt.$$

where m is the first argument of `ellipke`.

The complete elliptic integral of the second kind is

$$E(m) = \int_0^1 (1-t^2)^{-\frac{1}{2}} (1-mt^2)^{\frac{1}{2}} dt.$$

Some definitions of the elliptic functions use the elliptical modulus k or modular angle α instead of the parameter m. They are related by

$$k^2 = m = \sin^2 \alpha.$$

`ellipj`

Introduced before R2006a

ellipsoid

Generate ellipsoid

Syntax

```
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)
ellipsoid(axes_handle,...)
ellipsoid(...)
```

Description

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)` generates a surface mesh described by three `n+1`-by-`n+1` matrices, enabling `surf(x,y,z)` to plot an ellipsoid with center `(xc,yc,zc)` and semi-axis lengths `(xr,yr,zr)`.

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)` uses `n = 20`.

`ellipsoid(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

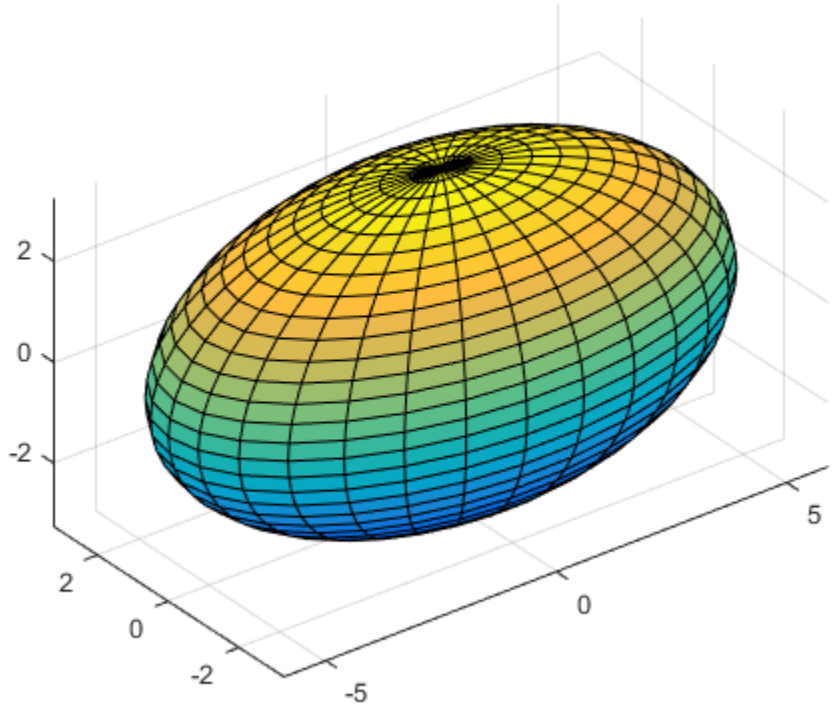
`ellipsoid(...)` with no output arguments plots the ellipsoid as a surface.

Examples

Surface Plot of Ellipsoid

Generate data for an ellipsoid with a center at (0,0,0) and semi-axis lengths (5.9,3.25,3.25). Use `surf` to plot the ellipsoid.

```
[x, y, z] = ellipsoid(0,0,0,5.9,3.25,3.25,30);
figure
surf(x, y, z)
axis equal
```



More About

Algorithms

`ellipsoid` generates the data using the following equation:

$$\frac{(x-xc)^2}{xr^2}+\frac{(y-yc)^2}{yr^2}+\frac{(z-zc)^2}{zr^2}=1$$

Note that `ellipsoid(0,0,0,.5,.5,.5)` is equivalent to a unit sphere.

`cylinder` | `sphere` | `surf`

Introduced before R2006a

empty

Create empty array

Syntax

```
A = ClassName.empty
A = ClassName.empty(n,m,p,...)
A = ClassName.empty([n,m,p,...])
```

Description

Use `empty` to create empty arrays of the specified class, *`ClassName`*. Specify at least one dimension of the array as 0. MATLAB treats negative values as 0.

`A = ClassName.empty` returns an empty 0-by-0 array of the class of *`ClassName`*.

`A = ClassName.empty(n,m,p,...)` returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0.

`A = ClassName.empty([n,m,p,...])` returns an empty rectangular array with the specified dimensions. At least one of the dimensions must be 0. This syntax is useful when using the values returned by the `size` function to define an empty array that is the same size as an existing empty array:

```
A = ClassName.empty(size(otherEmptyArray));
```

Input Arguments

`n,m,p,...`

Dimensions of the empty array. At least one of the specified dimensions must be 0.

Output Arguments

A

An empty array of the specified dimensions and of the class used in the method invocation.

Attributes

`empty` is a hidden, public, static method of all nonabstract MATLAB classes.

`Access`	`Public`
`Hidden`	`true`
`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Use `empty` to create a rectangular empty array of class `int16`:

```
A = int16.empty(5,0);
whos
  Name      Size            Bytes  Class    Attributes

  A         5x0                 0  int16
```

Using the `empty` method of the `int16` class to produce an empty array in which some dimensions are not zero is simpler than using conversion and reshape operations:

```
A = int16([]);
A = reshape(A,5,0);
whos
  Name      Size            Bytes  Class    Attributes

  A         5x0                 0  int16
```

Given the following definition for a class,

```
classdef ExEmpty
   properties
      Color = [1,0,0];
   end
   methods
      function obj = ExEmpty(c)
         if nargin > 0
            obj.Color = c;
         end
      end
   end
end
```

Create an empty array of class `ExEmpty`:

```
A = ExEmpty.empty;
 whos
  Name        Size            Bytes  Class     Attributes

  A           0x0               104  ExEmpty
```

One dimension of an empty array must be zero:

```
A5 = ExEmpty.empty(0,5);
 whos
  Name        Size            Bytes  Class     Attributes

  A5           0x5               104  ExEmpty
```

Empty object arrays follow array concatenation behavior:

```
B = [A,A5]
B =

  0x5 ExEmpty array with properties:

    Color
```

You cannot index into an empty array:

```
A5(1)
Index exceeds matrix dimensions.
```

You can use the `isempty`, `size`, and `length` functions to identify empty object arrays:

```
isempty(A5)
```

```
ans =

     1
size(A5)

ans =

     0     5
length(A5)

ans =

     0
```

Class of Empty Object Array

The `empty` method enables you to initialize arrays of a specific class:

```
C = char.empty(0,7)

C =

   Empty string: 0-by-7

class(C)
ans =

char
```

Initializing an array with empty brackets (`[ ]`):

```
a = [];
```

produces an array of class `double`:

```
class(a)
ans =

double
```

See Also

`| isempty | size | length`

enableNETfromNetworkDrive

Enable access to .NET commands from network drive

Syntax

```
enableNETfromNetworkDrive
```

Description

`enableNETfromNetworkDrive` adds an entry for the MATLAB interface to .NET module to the security policy on your machine. You must have administrative privileges to make changes to your configuration.

Compatibility

Use `enableNETfromNetworkDrive` for MATLAB releases R2012b or earlier, which support installed versions 2.0, 3.0, and 3.5 of the Microsoft .NET Framework.

Related Examples

- "Troubleshooting Security Policy Settings From Network Drives"

Introduced in R2009b

enableservice

Enable, disable, or report status of MATLAB Automation server

Syntax

```
state = enableservice('AutomationServer',enable)
state = enableservice('AutomationServer')
```

Description

`state = enableservice('AutomationServer',enable)` enables or disables the MATLAB Automation server. If `enable` is `true` (logical `1`), `enableservice` converts an existing MATLAB session into an Automation server. If `enable` is `false` (logical `0`), `enableservice` disables the MATLAB Automation server. `state` indicates the previous state of the Automation server. If `state` = `1`, MATLAB was an Automation server. If `state` = `0`, MATLAB was not an Automation server.

`state = enableservice('AutomationServer')` returns the current state of the Automation server. If `state` is logical `1` (`true`), MATLAB is an Automation server.

COM functions are available on Microsoft Windows systems only.

Examples

Enable the Automation server in the current MATLAB session:

```
state = enableservice('AutomationServer',true);
```

Show the current state of the MATLAB session. MATLAB displays `true`:

```
state = enableservice('AutomationServer')
```

Enable the Automation server and show the previous state. MATLAB displays `true`. The previous state can be the same as the current state:

```
state = enableservice('AutomationServer',true)
```

To enable the Automation server every time you run MATLAB, see “Manually Create Automation Server”.

More About

- “MATLAB COM Automation Server Interface”

See Also

`actxserver`

Introduced before R2006a

end

Terminate block of code, or indicate last array index

Syntax

```
end
```

Description

`end` terminates `for`, `while`, `switch`, `try`, `if`, and `parfor` statements. Without an `end` statement, `for`, `while`, `switch`, `try`, `if`, and `parfor` wait for further input. Each `end` is paired with the closest previous unpaired `for`, `while`, `switch`, `try`, `if`, or `parfor` and serves to delimit its scope.

`end` also marks the termination of a function, although in many cases it is optional. If your function contains one or more nested functions, then you must terminate every function in the file, whether nested or not, with `end`. This includes primary, nested, private, and local functions.

The `end` function also serves as the last index in an indexing expression. In that context, `end = (size(x,k))` when used as part of the `k`th index. Examples of this use are `X(3:end)` and `X(1,1:2:end-1)`. When using `end` to grow an array, as in `X(end+1)=5`, make sure `X` exists first.

You can overload the `end` statement for a user object by defining an `end` method for the object. The `end` method should have the calling sequence `end(obj,k,n)`, where `obj` is the user object, `k` is the index in the expression where the `end` syntax is used, and `n` is the total number of indices in the expression. For example, consider the expression

```
A(end-1,:)
```

The MATLAB software calls the `end` method defined for `A` using the syntax

```
end(A,1,2)
```

Examples

This example shows `end` used with the `for` and `if` statements.

```
for k = 1:n
    if a(k) == 0
        a(k) = a(k) + 2;
    end
end
```

In this example, `end` is used in an indexing expression.

```
A = magic(5)

A =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9

B = A(end,2:end)

B =

    18    25     2     9
```

Introduced before R2006a

EndInvoke

Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method

Syntax

```
result = EndInvoke(asyncResult)
[res0,...,resN] = EndInvoke(res0,...,resN,asyncResult)
```

Description

`result = EndInvoke(asyncResult)` retrieves result of asynchronous call initiated by `BeginInvoke` method.

`[res0,...,resN] = EndInvoke(res0,...,resN,asyncResult)` for methods with `out` and/or `ref` parameters.

Input Arguments

`asyncResult`

.NET System.IAsyncResult object returned by `BeginInvoke`.

`res0,...,resN`

For methods with `out` and/or `ref` parameters, results of the asynchronous call. The number of arguments is the sum of:

- Number of return values (`0` or `1`).
- Number of `out` and `ref` arguments.

Output Arguments

`result`

Results of the asynchronous call.

`res0,...,resN`

For methods with `out` and/or `ref` parameters, results of the asynchronous call,

Examples

The following examples show how to call delegates with various input and output arguments. Each example contains:

1. The C# delegate signature. In order to execute the MATLAB code, build the delegate code into an assembly named `SignatureExamples` and load it into MATLAB. For information, see "Build a .NET Application for MATLAB Examples".
2. An example MATLAB function to use with the delegate, which must exist on your path.
3. The `BeginInvoke` and `EndInvoke` signatures MATLAB creates. To display the signatures, create a delegate instance, `myDel`, and call the `methodsview` function.
4. Simple MATLAB example.

This example shows how to use a delegate that has no return value.

1. C# delegate:

```
public delegate void delint(Int32 arg);
```

2. MATLAB function to call:

```
%Display input argument
function dispfnc(A)
%A = number
['Input is ' num2str(A)]
end
```

3. MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResult RetVal
    BeginInvoke (
        SignatureExamples.delint this,
        int32 scalar arg,
        System.AsyncCallback callback,
        System.Object object)
```

The `EndInvoke` signature:

```
    EndInvoke (
        SignatureExamples.delint this,
        System.IAsyncResult result)
```

4 Call `dispfnc`:

```
myDel = SignatureExamples.delint(@dispfnc);
asyncRes = myDel.BeginInvoke(6, [], []);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
myDel.EndInvoke(asyncRes)

Input is 6
```

This example shows how to use a delegate with a return value. The delegate does not have `out` or `ref` parameters.

1 C# delegate:

```
public delegate Int32 del2int(Int32 arg1, Int32 arg2);
```

2 MATLAB function to call:

```
%Add input arguments
function res = addfnc(A, B)
%A and B are numbers
res = A + B;
end
```

3 MATLAB creates the following signatures. For `BeginInvoke`:

```
System.IAsyncResult RetVal
    BeginInvoke (
        SignatureExamples.del2int this,
        int32 scalar arg1,
        int32 scalar arg2,
        System.AsyncCallback callback,
        System.Object object)
```

The `EndInvoke` signature:

```
int32 scalar RetVal
    EndInvoke (
        SignatureExamples.del2int this,
        System.IAsyncResult result)
```

4 Call `addfnc`:

```
myDel = SignatureExamples.del2int(@addfnc);
asyncRes = myDel.BeginInvoke(6,8,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
result = myDel.EndInvoke(asyncRes)
```

```
result =
          14
```

This example shows how to use a delegate with a `ref` parameter, `refArg`, and no return value.

1 C# delegate:

```
public delegate void delrefvoid(ref Double refArg);
```

2 MATLAB maps the `ref` argument as both RHS and LHS arguments. MATLAB function to call:

```
%Increment input argument
function res = incfnc(A)
%A = number
res = A + 1;
end
```

3 MATLAB creates the following signatures. For `BeginInvoke`:

```
[System.IAsyncResult RetVal,
double scalar refArg]
    BeginInvoke (
        SignatureExamples.delrefvoid this,
        double scalar refArg,
        System.AsyncCallback callback,
        System.Object object)
```

The `EndInvoke` signature:

```
double scalar refArg
    EndInvoke (
        SignatureExamples.delrefvoid this,
        double scalar refArg,
        System.IAsyncResult result)
```

4 Call `incfnc`:

```
x = 6;
myDel = SignatureExamples.delrefvoid(@incfnc);
asyncRes = myDel.BeginInvoke(x,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
myRef = 0;
result = myDel.EndInvoke(myRef,asyncRes);
disp(['Increment of ' num2str(x) ' = ' num2str(result)]);

Increment of 6 = 7
```

This example shows how to use a delegate with an `out` parameter, `argOut`, and one return value.

1. C# delegate:

   ```
   public delegate Single deloutsingle(Single argIn, out Single argOut);
   ```

2. MATLAB maps the `out` argument as a return value for a total of two return values. MATLAB function to call:

   ```
   %Double input argument
   function [res1 res2] = times2fnc(A)
   res1 = A*2;
   res2 = res1;
   end
   ```

3. MATLAB creates the following signatures. For `BeginInvoke`:

   ```
   [System.IAsyncResult RetVal,
   single scalar argOut]
       BeginInvoke (
           SignatureExamples.deloutsingle this,
           single scalar argIn,
           System.AsyncCallback callback,
           System.Object object)
   ```

   The `EndInvoke` signature:

   ```
   [single scalar RetVal,
   single scalar argOut]
       EndInvoke (
           SignatureExamples.deloutsingle this,
           System.IAsyncResult result)
   ```

4 Call `times2fnc`:

```
myDel = SignatureExamples.deloutsingle(@times2fnc);
asyncRes = myDel.BeginInvoke(6,[],[]);
while asyncRes.IsCompleted ~= true
    pause(0.05); % Use pause() to let MATLAB process event
end
[a1 a2] = myDel.EndInvoke(asyncRes);
a1

a1 =
    12
```

More About

Tips

- If the delegate contains `out` or `ref` parameters, the signature for the `EndInvoke` method follows the MATLAB mapping rules. For information, see "Call Delegates With out and ref Type Arguments".

- "Calling .NET Methods Asynchronously"
- MSDN Calling Synchronous Methods Asynchronously

See Also

`BeginInvoke`

Introduced in R2011a

eomday

Last day of month

Syntax

```
E = eomday(Y,M)
```

Description

`E = eomday(Y,M)` returns the last day of the year and month given by corresponding elements of the numeric arrays `Y` and `M`.

Examples

Show the end of month for January through September for the year 1900:

```
eomday(1900, 1:9)
ans =
    31    28    31    30    31    30    31    31    30
```

Find the number of days during that period:

```
sum(eomday(1900, 1:9))
ans =
   273
```

Because 1996 is a leap year, the statement `eomday(1996,2)` returns `29`. To show all the leap years in the twentieth century, try:

```
y = 1900:1999;
E = eomday(y, 2);
y(find(E == 29))

ans =
  Columns 1 through 6
     1904     1908     1912     1916     1920     1924
```

```
Columns 7 through 12
   1928     1932     1936     1940     1944     1948

Columns 13 through 18
   1952     1956     1960     1964     1968     1972

Columns 19 through 24
   1976     1980     1984     1988     1992     1996
```

See Also

`datenum` | `datevec` | `weekday`

Introduced before R2006a

enumeration

Display class enumeration members and names

Syntax

```
enumeration ClassName
enumeration(obj)
m = enumeration(ClassName)
m = enumeration(obj)
[m,s] = enumeration(ClassName)
[m,s] = enumeration(obj)
```

Description

`enumeration ClassName` displays the names of the enumeration members for the MATLAB class with the name ClassName.

`enumeration(obj)` displays the names of the enumeration members for the class of obj.

`m = enumeration(ClassName)` returns the enumeration members for the class in the column vector m of objects.

`m = enumeration(obj)` returns the enumeration members for the class of object, obj, in the column vector m of objects.

`[m,s] = enumeration(ClassName)` returns the names of the enumeration members in the cell array of strings s. The names in s correspond element-wise to the enumeration members in m.

`[m,s] = enumeration(obj)` returns the enumeration members for the class of object, obj, in the column vector m of objects.

Input Arguments

`ClassName`

The name of the enumeration class, in single quotes.

obj

A instance of an enumeration class.

Output Arguments

m

Column vector of enumeration members.

s

Cell array of strings containing the enumeration names.

Examples

All examples use the following enumeration class.

```
classdef Boolean < logical
   enumeration
      No  (0)
      Yes (1)
      Off (0)
      On  (1)
   end
end
```

Display the names of the enumeration members for class `Boolean`:

```
enumeration Boolean
Enumerations for class Boolean:

    No
    Yes
```

Get the enumeration members for class `Boolean` in a column vector of objects:

```
members = enumeration('Boolean')
members =

    No
```

```
    Yes
```

Get all available enumeration members and their names:

```
[members, names] = enumeration('Boolean')
members =

    No
    Yes
    No
    Yes

names =

    'No'
    'Yes'
    'Off'
    'On'
```

More About

Tips

- An enumeration class that derives from a built-in class can specify more than one name for a given enumeration member.
- When you call the `enumeration` function with no output arguments, MATLAB displays only the first name for each enumeration member (as specified in the class definition). To see all available enumeration members and their names, use the two output arguments (for example, `[m, s] = enumeration(obj);`).

See Also

`classdef`

eps

Floating-point relative accuracy

Syntax

```
d = eps
d = eps(x)
d = eps(datatype)
```

Description

`d = eps` returns the distance from `1.0` to the next largest double-precision number, that is, `eps = 2^-52`.

`d = eps(x)`, where `x` has data type `single` or `double`, returns the positive distance from `abs(x)` to the next largest floating-point number of the same precision as `x`. The command `eps(1.0)` is equivalent to `eps`.

`d = eps(datatype)` returns `eps` according to the data type specified by `datatype`, which can be either `'double'` or `'single'`. The syntax `eps('double')` (default) is equivalent to `eps`, and `eps('single')` is equivalent to `eps(single(1.0))`.

Examples

Accuracy in Double Precision

Display the distance from `1.0` to the next largest double-precision number.

```
d = eps
```

```
d =

   2.2204e-16
```

`eps` is equivalent to `eps(1.0)` and `eps('double')`.

Compute `log2(eps)`.

```
d = log2(eps)
```

```
d =

   -52
```

In base `2`, `eps` is equal to `2^-52`.

Find the distance from `10.0` to the next largest double-precision number.

```
d = eps(10.0)
```

```
d =

   1.7764e-15
```

Accuracy in Single Precision

Display the distance from `1.0` to the next largest single-precision number.

```
d = eps('single')
```

```
d =

  1.1921e-07
```

`eps('single')` is equivalent to `eps(single(1.0))`.

Compute `log2(eps('single'))`.

```
d = log2(eps('single'))
```

```
d =

   -23
```

In base 2, single-precision `eps` is equal to `2^-23`.

Find the distance from the single-precision representation of 10.0 to the next largest single-precision number.

```
d = eps(single(10.0))
```

```
d =

  9.5367e-07
```

Input Arguments

x — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `d` is the same size as `x`. For all `x`, `eps(x) = eps(-x) = eps(abs(x))`. If `x` is complex, `d` is the distance to the next largest floating-point number in magnitude. If `x` is `Inf` or `NaN`, then `eps(x)` returns `NaN`.

Data Types: `single` | `double`
Complex Number Support: Yes

datatype — Output data type

`'double'` (default) | `'single'`

Output data type, specified as `'double'` or `'single'`.

- `eps('double')` is equivalent to `eps` and `eps(1.0)`.
- `eps('single')` is equivalent to `eps(single(1.0))` and `single(2^-23)`.

Data Types: `char`

`double` | `intmax` | `realmax` | `realmin` | `single`

Introduced before R2006a

eq, ==

Determine equality

Syntax

```
A == B
eq(A,B)
```

Description

`A == B` returns a logical array with elements set to logical `1` (`true`) where arrays `A` and `B` are equal; otherwise, it returns logical `0` (`false`). The test compares both real and imaginary parts of numeric arrays. `eq` returns logical `0` (`false`) where `A` or `B` have NaN or undefined categorical elements.

`eq(A,B)` is an alternative way to execute `A == B`, but is rarely used. It enables operator overloading for classes.

Examples

Equality of Two Vectors

Create two vectors containing both real and imaginary numbers.

```
A = [1+i 3 2 4+i];
B = [1 3+i 2 4+i];
```

Compare the two vectors for equality.

```
A == B
```

```
ans =

     0     0     1     1
```

The `eq` function tests both real and imaginary parts for equality, and returns logical `1` (`true`) only where both parts are equal.

Find Characters in String

Create a string of characters.

```
M = 'masterpiece';
```

Test the string for the presence of a specific character using `==`.

```
M == 'e'
```

```
ans =

     0     0     0     0     1     0     0     0     1     0     1
```

The value of logical `1` (`true`) in the vector indicates the presence of the character `'e'` in the string.

Find Values in Categorical Array

Create a categorical array.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =

     heads      heads      tails
     tails      heads      tails
```

The array has two categories: `'heads'` and `'tails'`.

Find all values in the `'heads'` category.

```
A == 'heads'
```

```
ans =

     1     1     0
     0     1     0
```

A value of logical `1` (`true`) indicates a value in the category.

Compare the rows of A for equality.

```
A(1,:) == A(2,:)
```

```
ans =

     0     1     1
```

The function returns logical 1 (true) where the rows have equal category values.

Compare Floating-Point Numbers

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the == operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in C.

```
C = 0.5-0.4-0.1
```

```
C =

  -2.7756e-17
```

Intuitively, C should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare C to zero for equality.

```
C == 0
```

```
ans =

     0
```

The result is logical 0 (false).

Compare floating-point numbers using a tolerance, tol, instead of ==.

```
tol = eps;
abs(C-0) < tol
```

```
ans =

     1
```

The two numbers, C and 0, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

Compare Datetime Values

Compare the elements of two `datetime` arrays.

Create two `datetime` arrays in different time zones.

```
t1 = [2014,04,14,9,0,0;2014,04,14,10,0,0];
A = datetime(t1,'TimeZone','America/Los_Angeles');
A.Format = 'd-MMM-y HH:mm:ss Z'
```

```
A =

   14-Apr-2014 09:00:00 -0700
   14-Apr-2014 10:00:00 -0700
```

```
t2 = [2014,04,14,12,0,0;2014,04,14,12,30,0];
B = datetime(t2,'TimeZone','America/New_York');
B.Format = 'd-MMM-y HH:mm:ss Z'
```

```
B =

   14-Apr-2014 12:00:00 -0400
   14-Apr-2014 12:30:00 -0400
```

Check where elements in A and B are equal.

```
A==B
```

```
ans =

     1
     0
```

Input Arguments

A — Left array

numeric array | logical array | character array | categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Complex Number Support: Yes

B — Right array

numeric array | logical array | character array | categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.
Complex Number Support: Yes

More About

Tips

- When comparing handle objects, use == to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.

Introduced before R2006a

erf

Error function

Syntax

```
erf(x)
```

Description

`erf(x)` returns the "Error Function" on page 1-2343 evaluated for each element of x.

Examples

Find Error Function

Find the error function of a value.

```
erf(0.76)
```

```
ans =

    0.7175
```

Find the error function of the elements of a vector.

```
V = [-0.5 0 1 0.72];
erf(V)
```

```
ans =

   -0.5205         0    0.8427    0.6914
```

Find the error function of the elements of a matrix.

```
M = [0.29 -0.11; 3.1 -2.9];
erf(M)
```

```
ans =

    0.3183   -0.1236
    1.0000   -1.0000
```

Find Cumulative Distribution Function of Normal Distribution

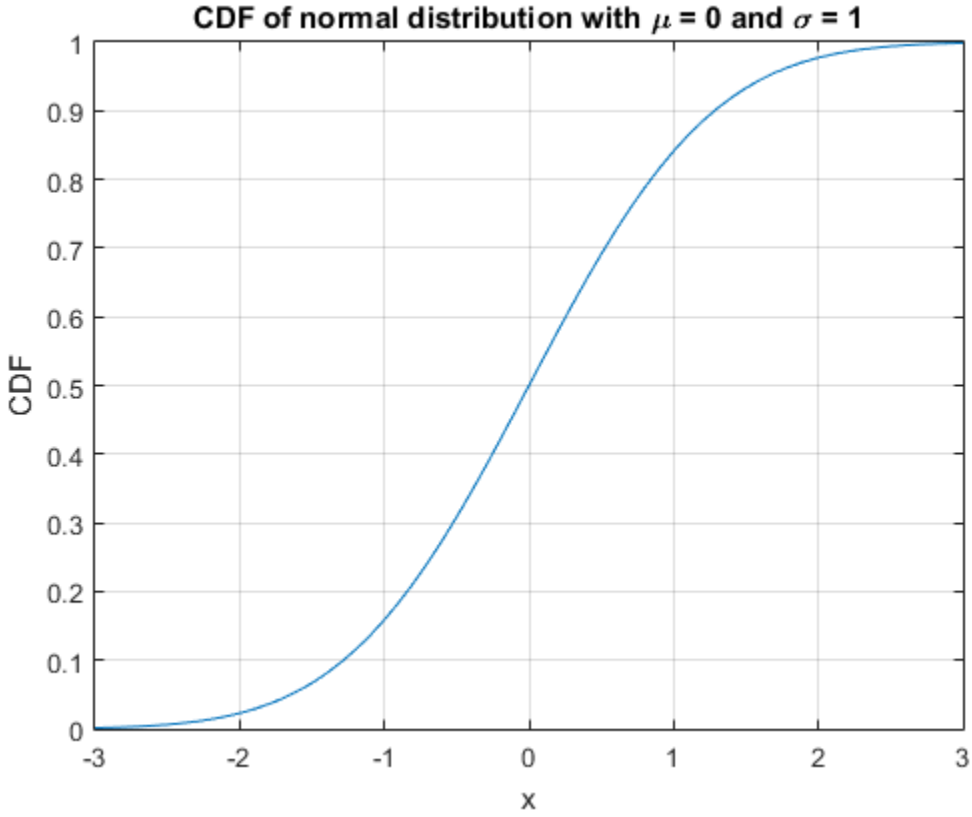
The cumulative distribution function (CDF) of the normal, or Gaussian, distribution with standard deviation σ and mean μ is

$$\phi(x) = \frac{1}{2}\left(1 + \mathrm{erf}\left(\frac{x - \mu}{\sigma\sqrt{2}}\right)\right).$$

Note that for increased computational accuracy, you can rewrite the formula in terms of `erfc` . For details, see “Tips”.

Plot the CDF of the normal distribution with $\mu = 0$ and $\sigma = 1$.

```
x = -3:0.1:3;
y = (1/2)*(1+erf(x/sqrt(2)));
plot(x,y)
grid on
title('CDF of normal distribution with \mu = 0 and \sigma = 1')
xlabel('x')
ylabel('CDF')
```



Calculate Solution of Heat Equation with Initial Condition

Where $u(x,t)$ represents the temperature at position x and time t, the heat equation is

$$\frac{\partial u}{\partial t} = c\frac{\partial^2 u}{\partial x^2},$$

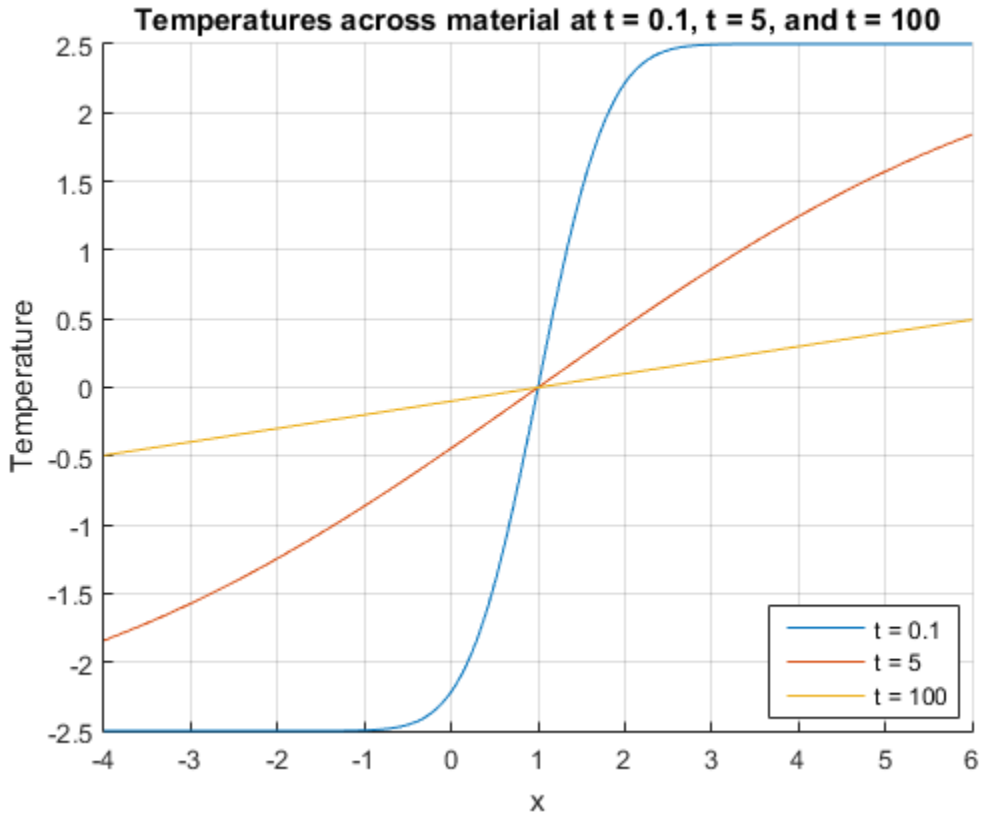
where c is a constant.

For a material with heat coefficient k, and for the initial condition $u(x,0) = a$ for $x > b$ and $u(x,0) = 0$ elsewhere, the solution to the heat equation is

$$u(x,t) = \frac{a}{2}\left(\text{erf}\left(\frac{\text{x} - \text{b}}{\sqrt{4\text{kt}}}\right)\right).$$

For `k = 2`, `a = 5`, and `b = 1`, plot the solution of the heat equation at times `t = 0.1`, `5`, and `100`.

```
x = -4:0.01:6;
t = [0.1 5 100];
a = 5;
k = 2;
b = 1;
figure(1)
hold on
for i = 1:3
    u(i,:) = (a/2)*(erf((x-b)/sqrt(4*k*t(i))));
    plot(x,u(i,:))
end
grid on
xlabel('x')
ylabel('Temperature')
legend('t = 0.1','t = 5','t = 100','Location','best')
title('Temperatures across material at t = 0.1, t = 5, and t = 100')
```



Input Arguments

x — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. x cannot be sparse.

Data Types: `single` | `double`

More About

Error Function

The error function erf of x is

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

Tips

- You can also find the standard normal probability distribution using the Statistics and Machine Learning Toolbox™ function `normcdf`. The relationship between the error function `erf` and `normcdf` is

$$\mathrm{normcdf}(x) = \frac{1}{2}\left(1 - \mathrm{erf}\left(\frac{-x}{\sqrt{2}}\right)\right).$$

- For expressions of the form `1 - erf(x)`, use the complementary error function `erfc` instead. This substitution maintains accuracy. When `erf(x)` is close to `1`, then `1 - erf(x)` is a small number and might be rounded down to `0`. Instead, replace `1 - erf(x)` with `erfc(x)`.

See Also

`erfc` | `erfcinv` | `erfcx` | `erfinv`

Introduced before R2006a

erfc

Complementary error function

Syntax

```
erfc(x)
```

Description

`erfc(x)` returns the "Complementary Error Function" on page 1-2347 evaluated for each element of x. Use the `erfc` function to replace `1 - erf(x)` for greater accuracy when `erf(x)` is close to `1`.

Examples

Find Complementary Error Function

Find the complementary error function of a value.

```
erfc(0.35)
```

```
ans =

    0.6206
```

Find the complementary error function of the elements of a vector.

```
V = [-0.5 0 1 0.72];
erfc(V)
```

```
ans =
```

```
    1.5205    1.0000    0.1573    0.3086
```

Find the complementary error function of the elements of a matrix.

```
M = [0.29 -0.11; 3.1 -2.9];
erfc(M)
```

```
ans =

    0.6817    1.1236
    0.0000    2.0000
```

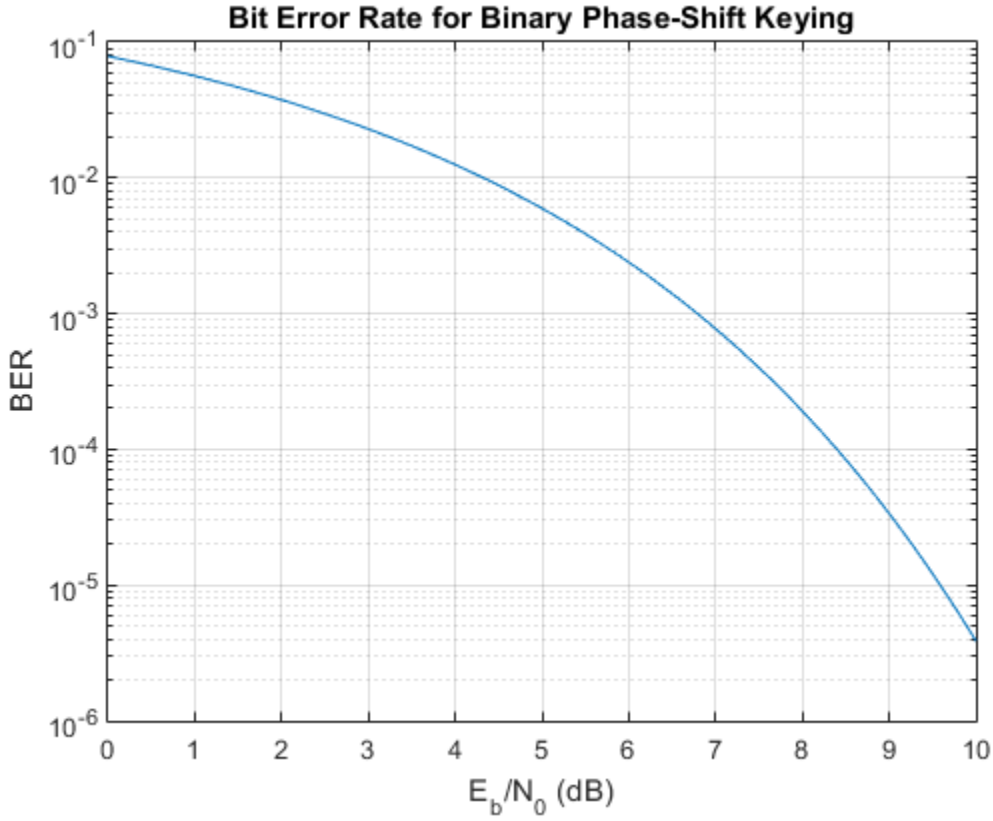
Find Bit Error Rate of Binary Phase-Shift Keying

The bit error rate (BER) of binary phase-shift keying (BPSK), assuming additive white gaussian noise (AWGN), is

$$P_b = \frac{1}{2}\mathrm{erfc}\left(\sqrt{\frac{\mathrm{E_b}}{\mathrm{N_0}}}\right).$$

Plot the BER for BPSK for values of E_b/N_0 from `0dB` to `10dB`.

```
EbNO_dB = 0:0.1:10;
EbNO = 10.^(EbNO_dB/10);
BER = 1/2.*erfc(sqrt(EbNO));
semilogy(EbNO_dB,BER)
grid on
ylabel('BER')
xlabel('E_b/N_O (dB)')
title('Bit Error Rate for Binary Phase-Shift Keying')
```



Avoid Roundoff Errors Using Complementary Error Function

You can use the complementary error function `erfc` in place of `1 - erf(x)` to avoid roundoff errors when `erf(x)` is close to `1`.

Show how to avoid roundoff errors by calculating `1 - erf(10)` using `erfc(10)`. The original calculation returns `0` while `erfc(10)` returns the correct result.

```
1 - erf(10)
erfc(10)
```

```
ans =
```

```
     0

ans =

   2.0885e-45
```

Input Arguments

x — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. x cannot be sparse.

Data Types: `single` | `double`

More About

Complementary Error Function

The complementary error function of x is defined as

$$\begin{aligned}\mathrm{erfc}(x) &= \frac{2}{\sqrt{\pi}}\int_x^\infty e^{-t^2}dt \\ &= 1-\mathrm{erf}(x).\end{aligned}$$

It is related to the error function as

$$\mathrm{erfc}(x) = 1-\mathrm{erf}(x).$$

Tips

- You can also find the standard normal probability distribution using the Statistics and Machine Learning Toolbox function `normcdf`. The relationship between the error function `erfc` and `normcdf` is

$$\text{normcdf}(x) = \left(\frac{1}{2}\right) \times \text{erfc}\left(\frac{-x}{\sqrt{2}}\right)$$

- For expressions of the form `1 - erfc(x)`, use the error function `erf` instead. This substitution maintains accuracy. When `erfc(x)` is close to `1`, then `1 - erfc(x)` is a small number and might be rounded down to `0`. Instead, replace `1 - erfc(x)` with `erf(x)`.
- For expressions of the form `exp(x^2)*erfc(x)`, use the scaled complementary error function `erfcx` instead. This substitution maintains accuracy by avoiding roundoff errors for large values of `x`.

erfcinv

Inverse complementary error function

Syntax

```
erfcinv(x)
```

Description

`erfcinv(x)` returns the value of the "Inverse Complementary Error Function" on page 1-2351 for each element of x. For inputs outside the interval `[0 2]`, `erfcinv` returns `NaN`. Use the `erfcinv` function to replace expressions containing `erfinv(1-x)` for greater accuracy when `x` is close to `1`.

Examples

Find Inverse Complementary Error Function

```
erfcinv(0.3)
```

```
ans =

    0.7329
```

Find the inverse complementary error function of the elements of a vector.

```
V = [-10 0 0.5 1.3 2 Inf];
erfcinv(V)
```

```
ans =

       NaN       Inf    0.4769   -0.2725      -Inf       NaN
```

Find the inverse complementary error function of the elements of a matrix.

```
M = [0.1 1.2; 1 0.9];
erfcinv(M)
```

```
ans =

    1.1631   -0.1791
         0    0.0889
```

Avoid Roundoff Errors Using Inverse Complementary Error Function

You can use the inverse complementary error function `erfcinv` in place of `erfinv(1-x)` to avoid roundoff errors when `x` is close to `0`.

Show how to avoid roundoff by calculating `erfinv(1-x)` using `erfcinv(x)` for `x = 1e-100`. The original calculation returns `Inf` while `erfcinv(x)` returns the correct result.

```
x = 1e-100;
erfinv(1-x)
erfcinv(x)
```

```
ans =

   Inf

ans =

   15.0656
```

Input Arguments

x — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. x cannot be sparse.

Data Types: `single` | `double`

More About

Inverse Complementary Error Function

The inverse complementary error function `erfcinv(x)` is defined as $\text{erfcinv}(\text{erfc}(x)) = x$.

Tips

- You can also find the inverse standard normal probability distribution using the Statistics and Machine Learning Toolbox function `norminv`. The relationship between the inverse complementary error function `erfcinv` and `norminv` is

  $$\text{norminv}(p) = \left(-\sqrt{2}\right) \times \text{erfcinv}(2p).$$

- For expressions of the form `erfcinv(1-x)`, use the inverse error function `erfinv` instead. This substitution maintains accuracy. When `x` is close to `1`, then `1 - x` is a small number and might be rounded down to `0`. Instead, replace `erfcinv(1-x)` with `erfinv(x)`.

See Also

`erf` | `erfc` | `erfcx` | `erfinv`

Introduced before R2006a

erfcx

Scaled complementary error function

Syntax

```
erfcx(x)
```

Description

`erfcx(x)` returns the value of the "Scaled Complementary Error Function" on page 1-2354 for each element of x. Use the `erfcx` function to replace expressions containing `exp(x^2)*erfc(x)` to avoid underflow or overflow errors.

Examples

Find Scaled Complementary Error Function

```
erfcx(5)
```

```
ans =

    0.1107
```

Find the scaled complementary error function of the elements of a vector.

```
V = [-Inf -1 0 1 10 Inf];
erfcx(V)
```

```
ans =

       Inf    5.0090    1.0000    0.4276    0.0561         0
```

Find the scaled complementary error function of the elements of a matrix.

```
M = [-0.5 15; 3.2 1];
erfcx(M)
```

```
ans =

    1.9524    0.0375
    0.1687    0.4276
```

Avoid Roundoff Errors Using Scaled Complementary Error Function

You can use the scaled complementary error function `erfcx` in place of `exp(x^2)*erfc(x)` to avoid underflow or overflow errors.

Show how to avoid roundoff errors by calculating `exp(35^2)*erfc(35)` using `erfcx(35)`. The original calculation returns `NaN` while `erfcx(35)` returns the correct result.

```
x = 35;
exp(x^2)*erfc(x)
erfcx(x)
```

```
ans =

   NaN

ans =

    0.0161
```

Input Arguments

x — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. x cannot be sparse.

Data Types: `single` | `double`

More About

Scaled Complementary Error Function

The scaled complementary error function `erfcx(x)` is defined as

$$\mathrm{erfcx}(x) = e^{x^2}\,\mathrm{erfc}(x).$$

For large `X`, `erfcx(X)` is approximately $\left(\frac{1}{\sqrt{\pi}}\right)\frac{1}{x}$.

Tips

- For expressions of the form `exp(-x^2)*erfcx(x)`, use the complementary error function `erfc` instead. This substitution maintains accuracy by avoiding roundoff errors for large values of `x`.

See Also

`erf` | `erfc` | `erfcinv` | `erfinv`

Introduced before R2006a

erfinv

Inverse error function

Syntax

```
erfinv(x)
```

Description

`erfinv(x)` returns the "Inverse Error Function" on page 1-2360 evaluated for each element of x. For inputs outside the interval `[-1 1]`, `erfinv` returns `NaN`.

Examples

Find Inverse Error Function of Value

```
erfinv(0.25)
```

```
ans =

    0.2253
```

For inputs outside `[-1,1]`, `erfinv` returns `NaN`. For `-1` and `1`, `erfinv` returns `-Inf` and `Inf`, respectively.

```
erfinv([-2 -1 1 2])
```

```
ans =

   NaN  -Inf   Inf   NaN
```

Find the inverse error function of the elements of a matrix.

```
M = [0 -0.5; 0.9 -0.2];
erfinv(M)

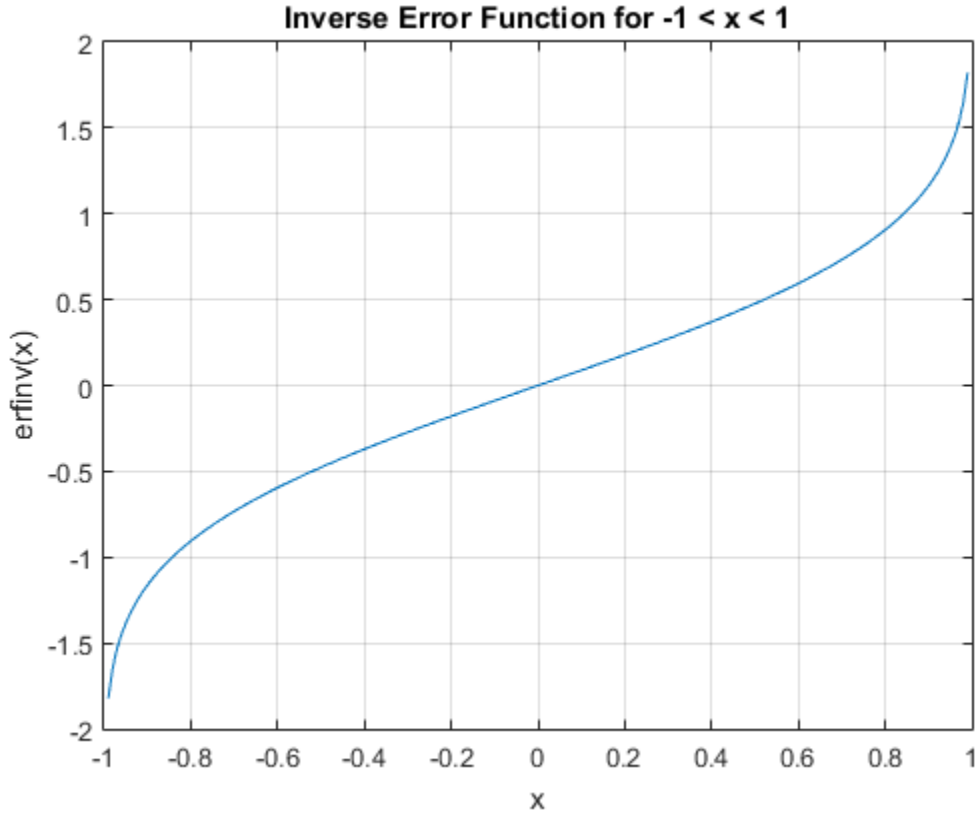
ans =

         0   -0.4769
    1.1631   -0.1791
```

Plot the Inverse Error Function

Plot the inverse error function for -1 < x < 1.

```
x = -1:0.01:1;
y = erfinv(x);
plot(x,y)
grid on
xlabel('x')
ylabel('erfinv(x)')
title('Inverse Error Function for -1 < x < 1')
```



Generate Gaussian Distributed Random Numbers

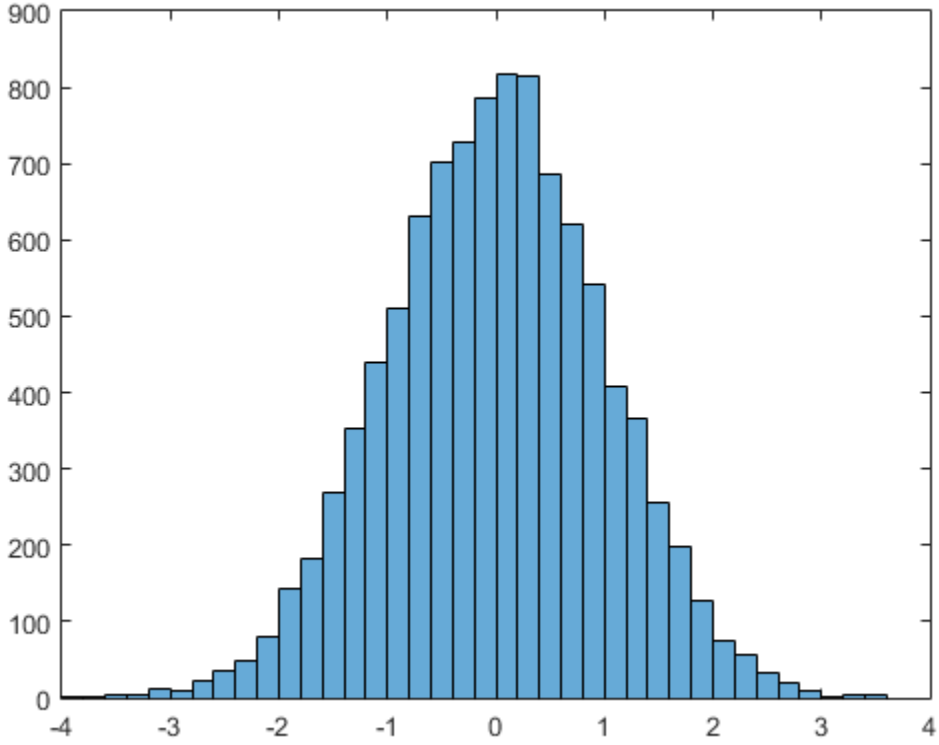
Generate Gaussian distributed random numbers using uniformly distributed random numbers. To convert a uniformly distributed random number x to a Gaussian distributed random number y, use the transform

$$y = \sqrt{2}\mathrm{erf}^{-1}(\mathrm{x}).$$

Note that because `x` has the form `-1 + 2*rand(1,10000)`, you can improve accuracy by using `erfcinv` instead of `erfinv`. For details, see “Tips”.

Generate 10,000 uniformly distributed random numbers on the interval `[-1,1]`. Transform them into Gaussian distributed random numbers. Show that the numbers follow the form of the Gaussian distribution using a histogram plot.

```
rng('default')
x = -1 + 2*rand(1,10000);
y = sqrt(2)*erfinv(x);
h = histogram(y);
```



Input Arguments

x — Input

real number | vector of real numbers | matrix of real numbers | multidimensional array of real numbers

Input, specified as a real number, or a vector, matrix, or multidimensional array of real numbers. x cannot be sparse.

Data Types: `single` | `double`

More About

Inverse Error Function

The inverse error function erfinv is defined as the inverse of the error function, such that

$$\mathrm{erfinv}(\mathrm{erf}(x)) = x.$$

Tips

- For expressions of the form `erfinv(1-x)`, use the complementary inverse error function `erfcinv` instead. This substitution maintains accuracy. When `x` is close to `1`, then `1 - x` is a small number and may be rounded down to `0`. Instead, replace `erfinv(1-x)` with `erfcinv(x)`.

`erf` | `erfc` | `erfcinv` | `erfcx`

Introduced before R2006a

error

Throw error and display message

Syntax

```
error(msg)
error(msg,A1,...,An)
error(msgID,___)

error(errorStruct)
```

Description

`error(msg)` throws an error and displays an error message.

`error(msg,A1,...,An)` displays an error message that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `msg` is converted to one of the values `A1,...,An`.

`error(msgID,___)` includes an error identifier on the exception. The identifier enables you to distinguish errors and to control what happens when MATLAB encounters the errors. You can include any of the input arguments in the previous syntaxes.

`error(errorStruct)` throws an error using the fields in a scalar structure.

Examples

Throw Error

```
msg = 'Error occurred.';
error(msg)
```

```
Error occurred.
```

Throw Error with Formatted Message

Throw a formatted error message with a line break. You must specify more than one input argument with `error` if you want MATLAB to convert special characters (such as

\n) in the error message string. Include information about the class of variable n in the error message.

```
n = 7;
if ~ischar(n)
   error('Error. \nInput must be a char, not a %s.',class(n))
end
```

```
Error.
Input must be a char, not a double.
```

If you only use one input argument with error, then MATLAB does not convert \n to a line break.

```
if ~ischar(n)
   error('Error. \nInput must be a char.')
end
```

```
Error. \nInput must be a char.
```

Throw an error with an identifier.

```
if ~ischar(n)
   error('MyComponent:incorrectType',...
       'Error. \nInput must be a char, not a %s.',class(n))
end
```

```
Error.
Input must be a char, not a double.
```

Use the MException.last to view the last uncaught exception.

```
exception = MException.last
```

```
exception =

  MException with properties:

    identifier: 'MyComponent:incorrectType'
       message: 'Error.
Input must be a char, not a double.'
         cause: {0x1 cell}
```

```
         stack: [0x1 struct]
```

Throw Error Using Structure

Create structure with message and identifier fields. To keep the example simple, do not use the stack field.

```
errorStruct.message = 'Data file not found.';
errorStruct.identifier = 'MyFunction:fileNotFound';
```

```
errorStruct =

       message: 'Data file not found.'
    identifier: 'MyFunction:fileNotFound'
```

Throw the error.

```
error(errorStruct)
```

```
Data file not found.
```

- " Capture Information About Exceptions"

Input Arguments

`msg` — Information about error

string

Information about the error, specified as a string. This message displays as the error message. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1,...,An` input arguments. For more information, see "Formatting Strings".

Note: You must specify more than one input argument with `error` if you want MATLAB to convert special characters (such as `\t`, `\n`, `%s`, and `%d`) in the error message string.

Example: `'File not found.'`

`msgID` — Identifier for error

string

Identifier for the error, specified as a string. Use the error identifier to help identify the source of the error or to control a selected subset of the errors in your program.

The error identifier includes a `component` and `mneumonic`. The identifier must always contain a colon and follows this simple format: `component:mnemonic`. The `component` and `mneumonic` fields must each begin with a letter. The remaining characters can be alphanumerics (A–Z, a–z, 0–9) and underscores. No whitespace characters can appear anywhere in msgID. For more information, see "Message Identifiers".

Example: `'MATLAB:singularMatrix'`

Example: `'MATLAB:narginchk:notEnoughInputs'`

`A1,...,An` — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msg`.

`errorStruct` — Error reporting information

scalar structure

Error reporting information, specified as a scalar structure. The structure must contain at least one of these fields.

`message`	Error message string. For more information, see msg.
`identifier`	Error message identifier. For more information, see msgID.
`stack`	Stack field for the error. When `errorStruct` includes a `stack` field, `error` uses it to set the stack field of the error. When you specify `stack`, use the absolute file name and the entire sequence of functions that nests the function in the stack frame. This string is the same as the string returned by `dbstack('-completenames')`.

More About

Tips

- When you throw an error, MATLAB captures information about it and stores it in a data structure that is an object of the `MException` class. You can access information

in the exception object by using `try/catch`. Or, if your program terminates because of an exception and returns control to the Command Prompt, you can use `MException.last`.

- MATLAB does not cease execution of a program if an error occurs within a `try` block. In this case, MATLAB passes control to the `catch` block.
- If all inputs to `error` are empty, MATLAB does not throw an error.

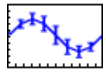
`MException` | `MException.last` | `assert` | `dbstack` | `errordlg` | `try` | `warning`

Introduced before R2006a

errorbar

Plot error bars along curve



Syntax

```
errorbar(Y,E)
errorbar(X,Y,E)
errorbar(X,Y,L,U)
errorbar(...,LineSpec)
errorbar(ax,...)
h = errorbar(...)
```

Description

Error bars show the confidence intervals of data or the deviation along a curve.

`errorbar(Y,E)` plots `Y` and draws an error bar at each element of `Y`. The error bar is a distance of `E(i)` above and below the curve so that each bar is symmetric and `2*E(i)` long.

`errorbar(X,Y,E)` plots `Y` versus `X` with symmetric error bars `2*E(i)` long. `X`, `Y`, `E` must be the same size. When they are vectors, each error bar is a distance of `E(i)` above and below the point defined by `(X(i),Y(i))`. When they are matrices, each error bar is a distance of `E(i,j)` above and below the point defined by `(X(i,j),Y(i,j))`.

`errorbar(X,Y,L,U)` plots `X` versus `Y` with error bars `L(i)+U(i)` long specifying the lower and upper error bars. `X`, `Y`, `L`, and `U` must be the same size. When they are vectors, each error bar is a distance of `L(i)` below and `U(i)` above the point defined by `(X(i),Y(i))`. When they are matrices, each error bar is a distance of `L(i,j)` below and `U(i,j)` above the point defined by `(X(i,j),Y(i,j))`.

`errorbar(...,LineSpec)` uses the color and line style specified by the string `'LineSpec'`. The color is applied to the data line and error bars. The linestyle and marker are applied to the data line only. See `linespec` for examples of styles.

`errorbar(ax,...)` plots into the axes specified by `ax` instead of the current axes.

`h = errorbar(...)` returns handles to the errorbarseries objects created. `errorbar` creates one object for vector input arguments and one object per column for matrix input arguments. See Errorbar Series Properties for more information.

When the arguments are all matrices, `errorbar` draws one line per matrix column. If `X` and `Y` are vectors, they specify one curve.

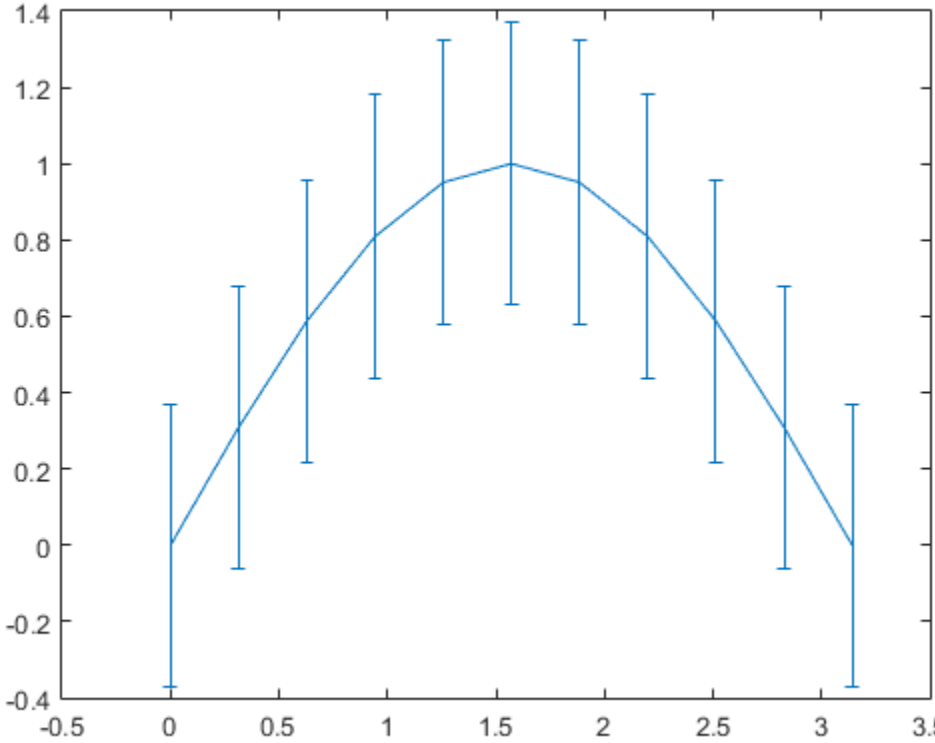
Examples

Symmetric Error Bars

Draw symmetric error bars that are two standard deviation units in length.

```
x = 0:pi/10:pi;
y = sin(x);
e = std(y)*ones(size(x));

figure
errorbar(x,y,e)
```



Change Error Bar Marker and Color

Load the `count` data set to get the three-column matrix `count` that contains traffic volume for three street locations over the course of a day. Compute the mean of `count` for each row.

```
load count.dat;
y = mean(count,2);
```

Compute the standard deviation of `count` for each row and normalize by the number of elements in the sample by setting the second input argument to 1.

```
e = std(count,1,2);
```

Plot the computed average traffic volume, `y`, and the computed standard deviations, `e`, for the three street locations. Set the `LineSpec` to specify a red color, cross markers, and no line.

```
figure
errorbar(y,e,'rx')
```

Properties
Errorbar Series Properties

Introduced before R2006a

Errorbar Series Properties

Control errorbar series appearance and behavior

Errorbar series properties control the appearance and behavior of errorbar series object. By changing property values, you can modify certain aspects of the errorbar series.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = errorbar(...);
s = h.LineStyle;
h.LineStyle = ':';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Lines

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	————
`'--'`	Dashed line	- - - - -
`':'`	Dotted line	.....
`'-.'`	Dash-dotted line	_._._._.-
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`Color` — Line color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the `Color` as `'none'`, then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`AlignVertexCenters` — Sharp vertical and horizontal lines

`'off'` (default) | `'on'`

Sharp vertical and horizontal lines, specified as `'off'` or `'on'`.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines

to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the errorbar series object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)

String	Marker Symbol
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerSize` — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Data

`XData` — x values

`[ ]` (default) | vector

x values, specified as a vector. The input argument `X` to the `errorbar` function sets the *x* values. If you do not specify `X`, then `errorbar` uses the indices of `YData` as the *x* values. `XData` and `YData` must have equal lengths.

Example: `1:10`

`YData` — y values

`[ ]` (default) | vector

y values, specified as a vector. The input argument `Y` to the `errorbar` function sets the *y* values. `XData` and `YData` must have equal lengths.

`LData` — Errorbar lengths below data points

`[ ]` (default) | vector

Errorbar lengths below the data points, specified as a vector with length equal to `XData` and `YData`. Specify the values in data units.

Example: `1:10`

`UData` — Errorbar lengths above data points

`[ ]` (default) | vector

Errorbar lengths above the data points, specified as a vector with length equal to `XData` and `YData`. Specify the values in data units.

Example: `1:10`

`XDataSource` — Variable linked to `XData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`LDataSource` — Variable linked to `LData`

`''` (default) | string containing MATLAB workspace variable

Variable linked to `LData`, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable to generate the `LData`.

By default, there is no linked variable so the value is an empty string, `''`. If you change the variable for this property, then MATLAB does not update the `LData` values. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`UDataSource` — Variable linked to `UData`

`''` (default) | string containing MATLAB workspace variable

Variable linked to `UData`, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable to generate the `UData`.

By default, there is no linked variable so the value is an empty string, `''`. If you change the variable for this property, then MATLAB does not update the `UData` values. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`XDataMode` — Selection mode for `XData`

`'auto'` (default) | `'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the indices of the values in `YData`.
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

Visibility

`Visible` — Visibility of errorbar series

`'on'` (default) | `'off'`

Visibility of errorbar series, specified as one of these values:

- `'on'` — Display the errorbar series.
- `'off'` — Hide the errorbar series without deleting it. You still can access the properties of an invisible errorbar series object.

`Clipping` — Clipping of errorbar series to axes limits

`'on'` (default) | `'off'`

Clipping of errorbar series to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the errorbar series that are outside the axes limits.
- `'off'` — Display the entire errorbar series, even if parts of it appear outside the axes limits. Parts of the errorbar series might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the errorbar series that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'errorbar'`

Type of graphics object, returned as `'errorbar'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

`Tag` — Tag to associate with errorbar series

`''` (default) | string

Tag to associate with the errorbar series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: `char`

`UserData` — Data to associate with errorbar series

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the errorbar series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the errorbar series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.

- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the errorbar series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the errorbar series from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the errorbar series object in the legend as one entry (default).
   - `'off'` — Do not include the errorbar series object in the legend.
   - `'children'` — Include only children of the errorbar series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of errorbar series

axes object | group object | transform object

Parent of errorbar series, specified as an axes, group, or transform object.

`Children` — Children of errorbar series

empty `GraphicsPlaceholder` array

The errorbar series has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of errorbar series object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The errorbar series object handle is always visible.
- `'off'` — The errorbar series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The errorbar series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the errorbar series at the command-line, but allows callback functions to access it.

If the errorbar series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the errorbar series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The errorbar series object — You can access properties of the errorbar series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the errorbar series. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the errorbar series when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the errorbar series.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the errorbar series that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the errorbar series responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the errorbar series passes the click to the object below it in the current view of the figure window. The HitTest property of the errorbar series has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the errorbar series. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the errorbar series that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the errorbar series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for errorbar series

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for errorbar series, specified as one of these values:

- `'off'` — Click the errorbar series plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the errorbar series plot to select it, that is, anywhere within the rectangle that encloses the errorbar series plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the errorbar series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the errorbar series tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the errorbar series. Setting the `CreateFcn` property on an existing errorbar series has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during errorbar series creation. MATLAB executes the callback after creating the errorbar series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The errorbar series object — You can access properties of the errorbar series object from within the callback function. You also can access the errorbar series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the errorbar series. MATLAB executes the callback before destroying the errorbar series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The errorbar series object — You can access properties of the errorbar series object from within the callback function. You also can access the errorbar series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of errorbar series

`'off'` (default) | `'on'`

Deletion status of errorbar series, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the errorbar series begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the errorbar series no longer exists.

Check the value of the BeingDeleted property to verify that the errorbar series is not about to be deleted before querying or modifying it.

errordlg

Create error dialog box

Syntax

```
h = errordlg
h = errordlg(errorstring)
h = errordlg(errorstring,dlgname)
h = errordlg(errorstring,dlgname,createmode)
```

Description

`h = errordlg` creates and displays a dialog box with title `Error Dialog` that contains the string, `This is the default error string`. The `errordlg` function returns the handle of the dialog box in `h`.

`h = errordlg(errorstring)` displays a dialog box with title `Error Dialog` that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname)` displays a dialog box with title`dlgname` that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname,createmode)` specifies whether the error dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `errorstring` and `dlgname`. The *`createmode`* argument can be a string or a structure.

If *`createmode`* is a string, it must be one of the values shown in the following table.

createmode Value	Description
`modal`	Replaces the error dialog box having the specified `Title`, that was last created or clicked on, with a modal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
`nonmodal` (default)	Creates a new nonmodal error dialog box with the specified parameters. Existing error dialog boxes with the same title are not deleted.

createmode Value	Description
`replace`	Replaces the error dialog box having the specified `Title`, that was last created or clicked on, with a nonmodal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

Note: A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

Modal dialogs (created using `errordlg`, `msgbox`, or `warndlg`) replace any existing dialogs created with these functions that also have the same name.

For more information about modal dialog boxes, see WindowStyle in Figure Properties.

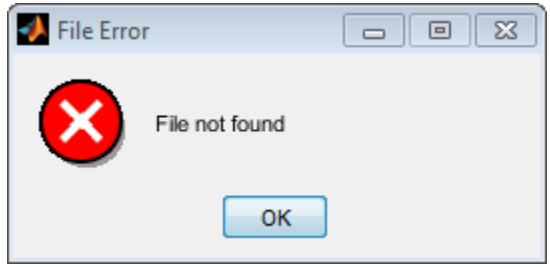
If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings `'tex'` or `'none'`. The default value for `Interpreter` is `'none'`.

Examples

This code,

```
errordlg('File not found','File Error');
```

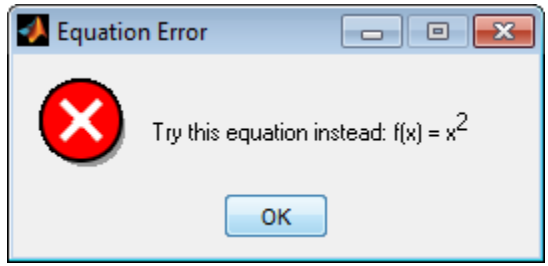
displays this dialog box:



This code,

```
mode = struct('WindowStyle','nonmodal',...
       'Interpreter','tex');
h = errordlg('Try this equation instead: f(x) = x^2',...
    'Equation Error', mode);
```

displays this dialog box:



More About

Tips

MATLAB sizes the dialog box to fit the string `'errorstring'`. The error dialog box has an **OK** push button and remains on the screen until you press the **OK** button or the **Return** key. After pressing the button, the error dialog box disappears.

The appearance of the dialog box depends on the platform you use.

Introduced before R2006a

etime

Time elapsed between date vectors

Syntax

```
e = etime(t2,t1)
```

Description

`e = etime(t2,t1)` returns the number of seconds between two date vectors or matrices of date vectors, `t1` and `t2`.

Examples

Compute Elapsed Time

Compute the time elapsed between a specific time and the current time, to 0.01-second accuracy.

Define the initial date and time and convert to date vector form.

```
format shortg
str = 'March 28, 2012 11:51:00';
t1 = datevec(str,'mmmm dd, yyyy HH:MM:SS')
```

```
t1 =

        2012           3          28          11          51           0
```

Determine the current date and time.

```
t2 = clock
```

```
t2 =
```

```
        2015           2          23          10          10      12.594
```

The `clock` function returns the current date and time as a date vector.

Use `etime` to compute the number of seconds between `t1` and `t2`.

```
e = etime(t2,t1)
```

```
e =

   9.1751e+07
```

Input Arguments

`t2,t1` — Date vectors

1-by-6 vector | `m`-by-6 matrix

Date vectors, specified as 1-by-6 vectors or `m`-by-6 matrices containing `m` full date vectors in the format:`[Year Month Day Hour Minute Second]`.

Example: `[2012 03 27 11 50 01]`

Data Types: `double`

More About

Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.

Algorithms

`etime` does not account for the following:

- Leap seconds.

- Daylight savings time adjustments.
- Differences in time zones.

See Also

`clock` | `cputime` | `now` | `tic` | `timeit` | `toc`

Introduced before R2006a

etree

Elimination tree

Syntax

```
p = etree(A)
p = etree(A,'col')
p = etree(A,'sym')
[p,q] = etree(...)
```

Description

`p = etree(A)` returns an elimination tree for the square symmetric matrix whose upper triangle is that of `A`. `p(j)` is the parent of column `j` in the tree, or `0` if `j` is a root.

`p = etree(A,'col')` returns the elimination tree of `A'*A`.

`p = etree(A,'sym')` is the same as `p = etree(A)`.

`[p,q] = etree(...)` also returns a postorder permutation `q` of the tree.

See Also

`treelayout` | `treeplot` | `etreeplot`

Introduced before R2006a

etreeplot

Plot elimination tree

Syntax

```
etreeplot(A)
etreeplot(A,nodeSpec,edgeSpec)
```

Description

`etreeplot(A)` plots the elimination tree of `A` (or `A+A'`, if non-symmetric).

`etreeplot(A,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `''` to omit one or both.

See Also

`etree` | `treeplot` | `treelayout`

Introduced before R2006a

eval

Execute MATLAB expression in text string

Syntax

```
eval(expression)
[output1,...,outputN] = eval(expression)
```

Description

`eval(expression)` evaluates the MATLAB code in the string `expression`. If you use `eval` within an anonymous function, nested function, or function that contains a nested function, the evaluated `expression` cannot create a variable.

`[output1,...,outputN] = eval(expression)` stores output from `expression` in the specified variables.

Input Arguments

`expression`

String that contains a valid MATLAB expression.

To include a numeric value in the expression, convert it to a string with `int2str`, `num2str`, or `sprintf`.

Output Arguments

`output1,...,outputN`

Outputs from the evaluated `expression`.

Examples

Variable Name Evaluation

Select a matrix to plot at runtime.

This example requires that you have a matrix in the current workspace. For example:

```
aMatrix = magic(5);
```

Interactively request the name of a matrix to plot, and call `eval` to use its value.

```
expression = input('Enter the name of a matrix: ','s');
if (exist(expression,'var'))
    mesh(eval(expression))
end
```

If you type `aMatrix` at the input prompt, this code creates a mesh plot of `magic(5)`.

More About

Tips

- Many common uses of the `eval` function are less efficient and are more difficult to read and debug than other MATLAB functions and language constructs. For more information, see “Alternatives to the eval Function”.
- Whenever possible, do not include output arguments within the input to the `eval` function, such as `eval(['output = ',expression])`. The preferred syntax,

  ```
  output = eval(expression)
  ```

  allows the MATLAB parser to perform stricter checks on your code, preventing untrapped errors and other unexpected behavior.

- “Alternatives to the eval Function”
- “Variables in Nested and Anonymous Functions”

See Also

`assignin` | `evalc` | `evalin` | `feval` | `try`

Introduced before R2006a

evalc

Evaluate MATLAB expression with capture

Syntax

```
T = evalc(expression)
[T,output1,...,outputN] = evalc(expression)
```

Description

`T = evalc(expression)` is the same as `eval(expression)` except that anything that would normally be written to the command window, except for error messages, is captured and returned in the character array `T` (lines in `T` are separated by `\n` characters).

`[T,output1,...,outputN] = evalc(expression)` is the same as `[output1,...,outputN] = eval(expression)` except that any output is captured into `T`.

Input Arguments

`expression`

String that contains a valid MATLAB expression.

To include a numeric value in the expression, convert it to a string with `int2str`, `num2str`, or `sprintf`.

Output Arguments

`T`

Output normally written to the command window during the evaluation of `expression`, except for error messages, returned in a character array. The lines in `T` are separated by `\n` characters.

`output1,...,outputN`

Outputs from the evaluated `expression`.

More About

Tips

When you are using `evalc`, functions `diary`, `more`, and `input` are disabled.

See Also

`eval` | `evalin` | `assignin` | `more` | `feval` | `diary` | `input`

Introduced before R2006a

evalin

Execute MATLAB expression in specified workspace

Syntax

```
evalin(ws, expression)
[a1, a2, a3, ...] = evalin(ws, expression)
```

Description

`evalin(ws, expression)` executes *`expression`*, a string containing any valid MATLAB expression, in the context of the workspace `ws`. `ws` can have a value of `'base'` or `'caller'` to denote the MATLAB base workspace or the workspace of the caller function. You can construct *`expression`* by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2,...]
```

`[a1, a2, a3, ...] = evalin(ws, expression)` executes *`expression`* and returns the results in the specified output variables. Using the `evalin` output argument list is recommended over including the output arguments in the expression string:

```
evalin(ws,'[a1, a2, a3, ...] = function(var)')
```

The above syntax avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

Examples

This example extracts the value of the variable `var` in the MATLAB base workspace and captures the value in the local variable `v`:

```
v = evalin('base', 'var');
```

Limitation

`evalin` cannot be used recursively to evaluate an expression. For example, a sequence of the form `evalin('caller', 'evalin(''caller'', ''x'')')` doesn't work.

More About

Tips

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line.

`evalin('caller', expression)` finds only *variables* in the caller's workspace; it does not find *functions* in the caller. For this reason, you cannot use `evalin` to construct a handle to a function that is defined in the caller.

If you use `evalin('caller', expression)` in the MATLAB debugger after having changed your local workspace context with `dbup` or `dbdown`, MATLAB evaluates the expression in the context of the function that is one level up in the stack from your current workspace context.

`assignin` | `eval` | `evalc` | `feval` | `try`

Introduced before R2006a

event.EventData

Base class for all data objects passed to event listeners

Description

The `event.EventData` class defines the event data objects passed to listeners. When you trigger an event using the `notify` handle class method, MATLAB assigns values to the properties of the `event.EventData` object that is passed to the listener callback function (the event handler).

If you want to provide additional information to event listeners, you can do so by subclassing `event.EventData`. See "Define Event-Specific Data" for more information.

Note: Subclasses of `event.EventData` must set the class `ConstructOnLoad` attribute.

Properties

The `event.EventData` class defines two properties and no methods:

- `EventName` — The name of the event described by this data object.
- `Source` — The source object whose class defines the event described by the data object.

More About

- "Learn to Use Events and Listeners"
- "Class with Custom Event Data"

See Also

`notify` | `event.PropertyEvent`

event.listener

Class defining listener objects

Syntax

```
lh = event.listener(Hobj,'EventName',@CallbackFunction)
```

Description

The `event.listener` class defines listener objects. Listener objects respond to the specified event and identify the callback function to invoke when the event is triggered.

`lh = event.listener(Hobj,'EventName',@CallbackFunction)` creates an `event.listener` object, `lh`, for the event named in *`EventName`*, on the specified object, `Hobj`.

If `Hobj` is an array of object handles, the listener responds to the named event on any of the objects referenced in the array.

The listener callback function must accept at least two input arguments. For example,

```
function CallbackFunction(source,eventData)
   ...
end
```

where `source` is the object that is the source of the event and `eventData` is an `event.EventData` object.

The `event.listener` class is a `handle` class.

Limiting Listener Lifecycle

Generally, you create a listener object using `addlistener`. However, you can call the `event.listener` constructor directly to create a listener. When you use the `event.listener` constructor, the listener's lifecycle is not tied to the object(s) being listened to—once the listener object goes out of scope, the listener no longer exists. See “Control Listener Lifecycle” for more information on creating listener objects.

Removing a Listener

If you call `delete(lh)` on the listener object, the listener ceases to exist, which means the event no longer causes the listener callback function to execute.

Disabling a Listener

You can enable or disable a listener by setting the value of the listener's `Enabled` property (see Properties table below).

More Information on Events and Listeners

See “Events” for more information and examples of how to use events and listeners.

Properties

Property	Purpose
`Source`	Cell array of source objects
`EventName`	Name of the event
`Callback`	Function to execute when the event is triggered and the `Enabled` property is set to `true`
`Enabled`	The callback executes when the event occurs if and only if `Enabled` is set to `true` (the default).
`Recursive`	When `false` (the default), this listener does not execute recursively. Therefore, if the callback triggers its own event, the listener does not execute again. When `true`, the listener callback can cause the same event that triggered the callback. This scheme can lead to infinite recursion, which ends when the MATLAB recursion limit eventually triggers an error.

See Also

`delete` | `addlistener` | `event.proplistener`

event.PropertyEvent

Data for property events

Description

The `event.PropertyEvent` class defines the data objects passed to listeners of the `meta.property` events:

- `PreGet`
- `PostGet`
- `PreSet`
- `PostSet`

`event.PropertyEvent` is a sealed subclass of `event.EventData` (i.e., you cannot subclass `event.PropertyEvent`).

Properties

`event.PropertyEvent` inherits the first two properties from the `event.EventData`, and defines one new property:

- `EventName` — One of the four event names listed in the Description section
- `Source` — `meta.property` object that triggers the event
- `AffectedObject` — The object whose property is affected.

More About

- "Listen for Changes to Property Values"

See Also

`meta.property` | `event.EventData`

event.proplistener

Define listener object for property events

Syntax

```
lh =
event.proplistener(Hobj,Properties,'PropEvent',@CallbackFunction)
```

Description

`lh = event.proplistener(Hobj,Properties,'PropEvent',@CallbackFunction)` creates a property listener object for one or more properties on the specified object.

- `Hobj` — handle of object whose property or properties are to be listened to. If `Hobj` is an array, the listener responds to the named event on all objects in the array.
- `Properties` — an object array or a cell array of `meta.property` object handles representing the properties to which you want to listen.
- `PropEvent` — must be one of the strings: `PreSet`, `PostSet`, `PreGet`, `PostGet`
- `@CallbackFunction` — function handle to the callback function that executes when the event occurs.

The `event.proplistener` class defines property event listener objects. It is a subclass of the `event.listener` class and adds one property to those defined by `event.listener`:

- `Object` — Cell array of objects whose property events are being listened to.

You can call the `event.proplistener` constructor instead of calling `addlistener` to create a property listener. However, when you do not use `addlistener`, the listener's lifecycle is not tied to the object(s) being listened to.

See “Listen for Changes to Property Values”.

See “Getting Information About Properties” for more information on using `meta.property` objects.

See Also

`event.listener` | `addlistener`

eventlisteners

List event handler functions associated with COM object events

Syntax

```
info = eventlisteners(h)
```

Description

`info = eventlisteners(h)` lists the events and their event handler routines registered with COM object `h`. The function returns a cell array of strings `info`, with each row containing the name of a registered event and the handler routine for that event. If the object has no registered events, `eventlisteners` returns an empty cell array. You can register events either when you create the control, using `actxcontrol`, or at any time afterward, using `registerevent`.

COM functions are available on Microsoft Windows systems only.

Examples

This example manages events for the MATLAB control, `mwsamp`.

```
f = figure('position',[100 200 200 200]);
% Create an mwsamp control and
% register the Click event
h = actxcontrol('mwsamp.mwsampctrl.2',...
    [0 0 200 200],f,{'Click' 'myclick'});
eventlisteners(h)
```

```
ans =
    'Click'    'myclick'
```

MATLAB displays the event name and its event handler, `myclick`.

Register two more events, `DblClick` and `MouseDown`:

```
registerevent(h,{'DblClick', 'my2click'; 'MouseDown' 'mymoused'});
```

```
eventlisteners(h)

ans =
    'Click'        'myclick'
    'Dblclick'     'my2click'
    'Mousedown'    'mymoused'
```

MATLAB displays all event names and handlers.

Unregister all events for the control:

```
unregisterallevents(h)
eventlisteners(h)

ans =
     {}
```

MATLAB displays an empty cell array, indicating the control has no registered events.

See Also

`events (COM)` | `registerevent` | `unregisterevent` | `unregisterallevents` | `isevent` | `actxcontrol`

Introduced before R2006a

events

Event names

Syntax

```
events('classname')
events(obj)
e = events(...)
```

Description

`events('classname')` displays the names of the public events for the MATLAB class *`classname`*, including events inherited from superclasses.

`events(obj)` `obj` is a scalar or array of objects of a MATLAB class.

`e = events(...)` returns the event names in a cell array of strings.

An event is public when the value of its `ListenAccess` attribute is `public` and its `Hidden` attribute value is `false` (default values for both attributes). See "Event Attributes" for a complete list of attributes.

`events` is also a MATLAB class-definition keyword. See `classdef` for more information on class definition keywords.

Examples

Get the names of the public events for the `handle` class:

```
events('handle')
Events for class handle:

    ObjectBeingDestroyed
```

See Also

`properties` | `methods`

Introduced before R2006a

events (COM)

List of events COM object can trigger

Syntax

```
S = events(h)
```

Description

`S = events(h)` returns structure array, `S`, containing all events, both registered and unregistered, known to the COM object, and the function prototype used when calling the event handler routine. For each array element, the structure field is the event name and the contents of that field is the function prototype for that event's handler.

COM functions are available on Microsoft Windows systems only.

Examples

List Control Events Example

Create an `mwsamp` control and list all events.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
events(h)
```

```
Click = void Click()
DblClick = void DblClick()
MouseDown = void MouseDown(int16 Button, int16 Shift,
  Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort, int32 typelong,
  double typedouble, string typestring, bool typebool)
```

Assign the output to a variable and get one field of the returned structure:

```
ev = events(h);
```

```
ev.MouseDown

ans =
  void MouseDown(int16 Button, int16 Shift, Variant x, Variant y)
```

List Workbook Events Example

Open a Microsoft Excel application and list all events for a `Workbook` object.

```
myApp = actxserver('Excel.Application');
wbs = myApp.Workbooks;
wb = Add(wbs);
events(wb)
```

The MATLAB software displays all events supported by the `Workbook` object.

See Also

`isevent` | `eventlisteners` | `registerevent` | `unregisterevent` | `unregisterallevents`

exceltime

Convert MATLAB datetime to Excel date number

Syntax

```
e = exceltime(t)
e = exceltime(t,dateType)
```

Description

`e = exceltime(t)` returns a `double` array containing Excel serial date numbers equivalent to the datetime values in `t`. Excel serial date numbers are the number of days and fractional days since 0-January-1900 00:00:00, and do not take into account time zone and leap seconds.

`e = exceltime(t,dateType)` returns the type of Excel serial date numbers specified by `dateType`. For example, you can convert datetime values to the number of days since 1-January-1904 00:00:00.

Examples

Convert Datetime Array to Excel Date Numbers

Create a `datetime` array. Then, convert the dates to the equivalent Excel® serial date numbers.

```
t = datetime('now') + calmonths(1:3)
```

```
t =

   23-Mar-2015 10:04:20   23-Apr-2015 10:04:20   23-May-2015 10:04:20
```

```
e = exceltime(t)
```

```
e =

   1.0e+04 *

    4.2086    4.2117    4.2147
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`dateType` — Type of Excel serial date numbers

`'1900'` (default) | `'1904'`

Type of Excel serial date numbers, specified as either `'1900'` or `'1904'`.

- If `dateType` is `'1900'`, then `exceltime` converts the datetime values in `t` to the equivalent the number of days and fractional days since 0-January-1900 00:00:00.
- If `dateType` is `'1904'`, then `exceltime` converts the datetime values in `t` to the equivalent the number of days and fractional days since 1-January-1904 00:00:00.

`exceltime` does not account for time zone.

Example:

Output Arguments

`e` — Excel serial date numbers

scalar | vector | matrix | multidimensional array

Excel serial date numbers, returned as a scalar, vector, matrix, or multidimensional array of type `double`. Excel serial date numbers are not defined prior to their epoch (0-January-1900 or 1-January-1904). Excel serial date numbers treat 1900 as a leap year. Therefore, dates after February 28, 1900 are offset by one day relative to MATLAB serial date numbers, and there is a discontinuity of one day between February 28, 1900 and March 1, 1900.

`datenum` | `datetime` | `juliandate` | `posixtime` | `yyyymmdd`

Introduced in R2014b

Execute

Execute MATLAB command in Automation server

Syntax

IDL Method Signature

```
BSTR Execute([in] BSTR command)
```

Microsoft Visual Basic Client

```
Execute(command As String) As String
```

MATLAB Client

```
result = Execute(h,'command')
result = invoke(h,'Execute','command')
```

Description

The `Execute` function executes the MATLAB statement specified by the string `command` in the MATLAB Automation server attached to handle `h`.

The server returns output from the command in the string, `result`. The `result` string also contains any MATLAB warning or error messages.

If you terminate the MATLAB command string with a semicolon and there are no warnings or error messages, `result` might be returned empty.

COM functions are available on Microsoft Windows systems only.

Visual Basic .NET Examples

Create a 6-by-6 matrix in the MATLAB server, remove rows 4-6, and return the results to the client.

```
Dim Matlab As Object
Dim server_version As String
Matlab = CreateObject("matlab.application")
MatLab.PutWorkspaceData("A","base",rand(6))
Matlab.Execute("A(4:6,:) = [];")
Matlab.GetWorkspaceData("A","base",B)
```

More About

Tips

If you want to display output from `Execute` in the client window, specify an output variable, `result`.

If there is an error, the `Execute` function returns the MATLAB error message with the characters `???` prepended to the text.

See Also

`Feval` | `GetFullMatrix` | `PutFullMatrix`

Introduced before R2006a

exifread

Read EXIF information from JPEG and TIFF image files

Syntax

Note: `exifread` has been removed. Use `imfinfo` instead.

```
output = exifread(filename)
```

Description

`output = exifread(filename)` reads the Exchangeable Image File Format (EXIF) data from the file specified by the string `filename`. `filename` must specify a JPEG or TIFF image file. `output` is a structure containing metadata values about the image or images in `imagefile`.

Note `exifread` returns all EXIF tags and does not process them in any way.

EXIF is a standard used by digital camera manufacturers to store information in the image file, such as, the make and model of a camera, the time the picture was taken and digitized, the resolution of the image, exposure time, and focal length. For more information about EXIF and the meaning of metadata attributes, see http://www.exif.org/.

See Also

`imfinfo` | `imread`

Introduced before R2006a

exist

Check existence of variable, function, folder, or class

Syntax

```
exist name
exist name kind
A = exist('name','kind')
```

Description

`exist name` returns the status of `name`:

0	`name` does not exist.
1	`name` is a variable in the workspace.
2	One of the following is true: • `name` exists on your MATLAB search path as a file with extension `.m`. • `name` is the name of an ordinary file on your MATLAB search path. • `name` is the full pathname to any file.
3	`name` exists as a MEX-file on your MATLAB search path.
4	`name` exists as a Simulink model or library file on your MATLAB search path.
5	`name` is a built-in MATLAB function.
6	`name` is a P-file on your MATLAB search path.
7	`name` is a folder.
8	`name` is a class. (`exist` returns 0 for Java classes if you start MATLAB with the `-nojvm` option.)

If `name` is a class, then `exist('name')` returns an `8`. However, if `name` is a class file, then `exist('name')` returns a `2`.

If a file or folder is not on the search path, then `name` must specify either a full pathname, a partial pathname relative to `MATLABPATH`, a partial pathname relative to your current folder, or the file or folder must reside in your current working folder.

If `name` specifies a filename, that filename may include an extension to preclude conflicting with other similar filenames. For example, `exist('file.ext')`.

`exist name kind` returns the status of `name` for the specified *`kind`*. If `name` of type *`kind`* does not exist, it returns `0`. The *`kind`* argument may be one of the following:

`builtin`	Checks only for built-in functions.
`class`	Checks only for classes.
`dir`	Checks only for folders.
`file`	Checks only for files or folders.
`var`	Checks only for variables.

If you do not specify a *`kind`* argument, and `name` belongs to more than one of these categories, `exist` returns one value according to the order of evaluation shown in the table below. For example, if `name` matches both a folder and a file that defines a MATLAB function, `exist` returns `7`, identifying it as a folder.

Order of Evaluation	Return Value	Type of Entity
1	1	Variable
2	5	Built-in
3	7	Folder
4	3	MEX-file
5	6	P-file
6	2	MATLAB function
7	4	SLX or MDL-file
8	8	Class

`A = exist('name','kind')` is the function form of the syntax.

Examples

Check Existence of Workspace Variable

Create a variable named |testresults, and then check its existence in the workspace.

```
testresults = magic(5);
exist testresults var
```

```
ans =

     1
```

A variable named `testresults` exists in the workspace.

Check if MATLAB Function is Built-In Function

Check whether the `plot` function is a built-in function or a file.

```
A = exist('plot')
```

```
A =

     5
```

This indicates that `plot` is a built-in MATLAB function.

More About

Tips

If `name` specifies a filename, MATLAB attempts to locate the file, examines the filename extension, and determines the value to return based on the extension alone. MATLAB does not examine the contents or internal structure of the file.

You can specify a partial path to a folder or file. A partial pathname is a pathname relative to the MATLAB path that contains only the trailing one or more components of the full pathname. For example, both of the following commands return `2`, identifying `mkdir.m` as a MATLAB function. The first uses a partial pathname:

```
exist('matlab/general/mkdir.m')
exist([matlabroot '/toolbox/matlab/general/mkdir.m'])
```

To check for the existence of more than one variable, use the `ismember` function. For example,

```
a = 5.83;
c = 'teststring';
ismember({'a','b','c'},who)

ans =

     1     0     1
```

Introduced before R2006a

exit

Terminate MATLAB program (same as `quit`)

Alternatives

As an alternative to the `exit` function, click the Close box in the MATLAB desktop.

Syntax

```
exit
exit(code)
```

Description

`exit` terminates the current session of MATLAB after running `finish.m`, if the file `finish.m` exists. It performs the same as `quit` and takes the same termination options, such as **`force`**. Call `exit` from the MATLAB command prompt. To interrupt a MATLAB command, see "Stop Execution".

`exit(code)` returns exit code when calling a MATLAB command from the system command line.

More About

- "Stop Execution"

See Also

`quit` | `finish`

Introduced before R2006a

exp

Exponential

Syntax

```
Y = exp(X)
```

Description

`Y = exp(X)` returns the exponential e^x for each element in array `X`. For complex elements $z = x + iy$, it returns the complex exponential

$$e^z = e^x (\cos y + i \sin y).$$

Use `expm` to compute a matrix exponential.

Examples

Numeric Representation of e

Calculate the exponential of 1, which is Euler's number, *e*.

```
exp(1)
```

```
ans =

    2.7183
```

Euler's Identity

Euler's identity is the equality $e^{i\pi} + 1 = 0$.

Compute the value of $e^{i\pi}$.

```
Y = exp(1i*pi)
```

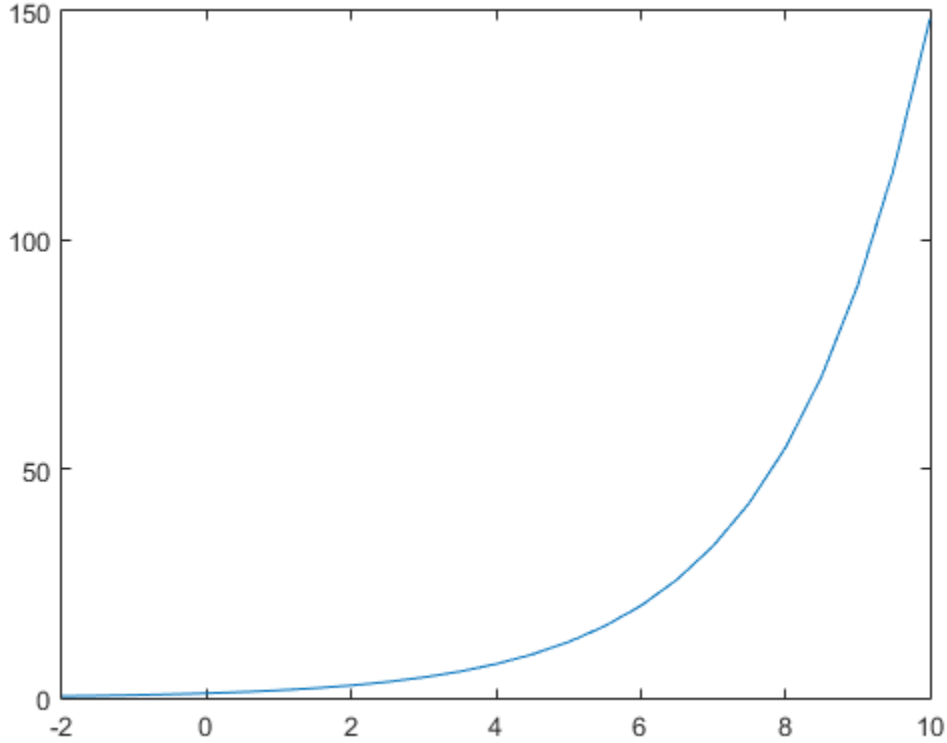
```
Y =

  -1.0000 + 0.0000i
```

Plot Exponential Function

Plot $y = e^{x/2}$ for `x` values in the range $[-2, 10]$.

```
X = -2:0.5:10;
Y = exp(X/2);
plot(X,Y)
```



Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Exponential values

scalar | vector | matrix | multidimensional array

Exponential values, returned as a scalar, vector, matrix, or multidimensional array.

For real values of `X` in the interval (`-Inf`, `Inf`), `Y` is in the interval (`0`,`Inf`). For complex values of `X`, `Y` is complex. The data type of `Y` is the same as that of `X`.

`expint` | `expm` | `expm1` | `log` | `log10` | `mpower` | `power`

Introduced before R2006a

expint

Exponential integral

Syntax

```
Y = expint(X)
```

Definitions

The exponential integral computed by this function is defined as

$$E_1(x) = \int_x^\infty e^{-t} / t \, dt$$

Another common definition of the exponential integral function is the Cauchy principal value integral

$$\mathrm{Ei}(x) = \int_{-\infty}^x e^t / t \, dt$$

which, for real positive x, is related to `expint` as

$$E_1(-x) = -\mathrm{Ei}(x) - i\pi$$

Description

`Y = expint(X)` evaluates the exponential integral for each element of `X`.

References

[1] Abramowitz, M. and I. A. Stegun. *Handbook of Mathematical Functions*. Chapter 5, New York: Dover Publications, 1965.

Introduced before R2006a

expm

Matrix exponential

Syntax

```
Y = expm(X)
```

Description

`Y = expm(X)` computes the matrix exponential of `X`.

Although it is not computed this way, if `X` has a full set of eigenvectors `V` with corresponding eigenvalues `D`, then

```
[V,D] = EIG(X) and EXPM(X) = V*diag(exp(diag(D)))/V
```

Use `exp` for the element-by-element exponential.

Examples

This example computes and compares the matrix exponential of `A` and the exponential of `A`.

```
A = [1         1         0
     0         0         2
     0         0        -1 ];

expm(A)
ans =
    2.7183   1.7183         1.0862
    0        1.0000         1.2642
    0             0         0.3679

exp(A)
ans =
    2.7183         2.7183         1.0000
    1.0000         1.0000         7.3891
```

```
    1.0000         1.0000         0.3679
```

Notice that the diagonal elements of the two results are equal. This would be true for any triangular matrix. But the off-diagonal elements, including those below the diagonal, are different.

More About

Algorithms

`expm` uses the Padé approximation with scaling and squaring. See reference [3], below.

Note The files, expmdemo1.m, expmdemo2.m, and expmdemo3.m illustrate the use of Padé approximation, Taylor series approximation, and eigenvalues and eigenvectors, respectively, to compute the matrix exponential. References [1] and [2] describe and compare many algorithms for computing a matrix exponential.

Introduced before R2006a

expm1

Compute exp(x)-1 accurately for small values of x

Syntax

```
y = expm1(x)
```

Description

`y = expm1(x)` computes `exp(x)-1`, compensating for the roundoff in `exp(x)`.

For small `x`, `expm1(x)` is approximately `x`, whereas `exp(x)-1` can be zero.

`exp` | `expm` | `log1p`

Introduced before R2006a

export2wsdlg

Create dialog box for exporting variables to workspace

Syntax

```
export2wsdlg(cklabels,defaultvars,xitems)
export2wsdlg(cklabels,defaultvars,xitems,title)
export2wsdlg(cklabels,defaultvars,xitems,title,selected)
export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction)
export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction,functionl
hdialog = export2wsdlg(...)
[hdialog,ok_pressed] = export2wsdlg(...)
```

Description

`export2wsdlg(cklabels,defaultvars,xitems)` creates a dialog with a series of check boxes and edit fields. `cklabels` is a cell array of labels for the check boxes. `defaultvars` is a cell array of strings that serve as a basis for variable names that appear in the edit fields. `xitems` is a cell array of the values to be stored in the variables. If there is only one item to export, `export2wsdlg` creates a text control instead of a check box.

Note: By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding.

`export2wsdlg(cklabels,defaultvars,xitems,title)` creates the dialog with `title` as its title.

`export2wsdlg(cklabels,defaultvars,xitems,title,selected)` creates the dialog allowing the user to control which check boxes are checked. `selected` is a logical array whose length is the same as `cklabels`. True indicates that the check box should initially be checked, false unchecked.

`export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction)` creates the dialog with a help button. `helpfunction` is a callback that displays help.

`export2wsdlg(cklabels,defaultvars,xitems,title,selected,helpfunction,functionl` creates a dialog that enables the user to pass in `functionlist`, a cell array of functions and optional arguments that calculate, then return the value to export. `functionlist` should be the same length as `cklabels`.

`hdialog = export2wsdlg(...)` returns the handle of the dialog.

`[hdialog,ok_pressed] = export2wsdlg(...)` sets `ok_pressed` to true if the OK button is pressed, or false otherwise. If two return arguments are requested, `hdialog` is `[]` and the function does not return until the dialog is closed.

The user can edit the text fields to modify the default variable names. If the same name appears in multiple edit fields, `export2wsdlg` creates a structure using that name. It then uses the `defaultvars` as field names for that structure.

The lengths of `cklabels`, `defaultvars`, `xitems` and `selected` must all be equal.

The strings in `defaultvars` must be unique.

Examples

This example creates a dialog box that enables the user to save the variables `sumA` and/or `meanA` to the workspace. The dialog box title is Save Sums to Workspace.

```
A = randn(10,1);
checkLabels = {'Save sum of A to variable named:' ...
               'Save mean of A to variable named:'};
varNames = {'sumA','meanA'};
items = {sum(A),mean(A)};
export2wsdlg(checkLabels,varNames,items,...
             'Save Sums to Workspace');
```

exportsetupdlg

Open figure Export Setup dialog box

The `exportseupdlg` function displays the Export Setup dialog box for a figure. The dialog box is the same as the one that displays when you select **File > Export Setup...** from the menu at the top of a figure.

Syntax

```
exportsetupdlg(f)
exportsetupdlg
```

Description

`exportsetupdlg(f)` displays the export settings dialog box. MATLAB applies your selections to the figure, `f`.

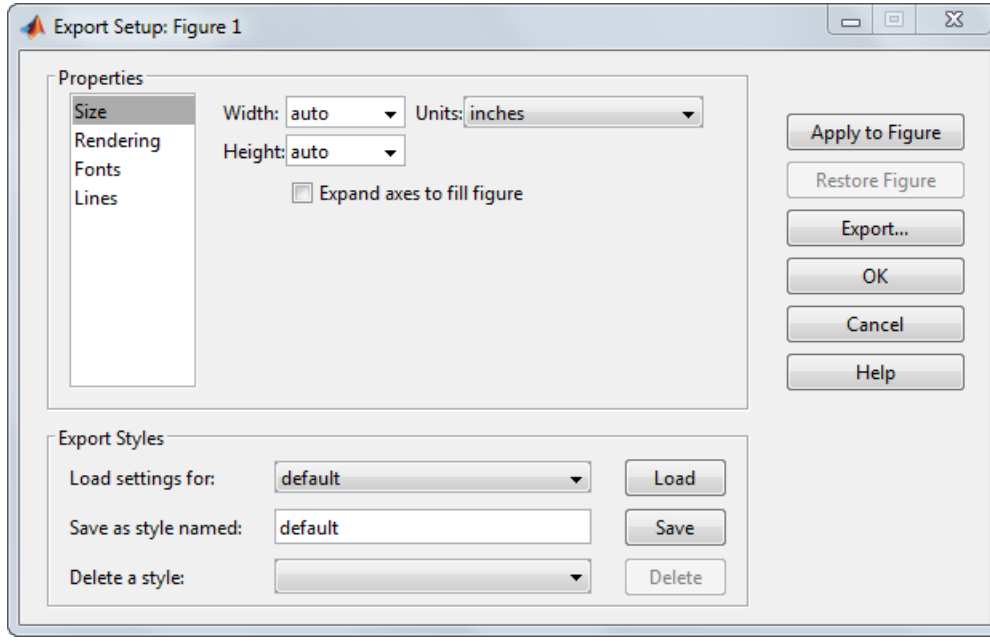
`exportsetupdlg` applies your selections to the current figure. If no figure exists, MATLAB creates a new figure.

Examples

Export Setting for a Figure

Create a figure and display the Export Setup dialog.

```
f = figure;
exportsetupdlg(f);
```



Input Arguments

`f` — Target figure

figure object

Target figure, specified as a figure object.

`printdlg` | `printpreview`

Introduced in R2006b

eye

Identity matrix

Syntax

```
I = eye
I = eye(n)
I = eye(n,m)
I = eye(sz)

I = eye(classname)
I = eye(n,classname)
I = eye(n,m,classname)
I = eye(sz,classname)

I = eye('like',p)
I = eye(n,'like',p)
I = eye(n,m,'like',p)
I = eye(sz,'like',p)
```

Description

`I = eye` returns the scalar, `1`.

`I = eye(n)` returns an `n`-by-`n` identity matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(n,m)` returns an `n`-by-`m` matrix with ones on the main diagonal and zeros elsewhere.

`I = eye(sz)` returns an array with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)`. For example, `eye([2,3])` returns a 2-by-3 array with ones on the main diagonal and zeros elsewhere.

`I = eye(classname)` returns a scalar, `1`, where the string, `classname`, specifies the data type. For example, `eye('int8')` returns a scalar, 8-bit integer.

`I = eye(n,classname)` returns an `n`-by-`n` identity matrix of data type `classname`.

`I = eye(n,m,classname)` returns an `n`-by-`m` matrix of data type `classname` with ones on the main diagonal and zeros elsewhere.

`I = eye(sz,classname)` returns a matrix with ones on the main diagonal and zeros elsewhere. The size vector, `sz`, defines `size(I)` and `classname` defines `class(I)`.

`I = eye('like',p)` returns a scalar, `1`, with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`I = eye(n,'like',p)` returns an `n`-by-`n` identity matrix like `p`.

`I = eye(n,m,'like',p)` returns an `n`-by-`m` matrix like `p`.

`I = eye(sz,'like',p)` returns a matrix like `p` where the size vector, `sz`, defines `size(I)`.

Examples

Square Identity Matrix

Create a 4-by-4 identity matrix.

```
I = eye(4)
```

```
I =

     1     0     0     0
     0     1     0     0
     0     0     1     0
     0     0     0     1
```

Rectangular Matrix

Create a 2-by-3 identity matrix.

```
I = eye(2,3)
```

```
I =

     1     0     0
```

```
     0     1     0
```

Identity Vector

Create a 3-by-1 identity vector.

```
sz = [3,1];
I = eye(sz)
```

```
I =

     1
     0
     0
```

Nondefault Numeric Data Type

Create a 3-by-3 identity matrix whose elements are 32-bit unsigned integers.

```
I = eye(3,'uint32'),
class(I)
```

```
I =

           1           0           0
           0           1           0
           0           0           1

ans =

uint32
```

Complex Identity Matrix

Create a 2-by-2 identity matrix that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create an identity matrix that is complex like `p`.

```
I = eye(2,'like',p)

I =

   1.0000 + 0.0000i   0.0000 + 0.0000i
   0.0000 + 0.0000i   1.0000 + 0.0000i
```

Sparse Identity Matrix

Define a 5-by-5 sparse matrix.

```
p = sparse(5,5,pi);
```

Create a 5-by-5 identity matrix that is sparse like `P`.

```
I = eye(5,'like',p)

I =

   (1,1)        1
   (2,2)        1
   (3,3)        1
   (4,4)        1
   (5,5)        1
```

Size and Numeric Data Type Defined by Existing Array

Define a 2-by-2 matrix of single precision.

```
p = single([1 3 ; 2 4]);
```

Create an identity matrix that is the same size and data type as `P`.

```
I = eye(size(p),'like',p),
class(I)

I =

     1     0
     0     1

ans =
```

`single`

Input Arguments

`n` — Size of first dimension of `I`

integer value

Size of first dimension of `I`, specified as an integer value.

- If `n` is the only integer input argument, then `I` is a square n-by-n identity matrix.
- If `n` is `0`, then `I` is an empty matrix.
- If `n` is negative, then it is treated as `0`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`m` — Size of second dimension of `I`

integer value

Size of second dimension of `I`, specified as an integer value.

- If `m` is `0`, then `I` is an empty matrix.
- If `m` is negative, then it is treated as `0`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Size of `I`

row vector of no more than two integer values

Size of `I`, specified as a row vector of no more than two integer values.

- If an element of `sz` is `0`, then `I` is an empty matrix.
- If an element of `sz` is negative, then the element is treated as `0`.

Example: `sz = [2,3]` defines `I` as a 2-by-3 matrix.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`classname` — Output class

`'double'` (default) | `'single'` | `'int8'` | `'uint8'` | ...

Output class, specified as `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

Data Types: `char`

`p` — Prototype

numeric variable

Prototype, specified as a numeric variable.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`ones` | `speye` | `zeros`

Introduced before R2006a

ezcontour

Easy-to-use contour plotter

Syntax

```
ezcontour(fun)
ezcontour(fun,domain)
ezcontour(...,n)
ezcontour(axes_handle,...)
h = ezcontour(...)
```

Description

`ezcontour(fun)` plots the contour lines of `fun(x,y)` using the `contour` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for a MATLAB file function or an anonymous function (see `function handle` and "Anonymous Functions") or a string (see Tips).

`ezcontour(fun,domain)` plots `fun(x,y)` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where $min < x < max$, $min < y < max$).

`ezcontour(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontour(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezcontour(...)` returns the handle to a contour object in `h`.

`ezcontour` automatically adds a title and axis labels.

Examples

Create Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables, x and y.

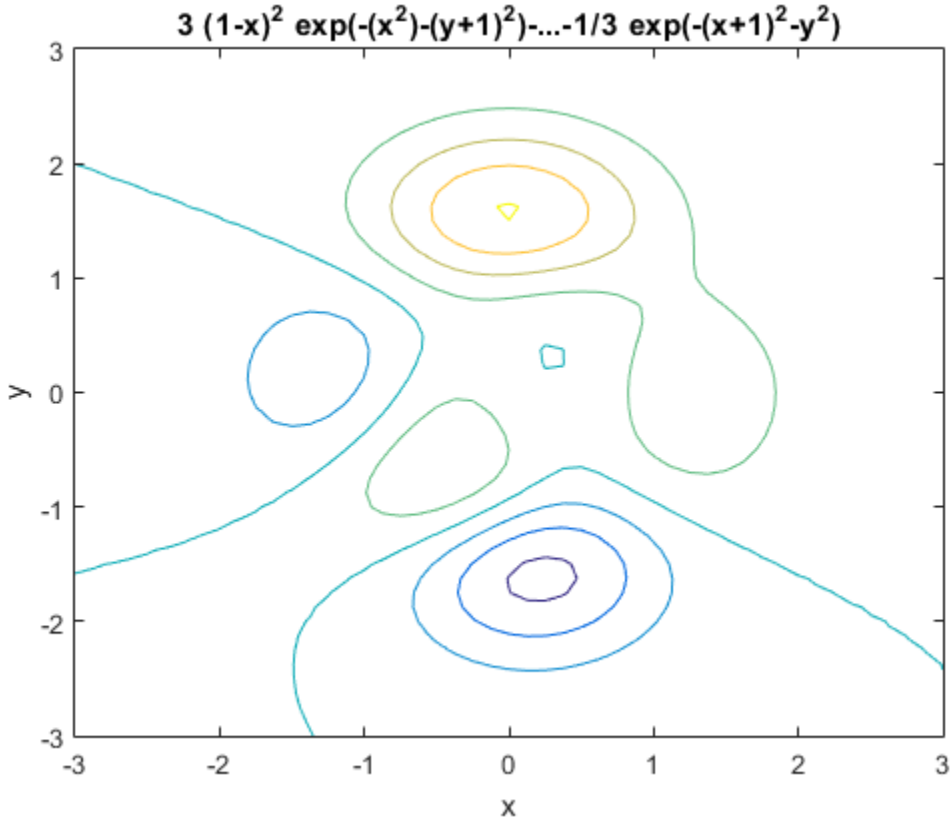
$$f(x,y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right)e^{-x^2-y^2} - \frac{1}{3}e^{-(x+1)^2-y^2}$$

The `ezcontour` function requires a function handle argument. Write this mathematical expression in MATLAB® syntax as an anonymous function with handle `f`. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
   - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
   - 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, `f`, to `ezcontour`. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontour(f,[-3,3],49)
```



3 (1-x)^2 exp(-(x^2)-(y+1)^2)-...-1/3 exp(-(x+1)^2-y^2)

In this particular case, the title string is too long to fit at the top of the graph so MATLAB® abbreviates the string.

More About

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontour`. For example, the MATLAB syntax for a contour plot of the expression

```
sqrt(x.^2 + y.^2)
```

is written as

```
ezcontour('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezcontour`.

If the function to be plotted is a function of the variables u and v (rather than x and y), the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontour('u^2 - v^3',[0,1],[3,6])` plots the contour lines for $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontour`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontour(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezcontour` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then use an anonymous function to specify that parameter:

```
ezcontour(@(x,y)myfun(x,y,2))
```

Introduced before R2006a

ezcontourf

Easy-to-use filled contour plotter

Syntax

```
ezcontourf(fun)
ezcontourf(fun,domain)
ezcontourf(...,n)
ezcontourf(axes_handle,...)
h = ezcontourf(...)
```

Description

`ezcontourf(fun)` plots the contour lines of `fun(x,y)` using the `contourf` function. `fun` is plotted over the default domain: -2π < `x` < 2π, -2π < `y` < 2π.

`fun` can be a function handle or a string (see Tips).

`ezcontourf(fun,domain)` plots `fun(x,y)` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]`, where `min` < `x` < `max`, `min` < `y` < `max`).

`ezcontourf(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontourf(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = ezcontourf(...)` returns the handle to a contour object in `h`.

`ezcontourf` automatically adds a title and axis labels.

Examples

Create Filled Contour Plot of Mathematical Expression

This mathematical expression defines a function of two variables, x and y.

$$f(x,y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right) e^{-x^2-y^2} - \frac{1}{3} e^{-(x+1)^2-y^2}$$

The `ezcontourf` function requires a function handle argument. Write this mathematical expression in MATLAB® syntax as an anonymous function with handle `f`. You can define an anonymous function in the command window without creating a separate file. For convenience, write the function on three lines.

```
f = @(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
   - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
   - 1/3*exp(-(x+1).^2 - y.^2);
```

Pass the function handle, `f`, to `ezcontourf`. Specify a domain from -3 to 3 in both the x-direction and y-direction and use a 49-by-49 computational grid.

```
ezcontourf(f,[-3,3],49)

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontourf`. For example, the MATLAB syntax for a filled contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezcontourf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezcontourf`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontourf('u^2 - v^3',[0,1],[3,6])` plots the contour lines for $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontourf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontourf(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezcontourf` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezcontourf(@(x,y)myfun(x,y,2))
```

- Anonymous Functions

`contourf` | `ezmesh` | `ezcontour` | `ezmeshc` | `ezplot` | `ezplot3` | `ezpolar` | `ezsurf` | `ezsurfc` | `function_handle`

Introduced before R2006a

ezmesh

Easy-to-use 3-D mesh plotter

Syntax

```
ezmesh(fun)
ezmesh(fun,domain)
ezmesh(funx,funy,funz)
ezmesh(funx,funy,funz,[smin,smax,tmin,tmax])
ezmesh(funx,funy,funz,[min,max])
ezmesh(...,n)
ezmesh(...,'circ')
ezmesh(axes_handle,...)
h = ezmesh(...)
```

Description

`ezmesh(fun)` creates a graph of `fun(x,y)` using the `mesh` function. `fun` is plotted over the default domain: -2π < `x` < 2π, -2π < `y` < 2π.

`fun` can be a function handle or a string (see the Tips section).

`ezmesh(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` < `x` < `max`, `min` < `y` < `max`).

`ezmesh(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: -2π < `s` < 2π, -2π < `t` < 2π.

`ezmesh(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmesh(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmesh(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmesh(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

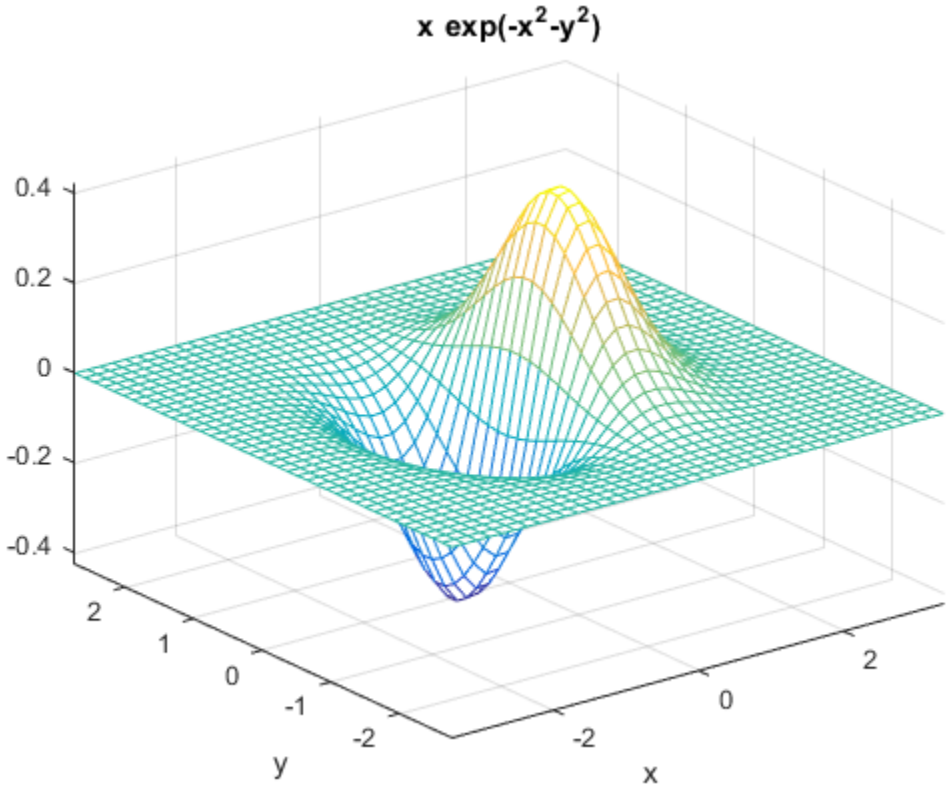
`h = ezmesh(...)` returns the handle to a surface object in `h`.

Examples

Mesh Plot of Mathematical Function

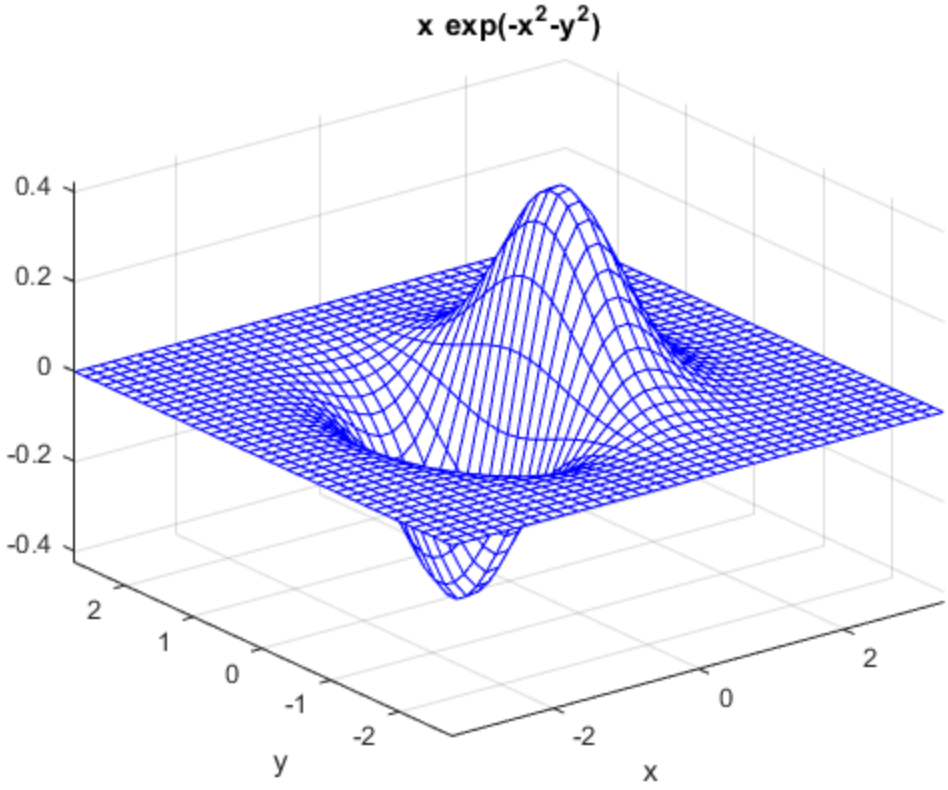
Create a mesh plot of the function $f(x,y) = xe^{-x^2-y^2}$ over a 40-by-40 grid.

```
fh = @(x,y) x.*exp(-x.^2-y.^2);
ezmesh(fh,40)
```



Set the mesh lines to a uniform blue color by setting the colormap to a single color.

```
colormap([0 0 1])
```



More About

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmesh`. For example, the MATLAB syntax for a mesh plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmesh('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezmesh`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmesh('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmesh`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmesh(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezmesh` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmesh(@(x,y)myfun(x,y,2))
```

- Anonymous Functions

`ezmeshc` | `mesh` | `function_handle`

Introduced before R2006a

ezmeshc

Easy-to-use combination mesh/contour plotter

Syntax

```
ezmeshc(fun)
ezmeshc(fun,domain)
ezmeshc(funx,funy,funz)
ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])
ezmeshc(funx,funy,funz,[min,max])
ezmeshc(...,n)
ezmeshc(...,'circ')
ezmesh(axes_handle,...)
h = ezmeshc(...)
```

Description

`ezmeshc(fun)` creates a graph of `fun(x,y)` using the `meshc` function. `fun` is plotted over the default domain -2π < `x` < 2π, -2π < `y` < 2π.

`fun` can be a function handle or a string (see the Tips section).

`ezmeshc(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` < `x` < `max`, `min` < `y` < `max`).

`ezmeshc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: -2π < `s` < 2π, -2π < `t` < 2π.

`ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmeshc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmeshc(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmeshc(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

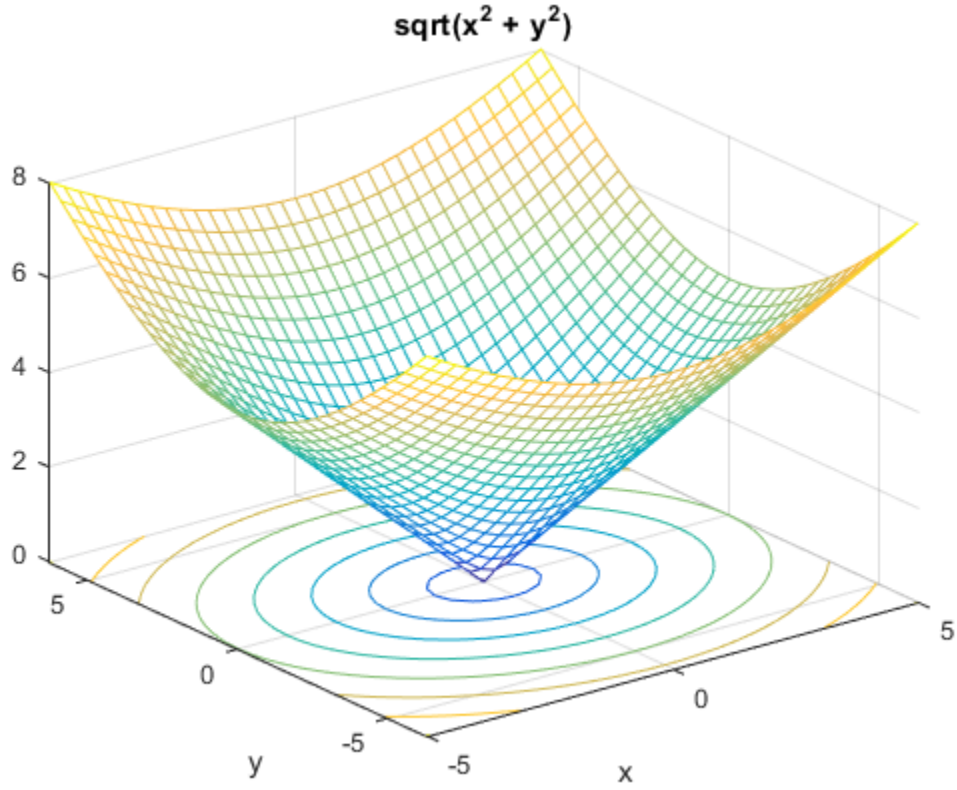
`h = ezmeshc(...)` returns the handle to a surface object in `h`.

Examples

Mesh and Contour Plot of Mathematical Function

Create a mesh/contour plot of the expression $f(x,y) = \sqrt{x^2 + y^2}$ over the domain $-5 < x < 5$ and $-2\pi < y < 2\pi$ with a computational grid size of 35-by-35.

```
ezmeshc('sqrt(x^2 + y^2)',[-5,5,-2*pi,2*pi],35)
```



More About

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmeshc`. For example, the MATLAB syntax for a mesh/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmeshc('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezmeshc`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmeshc('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmeshc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmeshc(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezmeshc` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmeshc(@(x,y)myfun(x,y,2))
```

- Anonymous Functions

See Also

`ezmesh` | `ezsurfc` | `meshc` | `function_handle`

ezplot

Easy-to-use function plotter

Syntax

```
ezplot(fun)
ezplot(fun,[xmin,xmax])
ezplot(fun2)
ezplot(fun2,[xymin,xymax])
ezplot(fun2,[xmin,xmax,ymin,ymax])
ezplot(funx,funy)
ezplot(funx,funy,[tmin,tmax])
ezplot(...,figure_handle)
ezplot(axes_handle,...)
h = ezplot(...)
```

Description

`ezplot(fun)` plots the expression `fun(x)` over the default domain -2π < `x` < 2π, where `fun(x)` is an explicit function of only `x`.

`fun` can be a function handle or a string.

`ezplot(fun,[xmin,xmax])` plots `fun(x)` over the domain: `xmin` < `x` < `xmax`.

For an implicit function, `fun2(x,y)`:

`ezplot(fun2)` plots `fun2(x,y) = 0` over the default domain -2π < `x` < 2π, -2π < `y` < 2π.

`ezplot(fun2,[xymin,xymax])` plots `fun2(x,y) = 0` over `xymin` < `x` < `xymax` and `xymin` < `y` < `xymax`.

`ezplot(fun2,[xmin,xmax,ymin,ymax])` plots `fun2(x,y) = 0` over `xmin` < `x` < `xmax` and `ymin` < `y` < `ymax`.

`ezplot(funx,funy)` plots the parametrically defined planar curve `funx(t)` and `funy(t)` over the default domain $0 < t < 2\pi$.

`ezplot(funx,funy,[tmin,tmax])` plots `funx(t)` and `funy(t)` over `tmin` < `t` < `tmax`.

`ezplot(...,figure_handle)` plots the given function over the specified domain in the figure window identified by the handle `figure`.

`ezplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

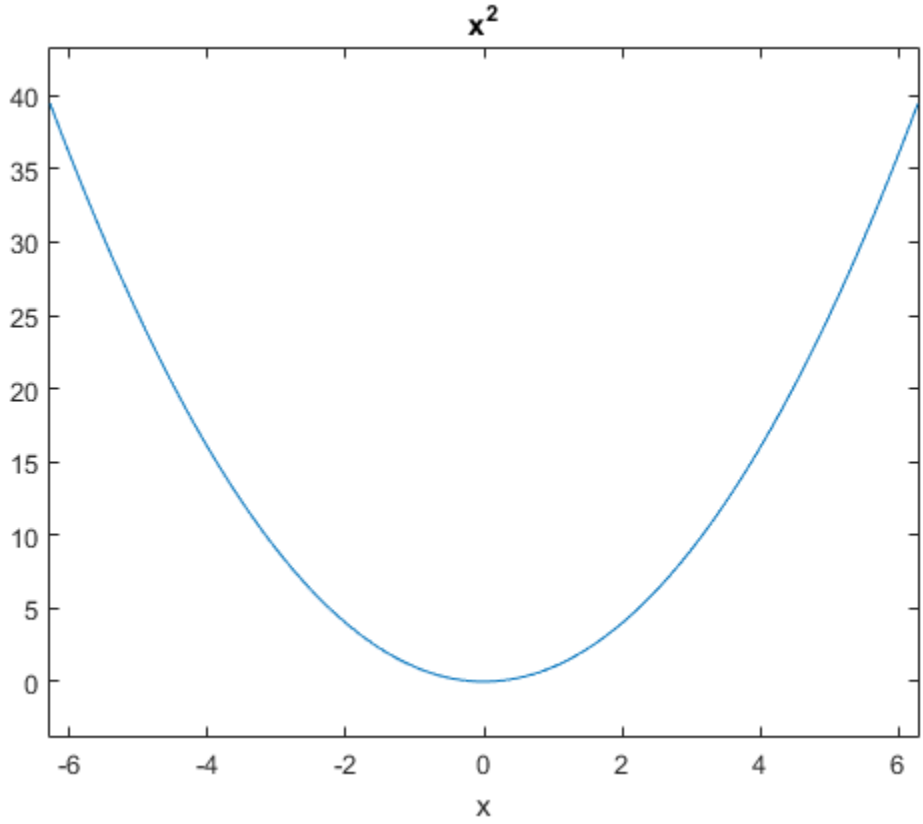
`h = ezplot(...)` returns either a chart line or contour object.

Examples

Plot an Explicit Function

Plot the explicit function x^2 over the domain $[-2\pi, 2\pi]$.

```
ezplot('x^2')
```

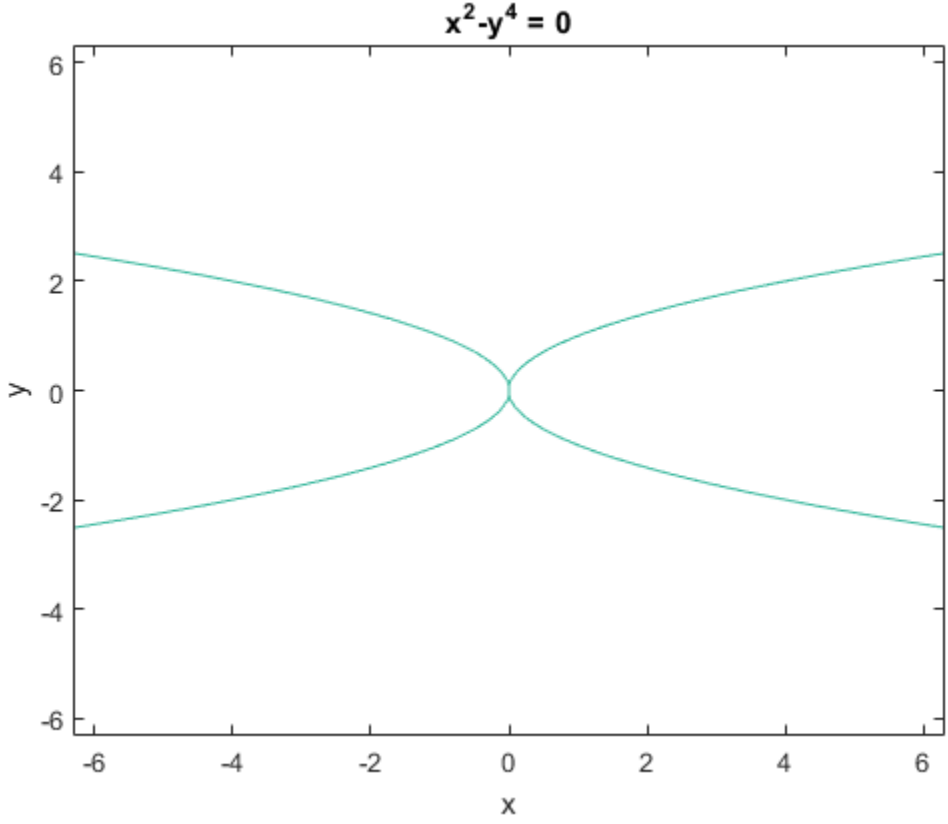


The default domain is $[-2\pi, 2\pi]$.

Plot an Implicit Function

Plot the implicitly defined function $x^2 - y^4 = 0$ over the domain $[-2\pi, 2\pi]$.

```
ezplot('x^2-y^4')
```



The default domain is $[-2\pi, 2\pi]$.

More About

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot`. For example, the MATLAB syntax for a plot of the expression

```
x.^2 - y.^2
```

which represents an implicitly defined function, is written as

```
ezplot('x^2 - y^2')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezplot`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot`.

```
fh = @(x,y) x.^2 + y.^3 - 2*y - 1;
ezplot(fh)
axis equal
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezplot(@(x,y)myfun(x,y,2))
```

- Anonymous Functions

`ezplot3` | `ezpolar` | `function_handle` | `plot`

Introduced before R2006a

ezplot3

Easy-to-use 3-D parametric curve plotter

Syntax

```
ezplot3(funx,funy,funz)
ezplot3(funx,funy,funz,[tmin,tmax])
ezplot3(...,'animate')
ezplot3(axes_handle,...)
h = ezplot3(...)
```

Description

`ezplot3(funx,funy,funz)` plots the spatial curve `funx(t)`, `funy(t)`, and `funz(t)` over the default domain $0 < t < 2\pi$.

`funx`, `funy`, and `funz` can be function handles or strings (see the Tips section).

`ezplot3(funx,funy,funz,[tmin,tmax])` plots the curve `funx(t)`, `funy(t)`, and `funz(t)` over the domain `tmin` < `t` < `tmax`.

`ezplot3(...,'animate')` produces an animated trace of the spatial curve.

`ezplot3(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot3(...)` returns the handle to the plotted objects in `h`.

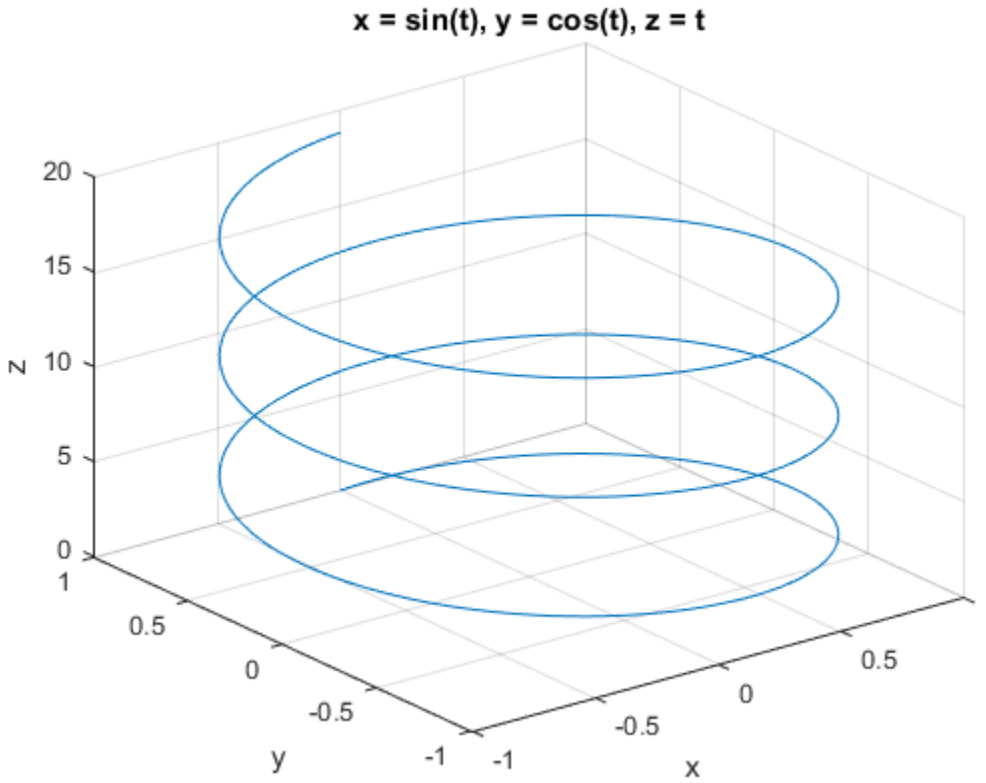
Examples

Plot a Parametric Curve

Plot this parametric curve over the domain $[0, 6\pi]$.

$$x = \sin(t), \quad y = \cos(t), \quad z = t$$

```
ezplot3('sin(t)','cos(t)','t',[0,6*pi])
```



More About

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot3`. For example, the MATLAB syntax for a plot of the expression

```
x = s./2, y = 2.*s, z = s.^2;
```

which represents a parametric function, is written as

```
ezplot3('s/2','2*s','s^2')
```

That is, `s/2` is interpreted as `s./2` in the string you pass to `ezplot3`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot3`.

```
fh1 = @(s) s./2; fh2 = @(s) 2.*s; fh3 = @(s) s.^2;
ezplot3(fh1,fh2,fh3)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezplot3` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfuntk`:

```
function s = myfuntk(t,k)
s = t.^k.*sin(t);
```

then you can use an anonymous function to specify that parameter:

```
ezplot3(@cos,@(t)myfuntk(t,1),@sqrt)
```

- Anonymous Functions

See Also

`ezplot` | `ezpolar` | `plot3` | `function_handle`

Introduced before R2006a

ezpolar

Easy-to-use polar coordinate plotter

Syntax

```
ezpolar(fun)
ezpolar(fun,[a,b])
ezpolar(axes_handle,...)
h = ezpolar(...)
```

Description

`ezpolar(fun)` plots the polar curve `rho = fun(theta)` over the default domain $0 <$ `theta` $< 2\pi$.

`fun` can be a function handle or a string (see the Tips section).

`ezpolar(fun,[a,b])` plots `fun` for `a` < `theta` < `b`.

`ezpolar(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

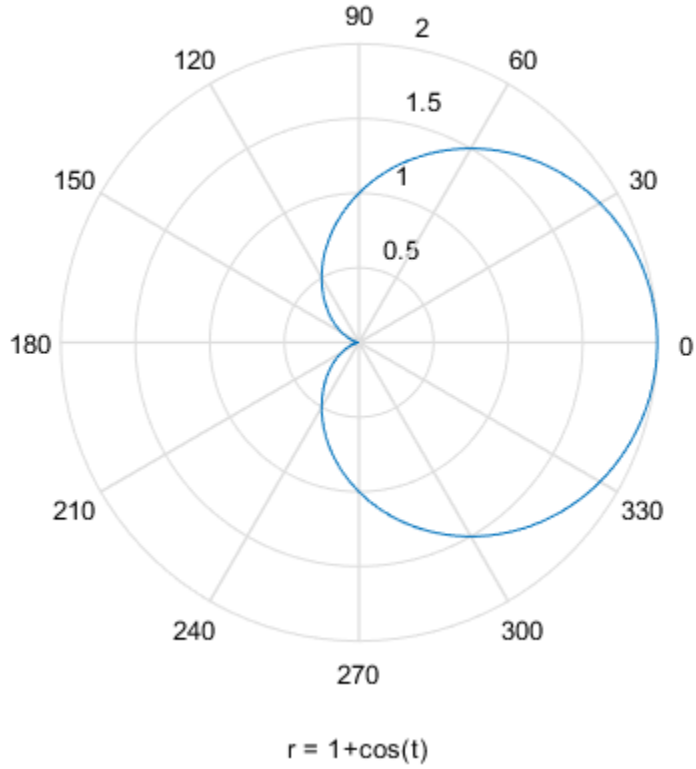
`h = ezpolar(...)` returns the handle to a line object in `h`.

Examples

Polar Plot of Mathematical Function

Plot the function $1 + \cos(t)$ over the domain $[0, 2\pi]$.

```
figure
ezpolar('1+cos(t)')
```



More About

Tips

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezpolar`. For example, the MATLAB syntax for a plot of the expression

```
t.^2.*cos(t)
```

which represents an implicitly defined function, is written as

```
ezpolar('t^2*cos(t)')
```

That is, `t^2` is interpreted as `t.^2` in the string you pass to `ezpolar`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezpolar`.

```
fh = @(t) t.^2.*cos(t);
ezpolar(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezpolar` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k1` and `k2` in `myfun`:

```
function s = myfun(t,k1,k2)
s = sin(k1*t).*cos(k2*t);
```

then you can use an anonymous function to specify the parameters:

```
ezpolar(@(t)myfun(t,2,3))
```

- Anonymous Functions

See Also

`ezplot` | `ezplot3` | `plot` | `plot3` | `polar` | `function_handle`

Introduced before R2006a

ezsurf

Easy-to-use 3-D colored surface plotter

Syntax

```
ezsurf(fun)
ezsurf(fun,domain)
ezsurf(funx,funy,funz)
ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])
ezsurf(funx,funy,funz,[min,max])
ezsurf(...,n)
ezsurf(...,'circ')
ezsurf(axes_handle,...)
h = ezsurf(...)
```

Description

`ezsurf(fun)` creates a graph of `fun(x,y)` using the `surf` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle or a string (see the Tips section).

`ezsurf(fun,domain)` plots `fun` over the specified `domain`. `domain` must be a vector. See the “Algorithms” on page 1-2479 section for details on vector inputs vs axes limit outputs.

`ezsurf(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

`ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezsurf(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezsurf(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezsurf(...,'circ')` plots `fun` over a disk centered on the domain.

`ezsurf(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

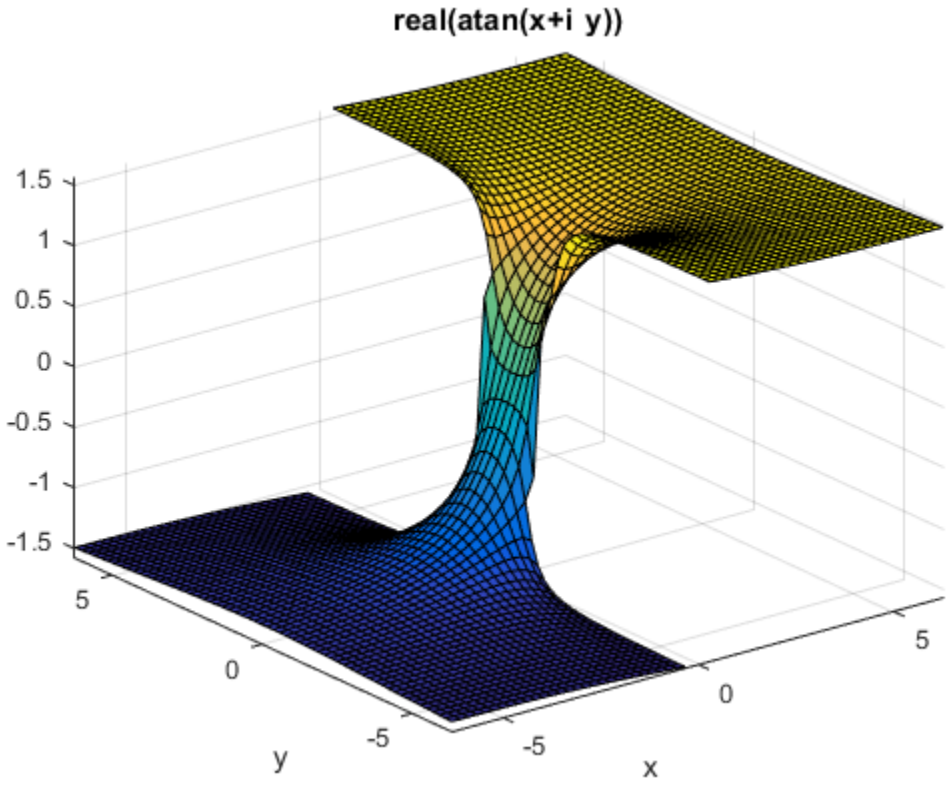
`h = ezsurf(...)` returns the handle to a surface object in `h`.

Examples

Surface Plot of Mathematical Function

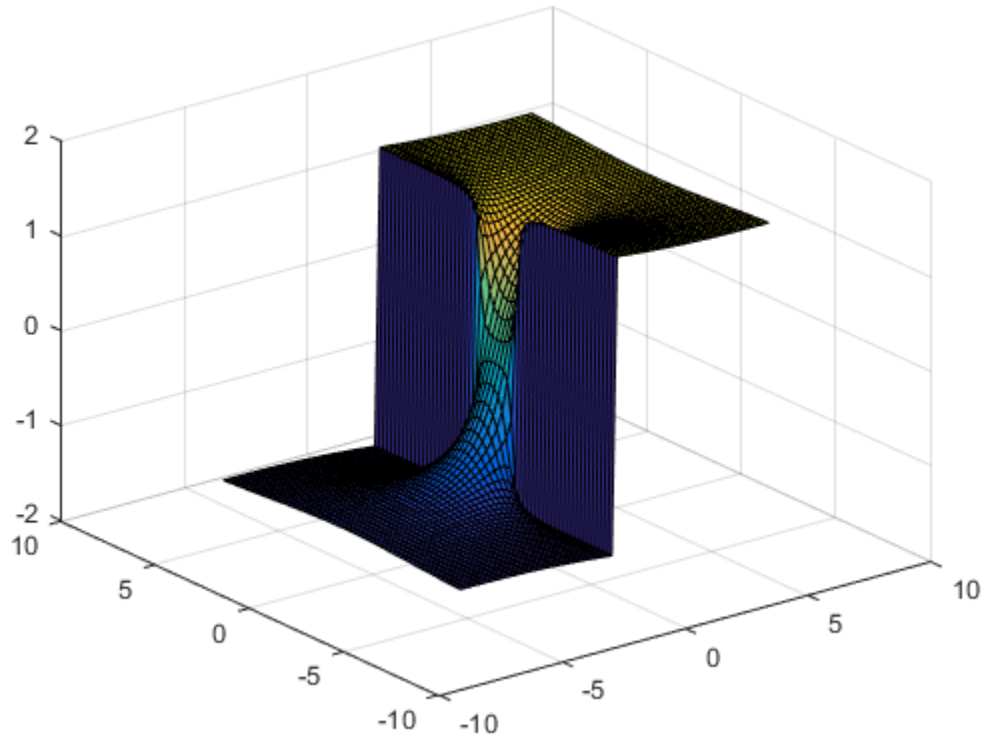
Plot the function $f(x,y) = real(a\tan(x+iy))$ over the domain $-2\pi < x < 2\pi$ and $-2\pi < y < 2\pi$. The `ezsurf` function does not plot points where the mathematical function is not defined. These points are set to `NaN` so that they do not plot.

```
figure
ezsurf('real(atan(x+i*y))')
```



Use `surf` to plot the same data without filtering discontinuities.

```
figure
[x,y] = meshgrid(linspace(-2*pi,2*pi,60));
z = real(atan(x+1i.*y));
surf(x,y,z)
```



More About

Tips

`ezsurf` and `ezsurfc` do not accept complex inputs.

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurf`. For example, the MATLAB syntax for a surface plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurf`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurf('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezsurf` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

Algorithms

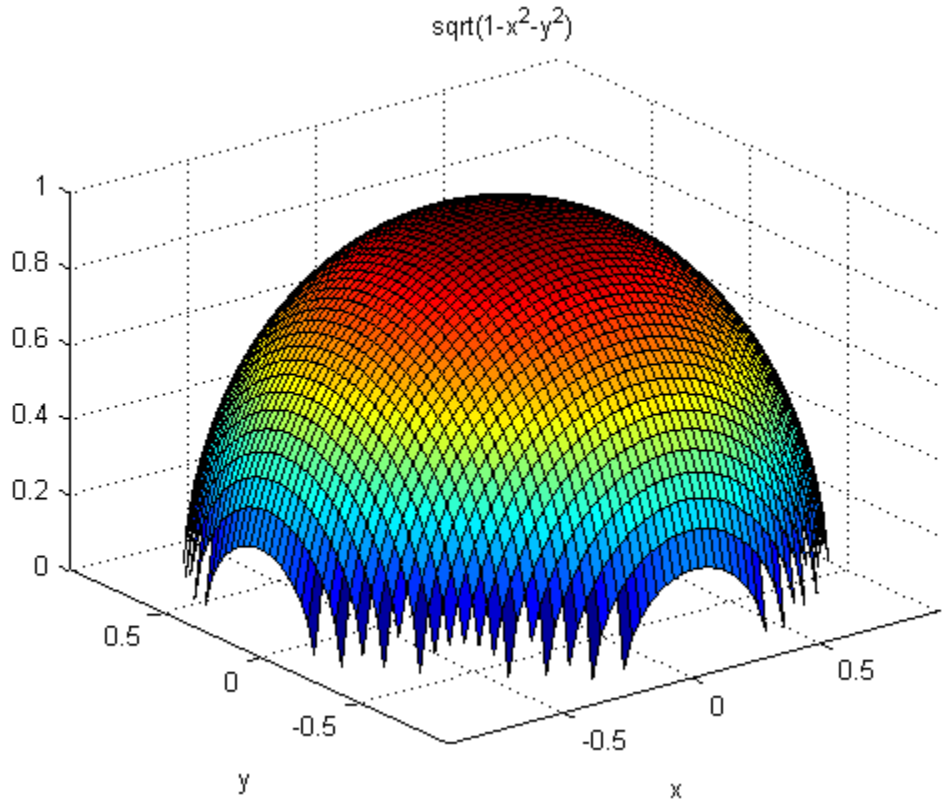
`ezsurf` determines the *x*- and *y*-axes limits in different ways depending on how you input the domain (if at all). In the following table, `R` is the vector [`xmin`, `xmax`, `ymin`, `ymax`] and `v` is the manually entered domain vector.

Number of domain values specified:	Resulting domain vector:
`v = [ ];`	`R = [-2*pi, 2*pi, -2*pi, 2*pi];`
`v = [ v(1) ];`	`R = double([-abs(v),abs(v),-abs(v),abs(v)]);`
`v = [ v(1) v(2) ];`	`R = double([v(1),v(2),v(1),v(2)]);`
`v = [ v(1) v(2) v(3) ];`	`R = double([-v(1),v(2),-abs(v(3)),abs(v(3))]);`
`v = [ v(1) v(2) v(3) v(4) ];`	`R = double(v);`
`v = [ v(1)..v(n) ]; n>4`	`R = double([-abs(v(1)), abs(v(1)), -abs(v(1)), abs(v(1))]);`

If you specify a single number in non-vector format (without square brackets, [ ]), `ezsurf` interprets it as the `n`, the number of points desired between the axes `max` and `min` values.

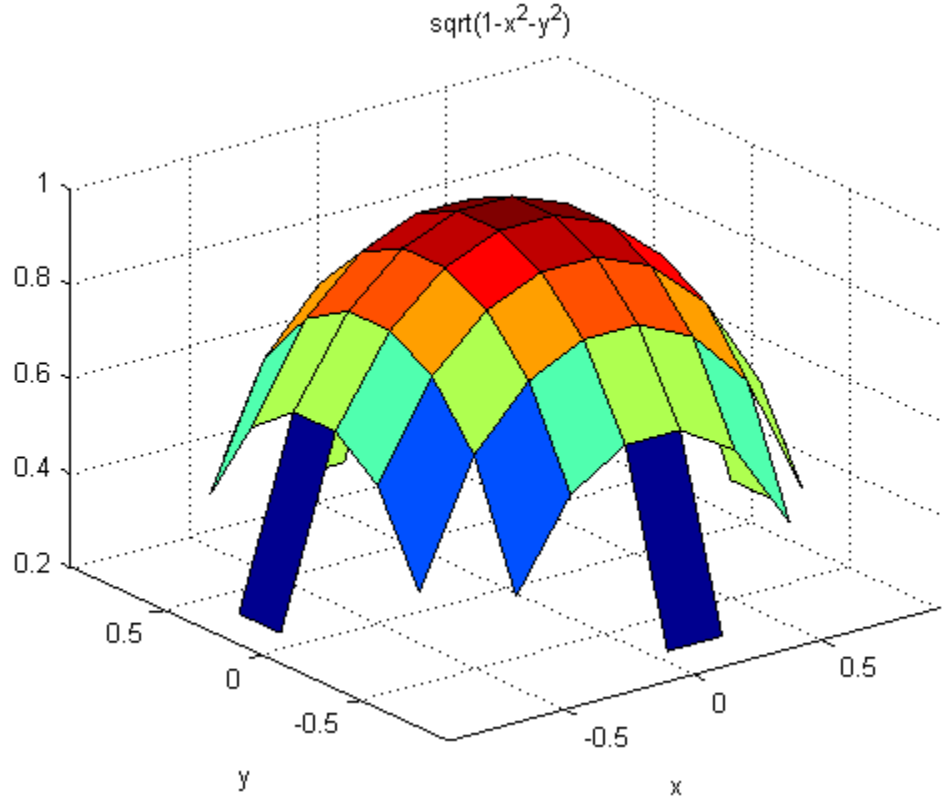
By default, `ezsurf` uses 60 points between the `max` and `min` values of an axes. When the `min` and `max` values are the default values (`R = [-2*pi, 2*pi, -2*pi, 2*pi];`), `ezsurf` ensures the 60 points fall within the non-complex range of the specified equation. For example, $\sqrt{1-x^2-y^2}$ is only real when $x^2-y^2 \le 1$. The default graph of this function looks like this:

```
ezsurf('sqrt(1-x^2-y^2)')
```



You can see that there are 60 points between the minimum and maximum values for which $\sqrt{1-x^2-y^2}$ has real values. However, when you specify the domain values to be the same as the default (`R = [-2*pi, 2*pi, -2*pi, 2*pi];`), a different result appears:

```
ezsurf('sqrt(1-x^2-y^2)',[-2*pi 2*pi])
```



In this case, the graphic limits are the same, but `ezsurf` used 60 points between the user-defined limits instead of checking to see if all those points would have real answers.

- Anonymous Functions

`ezmesh` | `ezsurfc` | `surf` | `function_handle`

Introduced before R2006a

ezsurfc

Easy-to-use combination surface/contour plotter

Syntax

```
ezsurfc(fun)
ezsurfc(fun,domain)
ezsurfc(funx,funy,funz)
ezsurfc(funx,funy,funz,[smin,smax,tmin,tmax])
ezsurfc(funx,funy,funz,[min,max])
ezsurfc(...,n)
ezsurfc(...,'circ')
ezsurfc(axes_handle,...)
h = ezsurfc(...)
```

Description

`ezsurfc(fun)` creates a graph of `fun(x,y)` using the `surfc` function. The function `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle or a string (see the Tips section).

`ezsurfc(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where $min < x < max$, $min < y < max$).

`ezsurfc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

`ezsurfc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezsurfc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezsurfc(...,n)` plots *f* over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezsurfc(...,'circ')` plots *f* over a disk centered on the domain.

`ezsurfc(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

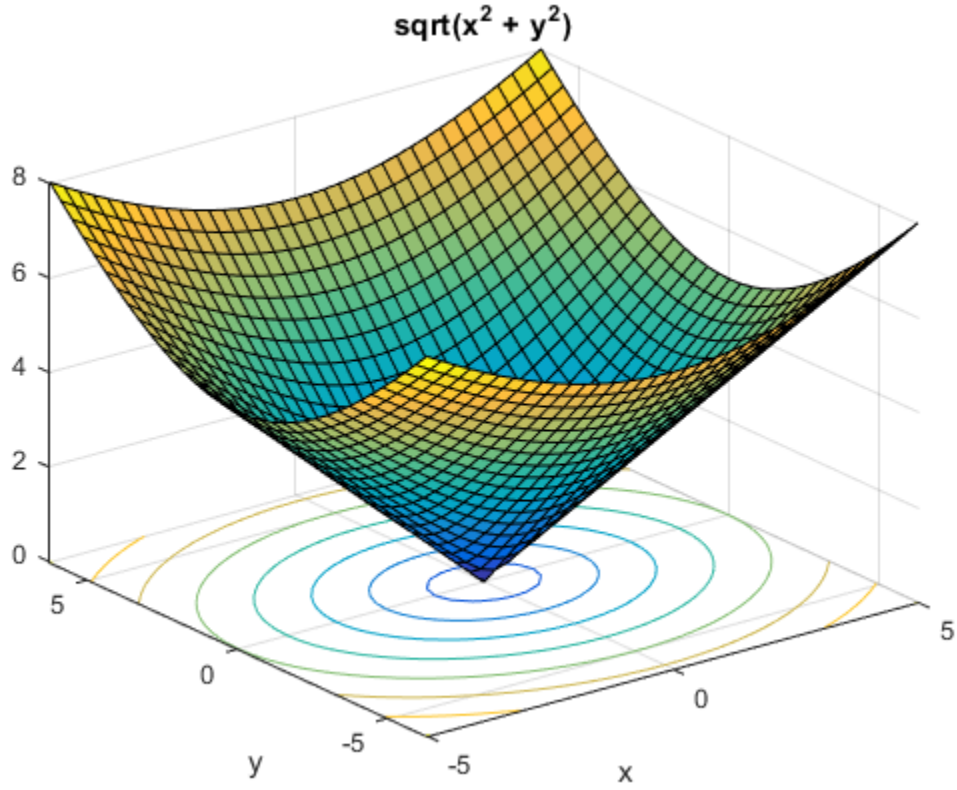
`h = ezsurfc(...)` returns the handles to the graphics objects in `h`.

Examples

Surface and Contour Plot of Mathematical Function

Create a surface/contour plot of the expression $f(x,y) = \sqrt{x^2 + y^2}$ over the domain $-5 < x < 5$ and $-2\pi < y < 2\pi$ with a computational grid size of 35-by-35.

```
ezsurfc('sqrt(x^2 + y^2)',[-5,5,-2*pi,2*pi],35)
```



More About

Tips

`ezsurf` and `ezsurfc` do not accept complex inputs.

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurfc`. For example, the MATLAB syntax for a surface/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurfc('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurfc`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurfc('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurfc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezsurfc` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurfc(@(x,y)myfun(x,y,2,2,4))
```

- Anonymous Functions

Introduced before R2006a

faceNormals

Class: TriRep

(Will be removed) Unit normals to specified triangles

Note: `faceNormals(TriRep)` will be removed in a future release. Use `faceNormal(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
FN = faceNormals(TR, TI)
```

Description

`FN = faceNormals(TR, TI)` returns the unit normal vector to each of the specified triangles TI.

Note: This query is only applicable to triangular surface meshes.

Input Arguments

`TR`	Triangulation representation.
`TI`	Column vector of indices that index into the triangulation matrix `TR.Triangulation`.

Output Arguments

`FN`	m-by-3 matrix. `m = length(TI)`, the number of triangles to be queried. Each row `FN(i,:)` represents the unit normal vector to triangle `TI(i)`.

If TI is not specified the unit normal information for the entire triangulation is returned, where the normal associated with triangle i is the `i`'th row of `FN`.

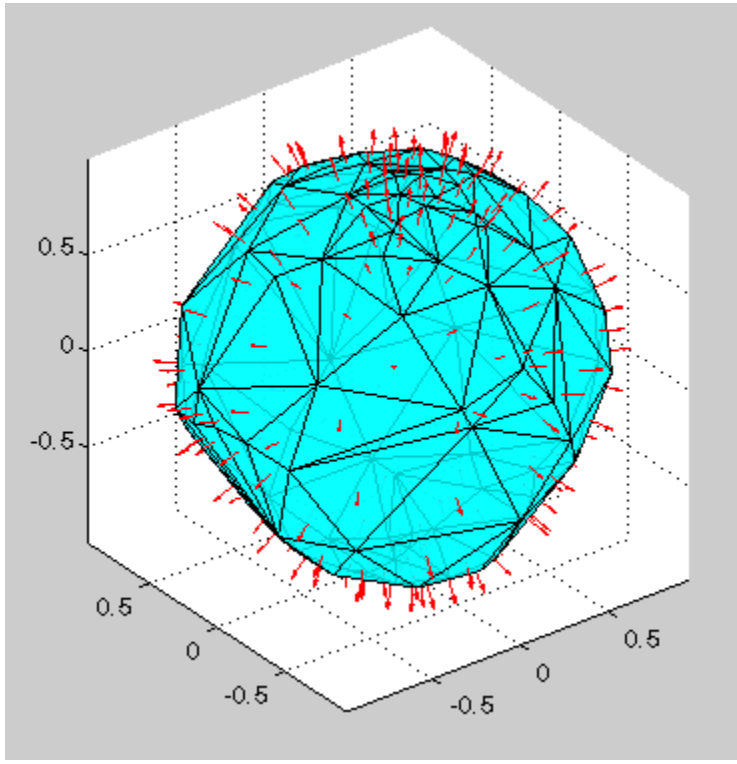
Examples

Triangulate a sample of random points on the surface of a sphere and use the `TriRep` to compute the normal to each triangle:

```
numpts = 100;
thetha = rand(numpts,1)*2*pi;
phi = rand(numpts,1)*pi;
x = cos(thetha).*sin(phi);
y = sin(thetha).*sin(phi);
z = cos(phi);
dt = DelaunayTri(x,y,z);
[tri Xb] = freeBoundary(dt);
tr = TriRep(tri, Xb);
P = incenters(tr);
fn = faceNormals(tr);
trisurf(tri,Xb(:,1),Xb(:,2),Xb(:,3), ...
     'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

Display the result using a quiver plot:

```
quiver3(P(:,1),P(:,2),P(:,3), ...
     fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```



See Also

`delaunayTriangulation` | `freeBoundary` | `triangulation`

factor

Prime factors

Syntax

```
f = factor(n)
```

Description

`f = factor(n)` returns a row vector containing the prime factors of `n`. Vector `f` is of the same data type as `n`.

Examples

Prime Factors of Double Integer Value

```
f = factor(200)
```

```
f =

     2     2     2     5     5
```

Multiply the elements of `f` to reproduce the input value.

```
prod(f)
```

```
ans =

   200
```

Prime Factors of Unsigned Integer Value

```
n = uint16(138);
f = factor(n)
```

```
f =

       2       3      23
```

Multiply the elements of `f` to reproduce `n`.

```
prod(f)
```

```
ans =

   138
```

Input Arguments

n — Input value

real, nonnegative integer scalar

Input value, specified as a real, nonnegative integer scalar.

Example: `10`

Example: `int16(64)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

See Also

`isprime` | `primes`

Introduced before R2006a

factorial

Factorial of input

Syntax

```
f = factorial(n)
```

Description

`f = factorial(n)` returns the product of all positive integers less than or equal to `n`, where `n` is a nonnegative integer value. If `n` is an array, then `f` contains the factorial of each value of `n`. The data type and size of `f` is the same as that of `n`.

Examples

10!

```
f = factorial(10)
```

```
f =

     3628800
```

22!

```
format long
f = factorial(22)
```

```
f =

     1.124000727777608e+21
```

In this case, `f` is accurate up to 15 digits, `1.12400072777760e+21`, because double-precision numbers are only accurate up to 15 digits.

Reset the output format to the default.

```
format
```

Factorial of Array Elements

```
n = [0 1 2; 3 4 5];
f = factorial(n)
```

```
f =

     1     1     2
     6    24   120
```

Factorial of Unsigned Integer Values

```
n = uint64([5 10 15 20]);
f = factorial(n)
```

```
f =

   120     3628800    1307674368000    2432902008176640000
```

Input Arguments

n — Input values

scalar, vector, or array of real, nonnegative integer values

Input values, specified as a scalar, vector, or array of real, nonnegative integers.

Example: `5`

Example: `[0 1 2 3 4]`

Example: `int16([10 15 20])`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

More About

Tips

Limitations

- For double-precision inputs, the result is exact when `n` is less than or equal to `21`. Larger values of `n` produce a result that has the correct order of magnitude and is accurate for the first 15 digits. This is because double-precision numbers are only accurate up to 15 digits.
- For single-precision inputs, the result is exact when `n` is less than or equal to `13`. Larger values of `n` produce a result that has the correct order of magnitude and is accurate for the first 8 digits. This is because single-precision numbers are only accurate up to 8 digits.

Saturation

- The table below describes the saturation behavior of each data type when used with the `factorial` function. The values in the last column indicate the saturation point; that is, the first positive integer whose actual factorial is larger than the maximum representable value in the middle column. For `single` and `double`, all values larger than the maximum value are returned as `Inf`. For the integer data types, the saturation value is equal to the maximum value in the middle column.

Data type	Maximum Value	Factorial Saturation Threshold
`double`	`realmax`	`factorial(171)`
`single`	`realmax('single')`	`factorial(single(35))`
`uint64`	2^{64}-1	`factorial(uint64(21))`
`int64`	2^{63}-1	`factorial(int64(21))`
`uint32`	2^{32}-1	`factorial(uint32(13))`
`int32`	2^{31}-1	`factorial(int32(13))`
`uint16`	2^{16}-1	`factorial(uint16(9))`
`int16`	2^{15}-1	`factorial(int16(8))`
`uint8`	2^{8}-1	`factorial(uint8(6))`
`int8`	2^{7}-1	`factorial(int8(6))`

`prod`

Introduced before R2006a

false

Logical 0 (false)

Syntax

```
false
F = false(n)
F = false(sz)
F = false(sz1,...,szN)
F = false(___,'like',p)
```

Description

`false` is shorthand for `logical(0)`.

`F = false(n)` is an `n`-by-`n` array of logical zeros.

`F = false(sz)` is an array of logical zeros where the size vector, `sz`, defines `size(F)`. For example, `false([2 3])` returns a 2-by-3 array of logical zeros.

`F = false(sz1,...,szN)` is a `sz1`-by-`...`-by-`szN` array of logical zeros where `sz1,...,szN` indicates the size of each dimension. For example, `false(2,3)` returns a 2-by-3 array of logical zeros.

`F = false(___,'like',p)` returns an array of logical zeros of the same sparsity as the logical variable `p` using any of the previous size syntaxes.

Examples

Generate Square Matrix of Logical Zeros

Use `false` to generate a 3-by-3 square matrix of logical zeros.

```
A = false(3)
class(A)
```

```
A =
     0     0     0
     0     0     0
     0     0     0
ans =
logical
```

The result is of class `logical`.

Generate Array of Logical Zeros with Arbitrary Dimensions

Use `false` to generate a 3-by-2-by-2 array of logical zeros.

```
false(3,2,2)
```

```
ans(:,:,1) =
     0     0
     0     0
     0     0

ans(:,:,2) =
     0     0
     0     0
     0     0
```

Alternatively, use a size vector to specify the size of the matrix.

```
false([3 2 2])
```

```
ans(:,:,1) =
     0     0
     0     0
     0     0

ans(:,:,2) =
     0     0
     0     0
     0     0
```

Note that specifying multiple vector inputs returns an error.

Execute Logic Statement

`false` along with `true` can be used to execute logic statements.

Test the logical statement $\sim(A\ and\ B) \equiv (\sim A)\ or\ (\sim B)$ for A = logical false and B = logical true.

```
~(false & true) == (~false) | (~true)
```

```
ans =
     1
```

The result is logical 1 (true), since the logical statements on both sides of the equation are equivalent. This logical statement is an instance of De Morgan's Law.

Generate Logical Array of Selected Sparsity

Generate a logical array of the same data type and sparsity as the selected array.

```
A = logical(sparse(5,3));
whos A
F = false(4,'like',A);
whos F
```

```
  Name      Size            Bytes  Class      Attributes
  A         5x3                41  logical    sparse
  Name      Size            Bytes  Class      Attributes
  F         4x4                49  logical    sparse
```

The output array F has the same `sparse` attribute as the specified array A.

Input Arguments

n — Size of square matrix

integer

Size of square matrix, specified as an integer. `n` sets the output array size to `n`-by-`n`. For example, `false(3)` returns a 3-by-3 array of logical zeros.

- If n is `0`, then F is an empty matrix.
- If n is negative, then it is treated as `0`.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

sz — Size vector

row vector of integers

Size vector, specified as a row vector of integers. For example, `false([2 3])` returns a 2-by-3 array of logical zeros.

- If the size of any dimension is `0`, then F is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- If any trailing dimensions greater than `2` have a size of `1`, then the output, F, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz1,...,szN` — Size inputs

comma-separated list of integers

Size inputs, specified by a comma-separated list of integers. For example, `false(2,3)` returns a 2-by-3 array of logical zeros.

- If the size of any dimension is `0`, then F is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- If any trailing dimensions greater than `2` have a size of `1`, then the output, F, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`p` — Prototype

logical variable

Prototype, specified as a logical variable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`F` — Output of logical zeros

scalar | vector | matrix | N-D array

Output of logical zeros, returned as a scalar, vector, matrix, or N-D array.

Data Types: `logical`

More About

Tips

- `false(n)` is much faster and more memory efficient than `logical(zeros(n))`.
- "Class Support for Array-Creation Functions"

See Also

`logical` | `true`

Introduced before R2006a

fclose

Close one or all open files

Syntax

```
fclose(fileID)
fclose('all')
status = fclose(...)
```

Description

`fclose(fileID)` closes an open file. *`fileID`* is an integer file identifier obtained from `fopen`.

`fclose('all')` closes all open files.

`status` `= fclose(...)` returns a *`status`* of `0` when the close operation is successful. Otherwise, it returns `-1`.

See Also

`ferror` | `fopen` | `frewind` | `fread` | `fwrite` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf`

Introduced before R2006a

fclose (serial)

Disconnect serial port object from device

Syntax

```
fclose(obj)
```

Description

`fclose(obj)` disconnects `obj` from the device, where `obj` is a serial port object or an array of serial port objects.

Examples

This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, and then disconnects `s` from the device using `fclose`.

```
s = serial('COM1');
fopen(s)
fprintf(s, '*IDN?')
idn = fscanf(s);
fclose(s)
```

At this point, the device is available to be connected to a serial port object. If you no longer need `s`, you should remove from memory with the `delete` function, and remove it from the workspace with the `clear` command.

More About

Tips

If `obj` was successfully disconnected, then the `Status` property is configured to `closed` and the `RecordStatus` property is configured to `off`. You can reconnect `obj` to the device using the `fopen` function.

An error is returned if you issue `fclose` while data is being written asynchronously. In this case, you should abort the write operation with the `stopasync` function, or wait for the write operation to complete.

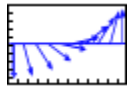
See Also

`clear` | `fopen` | `stopasync` | `delete` | `RecordStatus` | `Status`

Introduced before R2006a

feather

Plot velocity vectors



Syntax

```
feather(U,V)
feather(Z)
feather(...,LineSpec)
feather(axes_handle,...)
h = feather(...)
```

Description

A feather plot displays vectors emanating from equally spaced points along a horizontal axis. You express the vector components relative to the origin of the respective vector.

`feather(U,V)` displays the vectors specified by `U` and `V`, where `U` contains the x components as relative coordinates, and `V` contains the y components as relative coordinates.

`feather(Z)` displays the vectors specified by the complex numbers in `Z`. This is equivalent to `feather(real(Z),imag(Z))`.

`feather(...,LineSpec)` draws a feather plot using the line type, marker symbol, and color specified by `LineSpec`.

`feather(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = feather(...)` returns the handles to line objects in `h`.

Examples

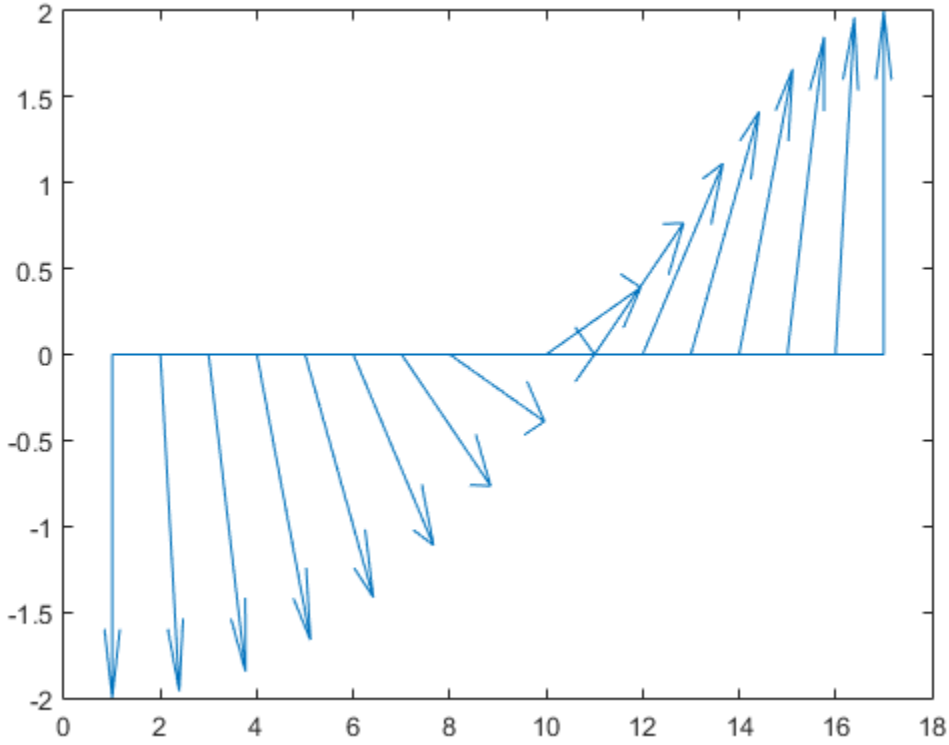
Create Feather Plot

Define `theta` as values between -2π and 2π. Define `r` as a vector the same size as `theta`.

```
theta = -pi/2:pi/16:pi/2;
r = 2*ones(size(theta));
```

Create a feather plot showing the direction of `theta`. Since `feather` uses Cartesian coordinates, convert `theta` and `r` to Cartesian coordinates using `pol2cart`.

```
[u,v] = pol2cart(theta,r);
feather(u,v)
```



See Also

`compass` | `rose` | `LineSpec`

Introduced before R2006a

featureEdges

Class: TriRep

(Will be removed) Sharp edges of surface triangulation

Note: `featureEdges(TriRep)` will be removed in a future release. Use `featureEdges(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
FE = featureEdges(TR, filterangle)
```

Description

`FE = featureEdges(TR, filterangle)` returns an edge matrix `FE`. This method is typically used to extract the sharp edges in the surface mesh for the purpose of display. Edges that are shared by only one triangle and edges that are shared by more than two triangles are considered to be feature edges by default.

Note: This query is only applicable to triangular surface meshes.

Input Arguments

`TR`	Triangulation representation.
`filterangle`	The threshold angle in radians. Must be in the range $(0, \pi)$. `featureEdges` will return adjacent triangles that have a dihedral angle that deviates from π by an angle greater than `filterangle`.

Output Arguments

FE	Edges of the triangulation. FE is of size m-by-2 where m is the number of computed feature edges in the mesh. The vertices of the edges index into the array of points representing the vertex coordinates, TR.X.

Examples

Create a surface triangulation:

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
dt = DelaunayTri(x,y);
tri = dt(:,:);
```

Elevate the 2-D mesh to create a surface:

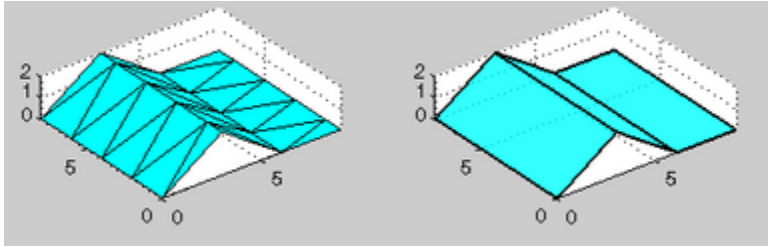
```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(tri,x,y,z, 'FaceColor', 'cyan');
axis equal;
% TRISURF display of surface mesh
% showing mesh edges
```

Compute the feature edges using a filter angle of pi/6:

```
tr = TriRep(tri, x,y,z);
fe = featureEdges(tr,pi/6)';
subplot(1,2,2);
trisurf(tr, 'FaceColor', 'cyan', 'EdgeColor','none', ...
     'FaceAlpha', 0.8); axis equal;
```

Add the feature edges to the plot:

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
% TRISURF display of surface mesh
% suppressing mesh edges
% and showing feature edges
```



See Also

`delaunayTriangulation` | `edges` | `triangulation`

feof

Test for end-of-file

Syntax

```
status = feof(fileID)
```

Description

`status = feof(fileID)` returns `1` if a previous operation set the end-of-file indicator for the specified file. Otherwise, `feof` returns `0`. *`fileID`* is an integer file identifier obtained from `fopen`.

Opening an empty file does *not* set the end-of-file indicator. Read operations, and the `fseek` and `frewind` functions, move the file position indicator.

Examples

Read `bench.dat`, which contains MATLAB benchmark data, one character at a time:

```
fid = fopen('bench.dat');

k = 0;
while ~feof(fid)
    curr = fscanf(fid,'%c',1);
    if ~isempty(curr)
       k = k+1;
       benchstr(k) = curr;
    end
end

fclose(fid);
```

More About

- "Testing for End of File (EOF)"

See Also

`fclose` | `ferror` | `fopen` | `frewind` | `fseek` | `ftell`

Introduced before R2006a

ferror

Information about file I/O errors

Syntax

```
message = ferror(fileID)
[message, errnum] = ferror(fileID)
[...] = ferror(fileID, 'clear')
```

Description

`message = ferror(fileID)` returns the error message for the most recent file I/O operation on the specified file. If the operation was successful, `message` is an empty string. `fileID` is an integer file identifier obtained from `fopen`, or an identifier reserved for standard input (`0`), standard output (`1`), or standard error (`2`).

`[message, errnum] = ferror(fileID)` returns the error number. If the most recent file I/O operation was successful, `errnum` is `0`. Negative error numbers correspond to MATLAB error messages. Positive error numbers correspond to C library error messages for your system.

`[...] = ferror(fileID, 'clear')` clears the error indicator for the specified file.

See Also

`fclose` | `fopen` | `fseek` | `ftell` | `feof` | `fscanf` | `fprintf` | `fread` | `fwrite`

Introduced before R2006a

feval

Evaluate function

Syntax

```
[y1, y2, ...] = feval(fhandle, x1, ..., xn)
[y1, y2, ...] = feval(fname, x1, ..., xn)
```

Description

`[y1, y2, ...] = feval(fhandle, x1, ..., xn)` evaluates the function handle, `fhandle`, using arguments `x1` through `xn`. If the function handle is bound to more than one built-in or `.m` function, (that is, it represents a set of overloaded functions), then the data type of the arguments `x1` through `xn` determines which function is dispatched to.

Note It is not necessary to use `feval` to call a function by means of a function handle. This is explained in "Calling a Function Using Its Handle" in the MATLAB Programming Fundamentals documentation.

`[y1, y2, ...] = feval(fname, x1, ..., xn)`. If `fname` is a quoted string containing the name of a function (usually defined within file having a .m file extension), then `feval(fname, x1, ..., xn)` evaluates that function at the given arguments. The `fname` parameter must be a simple function name; it cannot contain path information.

Examples

The following example passes a function handle, `fhandle`, in a call to `fminbnd`. The `fhandle` argument is a handle to the `humps` function.

```
fhandle = @humps;
x = fminbnd(fhandle, 0.3, 1);
```

The `fminbnd` function uses `feval` to evaluate the function handle that was passed in.

```
function [xf, fval, exitflag, output] = ...
    fminbnd(funfcn, ax, bx, options, varargin)
             .
             .
             .
fx = feval(funfcn, x, varargin{:});
```

More About

Tips

The following two statements are equivalent.

```
[V,D] = eig(A)
[V,D] = feval(@eig, A)
```

Nested functions are not accessible to `feval`. To call a nested function, you must either call it directly by name, or construct a function handle for it using the `@` operator.

Introduced before R2006a

fewerbins

Decrease number of histogram bins

Syntax

```
N = fewerbins(h)
```

Description

`N = fewerbins(h)` decreases the number of bins in histogram `h` by 10% (rounded down to the nearest integer) and returns the new number of bins.

Examples

Decrease Number of Histogram Bins

Plot a histogram of 1,000 random numbers and return a handle to the histogram object.

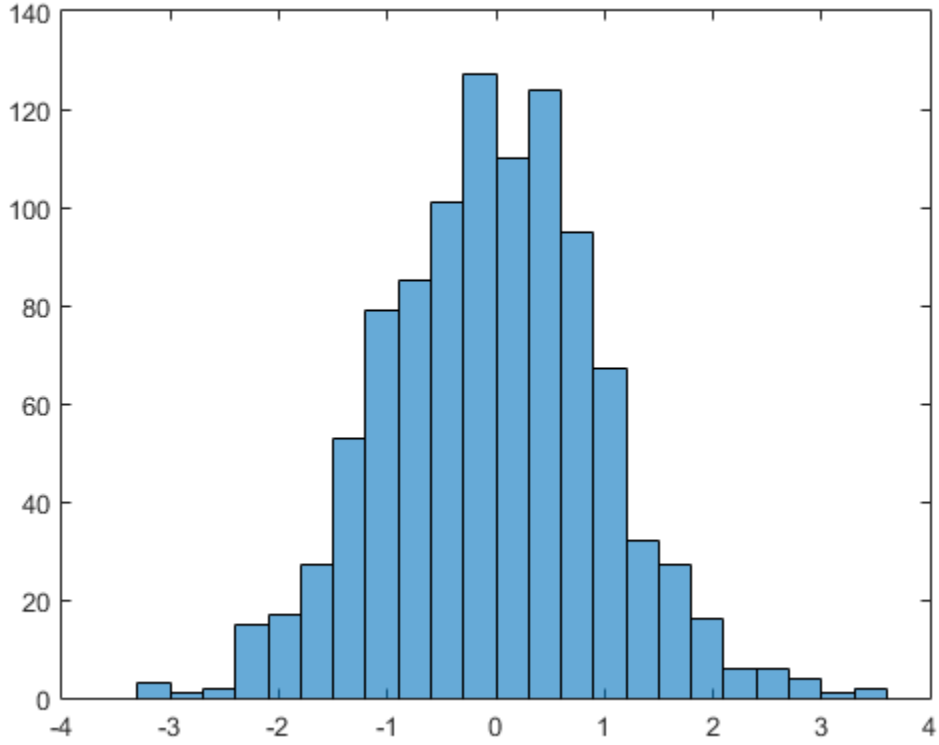
```
x = randn(1000,1);
h = histogram(x)
```

```
h =

  Histogram with properties:

            Data: [1000x1 double]
          Values: [1x23 double]
         NumBins: 23
        BinEdges: [1x24 double]
        BinWidth: 0.3000
       BinLimits: [-3.3000 3.6000]
    Normalization: 'count'
        FaceColor: 'auto'
        EdgeColor: [0 0 0]
```

```
Use GET to show all properties
```

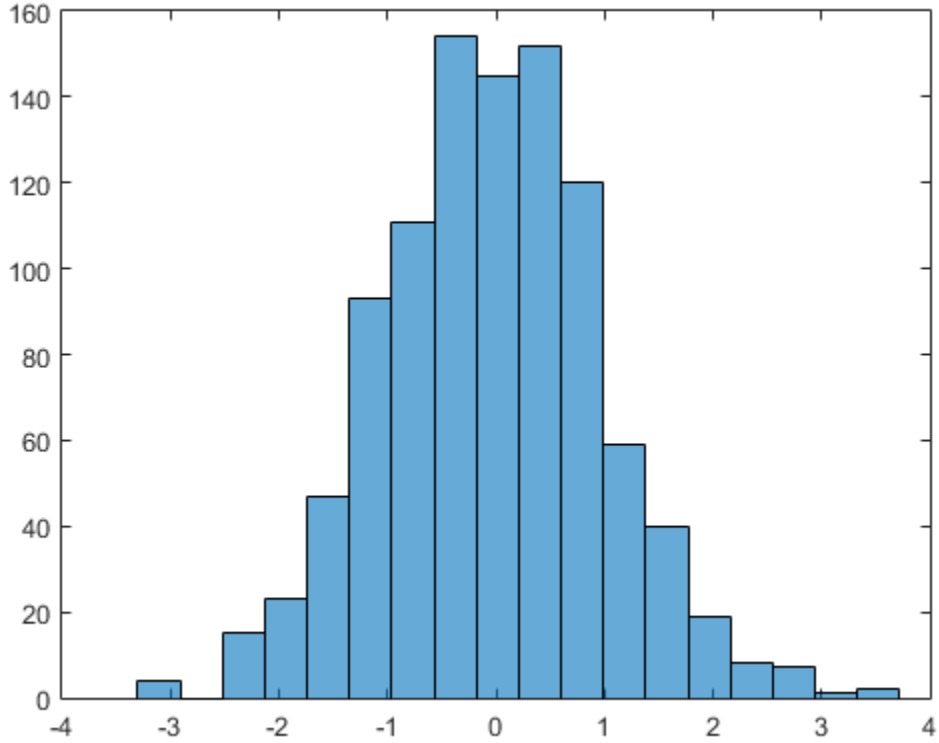


Use `fewerbins` to decrease the number of bins in the histogram.

```
fewerbins(h);
fewerbins(h)
```

```
ans =

    18
```



Input Arguments

h — Input histogram

histogram object

Input histogram, specified as a histogram object. For more information, see Using histogram Objects.

Output Arguments

`N` — Number of bins

scalar

Number of bins, returned as a scalar. `N` is the new number of bins in the histogram after decrease.

More About

- Using histogram Objects
- Histogram Properties

See Also

`histcounts` | `histogram` | `morebins`

Introduced in R2014b

Feval (COM)

Evaluate MATLAB function in Automation server

Syntax

IDL Method Signature

```
HRESULT Feval([in] BSTR functionname, [in] long nargout,
[out] VARIANT* result, [in, optional] VARIANT arg1, arg2, ...)
```

Microsoft Visual Basic Client

```
Feval(String functionname, long numout,
arg1, arg2, ...) As Object
```

MATLAB Client

```
result = Feval(h,'functionname',numout,arg1,arg2,...)
```

Description

`result = Feval(h,'functionname',numout,arg1,arg2,...)` executes the MATLAB function specified by the string `functionname` in the Automation server attached to handle `h`. The function name is case-sensitive.

COM functions are available on Microsoft Windows systems only.

Indicate the number of outputs to be returned by the function in a `1`-by-`1` `double` array, `numout`. The server returns output from the function in the cell array, `result`.

You can specify as many as 32 input arguments to be passed to the function. These arguments follow `numout` in the `Feval` argument list. The following table shows ways to pass an argument.

Passing Mechanism	Description
Pass the value itself	To pass any numeric or string value, specify the value in the `Feval` argument list: `a = Feval(h,'sin',1,-pi:0.01:pi);`

Pass a client variable	To pass an argument assigned to a variable in the client, specify the variable name alone:
	
	`x = -pi:0.01:pi;`
	`a = Feval(h,'sin',1,x);`

Reference a server variable	To reference a variable defined in the server, specify the variable name followed by an equals (=) sign:
	
	`PutWorkspaceData(h,'x','base',-pi:0.01:pi);`
	`a = Feval(h,'sin',1,'x=');`
	
	MATLAB does not reassign the server variable.

Visual Basic .NET Examples

Passing Arguments

This example shows how to pass arguments using `Feval` to execute MATLAB commands on a MATLAB Automation server from a Visual Basic® .NET client.

- Pass two strings to the MATLAB function `strcat` on the server:

```
Dim Matlab As Object
Dim out As Object
out = Nothing
Matlab = CreateObject("matlab.application")
Matlab.Feval("strcat",1,out,"hello"," world")
```

- Define `clistr` locally and pass this variable:

```
Dim clistr As String
clistr = " world"
Matlab.Feval("strcat",1,out,"hello",clistr)
```

- Pass the name of a variable defined on the server:

```
Matlab.PutCharArray("srvstr","base"," world")
Matlab.Feval("strcat",1,out,"hello","srvstr=")
```

Defining Feval Return Values

`Feval` returns data from the evaluated function in a cell array. The cell array has one row for every return value. You control the number of return values using the `numout` argument.

```
Dim Matlab As Object
Dim out As Object
Matlab = CreateObject("matlab.application")
Matlab.Feval("fileparts",3,out,"d:\work\ConsoleApp.cpp")
```

Creating Server Variables

Use variables defined in the client, `rows` and `cols`, to modify a server variable, `A`.

- Create a matrix, `A`, in the server.

  ```
  Dim Matlab As Object
  Dim server_version As String
  Matlab = CreateObject("matlab.application")
  MatLab.PutWorkspaceData("A","base",rand(6))
  ```

- Reshape `A`.

  ```
  rows = 6
  cols = 3
  Matlab.Feval("reshape",0,"A=",rows,cols)
  ```

  MATLAB interprets `A` in the expression `'A='` as a server variable name.

- The `reshape` function does not modify variable `A`.

  ```
  Matlab.GetWorkspaceData("A","base",B)
  ```

  `A` is unchanged.

- To get the result of the `reshape` function, use the `numout` argument to assign the value to `C`.

  ```
  Matlab.Feval("reshape",1,"A=",rows,cols,C)
  ```

More About

Tips

To display the output from `Feval` in the client window, assign a return value.

fft

Fast Fourier transform

Syntax

```
Y = fft(x)
Y = fft(X,n)
Y = fft(X,[],dim)
Y = fft(X,n,dim)
```

Definitions

The functions `Y = fft(x)` and `y = ifft(X)` implement the transform and inverse transform pair given for vectors of length N by:

$$X(k) = \sum_{j=1}^{N} x(j)\omega_N^{(j-1)(k-1)}$$

$$x(j) = (1/N)\sum_{k=1}^{N} X(k)\omega_N{}^{-(j-1)(k-1)}$$

where

$$\omega_N = e^{(-2\pi i)/N}$$

is an Nth root of unity.

Description

`Y = fft(x)` returns the discrete Fourier transform (DFT) of vector `x`, computed with a fast Fourier transform (FFT) algorithm.

If the input `X` is a matrix, `Y = fft(X)` returns the Fourier transform of each column of the matrix.

If the input `X` is a multidimensional array, `fft` operates on the first nonsingleton dimension.

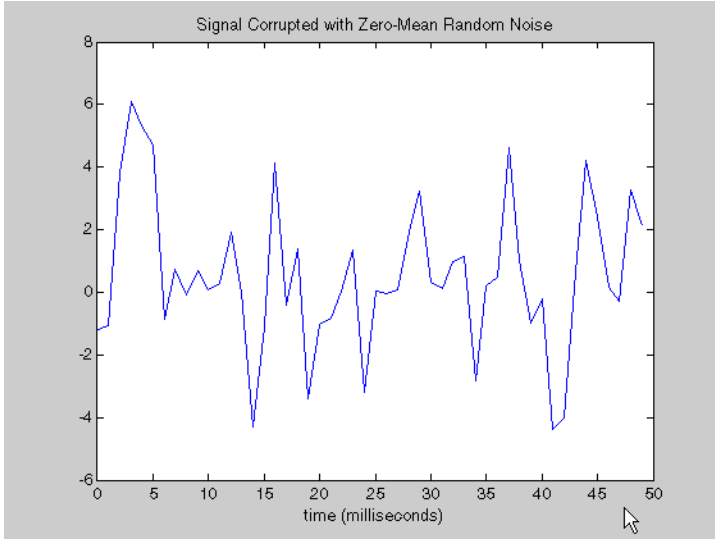
`Y = fft(X,n)` returns the `n`-point DFT. `fft(X)` is equivalent to `fft(X, n)` where `n` is the size of `X` in the first nonsingleton dimension. If the length of `X` is less than `n`, `X` is padded with trailing zeros to length `n`. If the length of `X` is greater than `n`, the sequence `X` is truncated. When `X` is a matrix, the length of the columns are adjusted in the same manner.

`Y = fft(X,[],dim)` and `Y = fft(X,n,dim)` applies the FFT operation across the dimension `dim`.

Examples

A common use of Fourier transforms is to find the frequency components of a signal buried in a noisy time domain signal. Consider data sampled at 1000 Hz. Form a signal containing a 50 Hz sinusoid of amplitude 0.7 and 120 Hz sinusoid of amplitude 1 and corrupt it with some zero-mean random noise:

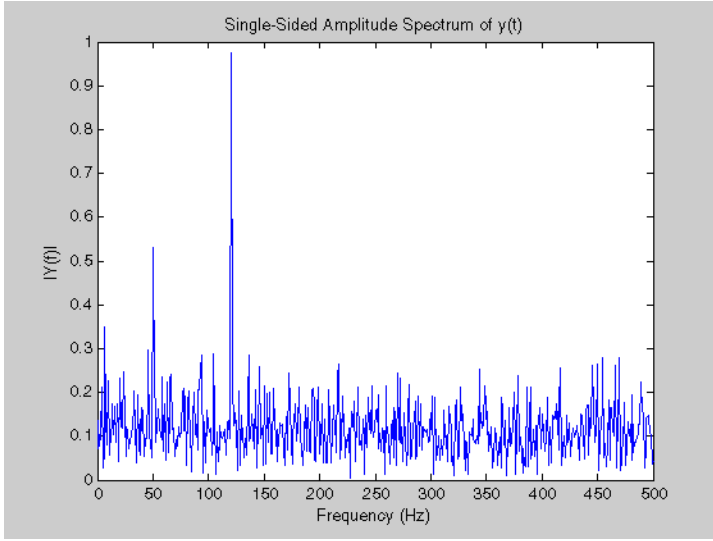
```
Fs = 1000;                    % Sampling frequency
T = 1/Fs;                     % Sample time
L = 1000;                     % Length of signal
t = (0:L-1)*T;                % Time vector
% Sum of a 50 Hz sinusoid and a 120 Hz sinusoid
x = 0.7*sin(2*pi*50*t) + sin(2*pi*120*t);
y = x + 2*randn(size(t));     % Sinusoids plus noise
plot(Fs*t(1:50),y(1:50))
title('Signal Corrupted with Zero-Mean Random Noise')
xlabel('time (milliseconds)')
```



It is difficult to identify the frequency components by looking at the original signal. Converting to the frequency domain, the discrete Fourier transform of the noisy signal `y` is found by taking the fast Fourier transform (FFT):

```
NFFT = 2^nextpow2(L); % Next power of 2 from length of y
Y = fft(y,NFFT)/L;
f = Fs/2*linspace(0,1,NFFT/2+1);

% Plot single-sided amplitude spectrum.
plot(f,2*abs(Y(1:NFFT/2+1)))
title('Single-Sided Amplitude Spectrum of y(t)')
xlabel('Frequency (Hz)')
ylabel('|Y(f)|')
```



The main reason the amplitudes are not exactly at 0.7 and 1 is because of the noise. Several executions of this code (including recomputation of `y`) will produce different approximations to 0.7 and 1. The other reason is that you have a finite length signal. Increasing `L` from 1000 to 10000 in the example above will produce much better approximations on average.

Data Type Support

`fft` supports inputs of data types `double` and `single`. If you call `fft` with the syntax `y = fft(X, ...)`, the output `y` has the same data type as the input `X`.

More About

Algorithms

The FFT functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, `ifftn`) are based on a library called FFTW [3],[4]. To compute an N-point DFT when N is composite (that is, when $N = N_1N_2$), the FFTW library decomposes the problem using the Cooley-Tukey algorithm [1], which first computes N_1 transforms of size N_2, and then computes N_2 transforms of size N_1. The

decomposition is applied recursively to both the N_1- and N_2-point DFTs until the problem can be solved using one of several machine-generated fixed-size "codelets." The codelets in turn use several algorithms in combination, including a variation of Cooley-Tukey [5], a prime factor algorithm [6], and a split-radix algorithm [2]. The particular factorization of N is chosen heuristically.

When N is a prime number, the FFTW library first decomposes an N-point problem into three $(N-1)$-point problems using Rader's algorithm [7]. It then uses the Cooley-Tukey decomposition described above to compute the $(N-1)$-point DFTs.

For most N, real-input DFTs require roughly half the computation time of complex-input DFTs. However, when N has large prime factors, there is little or no speed difference.

The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fft` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

Introduced before R2006a

fft2

2-D fast Fourier transform

Syntax

```
Y = fft2(X)
Y = fft2(X,m,n)
```

Description

`Y = fft2(X)` returns the two-dimensional discrete Fourier transform (DFT) of `X`. The DFT is computed with a fast Fourier transform (FFT) algorithm. The result, `Y`, is the same size as `X`.

If the dimensionality of `X` is greater than `2`, the `fft2` function returns the 2-D DFT for each higher dimensional slice of `X`. For example, if `size(X) = [100 100 3]`, then `fft2` computes the DFT of `X(:,:,1)`, `X(:,:,2)` and `X(:,:,3)`.

`Y = fft2(X,m,n)` truncates `X`, or pads `X` with zeros to create an `m`-by-`n` array before doing the transform. The result is `m`-by-`n`.

Data Type Support

`fft2` supports inputs of data types `double` and `single`. If you call `fft2` with the syntax `y = fft2(X, ...)`, the output `y` has the same data type as the input `X`.

More About

Algorithms

`fft2(X)` can be simply computed as

```
fft(fft(X).').'
```

This computes the one-dimensional DFT of each column `X`, then of each row of the result. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fft2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

`fft` | `fftn` | `fftw` | `fftshift` | `ifft2`

Introduced before R2006a

fftn

N-D fast Fourier transform

Syntax

```
Y = fftn(X)
Y = fftn(X,siz)
```

Description

`Y = fftn(X)` returns the discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`Y = fftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the transform. The size of the result `Y` is `siz`.

Data Type Support

`fftn` supports inputs of data types `double` and `single`. If you call `fftn` with the syntax `y = fftn(X, ...)`, the output `y` has the same data type as the input `X`.

More About

Algorithms

`fftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
    Y = fft(Y,[],p);
end
```

This computes in-place the one-dimensional fast Fourier transform along each dimension of `X`. The execution time for `fft` depends on the length of the transform. It is fastest

for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fftn` using the utility function `fftw`, which controls the optimization of the algorithm used to compute an FFT of a particular size and dimension.

See Also

`fft` | `fft2` | `fftw` | `ifftn`

Introduced before R2006a

fftshift

Shift zero-frequency component to center of spectrum

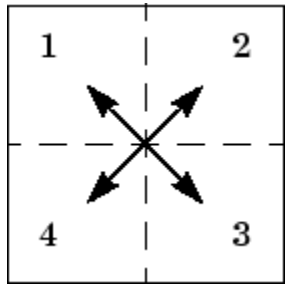
Syntax

```
Y = fftshift(X)
Y = fftshift(X,dim)
```

Description

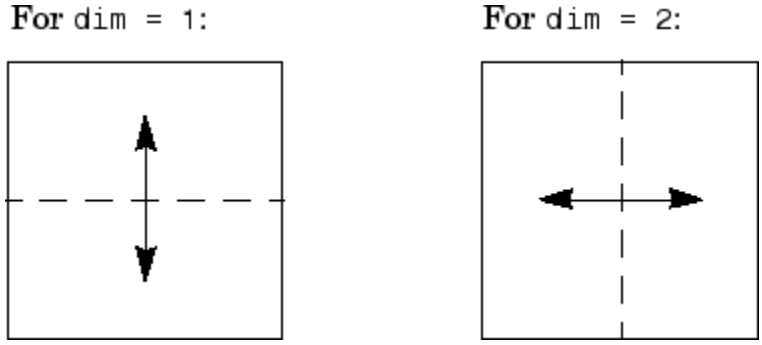
`Y = fftshift(X)` rearranges the outputs of `fft`, `fft2`, and `fftn` by moving the zero-frequency component to the center of the array. It is useful for visualizing a Fourier transform with the zero-frequency component in the middle of the spectrum.

For vectors, `fftshift(X)` swaps the left and right halves of `X`. For matrices, `fftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth.



For higher-dimensional arrays, `fftshift(X)` swaps “half-spaces” of `X` along each dimension.

`Y = fftshift(X,dim)` applies the `fftshift` operation along the dimension `dim`.



Note: `ifftshift` will undo the results of `fftshift`. If the matrix `X` contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original `X`. Simply performing `fftshift(X)` twice will not produce `X`.

Examples

For any matrix `X`

```
Y = fft2(X)
```

has `Y(1,1) = sum(sum(X))`; the zero-frequency component of the signal is in the upper-left corner of the two-dimensional FFT. For

```
Z = fftshift(Y)
```

this zero-frequency component is near the center of the matrix.

The difference between `fftshift` and `ifftshift` is important for input sequences of odd-length.

```
N = 5;
X = 0:N-1;
Y = fftshift(fftshift(X));
Z = ifftshift(fftshift(X));
```

Notice that `Z` is a correct replica of `X`, but `Y` is not.

```
isequal(X,Y),isequal(X,Z)
```

```
ans =

     0

ans =

     1
```

circshift | fft | fft2 | fftn | ifftshift

Introduced before R2006a

fftw

Interface to FFTW library run-time algorithm tuning control

Syntax

```
fftw('planner', method)
method = fftw('planner')
str = fftw('dwisdom')
str = fftw('swisdom')
fftw('dwisdom', str)
fftw('swisdom', str)
```

Description

`fftw` enables you to optimize the speed of the MATLAB FFT functions `fft`, `ifft`, `fft2`, `ifft2`, `fftn`, and `ifftn`. You can use `fftw` to set options for a tuning algorithm that experimentally determines the fastest algorithm for computing an FFT of a particular size and dimension at run time. MATLAB software records the optimal algorithm in an internal data base and uses it to compute FFTs of the same size throughout the current session. The tuning algorithm is part of the FFTW library that MATLAB software uses to compute FFTs.

`fftw('planner', method)` sets the method by which the tuning algorithm searches for a good FFT algorithm when the dimension of the FFT is not a power of 2. You can specify `method` to be one of the following. The default method is `estimate`:

- `'estimate'`
- `'measure'`
- `'patient'`
- `'exhaustive'`
- `'hybrid'`

When you call `fftw('planner', method)`, the next time you call one of the FFT functions, such as `fft`, the tuning algorithm uses the specified method to optimize the

FFT computation. Because the tuning involves trying different algorithms, the first time you call an FFT function, it might run more slowly than if you did not call `fftw`. However, subsequent calls to any of the FFT functions, for a problem of the same size, often run more quickly than they would without using `fftw`.

Note The FFT functions only use the optimal FFT algorithm during the current MATLAB session. "Reusing Optimal FFT Algorithms" on page 1-2537 explains how to reuse the optimal algorithm in a future MATLAB session.

If you set the method to `'estimate'`, the FFTW library does not use run-time tuning to select the algorithms. The resulting algorithms might not be optimal.

If you set the method to `'measure'`, the FFTW library experiments with many different algorithms to compute an FFT of a given size and chooses the fastest. Setting the method to `'patient'` or `'exhaustive'` has a similar result, but the library experiments with even more algorithms so that the tuning takes longer the first time you call an FFT function. However, subsequent calls to FFT functions are faster than with `'measure'`.

If you set `'planner'` to `'hybrid'`, MATLAB software

- Sets method to `'measure'` method for FFT dimensions 8192 or smaller.
- Sets method to `'estimate'` for FFT dimensions greater than 8192.

`method = fftw('planner')` returns the current planner method.

`str = fftw('dwisdom')` returns the information in the FFTW library's internal double-precision database as a string. The string can be saved and then later reused in a subsequent MATLAB session using the next syntax.

`str = fftw('swisdom')` returns the information in the FFTW library's internal single-precision database as a string.

`fftw('dwisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal double-precision wisdom database. `fftw('dwisdom','')` or `fftw('dwisdom',[])` clears the internal wisdom database.

`fftw('swisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal single-precision wisdom database. `fftw('swisdom','')` or `fftw('swisdom',[])` clears the internal wisdom database.

Note on large powers of 2 For FFT dimensions that are powers of 2, between 2^{14} and 2^{22}, MATLAB software uses special preloaded information in its internal database to optimize the FFT computation. No tuning is performed when the dimension of the FTT is a power of 2, unless you clear the database using the command `fftw('wisdom', [])`.

For more information about the FFTW library, see http://www.fftw.org.

Examples

Comparison of Speed for Different Planner Methods

The following example illustrates the run times for different settings of `planner`. The example first creates some data and applies `fft` to it using the default method, `estimate`.

```
t=0:.001:5;
x = sin(2*pi*50*t)+sin(2*pi*120*t);
y = x + 2*randn(size(t));

tic; Y = fft(y,1458); toc
Elapsed time is 0.000521 seconds.
```

If you execute the commands

```
tic; Y = fft(y,1458); toc
Elapsed time is 0.000151 seconds.
```

a second time, MATLAB software reports the elapsed time as essentially 0. To measure the elapsed time more accurately, you can execute the command `Y = fft(y,1458)` 1000 times in a loop.

```
tic; for k=1:1000
Y = fft(y,1458);
end; toc
Elapsed time is 0.056532 seconds.
```

This tells you that it takes on order of 1/10000 of a second to execute `fft(y, 1458)` a single time.

For comparison, set `planner` to `patient`. Since this `planner` explores possible algorithms more thoroughly than `hybrid`, the first time you run `fft`, it takes longer to compute the results.

```
fftw('planner','patient')
tic;Y = fft(y,1458);toc
Elapsed time is 0.100637 seconds.
```

However, the next time you call `fft`, it runs at approximately the same speed as before you ran the method `patient`.

```
tic;for k=1:1000
Y=fft(y,1458);
end;toc
Elapsed time is 0.057209 seconds.
```

Reusing Optimal FFT Algorithms

In order to use the optimized FFT algorithm in a future MATLAB session, first save the "wisdom" using the command

```
str = fftw('wisdom')
```

You can save `str` for a future session using the command

```
save str
```

The next time you open a MATLAB session, load `str` using the command

```
load str
```

and then reload the "wisdom" into the FFTW database using the command

```
fftw('wisdom', str)
```

Introduced before R2006a

fgetl

Read line from file, removing newline characters

Syntax

```
tline = fgetl(fileID)
```

Description

`tline = fgetl(fileID)` returns the next line of the specified file, removing the newline characters. `fileID` is an integer file identifier obtained from `fopen`. `tline` is a text string unless the line contains only the end-of-file marker. In this case, `tline` is the numeric value `-1`.

`fgetl` reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use `fopen`.

Examples

Read and display the file `fgetl.m` one line at a time:

```
fid = fopen('fgetl.m');

tline = fgetl(fid);
while ischar(tline)
    disp(tline)
    tline = fgetl(fid);
end

fclose(fid);
```

Compare these results to the `fgets` example, which replaces the calls to `fgetl` with `fgets`.

More About

- "Testing for EOF with fgetl and fgets"

See Also

`fclose` | `feof` | `ferror` | `fgets` | `fopen` | `fprintf` | `fread` | `fscanf` | `fwrite`

Introduced before R2006a

fgetl (serial)

Read line of ASCII text from device and discard terminator

Syntax

```
tline = fgetl(obj)
[tline,count] = fgetl(obj)
[tline,count,msg] = fgetl(obj)
```

Description

`tline = fgetl(obj)` reads one line of ASCII text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data does not include the terminator with the text line. To include the terminator, use `fgets`.

`[tline,count] = fgetl(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgetl(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

Examples

On a Windows platform, create the serial port object `s`, connect `s` to a Tektronix® TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable
```

```
ans =
    17
```

Use `fgetl` to read the data returned from the previous write operation, and discard the terminator.

```
settings = fgetl(s)
```

```
settings =
9600;0;0;NONE;LF
```

```
length(settings)
```

```
ans =
    16
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

More About

Tips

Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgetl` is issued.

Rules for Completing a Read Operation with fgetl

A read operation with `fgetl` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.

- The time specified by the `Timeout` property passes.
- The input buffer is filled.

Introduced before R2006a

fgets

Read line from file, keeping newline characters

Syntax

```
tline = fgets(fileID)
tline = fgets(fileID, nchar)
```

Description

`tline = fgets(fileID)` reads the next line of the specified file, including the newline characters. `fileID` is an integer file identifier obtained from `fopen`. `tline` is a text string unless the line contains only the end-of-file marker. In this case, `tline` is the numeric value `-1`. `fgets` reads characters using the encoding scheme associated with the file. To specify the encoding scheme, use `fopen`.

`tline = fgets(fileID, nchar)` returns at most `nchar` characters of the next line. `tline` does not include any characters after the newline characters or the end-of-file marker.

Examples

Read and display the file `fgets.m`. Because `fgets` keeps newline characters and `disp` adds a newline character, this code displays the file with double-spacing:

```
fid = fopen('fgets.m');

tline = fgets(fid);
while ischar(tline)
    disp(tline)
    tline = fgets(fid);
end

fclose(fid);
```

Compare these results to the `fgetl` example, which replaces the calls to `fgets` with `fgetl`.

fgets (serial)

Read line of text from device and include terminator

Syntax

```
tline = fgets(obj)
[tline,count] = fgets(obj)
[tline,count,msg] = fgets(obj)
```

Description

`tline = fgets(obj)` reads one line of text from the device connected to the serial port object, `obj`, and returns the data to `tline`. This returned data includes the terminator with the text line. To exclude the terminator, use `fgetl`.

`[tline,count] = fgets(obj)` returns the number of values read to `count`, including the terminator.

`[tline,count,msg] = fgets(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

Examples

Create the serial port object `s`, connect `s` to a Tektronix TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable
```

```
ans =
```

```
    17
```

Use `fgets` to read the data returned from the previous write operation, and include the terminator.

```
settings = fgets(s)
```

```
settings =
9600;0;0;NONE;LF
```

```
length(settings)
```

```
ans =
    17
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

fieldnames

Field names of structure, or public fields of object

Syntax

```
names = fieldnames(s)
names = fieldnames(obj)
names = fieldnames(obj,'-full')
```

Description

`names = fieldnames(s)` returns a cell array of strings containing the names of the fields in structure `s`.

`names = fieldnames(obj)` returns a cell array of strings containing the names of the public properties of `obj`. MATLAB objects can overload `fieldnames` and define their own behavior.

`names = fieldnames(obj,'-full')` returns a cell array of strings containing the name, type, attributes, and inheritance of the properties of `obj`. Only supported for COM or Java objects.

Examples

Structure Fields

Create a structure array and view its fields.

```
s(1,1).name = 'alice';
s(1,1).ID = 0;
s(2,1).name = 'gertrude';
s(2,1).ID = 1;

names = fieldnames(s)
```

```
names =

    'name'
    'ID'
```

Java Object Properties

Create a Java® object and view its public properties.

```
obj = java.lang.Integer(0);
names = fieldnames(obj)
```

```
names =

    'MIN_VALUE'
    'MAX_VALUE'
    'TYPE'
    'SIZE'
```

Introduced before R2006a

figure

Create figure window

Syntax

```
figure
figure('PropertyName',propertyvalue,...)
figure(h)
h = figure(...)
```

Properties

For a list of properties, see Figure Properties.

Description

`figure` creates a new figure window using default property values. This new figure window becomes the current figure, and it displays on top of all other figures on the screen. The title of the figure is an integer value that is not already used by an existing figure. MATLAB saves this integer value in the figure's `Number` property.

`figure('PropertyName',propertyvalue,...)` creates a new figure window using specific property values. For a list of available properties, see Figure Properties. MATLAB uses default values for any properties that you do not explicitly define as arguments.

`figure(h)` does one of the following:

- If `h` is the handle or the `Number` property value of an existing figure, then `figure(h)` makes that existing figure the current figure, makes it visible, and moves it on top of all other figures on the screen. The current figure is the target for graphics output.
- If `h` is not the handle and is not the `Number` property value of an existing figure, but is an integer, then `figure(h)` creates a figure object and assigns its `Number` property the value `h`.

- If `h` is not the handle to a figure and is not a positive integer, then MATLAB returns an error.

`h = figure(...)` returns the handle to the figure object.

Examples

Specifying Figure Size and Screen Location

To create a figure window that is one quarter the size of your screen and is positioned in the upper left corner, use the root object's `ScreenSize` property to determine the size. The `ScreenSize` property value is a four-element vector: `[left bottom width height]`.

```
scrsz = get(groot,'ScreenSize');
figure('Position',[1 scrsz(4)/2 scrsz(3)/2 scrsz(4)/2])
```

To position the full figure window including the menu bar, title bar, tool bars, and outer edges, use the `OuterPosition` property in the same manner.

Specifying the Figure Window Title

You can add your own title to a figure by setting the `Name` property and turning off the `NumberTitle` property:

```
figure('Name','Simulation Plot Window','NumberTitle','off')
```

Setting Default Properties

You can set default figure properties only on the `groot` level.

```
set(groot,'DefaultFigure'Property',PropertyValue...)
```

where *`Property`* is the name of the figure property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access figure properties.

More About

Tips

Use dot notation to query or modify a particular figure's property. For example, `f.Units = 'inches'` sets the Units property of figure `f` to inches.

Figures can be docked in the desktop. The `DockControls` property determines whether you can dock the figure.

Making a Figure Current

The current figure is the target for graphics output. There are two ways to make a figure `h` the current figure.

- Make the figure `h` current, visible, and displayed on top of other figures:

  ```
  figure(h);
  ```

- Make the figure `h` current, but do not change its visibility or stacking with respect to other figures:

  ```
  set(groot,'CurrentFigure',h);
  ```

Introduced before R2006a

Figure Properties

Control figure window appearance and behavior

Figures are windows that contain graphics or user interface components. Figure properties control the appearance and behavior of a particular instance of a figure. To modify aspects of a figure, change property values.

Starting in R2014b, you can use dot notation to query and set properties.

```
fig = figure;
u = fig.Units;
fig.Units = 'inches';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Figure Appearance

`Color` — Figure window background color

RGB triplet | short name | long name | `'none'`

The figure window background color, specified as an RGB triplet, a predefined color name string, or `'none'`. If you specify `'none'`, the figure background color appears black on screen, but if you print it, the background prints as though the figure window is transparent.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Data Types: double | char

DockControls — Interactive figure docking

'on' (default) | 'off'

Interactive figure docking, specified as one of the following:

- 'on' — Figure can be docked in the MATLAB desktop. The **Desktop** > **Dock Figure** menu item and the Dock Figure button  in the menu bar are enabled.
- 'off' — MATLAB disables the **Desktop** > **Dock Figure** menu item and does not display the figure dock button.

  You cannot set the DockControls property to 'off' if the WindowStyle is set to 'docked'.

MenuBar — Figure menu bar display

'figure' (default) | 'none'

Figure menu bar display, specified as 'figure' or 'none'. The MenuBar property enables you to display or hide the default menus at the top of a figure window. Specify 'figure' to display the menu bar. Specify 'none' to hide it.

This property affects only default menus, and does not affect menus defined with the uimenu command.

Menu bars do not appear in figures whose WindowStyle property is set to 'Modal'. If a figure containing uimenu children is changed to 'Modal', the uimenu children still exist in the Children property of the figure. However, the uimenus do not display while WindowStyle is set to 'Modal'.

Note: If you do not want to display the default menus in the figure, then set this property to 'none' when you create the figure.

`Name` — Figure window title

`''` (default) | string

Figure window title, specified as a string. The Name property specifies the title that the figure window displays. By default, the figure title displays as `Figure 1`, `Figure 2`, and so on. When you set this property to a string, the figure title becomes `Figure:`*`n string`*. If you want only the Name value to display, set `IntegerHandle` or `NumberTitle` to `'off'`.

Example: `'Results'`

`NumberTitle` — Figure window title number

`'on'` (default) | `'off'`

Figure window title number, specified as `'on'` or `'off'`. The NumberTitle property determines whether MATLAB includes the string `Figure` *n* in the title bar, where *n* is the figure `Number` property value.

If you set `IntegerHandle` to `'off'`, then a number does not display in the figure window title, regardless of the NumberTitle property setting.

`ToolBar` — Figure toolbar display

`'auto'` (default) | `'figure'` | `'none'`

Figure toolbar display, specified as one of the following:

- `'auto'` — Uses the same value as the `MenuBar` property.
- `'figure'` — Toolbar displays.
- `'none'` — Toolbar does not display.

This property affects only the default toolbar. It does not affect other toolbars such as, the Camera Toolbar or Plot Edit Toolbar. Selecting **Figure Toolbar** from the figure **View** menu sets this property to `'figure'`.

Toolbars do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing a toolbar is changed to `'Modal'`, the tool bar children still exist in the `Children` property of the figure. However, the toolbar does not display while WindowStyle is set to `'Modal'`.

Note: If you want to hide the default tool bar, then set this property to `'none'` when you create the figure.

`Visible` — Figure visibility

`'on'` (default) | `'off'`

Figure visibility, specified as `'on'` or `'off'`. The Visible property determines whether the figure displays on the screen. If the Visible property of a figure is set to `'off'`, the entire figure is invisible, but you can still specify and access its properties.

Changing the size of an invisible figure triggers the SizeChangedFcn callback when the figure becomes visible.

Note Changing the Visible property of a figure does *not* change the Visible property of its child components even though hiding the figure prevents its children from displaying.

`Clipping` — Clipping of child components to figure

`'on'` (default) | `'off'`

This property has no effect on figures.

Axes and Plot Appearance

`GraphicsSmoothing` — Axes graphics smoothing

`'on'` (default) | `'off'`

Axes graphics smoothing, specified as `'on'` or `'off'`. Smoothing reduces the appearance of jagged lines in an axes graphic. MATLAB applies a smoothing technique to an axes graphic (and the axes rulers) if `GraphicsSmoothing` is set to `'on'`, and either of these conditions is true:

- The `Renderer` property is set to `'painters'`.
- The Renderer property is set to `'opengl'` and your hardware card supports OpenGL.

If your axes graphic contains mostly vertical or horizontal lines, consider setting the GraphicsSmoothing property to `'on'` and the line or lines `AlignVertexCenters` property to `'on'`. The smoothing technique sacrifices some sharpness for smoothness, which might be particularly noticeable in such graphics.

Note: Graphics smoothing has no affect on text. MATLAB smooths text regardless of the value of the GraphicsSmoothing property.

`Renderer` — Rendering method used for screen display and printing

`'opengl'` (default) | `'painters'`

Rendering method used for screen display and printing, specified as one of these values:

- `'opengl'` — OpenGL renderer. This option enables MATLAB to access graphics hardware if it is available on your system. The OpenGL renderer displays objects sorted in front to back order, as seen on the monitor. Lines always draw in front of faces when at the same location on the plane of the monitor.
- `'painters'` — Painters renderer. This option works well for axes in a 2-D view. In 2-D, the Painters renderer sorts graphics objects by child order (order specified). In 3-D, the Painters renderer sorts objects in front to back order. However, it might not correctly draw intersecting polygons in 3-D.

Note: The `'zbuffer'` option has been removed. Use `'opengl'` or `'painters'` instead.

OpenGL Hardware and Software Implementations

OpenGL is available on all computers that run MATLAB since a software version of OpenGL is built-into MATLAB. However, if you have graphics hardware that supports a hardware-accelerated version of OpenGL, then MATLAB automatically uses the hardware-accelerated version to increase performance.

In some cases, MATLAB automatically uses software OpenGL even if a hardware version is available. For example, MATLAB uses the software version if it detects graphics hardware with known driver issues or detects that you are using a virtual machine or remote desktop on Windows.

MATLAB issues a warning if it cannot find a usable OpenGL library.

Software OpenGL Selection

To switch from hardware to software OpenGL, do the following:

- On Linux systems, start MATLAB with the command `matlab -softwareopengl`.
- On Windows systems, execute the command `opengl software` in MATLAB or start MATLAB with the command `matlab -softwareopengl`.

- On Macintosh systems, software OpenGL is not supported.

The following software versions are available:

- On Linux systems, MATLAB uses the software implementation of OpenGL that is included in the MATLAB distribution.
- On Windows, OpenGL is available as part of the operating system. If you experience problems with OpenGL, contact your graphics driver vendor to obtain the latest qualified version of OpenGL.
- On Macintosh systems, software OpenGL is not available.

Determine OpenGL Library Version

To determine the version and vendor of the OpenGL library that MATLAB is using on your system, type the following command at the MATLAB prompt:

```
opengl info
```

The returned information contains a line that indicates if MATLAB is using software OpenGL (`Software = true`) or hardware-accelerated OpenGL (`Software = false`).

This command also returns a string of extensions to the OpenGL specification that are available with the particular library MATLAB is using. Include this information if you report a bug.

Be aware that issuing the `opengl info` command causes MATLAB to initialize OpenGL.

XServer Connection Lost

When using Linux, if there is a break in the connection to the XServer, MATLAB can crash with a segmentation violation . If this happens, ensure that the system has the latest XServer installed.

On a Linux system, you also can try upgrading the OpenGL driver or starting MATLAB with software OpenGL using this command:

```
matlab -softwareopengl
```

`RendererMode` — Renderer selection

`'auto'` (default) | `'manual'`

Renderer selection, specified as:

- `'auto'` — MATLAB selects the rendering method for printing and screen display based on the size and complexity of the graphics objects in the figure.
- `'manual'` — MATLAB uses the renderer specified with the `Renderer` property.

MATLAB sets the `RendererMode` property to `'manual'` if you explicitly set the Renderer property to `'painters'` or `'opengl'`.

Color and Transparency Mapping

`Alphamap` — Transparency map for axes content of figure

array of 64 values from 0 to 1 (default) | array of finite alpha values from 0 to 1

Transparency map for axes content of figure, specified as an array of finite alpha values that progress linearly from 0 to 1. The size of the array can be m-by-1 or 1-by-m. MATLAB accesses alpha values by their row number. For example, an index of 1 specifies the first alpha value, an index of 2 specifies the second alpha value, and so on. Alphamaps can be any length.

Alphamaps affect the rendering of objects created with the `surface`, `image`, and `patch` functions, but do not affect other graphics objects.

`Colormap` — Color map for axes content of figure

parula (default) | `m`-by-3 array of RGB triplets

Color map for axes content of a figure, specified as an `m`-by-3 array of RGB (red, green, blue) triplets that define `m` individual colors. MATLAB accesses these colors by their row number. For example, an index of 1 specifies the first RGB triplet, an index of 2 specifies the second RGB triplet, and so on.

Colormaps affect the rendering of objects created with the `surface`, `image`, and `patch` functions, but generally do not affect other graphics objects.

Colormaps can be any length, but must be three columns wide.

Example: `[1 0 1; 0 0 1; 1 1 0]`

Location and Size

`Position` — Location and size of figure's drawable area

`[left bottom width height]`

Location and size of figure's drawable area, specified as the vector, `[left bottom width height]`. The drawable area is the inner area of the window, excluding the title bar, menu bar, and tool bars. This table describes each element in the Position vector.

Element	Description
`left`	Distance from the left edge of the primary display to the inner left edge of the figure window. This value can be negative on systems that have more than one monitor.
`bottom`	Distance from the bottom edge of the primary display to the inner bottom edge of the figure window. This value can be negative on systems that have more than one monitor.
`width`	Distance between the right and left inner edges of the figure.
`height`	Distance between the top and bottom inner edges of the figure.

All measurements are in units specified by the Units property.

You cannot specify the figure Position property when the figure is docked.

To place the full window, including the title bar, menu bar, tool bars, and outer edges, use the `OuterPosition` property.

Note: On Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the Position property.

Example: `[230 250 570 510]`

Data Types: `double`

`OuterPosition` — Location and size of figure's outer bounds

`[left bottom width height]`

Location and size of outer bounds, specified as the vector, `[left bottom width height]`. This table describes each element in the vector.

Element	Description
`left`	Distance from the left edge of the primary display to the outer left edge of the figure window. This value can be negative on systems that have more than one monitor.
`bottom`	Distance from the bottom edge of the primary display to the outer bottom edge of the figure window. This value can be negative on systems that have more than one monitor.
`width`	Distance between the right and left outer edges of the figure.
`height`	Distance between the top and bottom outer edges of the figure.

All measurements are in units specified by the Units property.

If you attempt to set the OuterPosition property when the figure is docked, this warning displays:

```
Warning: Cannot set OuterPosition while
WindowStyle is 'docked'
```

Note: On Microsoft Windows systems, figure windows are always at least 104 pixels wide, regardless of the value of the OuterPosition property.

Example: `[230 250 570 510]`

Data Types: `double`

`Units` — Units of measurement

`'pixels'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'points'` | `'characters'`

Units of measurement, specified as `'pixels'`, `'normalized'`, `'inches'`, `'centimeters'`, `'points'`, or `'characters'`.

MATLAB uses these units to interpret the location and size values of the Position property:

- The size of a figure specified in pixel units depends on the system display settings and resolution.
- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- Character units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

The order in which you specify the Units and Position properties has these effects:

- If you specify the Units before the Position property, then MATLAB sets Position using the units you specify.
- If you specify the Units property after the Position property, MATLAB sets the position using the default Units. Then, MATLAB converts the Position value to the equivalent value in units you specify.

`Resize` — Window resize mode

`'on'` (default) | `'off'`

Window resize mode, specified as:

- `'on'` — Users can resize the figure window.
- `'off'` — Users cannot resize the figure window. The figure window does not display any resizing controls.

`SizeChangedFcn` — Window resize callback function

`''` (default) | function handle | cell array | string

Callback function that executes when the figure size changes, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function when you want to customize a UI layout beyond what the Position and Units properties provide.

The SizeChangedFcn callback executes under these circumstances:

- The figure becomes visible for the first time.
- The figure is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the figure.
- The figure becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the figure is invisible, and then it becomes visible later.

These are some of the important characteristics of the SizeChangedFcn callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the figure's SizeChangedFcn uses are defined. This practice can prevent the figure's SizeChangedFcn callback from returning an error. To delay the display of the figure, set its Visible property to `'off'`. Then, set the Visible property to `'on'` after you define the variables that your SizeChangedFcn callback uses.
- Use the `gcbo` function in your SizeChangedFcn code to get the figure object that the user is resizing.

Example: Uicontrol That has Constant Height

This example code shows how to create a UI containing a uicontrol having a constant height at the top of the figure. To see how it works, copy and paste this code into an editor and save it as `sbar.m`.

```
function sbar(src,callbackdata)
   u = findobj(gcbo,'Tag','StatusBar');
   fig = gcbo;
   old_units = fig.Units;
   fig.Units = 'pixels';
   sbar_units = u.Units;
   u.Units = 'pixels';
   figpos = fig.Position;
   upos = [1 figpos(4) - 20 figpos(3) 20];
```

```
   u.Position = upos;
   u.Units = sbar_units;
   fig.Units = old_units;
   u.Visible = 'on';
end
```

Then, run the following code:

```
f = figure('Visible','off');
u = uicontrol('Style','edit', 'Tag','StatusBar');
f.SizeChangedFcn = @sbar;
f.Visible = 'on';
```

The `sbar` function maintains a 20-pixel uicontrol height and sets the uicontrol width equal to the width of the figure. Notice the use of the `findobj` function to retrieve the uicontrol object. This function also calls the `gcbo` function to access the figure object.

Data Types: `function_handle` | `cell` | `char`

`ResizeFcn` — Figure resize callback function

`''` (default) | function handle | cell array | string

Callback function that executes when the figure size changes, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Note: Use of the ResizeFcn property is not recommended. It might be removed in a future release. Use SizeChangedFcn instead.

Data Types: `function_handle` | `cell` | `char`

Multiple Plots

`NextPlot` — Directive on how to add next plot

`'add'` (default) | `'new'` | `'replace'` | `'replacechildren'`

Directive on how to add next plot, specified as `'add'`, `'new'`, `'replace'`, or `'replacechildren'`.

This table describes the effects of each value.

Property Value	Effect
`'new'`	Creates a new figure and uses it as the current figure.
`'add'`	Adds new graphics objects without clearing or resetting the current figure.
`'replacechildren'`	Removes all axes objects who are not hidden before adding new objects. Does not reset figure properties. Equivalent to using the `clf` command.
`'replace'`	Removes all axes objects and resets figure properties to their defaults before adding new graphics objects. Equivalent to using the `clf reset` command.

Consider using the `newplot` function to handle the NextPlot property. For more information, see the axes `NextPlot` property and "Prepare Figures and Axes for Graphs".

Interactive Control

`Selected` — Selection status of figure

`'off'` (default) | `'on'`

Note: The behavior of the Selected property changed in R2014b, and it is not recommended. It no longer has any effect on figures. This property might be removed in a future release.

`SelectionHighlight` — Ability of figure to highlight when user selects it

`'on'` (default) | `'off'`

Note: Use of the figure SelectionHighlight property is not recommended. This property might be removed in a future release.

This property has no effect on figures.

Callback Execution Control

`Interruptible` — Callback interruption

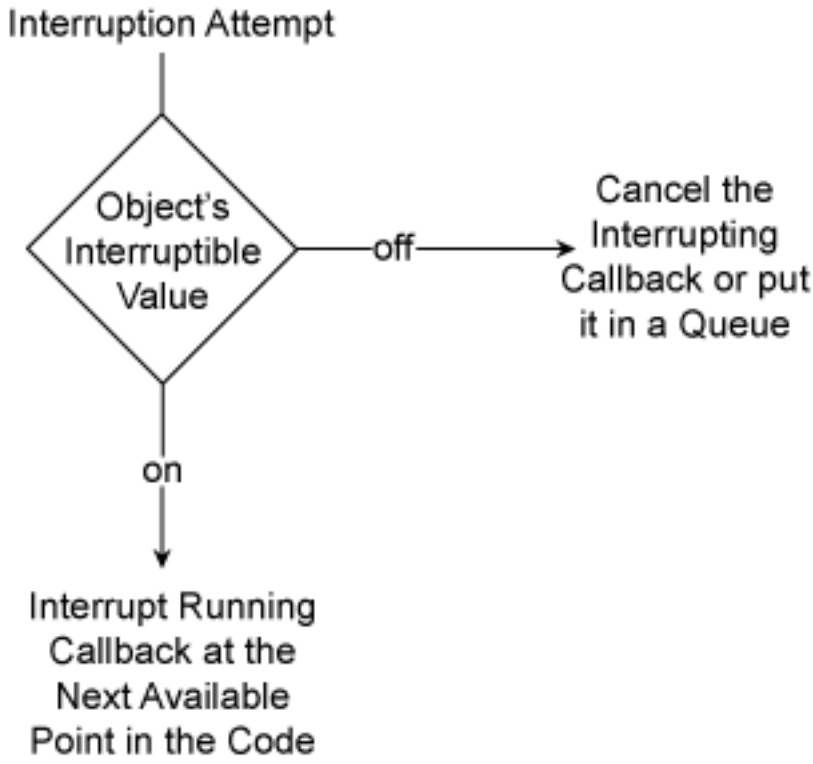
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a figure callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See "Interrupt Callback Execution" for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

Ability to become current object, specified as `'on'` or `'off'`:

- Setting the value to `'on'` allows the figure to become the current object when the user clicks on it. A value of `'on'` also allows the figure CurrentObject property and the `gco` function to report the figure as the current object.
- Setting the value to `'off'` sets the figure CurrentObject property to an empty `GraphicsPlaceholder` array when the user clicks on the figure.

Keyboard Control

`CurrentCharacter` — Last key pressed in figure

`''` (default) | 1-character string

The last key pressed in the figure, returned as a 1-character string. Use the CurrentCharacter property to obtain user input.

Example: `'t'`

`KeyPressFcn` — Key-press callback function

`''` (default) | function handle | cell array | string

The callback function that executes when a user presses a key, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes when the figure window has focus and the user presses a key. If you do not define a function for this property, MATLAB passes key presses to the Command Window. Repeated key presses retain the focus of the figure, and the function executes with each key press. If the user presses multiple keys at approximately the same time, MATLAB detects the key press for the last key pressed.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Contents
`Character`	The character that displays as a result of pressing the key or keys. The character can be empty or unprintable.
`Modifier`	A cell array containing the names of one or more modifier keys that are being pressed (such as , **control**, **alt**, **shift**). On Macintosh computers, the cell array contains `'command'` when the **command** modifier key is pressed.
`Key`	The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.
`Source`	The object that has focus when the user presses the key.
`Eventname`	The action that caused the callback function to execute.

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the `Character` property, but do not change the `Key` property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the `Character` property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate `Character` property data.

You also can query the CurrentCharacter property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

`KeyReleaseFcn` — Key-release callback function

`''` (default) | function handle | cell array | string

Key press callback function, specified as one of these values

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes when the figure object has focus and the user releases a key.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
`Character`	Character interpretation of the key that was released.	`'a'`	`'='`	`''`	`'A'`
`Modifier`	Current modifier, such as `'control'`, or an empty cell array if there is no modifier	`{1x0 cell}`	`{1x0 cell}`	`{'shift'`	`{'shift'}`
`Key`	The key being released, identified by the (lowercase) label on the key, or a descriptive string.	`'a'`	`'equal'`	`'shift'`	`'a'`

Property	Description	Examples:			
		a	=	Shift	Shift-a
`Source`	The object that has focus when the user presses the key.	figure	figure	figure	figure
`Eventname`	The action that caused the callback function to execute.	`'KeyRel`	`'KeyRel`	`'KeyRele`	`'KeyRelease'`

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the `Character` property, but do not change the `Key` property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the `Character` property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate `Character` property data.

You also can query the CurrentCharacter property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

`WindowKeyPressFcn` — Key-press callback function for the figure window

`''` (default) | function handle | cell array | string

Key-press callback function for the figure window, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever a key press occurs while either the figure window or any of its children has focus.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to

the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Contents
`Character`	The character displayed as a result of pressing the key. The character which can be empty or unprintable
`Modifier`	A cell array containing the names of one or more modifier keys being pressed (such as **control**, **alt**, **shift**). On Macintosh computers, it contains `'command'` when pressing the **command** modifier key.
`Key`	The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.
`Source`	The object that has focus when the user presses the key.
`Eventname`	The action that caused the callback function to execute.

Example: `@myfun`

Example: `{@myfun,x}`

`WindowKeyReleaseFcn` — Key-release callback function for the figure window

`''` (default) | function handle | cell array | string

Key-release callback function for the figure window, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever a key release occurs while the figure window or any of its children has focus.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Contents
`Character`	The character displayed as a result of the releasing the key or keys. The character which can be empty or unprintable.
`Modifier`	A cell array containing the names of one or more modifier keys being released (such as **control**, **alt**, **shift**). On Macintosh computers, it contains `'command'` when releasing the **command** modifier key.
`Key`	The key being released, identified by the (lowercase) label on the key, or a descriptive string.
`Source`	The object that has focus when the user releases the key.
`Eventname`	The action that caused the callback function to execute.

Example: `@myfun`

Example: `{@myfun,x}`

Mouse Control

`ButtonDownFcn` — Button-press callback function

`''` (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever the user clicks a mouse button while the pointer is in the figure window, but not over a child object such as a uicontrol, uipanel, axes, or axes child.

See the figure's `SelectionType` property to determine whether modifier keys are also pressed.

`CurrentPoint` — Location of last button click in figure

two-element vector: `[x-coordinate, y-coordinate]`

Location of the last button click in this figure, returned as a two-element vector. The CurrentPoint property value is measured from the lower left corner of the figure window, in units determined by the Units property. MATLAB updates this property whenever a user presses the mouse button while the pointer is in the figure window.

If a user selects a point in the figure, and you use the values returned by the CurrentPoint property to plot that point, there can be differences in the position due to round-off errors.

CurrentPoint and Cursor Motion

MATLAB updates CurrentPoint before executing callback functions defined for the figure `WindowButtonMotionFcn` and `WindowButtonUpFcn` properties. This enables you to query CurrentPoint from these callback functions. It behaves like this:

- If you define a callback function for the `WindowButtonMotionFcn` property or the `WindowButtonUpFcn` property, then MATLAB updates the CurrentPoint property only when the user presses the mouse button within the figure window.
- If you define a callback function for the WindowButtonMotionFcn property, then MATLAB updates the CurrentPoint property just before executing the callback. The WindowButtonMotionFcn property executes only within the figure window, unless the user presses the mouse button within the figure and *keeps the mouse button down* while moving the pointer around the screen. In this case, the function executes (and MATLAB updates the CurrentPoint property) anywhere on the screen until the user releases the mouse button.
- If you define a callback function for the WindowButtonUpFcn property, then MATLAB updates the CurrentPoint property just before executing the callback. The WindowButtonUpFcn callback executes only while the pointer is within the figure window, unless the user presses the mouse button within the window and *releases the mouse button* anywhere on the screen. In this case, the function executes, preceded by an update of the CurrentPoint property value.
- If you add a uicontrol or uitable component to the figure, then MATLAB updates the CurrentPoint property when the user right-clicks the component, or when they left-click the component while the Enable property of that component is `'off'` or `'inactive'`.

In some situations (such as when the WindowButtonMotionFcn callback takes a long time to execute and the user moves the pointer very rapidly), the CurrentPoint property might not reflect the actual location of the pointer, but rather the location at the time when the WindowButtonMotionFcn callback began execution.

The root `PointerLocation` property contains the location of the pointer updated synchronously with pointer movement. However, the location is measured with respect to the screen, not a figure window.

`SelectionType` — Mouse selection type

`'normal'` (default) | `'extend'` | `'alt'` | `'open'`

Mouse selection type, returned as `'normal'`, `'extend'` , `'alt'` , or `'open'`. MATLAB maintains this property to provide information about the last mouse-button press that occurred within the figure window. This information indicates the type of selection made. Selection types are actions that MATLAB generally associates with particular responses from the user interface software (for example, single-clicking a graphics object places it in move or resize mode; double-clicking a file name opens it, and so on).

The value of this property depends on the type of mouse click and the user's operating system.

Selection Type	Microsoft Windows	Linux	Mac
`'normal'`	Click left mouse button.	Click left mouse button.	Click left mouse button.
`'extend'`	Either of the following: • **Shift**-click left mouse button. • Click both left and right mouse buttons.	Either of the following: • **Shift**-click left mouse button. • Click middle mouse button.	Any one of the following: • **Shift**-click left mouse button. • Click middle mouse button. • Click both left and right mouse buttons.
`'alt'`	**Control**-click left mouse button or click right mouse button.	**Control**-click left mouse button or click right mouse button.	**Control**-click left mouse button or click right mouse button.
`'open'`	Double-click any mouse button.	Double-click any mouse button.	Double-click any mouse button.

Note: For a list box (uicontrol), the second click of a double-click sets the SelectionType property to `'open'`.

`WindowButtonDownFcn` — Button press callback function

`''` (default) | function handle | cell array | string

Button press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes whenever a user clicks a mouse button while the pointer is in the figure window. See the `WindowButtonMotionFcn` property for an example.

Note: When using a two-button or three-button mouse on Macintosh systems, right-button and middle-button presses are not always reported. This happens *only* when a new figure window appears under the mouse cursor and the user clicks the mouse without first moving the mouse. In this circumstance, for the WindowButtonDownFcn callback to work, the user needs to do one of the following:

- Move the mouse after the figure is created, and then click any mouse button.
- Press **Shift** or **Ctrl** while clicking the left mouse button to perform the Extend and Alternate selection types.

Pressing the left mouse button (or single mouse button) works without having to take either of the above actions.

For information on how callbacks interact, see the Interruptible and BusyAction properties.

Example: `@myfun`

Example: `{@myfun,x}`

`WindowButtonMotionFcn` — Mouse-motion callback function

`''` (default) | function handle | cell array | string

Mouse-motion callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes whenever the user moves the pointer within the figure window.

Note: On some systems, the WindowButtonMotionFcn callback executes when MATLAB creates a figure, even though there has been no mouse motion within the figure.

Your callback functions might need to update the display by calling the `drawnow` or `pause` function, which causes MATLAB to process all callbacks in the queue. Processing the callback queue can cause your callback function to be reentered. Design your code to handle reentrancy and do not depend on global variables that might change state during reentrance.

For information on how callbacks interact, see the Interruptible and BusyAction properties.

Example: Coding Window Button Callback Functions

This example shows how to code all three window button callback functions so that the user can draw lines using mouse motions.

Copy and save the following code to a file on a writable folder on your system. Then, run the code. Click the left mouse button in the axes and move the cursor. Left-click to define the line end point. Right-click to end drawing mode.

```
function window_motion_test
```

```
%
figure('WindowButtonDownFcn',@wbdcb)
ah = axes('SortMethod','childorder');
axis ([1 10 1 10])
title('Click and drag')
   function wbdcb(src,callbackdata)
     if strcmp(src.SelectionType,'normal')
        src.Pointer = 'circle';
        cp = ah.CurrentPoint;
        xinit = cp(1,1);
        yinit = cp(1,2);
        hl = line('XData',xinit,'YData',yinit,...
        'Marker','p','color','b');
        src.WindowButtonMotionFcn = @wbmcb;
        src.WindowButtonUpFcn = @wbucb;
     end

        function wbmcb(src,callbackdata)
           cp = ah.CurrentPoint;
           xdat = [xinit,cp(1,1)];
           ydat = [yinit,cp(1,2)];
           hl.XData = xdat;
           hl.YData = ydat;
           drawnow
        end

        function wbucb(src,callbackdata)
           if strcmp(src.SelectionType,'alt')
              src.Pointer = 'arrow';
              src.WindowButtonMotionFcn = '';
              src.WindowButtonUpFcn = '';
           else
              return
           end
        end
  end
end
```

`WindowButtonUpFcn` — Button-release callback function

`''` (default) | function handle | cell array | string

Button-release callback function, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes whenever a user releases a mouse button.

The button-up callback is associated with the figure window in which a previous button-down action occurred. Therefore, the pointer need not be in the figure window when the user releases the button to generate the button-up callback.

If the callback functions defined by the `WindowButtonDownFcn` or `WindowButtonMotionFcn` properties contain `drawnow` commands or call other functions that contain `drawnow` commands and the `Interruptible` property is set to `'off'`, then the WindowButtonUpFcn callback might not be called. You can prevent this situation by setting the Interruptible property to `'on'`.

Your callback functions might need to update the display by calling the `drawnow` or `pause` function, which causes MATLAB to process all callbacks in the queue. Processing the queue can cause your callback function to be reentered. For example, a `drawnow` command in the WindowButtonUpFcn callback might result in the WindowButtonUpFcn callback being called again before the first call has finished. Design your code to handle reentrancy and do not depend on global variables that might change state during reentrance.

You can use the Interruptible and BusyAction figure properties to control how callbacks interact.

Example: `@myfun`

Example: `{@myfun,x}`

`WindowScrollWheelFcn` — Mouse-scroll-wheel callback

`''` (default) | function handle | cell array | string

Mouse-scroll-wheel callback, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes when the user moves the mouse-scroll-wheel while the figure has focus. MATLAB executes the callback with each single mouse-scroll-wheel click.

Be aware that it is possible for another object to capture the mouse-scroll-wheel movement from MATLAB. For example, if the figure contains Java or ActiveX control objects that are listening for mouse-scroll-wheel movements, then these objects can capture the activity and prevent the WindowScrollWheelFcn callback from executing.

WindowScrollWheelFcn Callback Data

When the callback is a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Contents
`VerticalScrollCount`	A positive or negative integer that indicates the number of mouse-scroll-wheel clicks. Positive values indicate clicks of the wheel scrolled in the down direction. Negative values indicate clicks of the wheel scrolled in the up direction.
`VerticalScrollAmount`	The current system setting for the number of lines that are scrolled for each click of the scroll wheel. If the mouse property setting for scrolling is set to `One screen at a time`, the `VerticalScrollAmount` property is `1`.

Effects on Other Properties

The WindowScrollWheelFcn property value has the following effects on these properties:

- `CurrentObject` property — The WindowScrollWheelFcn property has no effect on the CurrentObject property.

- `CurrentPoint` property — If there is no callback defined for the WindowScrollWheelFcn property, then MATLAB does not update the CurrentPoint property as the user turns the scroll wheel. However, if there is a callback defined for the WindowScrollWheelFcn property, then MATLAB updates the CurrentPoint property just before executing the callback. This enables you to determine the point at which the mouse scrolling occurred.
- `SelectionType` property — The WindowScrollWheelFcn property has no effect on the SelectionType property.

Values Returned by VerticalScrollCount

When a user moves the mouse scroll wheel by one click, MATLAB increments the count by +/- 1, depending on the direction of the scroll (scroll down being positive). When MATLAB calls the WindowScrollWheelFcn callback, the counter resets. In most cases, this means that the absolute value of the returned value is 1. However, if the WindowScrollWheelFcn callback takes a long enough time to return or the user spins the scroll wheel very fast, or both, then the returned value can have an absolute value greater than one.

The actual value returned by `VerticalScrollCount` property is the algebraic sum of all mouse-scroll-wheel clicks that occurred since last processed. This enables your callback to respond correctly to the user action.

Example: Code WindowScrollWheelFcn Callback

This example creates a graph and enables users to use the mouse scroll wheel to change the range over which MATLAB evaluates a mathematical function. In addition, it updates the graph to reflect the new limits as the user turns the scroll wheel.

Copy and save the function to a writable folder on your system. Then, run the code. Mouse over the figure and scroll your mouse wheel.

```
function scroll_wheel
% Illustrates how to use WindowScrollWheelFcn property
%
   f = figure('WindowScrollWheelFcn',@figScroll,'Name','Scroll Wheel Demo');
   x = [0:.1:40];
   y = 4.*cos(x)./(x+2);
   a = axes;
   h = plot(x,y);
```

```
   title('Rotate the scroll wheel')
   function figScroll(src,callbackdata)
      if callbackdata.VerticalScrollCount > 0
         xd = h.XData;
         inc = xd(end)/20;
         x = [0:.1:xd(end)+inc];
         re_eval(x)
      elseif callbackdata.VerticalScrollCount < 0
         xd = h.XData;
         inc = xd(end)/20;
         x = [0:.1:xd(end)-inc+.1]; % Don't let xd = 0;
         re_eval(x)
      end
   end % figScroll

   function re_eval(x)
      y = 4.*cos(x)./(x+2);
      h.YData = y;
      h.XData = x;
      a.XLim = [0 x(end)];
      drawnow
   end % re_eval
end % scroll_wheel
```

`UIContextMenu` — Figure context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu object

Figure context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the figure. Create the context menu using the `uicontextmenu` function.

Window Control

`CloseRequestFcn` — Figure close request callback function

`''` (default) | function handle | cell array | string

Figure close request callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback executes whenever a user attempts to close a figure window. You can, for example, display a dialog box to ask a user to confirm or cancel the close operation or to prevent users from closing a figure that contains a UI.

The basic mechanism is:

1. A user issues the `close` or `close all` command from the command line, closes the figure from the computer window manager menu, or closes the figure by quitting MATLAB.
2. The close operation executes the function defined by the figure CloseRequestFcn property. The default function is `closereq`.

   The `closereq` function unconditionally deletes the current figure, destroying the window. The `closereq` function takes advantage of the fact that the `close` command makes each figure specified as an argument the current figure before calling its respective close request function.

The `closereq` function honors the ShowHiddenHandles property setting during figure deletion and does not delete hidden figures.

Unless the close request function calls the `delete` or `close` function, MATLAB never closes the figure. (You can call `delete(f)` from the command line if you have created a window with a nondestructive close request function.)

Example: Code CloseRequestFcn to Display Dialog Box

This example shows how to code the close request function to display a question dialog box asking the user to confirm the close operation. Save the code to a writable folder on your system.

```
function my_closereq(src,callbackdata)
% Close request function
% to display a question dialog box
   selection = questdlg('Close This Figure?',...
      'Close Request Function',...
      'Yes','No','Yes');
   switch selection,
      case 'Yes',
         delete(gcf)
      case 'No'
      return
```

```
    end
end
```

Now, create a figure specifying `my_closereq` for the CloseRequestFcn:

```
figure('CloseRequestFcn',@my_closereq)
```

Close the figure window and the question dialog box displays.

`WindowStyle` — Figure window behavior

`'normal'` (default) | `'modal'` | `'docked'`

Figure window behavior, specified as one of the following:

- `'normal'` — The figure window is independent of other windows, and the other windows are accessible while the figure is displaying.
- `'modal'` — The figure displays on top of all existing figure windows, making them inaccessible as long as the top figure exists and remains modal. However, any new figures created after a modal figure will display.

  When multiple modal windows exist, the most recently created window keeps focus and stays above all other windows until it becomes invisible, or is returned to a normal window style, or is deleted. At that time, focus reverts to the window that last had focus.
- `'docked'` — The figure displays in the desktop or a document window. This code docks the figure and sets the `DockControls` property to `'on'`, if it was set to `'off'`.

  ```
  f = figure;
  f.WindowStyle = 'docked';
  ```

  If the WindowStyle property is set to `'docked'`, you cannot set the DockControls property to `'off'`.

Note: These are some important characteristics of the WindowStyle property and some recommended best practices:

- When you create UI windows, always specify the WindowStyle property. If you also want to set the Resize, Position, or OuterPosition properties of the figure, then set the WindowStyle property first.
- You can change the WindowStyle property of a figure at any time, including when the figure is visible and contains children. However on some systems, setting this

property might cause the figure to flash or disappear and reappear, depending on the system's implementation of normal and modal windows. For best visual results, set the WindowStyle property at creation time or when the figure is invisible.

- Calling `reset` on a figure does not change the value of the WindowStyle property.

Modal Window Style Behavior

When WindowStyle is set to `'modal'`, the figure window traps all keyboard and mouse actions over all MATLAB windows as long as the windows are visible. Windows belonging to applications other than MATLAB are unaffected.

Typing **Ctrl+C** when a modal figure has focus causes that figure to revert to a `'normal'` WindowStyle property setting. This allows the user to type at the command line.

Figures with the WindowStyle property set to `'modal'` and the Visible property set to `'off'` do not behave modally until MATLAB makes them visible. Therefore, you can hide a modal window for later reuse, instead of destroying it.

Modal figures do not display uimenu children, built-in menus, or toolbars. But, it is not an error to create uimenus in a modal figure or to change the WindowStyle property setting to `'modal'` on a figure with uimenu children. The uimenu objects exist and the figure retains them. If you reset the figure's WindowStyle property to `'normal'`, the uimenus display.

Creation and Deletion Control

`BeingDeleted` — Deletion status of figure

`'off'` (default) | `'on'`

Deletion status of figure, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the figure begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the figure no longer exists.

Check the value of the BeingDeleted property to verify that the figure is not about to be deleted before querying or modifying it.

`CreateFcn` — Figure creation function

function handle | cell array | string

Figure creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the figure. MATLAB initializes all figure property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the figure that is being created.

Setting the CreateFcn property on an existing figure has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the figure object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Figure deletion function

function handle | cell array | string

Figure deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the figure (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the figure. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the figure that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`CurrentAxes` — Target axes in current figure

`axes object`

Target axes in the current figure, specified as an axes object. MATLAB sets this property to the figure's current axes object. In all figures for which axes children exist, there is always a current axes. The current axes does not have to be the topmost axes, and setting an axes to be the current axes does not restack it above all other axes. If a figure contains no axes, the `get(gcf,'CurrentAxes')` command returns an empty array.

To get the current axes object without forcing the creation of an axes if one does not exist, query the figure `CurrentAxes` property.

```
fh = gcf;
ah = fh.CurrentAxes
```

MATLAB returns `h` as an empty array if there is no current axes. Be aware that `gcf` creates a figure if one does not exist.

`CurrentObject` — Most recently selected component in figure

object

Most recently selected component in the Figure, specified as an object. MATLAB sets the CurrentObject property to the last object the user clicked. This object is the front-

most object in the view. You can use this property to determine which object a user has selected.

An object's HitTest property controls whether that object can become the CurrentObject.

Clicking an object whose HandleVisibility property is `off` (such as axis labels and title) causes the CurrentObject property to be set to empty. To avoid returning an empty value when users click a hidden object, set HitTest property of the hidden object to `'off'`.

Moving the cursor over objects does not update the CurrentObject. Users must click objects to update this property. See the `CurrentPoint` property for related information.

If you are looking for a quick way to access the current object, consider using the `gco` command.

`FileName` — FIG-file name

string

FIG-file name, specified as a string. GUIDE uses this property to store the name of the UI layout file that it saves. If you are not working in GUIDE, then the FileName property is empty.

Example: `'myguifile.fig'`

`IntegerHandle` — Ability to assign figure number

`'on'` (default) | `'off'`

Ability to assign figure number, specified as `'on'` or `'off'`.

If you set the IntegerHandle property to `'on'`, MATLAB finds the lowest integer value not used by an existing figure and sets the Number property to that value. If you delete a figure, MATLAB can reuse the number on a new figure window.

If you set the IntegerHandle property to `'off'`, MATLAB does not assign an integer value to the figure and sets the Number property to an empty array (`[]`).

`Number` — Figure number

integer | `[]`

Figure number, returned as an integer or empty array. You can refer to a figure using this value. For example, `figure(2)` makes the figure with a Number property value of 2 the current figure.

If the `IntegerHandle` property is set to `'off'`, Number is an empty array.

If IntegerHandle is `'on'`, the Number property value is an integer value. If a figure is deleted, MATLAB reuses that figure's number for the next figure window created.

Example: `3`

`Type` — Type of Figure object

`'figure'`

Type of Figure object, returned as the string, `'figure'`. Use this property to find all objects of a given type within a plotting hierarchy.

`Tag` — Figure identifier

`' '` (default) | string

Figure identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the figure. When you need access to the figure elsewhere in your code, you can use the `findobj` function to search for the figure based on the Tag value.

Example: `'Plotting Figure'`

`UserData` — Data to associate with the figure object

empty array (default) | array

Data to associate with the figure object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See "Share Data Among Callbacks" for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Figure parent

root object

Figure parent, returned as a root object.

`Children` — Children of figure

empty `GraphicsPlaceholder` array (default) | 1-D array of objects

Children of the figure, returned as an empty `GraphicsPlaceholder` or a 1-D array of objects.

You cannot add or remove children using the `Children` property of the figure. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the figure object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of figure handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of figure handle, specified as `'on'`, `'callback'`, or `'off'`.

This property determines whether a figure is in its parent's (the root's) list of children. HandleVisibility is useful for preventing command-line users from accidentally drawing into, or deleting a figure that contains only user interface components (such as a dialog box).

If an object is not in its parent's list of children, functions that find objects by searching the object hierarchy or querying properties cannot return that object. Such functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When the HandleVisibility property value is restricted using the `'callback'` or `'off'` settings, the object does not appear in the parent object Children property, figures do not appear in the root `CurrentFigure` property, objects do not appear in the root `CallbackObject` property or in the figure `CurrentObject` property, and axes do not appear in their parent CurrentAxes property.

Set the root `ShowHiddenHandles` property to `'on'` to make all objects visible, regardless of their HandleVisibility settings (this does not affect the values of the HandleVisibility properties).

Pointers

`Pointer` — Pointer symbol

`'arrow'` (default) | string

Pointer symbol, specified as a string. Valid strings are listed in the following table. By convention, each symbol commonly indicates a particular usage. However, MATLAB does not enforce rules for the use of any symbols. The appearance of the symbol that displays for a given string is operating-system dependent.

Typical Usage Indicated	Symbol String
Editing location in text	`'ibeam'`
Point on a graphics object	`'crosshair'`
Point anywhere in the figure	`'arrow'`
Busy system	`'watch'`
Resizing an object from a top-left or bottom-right corner	`'topl'` or `'botr'`
Resizing an object from a top-right or bottom-left corner	`'topr'` or `'botl'`
A hot spot	`'circle'`
A point	`'cross'`
Moving an object	`'fleur'`
Resizing an object from the left side	`'left'`
Resizing an object from the right side	`'right'`
Resizing an object from the top or bottom	`'top'` or `'bottom'`
Clickable icon	`'hand'`

Note: The `'fullcrosshair'` option was removed in R2014b.

Setting Pointer property to `'custom'` enables you to define your own pointer symbol. See the `PointerShapeCData` property for more information.

`PointerShapeCData` — Pointer shape

`16-by-16 matrix`

Pointer shape MATLAB uses when the Pointer property is set to `'custom'`, specified as a `16-by-16 matrix`. The matrix defines a 16-by-16 pixel pointer using the following values:

- `1` — Color pixel black.
- `2` — Color pixel white.
- `NaN` — Make pixel transparent, such that underlying screen shows through

Element `(1,1)` of the PointerShapeCData matrix corresponds to the upper-left corner of the pointer. Setting the `Pointer` property to one of the predefined pointer symbols does not change the value of the PointerShapeCData. Computer systems supporting `32`-by-`32` pixel pointers fill only one quarter of the available pixmap.

`PointerShapeHotSpot` — Active area of pointer

`[1 1]` — upper-left corner (default) | `two-element vector`

Active area of pointer, specified as a two-element vector. The vector specifies the row and column indices in the `PointerShapeCData` matrix defining the pixel indicating the pointer location. The `CurrentPoint` property and the root object's `PointerLocation` property specify the location.

Printing

`PaperSize` — Size of the current `PaperType`

[width height]

Size of the current PaperType, specified as `[width height]`. The default value is locale-dependent, as follows:

- United States — [8.5000 11]
- Europe and Asia — [21 29.7]

The `PaperUnits` property specifies the units of measurement. You cannot set this property if the PaperUnits property is set to `'normalized'`. Attempting to do so results in an error.

See the `PaperType` property to select a standard paper size.

Tip Use the PaperType property instead of the PaperSize property if you do not want to be concerned with setting the PaperUnits property.

`PaperUnits` — Output measurement units

`'inches' | 'centimeters' | 'normalized' | 'points'`

Output measurement units measured from the bottom of the page, specified as one of the following values:

- `'inches'`— absolute unit

  This is the default when the locale is the United States.
- `'normalized'` — maps the lower left corner of the page to (0, 0) and the upper right corner to (1.0, 1.0)
- `'centimeters'`— absolute unit

  This is the default when the locale is Europe or Asia.
- `'points'` — absolute unit. One point equals 1/72 of an inch

This property affects all printed and exported output, not just output printed to paper.

MATLAB uses these units with the `PaperPosition` and `PaperSize` properties.

If you change the value of the PaperUnits property, it is good practice to return the property to its default value after completing your computation so as not to affect other functions that assume the PaperUnits property is set to the default value.

`PaperOrientation` — Figure orientation on printed page

`'portrait'` (default) | `'landscape'`

Figure orientation on printed page, specified as `'portrait'` or `'landscape'`.

- `'portrait'` — Orients the longest page dimension vertically.
- `'landscape'` — Orients the longest page dimension horizontally.

See the `orient` function for more information.

`PaperPosition` — Figure location and size on page

`[left bottom width height]`

Figure location and size on the page, specified as `[left bottom width height]`. Page refers to printed pages and files exported to PDF or PostScript® formats. The `left` value specifies the distance from the left side of the page to the left side of the figure. The `bottom` value specifies the distance from the bottom of the page to the bottom of the figure. Together these distances specify the lower left corner of the figure position.

The `width` and `height` values define the dimensions of the figure. When exporting to a nonpage format, such as to image file formats or encapsulated PostScript (EPS), MATLAB uses the width and height values only.

Note: If the width and height values are too large, then the figure might not reach the specified size. If the figure does not reach the specified size, then UI components on the figure, such as uicontrols or a uitable, might not save or print as expected.

The `PaperUnits` property specifies the units of measurement.

Example: `[.25 .25 8 6]`

`PaperPositionMode` — Directive for honoring `PaperPosition` property

`'manual'` (default) | `'auto'`

Directive for honoring the `PaperPosition` property, specified as one of the following:

- `'manual'` — MATLAB honors the value specified by the PaperPosition property.
- `'auto'` — MATLAB prints the figure the same size as it appears on the computer screen. For page formats, the output is centered on the page.

  To determine the output size when `PaperPosition` is `'auto'`, the figure's size (width and height) is converted to inches based on the screen resolution. MATLAB generates output to match that size, based on the output resolution. For example, a figure that is 500 x 400 pixels on a screen that has a resolution of 100 dpi measures 5x4 inches; when output at 150 dpi, the image will be 750 x 600 pixels (5 inches * 150 dpi x 4 inches * 150 dpi)

  Tip To generate output that matches the on-screen size in pixels, call `print` with the `-r0` option.

`PaperType` — Standard paper size selection

string

Standard paper size selection, specified as a string.

The default setting is locale-dependent, as follows:

- United States — `'usletter'`

- Europe and Asia — `'a4'`

Valid strings are described in the table that follows. You can enter strings using uppercase or lowercase letters, but MATLAB always stores the strings using lowercase.

To position the printed figure on a new paper size, you might need to change the setting of the `PaperPosition` property. Consider setting the `PaperUnits` property to `'normalized'`. This setting enables MATLAB to automatically size the figure to occupy the same relative amount of the printed page, regardless of the paper size.

Property Value	Size (Width x Height)
`'usletter'`	8.5-by-11 inches
`'uslegal'`	8.5-by-14 inches
`'tabloid'`	11-by-17 inches
`'a0'`	841-by-1189 mm
`'a1'`	594-by-841 mm
`'a2'`	420-by-594 mm
`'a3'`	297-by-420 mm
`'a4'`	210-by-297 mm
`'a5'`	148-by-210 mm
`'b0'`	1029-by-1456 mm
`'b1`	728-by-1028 mm
`'b2'`	514-by-728 mm
`'b3'`	364-by-514 mm
`'b4'`	257-by-364 mm
`'b5'`	182-by-257 mm
`'arch-a'`	9-by-12 inches
`'arch-b'`	12-by-18 inches
`'arch-c'`	18-by-24 inches
`'arch-d'`	24-by-36 inches
`'arch-e'`	36-by-48 inches
`'a'`	8.5-by-11 inches

Property Value	Size (Width x Height)
'b'	11-by-17 inches
'c'	17-by-22 inches
'd'	22-by-34 inches
'e'	34-by-43 inches

InvertHardcopy — Directive to use black on white background when printing or exporting

'on' (default) | 'off'

Directive to use black on white background when printing or exporting, specified as the string 'on' or 'off'. Printing a figure that has a background color (Color property) that is not white results in poor contrast between graphics objects and the figure background; and also consumes a lot of printer toner.

If you set the InvertHardCopy property to 'on', MATLAB changes the color of the figure and axes to white and the axis lines, tick marks, axis labels, etc., that are currently white to black. The lines, text, and edges of patches and surfaces might be changed, depending on the print command options you specify.

If you set InvertHardCopy to 'off', the printed or exported output matches the colors displayed on the screen.

- "Default Property Values"

figurepalette

Show or hide **Figure Palette**

Syntax

```
figurepalette('show')
figurepalette('hide')
figurepalette
figurepalette(figure_handle,...)
```

Description

`figurepalette('show')` displays the palette on the current figure.

`figurepalette('hide')` hides the palette on the current figure.

`figurepalette` toggles the visibility of the palette on the current figure. You can also use `figurepalette('toggle')` instead for the same functionality.

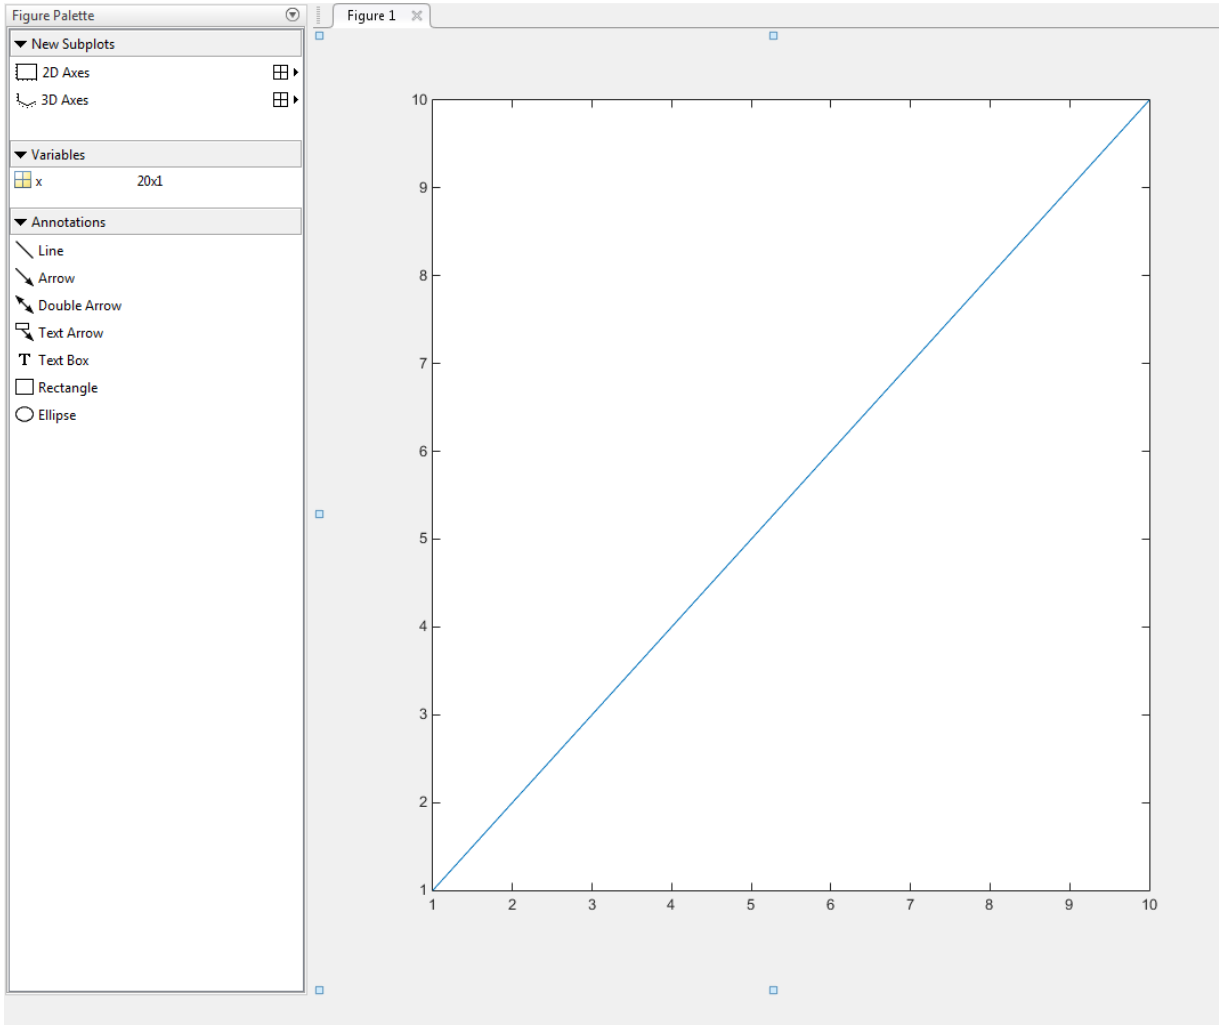
`figurepalette(figure_handle,...)` shows or hides the palette on the figure specified by `figure_handle`.

Examples

Open Figure Palette

Plot a line and open the figure palette.

```
plot(1:10)
figurepalette('show')
```



Alternatives

To collectively enable Plotting Tools, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the Plotting Tools, use the smaller icon  . Open or close the **Figure Palette** tool from the figure's **View** menu.

More About

Tips

If you call `figurepalette` in a MATLAB program and subsequent lines depend on the Figure Palette being fully initialized, follow it by `drawnow` to ensure complete initialization.

Introduced before R2006a

fileattrib

Set or get attributes of file or folder

Syntax

```
fileattrib
fileattrib(name)

fileattrib(name,attribs)
fileattrib(name,attribs,users)
fileattrib(name,attribs,users,'s')

[status,message,messageid] = fileattrib(name,attribs, ___ )
[status,message] = fileattrib(name)
```

Description

`fileattrib` gets attribute values for the current folder, using the following structure, where `Name` is always a string containing the current folder name. For the other fields, a value of `0` indicates that the attribute is off, `1` indicates that the attribute is on, and `NaN` indicates that the attribute does not apply:

```
Name
archive
system
hidden
directory
UserRead
UserWrite
UserExecute
GroupRead
GroupWrite
GroupExecute
OtherRead
OtherWrite
OtherExecute
```

`fileattrib(name)` gets the attribute values for the named file or folder.

`fileattrib(name,attribs)` sets the specified attributes for the named file or folder.

`fileattrib(name,attribs,users)` sets the file or folder attributes for the specified subset of users.

`fileattrib(name,attribs,users,'s')` sets the specified attributes for the specified users for the contents of the named folder.

`[status,message,messageid] = fileattrib(name,attribs, ___ )` sets the specified file attributes and gets the function status:

- If status is `0`, then message is the error message, and messageid is the error message identifier.
- If status is `1`, then message is a structure containing the attributes of the named file or folder, and messageid is an empty string.

`[status,message] = fileattrib(name)` gets status and the last *successfully* set attribute structure values for the named file or folder and returns the structure to message. (status is always `1`.)

Examples

View Current Folder Attributes

View attributes of the current folder, assuming the current folder is `C:\my_MATLAB_files`.

```
fileattrib
```

```
ans =

           Name: 'C:\my_MATLAB_files'
        archive: 0
         system: 0
         hidden: 0
      directory: 1
       UserRead: 1
      UserWrite: 1
    UserExecute: 1
      GroupRead: NaN
     GroupWrite: NaN
   GroupExecute: NaN
```

```
       OtherRead: NaN
      OtherWrite: NaN
    OtherExecute: NaN
```

The attributes indicate that you have read, write, and execute permissions for the current folder.

View File Attributes

View attributes of file `collatz.m`.

```
fileattrib('collatz.m')
```

```
ans =

           Name: 'C:\my_MATLAB_files\collatz.m'
        archive: 1
         system: 0
         hidden: 0
      directory: 0
       UserRead: 1
      UserWrite: 0
    UserExecute: 1
      GroupRead: NaN
     GroupWrite: NaN
   GroupExecute: NaN
      OtherRead: NaN
     OtherWrite: NaN
   OtherExecute: NaN
```

The attributes indicate that the specified item is a file. You can read and execute the file, but cannot update it. The file is archived.

View Folder Attributes on a Windows System

View attributes for the folder `C:\my_MATLAB_files\doc`.

```
fileattrib('C:\my_MATLAB_files\doc')
```

```
ans =

           Name: 'C:\my_MATLAB_files\doc'
        archive: 0
         system: 0
         hidden: 0
```

```
       directory: 1
        UserRead: 1
       UserWrite: 1
     UserExecute: 1
       GroupRead: NaN
      GroupWrite: NaN
    GroupExecute: NaN
       OtherRead: NaN
      OtherWrite: NaN
    OtherExecute: NaN
```

The attributes indicate that you have read, write, and execute permissions for the specified folder.

View Folder Attributes on a UNIX System

View attributes for the folder `/public` on a UNIX system.

```
fileattrib('/public')

ans =

           Name: '/public'
        archive: NaN
         system: NaN
         hidden: NaN
       directory: 1
        UserRead: 1
       UserWrite: 1
     UserExecute: 1
       GroupRead: 1
      GroupWrite: 0
    GroupExecute: 1
       OtherRead: 1
      OtherWrite: 0
    OtherExecute: 1
```

The attributes indicate that you have read, write, and execute permissions for the specfied folder. In addition, users in your UNIX group and all others have read and execute permissions for the specified folder, but not write permissions.

Set File Attributes

Make `myfile.m` writeable.

```
fileattrib('myfile.m','+w')
```

Set File Attributes for Specific Users on UNIX

Make the folder `/home/work/results` a read-only folder for *all users* on UNIX platforms.

```
fileattrib('/home/work/results','-w','a')
```

The minus (`-`) preceding the write attribute, `w`, removes the write status.

Set Attributes for Folder and Its Contents

On Windows platforms, make the folder `D:\work\results` and all its contents read only and hidden.

```
fileattrib('D:\work\results','+h -w','','s')
```

Because a value for the users argument is not applicable on Windows systems, the argument is an empty string. The `s` argument applies the hidden and read-only attributes to the contents of the folder.

Get Attributes Structure for a Folder

Get the attributes for the folder `results` and return them to a structure:

```
[stat,struc] = fileattrib('results')
```

```
stat =
     1

struc =
           Name: 'D:\work\results'
        archive: 0
         system: 0
         hidden: 0
      directory: 1
       UserRead: 1
      UserWrite: 1
    UserExecute: 1
      GroupRead: NaN
     GroupWrite: NaN
   GroupExecute: NaN
      OtherRead: NaN
```

```
      OtherWrite: NaN
    OtherExecute: NaN
```

The operation is successful as indicated by the status, `stat`, value of 1. The structure, `struc`, contains the file attributes.

Access the name attribute value in the structure. MATLAB returns the path for `results`.

```
struc.Name
```

```
ans =
D:\work\results
```

Get Attributes Structure for Multiple Files

Get the attributes for all files in the current folder with names that begin with `new`.

```
[stat,struc] = fileattrib('new*')
```

```
stat =
     1

mess =
1x3 struct array with fields:
    Name
    archive
    system
    hidden
    directory
    UserRead
    UserWrite
    UserExecute
    GroupRead
    GroupWrite
    GroupExecute
    OtherRead
    OtherWrite
    OtherExecute
```

The results indicate there are three matching files.

View the file names.

```
struc.Name
```

```
ans =
D:\work\results\newname.m

ans =
D:\work\results\newone.m

ans =
D:\work\results\newtest.m
```

View just the second file name.

```
struct(2).Name

ans =
D:\work\results\newname.m
```

Successfully Set Attributes for a File and Get Messages

Show output that results when an attempt to set file attributes is successful.

```
[status,message,messageid] = fileattrib('C:/my_MATLAB_files\doc',...
'+h -w','','s')

status =

     1

message =

     ''

messageid =

     ''
```

The `status` value of `1` indicates the set operation was successful; therefore, no error `message` or `messageid` is returned.

Unsuccessfully Set Attributes for a File and Get Messages

Show output that results when an attempt to set file attributes is unsuccessful.

```
[status,message,messageid] = fileattrib('C:/my_MATLAB_files\doc',...
'+h w-','','s')

status =

     0

message =

Illegal file mode characters on the current platform.

messageid =

MATLAB:FILEATTRIB:ModeSyntaxError
```

The `status` value of `0` indicates the set operation was unsuccessful. The minus sign incorrectly appears after `w`, instead of before it.

Input Arguments

`name` — File or folder name

string

The absolute or relative path for a folder or file, specified as a string. To specify all names beginning with certain characters, add the wildcard character, `*`.

Example: `fileattrib('myfile.m')`

`attribs` — File or folder attribute values

`'a' | 'h' | 's' | 'w' | 'x'`

File or folder attribute values, specified as a space delimited string. Use the plus (+) qualifier before an attribute to set it, and the minus (-) qualifier before an attribute to clear it.

attribvalue	Description
`'a'`	Archive (Microsoft Windows platform only).
`'h'`	Hidden file (Windows platform only).

attribvalue	Description
`'s'`	System file (Windows platform only).
`'w'`	Write access (Windows and UNIX platforms). Results differ by platform and application. For example, even though `fileattrib` disables the "write" privilege for a folder, making it read only, files in the folder could be writable for some platforms or applications.
`'x'`	Executable (UNIX platform only).

Example: `fileattrib('myfile.m', '+w -h')`

`users` — Subset of users

`'a' | 'g' | 'o' | 'u' | ''`

Subset of users (on UNIX platforms only), specified as a string. For all platforms other than UNIX, specify the users argument as an empty string, `''`. This value is not returned by `fileattrib` get operations.

Value for UNIX Users	Description
`'a'`	All users on UNIX platforms
`'g'`	Group of users
`'o'`	All other users
`'u'`	Current user

Example: `fileattrib('D:/work/results','-w','a')`

Output Arguments

`status` — Indication of whether attempt to set attribute was successful

`0 | 1`

If attempt to set attribute was unsuccessful, `status` is `0`. Otherwise, `status` is `1`.

`message` — Attribute structure or error message

string | structure array

Attribute structure or error message, depending on whether you are setting or getting attributes and `status`.

Getting or Setting Attributes	Status	Message contents
Setting	0	Error message
Setting	1	Empty string
Getting	1	Structure containing file attributes and values

When you are getting file attributes, the structure contains these fields and possible values.

Field name	Possible Values
`Name`	String containing name of file or folder
`archive`	`0` (not set), `1 (set)`, or `NaN (not applicable)`
`system`	`0`, `1`, or `NaN`
`hidden`	`0`, `1`, or `NaN`
`directory`	`0`, `1`, or `NaN`
`UserRead`	`0`, `1`, or `NaN`
`UserWrite`	`0`, `1`, or `NaN`
`UserExecute`	`0`, `1`, or `NaN`
`GroupRead`	`0`, `1`, or `NaN`
`GroupWrite`	`0`, `1`, or `NaN`
`GroupExecute`	`0`, `1`, or `NaN`
`OtherRead`	`0`, `1`, or `NaN`
`OtherWrite`	`0`, `1`, or `NaN`
`OtherExecute`	`0`, `1`, or `NaN`

`messageid` — Error message identifier

string

Error message identifier when the attempt to set attribute is unsuccessful (status is 0), returned as a string. If status is 1, then messageid is an empty string.

More About

Tips

- `fileattrib` is like the DOS `attrib` command, or the UNIX `chmod` command. [1]

See Also

`cd` | `copyfile` | `delete` | `dir` | `ls` | `mkdir` | `movefile` | `rmdir`

Introduced before R2006a

1. UNIX is a registered trademark of The Open Group in the United States and other countries.

filebrowser

Open Current Folder browser, or select it if already open

Syntax

```
filebrowser
```

Description

`filebrowser` opens the Current Folder browser, or if it is already open, makes it the selected tool.

More About

- "Manage Files and Folders"

See Also

`cd` | `copyfile` | `ls` | `mkdir` | `fileattrib` | `movefile` | `pwd` | `rmdir`

Introduced before R2006a

filemarker

Character to separate file name and internal function name

Syntax

```
M = filemarker
```

Description

`M = filemarker` returns the character that separates a file and a within-file function name.

Examples

On the Microsoft Windows platform, for example, `filemarker` returns the '>' character:

```
filemarker

ans =
   >
```

You can use the following command on any platform to get the help text for the local function `validateSizes` defined in `imwrite.m`:

```
 helptext = help(['imwrite' filemarker 'validateSizes'])

helptext =
  How many bytes does each element occupy in memory?
```

You can use the `filemarker` character to indicate a location within a MATLAB program file where you want to set a breakpoint, for example. On all platforms, if you need to distinguish between two nested functions with the same name, use the forward slash (/) character to indicate the path to a particular instance of a function.

For instance, suppose `myfile.m` contains the following code:

```
function x = A(p1, p2)
```

```
...
  function y = B(p3)
    ...
  end
  function m = C(p4)
    ...
    end
end

function z = C(p5)
...
  function y = D(p6)
    ...
  end
end
```

To indicate that you want to set a breakpoint at `function y` nested within `function x`, use the following command on the Windows platform:

```
dbstop myfile>x/y
```

To indicate that you want to set a breakpoint at `function m` nested within `function x` use the following command on the Windows platform:

```
dbstop myfile>m
```

In the first case, you specify `x/y` because `myfile.m` contains two nested functions named `y`. In the second case, there is no need to specify `x/m` because there is only one function `m` within `myfile.m`.

See Also

`filesep`

fileparts

Parts of file name and path

Syntax

```
[pathstr,name,ext] = fileparts(filename)
```

Description

`[pathstr,name,ext] = fileparts(filename)` returns the path name, file name, and extension for the specified file. The file does not have to exist. `filename` is a string enclosed in single quotes. The returned `ext` field contains a dot (`.`) before the file extension.

Input Arguments

`filename`

String containing a name of a file or folder, which can include a path and file extension. The function interprets all characters following the right-most delimiter as a file name plus extension.

Output Arguments

`pathstr`

String containing the part of `filename` interpreted as a path name

`name`

String containing the name of the file without any extension

`ext`

String containing the file extension only, beginning with a period (`.`)

Examples

Return the pieces of a file specification string to the separate string outputs `pathstr`, `name`, and `ext`. The full file specification is:

```
file = 'H:\user4\matlab\myfile.txt';
[pathstr,name,ext] = fileparts(file)

pathstr =
H:\user4\matlab

name =
myfile

ext =
.txt
```

Query parts of a user `.cshrc` file:

```
[pathstr,name,ext] = fileparts('/home/jsmith/.cshrc')

pathstr =
/home/jsmith

name =
   Empty string: 1-by-0

ext =
.cshrc
```

`fileparts` interprets the entire file name as an extension because it begins with a period.

Alternatives

Use `uigetfile` to interactively select and return a file name and path, or `uigetdir` to interactively select and return a path name. If you call `fileparts` with the output of `uigetfile`, you can parse out the file name and extension.

More About

Path Name

The full or partial path to a destination folder location, always the initial portion of the filename string. Path names end with a slash character and, where appropriate, can begin with a drive letter. Windows paths use backward slashes (\). UNIX and Macintosh paths use forward slashes (/).

Tips

- `fileparts` only parses file names. It does not verify that a file or a folder exists.
- You can reconstruct the file from the parts using:

  ```
  fullfile(pathstr,[name ext])
  ```

- On Microsoft Windows systems, you can use either forward (/) or back (\) slashes as path delimiters, even within the same string. On UNIX and Macintosh systems, use only / as a delimiter. You can use the `filesep` function to insert the correct separator character for the platform on which your code executes:

  ```
  sep = filesep;
  file = ['H:' sep 'user4' sep 'matlab' sep 'myfile.txt'];

  file =
  H:\user4\matlab\myfile.txt
  ```

- If the input consists of a folder name only, be sure that the right-most character is a delimiter (/ or \). Otherwise, `fileparts` parses the trailing portion of `filename` as the name of a file and returns it in `name` instead of in `pathstr`.

`filesep` | `fullfile` | `pathsep` | `uigetdir` | `uigetfile`

Introduced before R2006a

fileread

Read contents of file into string

Syntax

```
text = fileread(filename)
```

Description

`text = fileread(filename)` returns the contents of the file *`filename`* as a MATLAB string.

Examples

Read and search the file `Contents.m` in the MATLAB `iofun` directory for the reference to `fileread`:

```
% find the correct directory and file
io_contents = ...
  fullfile(matlabroot,'toolbox','matlab','iofun','Contents.m');

% read the file
filetext = fileread(io_contents);

% search for the line of code that includes 'fileread'
% each line is separated by a newline ('\n')

expr = '[^\n]*fileread[^\n]*';
fileread_info = regexp(filetext,expr,'match');
```

See Also

`fgetl` | `fgets` | `fscanf` | `fread` | `importdata` | `type` | `textscan`

filesep

File separator for current platform

Syntax

```
f = filesep
```

Description

`f = filesep` returns the platform-specific file separator character. The file separator is the character that separates individual folder and file names in a path string.

Examples

Create a path to the `iofun` folder on a Microsoft Windows platform:

```
iofun_dir = ['toolbox' filesep 'matlab' filesep 'iofun']

iofun_dir =
   toolbox\matlab\iofun
```

Create a path to `iofun` on a UNIX[2] platform.

```
iodir = ['toolbox' filesep 'matlab' filesep 'iofun']

iodir =
   toolbox/matlab/iofun
```

fill

Filled 2-D polygons

Syntax

```
fill(X,Y,C)
fill(X,Y,ColorSpec)
fill(X1,Y1,C1,X2,Y2,C2,...)
fill(...,'PropertyName',PropertyValue)
h = fill(...)
```

Description

The `fill` function creates colored polygons.

`fill(X,Y,C)` creates filled polygons from the data in `X` and `Y` with vertex color specified by `C`. `C` is a vector or matrix used as an index into the colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`. If necessary, `fill` closes the polygon by connecting the last vertex to the first.

`fill(X,Y,ColorSpec)` fills two-dimensional polygons specified by `X` and `Y` with the color specified by `ColorSpec`.

`fill(X1,Y1,C1,X2,Y2,C2,...)` specifies multiple two-dimensional filled areas.

`fill(...,'PropertyName',PropertyValue)` allows you to specify property names and values for a patch graphics object.

`h = fill(...)` returns a vector of handles to patch graphics objects, one handle per patch object.

Examples

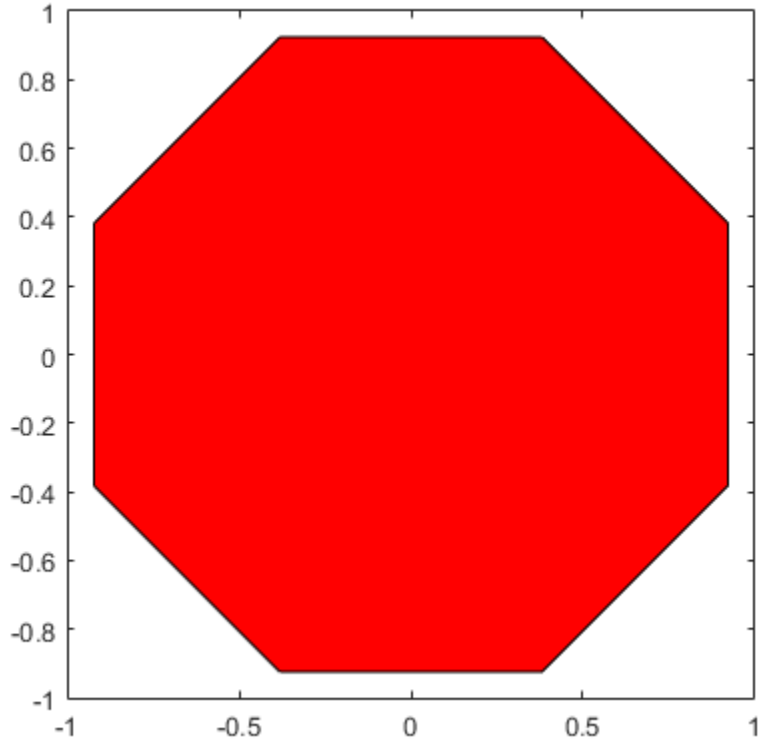
Create Red Octagon

Define the data.

```
t = (1/16:1/8:1)'*2*pi;
x = cos(t);
y = sin(t);
```

Create a red octagon using the `fill` function.

```
fill(x,y,'r')
axis square
```



More About

Tips

If `X` or `Y` is a matrix, and the other is a column vector with the same number of elements as rows in the matrix, `fill` replicates the column vector argument to produce a matrix of the required size. `fill` forms a vertex from corresponding elements in `X` and `Y` and creates one polygon from the data in each column.

If `X` or `Y` contains one or more `NaN` values, then `fill` does not fill the polygons.

The type of color shading depends on how you specify color in the argument list. If you specify color using `ColorSpec`, `fill` generates flat-shaded polygons by setting the patch object's `FaceColor` property to the corresponding RGB triplet.

If you specify color using `C`, `fill` scales the elements of `C` by the values specified by the axes property `CLim`. After scaling `C`, `C` indexes the current colormap.

If `C` is a row vector, `fill` generates flat-shaded polygons where each element determines the color of the polygon defined by the respective column of the `X` and `Y` matrices. Each patch object's `FaceColor` property is set to `'flat'`. Each row element becomes the `CData` property value for the `n`th patch object, where *n* is the corresponding column in `X` or `Y`.

If `C` is a column vector or a matrix, `fill` uses a linear interpolation of the vertex colors to generate polygons with interpolated colors. It sets the patch graphics object `FaceColor` property to `'interp'` and the elements in one column become the `CData` property value for the respective patch object. If `C` is a column vector, `fill` replicates the column vector to produce the required sized matrix.

Properties

Patch Properties

Introduced before R2006a

fill3

Filled 3-D polygons

Syntax

```
fill3(X,Y,Z,C)
fill3(X,Y,Z,ColorSpec)
fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)
fill3(...,'PropertyName',PropertyValue)
h = fill3(...)
```

Description

The `fill3` function creates flat-shaded and Gouraud-shaded polygons.

`fill3(X,Y,Z,C)` fills three-dimensional polygons. `X`, `Y`, and `Z` triplets specify the polygon vertices. If `X`, `Y`, or `Z` is a matrix, `fill3` creates n polygons, where n is the number of columns in the matrix. `fill3` closes the polygons by connecting the last vertex to the first when necessary.

`C` specifies color, where `C` is a vector or matrix of indices into the current colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`.

`fill3(X,Y,Z,ColorSpec)` fills three-dimensional polygons defined by `X`, `Y`, and `Z` with color specified by `ColorSpec`.

`fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)` specifies multiple filled three-dimensional areas.

`fill3(...,'PropertyName',PropertyValue)` allows you to set values for specific patch properties.

`h = fill3(...)` returns a vector of handles to patch graphics objects, one handle per patch.

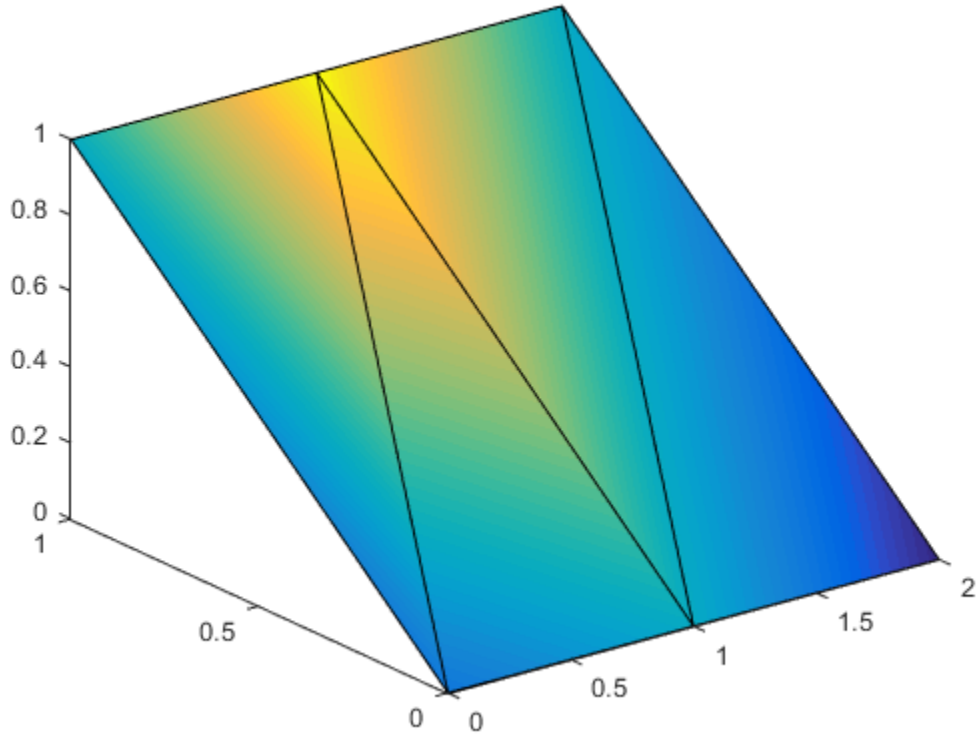
Examples

Create Filled 3-D Polygon

Create four triangles with interpolated colors.

```
X = [0 1 1 2; 1 1 2 2; 0 0 1 1];
Y = [1 1 1 1; 1 0 1 0; 0 0 0 0];
Z = [1 1 1 1; 1 0 1 0; 0 0 0 0];
C = [0.5000 1.0000 1.0000 0.5000;
     1.0000 0.5000 0.5000 0.1667;
     0.3330 0.3330 0.5000 0.5000];

figure
fill3(X,Y,Z,C)
```



More About

Algorithms

If `X`, `Y`, and `Z` are matrices of the same size, `fill3` forms a vertex from the corresponding elements of `X`, `Y`, and `Z` (all from the same matrix location), and creates one polygon from the data in each column.

If `X`, `Y`, or `Z` is a matrix, `fill3` replicates any column vector argument to produce matrices of the required size.

If you specify color using `ColorSpec`, `fill3` generates flat-shaded polygons and sets the patch object `FaceColor` property to an RGB triplet.

If you specify color using `C`, `fill3` scales the elements of `CLim` by the axes property `CLim`, which specifies the color axis scaling parameters, before indexing the current colormap.

If `C` is a row vector, `fill3` generates flat-shaded polygons and sets the `FaceColor` property of the patch objects to `'flat'`. Each element becomes the `CData` property value for the respective patch object.

If `C` is a column vector or a matrix, `fill3` generates polygons with interpolated colors and sets the patch object `FaceColor` property to `'interp'`. `fill3` uses a linear interpolation of the vertex colormap indices when generating polygons with interpolated colors. The elements in one column become the `CData` property value for the respective patch object. If `C` is a column vector, `fill3` replicates the column vector to produce the required sized matrix.

Properties

Patch Properties

Introduced before R2006a

filter

1-D digital filter

Syntax

```
y = filter(b,a,x)
y = filter(b,a,x,zi)
y = filter(b,a,x,zi,dim)
[y,zf] = filter( ___ )
```

Description

`y = filter(b,a,x)` filters the input data, x, using a rational transfer function defined by the numerator and denominator coefficients b and a, respectively.

If `a(1)` is not equal to `1`, then `filter` normalizes the filter coefficients by `a(1)`. Therefore, `a(1)` must be nonzero.

- If `x` is a vector, then `filter` returns the filtered data as a vector of the same size as `x`.
- If `x` is a matrix, then `filter` acts along the first dimension and returns the filtered data for each column.
- If `x` is a multidimensional array, then `filter` acts along the first array dimension whose size does not equal 1.

`y = filter(b,a,x,zi)` uses initial conditions, zi, for the filter delays. The length of zi must equal `max(length(a),length(b))-1`.

`y = filter(b,a,x,zi,dim)` acts along dimension `dim`. For example, if `x` is a matrix, then `filter(b,a,x,zi,2)` returns the filtered data for each row.

`[y,zf] = filter( ___ )` also returns the final conditions, `zf`, of the filter delays, using any of the previous syntax arguments.

Examples

Moving-Average Filter of Vector Data

Find the moving-average of a vector without using a `for` loop.

Create a 1-by-100 row vector of sinusoidal input data corrupted by random noise. Initialize the random number generator to make the output of `rand` repeatable.

```
t = linspace(-pi,pi,100);
rng default
x = sin(t) + 0.25*rand(size(t));
```

A moving-average filter is represented by the following difference equation,

$$y(n) = \frac{1}{windowSize}\left(x(n) + x(n-1) + \ldots + x(n-(windowSize-1))\right).$$

Define the numerator coefficients of the rational transfer function. Use a window size of 5.

```
windowSize = 5;

b = (1/windowSize)*ones(1,windowSize)
```

```
b =

    0.2000    0.2000    0.2000    0.2000    0.2000
```

Define the denominator coefficients of the rational transfer function.

```
a = 1;
```

Find the moving-average of the data with a window size of 5.

```
y = filter(b,a,x);
```

`y(1)` is equivalent to `0.2*x(1)`.

`y(2)` is equivalent to `0.2*(x(1)+x(2))`.

...

`y(5)` is equivalent to `0.2*(sum(x(1:5)) = mean(x(1:5))`.

`y(6)` is equivalent to `mean(x(2:6))`.

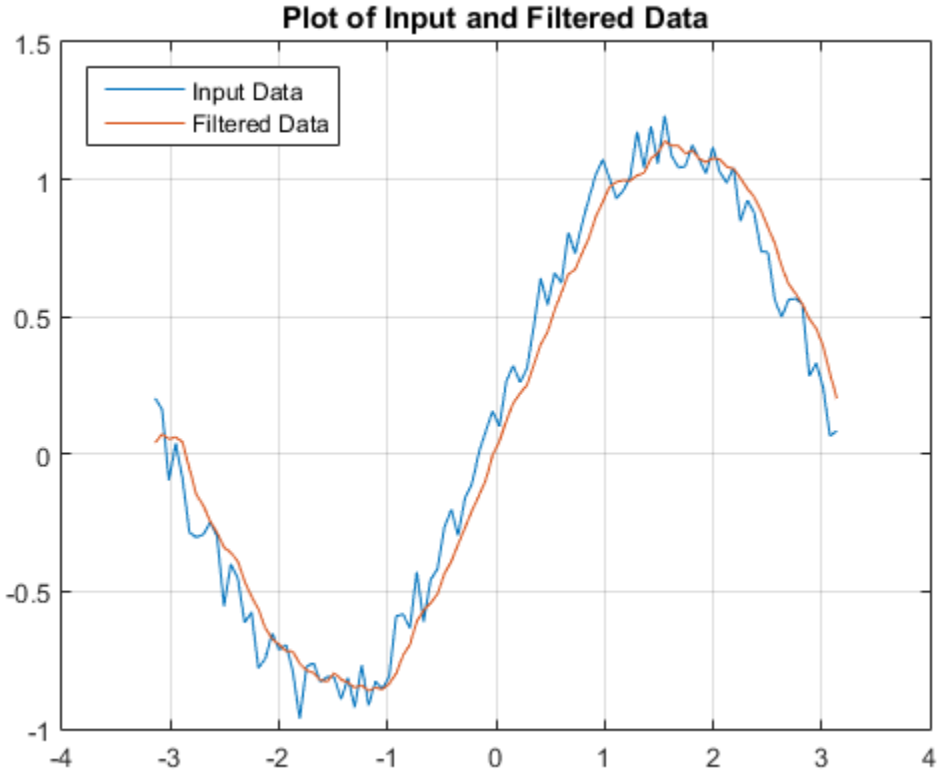
...

`y(100)` is equivalent to `mean(x(96:100))`.

Compare the original data and the filtered data using an overlaid plot.

```
plot(t,x)
hold on
plot(t,y)

grid on
legend('Input Data','Filtered Data','Location','NorthWest')
title('Plot of Input and Filtered Data')
```



Apply Rational Transfer Function to Matrix

Filter the rows or columns of a matrix with the following rational transfer function,

$$H(z) = \frac{b(1)}{a(1) + a(2)z^{-1}} = \frac{1}{1 - 0.2z^{-1}}.$$

Create a 15-by-2 matrix of random input data. Initialize the random number generator to make the output of `rand` repeatable.

```
rng default
x = rand(15,2)
```

```
x =

    0.8147    0.1419
    0.9058    0.4218
    0.1270    0.9157
    0.9134    0.7922
    0.6324    0.9595
    0.0975    0.6557
    0.2785    0.0357
    0.5469    0.8491
    0.9575    0.9340
    0.9649    0.6787
    0.1576    0.7577
    0.9706    0.7431
    0.9572    0.3922
    0.4854    0.6555
    0.8003    0.1712
```

Define the numerator and denominator coefficients for the rational transfer function.

```
b = 1;
a = [1 -0.2];
```

Apply the transfer function along the first dimension (default) and return the 1-D digital filter of each column.

```
y = filter(b,a,x)
```

```
y =

    0.8147    0.1419
    1.0687    0.4501
    0.3407    1.0058
    0.9815    0.9934
    0.8287    1.1582
    0.2633    0.8874
    0.3312    0.2132
    0.6131    0.8918
    1.0801    1.1123
    1.1809    0.9012
    0.3938    0.9380
    1.0494    0.9307
    1.1670    0.5784
```

```
    0.7188    0.7712
    0.9440    0.3254
```

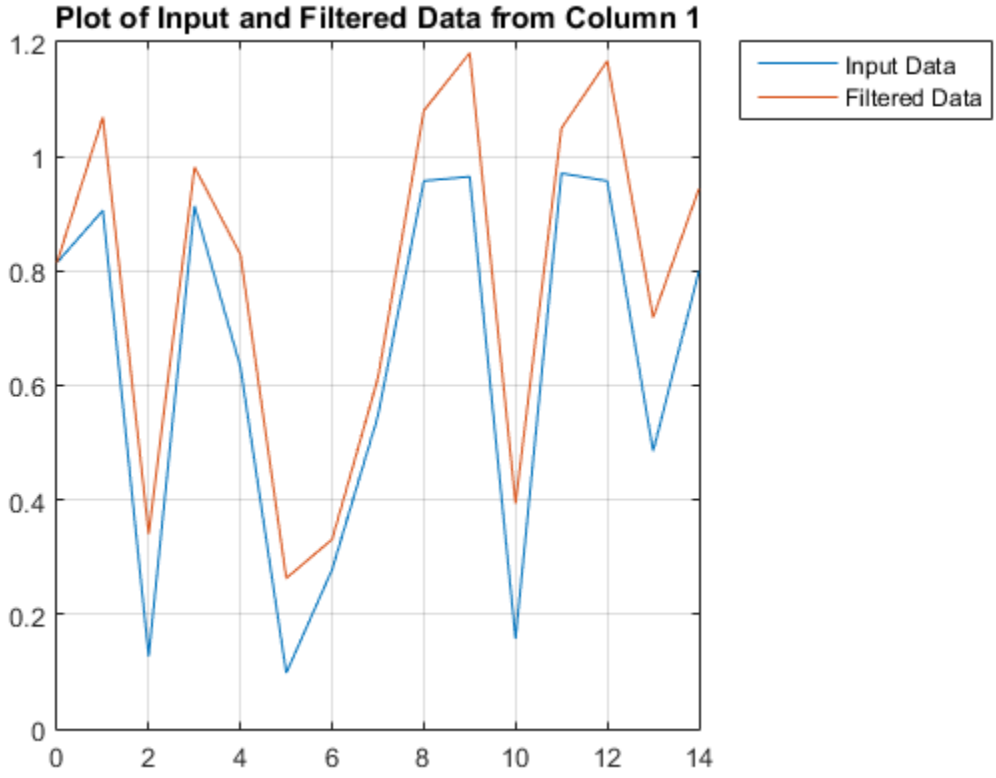
Compare the original data and the filtered data using an overlaid plot for each column.

Plot the first column of input and filtered data.

```
t = 0:length(x)-1;

plot(t,x(:,1))
hold on
plot(t,y(:,1))

grid on
legend('Input Data','Filtered Data','Location','BestOutside')
title('Plot of Input and Filtered Data from Column 1')
```

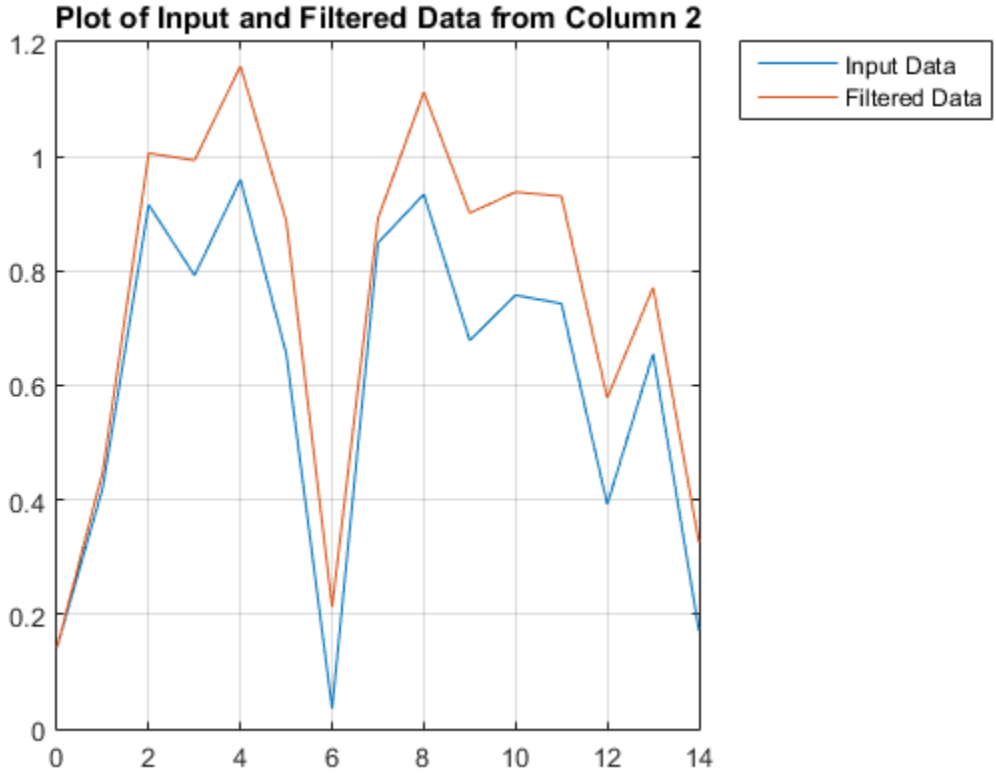


Plot the second column of input and filtered data.

```
figure

plot(t,x(:,2))
hold on
plot(t,y(:,2))

grid on
legend('Input Data','Filtered Data','Location','BestOutside')
title('Plot of Input and Filtered Data from Column 2')
```



Alternatively, you can filter the rows of a matrix by specifying `dim = 2`.

Consider the 2-by-15 matrix, `x'`, whose rows contain the data to filter.

Filter the matrix along the second dimension. Use the default initial conditions for filter delays.

```
dim = 2;
y2 = filter(b,a,x',[],dim)
```

```
y2 =

  Columns 1 through 7
```

```
    0.8147    1.0687    0.3407    0.9815    0.8287    0.2633    0.3312
    0.1419    0.4501    1.0058    0.9934    1.1582    0.8874    0.2132

  Columns 8 through 14

    0.6131    1.0801    1.1809    0.3938    1.0494    1.1670    0.7188
    0.8918    1.1123    0.9012    0.9380    0.9307    0.5784    0.7712

  Column 15

    0.9440
    0.3254
```

`y2` is the transpose of `y` from above.

Filter Data in Sections

Use initial and final conditions for filter delays to filter data in sections, especially if memory limitations are a consideration.

Generate a large random data sequence and split it into two segments, `x1` and `x2`.

```
x = randn(10000,1);

x1 = x(1:5000);
x2 = x(5001:end);
```

The whole sequence, `x`, is the vertical concatenation of `x1` and `x2`.

Define the numerator and denominator coefficients for the rational transfer function,

$$H(z) = \frac{b(1) + b(2)z^{-1}}{a(1) + a(2)z^{-1}} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}.$$

```
b = [2,3];
a = [1,0.2];
```

Filter the subsequences `x1` and `x2` one at a time. Output the final conditions from filtering `x1` to store the internal status of the filter at the end of the first segment.

```
[y1,zf] = filter(b,a,x1);
```

Use the final conditions from filtering `x1` as initial conditions to filter the second segment, `x2`.

```
y2 = filter(b,a,x2,zf);
```

`y1` is the filtered data from `x1`, and `y2` s the filtered data from `x2`. The entire filtered sequence is the vertical concatenation of `y1` and `y2`.

Filter the entire sequence simultaneously for comparison.

```
y = filter(b,a,x);
```

```
isequal(y,[y1;y2])
```

```
ans =

     1
```

Input Arguments

b — Numerator coefficients of rational transfer function

vector

Numerator coefficients of the rational transfer function, specified as a vector.

Data Types: `double` | `single`
Complex Number Support: Yes

a — Denominator coefficients of rational transfer function

vector

Denominator coefficients of the rational transfer function, specified as a vector.

Data Types: `double` | `single`
Complex Number Support: Yes

x — Input data

vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single`
Complex Number Support: Yes

`zi` — Initial conditions for filter delays

`[]` (default) | vector | matrix | multidimensional array

Initial conditions for filter delays, specified as a vector, matrix, or multidimensional array.

- If `zi` is a vector, then its length must be `max(length(a),length(b))-1`.
- If `zi` is a matrix or multidimensional array, then the size of the leading dimension must be `max(length(a),length(b))-1`. The size of each remaining dimension must match the size of the corresponding dimension of `x`.

The default value, specified by `[]`, initializes all filter delays to zero.

Data Types: `double` | `single`
Complex Number Support: Yes

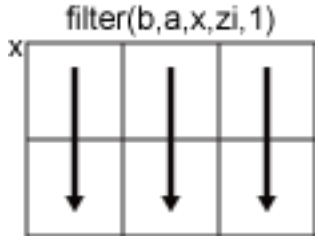
`dim` — Dimension to operate along

positive integer scalar

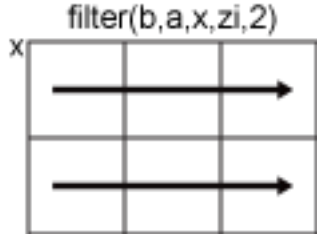
Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `x`.

- If `dim = 1`, then `filter(b,a,x,zi,1)` works along the rows of `x` and returns the filter applied to each column.



- If `dim = 2`, then `filter(b,a,zi,2)` works along the columns of `x` and returns the filter applied to each row.



If `dim` is greater than `ndims(x)`, then `filter` returns `x`.

Data Types: `double` | `single`

Output Arguments

`y` — Filtered data

vector | matrix | multidimensional array

Filtered data, returned as a vector, matrix, or multidimensional array of the same size as the input data, `x`.

`zf` — Final conditions for filter delays

vector | matrix | multidimensional array

Final conditions for filter delays, returned as a vector, matrix, or multidimensional array.

- If `x` is a vector, then `zf` is a column vector of length `max(length(a),length(b))-1`.
- If `x` is a matrix or multidimensional array, then `zf` is an array of column vectors of length `max(length(a),length(b))-1`, such that the number of columns in `zf` is equivalent to the number of columns in `x`.

More About

Rational Transfer Function

The input-output description of the `filter` operation on a vector in the Z-transform domain is a rational transfer function. A rational transfer function is of the form,

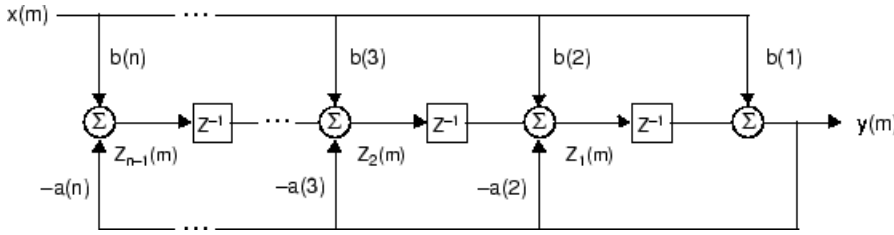
$$Y(z) = \frac{b(1) + b(2)z^{-1} + ... + b(n_b + 1)z^{-n_b}}{1 + a(2)z^{-1} + ... + a(n_a + 1)z^{-n_a}} X(z),$$

which handles both FIR and IIR filters [1]. n_a is the feedback filter order, and n_b is the feedforward filter order.

You also can express the rational transfer function as the following difference equation,

$$\begin{aligned} a(1)y(n) = {} & b(1)x(n) + b(2)x(n-1) + ... + b(n_b + 1)x(n - n_b) \\ & - a(2)y(n-1) - ... - a(n_a + 1)y(n - n_a). \end{aligned}$$

Furthermore, you can represent the rational transfer function using its direct form II transposed implementation, as in the following diagram. Due to normalization, assume `a(1) = 1`.



The operation of `filter` at sample m is given by the time domain difference equations

$$\begin{aligned} y(m) &= b(1)x(m) + z_1(m-1) \\ z_1(m) &= b(2)x(m) + z_2(m-1) - a(2)y(m) \\ \vdots \quad &= \quad \vdots \qquad \vdots \\ z_{n-2}(m) &= b(n-1)x(m) + z_{n-1}(m-1) - a(n-1)y(m) \\ z_{n-1}(m) &= b(n)x(m) - a(n)y(m). \end{aligned}$$

Tips

- If you have the Signal Processing Toolbox™, you can design a filter, `d`, using `designfilt`. Then, you can use `Y = filter(d,X)` to filter your data.

Introduced before R2006a

filter2

2-D digital filter

Syntax

```
Y = filter2(h,X)
Y = filter2(h,X,shape)
```

Description

`Y = filter2(h,X)` filters the data in `X` with the two-dimensional FIR filter in the matrix `h`. It computes the result, `Y`, using two-dimensional correlation, and returns the central part of the correlation that is the same size as `X`.

`Y = filter2(h,X,shape)` returns the part of `Y` specified by the `shape` parameter. *`shape`* is a string with one of these values:

`'full'`	Returns the full two-dimensional correlation. In this case, `Y` is larger than `X`.
`'same'`	(default) Returns the central part of the correlation. In this case, `Y` is the same size as `X`.
`'valid'`	Returns only those parts of the correlation that are computed without zero-padded edges. In this case, `Y` is smaller than `X`.

More About

Tips

Two-dimensional correlation is equivalent to two-dimensional convolution with the filter matrix rotated 180 degrees. See the Algorithm section for more information about how `filter2` performs linear filtering.

Algorithms

Given a matrix `X` and a two-dimensional FIR filter `h`, `filter2` rotates your filter matrix 180 degrees to create a convolution kernel. It then calls `conv2`, the two-dimensional convolution function, to implement the filtering operation.

`filter2` uses `conv2` to compute the full two-dimensional convolution of the FIR filter with the input matrix. By default, `filter2` then extracts the central part of the convolution that is the same size as the input matrix, and returns this as the result. If the `shape` parameter specifies an alternate part of the convolution for the result, `filter2` returns the appropriate part.

`conv2` | `filter`

Introduced before R2006a

find

Find indices and values of nonzero elements

Syntax

```
k = find(X)
k = find(X,n)
k = find(X,n,direction)

[row,col] = find( ___ )
[row,col,v] = find( ___ )
```

Description

`k = find(X)` returns a vector containing the linear indices of each nonzero element in array `X`.

- If `X` is a vector, then `find` returns a vector with the same orientation as `X`.
- If `X` is a multidimensional array, then `find` returns a column vector of the linear indices of the result.
- If `X` contains no nonzero elements or is empty, then `find` returns an empty array.

`k = find(X,n)` returns the first `n` indices corresponding to the nonzero elements in `X`.

`k = find(X,n,direction)`, where `direction` is `'last'`, finds the last `n` nonzero elements in `X`. The default for `direction` is `'first'`, which finds the first `n` nonzero elements.

`[row,col] = find( ___ )` returns the row and column subscripts of each nonzero element in array `X` using any of the input arguments in previous syntaxes.

`[row,col,v] = find( ___ )` also returns vector `v`, which contains the nonzero elements of `X`.

Examples

Zero and Nonzero Elements in Matrix

Find the nonzero elements in a 3-by-3 matrix.

```
X = [1 0 2; 0 1 1; 0 0 4]
```

```
X =

     1     0     2
     0     1     1
     0     0     4
```

```
k = find(X)
```

```
k =

     1
     5
     7
     8
     9
```

Use the logical `not` operator on `X` to locate the zeros.

```
k2 = find(~X)
```

```
k2 =

     2
     3
     4
     6
```

Elements Satisfying a Condition

Find the first five elements that are less than `10` in a 4-by-4 magic square matrix.

```
X = magic(4)
```

```
X =

    16     2     3    13
     5    11    10     8
     9     7     6    12
```

```
     4    14    15     1
```

```
k = find(X<10,5)
```

```
k =

     2
     3
     4
     5
     7
```

View the corresponding elements of `X`.

```
X(k)
```

```
ans =

     5
     9
     4
     2
     7
```

Elements Equal to Specific Values

To find a specific integer value, use the `==` operator. For instance, find the element equal to `13` in a 1-by-10 vector of odd integers.

```
x = 1:2:20
```

```
x =

     1     3     5     7     9    11    13    15    17    19
```

```
k = find(x==13)
```

```
k =

     7
```

To find a noninteger value, use a tolerance value based on your data. Otherwise, the result is sometimes an empty matrix due to floating-point roundoff error.

```
y = 0:0.1:1
```

```
y =
```

```
         0    0.1000    0.2000    0.3000    0.4000    0.5000    0.6000    0.7000    0.8
k = find(y==0.3)

k =

   Empty matrix: 1-by-0

k = find(abs(y-0.3) < 0.001)

k =

     4
```

Last Several Nonzero Elements

Create a 6-by-6 magic square matrix with all of the odd-indexed elements equal to zero.

```
X = magic(6);
X(1:2:end) = 0

X =

     0     0     0     0     0     0
     3    32     7    21    23    25
     0     0     0     0     0     0
     8    28    33    17    10    15
     0     0     0     0     0     0
     4    36    29    13    18    11
```

Locate the *last* four nonzeros.

```
k = find(X,4,'last')

k =

    30
    32
    34
    36
```

Elements Satisfying Multiple Conditions

Find the first three elements in a 4-by-4 matrix that are greater than 0 and less than 10. Specify two outputs to return the row and column subscripts to the elements.

```
X = [18 3 1 11; 8 10 11 3; 9 14 6 1; 4 3 15 21]

X =

    18     3     1    11
     8    10    11     3
     9    14     6     1
     4     3    15    21

[row,col] = find(X>0 & X<10,3)

row =

     2
     3
     4

col =

     1
     1
     1
```

The first instance is `X(2,1)`, which is `8`.

Subscripts and Values for Nonzero Elements

Find the nonzero elements in a 3-by-3 matrix. Specify three outputs to return the row subscripts, column subscripts, and element values.

```
X = [3 2 0; -5 0 7; 0 0 1]

X =

     3     2     0
    -5     0     7
     0     0     1

[row,col,v] = find(X)

row =

     1
     2
     1
```

```
     2
     3

col =

     1
     1
     2
     3
     3

v =

     3
    -5
     2
     7
     1
```

- “Find Array Elements That Meet a Condition”

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. If `X` is an empty array or has no nonzero elements, then `k` is an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

n — Number of nonzeros to find

positive integer scalar

Number of nonzeros to find, specified as a positive integer scalar. By default, `find(X,n)` looks for the first `n` nonzero elements in `X`.

direction — Search direction

`'first'` (default) | `'last'`

Search direction, specified as the string `'first'` or `'last'`. Look for the *last* `n` nonzero elements in `X` using `find(X,n,'last')`.

Output Arguments

`k` — Indices to nonzero elements

vector

Indices to nonzero elements, returned as a vector. If `X` is a row vector, then `k` is also a row vector. Otherwise, `k` is a column vector. `k` is an empty array when `X` is an empty array or has no nonzero elements.

You can return the nonzero values in `X` using `X(k)`.

`row` — Row subscripts

vector

Row subscripts, returned as a vector. Together, `row` and `col` specify the `X(row,col)` subscripts corresponding to the nonzero elements in `X`.

`col` — Column subscripts

vector

Column subscripts, returned as a vector. Together, `row` and `col` specify the `X(row,col)` subscripts corresponding to the nonzero elements in `X`.

`v` — Nonzero elements of `X`

vector

Nonzero elements of `X`, returned as a vector.

More About

Linear Indices

A linear index allows use of a single subscript to index into an array, such as `A(k)`. MATLAB treats the array as a single column vector with each column appended to the bottom of the previous column. Thus, linear indexing numbers the elements in the columns from top to bottom, left to right.

For example, consider a 3-by-3 matrix. You can reference the `A(2,2)` element with `A(5)`, and the `A(2,3)` element with `A(8)`. The linear index changes depending on the size of the array; `A(5)` returns a differently located element for a 3-by-3 matrix than it does for a 4-by-4 matrix.

The `sub2ind` and `ind2sub` functions are useful in converting between subscripts and linear indices.

Tips

- To find array elements that meet a condition, use `find` in conjunction with a relational expression. For example, `find(X<5)` returns the linear indices to the elements in `X` that are less than `5`.
- To directly find the elements in `X` that satisfy the condition `X<5`, use `X(X<5)`. Avoid function calls like `X(find(X<5))`, which unnecessarily use `find` on a logical matrix.
- When you execute `find` with a relational operation like `X>1`, it is important to remember that the result of the relational operation is a logical matrix of ones and zeros. For example, the command `[row,col,v] = find(X>1)` returns a column vector of logical `1` (`true`) values for `v`.
- The row and column subscripts, `row` and `col`, are related to the linear indices in `k` by `k = sub2ind(size(X),row,col)`.

Introduced before R2006a

findall

Find all graphics objects

Syntax

```
object_handles = findall(handle_list)
object_handles = findall(handle_list,'property','value',...)
```

Description

`object_handles = findall(handle_list)` returns the handles, including hidden handles, of all objects in the hierarchy under the objects identified in `handle_list`.

`object_handles = findall(handle_list,'property','value',...)` returns the handles of all objects in the hierarchy under the objects identified in `handle_list` that have the specified properties set to the specified values.

Examples

```
plot(1:10)
xlabel xlab
a = findall(gcf)
b = findobj(gcf)
c = findall(b,'Type','text')
% returns the xlabel handle twice
d = findobj(b,'Type','text')
% can't find the xlabel handle
```

More About

Tips

`findall` is similar to `findobj`, except that it finds objects even if their `HandleVisibility` is set to `off`.

See Also

`allchild` | `findobj`

Introduced before R2006a

findfigs

Find visible offscreen figures

Syntax

```
findfigs
```

Description

`findfigs` finds all visible figure windows whose display area is off the screen and positions them on the screen.

A window appears to the MATLAB software to be offscreen when its display area (the area not covered by the window's title bar, menu bar, and toolbar) does not appear on the screen.

This function is useful when you are bringing an application from a larger monitor to a smaller one (or one with lower resolution). Windows visible on the larger monitor may appear offscreen on a smaller monitor. Using `findfigs` ensures that all windows appear on the screen.

Introduced before R2006a

findobj

Locate graphics objects with specific properties

Syntax

```
findobj
h = findobj
h = findobj('PropertyName',PropertyValue,...)
h = findobj('PropertyName',PropertyValue,'-logicaloperator',
PropertyName',PropertyValue,...)
h = findobj('-regexp','PropertyName','regexp',...)
h = findobj('-property','PropertyName')
h = findobj(objhandles,...)
h = findobj(objhandles,'-depth',d,...)
h = findobj(objhandles,'flat','PropertyName',PropertyValue,...)
```

Description

`findobj` returns handles of the root object and all its descendants without assigning the result to a variable.

`h = findobj` returns handles of the root object and all its descendants.

`h = findobj('PropertyName',PropertyValue,...)` returns handles of all graphics objects having the property *`PropertyName`*, set to the value `PropertyValue`. You can specify more than one property/value pair, in which case, `findobj` returns only those objects having all specified values.

`h = findobj('PropertyName',PropertyValue,'-logicaloperator', PropertyName',PropertyValue,...)` applies the logical operator to the property value matching. Possible values for *`-logicaloperator`* are:

- `-and`
- `-or`
- `-xor`
- `-not`

For more information on logical operators, see “Logical Operations”.

`h = findobj('-regexp','PropertyName','regexp',...)` matches objects using regular expressions as if the value of you passed the property `PropertyName` to the `regexp` function as

`regexp(PropertyValue,'regexp')`
If a match occurs, `findobj` returns the object handle. See the `regexp` function for information on how the MATLAB software uses regular expressions.

`h = findobj('-property','PropertyName')` finds all objects having the specified property.

`h = findobj(objhandles,...)` restricts the search to objects listed in `objhandles` and their descendants.

`h = findobj(objhandles,'-depth',d,...)` specifies the depth of the search. The depth argument `d` controls how many levels under the handles in `objhandles` MATLAB traverses. Specify `d` as `inf` to get the default behavior of all levels. Specify `d` as `0` to get the same behavior as using the `flat` argument.

`h = findobj(objhandles,'flat','PropertyName',PropertyValue,...)` restricts the search to those objects listed in `objhandles` and does not search descendants.

`findobj` returns an error if a handle refers to a nonexistent graphics object.

`findobj` correctly matches any legal property value. For example,

`findobj('Color','r')`
finds all objects having a `Color` property set to `red`, `r`, or `[1 0 0]`.

When a graphics object is a descendant of more than one object identified in `objhandles`, MATLAB searches the object each time `findobj` encounters its handle. Therefore, implicit references to a graphics object can result in multiple returns of its handle.

To find handle objects that meet specified conditions, use `findobj`.

Examples

Find all line objects in the current axes:

```
h = findobj(gca,'Type','line')
```

Find all objects having a `Label` set to `'foo'` and a `String` set to `'bar'`:

```
h = findobj('Label','foo','-and','String','bar');
```

Find all objects whose `String` is not `'foo'` and is not `'bar'`:

```
h = findobj('-not','String','foo','-not','String','bar');
```

Find all objects having a `String` set to `'foo'` and a `Tag` set to `'button one'` and whose `Color` is not `'red'` or `'blue'`:

```
h = findobj('String','foo','-and','Tag','button one',...
 '-and','-not',{'Color','red','-or','Color','blue'})
```

Find all objects for which you have assigned a value to the `Tag` property (that is, the value is not the empty string `''`):

```
h = findobj('-regexp','Tag','[^'']')
```

Find all children of the current figure that have their `BackgroundColor` property set to a certain shade of gray (`[.7 .7 .7]`). This statement also searches the current figure for the matching property value pair.

```
h = findobj(gcf,'-depth',1,'BackgroundColor',[.7 .7 .7])
```

Introduced before R2006a

findstr

Find string within another, longer string

Note: `findstr` is not recommended. Use `strfind` instead.

Syntax

```
k = findstr(str1, str2)
```

Description

`k = findstr(str1, str2)` searches the longer of the two input strings for any occurrences of the shorter string, returning the starting index of each such occurrence in the double array `k`. If no occurrences are found, then `findstr` returns the empty array, `[]`.

The search performed by `findstr` is case sensitive. Any leading and trailing blanks in either input string are explicitly included in the comparison.

Unlike the `strfind` function, the order of the input arguments to `findstr` is not important. This can be useful if you are not certain which of the two input strings is the longer one.

Examples

```
s = 'Find the starting indices of the shorter string.';

findstr(s, 'the')
ans =
     6    30

findstr('the', s)
ans =
```

```
     6    30
```

Introduced before R2006a

finish

Termination file for MATLAB program

Description

When the MATLAB program quits, it runs a script called `finish.m`, if the script exists and is on the search path MATLAB uses or in the current directory. `finish.m` is a file you create that instructs MATLAB to perform any final tasks before terminating. For example, you can save the data in your workspace to a MAT-file.

`finish.m` is invoked whenever you do one of the following:

- Click the Close box in the MATLAB desktop on Microsoft Windows platforms or the equivalent on UNIX platforms
- Type `quit` or `exit` at the command prompt

Examples

Two sample termination files are provided with MATLAB in *`matlabroot`*`/toolbox/local`.

- `finishsav.m` — Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m` — Displays a dialog box allowing you to cancel quitting and saves the workspace. See also the "Confirmation Dialogs Preferences" and the option for exiting MATLAB.

To create a termination file, make a copy of one of these sample files and change the name to `finish.m`. Make sure that the file is on the MATLAB path. You can modify the file to include any operations you want the termination file to perform.

More About

Tips

When using Handle Graphics features in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible.

- “Exit MATLAB”

Introduced before R2006a

fitsdisp

Display FITS metadata

Syntax

```
fitsdisp(filename)
fitsdisp(filename,Name,Value)
```

Description

`fitsdisp(filename)` displays metadata for all the Header/Data Units (HDUs) found in the FITS file specified by `filename`.

`fitsdisp(filename,Name,Value)` displays metadata for all the Header/Data Units (HDUs) found in the FITS file with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`filename`

Text string specifying the name of an existing FITS file.

Default:

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Index'`

Positive scalar value or vector specifying the HDUs.

Default:

`'Mode'`

One of the following strings:

- `standard` – Display standard keywords
- `min` – Display only HDU types and sizes
- `full` – Display all HDU keywords

Default: `standard`

Examples

Display metadata in the 2nd HDU in the FITS file.

```
fitsdisp('tst0012.fits','Index',2);
```

Display the metadata in the 1st, 3rd, and 5th HDUs in a file.

```
fitsdisp('tst0012.fits','Index',[1 3 5]);
```

Display all metadata in the 5th HDU in a file

```
fitsdisp('tst0012.fits','Index',5,'Mode','full');
```

`fitsread` | `fitswrite` | `fitsinfo`

Introduced in R2012a

fitsinfo

Information about FITS file

Syntax

```
info = fitsinfo(filename)
```

Description

`info = fitsinfo(filename)` returns the structure, `info`, with fields that contain information about the contents of a Flexible Image Transport System (FITS) file. `filename` is a string enclosed in single quotes that specifies the name of the FITS file.

The `info` structure contains the following fields, listed in the order they appear in the structure. In addition, the info structure can also contain information about any number of optional file components, called *extensions* in FITS terminology. For more information, see "FITS File Extensions" on page 1-2665.

Field Name	Description	Return Type
`Filename`	Name of the file	String
`FileModDate`	File modification date	String
`FileSize`	Size of the file in bytes	`double`
`Contents`	List of extensions in the file in the order that they occur	Cell array of strings
`PrimaryData`	Information about the primary data in the FITS file	Structure array

PrimaryData

The `PrimaryData` field is a structure that describes the primary data in the file. The following table lists the fields in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String

Field Name	Description	Return Type
`Size`	Size of each dimension. The number of rows correspond to the value of the NAXIS2 keyword, while the number of columns correspond to the value of the NAXIS1 keyword. Any further dimensions correspond to NAXIS3, NAXIS4, and so on.	`double` array
`DataSize`	Size of the primary data in bytes	`double`
`MissingDataValue`	Value used to represent undefined data	`double`
`Intercept`	Value, used with `Slope`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	`double`
`Slope`	Value, used with `Intercept`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	`double`
`Offset`	Number of bytes from beginning of the file to the location of the first data value	`double`
`Keywords`	A number-of-keywords-by-3 cell array containing keywords, values, and comments of the header in each column	Cell array of strings

FITS File Extensions

A FITS file can also include optional extensions. If the file contains any of these extensions, the `info` structure can contain these additional fields.

- AsciiTable — Numeric information in tabular format, stored as ASCII characters
- BinaryTable — Numeric information in tabular format, stored in binary representation
- Image — A multidimensional array of pixels

- Unknown — Nonstandard extension

AsciiTable Extension

The `AsciiTable` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`Rows`	Number of rows in the table	`double`
`RowSize`	Number of characters in each row	`double`
`NFields`	Number of fields in each row	`double` array
`FieldFormat`	A 1-by-`NFields` cell containing formats in which each field is encoded. The formats are FORTRAN-77 format codes.	Cell array of strings
`FieldPrecision`	A 1-by-`NFields` cell containing precision of the data in each field	Cell array of strings
`FieldWidth`	A 1-by-`NFields` array containing the number of characters in each field	`double` array
`FieldPos`	A 1-by-`NFields` array of numbers representing the starting column for each field	`double` array
`DataSize`	Size of the data in the table in bytes	`double`
`MissingDataValue`	A 1-by-`NFields` array of numbers used to represent undefined data in each field	Cell array of strings
`Intercept`	A 1-by-`NFields` array of numbers used along with `Slope` to calculate actual data values from the array data values using the equation: `actual_value = Slope*array_value+Intercept`	`double` array
`Slope`	A 1-by-`NFields` array of numbers used with `Intercept` to calculate true data values from the array data values using the equation: `actual_value = Slope*array_value+Intercept`	`double` array

Field Name	Description	Return Type
`Offset`	Number of bytes from beginning of the file to the location of the first data value in the table	`double`
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, Values and Comments in the ASCII table header	Cell array of strings

BinaryTable Extension

The `BinaryTable` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`Rows`	Number of rows in the table	`double`
`RowSize`	Number of bytes in each row	`double`
`NFields`	Number of fields in each row	`double`
`FieldFormat`	A 1-by-`NFields` cell array containing the data type of the data in each field. The data type is represented by a FITS binary table format code.	Cell array of strings
`FieldPrecision`	A 1-by-`NFields` cell containing precision of the data in each field	Cell array of strings
`FieldSize`	A 1-by-`NFields` array, where each element contains the number of values in the Nth field	`double` array
`DataSize`	Size of the data in the Binary Table, in bytes. Includes any data past the main table.	`double`
`MissingDataValue`	An 1-by-`NFields` array of numbers used to represent undefined data in each field	Cell array of `double`
`Intercept`	A 1-by-`NFields` array of numbers used along with Slope to calculate actual data values from the array data values	`double` array

Field Name	Description	Return Type
	using the equation: `actual_value = slope*array_value+Intercept`	
`Slope`	A 1-by-`NFields` array of numbers used with Intercept to calculate true data values from the array data values using the equation: `actual_value = Slope*array_value+Intercept`	`double` array
`Offset`	Number of bytes from beginning of the file to the location of the first data value	`double`
`ExtensionSize`	Size of any data past the main table, in bytes	`double`
`ExtensionOffset`	Number of bytes from the beginning of the file to any data past the main table	`double`
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Image Extension

The `Image` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Size of each dimension. The number of rows correspond to the value of the NAXIS2 keyword, while the number of columns correspond to the value of the NAXIS1 keyword. Any further dimensions correspond to NAXIS3, NAXIS4, and so on.	`double` array
`DataSize`	Size of the data in the Image extension in bytes	`double`
`Offset`	Number of bytes from the beginning of the file to the first data value	`double`

Field Name	Description	Return Type
`MissingDataValue`	Value used to represent undefined data	`double`
`Intercept`	Value, used with `Slope`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value+Intercept`	`double`
`Slope`	Value, used with `Intercept`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	`double`
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Unknown Structure

The `Unknown` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Sizes of each dimension	`double` array
`DataSize`	Size of the data in nonstandard extensions, in bytes	`double`
`Offset`	Number of bytes from beginning of the file to the first data value	`double`
`MissingDataValue`	Representation of undefined data	`double`
`Intercept`	Value, used with `Slope`, to calculate actual data values from the array data values, using the equation: `actual_value = Slope*array_value+Intercept`	`double`

Field Name	Description	Return Type
`Slope`	Value, used with `Intercept`, to calculate actual data values from the array data values, using the equation: `actual_value = Slope*array_value+Intercept`	`double`
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Examples

Get Information About FITS File

Use `fitsinfo` to obtain information about the FITS file `tst0012.fits`. In addition to its primary data, the file also contains an example of the extensions `BinaryTable`, `Unknown`, `Image`, and `AsciiTable`.

```
S = fitsinfo('tst0012.fits')
```

```
S =
          Filename: 'matlabroot\toolbox\matlab\demos\tst0012.fits'
       FileModDate: '12-Mar-2001 18:37:46'
          FileSize: 109440
          Contents: {'Primary' 'Binary Table' 'Unknown'
'Image' 'ASCII Table'}
       PrimaryData: [1x1 struct]
       BinaryTable: [1x1 struct]
           Unknown: [1x1 struct]
             Image: [1x1 struct]
        AsciiTable: [1x1 struct]
```

View the `PrimaryData` field.

```
S.PrimaryData
```

```
ans =

              DataType: 'single'
                  Size: [109 102]
              DataSize: 44472
```

```
    MissingDataValue: []
           Intercept: 0
               Slope: 1
              Offset: 2880
            Keywords: {25x3 cell}
```

The `PrimaryData` field describes the data in the file. For example, the `Size` field indicates the data is a 109-by-102 matrix.

View the `AsciiTable` field.

```
S.AsciiTable
```

```
ans =
              Rows: 53
           RowSize: 59
           NFields: 8
       FieldFormat: {'A9' 'F6.2' 'I3' 'E10.4' 'D20.15' 'A5' 'A1' 'I4'}
    FieldPrecision: {1x8 cell}
        FieldWidth: [9 6.2000 3 10.4000 20.1500 5 1 4]
          FieldPos: [1 11 18 22 33 54 54 55]
          DataSize: 3127
  MissingDataValue: {'*' '---.--' '  *' [] '*' '*' '*' ''}
         Intercept: [0 0 -70.2000 0 0 0 0 0]
             Slope: [1 1 2.1000 1 1 1 1 1]
            Offset: 103680
          Keywords: {65x3 cell}
```

The `AsciiTable` field describes the `AsciiTable` extension. For example, using the `FieldWidth` and `FieldPos` fields you can determine the length and location of each field within a row.

`fitsread` | `fitswrite` | `fitsdisp`

Introduced before R2006a

fitsread

Read data from FITS file

Syntax

```
data = fitsread(filename)
data = fitsread(filename,extname)
data = fitsread(filename,extname,index)
data = fitsread(filename,Name,Value)
```

Description

`data = fitsread(filename)` reads the primary data of the Flexible Image Transport System (FITS) file specified by the text string `filename`. The function replaces undefined data values with `NaN` and scales numeric data by the slope and intercept values, always returning double precision values.

`data = fitsread(filename,extname)` reads data from the FITS file extension specified by `extname`.

`data = fitsread(filename,extname,index)` reads data from the FITS file extension specified by `extname` . If there is more than one of the specified extensions in the file, `index` specifies the one to read.

`data = fitsread(filename,Name,Value)` reads data from the FITS file with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`filename`

Text string specifying the name of a FITS file.

Default:

`extname`

One of the following text strings specifying the name of a data array or extension in the FITS file. To determine the contents of a FITS, view the `Contents` field of the structure returned by `fitsinfo`.

Data Arrays or Extensions

Extname	Description
`'primary'`	Read data from the primary data array.
`'asciitable'`	Read data from the ASCII Table extension. The return value, `data`, is a 1-D cell array.
`'binarytable'`	Read data from the Binary Table extension. The return value, `data`, is a 1-D cell array.
`'image'`	Read data from the Image extension.
`'unknown'`	Read data from the Unknown extension.

Default:

`index`

Numeric value specifying which extension to read, if more than one exists in the file.

Default:

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'info'`

`info` structure returned by `fitsinfo` specifying the location of data to read.

Note: Using the `info` structure returned by `fitsinfo` to specify the location of data in a FITS file can significantly improve performance, especially when reading multiple images from the file.

Default:

`'PixelRegion'`

Cell array `{rows,cols,...}` specifying the boundaries of a subimage region to read from the file. Each dimension (`rows`, `cols`) is a vector of 1-based indices given either as `START`, `[START STOP]`, or `[START INCREMENT STOP]`. This parameter is valid only for primary or image extensions.

Default:

`'raw'`

Specifies that `fitsread` should not scale the data read from the file or replace undefined values with `NaN`. Data read from the file is the same class as it is stored in the file.

Default:

`'TableColumns'`

Vector of 1-based indices specifying the columns to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

Default:

`'TableRows'`

Vector of 1-based indices specifying the rows to read from the ASCII or Binary table extension. This vector should contain unique and valid indices into the table data specified in increasing order. This parameter is valid only for ASCII or Binary extensions.

Default:

Output Arguments

`data`

Data returned from the FITS file.

Examples

Read primary data from FITS file

```
data = fitsread('tst0012.fits');

Name        Size             Bytes  Class     Attributes

data      109x102            88944  double
```

Inspect available extensions, read 'image' extension using the `extname` option.

```
info = fitsinfo('tst0012.fits');
 % List of contents, includes any extensions if present.
 disp(info.Contents);
 imageData = fitsread('tst0012.fits','image');
```

Subsample the fifth plane of 'image' extension by 2.

```
info        = fitsinfo('tst0012.fits');
 rowend      = info.Image.Size(1);
 colend      = info.Image.Size(2);
 primaryData = fitsread('tst0012.fits','image',...
               'Info', info,...
               'PixelRegion',{[1 2 rowend], [1 2 colend], 5 });
```

Read every other row from an ASCII table.

```
info      = fitsinfo('tst0012.fits');
rowend    = info.AsciiTable.Rows;
tableData = fitsread('tst0012.fits','asciitable',...
                     'Info',info,...
                     'TableRows',[1:2:rowend]);
```

Read all data for the first, second and fifth columns of the Binary table.

```
info      = fitsinfo('tst0012.fits');
rowend    = info.BinaryTable.Rows;
tableData = fitsread('tst0012.fits','binarytable',...
                     'Info',info,...
                     'TableColumns',[1 2 5]);
```

More About

extension

A FITS file contains primary data and can optionally contain any number of optional components, called *extensions* in FITS terminology.

See Also

`fitswrite` | `fitsinfo` | `fitsdisp`

Introduced before R2006a

fitswrite

Write image to FITS file

Syntax

```
fitswrite(imagedata,filename)
fitswrite(imagedata,filename,Name,Value)
```

Description

`fitswrite(imagedata,filename)` writes `imagedata` to the FITS file specified by `filename`. If `filename` does not exist, `fitswrite` creates the file as a simple FITS file. If `filename` exists, `fitswrite` overwrites the file or appends the image to the end of the file, depending on the value of the `writemode` argument.

`fitswrite(imagedata,filename,Name,Value)` writes `imagedata` to the FITS file specified by `filename` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`imagedata`

Image array.

Default:

`filename`

Text string specifying the name of an existing FITS file or the name you want to assign to a new FITS file.

Default:

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'WriteMode'`

One of these strings:

- `overwrite`
- `append`

Default: `overwrite`

`'Compression'`

One of these strings:

- `none`
- `gzip`
- `rice`
- `hcompress`
- `plio`

Default: `none`

Examples

Create a FITS file containing the red channel of an RGB image.

```
X = imread('ngc6543a.jpg');
R = X(:,:,1);
fitswrite(R,'myfile.fits');
fitsdisp('myfile.fits');
```

Create a FITS file with three images constructed from the channels of an RGB image.

```
X = imread('ngc6543a.jpg');
```

```
R = X(:,:,1);  G = X(:,:,2);  B = X(:,:,3);
fitswrite(R,'myfile.fits');
fitswrite(G,'myfile.fits','writemode','append');
fitswrite(B,'myfile.fits','writemode','append');
fitsdisp('myfile.fits');
```

`fitsinfo` | `fitsread`

Introduced in R2012a

fix

Round toward zero

Syntax

```
Y = fix(X)
```

Description

`Y = fix(X)` rounds each element of `X` to the nearest integer toward zero. For positive `X`, the behavior of `fix` is the same as `floor`. For negative `X`, the behavior of `fix` is the same as `ceil`.

Examples

Round Matrix Elements Toward Zero

```
X = [-1.9 -3.4; 1.6 2.5; -4.5 4.5]
```

```
X =

   -1.9000   -3.4000
    1.6000    2.5000
   -4.5000    4.5000
```

```
Y = fix(X)
```

```
Y =

    -1    -3
     1     2
    -4     4
```

Round Complex Numbers Toward Zero

```
X = [1.4+2.3i 3.1-2.2i -5.3+10.9i]
```

```
X =

   1.4000 + 2.3000i   3.1000 - 2.2000i  -5.3000 +10.9000i
```

```
Y = fix(X)
```

```
Y =

   1.0000 + 2.0000i   3.0000 - 2.0000i  -5.0000 +10.0000i
```

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex `X`, `fix` treats the real and imaginary parts independently.

`fix` converts logical and `char` elements of `X` into `double` values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`
Complex Number Support: Yes

matlab.unittest.fixtures

Summary of classes in MATLAB Fixtures Interface

Description

Fixtures ease creation of setup and teardown code. The `matlab.unittest.fixtures` package consists of the following customized MATLAB fixtures.

matlab.unittest.fixtures.CurrentFolderFixture	Fixture for changing current working folder
matlab.unittest.fixtures.Fixture	Interface class for test fixtures
matlab.unittest.fixtures.PathFixture	Fixture for adding a folder to the MATLAB path
matlab.unittest.fixtures.SuppressedWarningsFixture	Fixture to suppress display of warnings
matlab.unittest.fixtures.TemporaryFolderFixture	Fixture for creating a temporary folder

Related Examples

- "Write Tests Using Shared Fixtures"
- "Create Basic Custom Fixture"
- "Create Advanced Custom Fixture"

matlab.unittest.fixtures.CurrentFolderFixture class

Package: matlab.unittest.fixtures

Fixture for changing current working folder

Description

The `CurrentFolderFixture` class provides a fixture for changing the current working folder. When the test framework sets up the fixture, it changes the working folder. When the test framework tears down the fixture, it restores the working folder to its previous state.

Construction

`matlab.unittest.fixtures.CurrentFolderFixture(folder)` constructs a fixture for changing the current working folder to `folder`.

Input Arguments

`folder` — Folder to make the current working folder

string

Folder to make the current working folder, specified as a string. MATLAB throws an error if `folder` does not exist.

Properties

`Folder`

Folder to make the current working folder, specified as a string in the `folder` input argument.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Fixture to Change Current Working Folder

Create the following `changeFolderFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder `helperFiles` exists in your working folder. Create the `changeToFolder`in your working folder if it does not exist.

The `test1` function includes a call to `pwd` to demonstrate the current path changed to the `helperFiles` folder.

```
classdef changeFolderFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            import matlab.unittest.fixtures.CurrentFolderFixture

            changeToFolder = 'helperFiles';
            testCase.applyFixture(CurrentFolderFixture ...
                (changeToFolder));
            pwd
        end
    end
end
```

At the command prompt, run the test. For the purposes of this example, call `pwd` before and after `run` to show the fixture was properly torn down and the path returned to the pre-test state.

```
currentFolderBeforeTest = pwd
run(changeFolderFixtureTest);
currentFolderAfterTest = pwd
```

```
currentFolderBeforeTest =

H:\Documents\doc_examples

Running changeFolderFixtureTest

ans =

H:\Documents\doc_examples\helperFiles

.
Done changeFolderFixtureTest
```

```
__________

currentFolderAfterTest =

H:\Documents\doc_examples
```

matlab.unittest.fixtures.PathFixture | matlab.unittest.TestCase.applyFixture | matlab.unittest.fixtures

matlab.unittest.fixtures.Fixture class

Package: matlab.unittest.fixtures

Interface class for test fixtures

Description

The `Fixture` interface class is the means by which test authors create custom fixtures. Fixtures configure the environment state required for tests.

Classes deriving from the `Fixture` interface must implement the `setup` method. This method executes the changes to the environment. A fixture should restore the environment to its initial state when it is torn down. To restore the environment, use the `addTeardown` method in the `setup` method or implement the fixture's `teardown` method.

Subclasses can set the `SetupDescription` and `TeardownDescription` properties in their constructors to provide descriptions for the actions performed by the `setup` and `teardown` methods. The testing framework can display these descriptions when setting up and tearing down the fixture.

A class that derives from `Fixture` must implement the `isCompatible` method if its constructor accepts any input arguments or is otherwise configurable. `Fixture` subclasses use this method to define a notion of interchangeability of fixtures. Two `matlab.unittest.fixtures` instances of the same class are considered to be interchangeable if the `isCompatible` method returns `true`. The `TestRunner` uses the result of `isCompatible` to determine whether two fixture instances of the same class correspond to the same shared test fixture state.

Properties

`SetupDescription`

Description of fixture setup actions, specified as a string. The `SetupDescription` property describes the actions the fixture performs when the testing framework invokes the fixture's `setup` method.

`TeardownDescription`

Description of fixture teardown actions, specified as a string. The `TeardownDescription` property describes the actions the fixture performs when the testing framework invokes the fixture's `teardown` method.

Methods

log	Record diagnostic information
setup	Set up fixture
teardown	Tear down fixture
addTeardown	Dynamically add teardown routine
isCompatibile	Determine if two fixtures of the same class are interchangeable

Events

`AssertionFailed`	Triggered upon failing assertion. A `QualificationEventData` object is passed to listener callback functions.
`AssertionPassed`	Triggered upon passing assertion. A `QualificationEventData` object is passed to listener callback functions.
`AssumptionFailed`	Triggered upon failing assumption. A `QualificationEventData` object is passed to listener callback functions.
`AssumptionPassed`	Triggered upon passing assumption. A `QualificationEventData` object is passed to listener callback functions.

`FatalAssertionFailed`	Triggered upon failing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.
`FatalAssertionPassed`	Triggered upon passing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.
`ExceptionThrown`	Triggered by the `TestRunner` when an exception is thrown. An `ExceptionEventData` object is passed to listener callback functions.
`DiagnosticLogged`	Triggered by the `TestRunner` upon a call to the `log` method. A `LoggedDiagnosticEventData` object is passed to the listener callback functions.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

log

Class: matlab.unittest.fixtures.Fixture
Package: matlab.unittest.fixtures

Record diagnostic information

Syntax

```
log(f,diagnostic)
log(f,v,diagnostic)
```

Description

`log(f,diagnostic)` logs the supplied diagnostic. The log method provides a means for tests to log information during fixture setup and teardown routines. The testing framework displays logged messages only if you configure it to do so by adding an appropriate plugin, such as the `matlab.unittest.plugins.LoggingPlugin`.

`log(f,v,diagnostic)` logs the diagnostic at the specified verbosity level, `v`.

Input Arguments

`f` — Instance of fixture

`matlab.unittest.fixtures.Fixture` instance

Instance of fixture, specified as a `matlab.unittest.fixtures.Fixture`.

`diagnostic` — Diagnostic information to display upon a failure

string | function handle | `matlab.unittest.diagnostics.Diagnostic` instance

Diagnostic information to display upon a failure, specified as a string, function handle, or `matlab.unittest.diagnostics.Diagnostic` instance.

`v` — Verbosity level

2 (default) | 1 | 3 | 4 | `matlab.unittest.Verbosity` enumeration

Verbosity level, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The default verbosity level for diagnostic messages is `Concise`. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Member	Verbosity Description
1	`matlab.unittest.Verbosity.Terse`	Minimal amount of information
2	`matlab.unittest.Verbosity.Concis`	Typical amount of information
3	`matlab.unittest.Verbosity.Detail`	Supplemental amount of information
4	`matlab.unittest.Verbosity.Verbos`	Surplus of information

Examples

Log Diagnostic Information

In a file, `FormatHexFixture.m`, in your current working folder, create the following fixture.

```
classdef FormatHexFixture < matlab.unittest.fixtures.Fixture
    properties (Access=private)
        OriginalFormat
    end
    methods
        function setup(fixture)
            fixture.OriginalFormat = get(0,'Format');
            fixture.log(['The previous format setting was ',...
                fixture.OriginalFormat])
            log(fixture,'Setting Format')
            set(0,'Format','hex')
            log(fixture,3,'Format Set')
        end
        function teardown(fixture)
            log(fixture,'Resetting Format')
            set(0,'Format',fixture.OriginalFormat)
            log(fixture,3,'Original Format Restored')
        end
```

```
    end
end
```

In a file, `SampleTest.m`, in your current working folder, create the following test class.

```
classdef SampleTest < matlab.unittest.TestCase
    methods (Test)
        function test1(testCase)
            testCase.applyFixture(FormatHexFixture);
            actStr = getColumnForDisplay([1;2;3], 'Small Integers');
            expStr = ['Small Integers  '
                '3ff0000000000000'
                '4000000000000000'
                '4008000000000000'];
            testCase.verifyEqual(actStr, expStr)
        end
    end
end

function str = getColumnForDisplay(values, title)
elements = cell(numel(values)+1, 1);
elements{1} = title;
for idx = 1:numel(values)
    elements{idx+1} = displayNumber(values(idx));
end
str = char(elements);
end

function str = displayNumber(n)
str = strtrim(evalc('disp(n);'));
end
```

Run the test.

```
result = run(SampleTest);
```

```
Running SampleTest
.
Done SampleTest
__________
```

None of the logged messages are displayed because the default test runner has a verbosity level of 1 (`Terse`) and the default log message is at level 2 (`Concise`).

Create a test runner to report the diagnostics at levels 1, 2, and 3 and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin

ts = matlab.unittest.TestSuite.fromClass(?SampleTest);
runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(3);
runner.addPlugin(p);

results = runner.run(ts);
```

```
 [Concise] Diagnostic logged (2014-04-23T13:17:35): The previous format setting was sho
 [Concise] Diagnostic logged (2014-04-23T13:17:35): Setting Format
[Detailed] Diagnostic logged (2014-04-23T13:17:35): Format Set
 [Concise] Diagnostic logged (2014-04-23T13:17:35): Resetting Format
[Detailed] Diagnostic logged (2014-04-23T13:17:35): Original Format Restored
```

setup

Class: matlab.unittest.fixtures.Fixture
Package: matlab.unittest.fixtures

Set up fixture

Syntax

```
setup(f)
```

Description

`setup(f)` sets up a fixture by performing the defined environment modifications. Classes deriving from the `Fixture` interface must implement the `setup` method. This method executes the changes to the environment. A fixture should restore the environment to its initial state when it is torn down. To restore the environment, use the `addTeardown` method in the `setup` method or implement the fixture's `teardown` method.

Input Arguments

`f`

`matlab.unittest.fixtures.Fixture` instance

See Also

`matlab.unittest.fixtures.Fixture` |
`matlab.unittest.fixtures.Fixture.teardown` |
`matlab.unittest.fixtures.Fixture.addTeardown`

Related Examples

- “Create Basic Custom Fixture”
- “Create Advanced Custom Fixture”

teardown

Class: matlab.unittest.fixtures.Fixture
Package: matlab.unittest.fixtures

Tear down fixture

Syntax

```
teardown(f)
```

Description

`teardown(f)` tears down a fixture by performing the defined actions to restore the environment to the initial state.

Input Arguments

`f`

`matlab.unittest.fixtures.Fixture` instance

Alternatives

Instead of defining a `teardown` method, you can define teardown actions within the `setup` method by implementing the `addTeardown` method.

See Also

`matlab.unittest.fixtures.Fixture` |
`matlab.unittest.fixtures.Fixture.addTeardown` |
`matlab.unittest.fixtures.Fixture.setup`

Related Examples

- “Create Basic Custom Fixture”

- “Create Advanced Custom Fixture”

addTeardown

Class: matlab.unittest.fixtures.Fixture
Package: matlab.unittest.fixtures

Dynamically add teardown routine

Syntax

```
addTeardown(f,tearDownFcn)
addTeardown(f,tearDownFcn,arg1,...,argN)
```

Description

`addTeardown(f,tearDownFcn)` adds the tearDownFcn function handle that defines fixture teardown code to the Fixture instance. The teardown code is executed in the reverse order to which it is added. This is known as LIFO (or Last-In-First-Out).

`addTeardown(f,tearDownFcn,arg1,...,argN)` provides input arguments to the `tearDownFcn`.

Input Arguments

`f`

`matlab.unittest.fixtures.Fixture` instance

`tearDownFcn`

Function that defines the fixture teardown code, specified as a function handle.

`arg1,...,argN`

Input arguments required by tearDownFcn, specified by any type. The argument type is specified by the `tearDownFcn` function argument list.

Alternatives

Instead of defining teardown actions within the `setup` method by implementing the `addTeardown` method, you can implement the `teardown` method.

See Also

`matlab.unittest.fixtures.Fixture` |
`matlab.unittest.fixtures.Fixture.teardown` |
`matlab.unittest.fixtures.Fixture.setup`

Related Examples

- "Create Advanced Custom Fixture"

isCompatibile

Class: matlab.unittest.fixtures.Fixture
Package: matlab.unittest.fixtures

Determine if two fixtures of the same class are interchangeable

Syntax

```
TF = isCompatible(f1, f2)
```

Description

`TF = isCompatible(f1, f2)` determines if two fixtures of the same class are interchangeable. The `isCompatible` method returns either logical `1` (`true`) or logical `0` (`false`).

A class that derives from `Fixture` must implement the `isCompatible` method if its constructor accepts any input arguments or is otherwise configurable. `Fixture` subclasses use this method to define a notion of interchangeability of fixtures. Two `matlab.unittest.fixtures` instances of the same class are considered to be interchangeable if the `isCompatible` method returns `true`. The `TestRunner` uses the result of `isCompatible` to determine whether two fixture instances of the same class correspond to the same shared test fixture state. The test framework always calls the `isCompatible` method with two fixture instances of the same class, so the fixture author does not need to implement code to handle the case where the second fixture is a different `fixtures` class.

Input Arguments

`f`

`matlab.unittest.fixtures.Fixture` instance

Attributes

`Access`	`Protected`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

matlab.unittest.fixtures.PathFixture class

Package: matlab.unittest.fixtures

Fixture for adding a folder to the MATLAB path

Description

The `PathFixture` class provides a fixture for adding a folder to the MATLAB path. When the test framework sets up the fixture, it adds the specified folder to the path. When the test framework tears down the fixture, it restores the MATLAB path to its previous state.

Construction

`matlab.unittest.fixtures.PathFixture(folder)` constructs a fixture for adding a folder to the MATLAB path. When the test framework sets up the fixture, it adds `folder` to the path. When it tears down the fixture, it restores the MATLAB path to its previous state.

Input Arguments

`folder` — Folder to add to the MATLAB path

string

Folder to add to the MATLAB path, specified as a string. MATLAB throws an error if `folder` does not exist.

Properties

`Folder`

Folder to add to the MATLAB path, specified as a string in the `folder` input argument.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Add Directory to MATLAB Path for Testing

Create the following `addPathFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder,`helperFiles`, exists in your working folder. If it does not, define `addFolder` to be a directory that exists within your current folder.

```
classdef addPathFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            import matlab.unittest.fixtures.PathFixture

            addFolder = 'helperFiles';
            f = testCase.applyFixture(PathFixture(addFolder));
            disp(['Added to path: ' f.Folder])
        end
    end
end
```

At the command prompt, run the test.

```
run(addPathFixtureTest);
```

```
Running addPathFixtureTest
Added to path: H:\Documents\doc_examples\helperFiles
.
Done addPathFixtureTest
__________
```

After the tests finish running, the framework removes the folder from the path.

Add Directory to Path Using Shared Test Fixture

Create the following `sharedAddPathFixtureTest` class definition on your MATLAB path. This example assumes that the subfolder, `helperFiles`, exists in your working folder.

```
classdef (SharedTestFixtures={ ...
        matlab.unittest.fixtures.PathFixture('helperFiles')}) ...
        sharedAddPathFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            f = testCase.getSharedTestFixtures;
```

```
            disp(['Added to path: ' f.Folder])
        end
    end
end
```

At the command prompt, run the test.

```
run(sharedAddPathFixtureTest);
```

```
Setting up PathFixture
Done setting up PathFixture: Added 'H:\Documents\doc_examples\helperFiles' to the path.
__________

Running sharedAddPathFixtureTest
Added to path: H:\Documents\doc_examples\helperFiles
.
Done sharedAddPathFixtureTest
__________

Tearing down PathFixture
Done tearing down PathFixture: Restored the path to its original state.
__________
```

After the tests finish running, the framework removes the folder from the path.

`matlab.unittest.fixtures.CurrentFolderFixture` | `matlab.unittest.TestCase.applyFixture` | `matlab.unittest.fixtures`

matlab.unittest.fixtures.SuppressedWarningsFixture class

Package: matlab.unittest.fixtures

Fixture to suppress display of warnings

Description

The `SuppressedWarningsFixture` class provides a fixture to suppress the display of warnings. When set up, `SuppressedWarningsFixture` disables one ore more specified warnings. When torn down, the fixture restores the states of warnings to their previous values.

Construction

`matlab.unittest.fixtures.SuppressedWarningsFixture(warnIDs)` constructs a fixture to suppress the display of one or more warnings.

Input Arguments

`warnIDs` — Identifier for warnings disabled when the fixture is set up

string | cell array of strings

Warning identifiers for the warnings to be suppressed, specified as a string or cell array of strings.

Properties

`Warnings`

Warning identifiers describing warnings to suppress specified as a cell array of strings in the `warnings` input argument.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Fixture to Suppress Warnings

Suppress the warning that occurs when you try to remove a folder from the search path that is not on the search path.

Remove the folder, `folderthatisnotonpath` from your path, assuming it does not exist.

```
rmpath('folderthatisnotonpath')
```

```
Warning: "folderthatisnotonpath" not found in path.
> In rmpath at 58
```

A warning appears because `rmpath` cannot find the folder.

Suppress the warning during testing by creating the following `suppressWarningsTest` class definition on your MATLAB path.

```
classdef suppressWarningsTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            import matlab.unittest.fixtures.SuppressedWarningsFixture

            testCase.applyFixture(...
                SuppressedWarningsFixture('MATLAB:rmpath:DirNotFound'));

            % would otherwise cause warning
            rmpath('folderthatisnotonpath')
        end
    end
end
```

At the command prompt, run the test. For the purposes of this example, call `rmpath` before and after running the test to show the warning is not suppressed outside execution of the test.

```
rmpath('folderthatisnotonpath')
run(suppressWarningsTest);
rmpath('folderthatisnotonpath')
```

```
Warning: "folderthatisnotonpath" not found in path.
> In rmpath at 58
Running suppressWarningsTest
.
Done suppressWarningsTest
__________

Warning: "folderthatisnotonpath" not found in path.
> In rmpath at 58
```

Note that the call to `rmpath` within `suppressWarningsTest` does not result in a warning.

`matlab.unittest.TestCase.applyFixture` | `matlab.unittest.fixtures` | `warning`

matlab.unittest.fixtures.TemporaryFolderFixture class

Package: matlab.unittest.fixtures

Fixture for creating a temporary folder

Description

The `matlab.unittest.fixtures.TemporaryFolderFixture` provides a fixture to create a temporary folder. When the testing framework sets up the fixture, it creates the temporary folder. When it tears down the fixture, it deletes the folder and all its contents. Before it deletes the folder, the fixture clears from memory the definitions of any MATLAB-files, P-files, and MEX-files that are defined in the temporary folder.

Construction

`matlab.unittest.fixtures.TemporaryFolderFixture` constructs a fixture for creating a temporary folder.

`matlab.unittest.fixtures.TemporaryFolderFixture(Name,Value)` constructs a fixture for creating a temporary folder with additional options specified by one or more Name,Value pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'PreservingOnFailure'` — Preservation state of temporary folder and contents after test failure
`false` (default) | `true`

Indicator of whether the temporary folder and its contents are preserved in the event of a test failure, specified as `false` or `true` (`logical 0` or `1`). This property is `false` by default. You can specify it as `true` during fixture construction.

Data Types: `logical`

`'WithSuffix'` — Suffix for temporary folder name

string (default)

Suffix for temporary folder name, specified as a string.

Properties

`Folder`

Absolute path of the folder created by the fixture, specified as a string.

`PreserveOnFailure`

Indicator of whether the temporary folder and its contents are preserved in the event of a test failure. This property is `logical(0)` or `logical(1)`. It is `logical(0)` by default but is set to `logical(1)` if the `'PreservingOnFailure'` input value is set to `true` during fixture construction.

`Suffix`

Suffix used for temporary folder, specified as a string in the `Name,Value` pair argument, `'WithSuffix'`.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Temporary Folder Fixture

Create the following `tempFolderFixtureTest` class definition on your MATLAB path.

```
classdef tempFolderFixtureTest < matlab.unittest.TestCase
    methods(Test)
```

```
        function test1(testCase)
            import matlab.unittest.fixtures.TemporaryFolderFixture

            tempFolder = testCase.applyFixture(TemporaryFolderFixture);

            disp(['The temporary folder: ' tempFolder.Folder])
        end
    end
end
```

At the command prompt, run the test.

```
run(tempFolderFixtureTest);
```

```
Running tempFolderFixtureTest
The temporary folder: C:\Temp\tpfb1ae2cf_c9de_4de3_9557_00d52bfcc1b2
.
Done tempFolderFixtureTest
__________
```

The name of the temporary folder varies.

Create Temporary Folder Fixture Persisting Through Test Failure

Create the following `anotherTempFolderFixtureTest` class definition on your MATLAB path. For the purposes of this example, the `test1` function contains an assertion that causes test failure.

```
classdef anotherTempFolderFixtureTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            import matlab.unittest.fixtures.TemporaryFolderFixture

            testCase.applyFixture(TemporaryFolderFixture( ...
                'PreservingOnFailure',true,'WithSuffix','TestData'));

            % Failed assertion, perserved temporary folder
            testCase.assertEqual(1,2)
        end
    end
end
```

At the command prompt, run the test.

```
run(anotherTempFolderFixtureTest);
```

```
Running anotherTempFolderFixtureTest

================================================================================

flintmax

Largest consecutive integer in floating-point format

Syntax

```
f = flintmax
f = flintmax(precision)
```

Description

`f = flintmax` returns the largest consecutive integer in IEEE® double precision, which is `2^53`. Above this value, double-precision format does not have integer precision, and not all integers can be represented exactly.

`f = flintmax(precision)` returns the largest consecutive integer in IEEE single or double precision. `flintmax` returns `single(2^24)` for single precision and `2^53` for double precision.

Examples

Double Precision

Return the largest consecutive integer in IEEE double precision.

```
format long e
f = flintmax
```

```
f =

     9.007199254740992e+15
```

This is `2^53`.

Single Precision

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')

f =

    16777216
```

This is `single(2^24)`.

Check the class of `f`.

```
class(f)

ans =

single
```

Limit of Integer Single Precision

Above the value returned by `flintmax('single')`, not all integers can be represented exactly with single precision.

Return the largest consecutive integer in IEEE single precision.

```
f = flintmax('single')

f =

    16777216
```

This is `single(2^24)`.

Add `1` to the value returned from `flintmax`.

```
f1 = f + 1

f1 =

    16777216
```

`f1` is the same as `f`.

```
isequal(f,f1)

ans =

     1
```

Add 2 to the value returned from `flintmax`.

```
f2 = f + 2
```

```
f2 =

    16777218
```

`16777218` is represented exactly in single precision while `16777217` is not.

Input Arguments

`precision` — Floating-point precision type

`'double'` (default) | `'single'`

Floating-point precision type, specified as `'double'` or `'single'`.

Data Types: `char`

Output Arguments

`f` — Largest consecutive integer in floating-point format

scalar constant

Largest consecutive integer in floating-point format returned as a scalar constant. This constant is `2^53` for double precision and `single(2^24)` for single precision.

See Also

`eps` | `format` | `intmax` | `realmax`

flip

Flip order of elements

Syntax

```
B = flip(A)
B = flip(A,dim)
```

Description

`B = flip(A)` returns array `B` the same size as `A`, but with the order of the elements reversed. The dimension that is reordered in `B` depends on the shape of `A`:

- If `A` is vector, then `flip(A)` reverses the order of the elements along the length of the vector.
- If `A` is a matrix, then `flip(A)` reverses the elements in each column.
- If `A` is an N-D array, then `flip(A)` operates on the first dimension of `A` in which the size value is not `1`.

`B = flip(A,dim)` reverses the order of the elements in `A` along dimension `dim`. For example, if `A` is a matrix, then `flip(A,1)` reverses the elements in each column, and `flip(A,2)` reverses the elements in each row.

Examples

Flip String of Characters

```
A = 'no word, no bond, row on.';
B = flip(A)
```

```
B =

.no wor ,dnob on ,drow on
```

Flip Column Vector

```
A = [1;2;3];
```

```
B = flip(A)

B =

     3
     2
     1
```

Flip Matrix

Create a diagonal matrix, A.

```
A = diag([100 200 300])

A =

   100     0     0
     0   200     0
     0     0   300
```

Flip A without specifying the `dim` argument.

```
B = flip(A)

B =

     0     0   300
     0   200     0
   100     0     0
```

Now, flip A along the second dimension.

```
B = flip(A,2)

B =

     0     0   100
     0   200     0
   300     0     0
```

Flip N-D Array

Create a 1-by-3-by-2 array.

```
A = zeros(1,3,2);
```

```
A(:,:,1) = [1 2 3];
A(:,:,2) = [4 5 6];
A
```

```
A(:,:,1) =

     1     2     3

A(:,:,2) =

     4     5     6
```

Flip `A` without specifying the `dim` argument.

```
B = flip(A)
```

```
B(:,:,1) =

     3     2     1

B(:,:,2) =

     6     5     4
```

Now, flip `A` along the third dimension.

```
B = flip(A,3)
```

```
B(:,:,1) =

     4     5     6

B(:,:,2) =

     1     2     3
```

Flip Cell Array

Create a 3-by-2 cell array.

```
A = {'foo',1000; 999,true; 'aaa','bbb'}
```

```
A =
```

```
    'foo'    [1000]
    [999]    [   1]
    'aaa'    'bbb'
```

Flip A without specifying the `dim` argument.

```
B = flip(A)
```

```
B =

    'aaa'    'bbb'
    [999]    [   1]
    'foo'    [1000]
```

Now, flip A along the second dimension.

```
B = flip(A,2)
```

```
B =

    [1000]    'foo'
    [   1]    [999]
    'bbb'     'aaa'
```

Input Arguments

A — Input array

vector | matrix | array | cell array | table

Input array, specified as a vector, matrix, array, cell array, or table.

Example: `[1 2 3 4]`

Example: `['abcde']`

Example: `[1 2; 3 4]`

Example: `{'abcde',[1 2 3]}`

Example: `table(rand(1,5),rand(1,5))`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

The following illustration shows the difference between `dim=1` and `dim=2` when `A` is a matrix.

See Also

`fliplr` | `flipud` | `permute` | `rot90` | `transpose`

flipdim

Flip array along specified dimension

Compatibility

`flipdim` will be removed in a future release. Use `flip` instead.

Syntax

```
B = flipdim(A,dim)
```

Description

`B = flipdim(A,dim)` returns `A` with dimension `dim` flipped.

When the value of `dim` is `1`, the array is flipped row-wise down. When `dim` is `2`, the array is flipped columnwise left to right. `flipdim(A,1)` is the same as `flipud(A)`, and `flipdim(A,2)` is the same as `fliplr(A)`.

Examples

`flipdim(A,1)` where

```
A =

     1     4
     2     5
     3     6
```

produces

```
     3     6
     2     5
```

1 4

See Also

`fliplr` | `flipud` | `permute` | `rot90` | `flip`

Introduced before R2006a

fliplr

Flip array left to right

Syntax

```
B = fliplr(A)
```

Description

`B = fliplr(A)` returns `A` with its columns flipped in the left-right direction (that is, about a vertical axis).

If `A` is a row vector, then `fliplr(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a column vector, then `fliplr(A)` simply returns `A`. For multidimensional arrays, `fliplr` operates on the planes formed by the first and second dimensions.

Examples

Flip Row Vector

Create a row vector.

```
A = 1:10
```

```
A =

     1     2     3     4     5     6     7     8     9    10
```

Use `fliplr` to flip the elements of `A` in the horizontal direction.

```
B = fliplr(A)
```

```
B =

    10     9     8     7     6     5     4     3     2     1
```

The order of the elements in B is reversed compared to A.

Flip Cell Array of Strings

Create a 3-by-3 cell array of strings.

```
A = {'a' 'b' 'c'; 'd' 'e' 'f'; 'g' 'h' 'i'}
```

```
A =

    'a'    'b'    'c'
    'd'    'e'    'f'
    'g'    'h'    'i'
```

Change the order of the columns in the horizontal direction by using `fliplr`.

```
B = fliplr(A)
```

```
B =

    'c'    'b'    'a'
    'f'    'e'    'd'
    'i'    'h'    'g'
```

The order of the first and third columns of A is switched in B, while the second column remains unchanged.

Flip Multidimensional Array

Create a multidimensional array.

```
A = cat(3, [1 2; 3 4], [5 6; 7 8])
```

```
A(:,:,1) =

     1     2
     3     4

A(:,:,2) =

     5     6
     7     8
```

A is an array of size 2-by-2-by-2.

Flip the elements on each page of A in the horizontal direction.

```
B = fliplr(A)
```

```
B(:,:,1) =

     2     1
     4     3

B(:,:,2) =

     6     5
     8     7
```

The result, B, is the same size as A, but the horizontal order of the elements is flipped. The operation flips the elements on each page independently.

Input Arguments

A — Input array

vector | matrix | array | cell array | categorical array | table

Input array, specified as a vector, matrix, array, cell array, categorical array, or table of any data type.

Complex Number Support: Yes

More About

Tips

- `fliplr(A)` is equivalent to `flip(A,2)`.
- Use the `flipud` function to flip arrays in the vertical direction (that is, about a horizontal axis).
- The `flip` function can flip arrays in any direction.

See Also

`flip` | `flipud` | `rot90`

Introduced before R2006a

flipud

Flip array up to down

Syntax

```
B = flipud(A)
```

Description

`B = flipud(A)` returns `A` with its rows flipped in the up-down direction (that is, about a horizontal axis).

If `A` is a column vector, then `flipud(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a row vector, then `flipud(A)` simply returns `A`. For multidimensional arrays, `flipud` operates on the planes formed by the first and second dimensions.

Examples

Flip Column Vector

Create a column vector.

```
A=(1:10)'
```

```
A =

     1
     2
     3
     4
     5
     6
     7
     8
     9
    10
```

Use `flipud` to flip the elements of A in the vertical direction.

```
B = flipud(A)
```

```
B =

    10
     9
     8
     7
     6
     5
     4
     3
     2
     1
```

The order of the elements in B is reversed compared to A.

Flip Cell Array of Strings

Create a 3-by-3 cell array of strings.

```
A = {'a' 'b' 'c'; 'd' 'e' 'f'; 'g' 'h' 'i'}
```

```
A =

    'a'    'b'    'c'
    'd'    'e'    'f'
    'g'    'h'    'i'
```

Change the order of the rows in the vertical direction by using `flipud`.

```
B = flipud(A)
```

```
B =

    'g'    'h'    'i'
    'd'    'e'    'f'
    'a'    'b'    'c'
```

The order of the first and third rows of A is switched in B, while the second row remains unchanged.

Flip Multidimensional Array

Create a multidimensional array.

```
A = cat(3, [1 2; 3 4], [5 6; 7 8])

A(:,:,1) =

     1     2
     3     4

A(:,:,2) =

     5     6
     7     8
```

A is an array of size 2-by-2-by-2.

Flip the elements on each page of A in the vertical direction.

```
B = flipud(A)

B(:,:,1) =

     3     4
     1     2

B(:,:,2) =

     7     8
     5     6
```

The result, B, is the same size as A, but the vertical order of the elements is flipped. The operation flips the elements on each page independently.

Input Arguments

A — Input array

vector | matrix | array | cell array | categorical array | table

Input array, specified as a vector, matrix, array, cell array, categorical array, or table of any data type.
Complex Number Support: Yes

More About

Tips

- `flipud(A)` is equivalent to `flip(A,1)`.
- Use the `fliplr` function to flip arrays in the horizontal direction (that is, about a vertical axis).
- The `flip` function can flip arrays in any direction.

See Also

`flip` | `fliplr` | `rot90`

Introduced before R2006a

floor

Round toward negative infinity

Syntax

```
Y = floor(X)
```

```
Y = floor(t)
Y = floor(t,unit)
```

Description

`Y = floor(X)` rounds each element of `X` to the nearest integer less than or equal to that element.

`Y = floor(t)` rounds each element of the `duration` array `t` to the nearest number of seconds less than or equal to that element.

`Y = floor(t,unit)` rounds each element of `t` to the nearest number of the specified unit of time less than or equal to that element.

Examples

Round Matrix Elements Toward Negative Infinity

```
X = [-1.9  -0.2  3.4;  5.6  7.0  2.4+3.6i];
Y = floor(X)
```

```
Y =

  -2.0000 + 0.0000i  -1.0000 + 0.0000i   3.0000 + 0.0000i
   5.0000 + 0.0000i   7.0000 + 0.0000i   2.0000 + 3.0000i
```

Round Duration Values Toward Negative Infinity

Round each value in a `duration` array to the nearest number of seconds less than or equal to that value.

```
t = hours(8) + minutes(29:31) + seconds(1.23);
t.Format = 'hh:mm:ss.SS'
```

```
t =

   08:29:01.23   08:30:01.23   08:31:01.23
```

```
Y1 = floor(t)
```

```
Y1 =

   08:29:01.00   08:30:01.00   08:31:01.00
```

Round each value in `t` to the nearest number of hours less than or equal to that value.

```
Y2 = floor(t,'hours')
```

```
Y2 =

   08:00:00.00   08:00:00.00   08:00:00.00
```

Input Arguments

`X` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex `X`, `floor` treats the real and imaginary parts independently.

`floor` converts logical and `char` elements of `X` into `double` values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`
Complex Number Support: Yes

`t` — Input duration

`duration` array

Input duration, specified as a `duration` array.

`unit` — Unit of time

`'seconds'` (default) | `'minutes'` | `'hours'` | `'days'`

Unit of time, specified as `'seconds'`, `'minutes'`, `'hours'`, or `'days'`.

flow

Simple function of three variables

Syntax

```
v = flow
v = flow(n)
v = flow(x,y,z)
[x,y,z,v] = flow(...)
```

Description

`flow`, a function of three variables, generates fluid-flow data that is useful for demonstrating `slice`, `interp3`, and other functions that visualize scalar volume data.

`v = flow` produces a 25-by-50-by-25 array.

`v = flow(n)` produces a `n`-by-`2n`-by-`n` array.

`v = flow(x,y,z)` evaluates the speed profile at the points `x`, `y`, and `z`.

`[x,y,z,v] = flow(...)` returns the coordinates as well as the volume data.

fminbnd

Find minimum of single-variable function on fixed interval

Syntax

```
x = fminbnd(fun,x1,x2)
x = fminbnd(fun,x1,x2,options)
x = fminbnd(problem)
[x,fval] = fminbnd(...)
[x,fval,exitflag] = fminbnd(...)
[x,fval,exitflag,output] = fminbnd(...)
```

Description

`fminbnd` finds the minimum of a function of one variable within a fixed interval.

`x = fminbnd(fun,x1,x2)` returns a value `x` that is a local minimizer of the function that is described in `fun` in the interval `x1 < x < x2`. `fun` is a `function_handle`.

"Parameterizing Functions" in the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective function `fun`.

`x = fminbnd(fun,x1,x2,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminbnd` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge. See "Iterative Display" in MATLAB Mathematics for more information.
`FunValCheck`	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex` or `NaN`. `'off'` displays no error.
`MaxFunEvals`	Maximum number of function evaluations allowed.

`MaxIter`	Maximum number of iterations allowed.
`OutputFcn`	User-defined function that is called at each iteration. See "Output Functions" in MATLAB Mathematics for more information.
`PlotFcns`	Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none (`[ ]`). • `@optimplotx` plots the current point • `@optimplotfval` plots the function value • `@optimplotfunccount` plots the function count See "Plot Functions" in MATLAB Mathematics for more information.
`TolX`	Termination tolerance on `x`.

`x = fminbnd(problem)` finds the minimum for `problem`, where `problem` is a structure with the following fields:

`objective`	Objective function
`x1`	Left endpoint
`x2`	Right endpoint
`solver`	`'fminbnd'`
`options`	Options structure created using `optimset`

`[x,fval] = fminbnd(...)` returns the value of the objective function computed in `fun` at `x`.

`[x,fval,exitflag] = fminbnd(...)` returns a value `exitflag` that describes the exit condition of `fminbnd`:

`1`	`fminbnd` converged to a solution `x` based on `options.TolX`.
`0`	Maximum number of function evaluations or iterations was reached.
`-1`	Algorithm was terminated by the output function.
`-2`	Bounds are inconsistent (`x1 > x2`).

`[x,fval,exitflag,output] = fminbnd(...)` returns a structure `output` that contains information about the optimization in the following fields:

`algorithm`	`'golden section search, parabolic interpolation'`
`funcCount`	Number of function evaluations
`iterations`	Number of iterations
`message`	Exit message

Arguments

`fun` is the function to be minimized. `fun` accepts a scalar `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for a function file

```
x = fminbnd(@myfun,x1,x2);
```

where `myfun.m` is a function file such as

```
function f = myfun(x)
f = ...         % Compute function value at x.
```

or as a function handle for an anonymous function:

```
x = fminbnd(@(x) sin(x*x),x1,x2);
```

Other arguments are described in the syntax descriptions above.

Examples

`x = fminbnd(@cos,3,4)` computes π to a few decimal places and gives a message on termination.

```
[x,fval,exitflag] = ...
   fminbnd(@cos,3,4,optimset('TolX',1e-12,'Display','off'))
```

computes π to about 12 decimal places, suppresses output, returns the function value at `x`, and returns an `exitflag` of 1.

The argument `fun` can also be a function handle for an anonymous function. For example, to find the minimum of the function $f(x) = x^3 - 2x - 5$ on the interval `(0,2)`, create an anonymous function `f`

```
f = @(x)x.^3-2*x-5;
```

Then invoke `fminbnd` with

```
x = fminbnd(f, 0, 2)
```

The result is

```
x =
    0.8165
```

The value of the function at the minimum is

```
y = f(x)
```

```
y =
   -6.0887
```

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following function file:

```
function f = myfun(x,a)
f = (x - a)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminbnd`. To optimize for a specific value of `a`, such as `a = 1.5`.

1. Assign the value to `a`.

   ```
   a = 1.5; % define parameter first
   ```

2. Call `fminbnd` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

   ```
   x = fminbnd(@(x) myfun(x,a),0,1)
   ```

Limitations

The function to be minimized must be continuous. `fminbnd` may only give local solutions.

`fminbnd` often exhibits slow convergence when the solution is on a boundary of the interval.

`fminbnd` only handles real variables.

More About

Algorithms

`fminbnd` is a function file. Its algorithm is based on golden section search and parabolic interpolation. Unless the left endpoint x_1 is very close to the right endpoint x_2, `fminbnd` never evaluates `fun` at the endpoints, so `fun` need only be defined for x in the interval $x_1 < x < x_2$.

If the minimum actually occurs at x_1 or x_2, `fminbnd` returns a point `x` in the interior of the interval (x_1,x_2) that is close to the minimizer. In this case, the distance of `x` from the minimizer is no more than `2*(TolX + 3*abs(x)*sqrt(eps))`. See [1] or [2] for details about the algorithm.

`fminsearch` | `fzero` | `optimset` | `function_handle`

Introduced before R2006a

fminsearch

Find minimum of unconstrained multivariable function using derivative-free method

Syntax

```
x = fminsearch(fun,x0)
x = fminsearch(fun,x0,options)
x = fminsearch(problem)
[x,fval] = fminsearch(...)
[x,fval,exitflag] = fminsearch(...)
[x,fval,exitflag,output] = fminsearch(...)
```

Description

`fminsearch` finds the minimum of a scalar function of several variables, starting at an initial estimate. This is generally referred to as *unconstrained nonlinear optimization*.

`x = fminsearch(fun,x0)` starts at the point `x0` and returns a value `x` that is a local minimizer of the function described in `fun`. `x0` can be a scalar, vector, or matrix. `fun` is a `function_handle`.

"Parameterizing Functions" in the MATLAB Mathematics documentation explains how to pass additional parameters to your objective function `fun`. See also "Example 2" on page 1-2741 and "Example 3" on page 1-2742 below.

`x = fminsearch(fun,x0,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminsearch` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge. See "Iterative Display" in MATLAB Mathematics for more information.

`FunValCheck`	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex`, `Inf` or `NaN`. `'off'` (the default) displays no error.
`MaxFunEvals`	Maximum number of function evaluations allowed
`MaxIter`	Maximum number of iterations allowed
`OutputFcn`	User-defined function that is called at each iteration. See "Output Functions" in MATLAB Mathematics for more information.
`PlotFcns`	Plots various measures of progress while the algorithm executes, select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none (`[ ]`). • `@optimplotx` plots the current point • `@optimplotfval` plots the function value • `@optimplotfunccount` plots the function count See "Plot Functions" in MATLAB Mathematics for more information.
`TolFun`	Termination tolerance on the function value
`TolX`	Termination tolerance on `x`

`x = fminsearch(problem)` finds the minimum for `problem`, where `problem` is a structure with the following fields:

`objective`	Objective function
`x0`	Initial point for `x`
`solver`	`'fminsearch'`
`options`	Options structure created using `optimset`

`[x,fval] = fminsearch(...)` returns in `fval` the value of the objective function `fun` at the solution `x`.

`[x,fval,exitflag] = fminsearch(...)` returns a value `exitflag` that describes the exit condition of `fminsearch`:

`1`	`fminsearch` converged to a solution `x`.
`0`	Maximum number of function evaluations or iterations was reached.
`-1`	Algorithm was terminated by the output function.

`[x,fval,exitflag,output] = fminsearch(...)` returns a structure `output` that contains information about the optimization in the following fields:

`algorithm`	`'Nelder-Mead simplex direct search'`
`funcCount`	Number of function evaluations
`iterations`	Number of iterations
`message`	Exit message

Arguments

`fun` is the function to be minimized. It accepts an input `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for a function file

```
x = fminsearch(@myfun, x0)
```

where `myfun` is a function file such as

```
function f = myfun(x)
f = ...            % Compute function value at x
```

or as a function handle for an anonymous function, such as

```
x = fminsearch(@(x)sin(x^2), x0);
```

Other arguments are described in the syntax descriptions above.

Examples

Example 1

The Rosenbrock banana function is a classic test example for multidimensional minimization:

$$f(x) = 100\left(x_2 - x_1^2\right)^2 + (1 - x_1)^2 .$$

The minimum is at `(1,1)` and has the value `0`. The traditional starting point is `(-1.2,1)`. The anonymous function shown here defines the function and returns a function handle called `banana`:

```
banana = @(x)100*(x(2)-x(1)^2)^2+(1-x(1))^2;
```

Pass the function handle to `fminsearch`:

```
[x,fval] = fminsearch(banana,[-1.2, 1])
```

This produces

```
x =

    1.0000    1.0000

fval =

    8.1777e-010
```

This indicates that the minimizer was found to at least four decimal places with a value near zero.

Example 2

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following function file:

```
function f = myfun(x,a)
f = x(1)^2 + a*x(2)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminsearch`. To optimize for a specific value of `a`, such as `a = 1.5`.

1. Assign the value to `a`.

   ```
   a = 1.5; % define parameter first
   ```

2. Call `fminsearch` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

```
x = fminsearch(@(x) myfun(x,a),[0,1])
```

Example 3

You can modify the first example by adding a parameter a to the second term of the banana function:

$$f(x) = 100\left(x_2 - x_1^2\right)^2 + (a - x_1)^2.$$

This changes the location of the minimum to the point `[a,a^2]`. To minimize this function for a specific value of `a`, for example `a = sqrt(2)`, create a one-argument anonymous function that captures the value of `a`.

```
a = sqrt(2);
banana = @(x)100*(x(2)-x(1)^2)^2+(a-x(1))^2;
```

Then the statement

```
[x,fval] = fminsearch(banana, [-1.2, 1], ...
   optimset('TolX',1e-8));
```

seeks the minimum `[sqrt(2), 2]` to an accuracy higher than the default on `x`.

Limitations

`fminsearch` can often handle discontinuity, particularly if it does not occur near the solution. fminsearch may only give local solutions.

`fminsearch` only minimizes over the real numbers, that is, x must only consist of real numbers and $f(x)$ must only return real numbers. When x has complex variables, they must be split into real and imaginary parts.

More About

Algorithms

fminsearch uses the simplex search method of Lagarias et al. [1]. This is a direct search method that does not use numerical or analytic gradients.

If `n` is the length of `x`, a simplex in `n`-dimensional space is characterized by the `n+1` distinct vectors that are its vertices. In two-space, a simplex is a triangle; in three-space, it is a pyramid. At each step of the search, a new point in or near the current simplex is generated. The function value at the new point is compared with the function's values at the vertices of the simplex and, usually, one of the vertices is replaced by the new point, giving a new simplex. This step is repeated until the diameter of the simplex is less than the specified tolerance.

For more information, see “fminsearch Algorithm”.

- anonymous function

`fminbnd` | `optimset` | `function_handle`

Introduced before R2006a

fopen

Open file, or obtain information about open files

Syntax

```
fileID = fopen(filename)
fileID = fopen(filename,permission)
fileID = fopen(filename,permission,machinefmt,encodingIn)
[fileID,errmsg] = fopen( ___ )

fIDs = fopen('all')

filename = fopen(fileID)
[filename,permission,machinefmt,encodingOut] = fopen(fileID)
```

Description

`fileID = fopen(filename)` opens the file, `filename`, for binary read access, and returns an integer file identifier equal to or greater than 3. MATLAB reserves file identifiers `0`, `1`, and `2` for standard input, standard output (the screen), and standard error, respectively.

If `fopen` cannot open the file, then `fileID` is `-1`.

`fileID = fopen(filename,permission)` opens the file with the type of access specified by `permission`.

`fileID = fopen(filename,permission,machinefmt,encodingIn)` additionally specifies the order for reading or writing bytes or bits in the file using the `machinefmt` argument. The optional `encodingIn` argument specifies the character encoding scheme associated with the file.

`[fileID,errmsg] = fopen( ___ )` additionally returns a system-dependent error message if `fopen` fails to open the file. Otherwise, `errmsg` is an empty string. You can use this syntax with any of the input arguments of the previous syntaxes.

`fIDs = fopen('all')` returns a row vector containing the file identifiers of all open files. The identifiers reserved for standard input, output, and error are not included. The number of elements in the vector is equal to the number of open files.

`filename = fopen(fileID)` returns the file name that a previous call to `fopen` used when it opened the file specified by `fileID`. The output filename is resolved to the full path. The `fopen` function does not read information from the file to determine the output value.

`[filename,permission,machinefmt,encodingOut] = fopen(fileID)` additionally returns the permission, machine format, and encoding that a previous call to `fopen` used when it opened the specified file. If the file was opened in binary mode, `permission` includes the letter `'b'`. The `encodingOut` output is a standard encoding scheme name. `fopen` does not read information from the file to determine these output values. An invalid `fileID` returns empty strings for all output arguments.

Examples

Open File and Pass Identifier to File I/O Function

Open a file and pass the file identifier to the `fgetl` function to read data.

Open the file, `airfoil.m`, and obtain the file identifier.

```
fileID = fopen('airfoil.m');
```

Pass the `fileID` to the `fgetl` function to read one line from the file. Then, close the file.

```
tline = fgetl(fileID);
fclose(fileID)
```

Request Name of File to Open

Create a prompt to request the name of a file to open. If `fopen` cannot open the file, display the relevant error message.

```
fileID = -1;
errmsg = '';
while fileID < 0
   disp(errmsg);
   filename = input('Open file: ', 's');
   [fileID,errmsg] = fopen(filename);
```

```
end
```

Open File for Writing and Specify Access Type, Writing Order, Character Encoding

Open a file to write to a file using the Shift-JIS character encoding.

```
fileID = fopen('japanese_out.txt','w','n','Shift_JIS');
```

The `'w'` input specifies write access, the `'n'` input specifies native byte ordering, and `'Shift_JIS'` specifies the character encoding scheme.

Get Information About Open Files

Suppose you previously opened a file using `fopen`.

```
fileID = fopen('airfoil.m');
```

Get the file identifiers of all open files.

```
fIDs = fopen('all')
```

```
fIDs =

     3
```

Get the file name and character encoding for the open file. Use ~ in place of output arguments you want to omit.

```
[filename,~,~,encoding] = fopen(3)
```

```
filename =

matlabroot\toolbox\matlab\demos\airfoil.m

encoding =

windows-1252
```

The output shown here is representative. Your results might differ.

Input Arguments

`filename` — Name of file to open

string

Name of the file to open, including the file extension, specified as a string. If the file is not in the current folder, `filename` must include a full or a relative path.

On UNIX systems, if `filename` begins with `'~/'` or `'~username/'`, the `fopen` function expands the path to the current or specified user's home directory, respectively.

- If you open a file with read access and the file is not in the current folder, then `fopen` searches along the MATLAB search path.
- If you open a file with write or append access and the file is not in the current folder, then `fopen` creates a file in the current directory.

Example: `'myFile.txt'`

Data Types: `char`

`permission` — File access type

`'r'` (default) | `'w'` | `'a'` | `'r+'` | `'w+'` | `'a+'` | `'A'` | `'W'` | ...

File access type, specified as a string. You can open a file in binary mode or in text mode. On UNIX systems, both translation modes have the same effect. To open a file in binary mode, specify one of the following strings.

`'r'`	Open file for reading.
`'w'`	Open or create new file for writing. Discard existing contents, if any.
`'a'`	Open or create new file for writing. Append data to the end of the file.
`'r+'`	Open file for reading and writing.
`'w+'`	Open or create new file for reading and writing. Discard existing contents, if any.
`'a+'`	Open or create new file for reading and writing. Append data to the end of the file.
`'A'`	Append without automatic flushing of the current output buffer. (Used with tape drives.)
`'W'`	Write without automatic flushing of the current output buffer. (Used with tape drives.)

To open files in text mode, attach the letter `'t'` to the `permission` argument, such as `'rt'` or `'wt+'`.

On Windows systems, in text mode:

- Read operations that encounter a carriage return followed by a newline character (`'\r\n'`) remove the carriage return from the input.
- Write operations insert a carriage return before any newline character in the output.

Open or create a new file in text mode if you want to write to it in MATLAB and then open it in Microsoft Notepad, or any text editor that does not recognize `'\n'` as a newline sequence. When writing to the file, end each line with `'\r\n'`. For an example, see `fprintf`. Otherwise, open files in binary mode for better performance.

To read and write to the same file:

- Open the file with a value for `permission` that includes a plus sign, `'+'`.
- Call `fseek` or `frewind` between read and write operations. For example, do not call `fread` followed by `fwrite`, or `fwrite` followed by `fread`, unless you call `fseek` or `frewind` between them.

`machinefmt` — Order for reading or writing bytes or bits

`'n'` (default) | `'b'` | `'l'` | `'s'` | `'a'` | ...

Order for reading or writing bytes or bits in the file, specified as one of the following strings.

`'n'` or `'native'`	Your system byte ordering (default)
`'b'` or `'ieee-be'`	Big-endian ordering
`'l'` or `'ieee-le'`	Little-endian ordering
`'s'` or `'ieee-be.l64'`	Big-endian ordering, 64-bit long data type
`'a'` or `'ieee-le.l64'`	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

`encodingIn` — Character encoding

`'UTF-8'` | `'ISO-8859-1'` | `'windows-1251'` | `'windows-1252'` | ...

Character encoding to use for subsequent read and write operations, including `fscanf`, `fprintf`, `fgetl`, `fgets`, `fread`, and `fwrite`, specified as one of the following strings.

`'Big5'`	`'ISO-8859-1'`	`'windows-932'`
`'GB2312'`	`'ISO-8859-2'`	`'windows-936'`

'EUC-KR'	'ISO-8859-3'	'windows-949'
'EUC-JP'	'ISO-8859-4'	'windows-950'
'GBK'	'ISO-8859-9'	'windows-1250'
'KSC_5601'	'ISO-8859-13'	'windows-1251'
'Macintosh'	'ISO-8859-15'	'windows-1252'
'Shift_JIS'		'windows-1253'
'US-ASCII'		'windows-1254'
'UTF-8'		'windows-1257'

The default encoding is system-dependent.

If you specify a value for encoding that is not in the list of supported values, MATLAB issues a warning. Specifying other encoding names sometimes (but not always) produces correct results.

Data Types: `char`

`fileID` — File identifier of an open file

integer

File identifier of an open file, specified as an integer.

Data Types: `double`

More About

Tips

- In most cases, it is not necessary to open a file in text mode. MATLAB import functions, all UNIX applications, and Microsoft Word and WordPad recognize `'\n'` as a newline indicator.

`fclose` | `feof` | `ferror` | `fprintf` | `fread` | `frewind` | `fscanf` | `fseek` | `ftell` | `fwrite`

Introduced before R2006a

fopen (serial)

Connect serial port object to device

Syntax

```
fopen(obj)
```

Description

`fopen(obj)` connects the serial port object, `obj` to the device.

Examples

This example creates the serial port object `s`, connects `s` to the device using `fopen`, writes and reads text data, and then disconnects `s` from the device. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fclose(s)
```

More About

Tips

Before you can perform a read or write operation, `obj` must be connected to the device with the `fopen` function. When `obj` is connected to the device:

- Data remaining in the input buffer or the output buffer is flushed.
- The `Status` property is set to `open`.
- The `BytesAvailable`, `ValuesReceived`, `ValuesSent`, and `BytesToOutput` properties are set to 0.

An error is returned if you attempt to perform a read or write operation while `obj` is not connected to the device. You can connect only one serial port object to a given device.

Some properties are read-only while the serial port object is open (connected), and must be configured before using `fopen`. Examples include `InputBufferSize` and `OutputBufferSize`. Refer to the property reference pages to determine which properties have this constraint.

The values for some properties are verified only after `obj` is connected to the device. If any of these properties are incorrectly configured, then an error is returned when `fopen` is issued and `obj` is not connected to the device. Properties of this type include `BaudRate`, and are associated with device settings.

`fclose` | `BytesAvailable` | `BytesToOutput` | `Status` | `ValuesReceived` | `ValuesSent`

Introduced before R2006a

for

Execute statements specified number of times

Syntax

```
for index = values
   statements
end
```

Description

`for index = values, statements, end` executes a group of statements in a loop for a specified number of times. *`values`* has one of the following forms:

- *`initVal`*`:`*`endVal`* — Increment the *`index`* variable from *`initVal`* to *`endVal`* by `1`, and repeat execution of *`statements`* until *`index`* is greater than *`endVal`*.
- *`initVal`*`:`*`step`*`:`*`endVal`* — Increment *`index`* by the value *`step`* on each iteration, or decrements *`index`* when *`step`* is negative.
- *`valArray`* — Create a column vector, *`index`*, from subsequent columns of array *`valArray`* on each iteration. For example, on the first iteration, *`index`* `=` *`valArray`*`(:,1)`. The loop executes a maximum of *`n`* times, where *`n`* is the number of columns of *`valArray`*, given by `numel(`*`valArray`*`,1,:)`. The input *`valArray`* can be of any MATLAB data type, including a string, cell array, or struct.

Examples

Assign Matrix Values

Create a Hilbert matrix of order 10.

```
s = 10;
H = zeros(s);

for c = 1:s
    for r = 1:s
```

```
        H(r,c) = 1/(r+c-1);
    end
end
```

Decrement Values

Step by increments of `-0.2`, and display the values.

```
for v = 1.0:-0.2:0.0
   disp(v)
end
```

```
     1

    0.8000

    0.6000

    0.4000

    0.2000

     0
```

Execute Statements for Specified Values

```
for v = [1 5 8 17]
   disp(v)
end
```

```
     1

     5

     8

    17
```

Repeat Statements for Each Matrix Column

```
for I = eye(4,3)
    disp('Current unit vector:')
    disp(I)
```

```
end

Current unit vector:
     1
     0
     0
     0

Current unit vector:
     0
     1
     0
     0

Current unit vector:
     0
     0
     1
     0
```

More About

Tips

- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- Avoid assigning a value to the *`index`* variable within the loop statements. The `for` statement overrides any changes made to *`index`* within the loop.
- To iterate over the values of a single column vector, first transpose it to create a row vector.

Introduced before R2006a

format

Set Command Window output display format

Syntax

```
format style
format
```

Description

`format style` changes the output display format in the Command Window to the format specified by `style`.

`format`, by itself, resets the output format to the default, which is the short, fixed-decimal format for floating-point notation and loose line spacing for all output lines.

Numeric formats affect only how numbers appear in Command Window output, not how MATLAB computes or saves them.

Examples

Long Format

Set the output format to the long fixed-decimal format and display the value of `pi`.

```
format long
pi
```

```
ans =

   3.141592653589793
```

Reset Format to Default

Set the output format to the short engineering format with compact line spacing, and then reset the format to the default.

```
format shortEng
format compact
x = rand(3)

x =
   814.7237e-003   913.3759e-003   278.4982e-003
   905.7919e-003   632.3592e-003   546.8815e-003
   126.9868e-003    97.5404e-003   957.5068e-003

format
x

x =

    0.8147    0.9134    0.2785
    0.9058    0.6324    0.5469
    0.1270    0.0975    0.9575
```

Hexadecimal Format

Display the maximum values for integers and real numbers in hexadecimal format.

```
format hex
intmax('uint64')

ans =

   ffffffffffffffff

realmax

ans =

   7fefffffffffffff
```

Short and Long Engineering Notation

Display the difference between `shortEng` and `longEng` formats.

Set the output format to `shortEng`.

```
format shortEng
```

Create a variable and increase its value by a multiple of 10 each time through a `for` loop.

```
A = 5.123456789;
for k = 1:10
   disp(A)
   A = A*10;
end
```

```
     5.1235e+000

    51.2346e+000

   512.3457e+000

     5.1235e+003

    51.2346e+003

   512.3457e+003

     5.1235e+006

    51.2346e+006

   512.3457e+006

     5.1235e+009
```

The values display with 4 digits after the decimal point and an exponent that is a multiple of 3.

Set the output format to the long engineering format and view the same values.

```
format longEng
```

```
A = 5.123456789;
for k = 1:10
   disp(A)
   A = A*10;
end
```

```
    5.12345678900000e+000
```

```
   51.2345678900000e+000

   512.345678900000e+000

   5.12345678900000e+003

   51.2345678900000e+003

   512.345678900000e+003

   5.12345678900000e+006

   51.2345678900000e+006

   512.345678900000e+006

   5.12345678900000e+009
```

The values display with 15 digits and an exponent that is a multiple of 3.

Large Data Range Format

Use the `shortG` format when some of the values in an array are short numbers and some have large exponents. The `shortG` format picks whichever of `short` or `shortE` has the most compact display.

Create a variable and display output in the `short` format, which is the default.

```
x = [25 56 255 9876899999];
format short
x
```

```
x =

   1.0e+09 *

    0.0000    0.0000    0.0000    9.8769
```

Set the format to `shortG` and redisplay the values.

```
format shortG
```

```
x
```

```
x =

          25          56         255   9.8769e+09
```

Get Current Format

Get the current numeric format.

```
f = get(0,'Format')
```

```
f =

shortG
```

Get the current line spacing, which can be set to `loose` or `compact`.

```
S = get(0,'FormatSpacing')
```

```
S =

loose
```

- "Format Output in Command Window"

Input Arguments

`style` — Output display format

`short` (default) | `long` | `shortE` | `longE` | ...

Output display format, specified by a string from the tables below.

Numeric Format

These styles control the output display format for numeric variables.

Style	Result	Example
`short` (default)	Short, fixed-decimal format with 4 digits after the decimal point.	`3.1416`

Style	Result	Example
`long`	Long, fixed-decimal format with 15 digits after the decimal point for `double` values, and 7 digits after the decimal point for `single` values.	`3.141592653589793`
`shortE`	Short scientific notation with 4 digits after the decimal point.	`3.1416e+00`
`longE`	Long scientific notation with 15 digits after the decimal point for `double` values, and 7 digits after the decimal point for `single` values.	`3.141592653589793e+00`
`shortG`	`short` or `shortE`, whichever is more compact.	`3.1416`
`longG`	`long` or `longE`, whichever is more compact.	`3.14159265358979`
`shortEng`	Short engineering notation (exponent is a multiple of 3) with 4 digits after the decimal point.	`3.1416e+000`
`longEng`	Long engineering notation (exponent is a multiple of 3) with 15 significant digits.	`3.14159265358979e+000`
`+`	Positive/Negative format with `+`, `-`, and blank characters displayed for positive, negative, and zero elements.	`+`
`bank`	Currency format with 2 digits after the decimal point.	`3.14`
`hex`	Hexadecimal representation of a binary double-precision number.	`400921fb54442d18`
`rat`	Ratio of small integers.	`355/113`

Line Spacing Format

Style	Result	Example

`compact`	Suppress excess blank lines to show more output on a single screen.	`theta = pi/2`
		`theta =`
		`  1.5708`

Style	Result	Example

`loose`	Add blank lines to make output more readable.	`theta = pi/2`
		`theta =`
		`  1.5708`

More About

Tips

- The specified format applies only to the current MATLAB session. To maintain a format across sessions, choose a **Numeric format** or **Numeric display** option in the Command Window Preferences.
- You can insert a space between `short` or `long` and the presentation type, for instance, `format short E`.
- MATLAB always displays integer data types to the appropriate number of digits for the data type. For example, MATLAB uses 3 digits to display `int8` data types (for instance, -128:127). Setting the output format to `short` or `long` does not affect the display of integer-type variables.
- Integer-valued, floating-point numbers with a maximum of 9 digits do not display in scientific notation.
- If you are displaying a matrix with a wide range of values, consider using `shortG`. See “Large Data Range Format” on page 1-2758.

Introduced before R2006a

fplot

Plot function between specified limits

Syntax

```
fplot(fun,limits)
fplot(fun,limits,LineSpec)
fplot(fun,limits,tol)
fplot(fun,limits,tol,LineSpec)
fplot(fun,limits,n)
fplot(fun,lims,...)
fplot(axes_handle,...)
[X,Y] = fplot(fun,limits,...)
```

Description

`fplot` plots a function between specified limits. The function must be of the form $y = f(x)$, where x is a vector whose range specifies the limits, and `y` is a vector the same size as `x` and contains the function's value at the points in x (see the first example). If the function returns more than one value for a given x, then y is a matrix whose columns contain each component of $f(x)$ (see the second example).

`fplot(fun,limits)` plots `fun` between the limits specified by `limits`. `limits` is a vector specifying the x-axis limits (`[xmin xmax]`), or the x- and y-axes limits, (`[xmin xmax ymin ymax]`).

`fun` must be

- The name of a function
- A string with variable `x` that may be passed to `eval`, such as `'sin(x)'`, `'diric(x,10)'`, or `'[sin(x),cos(x)]'`
- A function handle

The function $f(x)$ must return a row vector for each element of vector x. For example, if $f(x)$ returns `[f1(x),f2(x),f3(x)]` then for input `[x1;x2]` the function should return the matrix

```
f1(x1) f2(x1) f3(x1)
f1(x2) f2(x2) f3(x2)
```

`fplot(fun,limits,LineSpec)` plots `fun` using the line specification `LineSpec`.

`fplot(fun,limits,tol)` plots `fun` using the relative error tolerance `tol` (the default is `2e-3`, i.e., 0.2 percent accuracy).

`fplot(fun,limits,tol,LineSpec)` plots `fun` using the relative error tolerance `tol` and a line specification that determines line type, marker symbol, and color. See `LineSpec` for more information.

`fplot(fun,limits,n)` with `n >= 1` plots the function with a minimum of `n+1` points. The default `n` is `1`. The maximum step size is restricted to be `(1/n)*(xmax-xmin)`.

`fplot(fun,lims,...)` accepts combinations of the optional arguments `tol`, `n`, and `LineSpec`, in any order.

`fplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

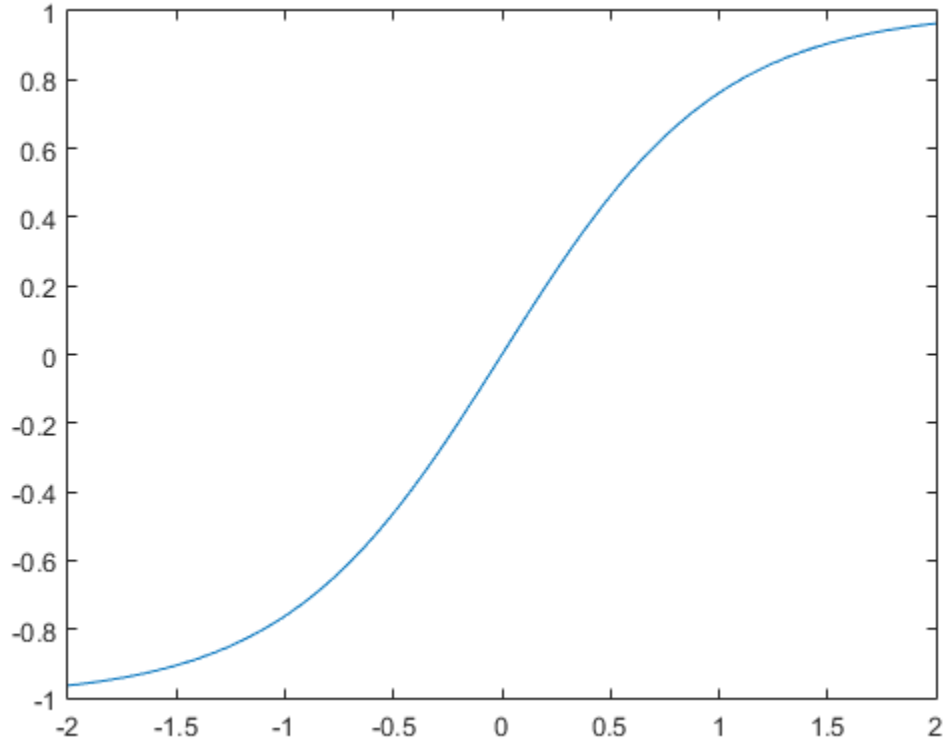
`[X,Y] = fplot(fun,limits,...)` returns the abscissas and ordinates for `fun` in `X` and `Y`. No plot is drawn on the screen; however, you can plot the function using `plot(X,Y)`.

Examples

MATLAB® Function Handle

Plot the hyperbolic tangent function from -2 to 2 using the MATLAB® function `tanh`.

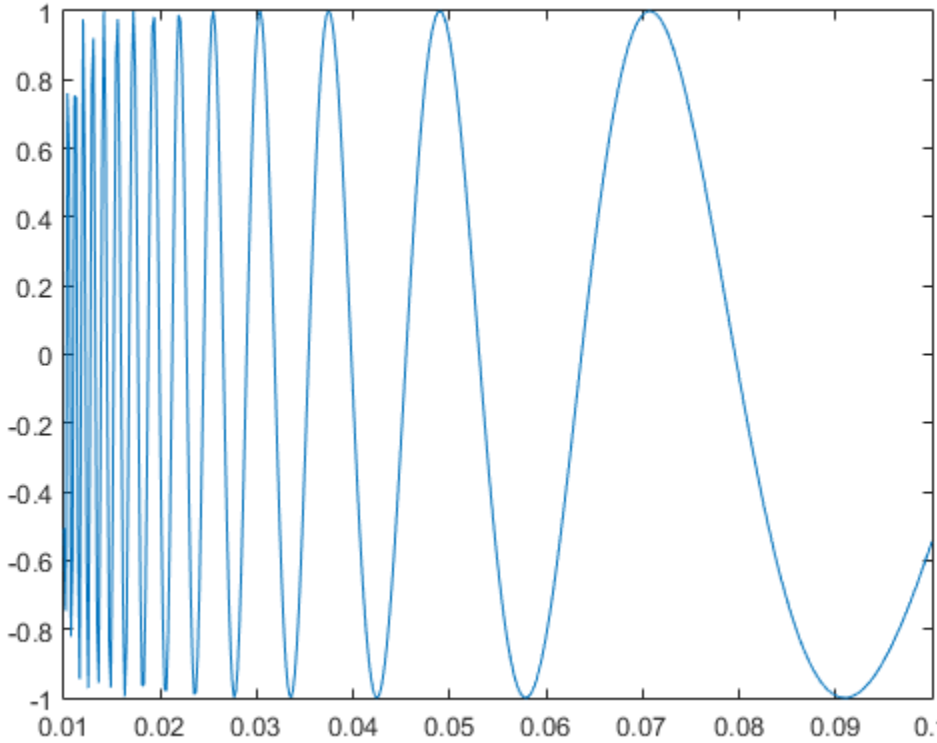
```
fh = @tanh;
fplot(fh,[-2,2])
```



Function Handle Created From Anonymous Function

Create a function handle from an anonymous function. Plot the function from 0.01 to 0.1.

```
sn = @(x) sin(1./x);
fplot(sn,[0.01,0.1])
```



Function Handle Created From Custom Function File

Create a file named `myfun.m` that contains the following code.

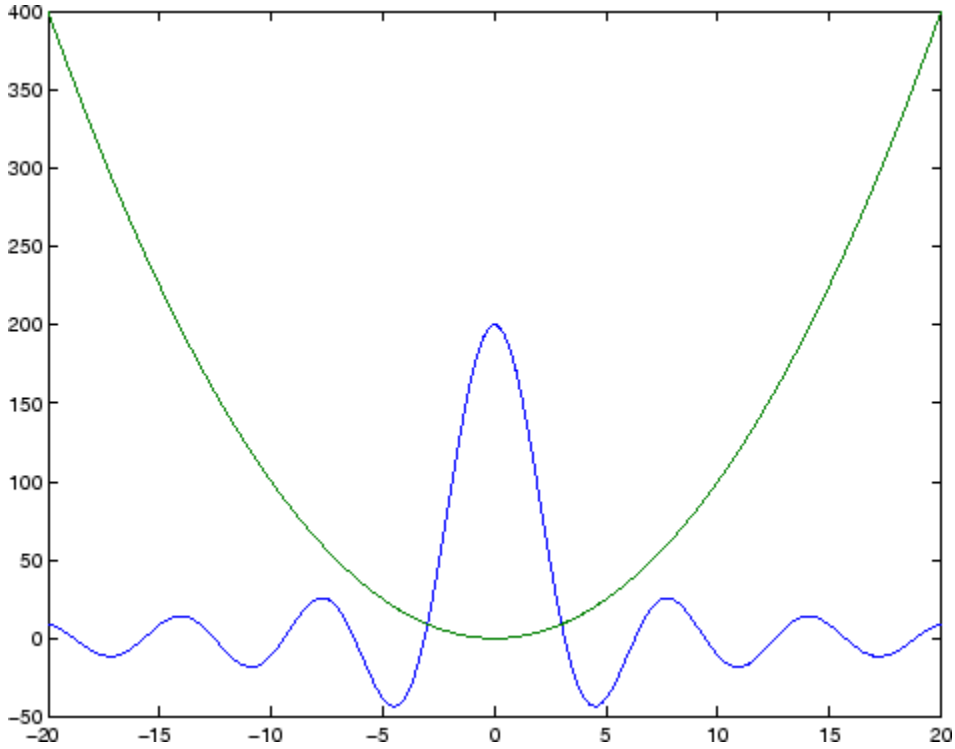
```
function Y = myfun(x)
Y(:,1) = 200*sin(x(:))./x(:);
Y(:,2) = x(:).^2;
```

Then, create a function handle pointing to `myfun`.

```
fh = @myfun;
```

Plot the function from -20 to 20.

```
fplot(fh,[-20 20])
```



More About

Tips

`fplot` uses adaptive step control to produce a representative graph, concentrating its evaluation in regions where the function's rate of change is the greatest.

- Anonymous Functions

Introduced before R2006a

fprintf

Write data to text file

Syntax

```
fprintf(fileID,formatSpec,A1,...,An)
fprintf(formatSpec,A1,...,An)

nbytes = fprintf( ___ )
```

Description

`fprintf(fileID,formatSpec,A1,...,An)` applies the `formatSpec` to all elements of arrays `A1,...An` in column order, and writes the data to a text file. `fprintf` uses the encoding scheme specified in the call to `fopen`.

`fprintf(formatSpec,A1,...,An)` formats data and displays the results on the screen.

`nbytes = fprintf( ___ )` returns the number of bytes that `fprintf` writes, using any of the input arguments in the preceding syntaxes.

Examples

Print Literal Text and Array Values

Print multiple numeric values and literal text to the screen.

```
A1 = [9.9, 9900];
A2 = [8.8,  7.7 ; ...
      8800, 7700];
formatSpec = 'X is %4.2f meters or %8.3f mm\n';
fprintf(formatSpec,A1,A2)
```

```
X is 9.90 meters or 9900.000 mm
X is 8.80 meters or 8800.000 mm
X is 7.70 meters or 7700.000 mm
```

`%4.2f` in the `formatSpec` input specifies that the first value in each line of output is a floating-point number with a field width of four digits, including two digits after the decimal point. `%8.3f` in the `formatSpec` input specifies that the second value in each line of output is a floating-point number with a field width of eight digits, including three digits after the decimal point. `\n` is a control character that starts a new line.

Print Double-Precision Values as Integers

Explicitly convert double-precision values with fractions to integer values.

```
a = [1.02, 3.04, 5.06];
fprintf('%d\n',round(a));
```

```
1
3
5
```

`%d` in the `formatSpec` input prints each value in the vector, `round(a)`, as a signed integer. `\n` is a control character that starts a new line.

Write Tabular Data to Text File

Write a short table of the exponential function to a text file called `exp.txt`.

```
x = 0:.1:1;
A = [x; exp(x)];

fileID = fopen('exp.txt','w');
fprintf(fileID,'%6s %12s\n','x','exp(x)');
fprintf(fileID,'%6.2f %12.8f\n',A);
fclose(fileID);
```

The first call to `fprintf` prints header text `x` and `exp(x)`, and the second call prints the values from variable `A`.

If you plan to read the file with Microsoft Notepad, use `'\r\n'` instead of `'\n'` to move to a new line. For example, replace the calls to `fprintf` with the following:

```
fprintf(fileID,'%6s %12s\r\n','x','exp(x)');
fprintf(fileID,'%6.2f %12.8f\r\n',A);
```

MATLAB import functions, all UNIX applications, and Microsoft Word and WordPad recognize `'\n'` as a newline indicator.

View the contents of the file with the `type` command.

```
type exp.txt
```

```
     x       exp(x)
  0.00   1.00000000
  0.10   1.10517092
  0.20   1.22140276
  0.30   1.34985881
  0.40   1.49182470
  0.50   1.64872127
  0.60   1.82211880
  0.70   2.01375271
  0.80   2.22554093
  0.90   2.45960311
  1.00   2.71828183
```

Get Number of Bytes Written to File

Write data to a file and return the number of bytes written.

Write an array of data, `A`, to a file and get the number of bytes that `fprintf` writes.

```
A = magic(4);

fileID = fopen('myfile.txt','w');
nbytes = fprintf(fileID,'%5d %5d %5d %5d\n',A)
```

```
nbytes =

    96
```

The `fprintf` function wrote 96 bytes to the file.

Close the file.

```
fclose(fileID);
```

View the contents of the file with the `type` command.

```
type('myfile.txt')
```

```
   16     5     9     4
    2    11     7    14
    3    10     6    15
```

```
    13     8    12     1
```

Display Hyperlinks in Command Window

Display a hyperlink (The MathWorks Web Site) on the screen.

```
site = 'http://www.mathworks.com';
title = 'The MathWorks Web Site';

fprintf('<a href = "%s">%s</a>\n',site,title)
```

`%s` in the `formatSpec` input indicates that the values of the variables `site` and `title`, should be printed as strings.

- "Export Cell Array to Text File"
- "Appending or Overwriting Existing Files"

Input Arguments

`fileID` — File identifier

1 (default) | 2 | scalar

File identifier, specified as one of the following:

- A file identifier obtained from `fopen`.
- `1` for standard output (the screen).
- `2` for standard error.

Data Types: `double`

`formatSpec` — Format of output fields

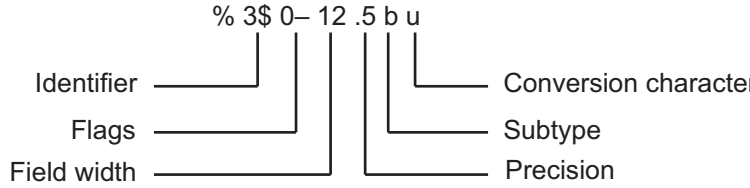
string containing formatting operators

Format of the output fields, specified as a string containing formatting operators. `formatSpec` also can include ordinary text and special characters.

Formatting Operator

A formatting operator starts with a percent sign, `%`, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier,

flags, field width, precision, and subtype operators between `%` and the conversion character. (Spaces are invalid between operators and are shown here only for readability).



Conversion Character

This table shows conversion characters to format numeric and character data as strings.

Value Type	Conversion	Details
Integer, signed	`%d` or `%i`	Base 10
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal), lowercase letters `a–f`
	`%X`	Same as `%x`, uppercase letters `A–F`
Floating-point number	`%f`	Fixed-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	`%e`	Exponential notation, such as `3.141593e+00` (Use a precision operator to specify the number of digits after the decimal point.)
	`%E`	Same as `%e`, but uppercase, such as `3.141593E+00` (Use a precision operator to specify the number of digits after the decimal point.)
	`%g`	The more compact of `%e` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)

Value Type	Conversion	Details
	`%G`	The more compact of `%E` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
Characters	`%c`	Single character
	`%s`	String of characters

Optional Operators

The optional identifier, flags, field width, precision, and subtype operators further define the format of the output string.

- **Identifier**

  Order for processing values from the input list. Use the syntax *n*`$`, where *n* represents the position of the value in the input list.

  Example: `'%3$s %2$s %1$s %2$s'` prints inputs `'A'`, `'B'`, `'C'` as follows: `C B A B`.

- **Flags**

  `'–'` Left-justify.
  Example: `%-5.2f`

  `'+'` Always print a sign character (+ or –) for any value.
  Example: `%+5.2f`

  `' '` Insert a space before the value.
  Example: `% 5.2f`

  `'0'` Pad to field width with zeros before the value.
  Example: `%05.2f`

  `'#'` Modify selected numeric conversions:

  - For `%o`, `%x`, or `%X`, print `0`, `0x`, or `0X` prefix.
  - For `%f`, `%e`, or `%E`, print decimal point even when precision is 0.
  - For `%g` or `%G`, do not remove trailing zeros or decimal point.

  Example: `%#5.0f`

- **Field Width**

Minimum number of characters to print. The field width operator can be a number, or an asterisk (`*`) to refer to an argument in the input list.

Example: The input list `('%12d',intmax)` is equivalent to `('%*d', 12, intmax)`.

The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For `%f`, `%e`, or `%E`	Number of digits to the right of the decimal point **Example:** `'%.4f'` prints `pi` as `'3.1416'`
For `%g` or `%G`	Number of significant digits **Example:** `'%.4g'` prints `pi` as `' 3.142'`

The precision operator can be a number, or an asterisk (`*`) to refer to an argument in the input list.

Example: The input list `('%6.4f', pi)` is equivalent to `('%*.*f', 6, 4, pi)`.

Note: If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

- **Subtypes**

Certain conversion characters can support a subtype. The subtype operator immediately precedes the conversion character. This table shows the conversions that can use subtypes.

Input Value Type	Subtype and Conversion Character	Output Value Type

Floating-point number	`%bx` or `%bX`
	`%bo`
	`%bu`
		Double-precision hexadecimal, octal, or decimal value
		Example: `%bx` prints `pi` as `400921fb54442d18`

Input Value Type	Subtype and Conversion Character	Output Value Type

	`%tx` or `%tX`
	`%to`
	`%tu`
		Single-precision hexadecimal, octal, or decimal value
		Example: `%tx` prints `pi` as `40490fdb`

Integer	`%ld` or `%li`
	`%lo`
	`%lu`
	`%lx` or `%lX`
		64-bit value

Integer	`%hd` or `%hi`
	`%ho`
	`%hu`
	`%hx` or `%hX`
		16-bit value

Text Before or After Formatting Operators

`formatSpec` can also include additional text before a percent sign, `%`, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in `formatSpec`.

Special Character	Representation
Single quotation mark	`''`
Percent character	`%%`
Backslash	`\\`
Alarm	`\a`
Backspace	`\b`
Form feed	`\f`
New line	`\n`
Carriage return	`\r`
Horizontal tab	`\t`

Special Character	Representation
Vertical tab	`\v`
Character whose ASCII code is the hexadecimal number, `N`	`\xN`
Character whose ASCII code is the octal number, `N`	`\N`

Notable Behavior of Conversions with Formatting Operators

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.

  Example: `'%s'` converts `pi` to `3.141593e+00`.
- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters.

  Example: `'%s'` converts `[65 66 67]` to `ABC`.

`A1,...,An` — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Output Arguments

`nbytes` — Number of bytes

scalar

Number of bytes that `fprintf` writes, returned as a scalar. When writing to a file, `nbytes` is determined by the character encoding. When printing data to the screen, `nbytes` is the number of characters displayed on the screen.

More About

Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.
- "Formatting Strings"

fprintf (serial)

Write text to device

Syntax

```
fprintf(obj,'cmd')
fprintf(obj,'format','cmd')
fprintf(obj,'cmd','mode')
fprintf(obj,'format','cmd','mode')
```

Description

`fprintf(obj,'cmd')` writes the string `cmd` to the device connected to the serial port object, `obj`. The default format is `%s\n`. The write operation is synchronous and blocks the command line until execution completes.

`fprintf(obj,'format','cmd')` writes the string using the format specified by *`format`*.

`fprintf(obj,'cmd','mode')` writes the string with command-line access specified by *`mode`*. *`mode`* specifies if `cmd` is written synchronously or asynchronously.

`fprintf(obj,'format','cmd','mode')` writes the string using the specified format. *`format`* is a C language conversion specification.

You need an open connection from the serial port object, `obj`, to the device before performing read or write operations.

Use the `fopen` function to open a connection to the device. When `obj` has an open connection to the device, it has a `Status` property value of `open`. Refer to "Troubleshooting Common Errors" for `fprintf` errors.

To understand the use of `fprintf` refer to "Completing a Write Operation with fprintf" and "Rules for Writing the Terminator".

Input Arguments

`format`

ANSI C conversion specification includes these conversion characters.

Specifier	Description
`%c`	Single character
`%d` or `%i`	Decimal notation (signed)
`%e`	Exponential notation (using lowercase `e` as in `3.1415e+00`)
`%E`	Exponential notation (using uppercase `E` as in `3.1415E+00`)
`%f`	Fixed-point notation
`%g`	The more compact of `%e` or `%f`. Insignificant zeros do not print.
`%G`	Same as `%g`, but using uppercase `E`
`%o`	Octal notation (unsigned)
`%s`	String of characters
`%u`	Decimal notation (unsigned)
`%x`	Hexadecimal notation (using lowercase letters `a`–`f`)
`%X`	Hexadecimal notation (using uppercase letters `A`–`F`)

`mode`

Specifies whether the string `cmd` is written synchronously or asynchronously:

- `sync`: `cmd` is written synchronously and the command line is blocked.
- `async`: `cmd` is written asynchronously and the command line is not blocked.

If *`mode`* is not specified, the write operation is synchronous.

If you specify asynchronous *`mode`*, when the write operation occurs:

- The `BytesToOutput` property value continuously updates to reflect the number of bytes in the output buffer.
- The MATLAB file callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

Use the `TransferStatus` property to determine whether an asynchronous write operation is in progress.

For more information on synchronous and asynchronous write operations, see Controlling Access to the MATLAB Command Line.

Examples

Create a serial port object `s` and connect it to a Tektronix TDS 210 oscilloscope. Write the `RS232?` command with `fprintf`. `RS232?` instructs the scope to return serial port communications settings. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Specify a format for the data that does not include the terminator, or configure the terminator to empty.

```
s = serial('COM1');
fopen(s)
fprintf(s,'%s','RS232?')
```

The default format for `fprintf` is `%s\n`. Therefore, the terminator specified by the `Terminator` property is automatically written. However, in some cases you might want to suppress writing the terminator.

Specify an array of formats and commands:

```
s = serial('COM1');
fopen(s)
fprintf(s,['ch:%d scale:%d'],[1 20e-3],'sync');
```

Introduced before R2006a

frame2im

Return image data associated with movie frame

Syntax

```
[X,Map] = frame2im(F)
```

Description

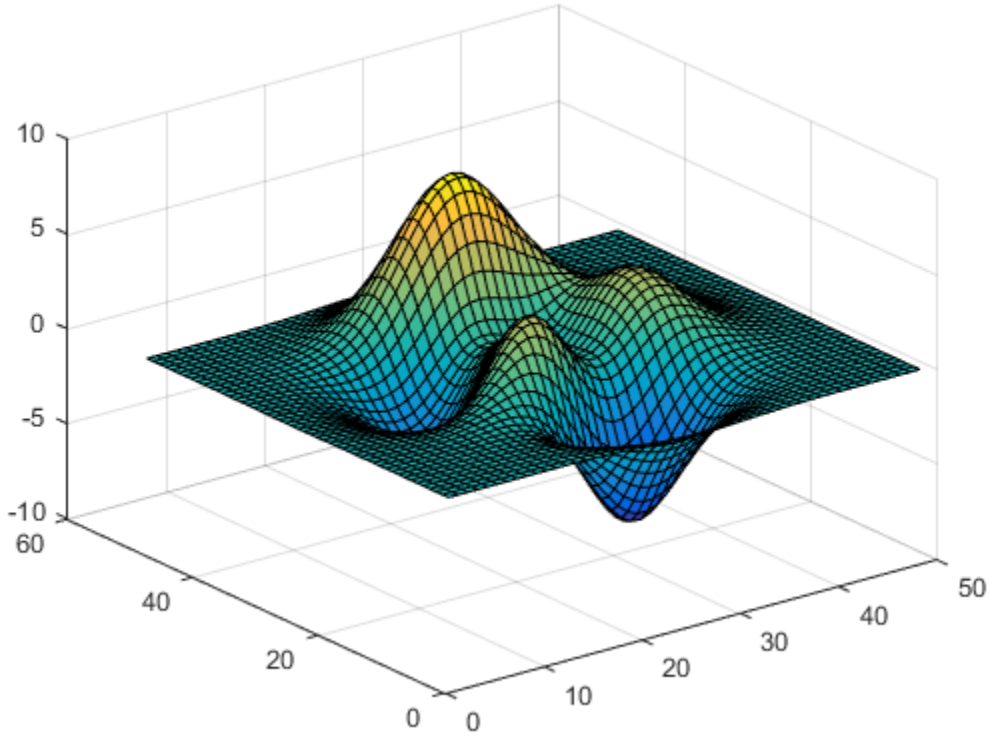
`[X,Map] = frame2im(F)` returns the indexed image data `X` and associated colormap `Map` from the single movie frame `F`. The output `Map` is a three-column matrix where each row of the matrix is an RGB triplet value that defines one color of the colormap. If the frame contains true-color data, then `Map` is empty. The functions `getframe` and `im2frame` create a movie frame.

Examples

Convert Movie Frame to Image Data

Create a surface plot.

```
surf(peaks)
```



Use `getframe` to capture the plot as a movie frame. Then, convert the captured movie frame to image data.

```
F = getframe;
[X,map] = frame2im(F);
```

See Also

`movie` | `getframe` | `im2frame` | `ind2rgb`

Introduced before R2006a

fread

Read data from binary file

Syntax

```
A = fread(fileID)
A = fread(fileID,sizeA)
A = fread(fileID,sizeA,precision)
A = fread(fileID,sizeA,precision,skip)
A = fread(fileID,sizeA,precision,skip,machinefmt)
[A,count] = fread( ___ )
```

Description

`A = fread(fileID)` reads data from an open binary file into column vector `A` and positions the file pointer at the end-of-file marker. The binary file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading, close the file by calling `fclose(fileID)`.

`A = fread(fileID,sizeA)` reads file data into an array, `A`, with dimensions, `sizeA`, and positions the file pointer after the last value read. `fread` populates `A` in column order.

`A = fread(fileID,sizeA,precision)` interprets values in the file according to the form and size described by `precision`. The `sizeA` argument is optional.

`A = fread(fileID,sizeA,precision,skip)` skips the number of bytes or bits specified by `skip` after reading each value in the file. The `sizeA` argument is optional.

`A = fread(fileID,sizeA,precision,skip,machinefmt)` additionally specifies the order for reading bytes or bits in the file. The `sizeA` and `skip` arguments are optional.

`[A,count] = fread( ___ )` additionally returns the number of characters that `fread` reads into `A`. You can use this syntax with any of the input arguments of the previous syntaxes.

Examples

Read Entire File of uint8 Data

Write a nine-element vector to a sample file, `nine.bin`.

```
fileID = fopen('nine.bin','w');
fwrite(fileID,[1:9]);
fclose(fileID);
```

Read all the data in the file into a vector of class `double`. By default, `fread` reads a file 1 byte at a time, interprets each byte as an 8-bit unsigned integer (`uint8`), and returns a `double` array.

```
fileID = fopen('nine.bin');
A = fread(fileID)
```

```
A =

     1
     2
     3
     4
     5
     6
     7
     8
     9
```

`fread` returns a column vector, with one element for each byte in the file.

View information about `A`.

```
whos A
```

```
  Name      Size            Bytes  Class     Attributes

  A         9x1                72  double
```

Close the file.

```
fclose(fileID);
```

Read Entire File of Double-Precision Data

Create a file named `doubledata.bin`, containing nine double-precision values.

```
fileID = fopen('doubledata.bin','w');
fwrite(fileID,magic(3),'double');
fclose(fileID);
```

Open the file, `doubledata.bin`, and read the data in the file into a 3-by-3 array, `A`. Specify that the source data is class `double`.

```
fileID = fopen('doubledata.bin');
A = fread(fileID,[3 3],'double')
```

```
A =

     8     1     6
     3     5     7
     4     9     2
```

Close the file.

```
fclose(fileID);
```

Read Text File

Read the contents of the file, `fread.m`. Transpose the output array, `A` so that it is a row vector.

```
fileID = fopen('fread.m');
A = fread(fileID,'*char')';
fclose(fileID);
```

`fread` returns the character array, `A`.

Read Selected Rows or Columns from File

Create a file named `nine.bin`, containing the values from 1 to 9. Write the data as `uint16` values.

```
fileID = fopen('nine.bin','w');
fwrite(fileID,[1:9],'uint16');
```

```
fclose(fileID);
```

Read the first six values into a 3-by-2 array. Specify that the source data is class `uint16`.

```
fileID = fopen('nine.bin');
A = fread(fileID,[3,2],'uint16')
```

```
A =

     1     4
     2     5
     3     6
```

`fread` returns an array populated column-wise with the first six values from the file, `nine.bin`.

Return to the beginning of the file.

```
frewind(fileID)
```

Read two values at a time, and skip one value before reading the next values. Specify this format using the `precision` value, `'2*uint16'`. Because the data is class `uint16`, one value is represented by 2 bytes. Therefore, specify the `skip` argument as `2`.

```
precision = '2*uint16';
skip = 2;
B = fread(fileID,[2,3],precision,skip)
```

```
B =

     1     4     7
     2     5     8
```

`fread` returns a 2-by-3 array populated column-wise with the values from `nine.bin`.

Close the file.

```
fclose(fileID);
```

Read Digits of Binary Coded Decimal Values

Create a file with binary coded decimal (BCD) values.

```
str = ['AB'; 'CD'; 'EF'; 'FA'];

fileID = fopen('bcd.bin','w');
fwrite(fileID,hex2dec(str),'ubit8');
fclose(fileID);
```

Read 1 byte at a time.

```
fileID = fopen('bcd.bin');
onebyte = fread(fileID,4,'*ubit8');
```

Display the BCD values.

```
disp(dec2hex(onebyte))
```

```
AB
CD
EF
FA
```

Return to the beginning of the file using `frewind`. If you read 4 bits at a time on a little-endian system, your results appear in the wrong order.

```
frewind(fileID)

err = fread(fileID,8,'*ubit4');
disp(dec2hex(err))
```

```
B
A
D
C
F
E
A
F
```

Return to the beginning of the file using `frewind`. Read the data 4 bits at a time as before, but specify a big-endian ordering to display the correct results.

```
frewind(fileID)

correct = fread(fileID,8,'*ubit4','ieee-be');
disp(dec2hex(correct))
```

```
A
B
C
D
E
F
F
A
```

Close the file.

```
fclose(fileID);
```

Input Arguments

`fileID` — File identifier

integer

File identifier of an open binary file, specified as an integer. Before reading a file with `fread`, you must use `fopen` to open the file and obtain the `fileID`.

Data Types: `double`

`sizeA` — Dimensions of output array

`Inf` (default) | integer | two-element row vector

Dimensions of the output array, `A`, specified as `Inf`, an integer, or a two-element row vector.

Form of the `sizeA` Input	Dimensions of the output array, `A`
`Inf`	Column vector, with each element containing a value in the file.
`n`	Column vector with `n` elements.
`[m,n]`	`m`-by-`n` matrix, filled in column order. `n` can be `Inf`, but `m` cannot.

`precision` — Class and size of values to read

`'uint8=>double'` (default) | string

Class and size in bits of the values to read, specified as a string in one of the following forms. Optionally the input specifies the class of the output matrix, A.

Form of the `precision` Input	Description
`source`	Input values are of the class specified by *`source`*. Output matrix A is class `double`. Example: `'int16'`
`source=>output`	Input values are of the class specified by *`source`*. The class of the output matrix, A, is specified by *`output`*. Example: `'int8=>char'`
`*source`	The input values and the output matrix, A, are of the class specified by *`source`*. For `bit`*n* or `ubit`*n* precisions, the output has the smallest class that can contain the input. Example: `'*ubit18'` This is equivalent to `'ubit18=>uint32'`
`N*source` or *`N*source=>output`*	Read *N* values before skipping the number of bytes specified by the `skip` argument. Example: `'4*int8'`

The following table shows possible values for *`source`* and *`output`*.

Value Type	Precision	Bits (Bytes)
Integers, unsigned	`uint`	`32 (4)`
	`uint8`	`8 (1)`
	`uint16`	`16 (2)`
	`uint32`	`32 (4)`
	`uint64`	`64 (8)`
	`uchar`	`8 (1)`
	`unsigned char`	`8 (1)`
	`ushort`	`16 (2)`
	`ulong`	`32 (4)`
	`ubit`*n*	$1 \le n \le 64$

Value Type	Precision	Bits (Bytes)
Integers, signed	`int`	32 (4)
	`int8`	8 (1)
	`int16`	16 (2)
	`int32`	32 (4)
	`int64`	64 (8)
	`integer*1`	8 (1)
	`integer*2`	16 (2)
	`integer*4`	32 (4)
	`integer*8`	64 (8)
	`schar`	8 (1)
	`signed char`	8 (1)
	`short`	16 (2)
	`long`	32 (4)
	`bit`*`n`	$1 \le n \le 64$
Floating-point numbers	`single`	32 (4)
	`double`	64 (8)
	`float`	32 (4)
	`float32`	32 (4)
	`float64`	64 (8)
	`real*4`	32 (4)
	`real*8`	64 (8)
Characters	`char*1`	8 (1)
	`char`	Depends on the encoding scheme associated with the file. Set encoding with `fopen`.

For most values of *`source`*, if `fread` reaches the end of the file before reading a complete value, it does not return a result for the final value. However, if *`source`* is `bit`*`n`* or `ubit`*`n`*, then `fread` returns a partial result for the final value.

Note: To preserve `NaN` and `Inf` values in MATLAB, read and write data of class `double` or `single`.

`skip` — Number of bytes to skip

0 (default) | scalar

Number of bytes to skip after reading each value, specified as a scalar. If you specify a `precision` of `bit`*n* or `ubit`*n*, specify `skip` in bits.

Use the `skip` argument to read data from noncontiguous fields in fixed-length records.

`machinefmt` — Order for reading bytes

`'n'` (default) | `'b'` | `'l'` | `'s'` | `'a'` | ...

Order for reading bytes in the file, specified as one of the strings in the table that follows. For `bit`*n* and `ubit`*n* precisions, `machinefmt` specifies the order for reading bits within a byte, but the order for reading bytes remains your system byte ordering.

`'n'` or `'native'`	Your system byte ordering (default)
`'b'` or `'ieee-be'`	Big-endian ordering
`'l'` or `'ieee-le'`	Little-endian ordering
`'s'` or `'ieee-be.l64'`	Big-endian ordering, 64-bit long data type
`'a'` or `'ieee-le.l64'`	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

Output Arguments

`A` — File data

column vector | matrix

File data, returned as a column vector. If you specified the `sizeA` argument, then `A` is a matrix of the specified size. Data in `A` is class `double` unless you specify a different class in the `precision` argument.

`count` — Number of characters read

scalar

Number of characters read, returned as a scalar value.

Introduced before R2006a

fread (serial)

Read binary data from device

Syntax

```
A = fread(obj)
A = fread(obj,size,'precision')
[A,count] = fread(...)
[A,count,msg] = fread(...)
```

Description

`A = fread(obj)` and `A = fread(obj,size)` read binary data from the device connected to the serial port object, `obj`, and returns the data to `A`. The maximum number of values to read is specified by `size`. If `size` is not specified, the maximum number of values to read is determined by the object's `InputBufferSize` property. Valid options for `size` are:

`n`	Read at most `n` values into a column vector.
`[m,n]`	Read at most m-by-n values filling an m–by–n matrix in column order.

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. A value is defined as a byte multiplied by the *`precision`* (see below).

`A = fread(obj,size,'precision')` reads binary data with precision specified by *`precision`*.

`precision` controls the number of bits read for each value and the interpretation of those bits as integer, floating-point, or character values. If *`precision`* is not specified, `uchar` (an 8-bit unsigned character) is used. By default, numeric values are returned in double-precision arrays. The supported values for *`precision`* are listed below in Tips.

`[A,count] = fread(...)` returns the number of values read to `count`.

`[A,count,msg] = fread(...)` returns a warning message to `msg` if the read operation was unsuccessful.

More About

Tips

Before you can read data from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read, each time `fread` is issued.

Rules for Completing a Binary Read Operation

A read operation with `fread` blocks access to the MATLAB command line until:

- The specified number of values are read.
- The time specified by the `Timeout` property passes.

Note The `Terminator` property is not used for binary read operations.

Supported Precisions

The supported values for *`precision`* are listed below.

Data Type	Precision	Interpretation
Character	`uchar`	8-bit unsigned character
	`schar`	8-bit signed character
	`char`	8-bit signed or unsigned character
Integer	`int8`	8-bit integer

Data Type	Precision	Interpretation
	`int16`	16-bit integer
	`int32`	32-bit integer
	`uint8`	8-bit unsigned integer
	`uint16`	16-bit unsigned integer
	`uint32`	32-bit unsigned integer
	`short`	16-bit integer
	`int`	32-bit integer
	`long`	32- or 64-bit integer
	`ushort`	16-bit unsigned integer
	`uint`	32-bit unsigned integer
	`ulong`	32- or 64-bit unsigned integer
Floating-point	`single`	32-bit floating point
	`float32`	32-bit floating point
	`float`	32-bit floating point
	`double`	64-bit floating point
	`float64`	64-bit floating point

Introduced before R2006a

freeBoundary

Class: TriRep

(Will be removed) Facets referenced by only one simplex

Note: `freeBoundary(TriRep)` will be removed in a future release. Use `freeBoundary(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
FF = freeBoundary(TR)
[FF XF] = freeBoundary(TR)
```

Description

`FF = freeBoundary(TR)` returns a matrix `FF` that represents the free boundary facets of the triangulation. A facet is on the free boundary if it is referenced by only one simplex (triangle/tetrahedron, etc). `FF` is of size `m`-by-`n`, where m is the number of boundary facets and n is the number of vertices per facet. The vertices of the facets index into the array of points representing the vertex coordinates `TR.X`. The array `FF` could be empty as in the case of a triangular mesh representing the surface of a sphere.

`[FF XF] = freeBoundary(TR)` returns a matrix of free boundary facets

Input Arguments

`TR`	Triangulation representation.

Output Arguments

`FF`	`FF` that has vertices defined in terms of a compact array of coordinates `XF`.

`XF`	`XF` is of size `m`-by-`ndim` where `m` is the number of free facets, and `ndim` is the dimension of the space where the triangulation resides

Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

Examples

Example 1

Use `TriRep` to compute the boundary triangulation of an imported triangulation.

Load a 3-D triangulation:

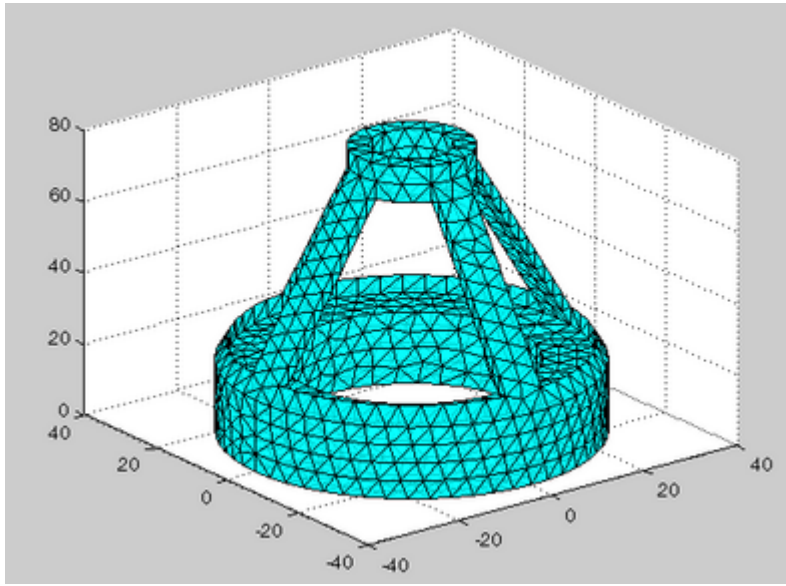
```
load tetmesh;
trep = TriRep(tet, X);
```

Compute the boundary triangulation:

```
 [tri xf] = freeBoundary(trep);
```

Plot the boundary triangulation:

```
trisurf(tri, xf(:,1),xf(:,2),xf(:,3), ...
     'FaceColor','cyan', 'FaceAlpha', 0.8);
```



Example 2

Perform a direct query of a 2-D triangulation created with `DelaunayTri`.

Plot the mesh:

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
fe = freeBoundary(dt)';
triplot(dt);
hold on;
```

Display the free boundary edges in red:

```
plot(x(fe), y(fe), '-r', 'LineWidth',2) ;
hold off;
```

In this instance the free edges correspond to the convex hull of `(x, y)`.

`convexHull` | `featureEdges` | `triangulation` | `delaunayTriangulation` | `faceNormal`

freqspace

Frequency spacing for frequency response

Syntax

```
[f1,f2] = freqspace(n)
[f1,f2] = freqspace([m n])
[x1,y1] = freqspace(...,'meshgrid')
f = freqspace(N)
f = freqspace(N,'whole')
```

Description

`freqspace` returns the implied frequency range for equally spaced frequency responses. `freqspace` is useful when creating desired frequency responses for various one- and two-dimensional applications.

`[f1,f2] = freqspace(n)` returns the two-dimensional frequency vectors `f1` and `f2` for an `n`-by-`n` matrix.

For `n` odd, both `f1` and `f2` are `[-n+1:2:n-1]/n`.

For `n` even, both `f1` and `f2` are `[-n:2:n-2]/n`.

`[f1,f2] = freqspace([m n])` returns the two-dimensional frequency vectors `f1` and `f2` for an `m`-by-`n` matrix.

`[x1,y1] = freqspace(...,'meshgrid')` is equivalent to

```
[f1,f2] = freqspace(...);
[x1,y1] = meshgrid(f1,f2);
```

`f = freqspace(N)` returns the one-dimensional frequency vector `f` assuming `N` evenly spaced points around the unit circle. For `N` even or odd, `f` is `(0:2/N:1)`. For `N` even, `freqspace` therefore returns `(N+2)/2` points. For `N` odd, it returns `(N+1)/2` points.

`f = freqspace(N,'whole')` returns `N` evenly spaced points around the whole unit circle. In this case, `f` is `0:2/N:2*(N-1)/N`.

See Also

`meshgrid`

Introduced before R2006a

frewind

Move file position indicator to beginning of open file

Syntax

```
frewind(fileID)
```

Description

`frewind(fileID)` sets the file position indicator to the beginning of a file. *`fileID`* is an integer file identifier obtained from `fopen`.

If the file is on a tape device and the rewind operation fails, `frewind` does not return an error message.

Alternatives

`frewind(fileID)` is equivalent to:

```
fseek(fileID, 0, 'bof');
```

`fclose` | `feof` | `ferror` | `fopen` | `fseek` | `ftell` | `fscanf` | `fprintf` | `fread` | `fwrite`

Introduced before R2006a

fscanf

Read data from text file

Syntax

```
A = fscanf(fileID,formatSpec)
A = fscanf(fileID,formatSpec,sizeA)
[A,count] = fscanf( ___ )
```

Description

`A = fscanf(fileID,formatSpec)` reads data from an open text file into column vector `A` and interprets values in the file according to the format specified by `formatSpec`. The `fscanf` function reapplies the format throughout the entire file and positions the file pointer at the end-of-file marker. If `fscanf` cannot match `formatSpec` to the data, it reads only the portion that matches and stops processing.

The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file, specify the character encoding, and obtain the `fileID` value. When you finish reading, close the file by calling `fclose(fileID)`.

`A = fscanf(fileID,formatSpec,sizeA)` reads file data into an array, `A`, with dimensions, `sizeA`, and positions the file pointer after the last value read. `fscanf` populates `A` in column order.

`[A,count] = fscanf( ___ )` additionally returns the number of fields that `fscanf` reads into `A`. For numeric data, this is the number of values read. You can use this syntax with any of the input arguments of the previous syntaxes.

Examples

Read File Contents into Column Vector

Create a sample text file that contains floating-point numbers.

```
x = 100*rand(8,1);
```

```
fileID = fopen('nums1.txt','w');
fprintf(fileID,'%4.4f\n',x);
fclose(fileID);
```

View the contents of the file.

```
type nums1.txt
```

```
81.4724
90.5792
12.6987
91.3376
63.2359
9.7540
27.8498
54.6882
```

Open the file for reading, and obtain the file identifier, `fileID`.

```
fileID = fopen('nums1.txt','r');
```

Define the format of the data to read. Use the string, `'%f'`, to specify floating-point numbers.

```
formatSpec = '%f';
```

Read the file data, filling output array, `A`, in column order. `fscanf` reapplies the format, `formatSpec`, throughout the file.

```
A = fscanf(fileID,formatSpec)
```

```
A =

   81.4724
   90.5792
   12.6987
   91.3376
   63.2359
    9.7540
   27.8498
   54.6882
```

`A` is a column vector containing data from the file.

Close the file.

```
fclose(fileID);
```

Read File Contents into Array

Create a sample text file that contains integers and floating-point numbers.

```
x = 1:1:5;
y = [x;rand(1,5)];
fileID = fopen('nums2.txt','w');
fprintf(fileID,'%d %4.4f\n',y);
fclose(fileID);
```

View the contents of the file.

```
type nums2.txt
```

```
1 0.8147
2 0.9058
3 0.1270
4 0.9134
5 0.6324
```

Open the file for reading, and obtain the file identifier, `fileID`.

```
fileID = fopen('nums2.txt','r');
```

Define the format of the data to read and the shape of the output array.

```
formatSpec = '%d %f';
sizeA = [2 Inf];
```

Read the file data, filling output array, `A`, in column order. `fscanf` reuses the format, `formatSpec`, throughout the file.

```
A = fscanf(fileID,formatSpec,sizeA)
fclose(fileID);
```

```
A =

    1.0000    2.0000    3.0000    4.0000    5.0000
    0.8147    0.9058    0.1270    0.9134    0.6324
```

Transpose the array so that A matches the orientation of the data in the file.

```
A = A'
```

```
A =

    1.0000    0.8147
    2.0000    0.9058
    3.0000    0.1270
    4.0000    0.9134
    5.0000    0.6324
```

Skip Specific Characters in File

Skip specific characters in a sample file, and return only numeric data.

Create a sample text file containing temperature values.

```
str = '78°C 72°C 64°C 66°C 49°C';
fileID = fopen('temperature.dat','w');
fprintf(fileID,'%s',str);
fclose(fileID);
```

Read the numbers in the file, skipping the text, °C. Also return the number of values that `fscanf` reads. The extended ASCII code 176 represents the degree sign.

```
fileID = fopen('temperature.dat','r');
degrees = char(176);
[A,count] = fscanf(fileID, ['%d' degrees 'C'])
fclose(fileID);
```

```
A =

    78
    72
    64
    66
    49

count =

     5
```

A is a vector containing the numeric values in the file. `count` indicates that `fscanf` read five values.

Input Arguments

`fileID` — File identifier

integer

File identifier of an open text file, specified as an integer. Before reading a file with `fscanf`, you must use `fopen` to open the file and obtain the `fileID`.

Data Types: `double`

`formatSpec` — Format of data fields

string

Format of the data fields in the file, specified as a string of one or more conversion specifiers. When `fscanf` reads a file, it attempts to match the data to the `formatSpec` string.

Numeric Fields

This table lists available conversion specifiers for numeric inputs. `fscanf` converts values to their decimal (base 10) representation.

Numeric Field Type	Conversion Specifier	Details
Integer, signed	`%d`	Base 10
	`%i`	The values in the file determine the base: • The default is base 10. • If the initial digits are `0x` or `0X`, then the values are hexadecimal (base 16). • If the initial digit is `0`, then values are octal (base 8).
	`%ld` or `%li`	64-bit values, base 10, 8, or 16
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)

Numeric Field Type	Conversion Specifier	Details
	`%x`	Base 16 (hexadecimal)
	`%lu`, `%lo`, `%lx`	64-bit values, base 10, 8, or 16
Floating-point number	`%f`	Floating-point fields can contain any of the following (not case sensitive): `Inf`, `-Inf`, `NaN`, or `-NaN`.
	`%e`	
	`%g`	

Character Fields

This table lists available conversion specifiers for character inputs.

Character Field Type	Conversion Specifier	Description
Characters	`%s`	Read a string until `fscanf` encounters white space.
	`%c`	Read any single character, including white space. To read multiple characters at a time, specify field width.
Pattern-matching string	`%[...]`	Read only characters in the brackets up to the first nonmatching character or white space. Example: `%[mus]` reads `'summer '` as `'summ'`.

If `formatSpec` contains a combination of numeric and character specifiers, then `fscanf` converts each character to its numeric equivalent. This conversion occurs even when the format explicitly skips all numeric values (for example, `formatSpec` is `'%*d %s'`).

Optional Operators

- Fields and Characters to Ignore

  `fscanf` reads all numeric values and characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field. To skip fields, insert an asterisk (`*`) after the percent sign (`%`). For example, to skip integers, specify `%*d`.

- Field Width

  To specify the maximum number of digits or text characters to read at a time, insert a number after the percent character. For example, `%10c` reads up to 10 characters at a time, including white space. `%4f` reads up to 4 digits at a time, including the decimal point.

- Literal Text to Ignore

  `fscanf` ignores specified text appended to the `formatSpec` string.

  Example: `Level%u` reads `'Level1'` as `1`.

  Example: `%uStep` reads `'2Step'` as `2`.

`sizeA` — Dimensions of output array

`Inf` (default) | integer | two-element row vector

Dimensions of the output array, `A`, specified as `Inf`, an integer, or a two-element row vector.

Form of the `sizeA` Input	Description
`Inf`	Read to the end of the file. For numeric data, the output, `A`, is a column vector. For text data, `A` is a string.
n	Read at most *n* numeric values or character fields. For numeric data, the output, `A`, is a column vector. For text data, `A`, is a string.
[*m*,*n*]	Read at most *m***n* numeric values or character fields. *n* can be `Inf`, but *m* cannot. The output, `A`, is `m`-by-`n`, filled in column order.

Output Arguments

`A` — File data

column vector | matrix | string | character array

File data, returned as a column vector, matrix, string, or character array. The class and size of `A` depend on the `formatSpec` input:

- If `formatSpec` contains only numeric specifiers, then `A` is numeric. If you specify the `sizeA` argument, then `A` is a matrix of the specified size. Otherwise, `A` is a column vector. If the input contains fewer than `sizeA` values, then `fscanf` pads `A` with zeros.
  - If `formatSpec` contains only 64-bit signed integer specifiers, then `A` is of class `int64`.
  - If `formatSpec` contains only 64-bit unsigned integer specifiers, then `A` is of class `uint64`.
  - Otherwise, `A` is of class `double`.
- If `formatSpec` contains only character or string specifiers (`%c` or `%s`), then `A` is a character array. If you specify `sizeA` and the input contains fewer characters, then `fscanf` pads `A` with `char(0)`.
- If `formatSpec` contains a combination of numeric and character specifiers, then `A` is numeric, of class `double`, and `fscanf` converts each text characters to its numeric equivalent. This occurs even when `formatSpec` explicitly skips all numeric fields (for example, `formatSpec` is `'%*d %s'`).
- If MATLAB cannot match the file data to `formatSpec`, then `A` can be numeric or a character array. The class of `A` depends on the values that `fscanf` reads before it stops processing.

`count` — Number of characters read

scalar

Number of characters read, returned as a scalar value.

More About

Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

Algorithms

MATLAB reads characters using the encoding scheme associated with the file. You specify the encoding when you open the file using the `fopen` function.

- “Reading Data in a Formatted Pattern”
- “Opening Files with Different Character Encodings”

See Also

`fgetl` | `fgets` | `fopen` | `fprintf` | `fread` | `sscanf` | `textscan`

Introduced before R2006a

fscanf (serial)

Read ASCII data from device, and format as text

Syntax

```
A = fscanf(obj)
A = fscanf(obj,'format')
A = fscanf(obj,'format',size)
[A,count] = fscanf(...)
[A,count,msg] = fscanf(...)
```

Description

`A = fscanf(obj)` reads ASCII data from the device connected to the serial port object, `obj`, and returns it to `A`. The data is converted to text using the `%c` format. For binary data, use `fread`.

`A = fscanf(obj,'format')` reads data and converts it according to *`format`*. *`format`* is a C language conversion specification. Conversion specifications involve the `%` character and the conversion characters d, i, o, u, x, X, f, e, E, g, G, c, and s. Refer to the `sscanf` file I/O format specifications or a C manual for more information.

`A = fscanf(obj,'format',size)` reads the number of values specified by `size`. Valid options for `size` are:

`n`	Read at most `n` values into a column vector.
`[m,n]`	Read at most m-by-n values filling an m–by–n matrix in column order.

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. If `size` is not of the form `[m,n]`, and a character conversion is specified, then `A` is returned as a row vector. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. An ASCII value is one byte.

`[A,count] = fscanf(...)` returns the number of values read to `count`.

`[A,count,msg] = fscanf(...)` returns a warning message to `msg` if the read operation did not complete successfully.

Examples

Create the serial port object `s` and connect `s` to a Tektronix TDS 210 oscilloscope, which is displaying sine wave. This example works on a Windows platform.

```
s = serial('COM1');
fopen(s)
```

Use the `fprintf` function to configure the scope to measure the peak-to-peak voltage of the sine wave, return the measurement type, and return the peak-to-peak voltage.

```
fprintf(s,'MEASUREMENT:IMMED:TYPE PK2PK')
fprintf(s,'MEASUREMENT:IMMED:TYPE?')
fprintf(s,'MEASUREMENT:IMMED:VALUE?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data associated with the two query commands is automatically returned to the input buffer.

```
s.BytesAvailable
```

```
ans =
    21
```

Use `fscanf` to read the measurement type. The operation will complete when the first terminator is read.

```
meas = fscanf(s)
```

```
meas =
PK2PK
```

Use `fscanf` to read the peak-to-peak voltage as a floating-point number, and exclude the terminator.

```
pk2pk = fscanf(s,'%e',14)
```

```
pk2pk =
    2.0200
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

More About

Tips

Before you can read data from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fscanf` is issued.

Rules for Completing a Read Operation with fscanf

A read operation with `fscanf` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is read.
- The time specified by the `Timeout` property passes.
- The number of values specified by `size` is read.
- The input buffer is filled (unless `size` is specified)

Introduced before R2006a

fseek

Move to specified position in file

Syntax

```
fseek(fileID, offset, origin)
status = fseek(fileID, offset, origin)
```

Description

`fseek(fileID, offset, origin)` sets the file position indicator `offset` bytes from `origin` in the specified file.

`status = fseek(fileID, offset, origin)` returns `0` when the operation is successful. Otherwise, it returns `-1`.

Input Arguments

`fileID`

Integer file identifier obtained from `fopen`.

`offset`

Number of bytes to move from `origin`. Can be positive, negative, or zero. The `n` bytes of a given file are in positions `0` through `n-1`.

`origin`

Starting location in the file:

`'bof'` or `-1`	Beginning of file
`'cof'` or `0`	Current position in file
`'eof'` or `1`	End of file

Examples

Copy 5 bytes from the file `test1.dat`, starting at the tenth byte, and append to the end of `test2.dat`:

```
% Create files test1.dat and test2.dat
% Each character uses 8 bits (1 byte)

fid1 = fopen('test1.dat', 'w+');
fwrite(fid1, 'ABCDEFGHIJKLMNOPQRSTUVWXYZ');

fid2 = fopen('test2.dat', 'w+');
fwrite(fid2, 'Second File');

% Seek to the 10th byte ('J'), read 5
fseek(fid1, 9, 'bof');
A = fread(fid1, 5, 'uint8=>char');
fclose(fid1);

% Append to test2.dat
fseek(fid2, 0, 'eof');
fwrite(fid2, A);
fclose(fid2);
```

Alternatives

To move to the beginning of a file, call

```
frewind(fileID)
```

This call is identical to

```
fseek(fileID, 0, 'bof')
```

Introduced before R2006a

ftell

Position in open file

Syntax

```
position = ftell(fileID)
```

Description

`position = ftell(fileID)` returns the current position in the specified file. `position` is a zero-based integer that indicates the number of bytes from the beginning of the file. If the query is unsuccessful, `position` is `-1`. `fileID` is an integer file identifier obtained from `fopen`.

`fclose` | `feof` | `ferror` | `fopen` | `frewind` | `fread` | `fwrite` | `fseek` | `fscanf` | `fprintf`

Introduced before R2006a

FTP class

Connect to FTP server

Description

Connect to an FTP server by calling the `ftp` function, which creates an FTP object. Perform file operations using methods on the FTP object, such as `mput` and `mget`. When you finish accessing the server, call the `close` method to close the connection.

Construction

`f = ftp(host,username,password)` connects to the FTP server host and creates FTP object f. If the host supports anonymous connections, you can use the `host` argument alone. To specify an alternate port, separate it from `host` with a colon (`:`).

Input Arguments

`host`

String enclosed in single quotation marks that specifies the FTP server.

`username`

String enclosed in single quotation marks that specifies your user name for the FTP server.

`password`

String enclosed in single quotation marks that specifies your password for the FTP server. Because FTP is not a secure protocol, others can see your user name and password.

Methods

ascii
: Set FTP transfer type to ASCII

binary	Set FTP transfer type to binary
cd	Change or view current folder on FTP server
close	Close connection to FTP server
delete	Remove file on FTP server
dir	View contents of folder on FTP server
mget	Download files from FTP server
mkdir	Create folder on FTP server
mput	Upload file or folder to FTP server
rename	Rename file on FTP server
rmdir	Remove folder on FTP server

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Modify the following code to connect to an FTP server, and display the FTP object:

```
mw = ftp('ftp.testsite.com');
disp(mw)
```

Connect to port 34 (not supported at `ftp.mathworks.com`, so this code returns an error):

```
mw = ftp('ftp.mathworks.com:34')
```

Modify the following code to connect to a host that requires a password:

```
test = ftp('ftp.testsite.com','myname','mypassword')
```

Algorithms

The `ftp` function is based on code from the Apache Jakarta Project.

Limitations

The `ftp` function does not support proxy server settings.

See Also

`urlwrite`

Introduced before R2006a

full

Convert sparse matrix to full matrix

Syntax

```
A = full(S)
```

Description

`A = full(S)` converts a sparse matrix `S` to full storage organization, such that `issparse(A)` returns logical `0` (`false`). If `S` is a full matrix, then `A` is identical to `S`.

Examples

Here is an example of a sparse matrix with a density of about two-thirds. `sparse(S)` and `full(S)` require about the same number of bytes of storage.

```
S = sparse(+(rand(200,200) < 2/3));
A = full(S);
whos
Name    Size    Bytes     Class
  A    200X200 320000 double array
  S    200X200 318432 double array (sparse)
```

More About

Tips

If `X` is an `m`-by-`n` matrix with `nz` nonzero elements then `full(X)` requires space to store `m*n` elements. On the other hand, `sparse(X)` requires space to store `nz` elements and `(nz+n+1)` integers.

The density of a matrix (`nnz(X)/numel(X)`) determines whether or not it is more efficient to store the matrix as sparse or full. The exact crossover point depends on the

matrix class as well as the platform. For example, in 32-bit MATLAB, a double sparse matrix with less than about 2/3 density will require less space than the same matrix in full storage. In 64-bit MATLAB, however, double matrices with less than half of their elements nonzero are more efficient to store as sparse matrices.

See Also

`issparse` | `sparse`

Introduced before R2006a

fullfile

Build full file name from parts

Syntax

```
f = fullfile(filepart1,...,filepartN)
```

Description

`f = fullfile(filepart1,...,filepartN)` builds a full file specification, `f`, from the folders and file names specified. `fullfile` inserts platform-dependent file separators where necessary, and does not add a trailing file separator. The output of `fullfile` is conceptually equivalent to

```
f = [filepart1 filesep filepart2 filesep ... filesep filepartN]
```

Examples

Create a Full File Name

```
f = fullfile('myfolder','mysubfolder','myfile.m')
```

```
f =
myfolder\mysubfolder\myfile.m
```

`fullfile` returns a string containing the full path to the file. On Windows platforms, the file separator character is a backslash, `\`. On other platforms, the file separator might be a different character.

Create Paths to Multiple Files

```
f = fullfile(toolboxdir('matlab'),'iofun',{'filesep.m';'fullfile.m'});
```

`fullfile` returns a cell array containing a path to the file `filesep.m`, and a path to the file `fullfile.m`.

Create a Path to a Folder

```
f = fullfile(matlabroot,'toolbox','matlab',filesep);
```

`fullfile` does not trim a leading or trailing `filesep`.

Input Arguments

`filepart1,...,filepartN` — Folder and file names

strings | cell arrays of strings

Folder and file names, specified as strings and cell arrays of strings. Any nonscalar cell arrays must be of the same size.

Example: `'folder1','folder2','myfile.m'`

Example: `{'folder1';'folder2'},{'subfolder1';'subfolder2'},'myfile.m'`

See Also

`fileparts` | `filesep` | `genpath` | `path` | `pathsep`

Introduced before R2006a

func2str

Construct function name string from function handle

Syntax

```
func2str(fhandle)
```

Description

`func2str(fhandle)` constructs a string `s` that holds the name of the function to which the function handle `fhandle` belongs.

When you need to perform a string operation, such as compare or display, on a function handle, you can use `func2str` to construct a string bearing the function name.

The `func2str` command does not operate on nonscalar function handles. Passing a nonscalar function handle to `func2str` results in an error.

Examples

Example 1

Convert a `sin` function handle to a string:

```
fhandle = @sin;

func2str(fhandle)
ans =
    sin
```

Example 2

The `catcherr` function shown here accepts function handle and data arguments and attempts to evaluate the function through its handle. If the function fails to execute, `catcherr` uses `sprintf` to display an error message giving the name of the failing

function. The function name must be a string for `sprintf` to display it. The code derives the function name from the function handle using `func2str`:

```
function catcherr(func, data)
try
    ans = func(data);
    disp('Answer is:');
    ans
catch
    disp(sprintf('Error executing function ''%s''\n', ...
        func2str(func)))
end
```

The first call to `catcherr` passes a handle to the `round` function and a valid data argument. This call succeeds and returns the expected answer. The second call passes the same function handle and an improper data type (a MATLAB structure). This time, `round` fails, causing `catcherr` to display an error message that includes the failing function name:

```
catcherr(@round, 5.432)
ans =
Answer is 5

xstruct.value = 5.432;
catcherr(@round, xstruct)
Error executing function "round"
```

More About

Tips

Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

See Also

`function_handle` | `str2func` | `functions`

Introduced before R2006a

function

Declare function name, inputs, and outputs

Syntax

```
function [y1,...,yN] = myfun(x1,...,xM)
```

Description

`function [y1,...,yN] = myfun(x1,...,xM)` declares a function named `myfun` that accepts inputs `x1,...,xM` and returns outputs `y1,...,yN`. This declaration statement must be the first executable line of the function.

Save the function code in a text file with a `.m` extension. The name of the file should match the name of the first function in the file. Valid function names begin with an alphabetic character, and can contain letters, numbers, or underscores.

Files can include multiple local functions or nested functions. Use the `end` keyword to indicate the end of each function in a file if:

- Any function in the file contains a nested function
- Any local function in the file uses the `end` keyword

Otherwise, the `end` keyword is optional.

Examples

Function with One Output

Define a function in a file named `average.m` that accepts an input vector, calculates the average of the values, and returns a single result.

```
function y = average(x)
if ~isvector(x)
    error('Input must be a vector')
end
```

```
y = sum(x)/length(x);
end
```

Call the function from the command line.

```
z = 1:99;
average(z)
```

```
ans =
    50
```

Function with Multiple Outputs

Define a function in a file named `stat.m` that returns the mean and standard deviation of an input vector.

```
function [m,s] = stat(x)
n = length(x);
m = sum(x)/n;
s = sqrt(sum((x-m).^2/n));
end
```

Call the function from the command line.

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];
[ave,stdev] = stat(values)
```

```
ave =
   47.3400
stdev =
   29.4124
```

Multiple Functions in a File

Define two functions in a file named `stat2.m`, where the first function calls the second.

```
function [m,s] = stat2(x)
n = length(x);
m = avg(x,n);
s = sqrt(sum((x-m).^2/n));
end

function m = avg(x,n)
m = sum(x)/n;
end
```

Function `avg` is a *local function*. Local functions are only available to other functions within the same file.

Call function `stat2` from the command line.

```
values = [12.7, 45.4, 98.9, 26.6, 53.1];
[ave,stdev] = stat2(values)
```

```
ave =
   47.3400
stdev =
   29.4124
```

Introduced before R2006a

function_handle (@)

Handle used in calling functions indirectly

Syntax

```
handle = @functionname
handle = @(arglist)anonymous_function
```

Description

`handle = @functionname` returns a handle to the specified MATLAB function.

A function handle is a MATLAB value that provides a means of calling a function indirectly. You can pass function handles in calls to other functions (often called *function functions*). You can also store function handles in data structures for later use (for example, as Handle Graphics callbacks). A function handle is one of the standard MATLAB data types.

At the time you create a function handle, the function you specify must be on the MATLAB path and in the current scope of the code creating the handle. For example, you can create a handle to a local function as long as you do so from within the file that defines that local function. This condition does not apply when you evaluate the function handle. You can, for example, execute a local function from a separate (out-of-scope) file using a function handle. This requires that the handle was created by the local function (in-scope).

`handle = @(arglist)anonymous_function` constructs an anonymous function and returns a `handle` to that function. The body of the function, to the right of the parentheses, is a single MATLAB statement or command. `arglist` is a comma-separated list of input arguments. Execute the function by calling it by means of the function handle, `handle`.

Examples

Example 1 — Constructing a Handle to a Named Function

The following example creates a function handle for the `humps` function and assigns it to the variable `fhandle`.

```
fhandle = @humps;
```

Pass the handle to another function in the same way you would pass any argument. This example passes the function handle just created to `fminbnd`, which then minimizes over the interval `[0.3, 1]`.

```
x = fminbnd(fhandle, 0.3, 1)
x =
    0.6370
```

The `fminbnd` function evaluates the `@humps` function handle. A small portion of the `fminbnd` file is shown below. In line 1, the `funfcn` input parameter receives the function handle `@humps` that was passed in. The statement, in line 113, evaluates the handle.

```
1    function [xf,fval,exitflag,output] = ...
         fminbnd(funfcn,ax,bx,options,varargin)
             .
             .
             .
113  fx = funfcn(x,varargin{:});
```

Example 2 — Constructing a Handle to an Anonymous Function

The statement below creates an anonymous function that finds the square of a number. When you call this function, MATLAB assigns the value you pass in to variable `x`, and then uses `x` in the equation `x.^2`:

```
sqr = @(x) x.^2;
```

The `@` operator constructs a function handle for this function, and assigns the handle to the output variable `sqr`. As with any function handle, you execute the function associated with it by specifying the variable that contains the handle, followed by a comma-separated argument list in parentheses. The syntax is

```
fhandle(arg1, arg2, ..., argN)
```

To execute the `sqr` function defined above, type

```
a = sqr(5)
a =
   25
```

Because `sqr` is a function handle, you can pass it in an argument list to other functions. The code shown here passes the `sqr` anonymous function to the MATLAB `integral` function to compute its integral from zero to one:

```
integral(sqr, 0, 1)
ans =
   0.3333
```

Example 3 — Using an Array of Function Handles

This example creates a structure array of function handles `S` and then applies each handle in the array to the output of a `linspace` calculation in one operation using `structfun`:

```
S.a = @sin;  S.b = @cos;  S.c = @tan;
structfun(@(x)x(linspace(1,4,3)), S, 'UniformOutput', false)
ans =
    a: [0.8415 0.5985 -0.7568]
    b: [0.5403 -0.8011 -0.6536]
    c: [1.5574 -0.7470 1.1578]
```

More About

Tips

The function handle is a standard MATLAB data type. As such, you can manipulate and operate on function handles in the same manner as on other MATLAB data types. This includes using function handles in structures and cell arrays:

```
S.a = @sin;  S.b = @cos;  S.c = @tan;
C = {@sin, @cos, @tan};
```

However, standard matrices or arrays of function handles are not supported:

```
A = [@sin, @cos, @tan];        % This is not supported
```

For nonoverloaded functions, local functions, and private functions, a function handle references just the one function specified in the `@functionname` syntax. When you evaluate an overloaded function by means of its handle, the arguments the handle is evaluated with determine the actual function that MATLAB dispatches to.

Use `isa(h, 'function_handle')` to see if variable `h` is a function handle.

functions

Information about function handle

Syntax

```
S = functions(funhandle)
```

Description

`S = functions(funhandle)` returns, in MATLAB structure `S`, the function name, type, filename, and other information for the function handle stored in the variable `funhandle`.

`functions` does not operate on nonscalar function handles. Passing a nonscalar function handle to `functions` results in an error.

Caution The `functions` function is provided for querying and debugging purposes. Because its behavior may change in subsequent releases, you should not rely upon it for programming purposes.

This table lists the standard fields of the return structure.

Field Name	Field Description
`function`	Function name
`type`	Function type (e.g., simple, overloaded)
`file`	The file to be executed when the function handle is evaluated with a nonoverloaded data type

Examples

Example 1

To obtain information on a function handle for the `poly` function, type

```
f = functions(@poly)
f =
    function: 'poly'
        type: 'simple'
        file:  '$matlabroot\toolbox\matlab\polyfun\poly.m'
```

(The term `$matlabroot` used in this example stands for the file specification of the directory in which MATLAB software is installed for your system. Your output will display this file specification.)

Access individual fields of the returned structure using dot selection notation:

```
f.type
ans =
   simple
```

Example 2

The function `get_handles` returns function handles for a local function and private function in output arguments `l` and `p` respectively:

```
function [l, p] = get_handles
l = @mylocfun;
p = @myprivatefun;
%
function mylocfun
disp 'Executing local function mylocfun'
```

Call `get_handles` to obtain the two function handles, and then pass each to the `functions` function. MATLAB returns information in a structure having the fields `function`, `type`, `file`, and `parentage`. The `file` field contains the file specification for the local or private function:

```
[floc fprv] = get_handles;

functions(floc)
ans =
     function: 'mylocfun'
         type: 'scopedfunction'
         file: 'c:\matlab\get_handles.m'
    parentage: {'mylocfun'  'get_handles'}

functions(fprv)
ans =
```

```
     function: 'myprivatefun'
         type: 'scopedfunction'
         file: 'c:\matlab\private\myprivatefun.m'
    parentage: {'myprivatefun'}
```

Example 3

In this example, the function `get_handles_nested.m` contains a nested function `nestfun`. This function has a single output which is a function handle to the nested function:

```
function handle = get_handles_nested(A)
nestfun(A);

   function y = nestfun(x)
   y = x + 1;
   end

handle = @nestfun;
end
```

Call this function to get the handle to the nested function. Use this handle as the input to `functions` to return the information shown here. Note that the `function` field of the return structure contains the names of the nested function and the function in which it is nested in the format. Also note that `functions` returns a `workspace` field containing the variables that are in context at the time you call this function by its handle:

```
fh = get_handles_nested(5);

fhinfo = functions(fh)
fhinfo =
     function: 'get_handles_nested/nestfun'
         type: 'nested'
         file: 'c:\matlab\get_handles_nested.m'
    workspace: [1x1 struct]

fhinfo.workspace
ans =
    handle: @get_handles_nested/nestfun
         A: 5
```

Introduced before R2006a

functiontests

Create array of tests from handles to local functions

Syntax

```
tests = functiontests(f)
```

Description

`tests = functiontests(f)` creates an array of tests, `tests`, from a cell array of handles to local functions, `f`. To apply defined setup and teardown functions, include their function handles in `f`.

Local test functions must include 'test' at the beginning or end of the function name. `functiontests` must be called from within a test file.

Examples

Create Test Array

Create the file `exampleTest.m` in your MATLAB path. In the main function, create a test array. Use local functions to define setup, teardown, and two function tests. Your file should look like this.

```
function tests = exampleTest
tests = functiontests(localfunctions);

function setup(testCase)
function teardown(testCase)
function exampleOneTest(testCase)
function testExampleTwo(testCase)
```

From the command line, call the `exampleTest` function.

```
tests = exampleTest
```

```
tests =

  1x2 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

Access the test suite to verify the names of the two function tests.

```
tests.Name
```

```
ans =

exampleTest/exampleOneTest

ans =

exampleTest/testExampleTwo
```

- "Write Function-Based Unit Tests"
- "Write Simple Test Case Using Functions"
- "Write Test Using Setup and Teardown Functions"

Input Arguments

`f` — Handles to local test functions

cell array of function handles

Handles to local test functions, specified as a cell array. Use `f=localfunctions` in your working file to automatically generate a cell array of function handles for that file. If you want explicit test enumeration, construct `f` by listing individual functions. `f` must include any setup or teardown functions necessary for your test.

Example: `f = localfunctions;`

Example: `f = {@setup,@exampleOneTest,@teardown};`

`matlab.unittest.Test` | `localfunctions` | `runtests`

funm

Evaluate general matrix function

Syntax

```
F = funm(A,fun)
F = funm(A,fun,options)
F = funm(A,fun,options,p1,p2,...)
[F,exitflag] = funm(...)
[F,exitflag,output] = funm(...)
```

Description

`F = funm(A,fun)` evaluates the user-defined function `fun` at the square matrix argument `A`. `F = fun(x,k)` must accept a vector `x` and an integer `k`, and return a vector `f` of the same size of `x`, where `f(i)` is the `k`th derivative of the function `fun` evaluated at `x(i)`. The function represented by fun must have a Taylor series with an infinite radius of convergence, except for `fun = @log`, which is treated as a special case.

You can also use `funm` to evaluate the special functions listed in the following table at the matrix `A`.

Function	Syntax for Evaluating Function at Matrix A
`exp`	`funm(A, @exp)`
`log`	`funm(A, @log)`
`sin`	`funm(A, @sin)`
`cos`	`funm(A, @cos)`
`sinh`	`funm(A, @sinh)`
`cosh`	`funm(A, @cosh)`

For matrix square roots, use `sqrtm(A)` instead. For matrix exponentials, which of `expm(A)` or `funm(A, @exp)` is the more accurate depends on the matrix `A`.

The function represented by `fun` must have a Taylor series with an infinite radius of convergence. The exception is `@log`, which is treated as a special case. “Parameterizing

Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`F = funm(A,fun,options)` sets the algorithm's parameters to the values in the structure `options`.

The following table lists the fields of `options`.

Field	Description	Values
`options.Display`	Level of display	`'off'` (default), `'on'`, `'verbose'`
`options.TolBlk`	Tolerance for blocking Schur form	Positive scalar. The default is `0.1`.
`options.TolTay`	Termination tolerance for evaluating the Taylor series of diagonal blocks	Positive scalar. The default is `eps`.
`options.MaxTerms`	Maximum number of Taylor series terms	Positive integer. The default is `250`.
`options.MaxSqrt`	When computing a logarithm, maximum number of square roots computed in inverse scaling and squaring method.	Positive integer. The default is `100`.
`options.Ord`	Specifies the ordering of the Schur form `T`.	A vector of length `length(A)`. `options.Ord(i)` is the index of the block into which `T(i,i)` is placed. The default is `[]`.

`F = funm(A,fun,options,p1,p2,...)` passes extra inputs `p1,p2,...` to the function.

`[F,exitflag] = funm(...)` returns a scalar `exitflag` that describes the exit condition of `funm`. `exitflag` can have the following values:

- `0` — The algorithm was successful.
- `1` — One or more Taylor series evaluations did not converge, or, in the case of a logarithm, too many square roots are needed. However, the computed value of `F` might still be accurate.

`[F,exitflag,output] = funm(...)` returns a structure `output` with the following fields:

Field	Description
`output.terms`	Vector for which `output.terms(i)` is the number of Taylor series terms used when evaluating the *i*th block, or, in the case of the logarithm, the number of square roots of matrices of dimension greater than 2.
`output.ind`	Cell array for which the `(i,j)` block of the reordered Schur factor `T` is `T(output.ind{i}, output.ind{j})`.
`output.ord`	Ordering of the Schur form, as passed to `ordschur`
`output.T`	Reordered Schur form

If the Schur form is diagonal then `output = struct('terms',ones(n,1),'ind',{1:n})`.

Examples

Example 1

The following command computes the matrix sine of the 3-by-3 magic matrix.

```
F=funm(magic(3), @sin)

F =

   -0.3850    1.0191    0.0162
    0.6179    0.2168   -0.1844
    0.4173   -0.5856    0.8185
```

Example 2

The statements

```
S = funm(X,@sin);
C = funm(X,@cos);
```

produce the same results to within roundoff error as

```
E = expm(i*X);
C = real(E);
S = imag(E);
```

In either case, the results satisfy `S*S+C*C = I`, where `I = eye(size(X))`.

Example 3

To compute the function `exp(x) + cos(x)` at `A` with one call to `funm`, use

```
F = funm(A,@fun_expcos)
```

where `fun_expcos` is the following function.

```
function f = fun_expcos(x, k)
% Return kth derivative of exp + cos at X.
        g = mod(ceil(k/2),2);
        if mod(k,2)
           f = exp(x) + sin(x)*(-1)^g;
        else
           f = exp(x) + cos(x)*(-1)^g;
        end
```

More About

Algorithms

The algorithm `funm` uses is described in [1].

fwrite

Write data to binary file

Syntax

```
fwrite(fileID,A)
fwrite(fileID,A,precision)
fwrite(fileID,A,precision,skip)
fwrite(fileID,A,precision,skip,machinefmt)

count = fwrite( ___ )
```

Description

`fwrite(fileID,A)` write the elements of array `A` as 8-bit unsigned integers to a binary file in column order. The binary file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading, close the file by calling `fclose(fileID)`.

`fwrite(fileID,A,precision)` writes the values in `A` in the form and size described by `precision`.

`fwrite(fileID,A,precision,skip)` skips the number of bytes or bits specified by `skip` before writing each value.

`fwrite(fileID,A,precision,skip,machinefmt)` additionally specifies the order for writing bytes or bits to the file. The `skip` argument is optional.

`count = fwrite( ___ )` returns the number of elements of `A` that `fwrite` successfully writes to the file. You can use this syntax with any of the input arguments of the previous syntaxes.

Examples

Write uint8 Data to Binary File

Open a file named `nine.bin` for writing. Specify write access using `'w'` in the call to `fopen`.

```
fileID = fopen('nine.bin','w');
```

`fopen` returns a file identifier, `fileID`.

Write the integers from 1 to 9 as 8-bit unsigned integers.

```
fwrite(fileID,[1:9]);
```

Close the file.

```
fclose(fileID);
```

Write 4-byte Integers to Binary File

Open a file named `magic5.bin` for writing.

```
fileID = fopen('magic5.bin','w');
```

Write the 25 elements of the 5-by-5 magic square. Use the `precision` argument, `'integer*4'`, to write 4-byte integers.

```
fwrite(fileID,magic(5),'integer*4');
```

Close the file.

```
fclose(fileID);
```

Append Data to Binary File

Write a binary file containing the elements of the 4-by-4 magic square, stored as double-precision floating-point numbers.

```
fileID = fopen('magic4.bin','w');
fwrite(fileID,magic(4),'double');
fclose(fileID);
```

Open the file, `magic4.bin`, with write-access that enables appending to the file. Specify the file-access type, `'a'`, in the call to `fopen`.

```
fileID = fopen('magic4.bin','a');
```

Append a 4-by-4 matrix of zeros to the file. Then, close the file.

```
fwrite(fileID,zeros(4),'double');
fclose(fileID);
```

Write Binary File with Big-Endian Byte Ordering

Write random double-precision numbers to a file named `myfile.bin` for use on a big-endian system. Specify a `machinefmt` value of `'ieee-be'` in the call to `fwrite`, to indicate big-endian byte ordering.

```
fileID = fopen('myfile.bin','w');
fwrite(fileID,rand(4),'double','ieee-be');
fclose(fileID);
```

- "Writing and Reading Complex Numbers"

Input Arguments

`fileID` — File identifier

integer | 1 | 2

File identifier, specified as an integer obtained from `fopen`, `1` for standard output (the screen), or `2` for standard error.

A — Data to write

numeric array | character array

Data to write, specified as a numeric or character array.

Example: `[1,2,3;4,5,6]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

`precision` — Class and size of values to write

`uint8` (default) | string

Class and size in bits of the values to write, specified as one of the following strings in the Precision column.

Value Type	Precision	Bits (Bytes)
Integers, unsigned	`uint`	32 (4)
	`uint8`	8 (1)
	`uint16`	16 (2)
	`uint32`	32 (4)
	`uint64`	64 (8)
	`uchar`	8 (1)
	`unsigned char`	8 (1)
	`ushort`	16 (2)
	`ulong`	32 (4)
	`ubit`*n*	$1 \le n \le 64$
Integers, signed	`int`	32 (4)
	`int8`	8 (1)
	`int16`	16 (2)
	`int32`	32 (4)
	`int64`	64 (8)
	`integer*1`	8 (1)
	`integer*2`	16 (2)
	`integer*4`	32 (4)
	`integer*8`	64 (8)
	`schar`	8 (1)
	`signed char`	8 (1)
	`short`	16 (2)
	`long`	32 (4)
	`bit`*n*	$1 \le n \le 64$
Floating-point numbers	`single`	32 (4)
	`double`	64 (8)

Value Type	Precision	Bits (Bytes)
	`float`	`32 (4)`
	`float32`	`32 (4)`
	`float64`	`64 (8)`
	`real*4`	`32 (4)`
	`real*8`	`64 (8)`
Characters	`char*1`	`8 (1)`
	`char`	Depends on the encoding scheme associated with the file. Set encoding with `fopen`.

If you specify a precision of `bit`*n* or `ubit`*n*, then `fwrite` saturates for all values outside the range.

Note: To preserve `NaN` and `Inf` values in MATLAB, read and write data of class `double` or `single`.

`skip` — Number of bytes to skip

0 (default) | scalar

Number of bytes to skip before writing each value, specified as a scalar. If you specify a `precision` of `bit`*n* or `ubit`*n*, specify `skip` in bits.

Use the `skip` argument to insert data into noncontiguous fields in fixed-length records.

`machinefmt` — Order for writing bytes

`'n'` (default) | `'b'` | `'l'` | `'s'` | `'a'`

Order for writing bytes within the file, specified as one of the strings in the table that follows. For `bit`*n* and `ubit`*n* precisions, `machinefmt` specifies the order for writing bits within a byte, but the order for writing bytes remains your system byte ordering.

`'n'` or `'native'`	Your system byte ordering (default)
`'b'` or `'ieee-be'`	Big-endian ordering
`'l'` or `'ieee-le'`	Little-endian ordering

`'s'` or `'ieee-be.l64'`	Big-endian ordering, 64-bit long data type
`'a'` or `'ieee-le.l64'`	Little-endian ordering, 64-bit long data type

By default, all currently supported platforms use little-endian ordering for new files. Existing binary files can use either big-endian or little-endian ordering.

fwrite (serial)

Write binary data to device

Syntax

```
fwrite(obj,A)
fwrite(obj,A,'precision')
fwrite(obj,A,'mode')
fwrite(obj,A,'precision','mode')
```

Description

`fwrite(obj,A)` writes the binary data `A` to the device connected to the serial port object, `obj`.

`fwrite(obj,A,'precision')` writes binary data with precision specified by *`precision`*.

`precision` controls the number of bits written for each value and the interpretation of those bits as integer, floating-point, or character values. If *`precision`* is not specified, `uchar` (an 8-bit unsigned character) is used. The supported values for *`precision`* are listed in Tips.

`fwrite(obj,A,'mode')` writes binary data with command-line access specified by *`mode`*. If *`mode`* is `sync`, `A` is written synchronously and the command line is blocked. If *`mode`* is `async`, `A` is written asynchronously and the command line is not blocked. If *`mode`* is not specified, the write operation is synchronous.

`fwrite(obj,A,'precision','mode')` writes binary data with precision specified by *`precision`* and command-line access specified by *`mode`*.

More About

Tips

Before you can write data to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error

is returned if you attempt to perform a write operation while `obj` is not connected to the device.

The `ValuesSent` property value is increased by the number of values written each time `fwrite` is issued.

An error occurs if the output buffer cannot hold all the data to be written. You can specify the size of the output buffer with the `OutputBufferSize` property.

If you set the `FlowControl` property to `hardware` on a serial object, and a hardware connection is not detected, `fwrite` returns an error message. This occurs if a device is not connected, or a connected device is not asserting that is ready to receive data. Check the remote device status and flow control settings to see if hardware flow control is causing errors in MATLAB.

Note: If you want to check to see if the device is asserting that it is ready to receive data, set the `FlowControl` to `none`. Once you connect to the device, check the `PinStatus` structure for `ClearToSend`. If `ClearToSend` is `off`, there is a problem on the remote device side. If `ClearToSend` is `on`, there is a hardware `FlowControl` device prepared to receive data and you can execute `fwrite`.

Synchronous Versus Asynchronous Write Operations

By default, data is written to the device synchronously and the command line is blocked until the operation completes. You can perform an asynchronous write by configuring the *`mode`* input argument to be `async`. For asynchronous writes:

- The `BytesToOutput` property value is continuously updated to reflect the number of bytes in the output buffer.
- The callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

You can determine whether an asynchronous write operation is in progress with the `TransferStatus` property.

Synchronous and asynchronous write operations are discussed in more detail in Writing Data.

Rules for Completing a Write Operation with fwrite

A binary write operation using `fwrite` completes when:

- The specified data is written.
- The time specified by the `Timeout` property passes.

Note The `Terminator` property is not used with binary write operations.

Supported Precisions

The following table shows the supported values for *`precision`*.

Data Type	Precision	Interpretation
Character	`uchar`	8-bit unsigned character
	`schar`	8-bit signed character
	`char`	8-bit signed or unsigned character
Integer	`int8`	8-bit integer
	`int16`	16-bit integer
	`int32`	32-bit integer
	`uint8`	8-bit unsigned integer
	`uint16`	16-bit unsigned integer
	`uint32`	32-bit unsigned integer
	`short`	16-bit integer
	`int`	32-bit integer
	`long`	32- or 64-bit integer
	`ushort`	16-bit unsigned integer
	`uint`	32-bit unsigned integer
	`ulong`	32- or 64-bit unsigned integer
Floating-point	`single`	32-bit floating point
	`float32`	32-bit floating point
	`float`	32-bit floating point

Data Type	Precision	Interpretation
	`double`	64-bit floating point
	`float64`	64-bit floating point

fzero

Root of nonlinear function

Syntax

```
x = fzero(fun,x0)
x = fzero(fun,x0,options)

x = fzero(problem)

[x,fval,exitflag,output] = fzero( ___ )
```

Description

`x = fzero(fun,x0)` tries to find a point `x` where `fun(x) = 0`. This solution is where `fun(x)` changes sign—`fzero` cannot find a root of a function such as `x^2`.

`x = fzero(fun,x0,options)` uses `options` to modify the solution process.

`x = fzero(problem)` solves a root-finding problem specified by `problem`.

`[x,fval,exitflag,output] = fzero( ___ )` returns `fun(x)` in the `fval` output, `exitflag` encoding the reason `fzero` stopped, and an output structure containing information on the solution process.

Examples

Root Starting From One Point

Calculate π by finding the zero of the sine function near `3`.

```
fun = @sin; % function
x0 = 3; % initial point
x = fzero(fun,x0)
```

```
x =

    3.1416
```

Root Starting From an Interval

Find the zero of cosine between 1 and 2.

```
fun = @cos; % function
x0 = [1 2]; % initial interval
x = fzero(fun,x0)
```

```
x =

    1.5708
```

Note that $\cos(1)$ and $\cos(2)$ differ in sign.

Root of a Function Defined by a File

Find a zero of the function $f(x) = x^3 - 2x - 5$.

First, write a file called `f.m`.

```
function y = f(x)
y = x.^3 - 2*x - 5;
```

Save `f.m` on your MATLAB path.

Find the zero of $f(x)$ near 2.

```
fun = @f; % function
x0 = 2; % initial point
z = fzero(fun,x0)
```

```
z =
    2.0946
```

Since `f(x)` is a polynomial, you can find the same real zero, and a complex conjugate pair of zeros, using the `roots` command.

```
roots([1 0 -2 -5])

   ans =
   2.0946
  -1.0473 + 1.1359i
  -1.0473 - 1.1359i
```

Root of Function with Extra Parameter

Find the root of a function that has an extra parameter.

```
myfun = @(x,c) cos(c*x);  % parameterized function
c = 2;                    % parameter
fun = @(x) myfun(x,c);    % function of x alone
x = fzero(fun,0.1)

x =

    0.7854
```

Nondefault Options

Plot the solution process by setting some plot functions.

Define the function and initial point.

```
fun = @(x)sin(cosh(x));
x0 = 1;
```

Examine the solution process by setting options that include plot functions.

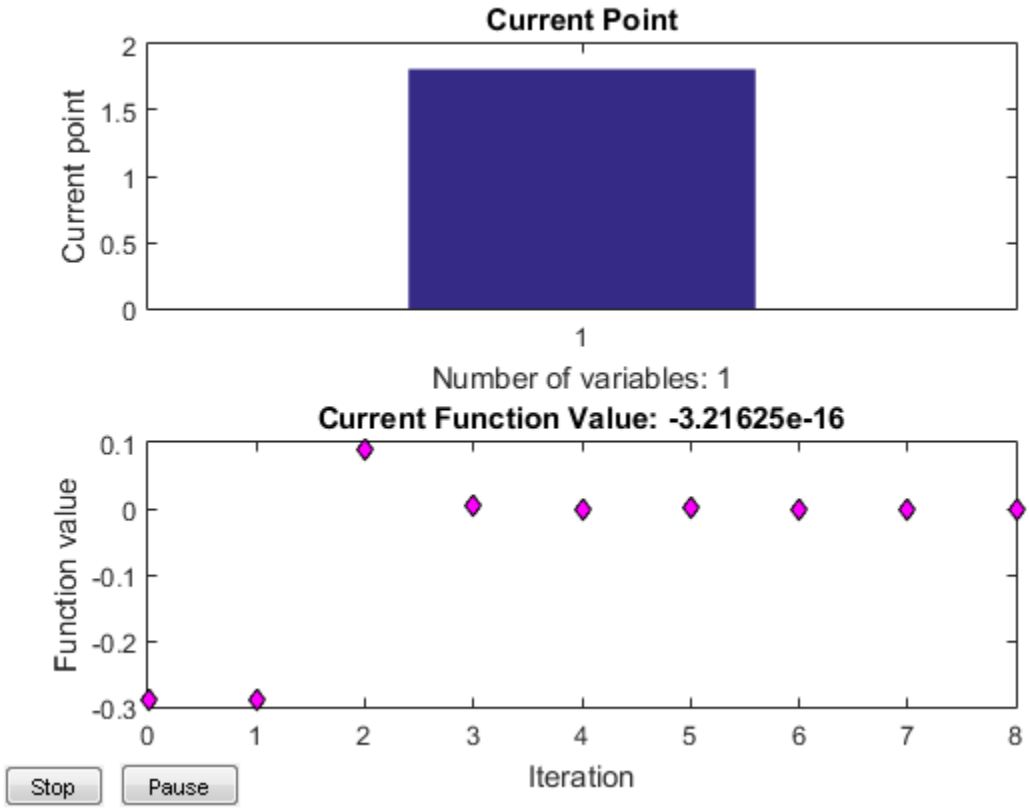
```
options = optimset('PlotFcns',{@optimplotx,@optimplotfval});
```

Run `fzero` including `options`.

```
x = fzero(fun,x0,options)

x =

    1.8115
```



Solve Problem Structure

Solve a problem that is defined by a problem structure.

Define a structure that encodes a root-finding problem.

```
problem.objective = @(x)sin(cosh(x));
problem.x0 = 1;
problem.solver = 'fzero'; % a required part of the structure
problem.options = optimset(@fzero); % default options
```

Solve the problem.

```
x = fzero(problem)
```

```
x =

    1.8115
```

More Information from Solution

Find the point where `exp(-exp(-x)) = x`, and display information about the solution process.

```
fun = @(x) exp(-exp(-x)) - x; % function
x0 = [0 1]; % initial interval
options = optimset('Display','iter'); % show iterations
[x fval exitflag output] = fzero(fun,x0,options)
```

```
 Func-count    x          f(x)             Procedure
    2              1     -0.307799        initial
    3        0.544459     0.0153522        interpolation
    4        0.566101    0.00070708        interpolation
    5        0.567143  -1.40255e-08        interpolation
    6        0.567143   1.50013e-12        interpolation
    7        0.567143             0        interpolation

Zero found in the interval [0, 1]

x =

    0.5671

fval =

     0

exitflag =

     1

output =

    intervaliterations: 0
```

```
       iterations: 5
        funcCount: 7
        algorithm: 'bisection, interpolation'
          message: 'Zero found in the interval [0, 1]'
```

`fval` = 0 means `fun(x) = 0`, as desired.

- "Roots of Scalar Functions"
- "Parameterizing Functions"

Input Arguments

`fun` — Function to solve

function handle

Function to solve, specified as a handle to a scalar-valued function. `fun` accepts a scalar `x` and returns a scalar `fun(x)`.

`fzero` solves `fun(x) = 0`. To solve an equation `fun(x) = c(x)`, instead solve `fun2(x) = fun(x) - c(x) = 0`.

To include extra parameters in your function, see the example "Root of Function with Extra Parameter" on page 1-2858 and the section "Parameterizing Functions".

Example: `@sin`

Example: `@myFunction`

Example: `@(x)(x-a)^5 - 3*x + a - 1`

Data Types: `function_handle`

`x0` — Initial value

scalar | 2-element vector

Initial value, specified as a real scalar or a 2-element real vector.

- Scalar — `fzero` begins at `x0` and tries to locate a point `x1` where `fun(x1)` has the opposite sign of `fun(x0)`. Then `fzero` iteratively shrinks the interval where `fun` changes sign to reach a solution.
- 2-element vector — `fzero` checks that `fun(x0(1))` and `fun(x0(2))` have opposite signs, and errors if they do not. It then iteratively shrinks the interval where `fun`

changes sign to reach a solution. An interval `x0` must be finite; it cannot contain `±Inf`.

Tip Calling `fzero` with an interval (`x0` with two elements) is often faster than calling it with a scalar `x0`.

Example: 3

Example: [2,17]

Data Types: `double`

`options` — Options for solution process

structure, typically created using `optimset`

Options for solution process, specified as a structure. Create or modify the `options` structure using `optimset`. `fzero` uses these `options` structure fields.

`Display`	Level of display: • `'off'` displays no output. • `'iter'` displays output at each iteration. • `'final'` displays just the final output. • `'notify'` (default) displays output only if the function does not converge.
`FunValCheck`	Check whether objective function values are valid. • `'on'` displays an error when the objective function returns a value that is `complex`, `Inf`, or `NaN`. • The default, `'off'`, displays no error.
`OutputFcn`	Specify one or more user-defined functions that an optimization function calls at each iteration, either as a function handle or as a cell array of function handles. The default is none (`[]`). See “Output Functions”.
`PlotFcns`	Plot various measures of progress while the algorithm executes. Select from predefined plots or write your own. Pass a function handle or a cell array of function handles. The default is none (`[]`).

	• `@optimplotx` plots the current point. • `@optimplotfval` plots the function value. For information on writing a custom plot function, see "Plot Functions".
`TolX`	Termination tolerance on `x`, a positive scalar. The default is `eps`, 2.2204e–16.

Example: `options = optimset('FunValCheck','on')`

Data Types: `struct`

`problem` — Root-finding problem

structure

Root-finding problem, specified as a structure with all of the following fields.

`objective`	Objective function
`x0`	Initial point for `x`, real scalar or 2-element vector
`solver`	`'fzero'`
`options`	Options structure, typically created using `optimset`

For an example, see "Solve Problem Structure" on page 1-2859.

Data Types: `struct`

Output Arguments

`x` — Location of root or sign change

real scalar

Location of root or sign change, returned as a scalar.

`fval` — Function value at `x`

real scalar

Function value at `x`, returned as a scalar.

`exitflag` — Integer encoding the exit condition

integer

Integer encoding the exit condition, meaning the reason `fsolve` stopped its iterations.

`1`	Function converged to a solution `x`.
`-1`	Algorithm was terminated by the output function or plot function.
`-3`	`NaN` or `Inf` function value was encountered while searching for an interval containing a sign change.
`-4`	Complex function value was encountered while searching for an interval containing a sign change.
`-5`	Algorithm might have converged to a singular point.
`-6`	`fzero` did not detect a sign change.

`output` — Information about root-finding process

structure

Information about root-finding process, returned as a structure. The fields of the structure are:

`intervaliterations`	Number of iterations taken to find an interval containing a root
`iterations`	Number of zero-finding iterations
`funcCount`	Number of function evaluations
`algorithm`	`'bisection, interpolation'`
`message`	Exit message

More About

Algorithms

The `fzero` command is a function file. The algorithm, created by T. Dekker, uses a combination of bisection, secant, and inverse quadratic interpolation methods. An Algol 60 version, with some improvements, is given in [1]. A Fortran version, upon which `fzero` is based, is in [2].

Introduced before R2006a

matlab.unittest.FunctionTestCase class

Package: matlab.unittest
Superclasses: matlab.unittest.TestCase

TestCase used for function-based tests

Description

The `FunctionTestCase` class is a subclass of `TestCase` that allows function-based tests to use qualification functions in the `matlab.unittest.qualifications` package. For each test function, MATLAB creates an instance of the `FunctionTestCase` class and passes it to the test function.

The `functiontests` function constructs `FunctionTestCase` instances, so there is no need for test authors to construct this class directly.

Introduced in R2013b

gallery

Test matrices

Syntax

```
[A,B,C,...] = gallery(matname,P1,P2,...)
[A,B,C,...] = gallery(matname,P1,P2,...,classname)
gallery(3)
gallery(5)
```

Description

`[A,B,C,...] = gallery(matname,P1,P2,...)` returns the test matrices specified by the quoted string `matname`. The `matname` input is the name of a matrix family selected from the table below. `P1,P2,...` are input parameters required by the individual matrix family. The number of optional parameters `P1,P2,...` used in the calling syntax varies from matrix to matrix. The exact calling syntaxes are detailed in the individual matrix descriptions below.

`[A,B,C,...] = gallery(matname,P1,P2,...,classname)` produces a matrix of class `classname`. The `classname` input is a quoted string that must be either `'single'` or `'double'` (unless `matname` is `'integerdata'`, in which case `'int8'`, `'int16'`, `'int32'`, `'uint8'`, `'uint16'`, and `'uint32'` are also allowed). If `classname` is not specified, then the class of the matrix is determined from those arguments among `P1,P2,...` that do not specify dimensions or select an option. If any of these arguments is of class `single` then the matrix is `single`; otherwise the matrix is `double`.

`gallery(3)` is a badly conditioned 3-by-3 matrix and `gallery(5)` is an interesting eigenvalue problem.

The gallery holds over fifty different test matrix functions useful for testing algorithms and other purposes.

binomial — Multiple of involutory matrix

`A = gallery('binomial',n)` returns an `n`-by-`n` matrix,with integer entries such that `A^2 = 2^(n-1)*eye(n)`.

Thus, `B = A*2^((1-n)/2)` is involutory, that is, `B^2 = eye(n)`.

cauchy — Cauchy matrix

`C = gallery('cauchy',x,y)` returns an `n`-by-`n` matrix, `C(i,j) = 1/(x(i)+y(j))`. Arguments `x` and `y` are vectors of length `n`. If you pass in scalars for `x` and `y`, they are interpreted as vectors `1:x` and `1:y`.

`C = gallery('cauchy',x)` returns the same as above with `y = x`. That is, the command returns `C(i,j) = 1/(x(i)+x(j))`.

Explicit formulas are known for the inverse and determinant of a Cauchy matrix. The determinant `det(C)` is nonzero if `x` and `y` both have distinct elements. `C` is totally positive if `0 < x(1) <... < x(n)` and `0 < y(1) < ... < y(n)`.

chebspec — Chebyshev spectral differentiation matrix

`C = gallery('chebspec',n,switch)` returns a Chebyshev spectral differentiation matrix of order `n`. Argument `switch` is a variable that determines the character of the output matrix. By default, `switch` = `0`.

For `switch` = `0` (“no boundary conditions”), `C` is nilpotent (`C^n = 0`) and has the null vector `ones(n,1)`. The matrix `C` is similar to a Jordan block of size `n` with eigenvalue zero.

For `switch` = `1`, `C` is nonsingular and well-conditioned, and its eigenvalues have negative real parts.

The eigenvector matrix of the Chebyshev spectral differentiation matrix is ill-conditioned.

chebvand — Vandermonde-like matrix for the Chebyshev polynomials

`C = gallery('chebvand',p)` produces the (primal) Chebyshev Vandermonde matrix based on the vector of points `p`, which define where the Chebyshev polynomial is calculated.

`C = gallery('chebvand',m,p)` where `m` is scalar, produces a rectangular version of the above, with `m` rows.

If p is a vector, then $C(i,j) = T_{i-1}(p(j))$ where T_{i-1} is the Chebyshev polynomial of degree $i-1$. If p is a scalar, then p equally spaced points on the interval [0,1] are used to calculate C.

chow — Singular Toeplitz lower Hessenberg matrix

A = gallery('chow',n,alpha,delta) returns A such that A = H(alpha) + delta*eye(n), where $H_{i,j}(\alpha) = \alpha^{(i-j+1)}$ and argument n is the order of the Chow matrix. Default value for scalars alpha and delta are 1 and 0, respectively.

H(alpha) has p = floor(n/2) eigenvalues that are equal to zero. The rest of the eigenvalues are equal to 4*alpha*cos(k*pi/(n+2))^2, k=1:n-p.

circul — Circulant matrix

C = gallery('circul',v) returns the circulant matrix whose first row is the vector v.

A circulant matrix has the property that each row is obtained from the previous one by cyclically permuting the entries one step forward. It is a special Toeplitz matrix in which the diagonals "wrap around."

If v is a scalar, then C = gallery('circul',1:v).

The eigensystem of C (n-by-n) is known explicitly: If t is an nth root of unity, then the inner product of v and $w = [1\ t\ t^2\ \ldots\ t^{(n-1)}]$ is an eigenvalue of C and w(n:-1:1) is an eigenvector.

clement — Tridiagonal matrix with zero diagonal entries

A = gallery('clement',n,k) returns an n-by-n tridiagonal matrix with zeros on its main diagonal and known eigenvalues. It is singular if n is odd. About 64 percent of the entries of the inverse are zero. The eigenvalues include plus and minus the numbers n-1, n-3, n-5, ..., (1 or 0).

For k=0 (the default), A is nonsymmetric. For k=1, A is symmetric.

gallery('clement',n,1) is diagonally similar to gallery('clement',n).

For odd N = 2*M+1, M+1 of the singular values are the integers sqrt((2*M+1)^2 - (2*K+1).^2), K = 0:M.

Note: Similar properties hold for `gallery('tridiag',x,y,z)` where `y = zeros(n,1)`. The eigenvalues still come in plus/minus pairs but they are not known explicitly.

compar — Comparison matrices

`A = gallery('compar',A,1)` returns `A` with each diagonal element replaced by its absolute value, and each off-diagonal element replaced by minus the absolute value of the largest element in absolute value in its row. However, if `A` is triangular `compar(A,1)` is too.

`gallery('compar',A)` is `diag(B) - tril(B,-1) - triu(B,1)`, where `B = abs(A)`. `compar(A)` is often denoted by M(*A*) in the literature.

`gallery('compar',A,0)` is the same as `gallery('compar',A)`.

condex — Counter-examples to matrix condition number estimators

`A = gallery('condex',n,k,theta)` returns a "counter-example" matrix to a condition estimator. It has order `n` and scalar parameter `theta` (default 100).

The matrix, its natural size, and the estimator to which it applies are specified by `k`:

`k = 1`	4-by-4	LINPACK
`k = 2`	3-by-3	LINPACK
`k = 3`	arbitrary	LINPACK (`rcond`) (independent of `theta`)
`k = 4`	`n >= 4`	LAPACK (RCOND) (default). It is the inverse of this matrix that is a counter-example.

If `n` is not equal to the natural size of the matrix, then the matrix is padded out with an identity matrix to order `n`.

cycol — Matrix whose columns repeat cyclically

`A = gallery('cycol',[m n],k)` returns an `m`-by-`n` matrix with cyclically repeating columns, where one "cycle" consists of `randn(m,k)`. Thus, the rank of matrix `A` cannot exceed `k`, and `k` must be a scalar.

Argument `k` defaults to `round(n/4)`, and need not evenly divide `n`.

`A = gallery('cycol',n,k)`, where `n` is a scalar, is the same as `gallery('cycol', [n n],k)`.

dorr — Diagonally dominant, ill-conditioned, tridiagonal matrix

`[c,d,e] = gallery('dorr',n,theta)` returns the vectors defining an `n`-by-`n`, row diagonally dominant, tridiagonal matrix that is ill-conditioned for small nonnegative values of `theta`. The default value of `theta` is `0.01`. The Dorr matrix itself is the same as `gallery('tridiag',c,d,e)`.

`A = gallery('dorr',n,theta)` returns the matrix itself, rather than the defining vectors.

dramadah — Matrix of zeros and ones whose inverse has large integer entries

`A = gallery('dramadah',n,k)` returns an `n`-by-`n` matrix of `0`'s and `1`'s for which `mu(A) = norm(inv(A),'fro')` is relatively large, although not necessarily maximal. An anti-Hadamard matrix `A` is a matrix with elements `0` or `1` for which `mu(A)` is maximal.

`n` and `k` must both be scalars. Argument `k` determines the character of the output matrix:

k = 1	Default. `A` is Toeplitz, with `abs(det(A)) = 1`, and `mu(A) > c(1.75)^n`, where `c` is a constant. The inverse of `A` has integer entries.
k = 2	`A` is upper triangular and Toeplitz. The inverse of `A` has integer entries.
k = 3	`A` has maximal determinant among lower Hessenberg (0,1) matrices. `det(A)` = the `n`th Fibonacci number. `A` is Toeplitz. The eigenvalues have an interesting distribution in the complex plane.

fiedler — Symmetric matrix

`A = gallery('fiedler',c)`, where `c` is a length `n` vector, returns the `n`-by-`n` symmetric matrix with elements `abs(n(i)-n(j))`. For scalar `c`, `A = gallery('fiedler',1:c)`.

Matrix `A` has a dominant positive eigenvalue and all the other eigenvalues are negative.

Explicit formulas for `inv(A)` and `det(A)` are given in [Todd, J., *Basic Numerical Mathematics*, Vol. 2: Numerical Algebra, Birkhauser, Basel, and Academic Press, New

York, 1977, p. 159] and attributed to Fiedler. These indicate that `inv(A)` is tridiagonal except for nonzero `(1,n)` and `(n,1)` elements.

forsythe — Perturbed Jordan block

`A = gallery('forsythe',n,alpha,lambda)` returns the `n`-by-`n` matrix equal to the Jordan block with eigenvalue `lambda`, excepting that `A(n,1) = alpha`. The default values of scalars `alpha` and `lambda` are `sqrt(eps)` and `0`, respectively.

The characteristic polynomial of `A` is given by:

```
det(A-t*I) = (lambda-t)^N - alpha*(-1)^n.
```

frank — Matrix with ill-conditioned eigenvalues

`F = gallery('frank',n,k)` returns the Frank matrix of order `n`. It is upper Hessenberg with determinant `1`. If `k = 1`, the elements are reflected about the anti-diagonal `(1,n)` — `(n,1)`. The eigenvalues of `F` may be obtained in terms of the zeros of the Hermite polynomials. They are positive and occur in reciprocal pairs; thus if `n` is odd, `1` is an eigenvalue. `F` has `floor(n/2)` ill-conditioned eigenvalues — the smaller ones.

gcdmat — Greatest common divisor matrix

`A = gallery('gcdmat',n)` returns the `n`-by-`n` matrix with `(i,j)` entry `gcd(i,j)`. Matrix`A` is symmetric positive definite, and `A.^r` is symmetric positive semidefinite for all nonnegative `r`.

gearmat — Gear matrix

`A = gallery('gearmat',n,i,j)` returns the `n`-by-`n` matrix with ones on the sub- and super-diagonals, `sign(i)` in the `(1,abs(i))` position, `sign(j)` in the `(n,n+1-abs(j))` position, and zeros everywhere else. Arguments `i` and `j` default to `n` and `-n`, respectively.

Matrix `A` is singular, can have double and triple eigenvalues, and can be defective.

All eigenvalues are of the form `2*cos(a)` and the eigenvectors are of the form `[sin(w+a), sin(w+2*a), ..., sin(w+n*a)]`, where `a` and `w` are given in Gear, C. W., "A Simple Set of Test Matrices for Eigenvalue Programs," *Math. Comp.*, Vol. 23 (1969), pp. 119-125.

grcar — Toeplitz matrix with sensitive eigenvalues

`A = gallery('grcar',n,k)` returns an `n`-by-`n` Toeplitz matrix with `-1`s on the subdiagonal, `1`s on the diagonal, and `k` superdiagonals of `1`s. The default is `k = 3`. The eigenvalues are sensitive.

hanowa — Matrix whose eigenvalues lie on a vertical line in the complex plane

`A = gallery('hanowa',n,d)` returns an `n`-by-`n` block 2-by-2 matrix of the form:

```
[d*eye(m) -diag(1:m)
diag(1:m) d*eye(m)]
```

Argument `n` is an even integer `n=2*m`. Matrix `A` has complex eigenvalues of the form `d ± k*i`, for `1 <= k <= m`. The default value of `d` is `-1`.

house — Householder matrix

`[v,beta,s] = gallery('house',x,k)` takes `x`, an `n`-element column vector, and returns `V` and `beta` such that `H*x = s*e1`. In this expression, `e1` is the first column of `eye(n)`, `abs(s) = norm(x)`, and `H = eye(n) - beta*V*V'` is a Householder matrix.

`k` determines the sign of `s`:

`k = 0`	`sign(s) = -sign(x(1))` (default)
`k = 1`	`sign(s) = sign(x(1))`
`k = 2`	`sign(s) = 1` (`x` must be real)

If `x` is complex, then `sign(x) = x./abs(x)` when `x` is nonzero.

If `x = 0`, or if `x = alpha*e1` (`alpha >= 0`) and either `k = 1` or `k = 2`, then `V = 0`, `beta = 1`, and `s = x(1)`. In this case, `H` is the identity matrix, which is not strictly a Householder matrix.

`[v, beta] = gallery('house',x)` takes `x`, a scalar or `n`-element column vector, and returns `v` and `beta` such that `eye(n,n) - beta*v*v'` is a Householder matrix. A Householder matrix `H` satisfies the relationship

```
H*x = -sign(x(1))*norm(x)*e1
```

where `e1` is the first column of `eye(n,n)`. Note that if `x` is complex, then `sign(x)` `exp(i*arg(x))` (which equals `x./abs(x)` when `x` is nonzero).

If `x = 0`, then `v = 0` and `beta = 1`.

integerdata — Array of arbitrary data from uniform distribution on specified range of integers

`A = gallery('integerdata',imax,[m,n,...],j)` returns an `m`-by-`n`-by-... array `A` whose values are a sample from the uniform distribution on the integers `1:imax`. `j` must be an integer value in the interval `[0, 2^32-1]`. Calling `gallery('integerdata', ...)` with different values of `J` will return different arrays. Repeated calls to `gallery('integerdata',...)` with the same `imax`, size vector and `j` inputs will always return the same array.

In any call to `gallery('integerdata', ...)` you can substitute individual inputs `m`,`n`,... for the size vector input `[m,n,...]`. For example, `gallery('integerdata',7,[1,2,3,4],5)` is equivalent to `gallery('integerdata',7,1,2,3,4,5)`.

`A = gallery('integerdata',[imin imax],[m,n,...],j)` returns an `m`-by-`n`-by-... array `A` whose values are a sample from the uniform distribution on the integers `imin:imax`.

`[A,B,...] = gallery('integerdata',[imin imax],[m,n,...],j)` returns multiple `m`-by-`n`-by-... arrays `A`, `B`, ..., containing different values.

`A = gallery('integerdata',[imin imax],[m,n,...],j,classname)` produces an array of class `classname`. `classname` must be `'uint8'`, `'uint16'`, `'uint32'`, `'int8'`, `'int16'`, `int32'`, `'single'` or `'double'`.

invhess — Inverse of an upper Hessenberg matrix

`A = gallery('invhess',x,y)`, where `x` is a length `n` vector and `y` is a length `n-1` vector, returns the matrix whose lower triangle agrees with that of `ones(n,1)*x'` and whose strict upper triangle agrees with that of `[1 y]*ones(1,n)`.

The matrix is nonsingular if `x(1) ~= 0` and `x(i+1) ~= y(i)` for all `i`, and its inverse is an upper Hessenberg matrix. Argument `y` defaults to `-x(1:n-1)`.

If `x` is a scalar, `invhess(x)` is the same as `invhess(1:x)`.

invol — Involutory matrix

`A = gallery('invol',n)` returns an `n`-by-`n` involutory (`A*A = eye(n)`) and ill-conditioned matrix. It is a diagonally scaled version of `hilb(n)`.

`B = (eye(n)-A)/2` and `B = (eye(n)+A)/2` are idempotent (`B*B = B`).

ipjfact — Hankel matrix with factorial elements

`[A,d] = gallery('ipjfact',n,k)` returns `A`, an `n`-by-`n` Hankel matrix, and `d`, the determinant of `A`, which is known explicitly. If `k = 0` (the default), then the elements of `A` are `A(i,j) = (i+j)!` If `k = 1`, then the elements of `A` are `A(i,j) 1/(i+j)`.

Note that the inverse of `A` is also known explicitly.

jordbloc — Jordan block

`A = gallery('jordbloc',n,lambda)` returns the `n`-by-`n` Jordan block with eigenvalue `lambda`. The default value for `lambda` is `1`.

kahan — Upper trapezoidal matrix

`A = gallery('kahan',n,theta,pert)` returns an upper trapezoidal matrix that has interesting properties regarding estimation of condition and rank.

If `n` is a two-element vector, then `A` is `n(1)`-by-`n(2)`; otherwise, `A` is `n`-by-`n`. The useful range of `theta` is `0 < theta < pi`, with a default value of `1.2`.

To ensure that the QR factorization with column pivoting does not interchange columns in the presence of rounding errors, the diagonal is perturbed by `pert*eps*diag([n:-1:1])`. The default `pert` is `25`, which ensures no interchanges for `gallery('kahan',n)` up to at least `n = 90` in IEEE arithmetic.

kms — Kac-Murdock-Szego Toeplitz matrix

`A = gallery('kms',n,rho)` returns the `n`-by-`n` Kac-Murdock-Szego Toeplitz matrix such that `A(i,j) = rho^(abs(i-j))`, for real `rho`.

For complex `rho`, the same formula holds except that elements below the diagonal are conjugated. `rho` defaults to 0.5.

The KMS matrix `A` has these properties:

- An LDL' factorization with `L inv(gallery('triw',n,-rho,1))'`, and `D(i,i) (1-abs(rho)^2)*eye(n)`, except `D(1,1) = 1`.
- Positive definite if and only if `0 < abs(rho) < 1`.
- The inverse `inv(A)` is tridiagonal.

krylov — Krylov matrix

`B = gallery('krylov',A,x,j)` returns the Krylov matrix

```
[x, Ax, A^2x, ..., A^(j-1)x]
```

where `A` is an `n`-by-`n` matrix and `x` is a length `n` vector. The defaults are `x ones(n,1)`, and `j = n`.

`B = gallery('krylov',n)` is the same as `gallery('krylov',randn(n))`.

lauchli — Rectangular matrix

`A = gallery('lauchli',n,mu)` returns the `(n+1)`-by-`n` matrix

```
[ones(1,n); mu*eye(n)]
```

The Lauchli matrix is a well-known example in least squares and other problems that indicates the dangers of forming `A'*A`. Argument `mu` defaults to `sqrt(eps)`.

lehmer — Symmetric positive definite matrix

`A = gallery('lehmer',n)` returns the symmetric positive definite `n`-by-`n` matrix such that `A(i,j) = i/j` for `j >= i`.

The Lehmer matrix `A` has these properties:

- `A` is totally nonnegative.
- The inverse `inv(A)` is tridiagonal and explicitly known.

- The order `n <= cond(A) <= 4*n*n`.

leslie — Matrix of birth numbers and survival rates

`L = gallery('leslie',a,b)` is the `n`-by-`n` matrix from the Leslie population model with average birth numbers `a(1:n)` and survival rates `b(1:n-1)`. It is zero, apart from the first row (which contains the `a(i)`) and the first subdiagonal (which contains the `b(i)`). For a valid model, the `a(i)` are nonnegative and the `b(i)` are positive and bounded by 1, i.e., `0 < b(i) <= 1`.

`L = gallery('leslie',n)` generates the Leslie matrix with `a = ones(n,1)`, `b = ones(n-1,1)`.

lesp — Tridiagonal matrix with real, sensitive eigenvalues

`A = gallery('lesp',n)` returns an `n`-by-`n` matrix whose eigenvalues are real and smoothly distributed in the interval approximately `[-2*N-3.5, -4.5]`.

The sensitivities of the eigenvalues increase exponentially as the eigenvalues grow more negative. The matrix is similar to the symmetric tridiagonal matrix with the same diagonal entries and with off-diagonal entries 1, via a similarity transformation with `D = diag(1!,2!,...,n!)`.

lotkin — Lotkin matrix

`A = gallery('lotkin',n)` returns the Hilbert matrix with its first row altered to all ones. The Lotkin matrix `A` is nonsymmetric, ill-conditioned, and has many negative eigenvalues of small magnitude. Its inverse has integer entries and is known explicitly.

minij — Symmetric positive definite matrix

`A = gallery('minij',n)` returns the `n`-by-`n` symmetric positive definite matrix with `A(i,j) = min(i,j)`.

The `minij` matrix has these properties:

- The inverse `inv(A)` is tridiagonal and equal to `-1` times the second difference matrix, except its `(n,n)` element is `1`.

- Givens' matrix, `2*A-ones(size(A))`, has tridiagonal inverse and eigenvalues `0.5*sec((2*r-1)*pi/(4*n))^2`, where `r=1:n`.
- `(n+1)*ones(size(A))-A` has elements that are `max(i,j)` and a tridiagonal inverse.

moler — Symmetric positive definite matrix

`A = gallery('moler',n,alpha)` returns the symmetric positive definite `n`-by-`n` matrix `U'*U`, where `U = gallery('triw',n,alpha)`.

For the default `alpha` = `-1`, `A(i,j) = min(i,j)-2`, and `A(i,i) = i`. One of the eigenvalues of `A` is small.

neumann — Singular matrix from the discrete Neumann problem (sparse)

`C = gallery('neumann',n)` returns the sparse `n`-by-`n` singular, row diagonally dominant matrix resulting from discretizing the Neumann problem with the usual five-point operator on a regular mesh. Argument `n` is a perfect square integer $n = m^2$ or a two-element vector. `C` is sparse and has a one-dimensional null space with null vector `ones(n,1)`.

normaldata — Array of arbitrary data from standard normal distribution

`A = gallery('normaldata',[m,n,...],j)` returns an `m`-by-`n`-by-... array `A`. The values of `A` are a random sample from the standard normal distribution. `j` must be an integer value in the interval `[0, 2^32-1]`. Calling `gallery('normaldata', ...)` with different values of `j` will return different arrays. Repeated calls to `gallery('normaldata',...)` with the same size vector and `j` inputs will always return the same array.

In any call to `gallery('normaldata', ...)` you can substitute individual inputs `m`,`n`,... for the size vector input `[m,n,...]`. For example, `gallery('normaldata', [1,2,3,4],5)` is equivalent to `gallery('normaldata',1,2,3,4,5)`.

`[A,B,...] = gallery('normaldata',[m,n,...],j)` returns multiple `m`-by-`n`-by-... arrays `A`, `B`, ..., containing different values.

`A = gallery('normaldata',[m,n,...],j, classname)` produces a matrix of class `classname`. `classname` must be either `'single'` or `'double'`.

Generate the arbitrary 6-by-4 matrix of data from the standard normal distribution `N(0, 1)` corresponding to `j = 2`:.

```
x = gallery('normaldata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the standard normal distribution `N(0, 1)` corresponding to `j = 17`:.

```
y = gallery('normaldata', 1, 2, 3, 17, 'single');
```

orthog — Orthogonal and nearly orthogonal matrices

`Q = gallery('orthog',n,k)` returns the kth type of matrix of order `n`, where `k > 0` selects exactly orthogonal matrices, and `k < 0` selects diagonal scalings of orthogonal matrices. Available types are:

`k = 1` `Q(i,j) = sqrt(2/(n+1)) * sin(i*j*pi/(n+1))`

Symmetric eigenvector matrix for second difference matrix. This is the default.

`k = 2` `Q(i,j) = 2/(sqrt(2*n+1)) * sin(2*i*j*pi/(2*n+1))`

Symmetric.

`k = 3` `Q(r,s) = exp(2*pi*i*(r-1)*(s-1)/n) / sqrt(n)`

Unitary, the Fourier matrix. Q^4 is the identity. This is essentially the same matrix as `fft(eye(n))/sqrt(n)!`

`k = 4` Helmert matrix: a permutation of a lower Hessenberg matrix, whose first row is `ones(1:n)/sqrt(n)`.

`k = 5` `Q(i,j) = sin(2*pi*(i-1)*(j-1)/n) + cos(2*pi*(i-1)*(j-1)/n)`

Symmetric matrix arising in the Hartley transform.

`k = 6` `Q(i,j) = sqrt(2/n)*cos((i-1/2)*(j-1/2)*pi/n)`

Symmetric matrix arising as a discrete cosine transform.

`k = -1` `Q(i,j) = cos((i-1)*(j-1)*pi/(n-1))`

Chebyshev Vandermonde-like matrix, based on extrema of `T(n-1)`.

`k = -2` `Q(i,j) = cos((i-1)*(j-1/2)*pi/n)`

Chebyshev Vandermonde-like matrix, based on zeros of `T(n)`.

parter — Toeplitz matrix with singular values near pi

`C = gallery('parter',n)` returns the matrix `C` such that `C(i,j) = 1/(i-j+0.5)`.

`C` is a Cauchy matrix and a Toeplitz matrix. Most of the singular values of `C` are very close to `pi`.

pei — Pei matrix

`A = gallery('pei',n,alpha)`, where `alpha` is a scalar, returns the symmetric matrix `alpha*eye(n) + ones(n)`. The default for `alpha` is 1. The matrix is singular for `alpha` equal to either `0` or `-n`.

poisson — Block tridiagonal matrix from Poisson's equation (sparse)

`A = gallery('poisson',n)` returns the block tridiagonal (sparse) matrix of order `n^2` resulting from discretizing Poisson's equation with the 5-point operator on an `n`-by-`n` mesh.

prolate — Symmetric, ill-conditioned Toeplitz matrix

`A = gallery('prolate',n,w)` returns the `n`-by-`n` prolate matrix with parameter `w`. It is a symmetric Toeplitz matrix.

If `0 < w < 0.5` then `A` is positive definite

- The eigenvalues of `A` are distinct, lie in `(0,1)`, and tend to cluster around `0` and `1`.
- The default value of `w` is 0.25.

randcolu — Random matrix with normalized cols and specified singular values

`A = gallery('randcolu',n)` is a random `n`-by-`n` matrix with columns of unit 2-norm, with random singular values whose squares are from a uniform distribution.

`A'*A` is a correlation matrix of the form produced by `gallery('randcorr',n)`.

`gallery('randcolu',x)` where `x` is an `n`-vector (`n` > 1), produces a random `n`-by-`n` matrix having singular values given by the vector `x`. The vector `x` must have nonnegative elements whose sum of squares is `n`.

`gallery('randcolu',x,m)` where `m >= n`, produces an `m`-by-`n` matrix.

`gallery('randcolu',x,m,k)` provides a further option:

`k = 0`	`diag(x)` is initially subjected to a random two-sided orthogonal transformation, and then a sequence of Givens rotations is applied (default).
`k = 1`	The initial transformation is omitted. This is much faster, but the resulting matrix may have zero entries.

For more information, see [4].

randcorr — Random correlation matrix with specified eigenvalues

`gallery('randcorr',n)` is a random `n`-by-`n` correlation matrix with random eigenvalues from a uniform distribution. A correlation matrix is a symmetric positive semidefinite matrix with `1`s on the diagonal (see `corrcoef`).

`gallery('randcorr',x)` produces a random correlation matrix having eigenvalues given by the vector `x`, where `length(x) > 1`. The vector `x` must have nonnegative elements summing to `length(x)`.

`gallery('randcorr',x,k)` provides a further option:

`k = 0`	The diagonal matrix of eigenvalues is initially subjected to a random orthogonal similarity transformation, and then a sequence of Givens rotations is applied (default).
`k = 1`	The initial transformation is omitted. This is much faster, but the resulting matrix may have some zero entries.

For more information, see [3] and [4].

randhess — Random, orthogonal upper Hessenberg matrix

`H = gallery('randhess',n)` returns an `n`-by-`n` real, random, orthogonal upper Hessenberg matrix.

`H = gallery('randhess',x)` if `x` is an arbitrary, real, length `n` vector with `n > 1`, constructs `H` nonrandomly using the elements of `x` as parameters.

Matrix `H` is constructed via a product of `n-1` Givens rotations.

randjorth — Random J-orthogonal matrix

`A = gallery('randjorth', n)`, for a positive integer `n`, produces a random `n`-by-`n` J-orthogonal matrix `A`, where

- `J = blkdiag(eye(ceil(n/2)),-eye(floor(n/2)))`
- `cond(A) = sqrt(1/eps)`

J-orthogonality means that A'*J*A = J. Such matrices are sometimes called *hyperbolic*.

`A = gallery('randjorth', n, m)`, for positive integers `n` and `m`, produces a random (`n`+`m`)-by-(`n`+`m`) J-orthogonal matrix `A`, where

- `J = blkdiag(eye(n),-eye(m))`
- `cond(A) = sqrt(1/eps)`

```
A = gallery('randjorth',n,m,c,symm,method)
```

uses the following optional input arguments:

- `c` — Specifies `cond(A)` to be the scalar `c`.
- `symm` — Enforces symmetry if the scalar `symm` is nonzero.
- `method` — calls `qr` to perform the underlying orthogonal transformations if the scalar `method` is nonzero. A call to `qr` is much faster than the default method for large dimensions

rando — Random matrix composed of elements -1, 0 or 1

`A = gallery('rando',n,k)` returns a random `n`-by-`n` matrix with elements from one of the following discrete distributions:

`k = 1`	`A(i,j)` = 0 or 1 with equal probability (default).
`k = 2`	`A(i,j)` = -1 or 1 with equal probability.

`k = 3`	`A(i,j)` = `-1`, `0` or `1` with equal probability.

Argument `n` may be a two-element vector, in which case the matrix is `n(1)`-by-`n(2)`.

randsvd — Random matrix with preassigned singular values

`A = gallery('randsvd',n,kappa,mode,kl,ku)` returns a banded (multidiagonal) random matrix of order `n` with `cond(A) = kappa` and singular values from the distribution mode. If `n` is a two-element vector, `A` is `n(1)`-by-`n(2)`.

Arguments `kl` and `ku` specify the number of lower and upper off-diagonals, respectively, in `A`. If they are omitted, a full matrix is produced. If only `kl` is present, `ku` defaults to `kl`.

Distribution `mode` can be:

`1`	One large singular value.
`2`	One small singular value.
`3`	Geometrically distributed singular values (default).
`4`	Arithmetically distributed singular values.
`5`	Random singular values with uniformly distributed logarithm.
`< 0`	If `mode` is `-1`, `-2`, `-3`, `-4`, or `-5`, then `randsvd` treats `mode` as `abs(mode)`, except that in the original matrix of singular values the order of the diagonal entries is reversed: small to large instead of large to small.

Condition number `kappa` defaults to `sqrt(1/eps)`. In the special case where `kappa < 0`, `A` is a random, full, symmetric, positive definite matrix with `cond(A) = -kappa` and eigenvalues distributed according to `mode`. Arguments `kl` and `ku`, if present, are ignored.

`A = gallery('randsvd',n,kappa,mode,kl,ku,method)` specifies how the computations are carried out. `method = 0` is the default, while `method = 1` uses an alternative method that is much faster for large dimensions, even though it uses more flops.

redheff — Redheffer's matrix of 1s and 0s

`A = gallery('redheff',n)` returns an `n`-by-`n` matrix of `0`'s and `1`'s defined by `A(i,j) = 1`, if `j = 1` or if `i` divides `j`, and `A(i,j) = 0` otherwise.

The Redheffer matrix has these properties:

- `(n-floor(log2(n)))-1` eigenvalues equal to `1`
- A real eigenvalue (the spectral radius) approximately `sqrt(n)`
- A negative eigenvalue approximately `-sqrt(n)`
- The remaining eigenvalues are provably "small."
- The Riemann hypothesis is true if and only if $\det(A) = O(n^{1/2+\varepsilon})$ for every $\varepsilon >$ `0`.

Barrett and Jarvis conjecture that "the small eigenvalues all lie inside the unit circle `abs(Z) = 1`," and a proof of this conjecture, together with a proof that some eigenvalue tends to zero as `n` tends to infinity, would yield a new proof of the prime number theorem.

riemann — Matrix associated with the Riemann hypothesis

`A = gallery('riemann',n)` returns an `n`-by-`n` matrix for which the Riemann hypothesis is true if and only if

$$\det(A) = O(n!n^{-1/2+\varepsilon})$$

for every $\varepsilon > 0$.

The Riemann matrix is defined by:

```
A = B(2:n+1,2:n+1)
```

where `B(i,j) = i-1` if `i` divides `j`, and `B(i,j) = -1` otherwise.

The Riemann matrix has these properties:

- Each eigenvalue `e(i)` satisfies `abs(e(i)) <= m-1/m`, where `m = n+1`.
- `i <= e(i) <= i+1` with at most `m-sqrt(m)` exceptions.
- All integers in the interval `(m/3, m/2]` are eigenvalues.

ris — Symmetric Hankel matrix

`A = gallery('ris',n)` returns a symmetric `n`-by-`n` Hankel matrix with elements

```
A(i,j) = 0.5/(n-i-j+1.5)
```

The eigenvalues of `A` cluster around $\pi/2$ and $-\pi/2$. This matrix was invented by F.N. Ris.

sampling — Nonsymmetric matrix with ill-conditioned integer eigenvalues.

`A = gallery('sampling',x)`, where `x` is an `n`-vector, is the `n`-by-`n` matrix with `A(i,j) = X(i)/(X(i)-X(j))` for `i ~= j` and `A(j,j)` the sum of the off-diagonal elements in column `j`. A has eigenvalues `0:n-1`. For the eigenvalues 0 and `n`–1, corresponding eigenvectors are `X` and `ones(n,1)`, respectively.

The eigenvalues are ill-conditioned. `A` has the property that `A(i,j) + A(j,i) = 1` for `i ~= j`.

Explicit formulas are available for the left eigenvectors of `A`. For scalar `n`, `sampling(n)` is the same as `sampling(1:n)`. A special case of this matrix arises in sampling theory.

smoke — Complex matrix with a 'smoke ring' pseudospectrum

`A = gallery('smoke',n)` returns an `n`-by-`n` matrix with `1`'s on the superdiagonal, `1` in the `(n,1)` position, and powers of roots of unity along the diagonal.

`A = gallery('smoke',n,1)` returns the same except that element `A(n,1)` is zero.

The eigenvalues of `gallery('smoke',n,1)` are the `n`th roots of unity; those of `gallery('smoke',n)` are the `n`th roots of unity times `2^(1/n)`.

toeppd — Symmetric positive definite Toeplitz matrix

`A = gallery('toeppd',n,m,w,theta)` returns an `n`-by-`n` symmetric, positive semi-definite (SPD) Toeplitz matrix composed of the sum of `m` rank 2 (or, for certain `theta`, rank 1) SPD Toeplitz matrices. Specifically,

```
T = w(1)*T(theta(1)) + ... + w(m)*T(theta(m))
```

where `T(theta(k))` has `(i,j)` element `cos(2*pi*theta(k)*(i-j))`.

By default: `m = n`, `w = rand(m,1)`, and `theta = rand(m,1)`.

toeppen — Pentadiagonal Toeplitz matrix (sparse)

`P = gallery('toeppen',n,a,b,c,d,e)` returns the `n`-by-`n` sparse, pentadiagonal Toeplitz matrix with the diagonals: `P(3,1) = a`, `P(2,1) = b`, `P(1,1) = c`, `P(1,2) = d`, and `P(1,3) = e`, where `a`, `b`, `c`, `d`, and `e` are scalars.

By default, `(a,b,c,d,e) = (1,-10,0,10,1)`, yielding a matrix of Rutishauser. This matrix has eigenvalues lying approximately on the line segment `2*cos(2*t) + 20*i*sin(t)`.

tridiag — Tridiagonal matrix (sparse)

`A = gallery('tridiag',c,d,e)` returns the tridiagonal matrix with subdiagonal `c`, diagonal `d`, and superdiagonal `e`. Vectors `c` and `e` must have `length(d)-1`.

`A = gallery('tridiag',n,c,d,e)`, where `c`, `d`, and `e` are all scalars, yields the Toeplitz tridiagonal matrix of order `n` with subdiagonal elements `c`, diagonal elements `d`, and superdiagonal elements `e`. This matrix has eigenvalues

```
d + 2*sqrt(c*e)*cos(k*pi/(n+1))
```

where `k = 1:n`. (see [1].)

`A = gallery('tridiag',n)` is the same as `A = gallery('tridiag',n,-1,2,-1)`, which is a symmetric positive definite M-matrix (the negative of the second difference matrix).

triw — Upper triangular matrix discussed by Wilkinson and others

`A = gallery('triw',n,alpha,k)` returns the upper triangular matrix with ones on the diagonal and `alpha`s on the first `k >= 0` superdiagonals.

Order `n` may be a 2-element vector, in which case the matrix is `n(1)`-by-`n(2)` and upper trapezoidal.

Ostrowski ["On the Spectrum of a One-parametric Family of Matrices," *J. Reine Angew. Math.,* 1954] shows that

```
cond(gallery('triw',n,2)) = cot(pi/(4*n))^2,
```

and, for large `abs(alpha)`, `cond(gallery('triw',n,alpha))` is approximately `abs(alpha)^n*sin(pi/(4*n-2))`.

Adding `-2^(2-n)` to the `(n,1)` element makes `triw(n)` singular, as does adding `-2^(1-n)` to all the elements in the first column.

uniformdata — Array of arbitrary data from standard uniform distribution

`A = gallery('uniformdata',[m,n,...],j)` returns an `m`-by-`n`-by-... array `A`. The values of `A` are a random sample from the standard uniform distribution. j must be an integer value in the interval `[0, 2^32-1]`. Calling `gallery('uniformdata', ...)` with different values of `j` will return different arrays. Repeated calls to `gallery('uniformdata',...)` with the same size vector and `j` inputs will always return the same array.

In any call to `gallery('uniformdata', ...)` you can substitute individual inputs `m`,`n`,... for the size vector input `[m,n,...]`. For example, `gallery('uniformdata', [1,2,3,4],5)` is equivalent to `gallery('uniformdata',1,2,3,4,5)`.

`[A,B,...] = gallery('uniformdata',[m,n,...],j)` returns multiple `m`-by-`n`-by-... arrays `A`, `B`, ..., containing different values.

`A = gallery('uniformdata',[m,n,...],j, classname)` produces a matrix of class `classname`. `classname` must be either `'single'` or `'double'`.

Generate the arbitrary 6-by-4 matrix of data from the uniform distribution on [0, 1] corresponding to `j = 2`.

```
x = gallery('uniformdata', [6, 4], 2);
```

Generate the arbitrary 1-by-2-by-3 single array of data from the uniform distribution on [0, 1] corresponding to `j = 17`.

```
y = gallery('uniformdata', 1, 2, 3, 17, 'single');
```

wathen — Finite element matrix (sparse, random entries)

`A = gallery('wathen',nx,ny)` returns a sparse, random, `n`-by-`n` finite element matrix where `n = 3*nx*ny + 2*nx + 2*ny + 1`.

Matrix `A` is precisely the "consistent mass matrix" for a regular `nx`-by-`ny` grid of 8-node (serendipity) elements in two dimensions. `A` is symmetric, positive definite for any (positive) values of the "density," `rho(nx,ny)`, which is chosen randomly in this routine.

`A = gallery('wathen',nx,ny,1)` returns a diagonally scaled matrix such that

```
0.25 <= eig(inv(D)*A) <= 4.5
```

where `D = diag(diag(A))` for any positive integers `nx` and `ny` and any densities `rho(nx,ny)`.

wilk — Various matrices devised or discussed by Wilkinson

`gallery('wilk',n)` returns a different matrix or linear system depending on the value of `n`.

`n = 3`	Upper triangular system `Ux=b` illustrating inaccurate solution.
`n = 4`	Lower triangular system `Lx=b`, ill-conditioned.
`n = 5`	`hilb(6)(1:5,2:6)*1.8144`. A symmetric positive definite matrix.
`n = 21`	`W21+`, a tridiagonal matrix. eigenvalue problem. For more detail, see [2].

Introduced before R2006a

gamma

Gamma function

Syntax

```
Y = gamma(X)
```

Definitions

The `gamma` function is defined by the integral:

$$\Gamma(x) = \int_0^\infty e^{-t} t^{x-1} dt$$

The `gamma` function interpolates the `factorial` function. For integer `n`:

```
gamma(n+1) = n! = prod(1:n)
```

Description

`Y = gamma(X)` returns the `gamma` function at the elements of `X`. `X` must be real.

More About

Algorithms

The computation of `gamma` is based on algorithms outlined in [1]. Several different minimax rational approximations are used depending upon the value of `A`.

`gammainc` | `gammaincinv` | `gammaln` | `psi`

Introduced before R2006a

gammainc

Incomplete gamma function

Syntax

```
Y = gammainc(X,A)
Y = gammainc(X,A,tail)
Y = gammainc(X,A,'scaledlower')
Y = gammainc(X,A,'scaledupper')
```

Definitions

The incomplete gamma function is

$$P(a,x) = \frac{1}{\Gamma(a)} \int_0^x e^{-t} t^{a-1} dt,$$

where $\Gamma(a)$ is the gamma function, `gamma(a)`.

Note: The syntax `gammainc(X,A)` is equivalent to the function `P(A,X)` defined above, where `X` is the limit of integration in each case.

For any `A` ≥ 0, `gammainc(X,A)` approaches 1 as `X` approaches infinity. For small `X` and `A`, `gammainc(X,A)` is approximately equal to `X^A`, so `gammainc(0,0) = 1`.

Description

`Y = gammainc(X,A)` returns the incomplete `gamma` function of corresponding elements of `X` and `A`. The elements of `A` must be nonnegative. Furthermore, `X` and `A` must be real and the same size (or either can be scalar).

`Y = gammainc(X,A,tail)` specifies the tail of the incomplete `gamma` function. The choices for `tail` are `'lower'` (the default) and `'upper'`. The upper incomplete `gamma` function is defined as:

$$Q(a,x) = \frac{1}{\Gamma(a)} \int_x^\infty e^{-t} t^{a-1} dt = 1 - P(a,x).$$

When the upper tail value is close to 0, the `'upper'` option provides a way to compute that value more accurately than by subtracting the lower tail value from 1.

`Y = gammainc(X,A,'scaledlower')` and `Y = gammainc(X,A,'scaledupper')` return the incomplete gamma function, scaled by

$$\Gamma(a+1)\left(\frac{e^x}{x^a}\right).$$

These functions are unbounded above, but are useful for values of `X` and `A` where `gammainc(X,A,'lower')` or `gammainc(X,A,'upper')` underflow to zero.

Note: When `X` is negative, `Y` can be inaccurate for `abs(X)>A+1`. This applies to all syntaxes.

`gamma` | `gammaincinv` | `psi` | `gammaln`

Introduced before R2006a

gammaincinv

Inverse incomplete gamma function

Syntax

```
x = gammaincinv(y,a)
x = gammaincinv(y,a,tail)
```

Description

`x = gammaincinv(y,a)` evaluates the inverse incomplete gamma function for corresponding elements of `y` and `a`, such that `y = gammainc(x,a)`. The elements of `y` must be in the closed interval `[0,1]`, and those of `a` must be nonnegative. `y` and `a` must be real and the same size (or either can be a scalar).

`x = gammaincinv(y,a,tail)` specifies the tail of the incomplete gamma function. Choices are `'lower'` (the default) to use the integral from 0 to `x`, or `'upper'` to use the integral from `x` to infinity.

These two choices are related as:

`gammaincinv(y,a,'upper') = gammaincinv(1-y,a,'lower')`.

When `y` is close to 0, the `'upper'` option provides a way to compute `x` more accurately than by subtracting `y` from 1.

Definitions

The lower incomplete gamma function is defined as:

$$\text{gammainc}(x,a) = \frac{1}{\Gamma(a)} \int_0^x e^{-t} t^{(a-1)} dt$$

The upper incomplete gamma function is defined as:

$$\text{gammainc}(x,a) = \frac{1}{\Gamma(a)} \int_x^\infty e^{-t} t^{(a-1)} dt$$

`gammaincinv` computes the inverse of the incomplete gamma function with respect to the integration limit `x` using Newton's method.

For any `a>0`, as `y` approaches 1, `gammaincinv(y,a)` approaches infinity. For small `x` and `a`, `gammainc(x,a)` $\cong x^a$, so `gammaincinv(1,0) = 0`.

`gamma` | `gammainc` | `psi` | `gammaln`

gammaln

Logarithm of gamma function

Syntax

```
Y = gammaln(A)
```

Description

`Y = gammaln(A)` returns the logarithm of the `gamma` function, `gammaln(A) = log(gamma(A))`. Input `A` must be nonnegative and real. The `gammaln` command avoids the underflow and overflow that may occur if it is computed directly using `log(gamma(A))`.

See Also

`gammainc` | `gamma` | `psi` | `gammaincinv`

Introduced before R2006a

gca

Current axes handle

Syntax

```
ax = gca
```

Description

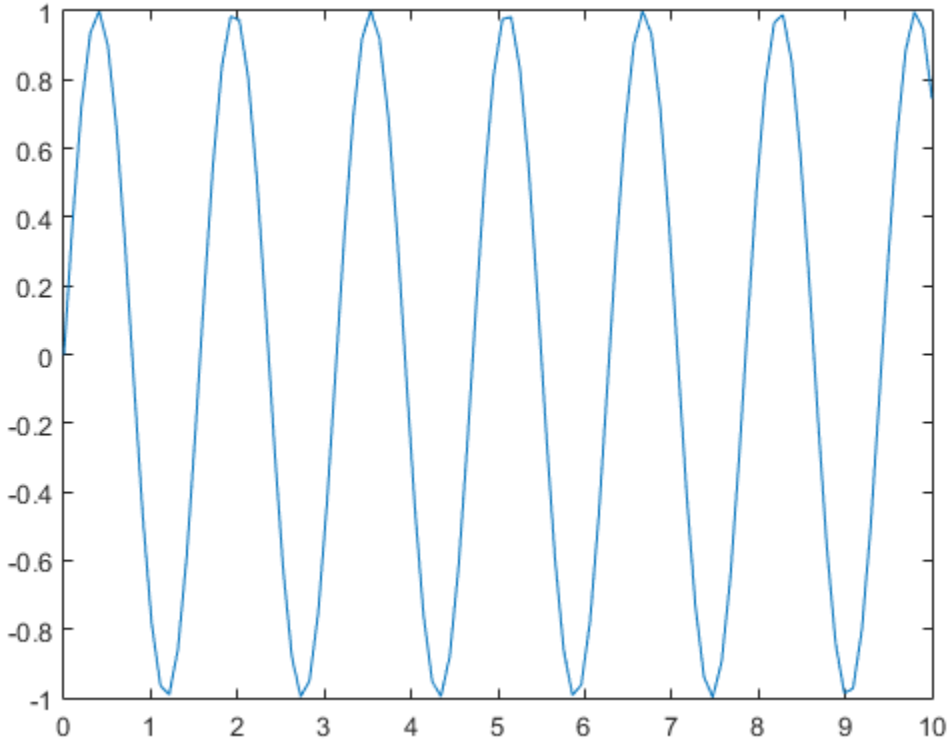
`ax = gca` returns the handle to the current axes for the current figure. If an axes does not exist, then `gca` creates an axes and returns its handle. You can use the axes handle to query and modify axes properties. For more information, see Axes Properties.

Examples

Specify Properties for Current Axes

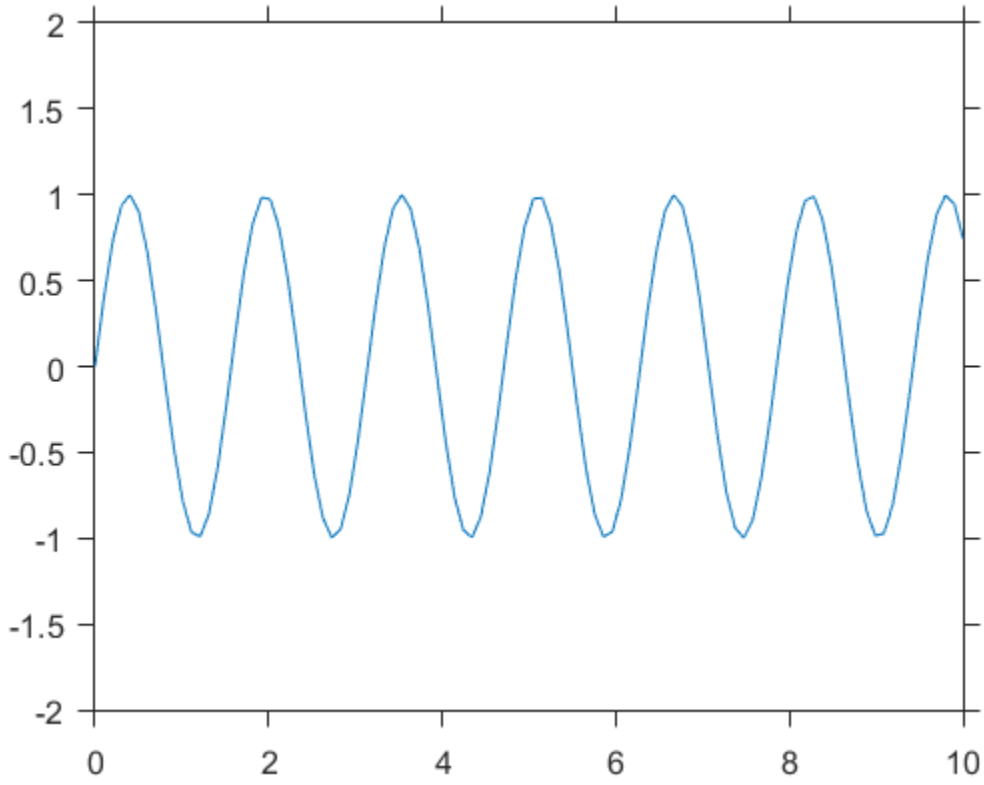
Plot a sine wave.

```
x = linspace(0,10);
y = sin(4*x);
plot(x,y)
```



Set the font size, tick direction, tick length, and *y*-axis limits for the current axes. Use `gca` to refer to the current axes. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
ax = gca; % current axes
ax.FontSize = 12;
ax.TickDir = 'out';
ax.TickLength = [0.02 0.02];
ax.YLim = [-2 2];
```



More About

Current Axes

The current axes is the target for graphics output. It is the axes in which graphics commands such as `plot`, `text`, and `surf` draw their results. It is typically the last axes created or the last axes clicked with the mouse. Changing the current figure also changes the current axes.

User interaction can change the current axes. If you need to access a specific axes, store the axes handle in your program code when you create the axes and use this handle instead of `gca`.

Tips

- To get the handle of the current axes without forcing the creation of an axes if one does not exist, query the figure `CurrentAxes` property.

  ```
  fig = gcf;
  ax = fig.CurrentAxes;
  ```
  MATLAB returns `ax` as an empty array if there is no current axes.
- Set axes properties after plotting since some plotting functions reset axes properties.

Introduced before R2006a

gcbf

Handle of figure containing object whose callback is executing

Syntax

```
fig = gcbf
```

Description

`fig = gcbf` returns the handle of the figure that contains the object whose callback is currently executing. This object can be the figure itself, in which case, `gcbf` returns the figure's handle.

When no callback is executing, `gcbf` returns the empty matrix, `[]`.

The value returned by `gcbf` is identical to the `figure` output argument returned by `gcbo`.

See Also

`gcbo` | `gco` | `gcf` | `gca`

Introduced before R2006a

gcbo

Handle of object whose callback is executing

Syntax

```
h = gcbo
[h,figure] = gcbo
```

Description

`h = gcbo` returns the handle of the graphics object whose callback is executing.

`[h,figure] = gcbo` returns the handle of the current callback object and the handle of the figure containing this object.

More About

Tips

The MATLAB software stores the handle of the object whose callback is executing in the root `CallbackObject` property. If a callback interrupts another callback, MATLAB replaces the `CallbackObject` value with the handle of the object whose callback is interrupting. When that callback completes, MATLAB restores the handle of the object whose callback was interrupted.

The root `CallbackObject` property is read only, so its value is always valid at any time during callback execution. The root `CurrentFigure` property, and the figure `CurrentAxes` and `CurrentObject` properties (returned by `gcf`, `gca`, and `gco`, respectively) are user settable, so they can change during the execution of a callback, especially if that callback is interrupted by another callback. Therefore, those functions are not reliable indicators of which object's callback is executing.

When you write callback routines for the `CreateFcn` and `DeleteFcn` of any object and the figure `ResizeFcn`, you must use `gcbo` since those callbacks do not update the root's `CurrentFigure` property, or the figure's `CurrentObject` or `CurrentAxes` properties; they only update the root's `CallbackObject` property.

When no callbacks are executing, `gcbo` returns `[]` (an empty matrix).

`gca` | `gcf` | `gco` | `groot`

Introduced before R2006a

gcd

Greatest common divisor

Syntax

```
G = gcd(A,B)
[G,U,V] = gcd(A,B)
```

Description

`G = gcd(A,B)` returns the greatest common divisors of the elements of `A` and `B`. The elements in `G` are always nonnegative, and `gcd(0,0)` returns `0`. This syntax supports inputs of any numeric type.

`[G,U,V] = gcd(A,B)` also returns the Bézout coefficients, `U` and `V`, which satisfy: `A.*U + B.*V = G`. The Bézout coefficients are useful for solving Diophantine equations. This syntax supports double, single, and signed integer inputs.

Examples

Greatest Common Divisors of Double Values

```
A = [-5 17; 10 0];
B = [-15 3; 100 0];
G = gcd(A,B)
```

```
G =

     5     1
    10     0
```

`gcd` returns positive values, even when the inputs are negative.

Greatest Common Divisors of Unsigned Integers

```
A = uint16([255 511 15]);
B = uint16([15 127 1023]);
```

```
G = gcd(A,B)

G =

     15      1      3
```

Solution to Diophantine Equation

Solve the Diophantine equation, $30x + 56y = 8$ for x and y.

Find the greatest common divisor and a pair of Bézout coefficients for `30` and `56`.

```
[g,u,v] = gcd(30,56)

g =

     2

u =

   -13

v =

     7
```

`u` and `v` satisfy the Bézout's identity, `(30*u) + (56*v) = g`.

Rewrite Bézout's identity so that it looks more like the original equation. Do this by multiplying by `4`. Use `==` to verify that both sides of the equation are equal.

```
(30*u*4) + (56*v*4) == g*4

ans =

   1
```

Calculate the values of x and y that solve the problem.

```
x = u*4
y = v*4

x =

   -52
```

```
y =

    28
```

Input Arguments

A,B — Input values

scalars, vectors, or arrays of real integer values

Input values, specified as scalars, vectors, or arrays of real integer values. A and B can be any numeric type, and they can be of different types within certain limitations:

- If A or B is of type `single`, then the other can be of type `single` or `double`.
- If A or B belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

A and B must be the same size or one must be a scalar.

Example: `[20 -3 13],[10 6 7]`

Example: `int16([100 -30 200]),int16([20 15 9])`

Example: `int16([100 -30 200]),20`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Output Arguments

G — Greatest common divisor

real, nonnegative integer values

Greatest common divisor, returned as an array of real nonnegative integer values. G is the same size as A and B, and the values in G are always real and nonnegative. G is returned as the same type as A and B. If A and B are of different types, then G is returned as the nondouble type.

U,V — Bézout coefficients

real integer values

Bézout coefficients, returned as arrays of real integer values that satisfy the equation, `A.*U + B.*V = G`. The data type of `U` and `V` is the same type as that of `A` and `B`. If `A` and `B` are of different types, then `U` and `V` are returned as the nondouble type.

More About

Algorithms

`g = gcd(A,B)` is calculated using the Euclidian algorithm.[1]

`[g,u,v] = gcd(A,B)` is calculated using the extended Euclidian algorithm.[1]

`lcm`

Introduced before R2006a

gcf

Current figure handle

Syntax

```
fig = gcf
```

Description

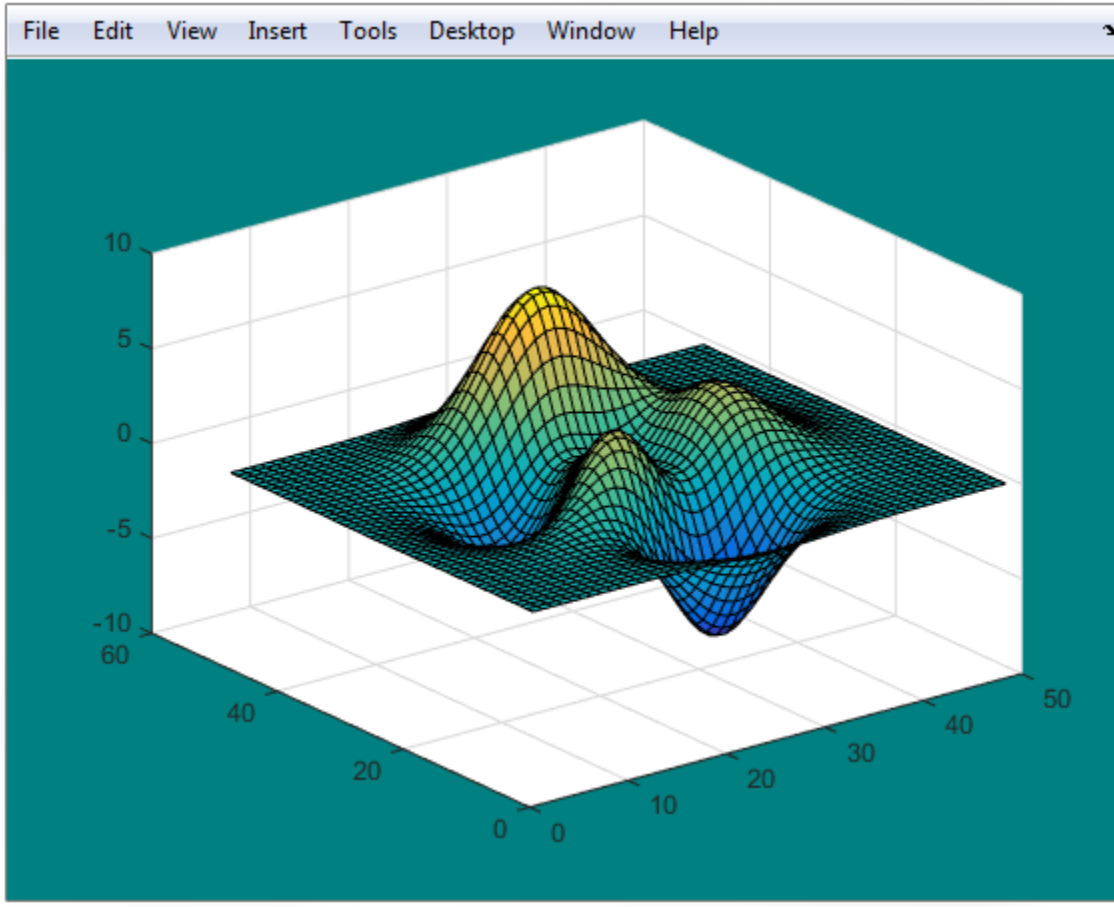
`fig = gcf` returns the current figure handle. If a figure does not exist, then `gcf` creates a figure and returns its handle. You can use the figure handle to query and modify figure properties. For more information, see Figure Properties.

Examples

Specify Properties for Current Figure

Set the background color and remove the toolbar for the current figure. Use the `gcf` command to get the current figure handle.

```
surf(peaks)
fig = gcf; % current figure handle
fig.Color = [0 0.5 0.5];
fig.ToolBar = 'none';
```



More About

Current Figure

The current figure is the target for graphics output. It is the figure window in which graphics commands such as `plot`, `title`, and `surf` draw their results. It is typically the last figure created or the last figure clicked with the mouse.

User interaction can change the current figure. If you need to access a specific figure, store the figure handle in your program code when you create the figure and use this handle instead of `gcf`.

Tips

- To get the handle of the current figure without forcing the creation of a figure if one does not exist, query the `CurrentFigure` property on the root object.

  ```
  fig = get(groot,'CurrentFigure');
  ```
  MATLAB returns `fig` as an empty array if there is no current figure.

`clf` | Figure Properties | `figure` | `gca` | `get` | `set`

Introduced before R2006a

gcmr

Get current mapreducer configuration

The `gcmr` function defines the global execution environment for `mapreduce`, and is most likely used with Parallel Computing Toolbox, MATLAB Distributed Computing Server™, or MATLAB Compiler™.

If you do not specify a configuration to use in your call to `mapreduce`, then by default `mapreduce` uses the configuration returned (or generated) by `gcmr`.

Syntax

```
mr = gcmr
mr = gcmr('nocreate')
```

Description

`mr = gcmr` returns an object representing the current global execution environment for `mapreduce`.

- If no global execution environment exists, then `gcmr` calls `mapreducer` to set the global execution environment to be the default.
- If a global execution environment currently exists, then `gcmr` returns the last visible MapReducer object created.

  When you create a MapReducer object using `mapreducer`, the object sets the global execution environment. The global execution environment persists even if the object representing it is later deleted.
- If the global execution environment is deleted or invalid, then `gcmr` returns the next visible MapReducer object available. For example, `delete(gcmr)` deletes the current global execution environment.

`mr = gcmr('nocreate')` returns the current global execution environment for `mapreduce`, if one already exists. If no global execution environment exists, then `gcmr` returns `[]`.

More About

Tips

- If you have Parallel Computing Toolbox, see the `mapreducer` function reference page for related information.
- If you have MATLAB Compiler, see the `mapreducer` function reference page for related information.
- "Speed Up and Deploy MapReduce Using Other Products"

See Also

`mapreduce` | `mapreducer`

Introduced in R2014b

gco

Handle of current object

Syntax

```
h = gco
h = gco(figure_handle)
```

Description

`h = gco` returns the handle of the current object.

`h = gco(figure_handle)` returns the handle of the current object in the figure specified by `figure_handle`.

More About

Tips

The current object is the last object clicked or selected via keyboard interaction, excluding `uimenu`s. If the mouse click did not occur over a figure child object, the figure becomes the current object. The MATLAB software stores the handle of the current object in the figure's `CurrentObject` property.

An object can become the current object as a result of pressing the space bar to invoke a callback in a dialog when a uicontrol in that dialog has focus (usually the result of using the **Tab** key to change focus).

The `CurrentObject` of the `CurrentFigure` does not always indicate the object whose callback is being executed. Interruptions of callbacks by other callbacks can change the `CurrentObject` or even the `CurrentFigure`. Some callbacks, such as `CreateFcn` and `DeleteFcn`, and uimenu `Callback`, intentionally do not update `CurrentFigure` or `CurrentObject`.

`gcbo` provides the only completely reliable way to retrieve the handle to the object whose callback is executing, at any point in the `callback` function, regardless of the type of callback or of any previous interruptions.

See Also

gca | gcbo | gcf

Introduced before R2006a

ge, >=

Determine greater than or equal to

Syntax

```
A >= B
ge(A,B)
```

Description

`A >= B` returns a logical array with elements set to logical 1 (`true`) where `A` is greater than or equal to `B`; otherwise, it returns logical `0` (`false`).

The test compares only the real part of numeric arrays. `ge` returns logical `0` (`false`) where `A` or `B` have NaN or undefined categorical elements.

`ge(A,B)` is an alternate way to execute `A >= B`, but is rarely used. It enables operator overloading for classes.

Examples

Test Vector Elements

Find which vector elements are greater than or equal to a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are greater than or equal to `11`.

```
A >= 11
```

```
ans =

     0     1     1     0     0     1     0     1
```

The result is a vector with values of logical 1 (`true`) where the elements of `A` satisfy the expression.

Use the vector of logical values as an index to view the values in `A` that are greater than or equal to `11`.

```
A(A >= 11)
```

```
ans =

    12    18    11    15
```

The result is a subset of the elements in `A`.

Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =

    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values greater than or equal to `9` with the value `10`.

```
A(A >= 9) = 10
```

```
A =

    10     2     3    10
     5    10    10     8
    10     7     6    10
     4    10    10     1
```

The result is a new matrix whose largest element is `10`.

Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
```

```
'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)

A =

     large       medium      small
     medium      small       large
```

The array has three categories: `'small'`, `'medium'`, and `'large'`.

Find all values greater than or equal to the category `'medium'`.

```
A >= 'medium'

ans =

     1     1     0
     1     0     1
```

A value of logical `1` (`true`) indicates a value greater than or equal to the category `'medium'`.

Compare the rows of `A`.

```
A(1,:) >= A(2,:)

ans =

     1     1     0
```

The function returns logical `1` (`true`) where the first row has a category value greater than or equal to the second row.

Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are greater than or equal to `2`.

```
A(A >= 2)

ans =

   2.0000 - 2.0000i   5.0000 - 1.0000i
```

`ge` compares only the real part of the elements in `A`.

Use `abs` to find which elements are outside a radius of `2` from the origin.

```
A(abs(A) >= 2)
```

```
ans =

   2.0000 - 2.0000i   1.0000 + 3.0000i   1.0000 - 2.0000i   5.0000 - 1.0000i
```

The result has more elements since `abs` accounts for the imaginary part of the numbers.

Test Duration Values

Create a `duration` array.

```
d = hours(21:25) + minutes(75)
```

```
d =

   22.25 hrs   23.25 hrs   24.25 hrs   25.25 hrs   26.25 hrs
```

Test the array for elements that are greater than or equal to one standard day.

```
d >= 1
```

```
ans =

     0     0     1     1     1
```

Input Arguments

A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

`B` — Right array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

More About

Tips

- Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `>=` operator reflects. For more information, see "Avoiding Common Problems with Floating-Point Arithmetic".
- "Ordinal Categorical Arrays"

`eq` | `gt` | `le` | `lt` | `ne`

Introduced before R2006a

genpath

Generate path string

Syntax

```
p = genpath
p = genpath(folderName)
```

Description

`p = genpath` returns a path string, `p`, that includes all the folders and subfolders below *`matlabroot`*`/toolbox`, including empty subfolders.

`p = genpath(folderName)` returns a path string that includes `folderName` and multiple levels of subfolders below `folderName`. The path string does not include folders named `private`, folders that begin with the `@` character (class folders), folders that begin with the `+` character (package folders), or subfolders within any of these.

Examples

Add Folder and Subfolders to Search Path

Use `genpath` in conjunction with `addpath` to add a folder and its subfolders to the search path.

Generate a path that includes *`matlabroot`*`/toolbox/images/colorspaces` and all folders below it.

```
folderName = fullfile(matlabroot,'toolbox','images','colorspaces');
p = genpath(folderName);
```

Add the folder and its subfolders to the search path.

```
addpath(p)
```

Input Arguments

`folderName` — Folder name

string

Folder name, specified as a string.

Example: `'c:/matlab/myfiles'`

More About

- "What Is the MATLAB Search Path?"

See Also

`addpath` | `path` | `rmpath`

Introduced before R2006a

genvarname

Construct valid variable name from string

Note: `genvarname` will be removed in a future release. Use `matlab.lang.makeValidName` and `matlab.lang.makeUniqueStrings` instead.

Syntax

```
varname = genvarname(str)
varname = genvarname(str, exclusions)
```

Description

`varname = genvarname(str)` constructs a string `varname` that is similar to or the same as the `str` input, and can be used as a valid variable name. `str` can be a single character array or a cell array of strings. If `str` is a cell array of strings, `genvarname` returns a cell array of strings in `varname`. The strings in a cell array returned by `genvarname` are guaranteed to be different from each other.

`varname = genvarname(str, exclusions)` returns a valid variable name that is different from any name listed in the `exclusions` input. The `exclusions` input can be a single character array or a cell array of strings. Specify the function `who` in the `exclusions` character array to create a variable name that will be unique in the current MATLAB workspace (see “Example 4” on page 1-2926, below).

Note `genvarname` returns a string that can be used as a variable name. It does not create a variable in the MATLAB workspace. You cannot, therefore, assign a value to the output of `genvarname`.

Examples

Example 1

Create four similar variable name strings that do not conflict with each other:

```
v = genvarname({'A', 'A', 'A', 'A'})
v =
    'A'    'A1'    'A2'    'A3'
```

Example 2

Read a column header `hdr` from worksheet `trial2` in Excel spreadsheet myproj_apr23:

```
[data hdr] = xlsread('myproj_apr23.xls', 'trial2');
```

Make a variable name from the text of the column header that will not conflict with other names:

```
v = genvarname(['Column ' hdr{1,3}]);
```

Assign data taken from the spreadsheet to the variable in the MATLAB workspace:

```
eval([v '= data(1:7, 3);']);
```

Example 3

Collect readings from an instrument once every minute over the period of an hour into different fields of a structure. Simulate instrument readings using a random number. `genvarname` not only generates unique fieldname strings, but also creates the structure and fields in the MATLAB workspace:

```
for k = 1:60
record.(genvarname(['reading' datestr(clock, 'HHMMSS')])) = rand(1);
pause(60)
end
```

After the program ends, display the recorded data from the workspace:

```
record
```

```
record =

    reading092610: 0.6541
    reading092710: 0.6892
    reading092811: 0.7482
    reading092911: 0.4505
    reading093011: 0.0838
          .
          .
          .
```

Example 4

Generate variable names that are unique in the MATLAB workspace by putting the output from the `who` function in the `exclusions` list.

```
for k = 1:5
   t = clock;
   pause(uint8(rand * 10));
   v = genvarname('time_elapsed', who);
   eval([v ' = etime(clock,t)'])
   end
```

As this code runs, you can see that the variables created by `genvarname` are unique in the workspace:

```
time_elapsed =
    5.0070
time_elapsed1 =
    2.0030
time_elapsed2 =
    7.0010
time_elapsed3 =
    8.0010
time_elapsed4 =
    3.0040
```

After the program completes, use the `who` function to view the workspace variables:

```
who

k           time_elapsed   time_elapsed2  time_elapsed4
t           time_elapsed1  time_elapsed3  v
```

Example 5

If you try to make a variable name from a MATLAB keyword, `genvarname` creates a variable name string that capitalizes the keyword and precedes it with the letter `x`:

```
v = genvarname('global')
v =
    xGlobal
```

Example 6

If you enter a string that is longer than the value returned by the `namelengthmax` function, `genvarname` truncates the resulting variable name string:

```
namelengthmax
ans =
    63

vstr = genvarname(sprintf('%s%s', ...
   'This name truncates because it contains ', ...
   'more than the maximum number of characters'))
vstr =
ThisNameTruncatesBecauseItContainsMoreThanTheMaximumNumberOfCha
```

More About

Tips

A valid MATLAB variable name is a character string of letters, digits, and underscores, such that the first character is a letter, and the length of the string is less than or equal to the value returned by the `namelengthmax` function. Any string that exceeds `namelengthmax` is truncated in the `varname` output. See “Example 6” on page 1-2927, below.

The variable name returned by `genvarname` is not guaranteed to be different from other variable names currently in the MATLAB workspace unless you use the `exclusions` input in the manner shown in “Example 4” on page 1-2926, below.

If you use `genvarname` to generate a field name for a structure, MATLAB does create a variable for the structure and field in the MATLAB workspace. See “Example 3” on page 1-2925, below.

If the `str` input contains any whitespace characters, `genvarname` removes then and capitalizes the next alphabetic character in `str`. If `str` contains any nonalphanumeric characters, `genvarname` translates these characters into their hexadecimal value.

Introduced before R2006a

get

Query graphics object properties

Syntax

```
v = get(h)
v = get(h,propertyName)
v = get(h,propertyArray)
v = get(h,'default')
v = get(h,defaultTypeProperty)
v = get(groot,'factory')
v = get(groot,factoryTypeProperty)
```

Description

Note: Do not use the `get` function on Java objects as it will cause a memory leak. For more information, see "Accessing Private and Public Data"

`v = get(h)` returns all properties and property values for the graphics object identified by `h`. `v` is a structure whose field names are the property names and whose values are the corresponding property values. `h` can be a single object or an `m`-by-`n` array of objects. If `h` is a single object and you do not specify an output argument, then MATLAB displays the information on the screen.

`v = get(h,propertyName)` returns the value for the specific property, `propertyName`. Use single quotes around the property name, for example, `get(h,'Color')`. If you do not specify an output argument, then MATLAB displays the information on the screen.

`v = get(h,propertyArray)` returns an *m*-by-*n* cell array, where *m* is equal to `length(h)` and *n* is equal to the number of property names contained in `propertyArray`.

`v = get(h,'default')` returns all default values currently defined on object `h` in a structure array. The field names are the object property names and the field values are

the corresponding property values. If you do not specify an output argument, MATLAB displays the information on the screen.

`v = get(h,defaultTypeProperty)` returns the current default value for a specific property. The argument `defaultTypeProperty` is the word `default` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`) in single quotes. For example, `get(groot,'defaultFigureColor')`.

`v = get(groot,'factory')` returns the factory-defined values of all user-settable properties in a structure array. The field names are the object property names and the field values are the corresponding property values. If you do not specify an output argument, MATLAB displays the information on the screen.

`v = get(groot,factoryTypeProperty)` returns the factory-defined value for a specific property. The argument `factoryTypeProperty` is the word `factory` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`) in single quotes. For example, `get(groot,'factoryFigureColor')`.

Examples

List All Property Values for Specific Object

Create a line plot and return the chart line object as `p`. List all the properties of the line and the current property values.

```
p = plot(1:10);
get(p)
```

```
    AlignVertexCenters: 'off'
            Annotation: [1x1 matlab.graphics.eventdata.Annotation]
          BeingDeleted: 'off'
            BusyAction: 'queue'
          ButtonDownFcn: ''
               Children: []
               Clipping: 'on'
                  Color: [0.9290 0.6940 0.1250]
             CreateFcn: ''
             DeleteFcn: ''
           DisplayName: ''
      HandleVisibility: 'on'
               HitTest: 'on'
```

```
         Interruptible: 'on'
             LineStyle: '-'

                Marker: 'none'
       MarkerEdgeColor: 'auto'
       MarkerFaceColor: 'none'
            MarkerSize: 6
                Parent: [1x1 Axes]
         PickableParts: 'visible'
              Selected: 'off'
    SelectionHighlight: 'on'
                   Tag: ''
                  Type: 'line'
         UIContextMenu: []
              UserData: []
               Visible: 'on'
                 XData: [1 2 3 4 5 6 7 8 9 10]
             XDataMode: 'auto'
           XDataSource: ''
                 YData: [1 2 3 4 5 6 7 8 9 10]
           YDataSource: ''
                 ZData: [1x0 double]
           ZDataSource: ''
```

Query Specific Property of Specific Object

Create a line plot and return the chart line object as `p`. Use `get` to return the current value of the `LineWidth` property.

```
p = plot(1:10);
get(p,'LineWidth')
```

```
ans =

    0.5000
```

Query Set of Properties for Specific Object

Create a line plot with circle markers and return the chart line object as `p`. Use `get` to return the current values of the `LineWidth`, `Marker`, and `MarkerSize` properties for the object.

```
p = plot(1:10,'ro-');
```

```
props = {'LineWidth','Marker','MarkerSize'};
get(p,props)
```

```
ans =

    [0.5000]    'o'    [6]
```

Query Default Property Value on Root

Return the default value of the `LineWidth` property defined on the root for all line graphics objects.

```
get(groot,'DefaultLineLineWidth')
```

```
ans =

    0.5000
```

More About

- "Graphics Object Properties"

`findobj` | `gca` | `gcf` | `gco` | `set`

Introduced before R2006a

get

Query property values for `audioplayer` object

Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
Values = get(obj)
get(obj)
```

Description

`Value = get(obj,Name)` returns the value of the specified property for object `obj`.

`Values = get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-`N` cell array.

`Values = get(obj)` returns a scalar structure that contains the values of all properties of `obj`. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

Examples

Create an `audioplayer` object from the example file `handel.mat` and query the object properties:

```
load handel.mat;
handelObj = audioplayer(y, Fs);

% Display all properties.
get(handelObj)

% Display only the SampleRate property.
get(handelObj, 'SampleRate')
```

```
% Create a cell array that contains
% values for two properties.
info = get(handelObj, {'BitsPerSample', 'NumberOfChannels'});
```

Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `TotalSamples` property for an object named `handelObj` (as created in the Example):

```
numSamples = handelObj.TotalSamples;
```

This command is exactly equivalent to:

```
numSamples = get(handelObj, 'TotalSamples');
```

See Also

`audioplayer` | `set`

get

Query property values for `audiorecorder` object

Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
Values = get(obj)
get(obj)
```

Description

`Value = get(obj,Name)` returns the value of the specified property for object `obj`.

`Values = get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-`N` cell array.

`Values = get(obj)` returns a scalar structure that contains the values of all properties of `obj`. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

Examples

Create an `audiorecorder` object and query the object properties:

```
recorderObj = audiorecorder;

% Display all properties.
get(recorderObj)

% Display only the SampleRate property.
get(recorderObj, 'SampleRate')

% Create a cell array that contains
% values for two properties.
```

```
info = get(recorderObj, {'BitsPerSample', 'NumberOfChannels'});
```

Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `TotalSamples` property for an object named `recorderObj` (as created in the Example):

```
numSamples = recorderObj.TotalSamples;
```

This command is exactly equivalent to:

```
numSamples = get(recorderObj, 'TotalSamples');
```

See Also

`audiorecorder` | `set`

get (COM)

Get property value from interface, or display properties

Syntax

```
V = get(h)
V = get(h,'name')
```

Description

`V = get(h)` returns a list of all properties and their values for the object or interface, `h`.

If `V` is empty, either there are no properties in the object, or MATLAB cannot read the object's type library. Refer to the COM vendors documentation.

`V = get(h,'name')` returns value of property specified in string, `name`.

COM functions are available on Microsoft Windows systems only.

Examples

Create a COM server running Microsoft Excel software:

```
e = actxserver('Excel.Application');
```

Retrieve a single property value.

```
e.Path
```

```
ans =
   C:\Program Files\MSOffice\OFFICE11
```

MATLAB displays the path to your program.

List of all properties for the `CommandBars` interface.

```
c = CommandBars.get(e)
```

MATLAB displays information for your version of Excel.

More About

Tips

The meaning and type of the return value is dependent upon the specific property being retrieved. The object's documentation should describe the specific meaning of the return value. MATLAB may convert the data type of the return value. For a description of how MATLAB converts COM data types, see “Handling COM Data in MATLAB Software”.

See Also

`set (COM)` | `inspect` | `isprop` | `addproperty` | `deleteproperty`

Introduced before R2006a

get

Class: VideoReader

Query property values for video reader object

Syntax

```
Value = get(obj,Name)
Values = get(obj,{Name1,...,NameN})
allValues = get(obj)
get(obj)
```

Description

`Value = get(obj,Name)` returns the value of the property with the specified Name for object obj.

`Values = get(obj,{Name1,...,NameN})` returns the values of the specified properties in a 1-by-N cell array.

`allValues = get(obj)` returns a scalar structure that contains the values of all properties of obj. Each field name corresponds to a property name.

`get(obj)` displays all property names and their current values.

Input Arguments

`obj`

`VideoReader` object created by the `VideoReader` function.

`Name`

String enclosed in single quotation marks that specifies a `VideoReader` property.

Output Arguments

`Value`

String containing the value associated with the specified `VideoReader` property.

`Values`

Cell array containing the values associated with the specified `VideoReader` properties. Values is a row vector, with one column for each property.

`allValues`

Scalar (1-by-1) structure array that contains the values of all properties of `VideoReader` object obj.

Examples

Display All Object Properties

Display all properties of an object associated with the example file, `xylophone.mp4`.

```
xyloObj = VideoReader('xylophone.mp4');
get(xyloObj)
```

```
obj =

  VideoReader with properties:

   General Properties:
           Name: 'xylophone.mp4'
           Path: 'matlabroot\toolbox\matlab\audiovideo'
       Duration: 4.7000
    CurrentTime: 0
            Tag: ''
       UserData: []

   Video Properties:
          Width: 320
         Height: 240
       FrameRate: 30
    BitsPerPixel: 24
```

```
    VideoFormat: 'RGB24'
```

Store Specific Object Properties

Create a 1-by-3 cell array that contains the values of the `Height`, `Width`, and `Duration` properties of an object associated with `xylophone.mp4`.

```
xyloObj = VideoReader('xylophone.mp4');
xyloProp = get(xyloObj,{'Height','Width','Duration'})
```

```
xyloProp =

    [240]    [320]    [4.7000]
```

Alternatives

To access a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, find the value of the `Duration` property for object `xyloObj` (as created in the Examples):

```
D = xyloObj.Duration;
```

This command is equivalent to:

```
D = get(xyloObj,'Duration');
```

See Also

`VideoReader` | `set`

get (RandStream)

Random stream properties

Class

`@RandStream`

Syntax

```
get(s)
P = get(s)
P = get(s,'PropertyName')
```

Description

`get(s)` prints the list of properties for the random stream `s`.

`P = get(s)` returns all properties of `s` in a scalar structure.

`P = get(s,'PropertyName')` returns the property `'PropertyName'`.

See Also

`RandStream` | `set (RandStream)`

get (serial)

Serial port object properties

Syntax

```
get(obj)
out = get(obj)
out = get(obj,'PropertyName')
```

Description

`get(obj)` returns all property names and their current values to the command line for the serial port object, `obj`.

`out = get(obj)` returns the structure `out` where each field name is the name of a property of `obj`, and each field contains the value of that property.

`out = get(obj,'PropertyName')` returns the value `out` of the property specified by *`PropertyName`* for `obj`. If *`PropertyName`* is replaced by a 1-by-n or n-by-1 cell array of strings containing property names, then `get` returns a 1-by-n cell array of values to `out`. If `obj` is an array of serial port objects, then `out` will be a m-by-n cell array of property values where m is equal to the length of `obj` and n is equal to the number of properties specified.

Examples

This example illustrates some of the ways you can use `get` to return property values for the serial port object `s` on a Windows platform.

```
s = serial('COM1');
out1 = get(s);
out2 = get(s,{'BaudRate','DataBits'});
s.Parity

ans =
none
```

More About

Tips

Refer to Displaying Property Names and Property Values for a list of serial port object properties that you can return with `get`.

When you specify a property name, you can do so without regard to case. For example, if `s` is a serial port object, then these commands are equivalent.

```
out = s.BaudRate;
out = s.baudrate;
```

See Also

`set`

Introduced before R2006a

get (tscollection)

Query `tscollection` object property values

Syntax

```
value = get(tsc,'PropertyName')
```

Description

`value = get(tsc,'PropertyName')` returns the value of the specified property of the `tscollection` object tsc. The following syntax is equivalent:

```
value = tsc.PropertyName
```

`get(tsc)` displays all properties and values of the `tscollection` object tsc.

See Also

`set (tscollection)` | `timeseries`

Introduced before R2006a

getabstime (tscollection)

Extract date-string time vector into cell array

Syntax

```
getabstime(tsc)
```

Description

`getabstime(tsc)` extracts the time vector from the `tscollection` object tsc as a cell array of date strings. To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the time-series collection. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

Examples

1. Create a `tscollection` object.

   ```
   tsc = tscollection(timeseries([3 6 8 0 10]));
   ```

2. Set the `StartDate` property.

   ```
   tsc.TimeInfo.StartDate = '10/27/2005 07:05:36';
   ```

3. Extract a vector of absolute time values.

   ```
   getabstime(tsc)

   ans =

       '27-Oct-2005 07:05:36'
       '27-Oct-2005 07:05:37'
       '27-Oct-2005 07:05:38'
       '27-Oct-2005 07:05:39'
       '27-Oct-2005 07:05:40'
   ```

4. Change the date-string format of the time vector.

```
tsc.TimeInfo.Format = 'mm/dd/yy';
```

5 Extract the time vector with the new date-string format.

```
getabstime(tsc)

ans =

    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
```

See Also

datestr | setabstime (tscollection) | tscollection

Introduced before R2006a

getappdata

Retrieve application-defined data

Use the `getappdata` function to retrieve data stored using the `setappdata` function. Both of these functions provide a convenient way to share data between callbacks or between separate UIs.

Syntax

```
val = getappdata(obj,name)
vals = getappdata(obj)
```

Description

`val = getappdata(obj,name)` returns a value stored in the graphics object, obj. The name identifier, name, uniquely identifies the value to retrieve.

`vals = getappdata(obj)` returns all values stored in the graphics object with their name identifiers.

Examples

Store and Retrieve Date and Time

Create a figure window.

```
f = figure;
```

Get the current date and time as separate variables.

```
dt = fix(clock);
currdate = dt(1:3);
currtime = dt(4:6);
```

Store `currdate` and `currtime` using the `setappdata` function.

```
setappdata(f,'todaysdate',currdate);
```

```
setappdata(f,'presenttime',currtime);
```

Retrieve the date information.

```
getappdata(f,'todaysdate')
```

```
ans =

    2014  12    23
```

Retrieve all data associated with figure `f`.

```
getappdata(f)
```

```
ans =

     todaysdate: [2014 12 23]
    presenttime: [16 51 5]
```

Input Arguments

`obj` — Graphics object containing the value

figure | uipanel | uibuttongroup | uicontrol | ...

Graphics object containing the value, specified as any graphics object (except an ActiveX component). This is the same graphics object passed to `setappdata` during the storage operation.

`name` — Name identifier

`string`

Name identifier, specified as a `string` value. This is the same name identifier passed to `setappdata` during the storage operation.

Data Types: `char`

Output Arguments

`val` — Stored value

any MATLAB data type

Stored value, returned as the same value and data type that was originally stored.

`vals` — All values stored in the graphics object with name identifiers

`struct`

All values stored in the graphics object with name identifiers, returned as a `struct`. Each field in the `struct` corresponds to a stored value. The field names of the `struct` correspond to the name identifiers assigned when each value was stored.

`guidata` | `isappdata` | `rmappdata` | `setappdata`

Introduced before R2006a

getaudiodata

Store recorded audio signal in numeric array

Syntax

```
y = getaudiodata(recorder)
y = getaudiodata(recorder, dataType)
```

Description

`y = getaudiodata(recorder)` returns recorded audio data associated with `audiorecorder` object `recorder` to `double` array `y`.

`y = getaudiodata(recorder, dataType)` converts the signal data to the specified data type: `'double'`, `'single'`, `'int16'`, `'int8'`, or `'uint8'`.

Output Arguments

y

Audio signal data `y` contains the same number of columns as the number of channels in the recording: one for mono, two for stereo. The range of values depends on the data type, as shown in the following table.

Data Type	Sample Value Range
`int8`	-128 to 127
`uint8`	0 to 255
`int16`	-32768 to 32767
`single`	-1 to 1
`double`	-1 to 1

Examples

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.
recObj = audiorecorder;
disp('Start speaking.')
recordblocking(recObj, 5);
disp('End of Recording.');

% Play back the recording.
play(recObj);

% Store data in double-precision array.
myRecording = getaudiodata(recObj);

% Plot the waveform.
plot(myRecording);
```

- “Record Audio”

GetCharArray

Character array from Automation server

Syntax

IDL Method Signature

```
HRESULT GetCharArray([in] BSTR varName, [in] BSTR Workspace,
    [out, retval] BSTR *mlString)
```

Microsoft Visual Basic Client

```
GetCharArray(varname As String, workspace As String) As String
```

MATLAB Client

```
str = GetCharArray(h,'varname','workspace')
```

Description

`str = GetCharArray(h,'varname','workspace')` gets the character array stored in `varname` from the specified *`workspace`* of the server attached to handle `h` and returns it in `str`. The values for *`workspace`* are `base` or `global`.

Examples

This example uses a Visual Basic .NET client.

1 Create the Visual Basic application. Use the `MsgBox` command to control flow between MATLAB and the application.

```
Dim Matlab As Object
Dim S As String
Matlab = CreateObject("matlab.application")
```

```
MsgBox("In MATLAB, type" & vbCrLf _
    & "str='new string';")
```

2 Open the MATLAB window, then type:

```
str='new string';
```

3 Click **Ok**.

```
Try
    S = Matlab.GetCharArray("str", "base")
    MsgBox("str = " & S)
Catch ex As Exception
    MsgBox("You did not set 'str' in MATLAB")
End Try
```

The Visual Basic `MsgBox` displays what you typed in MATLAB.

See Also

`PutCharArray` | `GetWorkspaceData` | `GetVariable`

Introduced before R2006a

getenv

Environment variable

Syntax

```
getenv 'name'
N = getenv('name')
```

Description

`getenv 'name'` searches the underlying operating system environment list for a string of the form `name=value`, where `name` is the input string. If found, MATLAB returns the string `value`. If the specified name cannot be found, an empty matrix is returned.

On UNIX platforms, the shell you use to start MATLAB determines the operating system environment. For example, starting MATLAB on a Mac platform from the `Applications` folder creates a different shell environment from launching MATLAB from Terminal.

`N = getenv('name')` returns `value` to the variable `N`.

Examples

```
os = getenv('OS')
```

```
os =
Windows_NT
```

See Also

`setenv` | `computer` | `pwd` | `ver` | `path`

Introduced before R2006a

getfield

Field of structure array

Syntax

```
value = getfield(struct, 'field')
value = getfield(struct,{sIndx1,...,sIndxM},'field',
{fIndx1,...,fIndxN})
```

Description

`value = getfield(struct, 'field')`, where `struct` is a 1-by-1 structure, returns the contents of the specified field, equivalent to `value = struct.field`. Pass field references as strings.

`value = getfield(struct,{sIndx1,...,sIndxM},'field', {fIndx1,...,fIndxN})` returns the contents of the specified field, equivalent to `value = struct(sIndx1,...,sIndxM).field(fIndx1,...,fIndxN)`. The `getfield` function supports multiple sets of `field` and `fIndx` inputs, and all `Indx` inputs are optional. If structure `struct` or any of the fields is a nonscalar structure, and you do not specify an `Indx`, the `getfield` function returns the values associated with the first index. If you specify a single colon operator for an `fIndx` input, enclose it in single quotation marks: `':'`.

Examples

The `what` function returns a structure array that describes the MATLAB files in the current folder. Find the files with the `.m` extension:

```
files = getfield(what, 'm');
```

To perform the same task by indexing requires that you create a temporary variable:

```
templist = what;
files = templist.m;
```

Find values within a structure that contains nested fields:

```
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student};

% Add data to a structure named grades.
grades(level).(semester).(subject).(student)(10,21:30) = ...
             [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];

% Retrieve the data added.
getfield(grades, {level}, fieldnames{:}, {10,21:30})
```

Using the structure defined in the previous example, find all values in the tenth row of the specified field:

```
getfield(grades, {level}, fieldnames{:}, {10,':'})
```

More About

Tips

- For most cases, retrieve data from a structure array by indexing rather than using the `getfield` function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.
- Call `getfield` to simplify references to structure arrays with nested fields, or to avoid creating unnecessary temporary variables, as shown in the Examples section.

- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

`setfield` | `fieldnames` | `isfield` | `orderfields` | `rmfield`

Introduced before R2006a

VideoReader.getFileFormats

Class: VideoReader

File formats that `VideoReader` supports

Syntax

```
formats = VideoReader.getFileFormats()
```

Description

`formats = VideoReader.getFileFormats()` returns an array of `audiovideo.FileFormatInfo` objects that indicate which formats `VideoReader` can read on the current system. Each object has the following properties: `Extension`, `Description`, `ContainsVideo`, and `ContainsAudio`.

Tips

- On Windows and UNIX systems, the list of file formats does not always contain all the formats that `VideoReader` can read on your system. `getFileFormats` returns a platform-dependent, static list of formats that `VideoReader` can read on most systems.
- On all systems, `VideoReader` cannot always read a particular video file even if `getFileFormats` lists its format. For more information, see Supported Video File Formats.

Output Arguments

`formats`

Array of `audiovideo.FileFormatInfo` objects, which have the following properties:

`Extension`	File extension.

`Description`	Text description of the file format.
`ContainsVideo`	Whether `VideoReader` can read video from this format.
`ContainsAudio`	Whether `VideoReader` can read audio from this format.

To convert this array to a filter list for dialog boxes generated with `uigetfile`, use the `getFilterSpec` method with the following syntax:

```
filterSpec = getFilterSpec(formats)
```

The filter list includes `'All Video Files'` in the first row of the cell array, and `'All Files (*.*)'` in the last row.

Examples

View the list of file formats that `VideoReader` supports on your system:

```
VideoReader.getFileFormats()
```

On a Windows system, this list appears as follows:

```
Video File Formats:
    .asf - ASF File
    .asx - ASX File
    .avi - AVI File
    .mj2 - Motion JPEG2000
    .mpg - MPEG-1
    .wmv - Windows Media Video
```

Create a dialog box to select a video file:

```
% Get the supported file formats.
formats = VideoReader.getFileFormats();

% Convert to a filter list.
filterSpec = getFilterSpec(formats);

% Create the dialog box.
[filename, pathname] = uigetfile(filterSpec);
```

Check whether `VideoReader` can read an `.avi` file on the current system:

```
fmtList = VideoReader.getFileFormats();

if any(ismember({fmtList.Extension},'avi'))
     disp('VideoReader can read AVI files on this system.');
else
     disp('VideoReader cannot read AVI files on this system.');
end
```

See Also

VideoReader

getframe

Capture axes or figure as movie frame

Syntax

```
F = getframe
F = getframe(ax)
F = getframe(fig)
F = getframe( ___ ,rect)
```

Description

`F = getframe` captures the current axes as it appears on the screen as a movie frame. `F` is a structure containing the image data. `getframe` captures the axes at the same size that it appears on the screen. It does not capture tick labels or other content outside the axes outline.

`F = getframe(ax)` captures the axes identified by `ax` instead of the current axes.

`F = getframe(fig)` captures the figure identified by `fig`. Specify a figure if you want to capture the entire interior of the figure window, including the axes title, labels, and tick marks. The captured movie frame does not include the figure menu and tool bars.

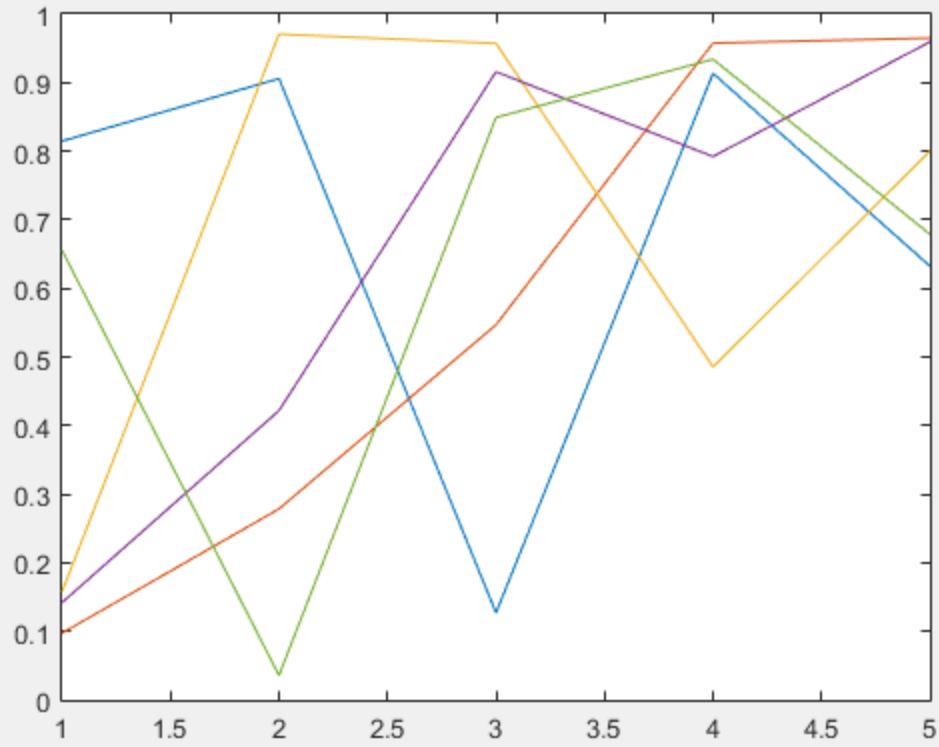
`F = getframe( ___ ,rect)` captures the area within the rectangle defined by `rect`. Specify `rect` as a four-element vector of the form `[left bottom width height]`. Use this option with either the `ax` or `fig` input arguments in the previous syntaxes.

Examples

Capture Contents of Current Axes

Create a plot of random data. Capture the axes and return the image data. `getframe` captures the interior of the axes and the axes outline. It does not capture content that extends beyond the axes outline.

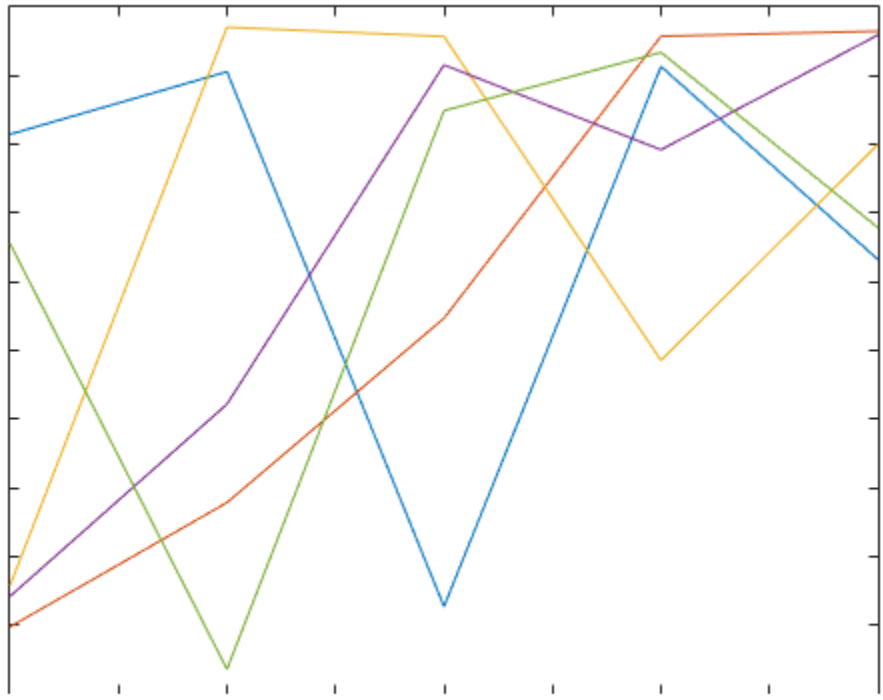
```
plot(rand(5))
F = getframe;
```



`F` is a structure with the field `cdata` that contains the captured image data.

Use `imshow` to display the captured image data.

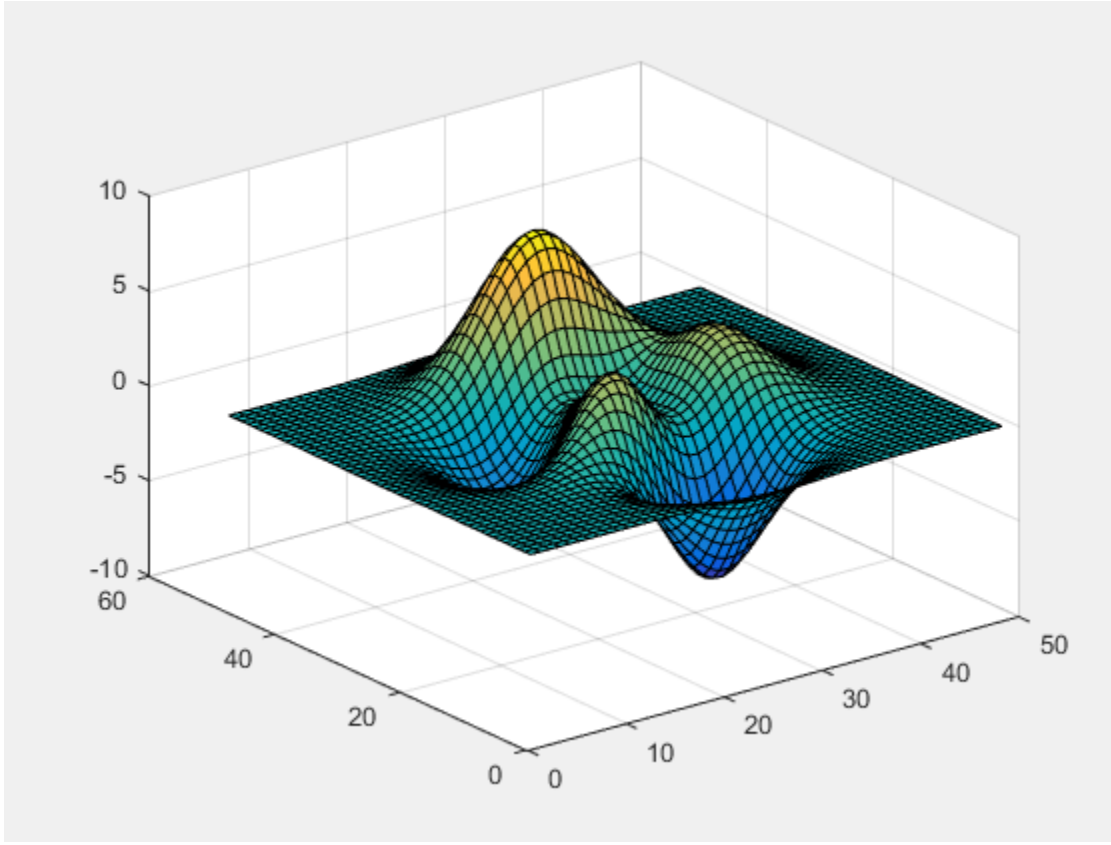
```
figure
imshow(F.cdata)
```



Capture Contents of Figure

Create a surface plot. Capture the interior of the figure window, excluding the menu and tool bars.

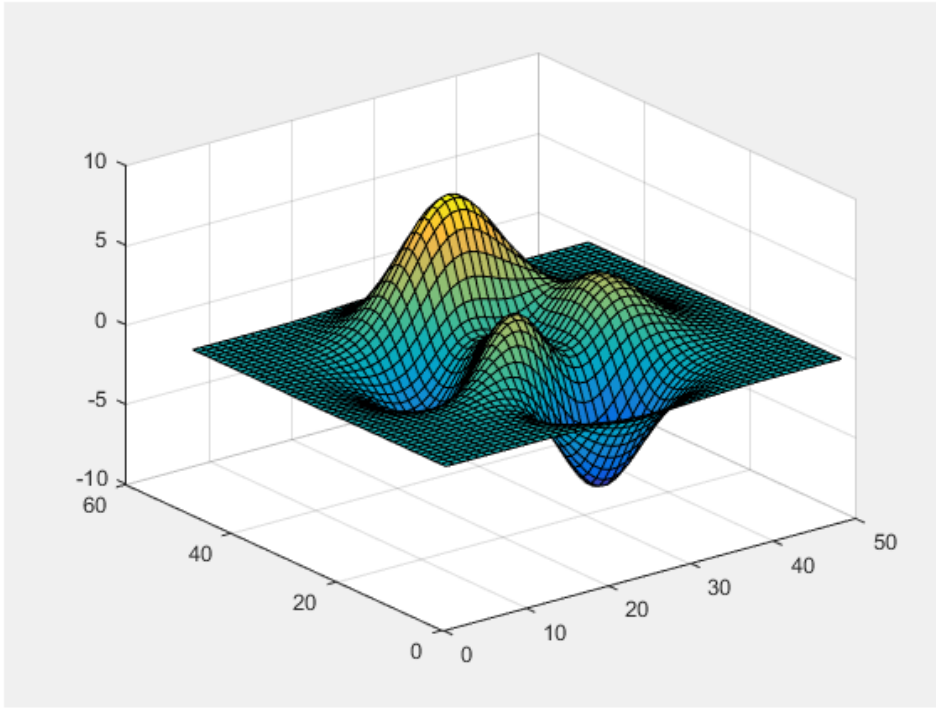
```
surf(peaks)
F = getframe(gcf);
```



`F` is a structure with the field `cdata` that contains the captured image data.

Use `imshow` to display the captured image data.

```
figure
imshow(F.cdata)
```

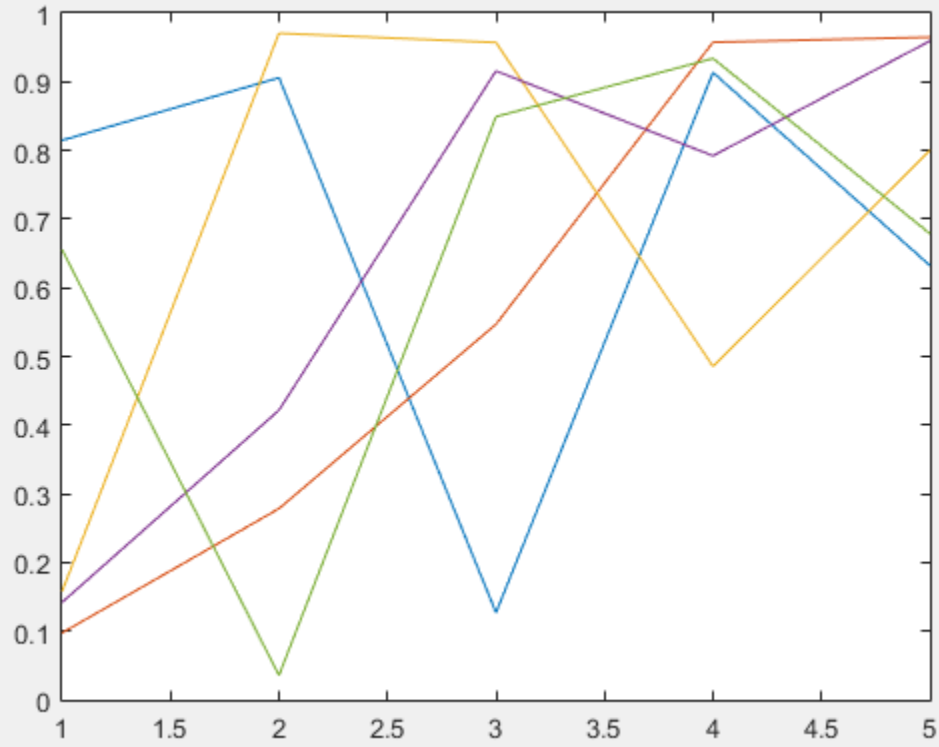


Capture Axes Plus 30 Pixel Border

Capture the interior of an axes plus a margin of 30 pixels in each direction. The added margin is necessary to include the tick labels in the capture frame. Depending on the size of the tick labels, the margin might need to be adjusted.

Create a plot of random data.

```
plot(rand(5))
```



Change the axes units to pixels and return the current axes position. The third and fourth elements of the position vector specify the axes width and height in pixels.

```
drawnow
ax = gca;
ax.Units = 'pixels';
pos = ax.Position
```

```
pos =

   73.8000   47.2000  434.0000  342.3000
```

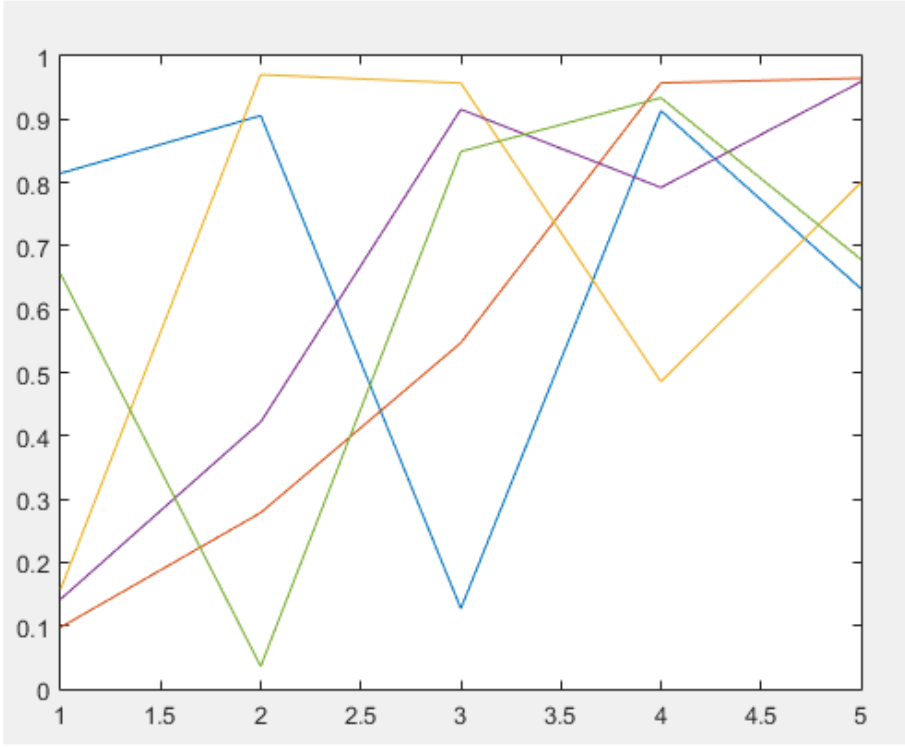
Create a four-element vector, `rect`, that defines a rectangular area covering the axes plus the desired margin. The first two elements of `rect` specify the lower left corner of

the rectangle relative to the lower left corner of the axes. The last two elements of `rect` specify the width and height of the rectangle. Reset the axes units to the default value of `'normalized'`.

```
marg = 30;
rect = [-marg, -marg, pos(3)+2*marg, pos(4)+2*marg];
F = getframe(gca,rect);
ax.Units = 'normalized';
```

Use `imshow` to display the captured image data.

```
figure
imshow(F.cdata)
```

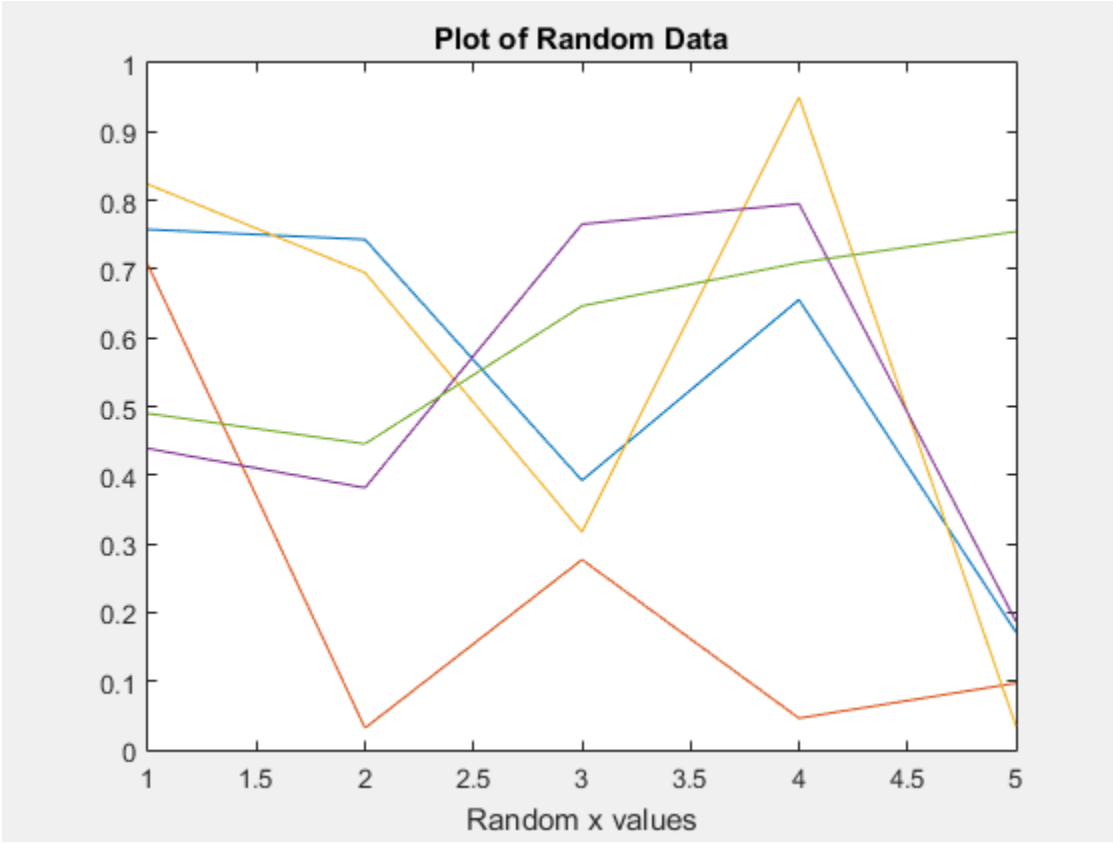


Automatically Calculate Margin to Include Title and Labels

Automatically calculate a margin around the axes so that the captured image data includes the title, axis labels, and tick labels.

Create a plot with a title and an *x*-axis label.

```
plot(rand(5))
xlabel('Random x values')
title('Plot of Random Data')
```



Change the axes units to pixels and store the `Position` and `TightInset` property values for the axes. The `TighInset` property is a four-element vector of the form `[left bottom right top]`. The values are the margins used around the axes for the tick values and text labels.

```
drawnow
ax = gca;
ax.Units = 'pixels';
pos = ax.Position;
ti = ax.TightInset;
```

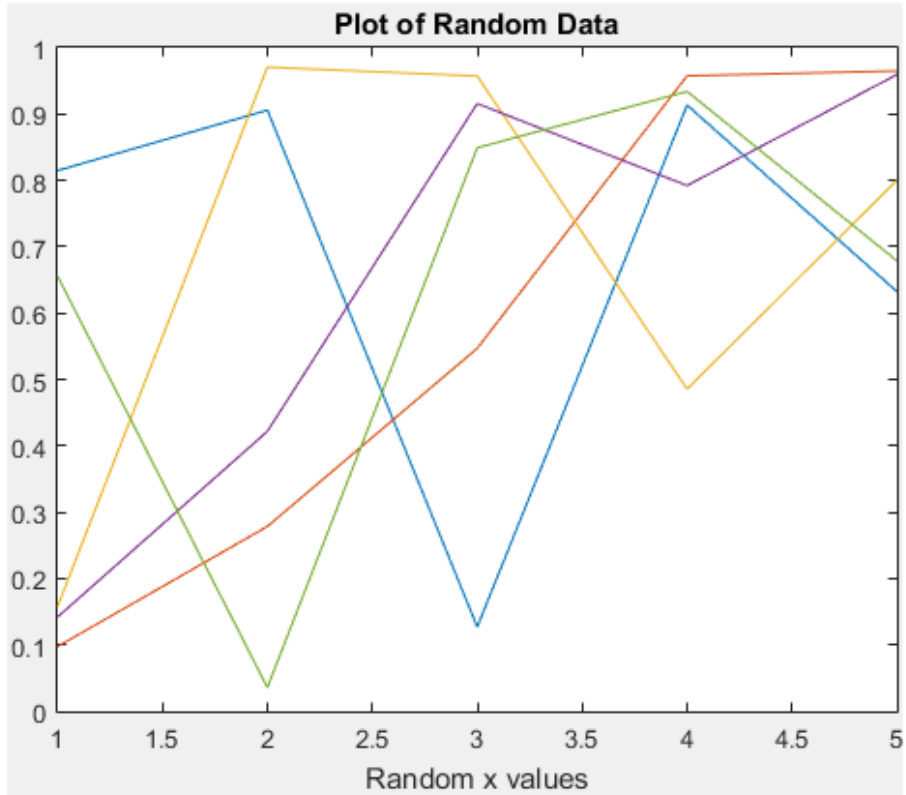
Create a four-element vector, `rect`, that defines a rectangular area covering the axes plus the automatically calculated margin. The first two elements of `rect` specify the

lower left corner of the rectangle relative to the lower left corner of the axes. The last two elements of `rect` specify the width and height of the rectangle.

```
rect = [-ti(1), -ti(2), pos(3)+ti(1)+ti(3), pos(4)+ti(2)+ti(4)];
F = getframe(ax,rect);
```

Use `imshow` to display the captured image data.

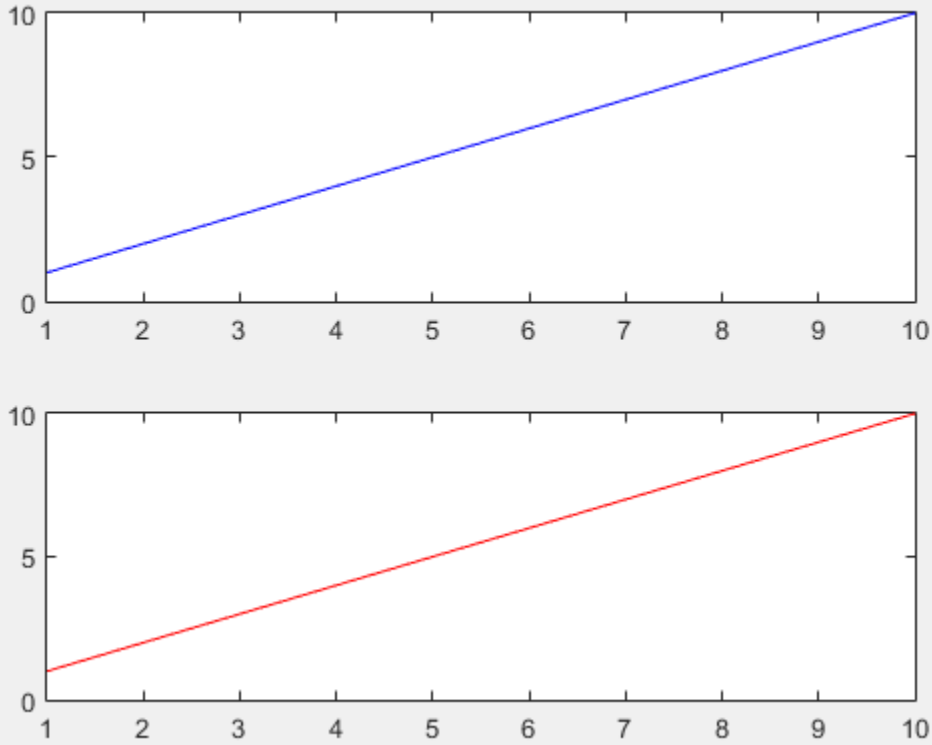
```
figure
imshow(F.cdata)
```



Capture Specific Subplot Axes

Create a figure with two subplots. In the upper subplot, plot a blue line. In the lower subplot, plot a red line.

```
ax1 = subplot(2,1,1);
plot(1:10,'b')
ax2 = subplot(2,1,2);
plot(1:10,'r')
```

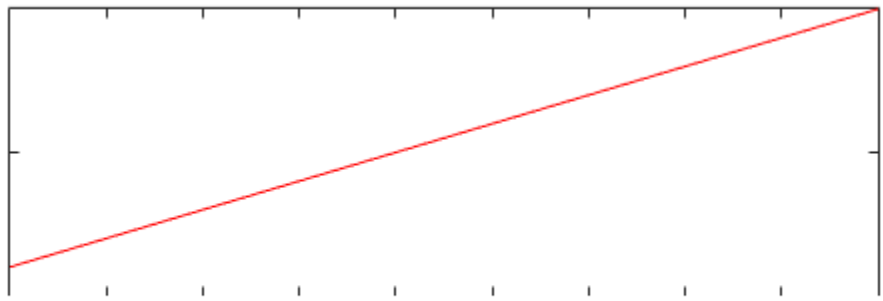


Capture the contents of the lower subplot. `getframe` captures the interior and border of the subplot. It does not capture tick values or labels that extend beyond the outline of the subplot.

```
F = getframe(ax2);
```

Use `imshow` to display the capture image data.

```
figure
imshow(F.cdata)
```



Record Frames and Play Movie

Use the `getframe` function in a loop to record frames of the peaks function vibrating. Preallocate an array to store the movie frames.

```
Z = peaks;
surf(Z)
axis tight manual
ax = gca;
ax.NextPlot = 'replaceChildren';

loops = 40;
F(loops) = struct('cdata',[],'colormap',[]);
for j = 1:loops
    X = sin(j*pi/10)*Z;
    surf(X,Z)
    drawnow
    F(j) = getframe(gcf);
end
```

Play back the movie two times.

```
fig = figure;
```

```
movie(fig,F,2)
```

Input Arguments

`ax` — Axes to capture

axes object

Axes to capture, specified as an axes object. Use this option if you want to capture an axes that is not the current axes.

`getframe` captures the content within the smallest rectangle that encloses the axes outline. If you want to capture all the tick values and labels, then use the `fig` input argument instead.

Example: `F = getframe(ax);`

`fig` — Figure to capture

figure object

Figure to capture, specified as a figure object. Use `gcf` to capture the current figure.

Example: `F = getframe(gcf);`

`rect` — Rectangular area to capture

four-element vector of the form `[left bottom width height]`

Rectangular area to capture, specified as a four-element vector of the form `[left bottom width height]`. The `left` and `bottom` elements define the position of the lower left corner of the rectangle. The position is relative to the figure or axes that is specified as the first input argument to `getframe`. The `width` and `height` elements define the dimensions of the rectangle. The values are in pixel units.

Specify a rectangle that is fully contained within the figure window.

Example: `F = getframe(gcf,[0 0 560 420]);`

Output Arguments

`F` — Movie frame

structure

Movie frame, returned as a structure with two fields:

- `cdata` — The image data stored as an array of `uint8` values.
- `colormap` — The colormap. On true color systems, this field is empty.

More About

Tips

- For the fastest performance when using `getframe`, make sure that the figure is visible on the screen. If the figure is not visible, `getframe` can still capture the figure, but performance can be slower.
- For more control over the resolution of the image data, use the `print` function instead. The `cdata` output argument with print returns the image data. The `resolution` input argument controls the resolution of the image.

Introduced before R2006a

GetFullMatrix

Matrix from Automation server workspace

Syntax

IDL Method Signature

```
GetFullMatrix([in] BSTR varname, [in] BSTR workspace,
    [in, out] SAFEARRAY(double) *pr, [in, out] SAFEARRAY(double) *pi)
```

Microsoft Visual Basic Client

```
GetFullMatrix(varname As String, workspace As String,
    [out] XReal As Double, [out] XImag As Double
```

MATLAB Client

```
[xreal ximag] = GetFullMatrix(h,'varname','workspace',zreal,zimag)
```

Description

`[xreal ximag] = GetFullMatrix(h,'varname','workspace',zreal,zimag)` gets matrix stored in variable `varname` from the specified *`workspace`* of the server attached to handle `h`. The function returns the real part in `xreal` and the imaginary part in `ximag`. The values for *`workspace`* are `base` or `global`.

The `zreal` and `zimag` arguments are matrices of the same size as the real and imaginary matrices (`xreal` and `ximag`) returned from the server. The `zreal` and `zimag` matrices are commonly set to zero.

Use `GetFullMatrix` for values of type `double` only. Use `GetVariable` or `GetWorkspaceData` for other types.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the

`variant` data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

Examples

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

1. Create the Visual Basic application. To control flow between MATLAB and the application, use the `MsgBox` command.

```
Dim MatLab As Object
Dim Result As String
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim i, j As Integer

MatLab = CreateObject("matlab.application")
Result = MatLab.Execute("M = rand(5);")
MsgBox("In MATLAB, type" & vbCrLf _
    & "M(3,4)")
```

2. Open the MATLAB window and type:

```
M(3,4)
```

3. Click **Ok**.

4. In the Visual Basic application:

```
MatLab.GetFullMatrix("M", "base", XReal, XImag)
i = 2   %0-based array
j = 3

MsgBox("XReal(" & i + 1 & "," & j + 1 & ")" & _
    " = " & XReal(i, j))
```

5. To close and terminate MATLAB, click **Ok**.

`PutFullMatrix` | `GetVariable` | `GetWorkspaceData` | `Execute`

Introduced before R2006a

getnext

Get next value from ValueIterator

Syntax

```
X = getnext(ValIter)
```

Description

`X = getnext(ValIter)` returns the next available value in `ValIter`. Use the `hasnext` function to confirm availability of values in `ValIter` before calling `getnext`.

Examples

Get Values from ValueIterator in Reduce Function

Use the `hasnext` and `getnext` functions in a `while` loop within the reduce function to iteratively get values from the `ValueIterator` object. For example,

```
function MeanDistReduceFun(sumLenKey, sumLenIter, outKVStore)
    sumLen = [0 0];
    while hasnext(sumLenIter)
        sumLen = sumLen + getnext(sumLenIter);
    end
    add(outKVStore, 'Mean', sumLen(1)/sumLen(2));
end
```

Always call `hasnext` before `getnext` to confirm availability of a value. `mapreduce` returns an error if you call `getnext` with no remaining values in the `ValueIterator` object.

Input Arguments

`ValIter` — Intermediate value iterator

`ValueIterator` object

Intermediate value iterator, specified as a `ValueIterator` object. The `mapreduce` function automatically creates this object during execution. The second input to the reduce function specifies the variable name for the `ValueIterator` object, which is the variable name to use with the `hasnext` and `getnext` functions.

For more information, see Using ValueIterator Objects.

More About

- Using ValueIterator Objects
- "Build Effective Algorithms with MapReduce"

See Also

`hasnext` | `mapreduce`

Introduced in R2014b

getpixelposition

Get component position in pixels

Syntax

```
position = getpixelposition(handle)
position = getpixelposition(handle,recursive)
```

Description

`position = getpixelposition(handle)` gets the position, in pixel units, of the component with handle `handle`. MATLAB returns the `position` as a four-element vector that specifies the location and size of the component: [distance from left, distance from bottom, width, height].

`position = getpixelposition(handle,recursive)` gets the position as above. If `recursive` is true, the returned position is relative to the parent figure of `handle`.

Use the `getpixelposition` function only to obtain coordinates for children of figures and container components (uipanels, or uibuttongroups). Results are not reliable for children of axes or other Handle Graphics objects.

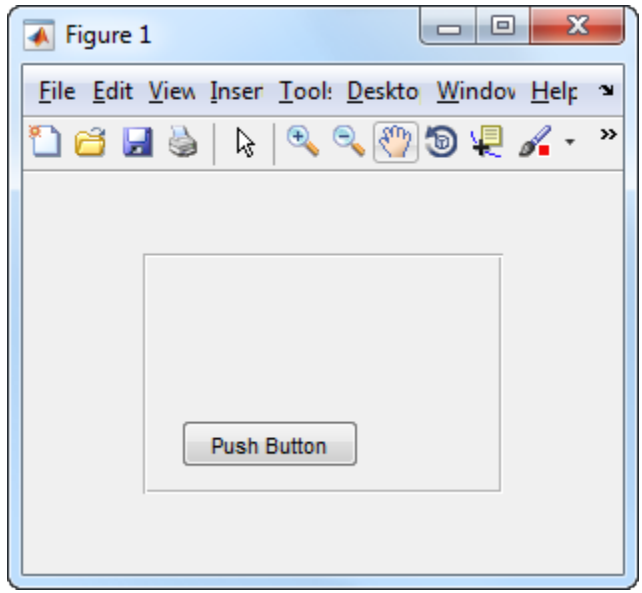
Examples

This example creates a push button within a panel, and then retrieves its position, in pixels, relative to the *panel*.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton',...
     'Units','Normalized',...
     'String','Push Button',...
     'Position',[.1 .1 .5 .2]);
drawnow;
pos1 = getpixelposition(h1)
```

```
pos1 =

   18.6000   12.6000   88.0000   23.2000
```



The following statement retrieves the position of the push button, in pixels, relative to the *figure*.

```
pos1 = getpixelposition(h1,true)
```

```
pos1 =
      78.6000   52.6000   88.0000   23.2000
```

See Also

`setpixelposition` | `uicontrol` | `uipanel`

getpoints

Return points that define animated line

To use this function, you must first create an animated line with the `animatedline` function. For more information on line animations, see Using Animated Line Objects.

Syntax

```
[x,y] = getpoints(h)
[x,y,z] = getpoints(h)
```

Description

`[x,y] = getpoints(h)` returns the *x* and *y* coordinates for the points that define the animated line specified by `h`.

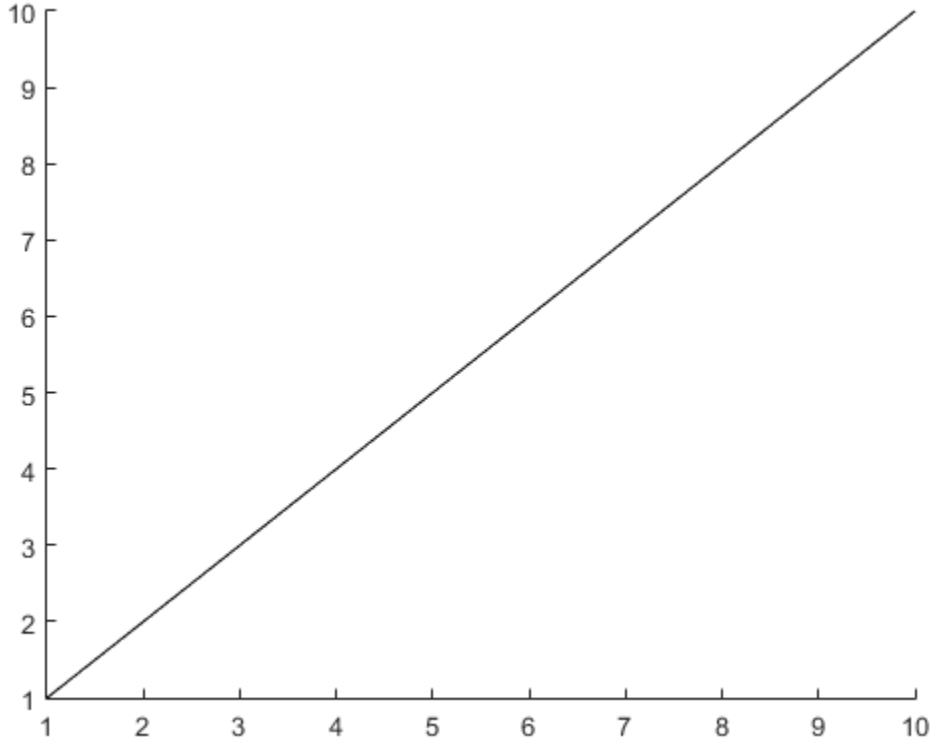
`[x,y,z] = getpoints(h)` returns the coordinates for the 3-D animated line specified by `h`. If the line does not have any *z* values, then `getpoints` returns `z` as a vector of zeros the same length as `x` and `y`.

Examples

Return Points from Animated Line

Create an animated line with 10 points. Then, return the points stored in the animated line.

```
h = animatedline(1:10,1:10);
```



```
[x,y] = getpoints(h)

x =

     1     2     3     4     5     6     7     8     9    10

y =

     1     2     3     4     5     6     7     8     9    10
```

Input Arguments

h — Animated line object

animated line object

Animated line object. Create an animated line object using the `animatedline` function.

Output Arguments

x — x values

vector

x values that define the animated line, returned as vector.

y — y values

vector

y values that define the animated line, returned as vector.

z — z values

vector

z values that define the 3-D animated line, returned as vector.

Functions

`addpoints` | `animatedline` | `clearpoints`

Using Objects

Using Animated Line Objects

getpref

Preference

Syntax

```
getpref('group','pref')
getpref('group','pref',default)
getpref('group',{'pref1','pref2',...'prefn'})
getpref('group',{'pref1',...'prefn'},{default1,...defaultn})
getpref('group')
getpref
```

Description

`getpref('group','pref')` returns the value for the preference specified by `group` and `pref`. It is an error to get a preference that does not exist.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`getpref('group','pref',default)` returns the current value if the preference specified by `group` and `pref` exists. Otherwise creates the preference with the specified default value and returns that value.

`getpref('group',{'pref1','pref2',...'prefn'})` returns a cell array containing the values for the preferences specified by `group` and the cell array of preference names. The return value is the same size as the input cell array. It is an error if any of the preferences do not exist.

`getpref('group',{'pref1',...'prefn'},{default1,...defaultn})` returns a cell array with the current values of the preferences specified by `group` and the cell array of preference names. Any preference that does not exist is created with the specified default value and returned.

`getpref('group')` returns the names and values of all preferences in the `group` as a structure.

`getpref` returns all groups and preferences as a structure.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Get the Value of an Existing Preference

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')

ans =
     1.0
```

Create a Preference Using Specified Default Value

```
setpref('mytoolbox','version','1.0')
rmpref('mytoolbox','version')
getpref('mytoolbox','version','1.0');
getpref('mytoolbox','version')

ans =

1.0
```

The first call to `getpref` adds the `'version'` preference and sets its value to the default value, `1.0`. The second call to `getpref` verifies that the preference exists, and that its value is `1.0`.

See Also

`addpref` | `ispref` | `rmpref` | `setpref` | `uigetpref` | `uisetpref`

Introduced before R2006a

VideoWriter.getProfiles

Class: VideoWriter

List profiles and file formats supported by `VideoWriter`

Syntax

```
profiles = VideoWriter.getProfiles()
```

Description

`profiles = VideoWriter.getProfiles()` returns an array of `audiovideo.writer.ProfileInfo` objects that indicate the types of files `VideoWriter` can create.

Output Arguments

`profiles`

An array of `audiovideo.writer.ProfileInfo` objects, which have the following read-only properties:

`Name`	String profile name, such as `'Uncompressed AVI'`.
`Description`	String description of the profile.
`FileExtensions`	Cell array of strings containing file extensions supported by the file format.
`ColorChannels`	Number of color channels in each output video frame.
`CompressionRatio`	Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. Only applies to objects associated with Motion JPEG 2000 files. Default: `10`.
`FrameRate`	Rate of playback for the video in frames per second. Default: `30`.

`LosslessCompression`	Boolean value (logical `true` or `false`) that specifies whether to use reversible mode, so that the decompressed data is identical to the input data. When `true`, `VideoWriter` ignores values for `CompressionRatio`. Only applies to objects associated with Motion JPEG 2000 files.
`MJ2BitDepth`	Number of least significant bits in the input image data, from 1 to 16. Only applies to objects associated with Motion JPEG 2000 files.
`Quality`	Number from 0 through 100. Higher values correspond to higher quality video and larger files. Only applies to objects associated with the `MPEG-4` or `Motion JPEG AVI` profile. Default: `75`.
`VideoBitsPerPixel`	Number of bits per pixel in each output video frame.
`VideoCompressionMethod`	String indicating the type of video compression, such as `'None'` or `'Motion JPEG'`.
`VideoFormat`	String indicating the MATLAB representation of the video format, such as `'RGB24'`.

Examples

Profile Information

View the list of available profiles and specific information about the `'Uncompressed AVI'` profile.

```
profiles = VideoWriter.getProfiles()

uncompAVI = find(ismember({profiles.Name},'Uncompressed AVI'));
profiles(uncompAVI)
profiles(uncompAVI).FileExtensions
```

See Also

`VideoWriter`

getsampleusingtime (tscollection)

Extract data samples into new `tscollection` object

Syntax

```
tsc2 = getsampleusingtime(tsc1,Time)
tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)
```

Description

`tsc2 = getsampleusingtime(tsc1,Time)` returns a new `tscollection` tsc2 with a single sample corresponding to Time in tsc1.

`tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)` returns a new `tscollection` tsc2 with samples between the times StartTime and EndTime in tsc1.

More About

Tips

When the time vector in ts1 is numeric, `StartTime` and `EndTime` must also be numeric. When the times in ts1 are date strings and the `StartTime` and `EndTime` values are numeric, then the `StartTime` and `EndTime` values are treated as `datenum` values.

See Also

`tscollection`

Introduced before R2006a

getTag

Class: Tiff

Value of specified tag

Syntax

```
tagValue = getTag(tagId)
```

Description

`tagValue = getTag(tagId)` retrieves the value of the TIFF tag specified by `tagId`. You can specify `tagId` as a character string (`'ImageWidth'`) or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

Examples

Get Value of Tag

Open a `Tiff` object and get the value of a tag. Specify the tag by name.

```
t = Tiff('example.tif','r');
tagval = t.getTag('ImageWidth')
```

```
tagval =

   600
```

Alternatively, specify the tag by numeric identifier.

```
tagval1 = t.getTag(256)
```

```
tagval1 =
```

```
   600
```

Another way to specify the numeric identifier is to use the `TagID` property.

```
tagval2 = t.getTag(Tiff.TagID.ImageWidth)
```

```
tagval2 =

   600
```

Close the `Tiff` object.

```
t.close();
```

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

References

This method corresponds to the `TIFFGetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTiff - TIFF Library and Utilities.

See Also

`Tiff.setTag`

Tiff.getTagNames

Class: Tiff

List of recognized TIFF tags

Syntax

```
tagNames = Tiff.getTagNames()
```

Description

`tagNames = Tiff.getTagNames()` returns a cell array of TIFF tags recognized by the `Tiff` object.

Examples

Retrieve a list of TIFF tags recognized by the `Tiff` object.

```
Tiff.getTagNames

ans =

    'SubFileType'
    'ImageWidth'
    'ImageLength'
    'BitsPerSample'
    'Compression'
    'Photometric'
    'Thresholding'
    'FillOrder'
    'DocumentName'
    'ImageDescription'
     .
     .
     .
```

See Also

`Tiff.getTag`

gettimeseriesnames

Cell array of names of `timeseries` objects in `tscollection` object

Syntax

```
names = gettimeseriesnames(tsc)
```

Description

`names = gettimeseriesnames(tsc)` returns `names` of `timeseries` objects in a `tscollection` object `tsc`. `names` is a cell array of strings.

Examples

1. Create `timeseries` objects `a` and `b`.

   ```
   a = timeseries(rand(1000,1),'name','position');
   b = timeseries(rand(1000,1),'name','response');
   ```

2. Create a `tscollection` object that includes these two time series.

   ```
   tsc = tscollection({a,b});
   ```

3. Get the names of the `timeseries` objects in `tsc`.

   ```
   names = gettimeseriesnames(tsc)

   names =

       'position'    'response'
   ```

See Also

`timeseries` | `tscollection`

Introduced before R2006a

gettsafteratevent

New `timeseries` object with samples occurring at or after event

Syntax

```
ts1 = gettsafteratevent(ts,event)
ts1 = gettsafteratevent(ts,event,n)
```

Description

`ts1 = gettsafteratevent(ts,event)` returns a new `timeseries` object ts1 with samples occurring at and after an event in ts, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of the time series ts that matches the event name specifies the time.

`ts1 = gettsafteratevent(ts,event,n)` returns a new `timeseries` object ts1 with samples at and after an event in ts, where n is the number of the event occurrence with a matching event name.

More About

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

gettsafterevent

New `timeseries` object with samples occurring after event

Syntax

```
ts1 = gettsafterevent(ts,event)
ts1 = ttsafterevent(ts,event,n)
```

Description

`ts1 = gettsafterevent(ts,event)` returns a new `timeseries` object ts1 with samples occurring after an event in ts, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = ttsafterevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring after an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

gettsatevent

New `timeseries` object with samples occurring at event

Syntax

```
ts1 = gettsatevent(ts,event)
ts1 = gettsatevent(ts,event,n)
```

Description

`ts1 = gettsatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsatevent(ts,event,n)` returns a new time series `ts1` with samples occurring at an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

gettsbeforeatevent

New `timeseries` object with samples occurring before or at event

Syntax

```
ts1 = gettsbeforeatevent(ts,event)
ts1 = gettsbeforeatevent(ts,event,n)
```

Description

`ts1 = gettsbeforeatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeatevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

gettsbetweenevents

New `timeseries` object with samples occurring between events

Syntax

```
ts1 = gettsbetweenevents(ts,event1,event2)
ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)
```

Description

`ts1 = gettsbetweenevents(ts,event1,event2)` returns a new `timeseries` object ts1 with samples occurring between events in `ts`, where `event1` and `event2` can be either a `tsdata.event` object or a string. When `event1` and `event2` are `tsdata.event` objects, the time defined by the events is used. When `event1` and `event2` are strings, the first `tsdata.event` object in the `Events` property of `ts` that matches the event names specifies the time.

`ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)` returns a new `timeseries` object ts1 with samples occurring between events in `ts`, where `n1` and `n2` are the `n`th occurrences of the events with matching event names.

More About

Tips

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

GetVariable

Data from variable in Automation server workspace

Syntax

IDL Method Signature

```
HRESULT GetVariable([in] BSTR varname, [in] BSTR workspace,
    [out, retval] VARIANT* pdata)
```

Microsoft Visual Basic Client

```
GetVariable(varname As String, workspace As String) As Object
```

MATLAB Client

```
D = GetVariable(h,'varname','workspace')
```

Description

`D = GetVariable(h,'varname','workspace')` gets data stored in variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in output argument `D`. The values for *`workspace`* are `base` or `global`.

Do *not* use `GetVariable` on sparse arrays, structures, or function handles.

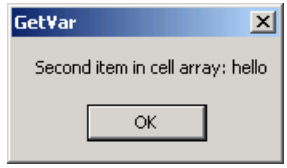
If your scripting language requires a result be returned explicitly, use the `GetVariable` function in place of `GetWorkspaceData`, `GetFullMatrix`, or `GetCharArray`.

Examples

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
```

```
Dim Result As String
Dim C2 As Variant
Matlab = CreateObject("matlab.application")
Result = Matlab.Execute("C1 = {25.72, 'hello', rand(4)};")
C2 = Matlab.GetVariable("C1", "base")
MsgBox("Second item in cell array: " & C2(0, 1))
```



See Also

GetWorkspaceData | GetFullMatrix | GetCharArray | Execute

Introduced before R2006a

Tiff.getVersion

Class: Tiff

LibTIFF library version

Syntax

```
versionString = Tiff.getVersion()
```

Description

`versionString = Tiff.getVersion()` returns the version number and other information about the LibTIFF library.

Examples

Display version of LibTIFF library:

```
Tiff.getVersion

ans =

LIBTIFF, Version 3.9.5
Copyright (c) 1988-1996 Sam Leffler
Copyright (c) 1991-1996 Silicon Graphics, Inc.
```

References

This method corresponds to the `TIFFGetVersion` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

GetWorkspaceData

Data from Automation server workspace

Syntax

IDL Method Signature

```
HRESULT GetWorkspaceData([in] BSTR varname, [in] BSTR workspace,
    [out] VARIANT* pdata)
```

Microsoft Visual Basic Client

```
GetWorkspaceData(varname As String, workspace As String) As Object
```

MATLAB Client

```
D = GetWorkspaceData(h,'varname','workspace')
```

Description

`D = GetWorkspaceData(h,'varname','workspace')` gets data stored in variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in output argument `D`. The values for *`workspace`* are `base` or `global`.

Use `GetWorkspaceData` instead of `GetFullMatrix` and `GetCharArray` to get numeric and character array data, respectively. Do *not* use `GetWorkspaceData` on sparse arrays, structures, or function handles.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the `variant` data type instead of the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`. VBScript does not support `safearray`.

Examples

This example uses a Visual Basic .NET client to read data from a MATLAB Automation server:

```
Dim Matlab As Object
Dim C2 As Variant
Dim Result As String
Matlab = CreateObject("matlab.application")
Result = MatLab.Execute("C1 = {25.72, 'hello', rand(4)};")
MsgBox("In MATLAB, type" & vbCrLf & "C1")
Matlab.GetWorkspaceData("C1", "base", C2)
MsgBox("second value of C1 = " & C2(0, 1))
```

PutWorkspaceData | GetFullMatrix | GetCharArray | GetVariable | Execute

Introduced before R2006a

ginput

Graphical input from mouse or cursor

Syntax

```
[x,y] = ginput(n)
[x,y] = ginput
[x,y,button] = ginput(...)
```

Description

`ginput` raises crosshairs in the current axes to for you to identify points in the figure, positioning the cursor with the mouse. The figure must have focus before `ginput` can receive input. If it has no axes, one is created upon the first click or keypress.

`[x,y] = ginput(n)` enables you to identify `n` points from the current axes and returns their *x*- and *y*-coordinates in the `x` and `y` column vectors. Press the **Return** key to terminate the input before entering `n` points. Specify `n` as a positive integer.

`[x,y] = ginput` gathers an unlimited number of points until you press the **Return** key.

`[x,y,button] = ginput(...)` returns the *x*-coordinates, the *y*-coordinates, and the button or key designation. `button` is a vector of integers indicating which mouse buttons you pressed (1 for left, 2 for middle, 3 for right), or ASCII numbers indicating which keys on the keyboard you pressed.

Clicking an axes makes that axes the current axes. Even if you set the current axes before calling `ginput`, whichever axes you click becomes the current axes and `ginput` returns points relative to that axes. If you select points from multiple axes, the results returned are relative to the coordinate system of the axes they come from.

Note: MATLAB returns errors such as the following if you start MATLAB with the `–noFigureWindows` or `–nodisplay` flag and then run `ginput`:

```
Error using ginput (line 31)
Terminal mode is no longer supported
```

Definitions

Coordinates returned by `ginput` are scaled to the `XLim` and `YLim` bounds of the axes you click (data units). Setting the axes or figure `Units` property has no effect on the output from `ginput`. You can click anywhere within the figure canvas to obtain coordinates. If you click outside the axes limits, `ginput` extrapolates coordinate values so they are still relative to the axes origin.

The figure `CurrentPoint` property, by contrast, is always returned in figure Units, irrespective of axes Units or limits.

Examples

Pick 4 two-dimensional points from the figure window.

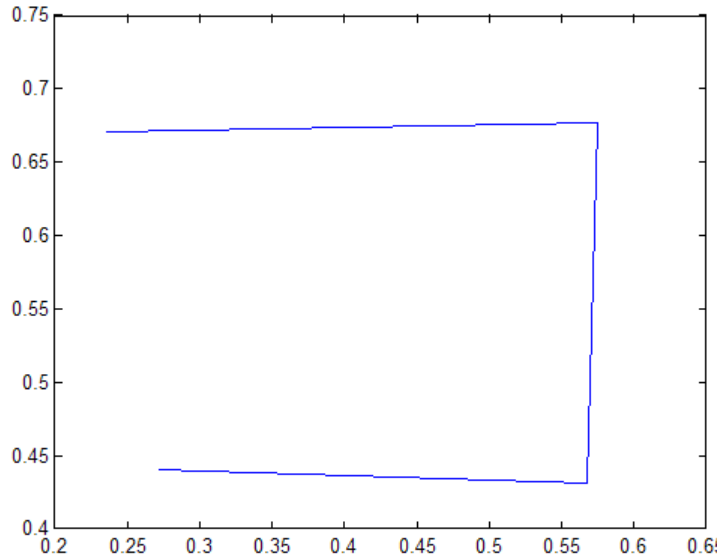
```
[x,y] = ginput(4)
```

Position the cursor with the mouse. Enter data points by pressing a mouse button or a key on the keyboard. To terminate input before entering 4 points, press the **Return** key.

```
x =
    0.2362
    0.5749
    0.5680
    0.2707

y =
    0.6711
    0.6769
    0.4313
    0.4401

plot(x,y)
```



In this example, `plot` rescaled the axes *x*-limits and *y*-limits from `[0 1]` and `[0 1]` to `[0.20 0.65]` and `[0.40 0.75]`. The rescaling occurred because the axes `XLimMode` and `YLimMode` are set to `'auto'` (the default). Consider setting `XLimMode` and `YLimMode` to `'manual'` if you want to maintain consistency when you gather results from `ginput` and plot them together.

Introduced before R2006a

global

Declare variables as global

Syntax

```
global var1 ... varN
```

Description

`global var1 ... varN` declares variables `var1 ... varN` as global in scope.

Ordinarily, each MATLAB function has its own local variables, which are separate from those of other functions and from those of the base workspace. However, if several functions all declare a particular variable name as `global`, then they all share a single copy of that variable. Any change of value to that variable, in any function, is visible to all the functions that declare it as global.

If the global variable does not exist the first time you issue the `global` statement, it is initialized to an empty `0x0` matrix.

If a variable with the same name as the global variable already exists in the current workspace, MATLAB issues a warning and changes the value of that variable and its scope to match the global variable.

Examples

Share Global Variable Between Functions

Create a function in your current working folder that sets the value of a global variable.

```
function setGlobalx(val)
global x
x = val;
```

Create a function in your current working folder that returns the value of a global variable. These two functions have separate function workspaces, but they both can access the global variable.

```
function r = getGlobalx
global x
r = x;
```

Set the value of the global variable, `x`, and obtain it from a different workspace.

```
setGlobalx(1138)
r = getGlobalx
```

```
r =

        1138
```

Share Global Variable Between Function and Command Line

Assign a value to the global variable using the function that you defined in the previous example.

```
clear all
setGlobalx(42)
```

Display the value of the global variable, `x`. Even though the variable is global, it is not accessible at the command line.

```
x
```

```
Undefined function or variable 'x'.
```

Declare `x` as a global variable at the command line, and display its value.

```
global x
x
```

```
x =

    42
```

Change the value of `x` and use the function that you defined in the previous example to return the global value from a different workspace.

```
x = 1701;
r = getGlobalx
```

```
r =
```

1701

More About

Tips

- To clear a global variable from all workspaces, use `clear global` *`variable`*.
- To clear a global variable from the current workspace but not other workspaces, use `clear` *`variable`*.
- "Share Data Between Workspaces"

Introduced before R2006a

gmres

Generalized minimum residual method (with restarts)

Syntax

```
x = gmres(A,b)
gmres(A,b,restart)
gmres(A,b,restart,tol)
gmres(A,b,restart,tol,maxit)
gmres(A,b,restart,tol,maxit,M)
gmres(A,b,restart,tol,maxit,M1,M2)
gmres(A,b,restart,tol,maxit,M1,M2,x0)
[x,flag] = gmres(A,b,...)
[x,flag,relres] = gmres(A,b,...)
[x,flag,relres,iter] = gmres(A,b,...)
[x,flag,relres,iter,resvec] = gmres(A,b,...)
```

Description

`x = gmres(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle, `afun`, such that `afun(x)` returns `A*x`. For this syntax, `gmres` does not restart; the maximum number of iterations is `min(n,10)`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `gmres` converges, a message to that effect is displayed. If `gmres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`gmres(A,b,restart)` restarts the method every `restart` inner iterations. The maximum number of outer iterations is `min(n/restart,10)`. The maximum number

of total iterations is `restart*min(n/restart,10)`. If `restart` is `n` or `[]`, then `gmres` does not restart and the maximum number of total iterations is `min(n,10)`.

`gmres(A,b,restart,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `gmres` uses the default, `1e-6`.

`gmres(A,b,restart,tol,maxit)` specifies the maximum number of outer iterations, i.e., the total number of iterations does not exceed `restart*maxit`. If `maxit` is `[]` then `gmres` uses the default, `min(n/restart,10)`. If `restart` is `n` or `[]`, then the maximum number of total iterations is `maxit` (instead of `restart*maxit`).

`gmres(A,b,restart,tol,maxit,M)` and `gmres(A,b,restart,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `gmres` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`gmres(A,b,restart,tol,maxit,M1,M2,x0)` specifies the first initial guess. If `x0` is `[]`, then `gmres` uses the default, an all-zero vector.

`[x,flag] = gmres(A,b,...)` also returns a convergence flag:

`flag = 0`	`gmres` converged to the desired tolerance `tol` within `maxit` outer iterations.
`flag = 1`	`gmres` iterated `maxit` times but did not converge.
`flag = 2`	Preconditioner `M` was ill-conditioned.
`flag = 3`	`gmres` stagnated. (Two consecutive iterates were the same.)

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = gmres(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`. The third output, `relres`, is the relative residual of the preconditioned system.

`[x,flag,relres,iter] = gmres(A,b,...)` also returns both the outer and inner iteration numbers at which `x` was computed, where `0 <= iter(1) <= maxit` and `0 <= iter(2) <= restart`.

`[x,flag,relres,iter,resvec] = gmres(A,b,...)` also returns a vector of the residual norms at each inner iteration. These are the residual norms for the preconditioned system.

Examples

Using gmres with a Matrix Input

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = gmres(A,b,10,tol,maxit,M1);
```

displays the following message:

```
gmres(10) converged at outer iteration 2 (inner iteration 9) to
a solution with relative residual 3.3e-013
```

Using gmres with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in a function `run_gmres` that

- Calls `gmres` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_gmres` are available to `afun` and `mfun`.

The following shows the code for `run_gmres`:

```
function x1 = run_gmres
n = 21;
b = afun(ones(n,1));
tol = 1e-12;  maxit = 15;
x1 = gmres(@afun,b,10,tol,maxit,@mfun);
```

```
    function y = afun(x)
        y = [0; x(1:n-1)] + ...
              [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
              [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_gmres;
```

MATLAB software displays the message

```
gmres(10) converged at outer iteration 2 (inner iteration 10)
to a solution with relative residual 1.1e-013.
```

Using a Preconditioner without Restart

This example demonstrates the use of a preconditioner without restarting `gmres`.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

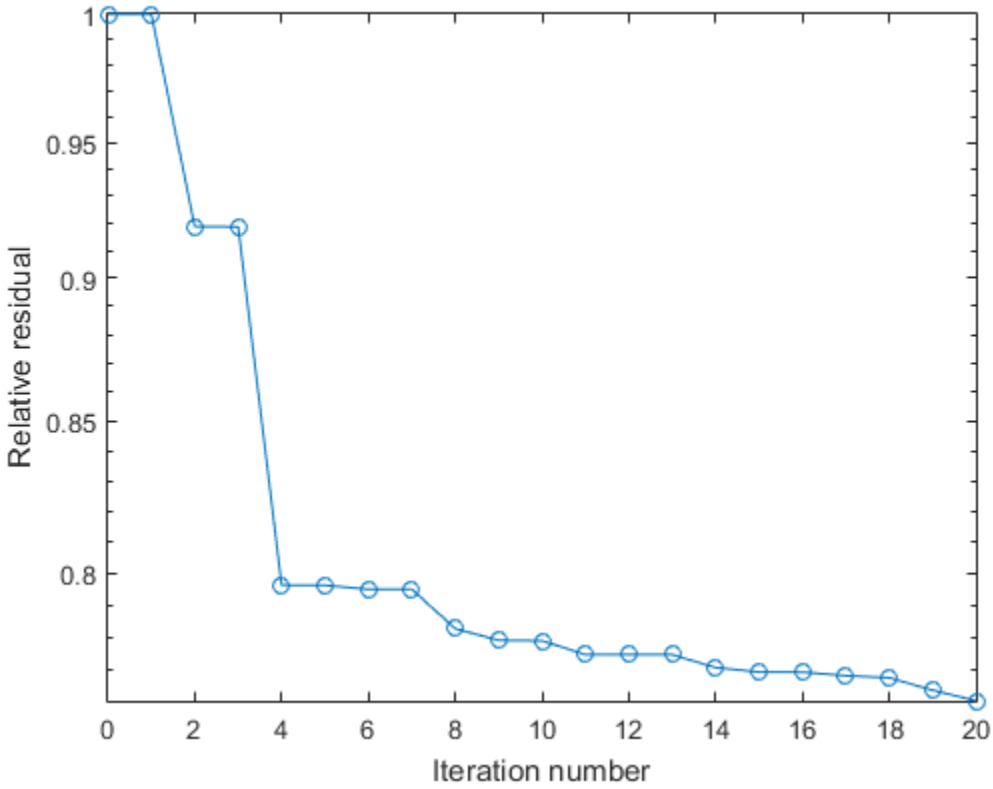
Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
[x0,fl0,rr0,it0,rv0] = gmres(A,b,[],tol,maxit);
```

`fl0` is 1 because `gmres` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The best approximate solution that `gmres` returns is the last one (as indicated by `it0(2) = 20`). MATLAB stores the residual history in `rv0`.

Plot the behavior of `gmres`.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution converges slowly. A preconditioner may improve the outcome.

Use `ilu` to form the preconditioner, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

```
Error using ilu
```

```
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

Note MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

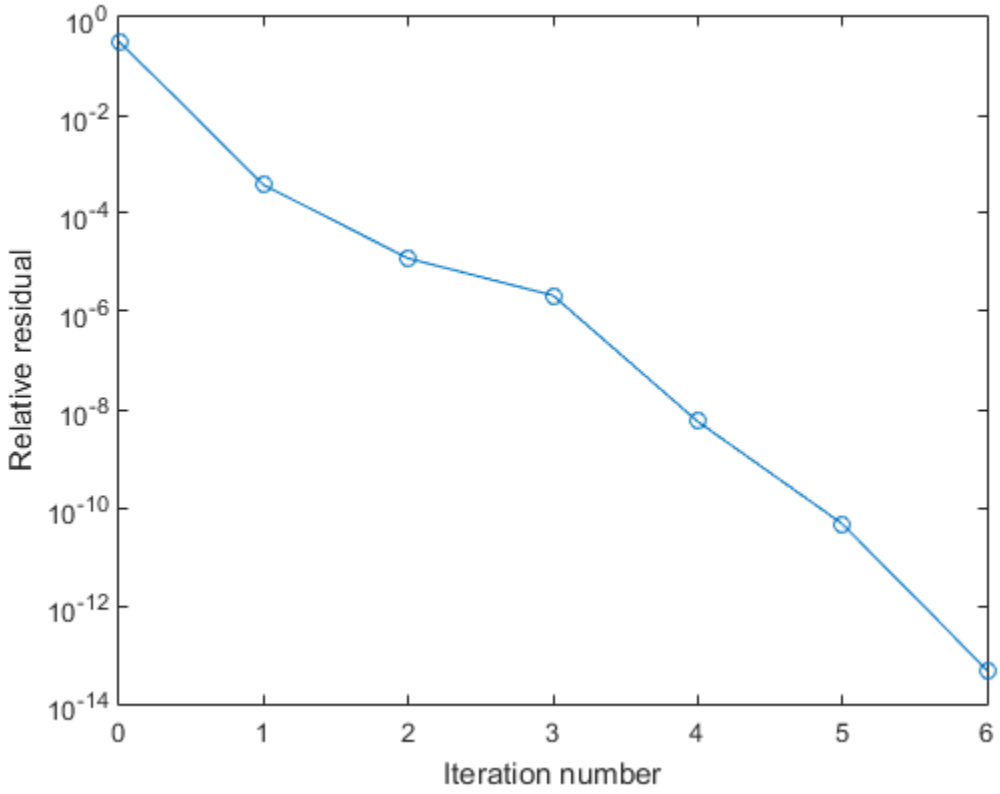
As indicated by the error message, try again with a reduced drop tolerance.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = gmres(A,b,[],tol,maxit,L,U);
```

`fl1` is 0 because `gmres` drives the relative residual to `9.5436e-14` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1(2)`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output, `rv1(1)`, is `norm(M\b)`, where `M = L*U`. The output, `rv1(7)`, is `norm(U\(L\(b-A*x1)))`.

Follow the progress of `gmres` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1(2),rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



Using a Preconditioner with Restart

This example demonstrates the use of a preconditioner with restarted `gmres`.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Construct an incomplete LU preconditioner as in the previous example.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
```

The benefit to using restarted `gmres` is to limit the amount of memory required to execute the method. Without restart, `gmres` requires `maxit` vectors of storage to keep the basis of the Krylov subspace. Also, `gmres` must orthogonalize against all of the previous vectors at each step. Restarting limits the amount of workspace used and the amount of work done per outer iteration. Note that even though preconditioned `gmres` converged in six iterations above, the algorithm allowed for as many as twenty basis vectors and therefore, allocated all of that space up front.

Execute `gmres(3)`, `gmres(4)`, and `gmres(5)`

```
tol = 1e-12;
maxit = 20;
re3 = 3;
[x3,fl3,rr3,it3,rv3] = gmres(A,b,re3,tol,maxit,L,U);
re4 = 4;
[x4,fl4,rr4,it4,rv4] = gmres(A,b,re4,tol,maxit,L,U);
re5 = 5;
[x5,fl5,rr5,it5,rv5] = gmres(A,b,re5,tol,maxit,L,U);
```

`fl3`, `fl4`, and `fl5` are all 0 because in each case restarted `gmres` drives the relative residual to less than the prescribed tolerance of `1e-12`.

The following plots show the convergence histories of each restarted `gmres` method. `gmres(3)` converges at outer iteration 5, inner iteration 3 (`it3 = [5, 3]`) which would be the same as outer iteration 6, inner iteration 0, hence the marking of 6 on the final tick mark.

```
figure

gobjects

Initialize array for graphics objects

Syntax

```
H = gobjects(n)
H = gobjects(s1,...,sn)
H = gobjects(v)

H = gobjects
H = gobjects(0)
```

Description

`H = gobjects(n)` returns an n-by-n graphics object array. Use the `gobjects` function instead of the `ones` or `zeros` functions to preallocate an array to store graphics objects.

`H = gobjects(s1,...,sn)` returns an `s1`-by-...-by-`sn` graphics object array, where the list of integers s1,...,sn defines the dimensions of the array. For example, `gobjects(2,3)` returns a 2-by-3 array.

`H = gobjects(v)` returns a graphics object array where the elements of the row vector, `v`, define the dimensions of the array. For example, `gobjects([2,3,4])` returns a 2-by-3-by-4 array.

`H = gobjects` returns a 1-by-1 graphics object array.

`H = gobjects(0)` returns an empty graphics object array.

Examples

Specify Array Dimensions

Preallocate a 4-by-1 array to store graphics handles.

```
H = gobjects(4,1)
```

```
H =

  4x1 GraphicsPlaceholder array:

  GraphicsPlaceholder
  GraphicsPlaceholder
  GraphicsPlaceholder
  GraphicsPlaceholder
```

Specify Array Dimensions with Size of Existing Array

Create an array to store graphics handles using the size of an existing array.

Define A as a 3-by-4 array.

```
A = [1,2,3,2; 4,5,6,6; 7,8,9,7];
```

Create an array of graphics handles using the size of A.

```
v = size(A);
H = gobjects(v);
```

The dimensions of the graphics handle array are the same as the dimensions of A.

```
isequal(size(H),size(A))
```

```
ans =

     1
```

Return Empty Handle Array

Use the `gobjects` function to return an empty array.

```
H = gobjects(0)
```

```
H =

  0x0 empty GraphicsPlaceholder array.
```

Input Arguments

n — defines n-by-n array

integer value

Size of the object array, specified as an integer value. Negative integers are treated as 0. The array has dimensions n-by-n.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

s1,...,sn — Size of each array dimension

two or more integer values

Size of each array dimension, specified as a list of two or more integer values. Negative integers are treated as 0.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

v — Size of each array dimension

row vector of integer values

Size of each array dimension, specified as a row vector of integer values. Negative integers are treated as 0.

Example: [2,4,6,7]

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

0 — Define an empty array

one or more dimensions equal to 0

Define an empty array by specifying one or more dimension equal to 0

Output Arguments

H — Initialized graphics object array

graphics object array of specified size

Initialized graphics object array of type `GraphicsPlaceholder`. Use this array to contain any type of graphics object.

More About

- "Graphics Arrays"

gplot

Plot nodes and links representing adjacency matrix

Syntax

```
gplot(A,Coordinates)
gplot(A,Coordinates,LineSpec)
```

Description

The `gplot` function graphs a set of coordinates using an adjacency matrix.

`gplot(A,Coordinates)` plots a graph of the nodes defined in `Coordinates` according to the n-by-n adjacency matrix `A`, where n is the number of nodes. `Coordinates` is an n-by-2 matrix, where n is the number of nodes and each coordinate pair represents one node.

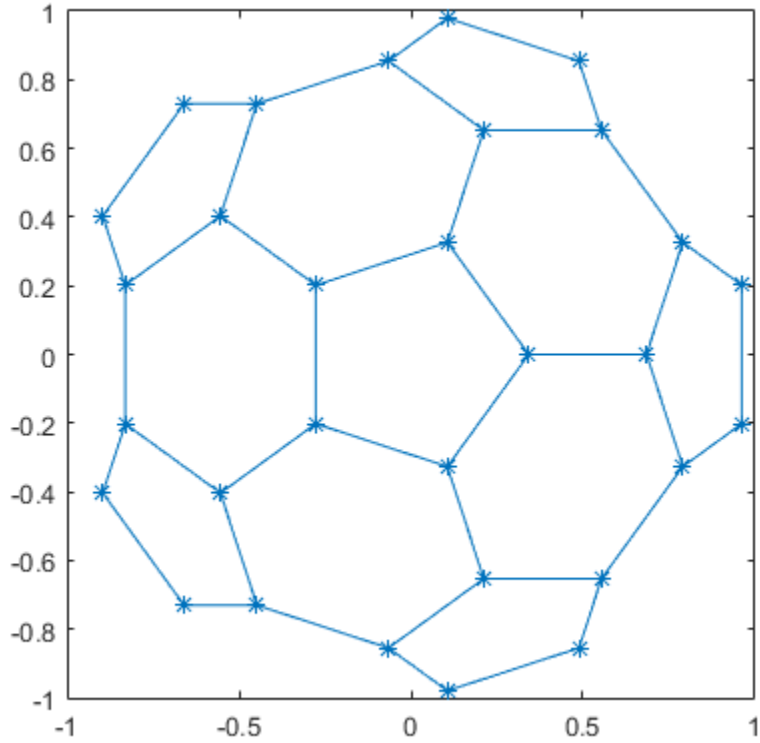
`gplot(A,Coordinates,LineSpec)` plots the nodes using the line type, marker symbol, and color specified by *`LineSpec`*.

Examples

Plot Graph of Nodes Using Asterisks

Plot half of a "Bucky ball" carbon molecule, placing asterisks at each node.

```
k = 1:30;
[B,XY] = bucky;
gplot(B(k,k),XY(k,:),'-*')
axis square
```



More About

Tips

For two-dimensional data, `Coordinates(i,:) = [x(i) y(i)]` denotes node `i`, and `Coordinates(j,:) = [x(j)y(j)]` denotes node `j`. If node `i` and node `j` are connected, `A(i,j)` or `A(j,i)` is nonzero; otherwise, `A(i,j)` and `A(j,i)` are zero.

`LineSpec` | `sparse` | `spy`

Introduced before R2006a

grabcode

Extract MATLAB code from file published to HTML

Syntax

```
grabcode('name.html')
grabcode('urlname')
codeString = grabcode('name.html')
```

Description

`grabcode('name.html')` copies MATLAB code from the file `name.html` and pastes it into an untitled document in the Editor. Use `grabcode` to get MATLAB code from published files when the source code is not readily available. The file `name.html` was created by publishing `name.m`, a MATLAB code file containing cells. The MATLAB code from `name.m` is included at the end of `name.html` as HTML comments.

`grabcode('urlname')` copies MATLAB code from the `urlname` location and pastes it into an untitled document in the Editor.

`codeString = grabcode('name.html')` gets MATLAB code from the file `name.html` and assigns it the variable `codeString`.

Examples

This example illustrates how to use `grabcode` to get MATLAB code from an existing HTML file:

```
% Copy sine_wave_f.html and the images it includes
% from the MATLAB examples directory to your
% current folder:

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
 'examples','sine_wave_f.html'), 'my_sine_wave.html')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
```

```
 'examples','sine_wave_f_01.png'), 'sine_wave_f_01.png')

copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
 'examples','sine_wave_f_02.png'), 'sine_wave_f_02.png')

% If you want to view the file, double-click my_sine_wave.html
% in your current folder.

% Extract the MATLAB code from sine_wave_f.html:
code = grabcode('my_sine_wave.html')
```

MATLAB returns:

```
code =

%% Plot Sine Wave
% Calculate and plot a sine wave.

%% Calculate and Plot Sine Wave
% Calculate and plot |y = sin(x)|.

function sine_wave_f(x)

y = sin(x);
plot(x,y)

%% Modify Plot Properties

title('Sine Wave', 'FontWeight','bold')
xlabel('x')
ylabel('sin(x)')
set(gca, 'Color', 'w')
set(gcf, 'MenuBar', 'none')
```

`publish`

Introduced before R2006a

gradient

Numerical gradient

Syntax

```
FX = gradient(F)
[FX,FY] = gradient(F)
[FX,FY,FZ,...] = gradient(F)
[...] = gradient(F,h)
[...] = gradient(F,h1,h2,...)
```

Definitions

The *gradient* of a function of two variables, $F(x,y)$, is defined as

$$\nabla F = \frac{\partial F}{\partial x}\hat{i} + \frac{\partial F}{\partial y}\hat{j}$$

and can be thought of as a collection of vectors pointing in the direction of increasing values of F. In MATLAB software, numerical gradients (differences) can be computed for functions with any number of variables. For a function of N variables, $F(x,y,z, ...)$,

$$\nabla F = \frac{\partial F}{\partial x}\hat{i} + \frac{\partial F}{\partial y}\hat{j} + \frac{\partial F}{\partial z}\hat{k} + \ldots$$

Description

`FX = gradient(F)`, where `F` is a vector, returns the one-dimensional numerical gradient of `F`. Here `FX` corresponds to $\partial F/\partial x$, the differences in x (horizontal) direction.

`[FX,FY] = gradient(F)`, where `F` is a matrix, returns the x and y components of the two-dimensional numerical gradient. `FX` corresponds to $\partial F/\partial x$, the differences in x (horizontal) direction. `FY` corresponds to $\partial F/\partial y$, the differences in the y (vertical) direction. The spacing between points in each direction is assumed to be one.

`[FX,FY,FZ,...] = gradient(F)`, where `F` has `N` dimensions, returns the `N` components of the gradient of `F`. There are two ways to control the spacing between values in `F`:

- A single spacing value, `h`, specifies the spacing between points in every direction.
- `N` spacing values (`h1,h2,...`) specifies the spacing for each dimension of `F`. Scalar spacing parameters specify a constant spacing for each dimension. Vector parameters specify the coordinates of the values along corresponding dimensions of `F`. In this case, the length of the vector must match the size of the corresponding dimension.

Note The first output `FX` is always the gradient along the 2nd dimension of `F`, going across columns. The second output `FY` is always the gradient along the 1st dimension of `F`, going across rows. For the third output `FZ` and the outputs that follow, the Nth output is the gradient along the Nth dimension of `F`.

`[...] = gradient(F,h)`, where `h` is a scalar, uses `h` as the spacing between points in each direction.

`[...] = gradient(F,h1,h2,...)` with `N` spacing parameters specifies the spacing for each dimension of `F`.

Examples

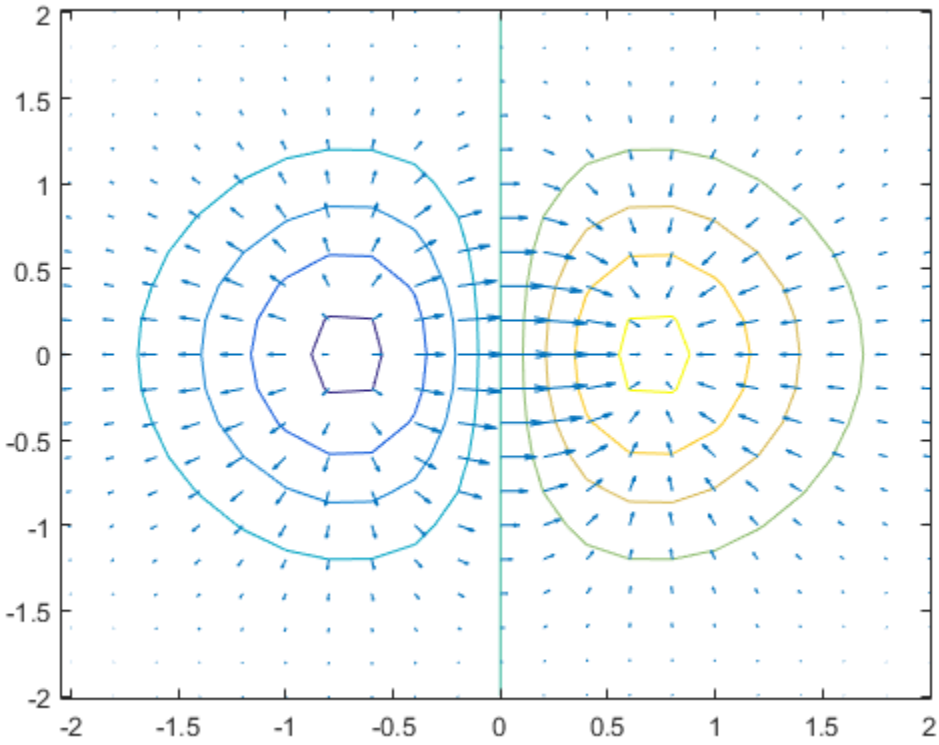
Contour Plot of Vector Field

Calculate the 2-D gradient of $xe^{-x^2-y^2}$ on a grid.

```
v = -2:0.2:2;
[x,y] = meshgrid(v);
z = x .* exp(-x.^2 - y.^2);
[px,py] = gradient(z,.2,.2);
```

Plot the contour lines and vectors in the same figure.

```
contour(v,v,z)
hold on
quiver(v,v,px,py)
hold off
```



Specify Dimensional Spacing of Points

Create a 3-D array.

```
F(:,:,1) = magic(3);
F(:,:,2) = pascal(3);
```

The command,

```
gradient(F)
```

takes `dx = dy = dz = 1`. However, the command,

```
[PX,PY,PZ] = gradient(F,0.2,0.1,0.2)
```

takes `dx = 0.2`, `dy = 0.1`, and `dz = 0.2`.

More About

Algorithms

`gradient` calculates the *central difference* for interior data points. For example, consider a matrix with unit-spaced data, `A`, that has horizontal gradient `G = gradient(A)`. The interior gradient values, `G(:,j)`, are:

```
G(:,j) = 0.5*(A(:,j+1) - A(:,j-1));
```

where `j` varies between `2` and `N-1`, where `N` is `size(A,2)`.

The gradient values along the edges of the matrix are calculated with *single-sided differences*, so that

```
G(:,1) = A(:,2) - A(:,1);
G(:,N) = A(:,N) - A(:,N-1);
```

If the point spacing is specified, then the differences are scaled appropriately. If two or more outputs are specified, `gradient` also calculates differences along other dimensions in a similar manner. Unlike the `diff` function, `gradient` returns an array with the same number of elements as the input.

Introduced before R2006a

matlab.graphics.Graphics class

Package: matlab.graphics

Common base class for graphics objects

Description

The `matlab.graphics.Graphics` class is the base class of all graphics objects. Because graphics objects are part of a heterogeneous hierarchy, you can create arrays of mixed classes (for example, an array can contain lines, surfaces, axes, and other graphics objects).

The class of an array of mixed objects is `matlab.graphics.Graphics` because this class is common to all graphics object.

Attributes

`Abstract`	`true`
`HandleCompatible`	`true`

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

matlab.graphics.GraphicsPlaceholder class

Package: matlab.graphics
Superclasses: matlab.graphics.Graphics

Default graphics object

Description

The `matlab.graphics.GraphicsPlaceholder` class defines the default graphics object. Instances of this class appear as:

- Elements of pre-allocated arrays created with `gobjects`.
- Unassigned array element placeholders
- Graphics object properties that hold object handles, but are set to empty values
- Empty values returned by functions that return object handles (for example, `findobj`).

Attributes

`Sealed`	`true`
`ConstructOnLoad`	`true`
`HandleCompatible`	`true`

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Test for Current Figure

```
if isempty(get(groot,'CurrentFigure')
   ... % There is no current figure
end
```

- Property Attributes

graymon

Set default figure properties for grayscale monitors

Syntax

```
graymon
```

Description

`graymon` sets defaults for graphics properties to produce more legible displays for grayscale monitors.

See Also

`axes` | `figure`

Introduced before R2006a

grid

Display or hide axes grid lines

Syntax

```
grid on
grid off
grid

grid minor

grid(ax, ___ )
```

Description

`grid on` displays the major grid lines for the current axes. Major grid lines extend from each tick mark.

`grid off` removes all grid lines from the current axes.

`grid` toggles the visibility of the major grid lines.

`grid minor` toggles the visibility of the minor grid lines. Minor grid lines lie between the tick marks.

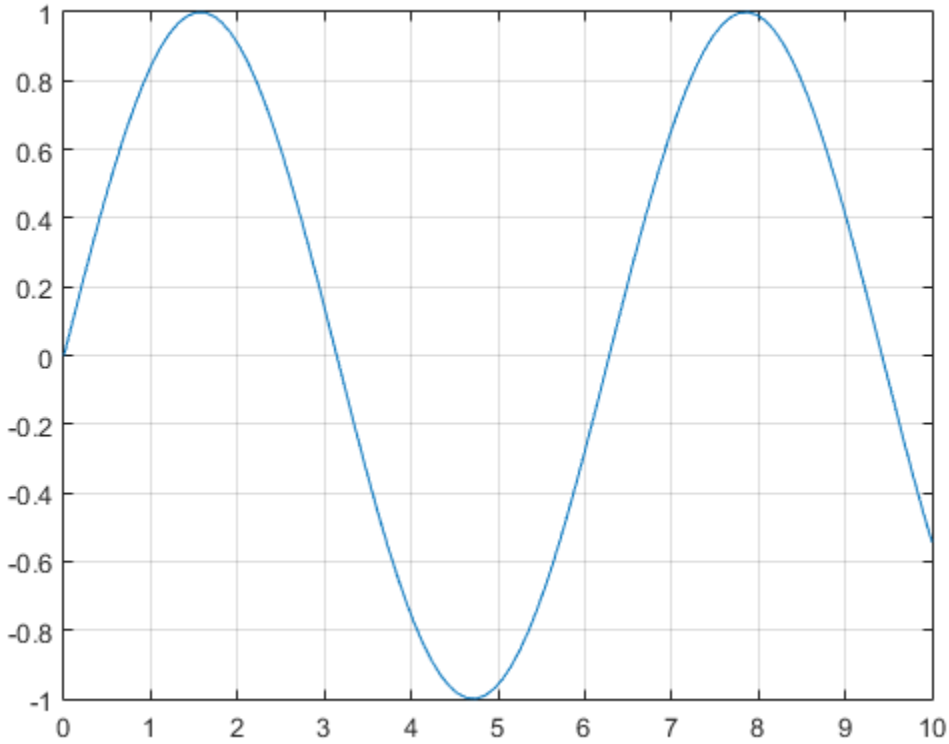
`grid(ax, ___ )` uses the axes defined by `ax` instead of the current axes (`gca`). Specify `ax` as a scalar axes object. You can specify an axes with any of the input arguments in the previous syntaxes. Use single quotes around input arguments that are character strings, for example, `grid(ax,'on')`, `grid(ax,'off')`, and `grid(ax,'minor')`.

Examples

Display Grid Lines

Display the grid lines for a sine plot.

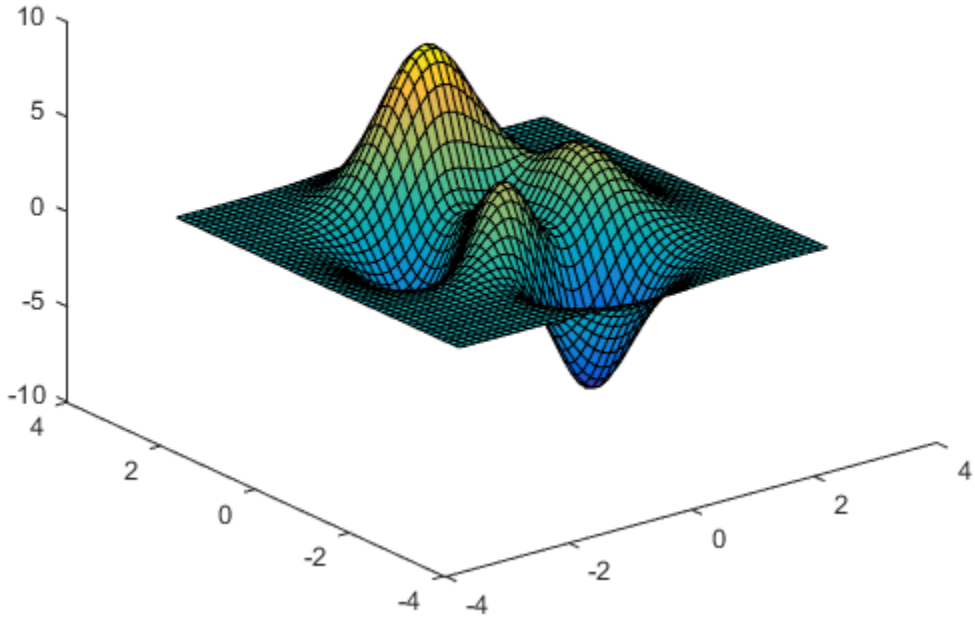
```
x = linspace(0,10);
y = sin(x);
plot(x,y)
grid on
```



Remove Grid Lines

Create a surface plot and remove the grid lines.

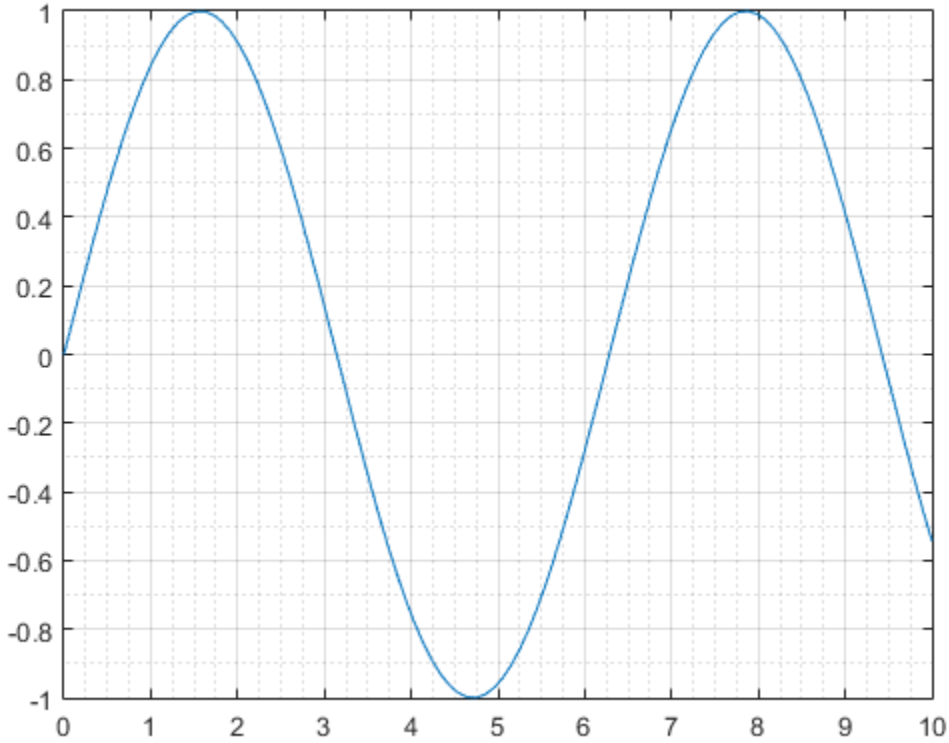
```
[X,Y,Z] = peaks;
surf(X,Y,Z)
grid off
```



Display Major and Minor Grid Lines

Display the major and minor grid lines for a sine plot.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
grid on
grid minor
```



By default, major grid lines use a solid line style and align with the tick marks. Minor grid lines use a dotted line style and lie between the tick marks.

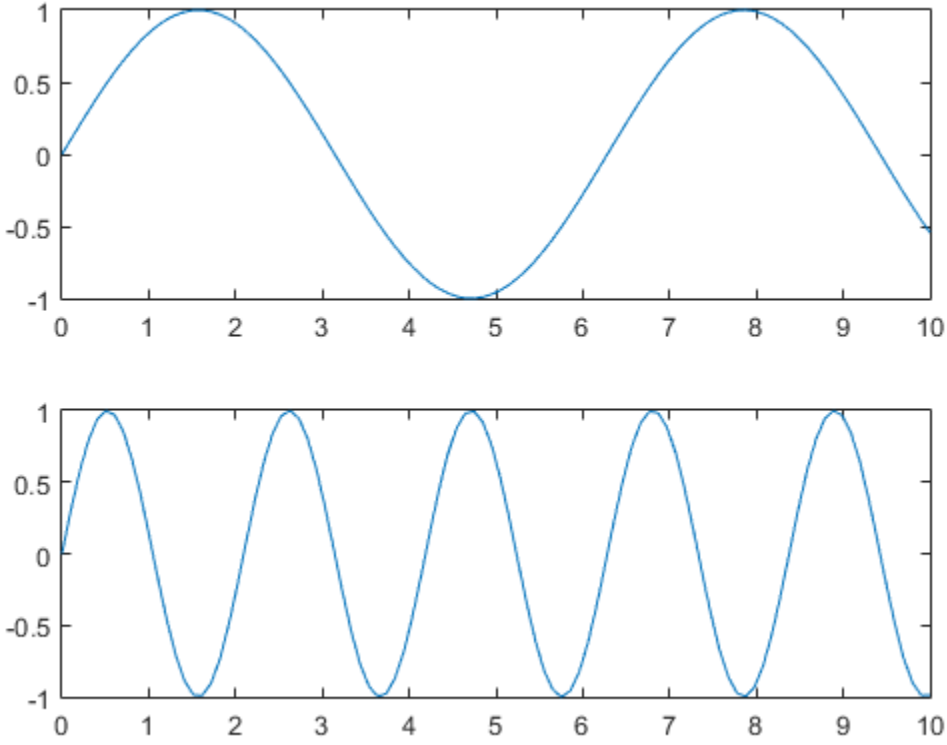
Display Grid Lines on Specific Axes

Create a figure with two subplots and plot a sine wave in each one.

```
x = linspace(0,10);
y = sin(x);
ax1 = subplot(2,1,1);
plot(x,y)

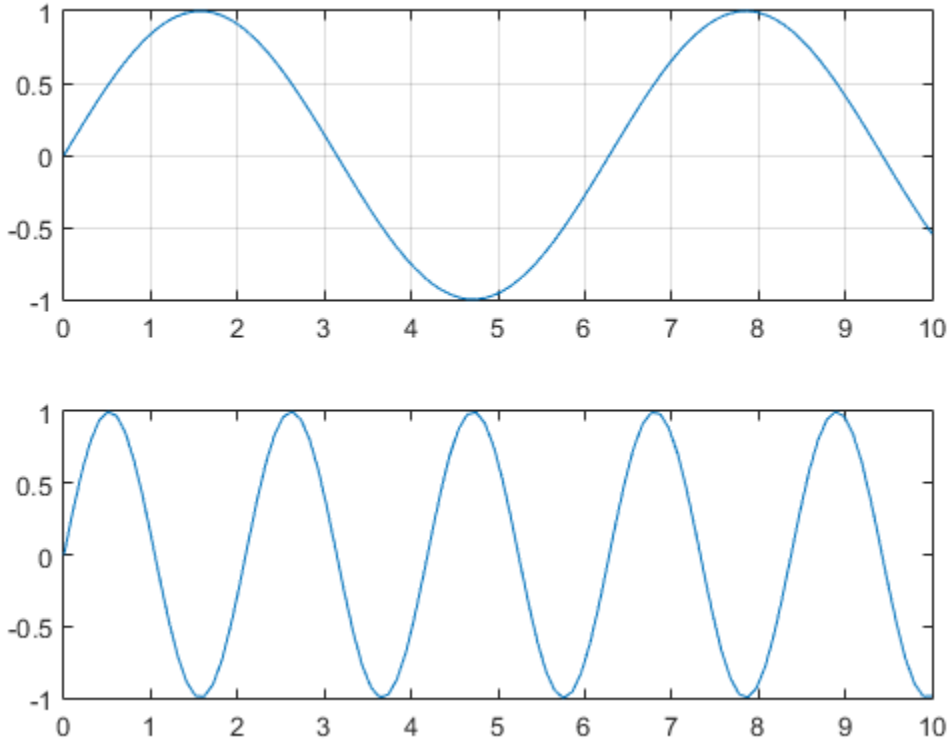
y2 = sin(3*x);
ax2 = subplot(2,1,2);
```

```
plot(x,y2)
```



Display the grid lines on the upper subplot.

```
grid(ax1,'on')
```



More About

Tips

- Some axes properties affect the appearance of the grid lines. By changing property values, you can modify the appearance. This table lists a subset of axes properties related to the grid.

Axes Property	Description
`XTick`, `YTick`, `ZTick`	Location of tick marks and major grid lines for each axis direction

Axes Property	Description
`XGrid`, `YGrid`, `ZGrid`	Display of major grid lines for each axis direction
`XMinorGrid`, `YMinorGrid`, `ZMinorGrid`	Display of minor grid lines for each axis direction
`LineWidth`	Line width of grid lines, axes box outline, and tick marks
`GridLineStyle`	Major grid line style
`MinorGridLineStyle`	Minor grid line style
`GridColor`	Major grid line color
`MinorGridColor`	Minor grid line style
`GridAlpha`	Major grid line transparency
`MinorGridAlpha`	Minor grid line transparency
`Layer`	Location of grid lines with respect to the plotted data

For a full list, see Axes Properties.

- To turn on or off grid lines for each axis direction separately, you must set the axes properties individually. The `grid` function controls all major and minor grid lines together, setting the corresponding axes properties to either `'on'` or `'off'`.

Introduced before R2006a

griddata

Interpolate scattered data

Note: Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `griddata`.

In a future release, the following syntaxes will be removed:

```
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq)
[Xq,Yq,Vq] = griddata(x,y,v,xq,yq, method)
```

In addition, `griddata` will not accept any input vectors of mixed orientation in a future release. To specify a grid of query points, construct a full grid with `ndgrid` or `meshgrid` before calling `griddata`.

Syntax

```
vq = griddata(x,y,v,xq,yq)
vq = griddata(x,y,z,v,xq,yq,zq)
vq = griddata( ___ ,method)
```

Description

`vq = griddata(x,y,v,xq,yq)` fits a surface of the form $v = f(x,y)$ to the scattered data in the vectors `(x,y,v)`. The `griddata` function interpolates the surface at the query points specified by `(xq,yq)` and returns the interpolated values, `vq`. The surface always passes through the data points defined by `x` and `y`.

`vq = griddata(x,y,z,v,xq,yq,zq)` fits a hypersurface of the form $v = f(x,y,z)$.

`vq = griddata( ___ ,method)` uses a specified interpolation method to compute vq using any of the input arguments in the previous syntaxes.

Input Arguments

x

Vector specifying the *x*- coordinates of the sample points.

y

Vector specifying the *y*- coordinates of the sample points.

z

Vector specifying the *z*- coordinates of the sample points.

v

Vector of sample values that correspond to the sample coordinates `x`, `y` (and `z` for 3-D interpolation).

xq

Vector or array that specifies *x*- coordinates of the query points to be evaluated. `xq` must be the same size as `yq` (and `zq` for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

yq

Vector or array that specifies *y*- coordinates of the query points to be evaluated. `yq` must be the same size as `xq` (and `zq` for 3-D interpolation).

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.
- Specify a vector if you want to pass a collection of scattered points.

zq

Vector or array that specifies *z*- coordinates of the query points to be evaluated. `zq` must be the same size as `xq` and `yq`.

- Specify an array if you want to pass a grid of query points. Use `ndgrid` or `meshgrid` to construct the array.

- Specify a vector if you want to pass a collection of scattered points.

`method`

Keyword that specifies the interpolation method. Use one of the following:

method string	Description	Continuity
`'nearest'`	Triangulation-based nearest neighbor interpolation supporting 2-D and 3-D interpolation.	Discontinuous
`'linear'`	Triangulation-based linear interpolation (default) supporting 2-D and 3-D interpolation	C^0
`'natural'`	Triangulation-based natural neighbor interpolation supporting 2-D and 3-D interpolation. This method is an efficient tradeoff between linear and cubic.	C^1 except at sample points
`'cubic'`	Triangulation-based cubic interpolation supporting 2-D interpolation only	C^2
`'v4'`	Biharmonic spline interpolation (MATLAB 4 `griddata` method) supporting 2-D interpolation only. Unlike the other methods, this interpolation is not based on a triangulation.	C^2

Output Arguments

`vq`

The interpolated values at the query points.

- For 2-D interpolation, where `xq` and `yq` specify an `m`-by-`n` grid of query points, `vq` is an `m`-by-`n` array.
- For 3-D interpolation, where `xq`, `yq`, and `zq` specify an `m`-by-`n`-by-`p` grid of query points, `vq` is an `m`-by-`n`-by-`p` array.
- If `xq`, `yq`, (and `zq` for 3-D interpolation) are vectors that specify scattered points, `vq` is a vector of the same length.

Examples

Interpolate Scattered Data Over a Uniform Grid

Sample a function at 200 random points between `-2.5` and `2.5`.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1);
y = xy(:,2);
v = x.*exp(-x.^2-y.^2);
```

`x`, `y`, and `v` are vectors containing scattered (nonuniform) sample points and data.

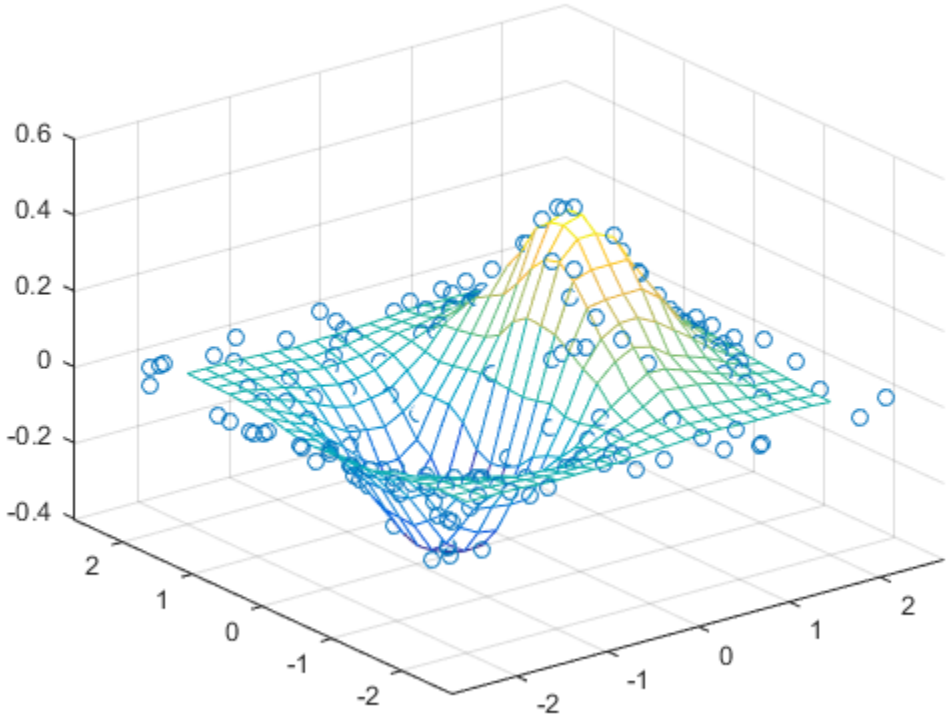
Define a regular grid and interpolate the scattered data over the grid.

```
[xq,yq] = meshgrid(-2:.2:2, -2:.2:2);
vq = griddata(x,y,v,xq,yq);
```

Plot the gridded data as a mesh and the scattered data as dots.

```
figure
mesh(xq,yq,vq);
hold on
plot3(x,y,v,'o');

h = gca;
h.XLim = [-2.7 2.7];
h.YLim = [-2.7 2.7];
```



Interpolate 3-D Data Set Over a Grid in the x-y Plane

Sample a function at 5000 random points between `-1` and `1`. Initialize the random number generator to make the output of `randn` repeatable.

```
rng default
x = 2*rand(5000,1) - 1;
y = 2*rand(5000,1) - 1;
z = 2*rand(5000,1) - 1;
v = x.^2 + y.^2 + z.^2;
```

`x`, `y`, and `z` are now vectors containing nonuniformly sampled data.

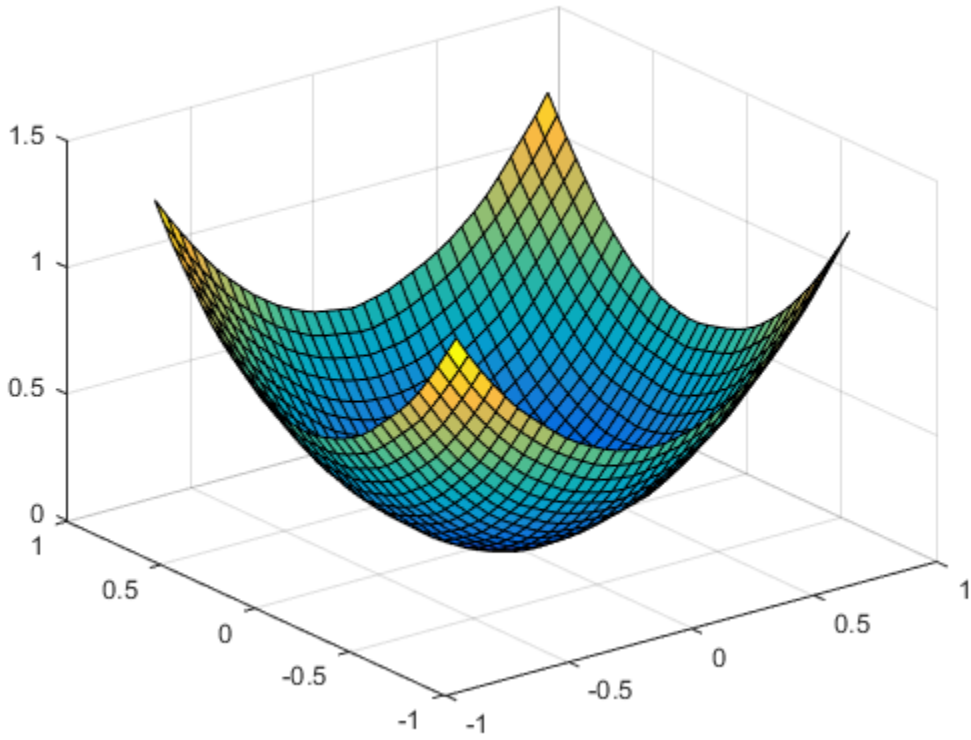
Define a regular grid with points in the range [-0.8, 0.8].

```
d = -0.8:0.05:0.8;
[xq,yq,zq] = meshgrid(d,d,0);
```

Interpolate the scattered data over a rectangular region at `z=0`. Then, plot the results.

```
vq = griddata(x,y,z,v,xq,yq,zq);
surf(xq,yq,vq);

h = gca;
h.XTick = [-1 -0.5 0 0.5 1];
h.YTick = [-1 -0.5 0 0.5 1];
```



See Also

`scatteredInterpolant` | `delaunay` | `griddatan` | `interpn` | `meshgrid` | `ndgrid`

Introduced before R2006a

griddatan

Data gridding and hypersurface fitting (dimension ≥ 2)

Syntax

```
yi = griddatan(x,y,xi)
yi = griddatan(x,y,xi,method)
yi = griddatan(x,y,xi,method,options)
```

Description

`yi = griddatan(x,y,xi)` fits a hyper-surface of the form $y = f(x)$ to the data in the (usually) nonuniformly-spaced vectors (`x`, `y`). `griddatan` interpolates this hyper-surface at the points specified by `xi` to produce `yi`. `xi` can be nonuniform.

`X` is of dimension `m`-by-`n`, representing `m` points in n-dimensional space. `y` is of dimension `m`-by-`1`, representing `m` values of the hyper-surface *f*(`X`). `xi` is a vector of size `p`-by-`n`, representing `p` points in the n-dimensional space whose surface value is to be fitted. `yi` is a vector of length `p` approximating the values *f*(`xi`). The hypersurface always goes through the data points (`X`,`y`). `xi` is usually a uniform grid (as produced by `meshgrid`).

`yi = griddatan(x,y,xi,method)` defines the type of surface fit to the data, where `'method'` is one of:

method string	Description	Continuity
`'linear'`	Triangulation-based linear interpolation (default).	C^0
`'nearest'`	Nearest neighbor interpolation.	Discontinuous

All the methods are based on a Delaunay triangulation of the data.

If `method` is `[]`, the default `'linear'` method is used.

`yi = griddatan(x,y,xi,method,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunayn`.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default.

Examples

Fit a Hypersurface

```
X = 2*gallery('uniformdata',[5000 3],0)-1;;
Y = sum(X.^2,2);
d = -0.8:0.05:0.8;
[y0,x0,z0] = ndgrid(d,d,d);
XI = [x0(:) y0(:) z0(:)];
YI = griddatan(X,Y,XI);
```

Since it is difficult to visualize 4-D data sets, use isosurface at 0.8:

```
YI = reshape(YI, size(x0));
figure
p = patch(isosurface(x0,y0,z0,YI,0.8));
isonormals(x0,y0,z0,YI,p)

p.FaceColor = 'blue';
p.EdgeColor = 'none';

view(3)
axis equal
camlight
lighting phong
```

`delaunayn` | `griddata` | `meshgrid`

Introduced before R2006a

griddedInterpolant class

Gridded data interpolation

Note: The behavior of `griddedInterpolant` has changed. All interpolation methods now support extrapolation by default. Set `F.ExtrapolationMethod` to `'none'` to preserve the pre-R2013a behavior when `F.Method` is `'linear'`, `'cubic'` or `'nearest'`. Before R2013a, evaluation returned `NaN` values at query points outside the domain when `F.Method` was set to `'linear'`, `'cubic'` or `'nearest'`.

Description

Use `griddedInterpolant` to perform interpolation on a 1-D, 2-D, 3-D, or N-D "Gridded Data" on page 1-3067 set. For example, you can pass a set of `(x,y)` points and values, `v`, to `griddedInterpolant`, and it returns a surface of the form $v = F(x, y)$. This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point, `(xq,yq)`, to produce an interpolated value, `vq`.

Use `griddedInterpolant` to create the "Interpolant" on page 1-3066, `F`. Then you can evaluate `F` at specific points using any of the following syntaxes:

- `Vq = F(Xq)` evaluates `F` at a set of query points in matrix `Xq`. The points in `Xq` are scattered, and each row of `Xq` contains the coordinates of a query point.
- `Vq = F(xq1,xq2,...,xqn)` specifies the query locations, `xq1,xq2,...,xqn`, as column vectors of length `m` representing `m` points scattered in `n`-dimensional space.
- `Vq = F(Xq1,Xq2,...,Xqn)` specifies the query locations as `n` `n`-dimensional arrays, `Xq1,Xq2,...,Xqn`, of equal size which define a "Full Grid" on page 1-3067 of points.
- `Vq = F({xgq1,xgq2,...,xgqn})` specifies the query locations as "Grid Vectors" on page 1-3067 . Use this syntax to conserve memory when you want to query a large grid of points.

Construction

`F = griddedInterpolant(x,v)` creates a 1-D interpolant from a vector of sample points, `x`, and corresponding values, `v`.

`F = griddedInterpolant(X1,X2,...,Xn,V)` creates a 2-D, 3-D, or N-D interpolant using a "Full Grid" on page 1-3067 of sample points passed as a set of `n`-dimensional arrays, `X1,X2,...,Xn`. The V array contains the sample values associated with the point locations in `X1,X2,...,Xn`. Each of the arrays, `X1,X2,...,Xn` must be the same size as `V`.

`F = griddedInterpolant(V)` uses the default grid to create the interpolant. When you use this syntax, `griddedInterpolant` defines the grid as set of points whose spacing is `1` and range is [`1`, `size(V,i)`] in the `i`th dimension. Use this syntax when you want to conserve memory and are not concerned about the absolute distances between points.

`F = griddedInterpolant({xg1,xg2,...,xgn},V)` specifies `n` "Grid Vectors" on page 1-3067 to describe an `n`-dimensional grid of sample points. Use this syntax when you want to use a specific grid and also conserve memory.

`F = griddedInterpolant(___,Method)` specifies a string that describes an interpolation method: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`, or `'spline'`. You can specify Method as the last input argument in any of the first four syntaxes.

`F = griddedInterpolant(___,Method,ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `griddedInterpolant` uses `ExtrapolationMethod` to estimate the value when your query points fall outside the domain of your sample points. Specify Method and ExtrapolationMethod together as the last two input arguments in any of the first four syntaxes.

Input Arguments

x

Sample points vector, specified as a vector of input coordinates the same size as `v`.

v

Sample values vector, specified as a vector of input values the same size as `x`.

`X1,X2,...,Xn`

Sample points in "Full Grid" on page 1-3067 form, specified as a set of `n`-dimensional arrays. You can create the arrays, `X1,X2,...,Xn`, using the `ndgrid` function. These arrays are all the same size, and each one is the same size as `V`.

`{xg1,xg2,...,xgn}`

Sample points in grid vector form, specified as a cell array of grid vectors. These vectors must specify a grid that is the same size as `V`. In other words, `size(V) = [length(xg1) length(xg2),...,length(xgn)]`. Use this form as an alternative to the full grid to save memory when your grid is very large.

`V`

Sample values, specified as an array. The elements of `V` are the values that correspond to the sample points. The size of `V` must be the size of the full grid of sample points.

- If you specify the sample points as a full grid consisting of N-D arrays, then `V` must be the same size as any one of: `X1,X2,...,Xn`.
- If you specify the sample points as grid vectors, then `size(V) = [length(xg1) length(xg2) ... length(xgn)]`.

`Method`

Interpolation method, specified as a string from the table below.

Method	Description	Continuity	Comments
`'linear'`(defa	The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension.	C^0	• Requires at least 2 grid points in each dimension. • Requires more memory than `'nearest'`.
`'nearest'`	Nearest neighbor interpolation. The interpolated value at a query point is the value at the nearest sample grid point.	Discontinuous	• Requires 2 grid points in each dimension. • Fastest computation with modest memory requirements
`'next'`	Next neighbor interpolation (for 1-D only). The interpolated	Discontinuous	• Requires at least 2 points.

Method	Description	Continuity	Comments
	value at a query point is the value at the next sample grid point.		• Same memory requirements and computation time as `'nearest'`.
`'previous'`	Previous neighbor interpolation (for 1-D only). The interpolated value at a query point is the value at the previous sample grid point.	Discontinuous	• Requires at least 2 points. • Same memory requirements and computation time as `'nearest'`.
`'pchip'`	Shape-preserving piecewise cubic interpolation (for 1-D only). The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points.	C^1	• Requires at least 4 points. • Requires more memory and computation time than `'linear'`.
`'cubic'`	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.	C^1	• Grid must have uniform spacing, though the spacing in each dimension does not have to be the same. • Requires at least 4 points in each dimension. • Requires more memory and computation time than `'linear'`.
`'spline'`	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline using not-a-knot end conditions.	C^2	• Requires 4 points in each dimension. • Requires more memory and computation time than `'cubic'`.

ExtrapolationMethod

Extrapolation method, specified as any of the `Method` choices: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`, or `'spline'`. In addition, you can specify `'none'` if you want queries outside the domain of your grid return `NaN` values.

If you omit `ExtrapolationMethod`, the default value is the string you specify for `Method`. If you omit both the `Method` and `ExtrapolationMethod` arguments, both default to `'linear'`.

Properties

GridVectors

Cell array containing grid vectors, `{xg1,xg2,...,xgn}`. These vectors specify the grid points (locations) for the values in `F.Values`.

Values

Array of values associated with the grid points in `F.GridVectors`.

Method

A string specifying the name of a method used to interpolate the data. `Method` is one of the strings: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`, or `'spline'`. The default value is `'linear'`.

ExtrapolationMethod

A string specifying the name of a method used to extrapolate the data. `ExtrapolationMethod` is one of the strings: `'linear'`, `'nearest'`, `'next'`, `'previous'`, `'pchip'`, `'cubic'`, `'spline'`, or `'none'`. A value of `'none'` indicates that extrapolation is disabled. The default value is the value of `F.Method`.

Definitions

Interpolant

Interpolating function that you can evaluate at query locations.

Gridded Data

A set of points that are axis-aligned and ordered.

Scattered Data

A set of points that have no structure among their relative locations.

Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices `X` and `Y`. You can represent the same grid using the grid vectors, `xg` and `yg`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Indexing

Index-based editing of the properties of F are not supported. Instead, wholly replace the `GridVectors` or `Values` arrays as necessary. See “Interpolation with the griddedInterpolant Class” in the MATLAB Mathematics documentation for more information.

Examples

2-D Interpolation Over Finer Grid

Interpolate coarsely sampled data using a full grid with spacing of `0.5`.

Define the sample points as a full grid with range [1, 10] in both dimensions.

```
[X,Y] = ndgrid(1:10,1:10);
```

Sample $f(x,y) = x^2 + y^2$ at the grid points.

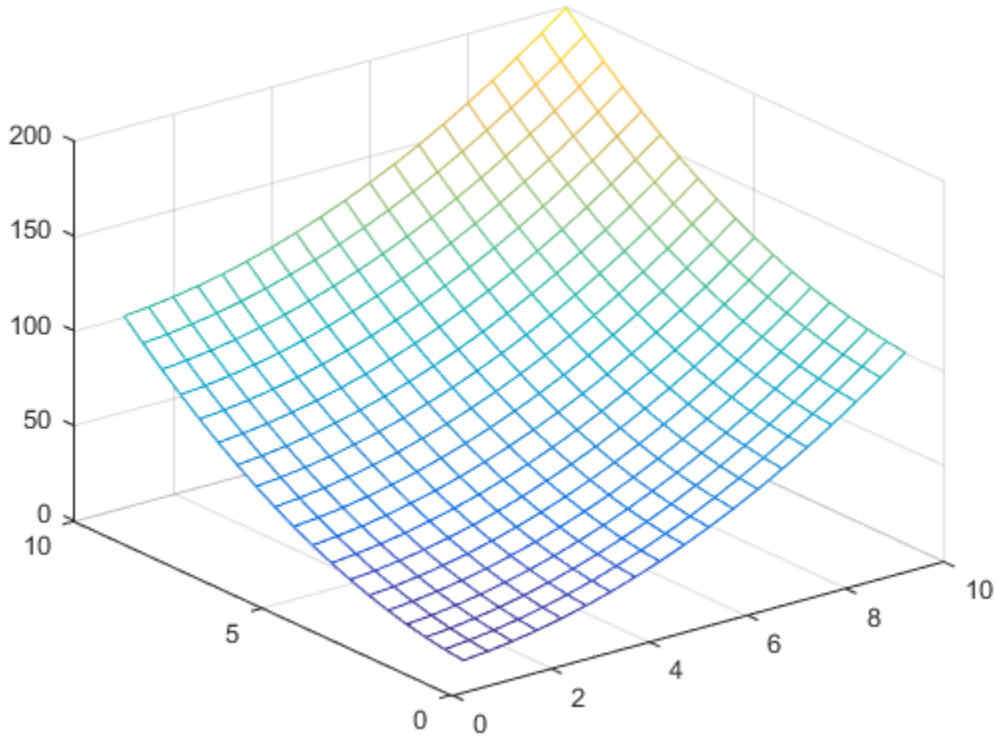
```
V = X.^2 + Y.^2;
```

Create the interpolant, specifying cubic interpolation.

```
F = griddedInterpolant(X,Y,V,'cubic');
```

Define a full grid of query points with `0.5` spacing and evaluate the interpolant at those points. Then plot the result.

```
[Xq,Yq] = ndgrid(1:0.5:10,1:0.5:10);
Vq = F(Xq,Yq);
mesh(Xq,Yq,Vq);
```



1-D Extrapolation

Compare results of querying the interpolant outside the domain of `F` using the `'pchip'` and `'nearest'` extrapolation methods.

Create the interpolant and specify `'pchip'` as the interpolation method.

```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
F = griddedInterpolant(x,v,'pchip')
```

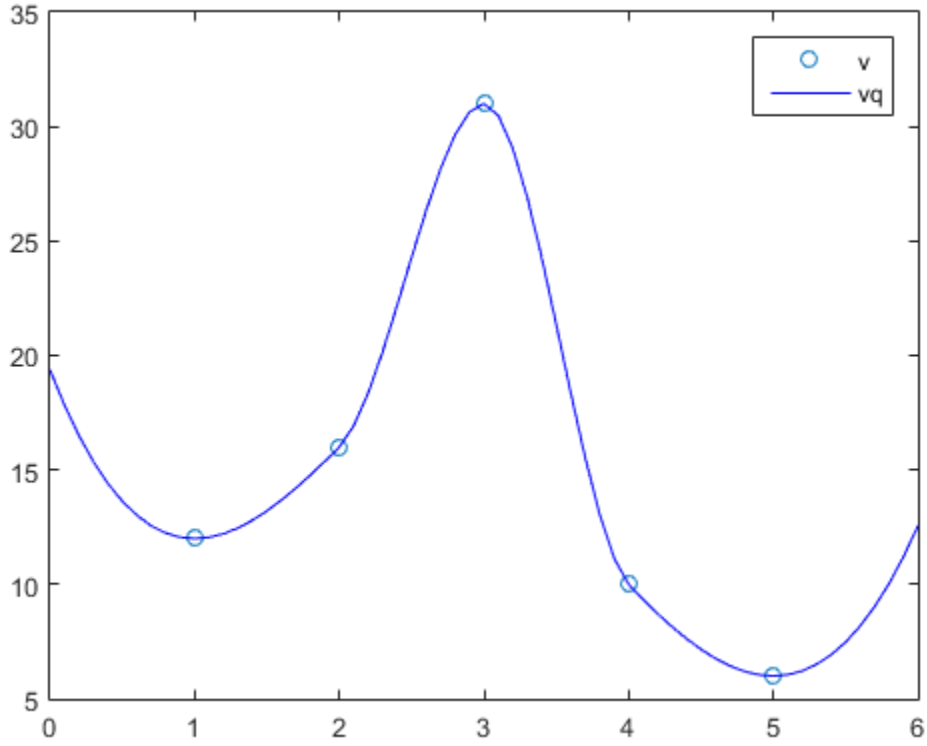
```
F =
```

```
  griddedInterpolant with properties:

            GridVectors: {[1 2 3 4 5]}
                 Values: [12 16 31 10 6]
                 Method: 'pchip'
   ExtrapolationMethod: 'pchip'
```

Query the interpolant, and include points outside the domain of `F`.

```
xq = 0:0.1:6;
vq = F(xq);
figure
plot(x,v,'o',xq,vq,'-b');
legend ('v','vq')
```



Query the interpolant at the same points again, using the nearest neighbor extrapolation method.

```
F.ExtrapolationMethod = 'nearest';
figure
vq = F(xq);
plot(x,v,'o',xq,vq,'-b');
legend ('v','vq')
```

- “Interpolating Gridded Data”

groot

Graphics root object

Syntax

```
groot
r = groot
```

Description

`groot` refers to the graphics root object. Use `groot` to access root properties. For a list of properties, see Root Properties.

`r = groot` stores the graphics root object handle. To set root properties using dot notation, you must store the handle first.

Examples

View Root Property Values

View a list of graphics root properties and their current values.

```
get(groot)
```

```
         CallbackObject: []
               Children: []
          CurrentFigure: []
     FixedWidthFontName: 'Courier New'
       HandleVisibility: 'on'
       MonitorPositions: [2x4 double]
                 Parent: []
        PointerLocation: [2957 348]
            ScreenDepth: 32
    ScreenPixelsPerInch: 96
             ScreenSize: [1 1 1920 1200]
      ShowHiddenHandles: 'off'
```

```
               Tag: ''
              Type: 'root'
             Units: 'pixels'
          UserData: []
```

Set Root Property Values

Set graphics root property values by storing the object handle and using dot notation.

```
r = groot;
r.ShowHiddenHandles = 'on';
```

More About

Tips

- Use the graphics root object to set default values on the root level for other types of objects. For example, set the default colormap for all future figures to the `summer` colormap.

  ```
  set(groot,'DefaultFigureColormap',summer)
  ```
  To restore a property to its original MATLAB default, use the `'remove'` keyword.

  ```
  set(groot,'DefaultFigureColormap','remove')
  ```
  For more information on setting default values, see “Default Property Values”.

Properties
Root Properties

gsvd

Generalized singular value decomposition

Syntax

```
[U,V,X,C,S] = gsvd(A,B)
sigma = gsvd(A,B)
```

Description

`[U,V,X,C,S] = gsvd(A,B)` returns unitary matrices `U` and `V`, a (usually) square matrix `X`, and nonnegative diagonal matrices `C` and `S` so that

```
A = U*C*X'
B = V*S*X'
C'*C + S'*S = I
```

`A` and `B` must have the same number of columns, but may have different numbers of rows. If `A` is `m`-by-`p` and `B` is `n`-by-`p`, then `U` is `m`-by-`m`, `V` is `n`-by-`n` and `X` is `p`-by-`q` where `q = min(m+n,p)`.

`sigma = gsvd(A,B)` returns the vector of generalized singular values, `sqrt(diag(C'*C)./diag(S'*S))`.

The nonzero elements of `S` are always on its main diagonal. If `m >= p` the nonzero elements of `C` are also on its main diagonal. But if `m < p`, the nonzero diagonal of `C` is `diag(C,p-m)`. This allows the diagonal elements to be ordered so that the generalized singular values are nondecreasing.

`gsvd(A,B,0)`, with three input arguments and either `m` or `n >= p`, produces the "economy-sized"decomposition where the resulting `U` and `V` have at most `p` columns, and `C` and `S` have at most `p` rows. The generalized singular values are `diag(C)./diag(S)`.

When `B` is square and nonsingular, the generalized singular values, `gsvd(A,B)`, are equal to the ordinary singular values, `svd(A/B)`, but they are sorted in the opposite order. Their reciprocals are `gsvd(B,A)`.

In this formulation of the gsvd, no assumptions are made about the individual ranks of A or B. The matrix X has full rank if and only if the matrix [A;B] has full rank. In fact, svd(X) and cond(X) are equal to svd([A;B]) and cond([A;B]). Other formulations, eg. G. Golub and C. Van Loan [1], require that null(A) and null(B) do not overlap and replace X by inv(X) or inv(X').

Note, however, that when null(A) and null(B) do overlap, the nonzero elements of C and S are not uniquely determined.

Examples

Example 1

The matrices have at least as many rows as columns.

```
A = reshape(1:15,5,3)
B = magic(3)
A =
         1     6    11
         2     7    12
         3     8    13
         4     9    14
         5    10    15
B =
         8     1     6
         3     5     7
         4     9     2
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 5-by-5 orthogonal U, a 3-by-3 orthogonal V, a 3-by-3 nonsingular X,

```
X =
        2.8284   -9.3761   -6.9346
       -5.6569   -8.3071  -18.3301
        2.8284   -7.2381  -29.7256
```

and

```
C =
        0.0000         0         0
```

```
             0    0.3155         0
             0         0    0.9807
             0         0         0
             0         0         0
S =
        1.0000         0         0
             0    0.9489         0
             0         0    0.1957
```

Since A is rank deficient, the first diagonal element of C is zero.

The economy sized decomposition,

```
[U,V,X,C,S] = gsvd(A,B,0)
```

produces a 5-by-3 matrix U and a 3-by-3 matrix C.

```
U =
        0.5700   -0.6457   -0.4279
       -0.7455   -0.3296   -0.4375
       -0.1702   -0.0135   -0.4470
        0.2966    0.3026   -0.4566
        0.0490    0.6187   -0.4661

C =
        0.0000         0         0
             0    0.3155         0
             0         0    0.9807
```

The other three matrices, V, X, and S are the same as those obtained with the full decomposition.

The generalized singular values are the ratios of the diagonal elements of C and S.

```
sigma = gsvd(A,B)
sigma =
        0.0000
        0.3325
        5.0123
```

These values are a reordering of the ordinary singular values

```
svd(A/B)
ans =
        5.0123
        0.3325
```

```
         0.0000
```

Example 2

The matrices have at least as many columns as rows.

```
A = reshape(1:15,3,5)
B = magic(5)
A =

     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15

B =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 3-by-3 orthogonal `U`, a 5-by-5 orthogonal `V`, a 5-by-5 nonsingular `X` and

```
C =

         0          0    0.0000          0          0
         0          0          0    0.0439          0
         0          0          0          0    0.7432

S =

    1.0000          0          0          0          0
         0    1.0000          0          0          0
         0          0    1.0000          0          0
         0          0          0    0.9990          0
         0          0          0          0    0.6690
```

In this situation, the nonzero diagonal of `C` is `diag(C,2)`. The generalized singular values include three zeros.

```
sigma = gsvd(A,B)
sigma =

         0
         0
    0.0000
    0.0439
    1.1109
```

Reversing the roles of `A` and `B` reciprocates these values, producing two infinities.

```
gsvd(B,A)
ans =

   1.0e+16 *

    0.0000
    0.0000
    8.8252
       Inf
       Inf
```

Diagnostics

The only warning or error message produced by `gsvd` itself occurs when the two input arguments do not have the same number of columns.

More About

Algorithms

The generalized singular value decomposition uses the C-S decomposition described in [1], as well as the built-in `svd` and `qr` functions. The C-S decomposition is implemented in a local function in the `gsvd` program file.

`qr` | `svd`

Introduced before R2006a

gt, >

Determine greater than

Syntax

```
A > B
gt(A,B)
```

Description

`A > B` returns a logical array with elements set to logical 1 (`true`) where `A` is greater than `B`; otherwise, it returns logical `0` (`false`).

The test compares only the real part of numeric arrays. `gt` returns logical `0` (`false`) where `A` or `B` have NaN or undefined categorical elements.

`gt(A,B)` is an alternate way to execute `A > B`, but is rarely used. It enables operator overloading for classes.

Examples

Test Vector Elements

Determine if vector elements are greater than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are greater than `10`.

```
A > 10
```

```
ans =

     0     1     1     0     0     1     0     1
```

The result is a vector with values of logical 1 (`true`) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are greater than 10.

```
A(A > 10)
```

```
ans =

    12    18    11    15
```

The result is a subset of the elements in A.

Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =

    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values greater than 9 with the value 10.

```
A(A > 9) = 10
```

```
A =

    10     2     3    10
     5    10    10     8
     9     7     6    10
     4    10    10     1
```

The result is a new matrix whose largest element is 10.

Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
```

```
'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)

A =

     large       medium      small
     medium      small       large
```

The array has three categories: `'small'`, `'medium'`, and `'large'`.

Find all values greater than the category `'medium'`.

```
A > 'medium'

ans =

     1     0     0
     0     0     1
```

A value of logical `1` (`true`) indicates a value greater than the category `'medium'`.

Compare the rows of `A`.

```
A(1,:) > A(2,:)

ans =

     1     1     0
```

The function returns logical `1` (`true`) where the first row has a category value greater than the second row.

Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are greater than `2`.

```
A(A > 2)

ans =

   5.0000 - 1.0000i
```

`gt` compares only the real part of the elements in `A`.

Use `abs` to find which elements are outside a radius of `2` from the origin.

```
A(abs(A) > 2)
```

```
ans =

   2.0000 - 2.0000i   1.0000 + 3.0000i   1.0000 - 2.0000i   5.0000 - 1.0000i
```

The result has more elements since `abs` accounts for the imaginary part of the numbers.

Compare Dates

Create a vector of dates.

```
A = datetime([2014,05,01;2014,05,31])
```

```
A =

   01-May-2014
   31-May-2014
```

Find the dates that occur after May 10, 2014.

```
A(A > '2014-05-10')
```

```
ans =

   31-May-2014
```

Input Arguments

A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical

arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

`B` — Right array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

Introduced before R2006a

gtext

Mouse placement of text in 2-D view

Syntax

```
gtext('string')
gtext({'string1','string2','string3',...})
gtext({'string1';'string2';'string3';...})
gtext(...,'PropertyName',PropertyValue,...)
h = gtext(...)
```

Description

`gtext` displays a text string in the current figure window after you select a location with the mouse.

`gtext('string')` waits for you to press a mouse button or keyboard key while the pointer is within a figure window. Pressing a mouse button or any key places `'string'` on the plot at the selected location.

`gtext({'string1','string2','string3',...})` places all strings with one click, each on a separate line.

`gtext({'string1';'string2';'string3';...})` places one string per click, in the sequence specified.

`gtext(...,'PropertyName',PropertyValue,...)` sets the values of the specified text properties. For a list of properties, see Text Properties.

`h = gtext(...)` returns the handle to a text graphics object that is placed on the plot at the location you select.

Examples

Place a label on the current plot:

```
gtext('Note this divergence!')
```

More About

Tips

As you move the pointer into a figure window, the pointer becomes crosshairs to indicate that `gtext` is waiting for you to select a location. `gtext` uses the functions `ginput` and `text`.

See Also

`ginput` | `text`

Introduced before R2006a

guidata

Store or retrieve UI data

Syntax

```
guidata(object_handle,data)
data = guidata(object_handle)
```

Description

`guidata(object_handle,data)` stores the variable `data` with the object specified by `object_handle`. If `object_handle` is not a figure, then the object's parent figure is used. `data` can be any MATLAB variable, but is typically a structure, which enables you to add new fields as required.

`guidata` can manage only one variable at any time. Subsequent calls to `guidata(object_handle,data)` overwrite the previously stored `data`.

GUIDE Uses guidata GUIDE uses `guidata` to store and maintain the `handles` structure. In a GUIDE code file, do not overwrite the `handles` structure or your program will no longer work. If you need to store other data, you can do so by adding new fields to the `handles` structure.

`data = guidata(object_handle)` returns previously stored data, or an empty matrix if nothing is stored.

To change the data managed by `guidata`:

1. Get a copy of the data with the command `data = guidata(object_handle)`.
2. Make the desired changes to `data`.
3. Save the changed version of `data` with the command `guidata(object_handle,data)`.

`guidata` provides application developers with a convenient interface to a figure's application data:

- You do not need to create and maintain a hard-coded property name for the application data throughout your source code.
- You can access the data from within a local function callback routine using the component's handle (which is returned by `gcbo`), without needing to find the figure's handle.

If you are not using GUIDE, `guidata` is particularly useful in conjunction with `guihandles`, which creates a structure containing the all of the components in a UI.

Examples

This example calls `guidata` to save a structure containing a figure's application data from within the initialization section of the application code file. The first section shows how to do this within a programmatic UI. The second section shows how the code differs when you use GUIDE to create a template code file. GUIDE provides a `handles` structure as an argument to all local function callbacks, so you do not need to call `guidata` to obtain it. You do, however, need to call `guidata` to save changes you make to the structure.

Using guidata in a Programmatic UI

Calling the `guihandles` function creates the structure into which your code places additional data. It contains all handles used by the figure at the time it is called, generating field names based on each object's `Tag` property.

```
% Create figure
figure_handle = figure('Toolbar','none');
% create structure of handles
myhandles = guihandles(figure_handle);
% Add some additional data as a new field called numberOfErrors
myhandles.numberOfErrors = 0;
% Save the structure
guidata(figure_handle,myhandles)
```

You can recall the data from within a local callback function, modify it, and then replace the structure in the figure:

```
function My_Callback()
% ...
% Get the structure using guidata in the local function
myhandles = guidata(gcbo);
% Modify the value of your counter
myhandles.numberOfErrors = myhandles.numberOfErrors + 1;
```

```
% Save the change you made to the structure
guidata(gcbo,myhandles)
```

Using guidata in GUIDE

If you use GUIDE, you do not need to call `guihandles` to create a structure. You can add your own data to the handles `structure`. For example, this code adds the field, `numberOfErrors`, to the structure:

```
% --- Executes just before simple_gui_tab is made visible.
function my_GUIDE_GUI_OpeningFcn(hObject, eventdata, handles, varargin)
% This function has no output args, see OutputFcn.
% hObject    handle to figure
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
% varargin   command line arguments to simple_gui_tab (see VARARGIN)
% ...

% add some additional data as a new field called numberOfErrors
handles.numberOfErrors = 0;
% Save the change you made to the structure
guidata(hObject,handles)
```

Notice that you use the input argument `hObject` in place of `gcbo` to refer to the object whose callback is executing.

Suppose you needed to access the `numberOfErrors` field in a push button callback. Your callback code now looks something like this:

```
% --- Executes on button press in pushbutton1.
function my_GUIDE_GUI_pushbutton1_Callback(hObject, eventdata, handles)
% hObject    handle to pushbutton1 (see GCBO)
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
% ...

% No need to call guidata to obtain a structure;
% it is provided by GUIDE via the handles argument
handles.numberOfErrors = handles.numberOfErrors + 1;
% save the changes to the structure
guidata(hObject,handles)
```

Introduced before R2006a

guide

Open GUIDE

Syntax

```
guide
guide('filename.fig')
guide('fullpath')
guide(HandleList)
```

Description

`guide` launches GUIDE, a UI design environment.

`guide` opens the GUIDE Quick Start dialog where you can choose to open a previously created or create a new one using one of the provided templates.

`guide('filename.fig')` opens the FIG-file named `filename.fig` for editing if it is on the MATLAB path.

`guide('fullpath')` opens the FIG-file at `fullpath` even if it is not on the MATLAB path.

`guide(HandleList)` opens the content of each of the figures in `HandleList` in a separate copy of the GUIDE design environment.

`inspect`

Introduced before R2006a

guihandles

Create structure of handles

Syntax

```
handles = guihandles(object_handle)
handles = guihandles
```

Description

`handles = guihandles(object_handle)` returns a structure containing the handles of the objects in a figure, using the value of their `Tag`properties as the field names, with the following caveats:

- Objects are excluded if their Tag properties are empty, or are not legal variable names.
- If several objects have the same Tag, that field in the structure contains a vector of handles.
- Objects with hidden handles are included in the structure.

`handles = guihandles` returns a structure of handles for the current figure.

Introduced before R2006a

gunzip

Uncompress GNU zip files

Syntax

```
gunzip(files)
gunzip(files,outputdir)
gunzip(url, ...)
filenames = gunzip(...)
```

Description

`gunzip(files)` uncompresses GNU zip files from the list of files specified in `files`. Directories recursively `gunzip` all of their content. The output files have the same name, excluding the extension `.gz`, and are written to the same directory as the input files.

`files` is a string or cell array of strings containing a list of files or directories. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gunzip(files,outputdir)` writes the gunzipped file into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`gunzip(url, ...)` extracts the GNU zip contents from an Internet universal resource locator (URL). The URL must include the protocol type (for example, `'http://'`). MATLAB downloads the URL to the temp directory, and then deletes it.

`filenames = gunzip(...)` gunzips the files and returns the relative path names of the gunzipped files in the string cell array `filenames`.

Examples

To `gunzip` all `.gz` files in the current directory, type:

```
gunzip('*.gz');
```

To `gunzip` Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`, type:

```
url ='http://www.mathworks.com/moler/ncm.tar.gz';
gunzip(url,'ncm')
untar('ncm/ncm.tar','ncm')
```

See Also

`gzip` | `tar` | `untar` | `unzip` | `zip`

Introduced before R2006a

gzip

Compress files into GNU zip files

Syntax

```
gzip(files)
gzip(files,outputdir)
filenames = gzip(...)
```

Description

`gzip(files)` creates GNU zip files from the list of files specified in `files`. Directories recursively `gzip` all their contents. Each output gzipped file is written to the same directory as the input file and with the file extension `.gz`.

`files` is a string or cell array of strings containing a list of files or directories to `gzip`. Individual files that are on the MATLAB path can be specified as partial path names. Otherwise, an individual file can be specified relative to the current directory or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`gzip(files,outputdir)` writes the gzipped files into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`filenames = gzip(...)` gzips the files and returns the relative path names of all gzipped files in the string cell array `filenames`.

Examples

To `gzip` all `.m` and `.mat` files in the current directory and store the results in the directory `archive`, type:

```
gzip({'*.m','*.mat'},'archive');
```

gunzip | tar | untar | unzip | zip

Introduced before R2006a

h5create

Create HDF5 data set

Syntax

```
h5create(filename,datasetname,size,Name,Value)
```

Description

`h5create(filename,datasetname,size,Name,Value)` creates an HDF5 data set in the file specified by `filename`.

Input Arguments

`filename`

Text string specifying the name of an HDF5 file. If `filename` does not already exist, `h5create` creates it, with additional options specified by one or more Name,Value pair arguments.

Default:

`datasetname`

Text string specifying the name of the data set you want to create. If `datasetname` is a full path name, `h5create` creates all intermediate groups, if they don't already exist.

Default:

`size`

Array specifying the extents of the dataset. To specify an unlimited extent, set the corresponding element of `size` to `Inf`.

Default:

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Datatype'`

Any of the following MATLAB datatypes.

`double`	`uint64`	`uint32`	`uint16`	`uint8`
`single`	`int64`	`int32`	`int16`	`int8`

Default: `double`

`'ChunkSize'`

Defines chunking layout.

Default: Not chunked

`'Deflate'`

Defines gzip compression level (0-9).

Default: 0

`'FillValue'`

Defines the fill value for numeric data sets.

Default:

`'Fletcher32'`

Turns on the Fletcher32 checksum filter.

Default: `false`

`'Shuffle'`

Turns on the Shuffle filter.

Default: `false`

Examples

Create a fixed-size 100-by-200 data set.

```
h5create('myfile.h5','/myDataset1',[100 200]);
h5disp('myfile.h5');
```

Create a single-precision 1000-by-2000 data set with a chunk size of 50-by-80. Apply the highest level of compression.

```
h5create('myfile.h5','/myDataset2',[1000 2000], 'Datatype','single', ...
         'ChunkSize',[50 80],'Deflate',9);
h5disp('myfile.h5');
```

Create a two-dimensional data set that is unlimited along the second extent.

```
h5create('myfile.h5','/myDataset3',[200 Inf],'ChunkSize',[20 20]);
h5disp('myfile.h5');
```

See Also

`h5read` | `h5write` | `h5info` | `h5disp`

Introduced in R2011a

h5disp

Display contents of HDF5 file

Syntax

```
h5disp(filename)
h5disp(filename,location)
h5disp(filename,location,mode)
```

Description

`h5disp(filename)` displays the structure (metadata) of the entire HDF5 file, `filename`.

`h5disp(filename,location)` displays the metadata for the specified location.

`h5disp(filename,location,mode)` displays the file metadata according to the value of `mode`.

Input Arguments

`filename`

Text string specifying the name of an HDF5 file.

Default:

`location`

Text string specifying the full path to a location in an HDF5 file. To display the metadata for the entire file, specify `'/'` as the value of `location`. If `location` is a group, `h5disp` displays all objects below the group.

Default:

`mode`

Either of the following text strings.

Value	Description
`min`	Minimal, display only group and data set names.
`simple`	Display data set metadata and attribute values, if the attribute is an integer, floating point, or a scalar string.

Default: `simple`

Examples

Display the entire contents of an HDF5 file.

```
h5disp('example.h5')
```

Display metadata for one data set in an HDF5 file.

```
 h5disp('example.h5','/g4/world');
```

See Also

`h5info`

Introduced in R2011a

h5info

Return information about HDF5 file

Syntax

```
info = h5info(filename)
info = h5info(filename,location)
```

Description

`info = h5info(filename)` returns information about the entire HDF5 file, specified by `filename`.

`info = h5info(filename,location)` returns information about the group, data set, or named datatype specified by `location` in the HDF5 file, `filename`.

Input Arguments

`filename`

Text string specifying the name of an HDF5 file.

Default:

`location`

Text string specifying the location of a group, data set, or named datatype in an HDF5 file.

Default:

Output Arguments

`info`

A structure containing information about the HDF5 file. The set of fields in the structure depends on the `location` parameter. The first field is always `'Filename'`. Other fields that might be present in the `info` structure are as follows.

Location Type	Field	Description
Files and Groups		
	`Name`	Text string specifying name of the group. If you specify only a file name, this value is `'/'`.
	`Groups`	Array of structures describing subgroups.
	`Datasets`	Array of structures describing data sets.
	`Datatypes`	Array of structures describing named datatypes.
	`Links`	Array of structures describing soft, external, user-defined, and certain hard links.
	`Attributes`	Array of structures describing group attributes.
Data sets		
	`Name`	Text string specifying the name of the data set.
	`Datatype`	Structure describing the datatype.
	`Dataspace`	Structure describing the size of the dataset.
	`ChunkSize`	Extents of the data set's chunk size, if defined.
	`FillValue`	Data set's fill value, if defined.
	`Filter`	Array of structures describing any defined filters such as compression.

Location Type	Field	Description
	`Attributes`	Array of structures describing data set attributes.
Named Datatypes		
	`Name`	Text string specifying the name of the datatype object.
	`Class`	HDF5 class of the named datatype.
	`Type`	Text string or struct further describing the datatype.
	`Size`	Size of the named datatype in bytes.

Examples

Return all information.

```
info = h5info('example.h5');
```

Return information about a group and all data sets contained within the group.

```
info = h5info('example.h5','/g4');
```

Return information about a specific dataset.

```
info = h5info('example.h5','/g4/time');
```

See Also

`h5disp`

Introduced in R2011a

h5read

Read data from HDF5 data set

Syntax

```
data = h5read(filename,datasetname)
data = h5read(filename,datasetname,start,count)
data = h5read(filename,datasetname,start,count,stride)
```

Description

`data = h5read(filename,datasetname)` retrieves all of the data from the HDF5 data set `datasetname` in the file `filename`.

`data = h5read(filename,datasetname,start,count)` reads a subset of data from the data set `datasetname`. `start` is the one-based index of the first element to be read. `count` defines how many elements to read along each dimension. If a particular element of `count` is `Inf`, `h5read` reads data until the end of the corresponding dimension.

`data = h5read(filename,datasetname,start,count,stride)` reads a subset of data, where `stride` specifies the interelement spacing along each data set extent.

Input Arguments

`filename`

Text string specifying the name of an HDF5 file.

Default:

`datasetname`

Text string specifying the name of a data set in an HDF5 file.

Default:

`start`

Numeric index value specifying the place to start reading data in the dataset in an HDF5 file. Indices are 1-based.

Default:

`count`

Numeric value specifying the amount of data to read.

Default:

`stride`

Numeric value specifying the intervalue spacing during the read operation. For example, a spacing of 2 indicates reading every other value.

Default:

Output Arguments

`data`

Data read from the data set.

Examples

Read an entire data set.

```
h5disp('example.h5','/g4/lat');
data = h5read('example.h5','/g4/lat');
```

Read the first 5-by-3 subset of a data set.

```
h5disp('example.h5','/g4/world');
data = h5read('example.h5','/g4/world',[1 1],[5 3]);
```

Read a data set of references to other data sets.

```
h5disp('example.h5','/g3/reference');
```

```
data = h5read('example.h5','/g3/reference');
```

h5write | h5readatt | h5disp | h5writeatt

Introduced in R2011a

h5readatt

Read attribute from HDF5 file

Syntax

```
attval = h5readatt(filename,location,attr)
```

Description

`attval = h5readatt(filename,location,attr)` retrieves the value for the named attribute `attr` from the given `location` in the HDF5 file `filename`.

Input Arguments

`filename`

Text string specifying the name of an HDF5 file.

Default:

`location`

Text string specifying the full path of the attribute in an HDF5 file. `location` can refer to either a group or a data set.

Default:

`attr`

Text string specifying the name of an attribute in an HDF5 file.

Default:

Output Arguments

`attval`

Value of the attribute.

Examples

Read a group attribute.

```
attval = h5readatt('example.h5','/','attr2');
```

Read a data set attribute.

```
attval = h5readatt('example.h5','/g4/lon','units');
```

See Also

h5writeatt | h5info

Introduced in R2011a

h5write

Write to HDF5 data set

Syntax

```
h5write(filename,datasetname,data)
h5write(filename,datasetname,data,start,count)
h5write(filename,datasetname,data,start,count,stride)
```

Description

`h5write(filename,datasetname,data)` writes `data` to an entire data set, `datasetname`, in the HDF5 file, `filename`.

`h5write(filename,datasetname,data,start,count)` writes a subset of the `data` to a data set, `datasetname`, in the HDF5 file, `filename`. `start` is a one-based index value that specifies the first element to be written. `count` specifies the number of elements to write along each dimension. `h5write` extends an extendable data set along any unlimited dimensions, if necessary.

`h5write(filename,datasetname,data,start,count,stride)` writes a hyperslab of data, where `stride` specifies the inter-element spacing along each dimension.

Input Arguments

`filename`

Text string specifying the name of an HDF5 file.

Default:

`datasetname`

Text string specifying the name of a data set in the HDF5 file.

Default:

`data`

Data to be written to the HDF5 file. You can specify only floating-point and integer data sets.

Default:

`start`

Numeric index value specifying where in the data set to start writing to the file.

Default:

`count`

Numeric value specifying how much data to write to the file.

Default:

`stride`

Numeric value specifying the interelement spacing of data to write to the file.

Default: Vector of ones.

Examples

Write to an entire data set.

```
h5create('myfile.h5','/DS1',[10 20]);
mydata = rand(10,20);
h5write('myfile.h5', '/DS1', mydata);
```

Write a hyperslab of data to the last 5-by-7 block of a data set.

```
 h5create('myfile.h5','/DS2',[10 20]);
        mydata = rand(5,7);
        h5write('myfile.h5','/DS2',mydata,[6 14],[5 7]);
```

Append data to an unlimited data set.

```
h5create('myfile.h5','/DS3',[20 Inf],'ChunkSize',[5 5]);
for j = 1:10
```

```
      data = j*ones(20,1);
      start = [1 j];
      count = [20 1];
      h5write('myfile.h5','/DS3',data,start,count);
end
h5disp('myfile.h5');
```

Limitations

- `h5write` supports only floating point and integer data sets. To write to string data sets, you must use the H5D package.

More About

Hyperslab

A hyperslab is a collection of points in a data space. The points can be contiguous or form a regular pattern of points or blocks in a data space.

See Also

`h5read` | `h5create` | `h5writeatt` | `h5disp` | `H5D.create` | `H5D.write`

Introduced in R2011a

h5writeatt

Write HDF5 attribute

Syntax

```
h5writeatt(filename,location,attname,attvalue)
```

Description

`h5writeatt(filename,location,attname,attvalue)` writes the attribute named `attname` with the value `attvalue` to the HDF5 file `filename`. The parent object `location` can be either a group or variable. `location` is the complete path name of the group or variable to which you want to associate the attribute.

Input Arguments

`filename`

Text string specifying the name of an HDF5 file.

Default:

`location`

Text string specifying the full path identifying a group or variable in an HDF5 file.

Default:

`attname`

Text string specifying the name of an attribute in an HDF5 file. If the attribute does not exist, `h5writeatt` creates the attribute with the name specified.

If the specified attribute already exists but does not have a datatype or dataspace consistent with `attvalue`, `h5writeatt` deletes the attribute and recreates it. String attributes are created with a scalar dataspace.

Default:

`attvalue`

Value to be written to the attribute in an HDF5 file.

Default:

Examples

Create a root group attribute whose value is the current time.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
h5writeatt('myfile.h5','/','creation_date',datestr(now));
```

Create a double-precision data set attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
attData = [0 1 2 3];
h5writeatt('myfile.h5','/g4/world','attr',attData);
h5disp('myfile.h5','/g4/world');
```

`H5.close`

H5.set_free_list_limits

Set size limits on free lists

Syntax

```
H5.set_free_list_limits(reg_global_lim,reg_list_lim,arr_global_lim,arr_list_li
```

Description

`H5.set_free_list_limits(reg_global_lim,reg_list_lim,arr_global_lim,arr_list_li`
sets size limits on all types of free lists.

H5A.close

Close specified attribute

Syntax

```
H5A.close(attr_id)
```

Description

`H5A.close(attr_id)` terminates access to the attribute specified by `attr_id`, releasing the identifier.

See Also

`H5A.open`

H5A.create

Create attribute

Syntax

```
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)
attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id,aapl_id)
```

Description

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id)` creates the attribute name that is attached to the object specified by `loc_id`. `loc_id` is a group, dataset, or named datatype identifier. The datatype and dataspace identifiers of the attribute, `type_id` and `space_id`, respectively, are created with the H5T and H5S interfaces. The attribute property list, `acpl_id`, is currently unused and should be set to `'H5P_DEFAULT'`. This interface corresponds to the 1.6.x version of `H5Acreate`.

`attr_id = H5A.create(loc_id,name,type_id,space_id,acpl_id,aapl_id)` creates the attribute with the additional attribute access property list identifier `aapl_id`. `aapl_id` should currently be set to `'H5P_DEFAULT'`. This interface corresponds to the 1.8.x version of `H5Acreate`.

Examples

```
acpl_id = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl_id);
H5A.close(attr_id);
H5F.close(fid);
```

See Also

`H5A.close` | `H5P.create`

H5A.delete

Delete attribute

Syntax

```
H5A.delete(loc_id,name)
```

Description

`H5A.delete(loc_id,name)` removes the attribute specified by `name` from the dataset, group, or named datatype specified by `loc_id`.

Examples

Delete a root group attribute.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
gid = H5G.open(fid,'/');
H5A.delete(gid,'attr1');
H5G.close(gid);
H5F.close(fid);
```

H5A.get_info

Information about attribute

Syntax

```
info = H5A.get_info(attr_id)
```

Description

`info = H5A.get_info(attr_id)` returns information about an attribute specified by `attr_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
info = H5A.get_info(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open`

H5A.get_name

Attribute name

Syntax

```
attr_name = H5A.get_name(attr_id)
```

Description

`attr_name = H5A.get_name(attr_id)` returns the name of the attribute specified by `attr_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
attr_id = H5A.open_by_idx(gid,'dset1.1.1',idx_type,order,0);
name = H5A.get_name(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open_by_idx`

H5A.get_space

Copy of attribute data space

Syntax

```
dspace_id = H5A.get_space(attr_id)
```

Description

`dspace_id = H5A.get_space(attr_id)` returns a copy of the data space for the attribute specified by `attr_id`.

Examples

Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
attr_id = H5A.open(fid,'attr2');
space = H5A.get_space(attr_id);
[~,dims] = H5S.get_simple_extent_dims(space);
H5A.close(attr_id);
H5F.close(fid);
```

See Also

`H5A.open` | `H5S.close`

H5A.get_type

Copy of attribute data type

Syntax

```
type_id = H5A.get_type(attr_id)
```

Description

`type_id = H5A.get_type(attr_id)` returns a copy of the data type for the attribute specified by `attr_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
type_id = H5A.get_type(attr_id);
H5T.close(type_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open` | `H5T.close`

H5A.iterate

Execute function for attributes attached to object

Syntax

```
[status,idx_stop,cdata_out] =
H5A.iterate(obj_id,idx_type,order,idx_start,iter_func,cdata_in)
H5A.iterate(loc_id,attr_idx,iterator_func)
```

Description

`[status,idx_stop,cdata_out] = H5A.iterate(obj_id,idx_type,order,idx_start,iter_func,cdata_in)` executes the specified function `iter_func` for each attribute connected to an object. `obj_id` identifies the object to which attributes are attached. `idx_type` is the type of index and valid values include the following.

`'H5_INDEX_NAME'`	An alpha-numeric index by attribute name
`'H5_INDEX_CRT_ORDER'`	An index by creation order

`order` specifies the index traversal order. Valid values include the following.

`'H5_ITER_INC'`	Iteration from beginning to end
`'H5_ITER_DEC'`	Iteration from end to beginning
`'H5_ITER_NATIVE'`	Iteration in the fastest available order

`idx_start` specifies the starting point of the iteration. `idx_stop` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function, `iter_func`, must have the following signature:

```
[status,cdata_out] = iter_func(obj_id,attr_name,info,cdata_in)
```

`cdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `cdata_in` parameter. The `cdata_out` of an iteration step

forms the `cdata_in` for the next iteration step. Then, the final `cdata_out` at the end of the iteration is returned to the caller as `cdata_out`. This form of `H5A.iterate` corresponds to the `H5Aiterate2` function in the HDF5 C API.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

`H5A.iterate(loc_id,attr_idx,iterator_func)` executes the specified function for each attribute of the group, dataset, or named datatype specified by `loc_id`. The `attr_idx` argument specifies where the iteration begins. `iterator_func` must be a function handle.

The iterator function must have the following signature:

```
status = iterator_func(loc_id,attr_name)
```

`loc_id` still specifies the group, dataset, or named data type passed into `H5A.iterate`, and `attr_name` specifies the current attribute. This form of `H5A.iterate` corresponds to `H5Aiterate1` function in the HDF5 C API.

H5A.open

Open attribute

Syntax

```
attr_id = H5A.open(obj_id,attr_name)
attr_id = H5A.open(obj_id,attr_name,aapl_id)
```

Description

`attr_id = H5A.open(obj_id,attr_name)` opens an attribute for an object specified by a parent object identifier and attribute name.

`attr_id = H5A.open(obj_id,attr_name,aapl_id)` opens an attribute with an attribute access property list identifier, `aapl_id`. The only currently valid value for `aapl_id` is `'H5P_DEFAULT'`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.close` | `H5A.open_by_idx` | `H5A.open_by_name`

H5A.open_by_idx

Open attribute specified by index

Syntax

```
attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n)
attr_id =
H5A.open_by_idx(loc_id,obj_name,idx_type,order,n,aapl_id,lapl_id)
```

Description

`attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n)` opens an existing attribute at index `n` attached to an object specified by its location, `loc_id`, and name, `obj_name`.

`idx_type` is the type of index and valid values include the following.

`'H5_INDEX_NAME'`	An alpha-numeric index by attribute name
`'H5_INDEX_CRT_ORDER'`	An index by creation order

`order` specifies the index traversal order. Valid values include the following.

`'H5_ITER_INC'`	Iteration from beginning to end
`'H5_ITER_DEC'`	Iteration from end to beginning
`'H5_ITER_NATIVE'`	Iteration in the fastest available order

`attr_id = H5A.open_by_idx(loc_id,obj_name,idx_type,order,n,aapl_id,lapl_id)` opens an attribute with attribute access property list, `aapl_id`, and link access property list, `lapl_id`. The `aapl_id` argument must currently be specified as `'H5P_DEFAULT'`. Also, `lapl_id` can be specified by `'H5P_DEFAULT'`.

Examples

Loop through a set of dataset attributes in reverse alphabetical order.

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
info = H5O.get_info(dset_id);
for idx = 0:info.num_attrs-1
  attr_id =H5A.open_by_idx(gid,'dset1.1.1','H5_INDEX_NAME','H5_ITER_DEC',idx);
  fprintf('attribute name:  %s\n',H5A.get_name(attr_id));
  H5A.close(attr_id);
end
H5G.close(gid);
H5F.close(fid);
```

See Also

H5A.close | H5A.open | H5A.open_by_name

H5A.open_by_name

Open attribute specified by name

Syntax

```
attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)
attr_id =
H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,lapl_id)
```

Description

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name)` opens an existing attribute `attr_name` attached to an object specified by its location `loc_id` and name `obj_name`.

`attr_id = H5A.open_by_name(loc_id,obj_name,attr_name,aapl_id,lapl_id)` opens an existing attribute with the attribute access property list `aapl_id` and link access property list `lacpl_id`. `aapl_id` must be specified as `'H5P_DEFAULT'`. `lapl_id` may also be specified by `'H5P_DEFAULT'`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.1');
attr_id = H5A.open_by_name(gid,'dset1.1.1','attr1');
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.close` | `H5A.open` | `H5A.open_by_idx`

H5A.read

Read attribute

Syntax

```
attr = H5A.read(attr_id)
attr = H5A.read(attr_id, mem_type_id)
```

Description

`attr = H5A.read(attr_id)` reads the attribute specified by `attr_id`. MATLAB will determine the appropriate memory datatype.

`attr = H5A.read(attr_id, mem_type_id)` reads the attribute specified by `attr_id`. `mem_type_id` specifies the attribute's memory datatype and should usually be given as `'H5ML_DEFAULT'`, which specifies that MATLAB will determine the appropriate memory datatype.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the HDF5 library reports the attribute size as 3-by-4-by-5, then the corresponding MATLAB array size is 5-by-4-by-3. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
attr_id = H5A.open(gid,'attr1');
data = H5A.read(attr_id);
H5A.close(attr_id);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.open` | `H5A.write`

H5A.write

Write attribute

Syntax

```
H5A.write(attr_id,type_id,buf)
```

Description

`H5A.write(attr_id,type_id,buf)` writes the data in buf into the attribute specified by `attr_id`. `type_id` specifies the attribute's memory datatype. The memory datatype should be `'H5ML_DEFAULT'`, which specifies that MATLAB should determine the appropriate memory datatype.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. If the MATLAB array size is 5-by-4-by-3, then the HDF5 library should be reporting the attribute size as 3-by-4-by-5. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Write a scalar double precision attribute.

```
acpl = H5P.create('H5P_ATTRIBUTE_CREATE');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
space_id = H5S.create('H5S_SCALAR');
fid = H5F.create('myfile.h5');
attr_id = H5A.create(fid,'my_attr',type_id,space_id,acpl);
H5A.write(attr_id,'H5ML_DEFAULT',10.0)
H5A.close(attr_id);
H5F.close(fid);
H5T.close(type_id);
```

See Also

`H5A.read`

H5D.close

Close dataset

Syntax

```
H5D.close(dataset_id)
```

Description

`H5D.close(dataset_id)` ends access to a dataset specified by `dataset_id` and releases resources used by it.

See Also

`H5D.create` | `H5D.open`

H5D.create

Create new dataset

Syntax

```
dataset_id = H5D.create(loc_id,name,type_id,space_id,plist_id)
dataset_id =
H5D.create(loc_id,name,type_id,space_id,lcpl_id,dcpl_id,dapl_id)
```

Description

`dataset_id = H5D.create(loc_id,name,type_id,space_id,plist_id)` creates the data set specified by `name` in the file or in the group specified by `loc_id`. `type_id` and `space_id` identify the datatype and dataspace, respectively. `plist_id` identifies the dataset creation property list. This interface corresponds to the `H5Dcreate1` function in the HDF5 library C 1.6 API.

`dataset_id = H5D.create(loc_id,name,type_id,space_id,lcpl_id,dcpl_id,dapl_id)` creates the data set with three distinct property lists:

`lcpl_id`	link creation property list
`dcpl_id`	dataset creation property list
`dapl_id`	dataset access property list

This interface corresponds to the `H5Dcreate` function in the HDF5 library C 1.8 API.

Examples

Create a 10x5 double precision dataset with default property list settings.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [10 5];
h5_dims = fliplr(dims);
```

```
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile.h5');
```

Create a 6x3 fixed length string dataset. Each string will have a length of 4 characters.

```
fid = H5F.create('myfile_strings.h5');
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,4);
dims = [6 3];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5S.close(space_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
h5disp('myfile_strings.h5');
```

See Also

H5D.close | H5S.close | H5S.create_simple | H5T.copy

H5D.get_access_plist

Copy of dataset access property list

Syntax

```
plist_id = H5D.get_access_plist(dataset_id)
```

Description

`plist_id = H5D.get_access_plist(dataset_id)` returns a copy of the dataset access property list used to open the specified dataset.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dapl = H5D.get_access_plist(dset_id);
H5P.close(dapl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.get_create_plist` | `H5P.close`

H5D.get_create_plist

Copy of dataset creation property list

Syntax

```
plist_id = H5D.get_create_plist(dataset_id)
```

Description

`plist_id = H5D.get_create_plist(dataset_id)` returns the identifier to a copy of the dataset creation property list for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dcpl = H5D.get_create_plist(dset_id);
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.get_access_plist` | `H5P.close`

H5D.get_offset

Location of dataset in file

Syntax

```
offset = H5D.get_offset(dataset_id)
```

Description

`offset = H5D.get_offset(dataset_id)` returns the location in the file of the dataset specified by `dataset_id`. The location is expressed as an offset, in bytes, from the beginning of the file.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
offset = H5D.get_offset(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

H5D.get_space

Copy of dataset data space

Syntax

```
dspace_id = H5D.get_space(dataset_id)
```

Description

`dspace_id = H5D.get_space(dataset_id)` returns an identifier for a copy of the data space for a dataset.

Examples

Retrieve the dimensions of an attribute data space.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
space = H5D.get_space(dset_id);
[~,dims] = H5S.get_simple_extent_dims(space);
H5S.close(space);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.open` | `H5S.close`

H5D.get_space_status

Determine if space is allocated

Syntax

```
status = H5D.get_space_status(dataset_id)
```

Description

`status = H5D.get_space_status(dataset_id)` determines whether space has been allocated for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
status = H5D.get_space_status(dset_id);
switch(status)
    case H5ML.get_constant_value('H5D_SPACE_STATUS_NOT_ALLOCATED')
        fprintf('Not allocated.\n');
    case H5ML.get_constant_value('H5D_SPACE_STATUS_ALLOCATED')
        fprintf('Allocated.\n');
    case H5ML.get_constant_value('H5D_SPACE_STATUS_PART_ALLOCATED')
        fprintf('Part allocated.\n');
end
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.get_space`

H5D.get_storage_size

Determine required storage size

Syntax

```
dataset_size = H5D.get_storage_size(dataset_id)
```

Description

`dataset_size = H5D.get_storage_size(dataset_id)` returns the amount of storage that is required for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dataset_size = H5D.get_storage_size(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

H5D.get_type

Copy of datatype

Syntax

```
type_id = H5D.get_type(dataset_id)
```

Description

`type_id = H5D.get_type(dataset_id)` returns an identifier for a copy of the data type for the dataset specified by `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
type_id = H5D.get_type(dset_id);
H5T.close(type_id);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5T.close`

H5D.open

Open specified dataset

Syntax

```
dataset_id = H5D.open(loc_id,name)
dataset_id = H5D.open(loc_id,name,dapl_id)
```

Description

`dataset_id = H5D.open(loc_id,name)` opens the dataset specified by `name` in the file or group specified by `loc_id`.

`dataset_id = H5D.open(loc_id,name,dapl_id)` opens the dataset specified by `name` in the file or group specified by `loc_id`. The dataset access property list, `dapl_id`, provides information regarding access to the dataset.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
dset_id = H5D.open(gid,'dset2.2');
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.close`

H5D.read

Read data from HDF5 dataset

Syntax

```
data = H5D.read(dataset_id)
data =
H5D.read(dataset_id,mem_type_id,mem_space_id,file_space_id,dxpl)
```

Description

`data = H5D.read(dataset_id)` reads the entire dataset specified by `dataset_id`.

`data =
H5D.read(dataset_id,mem_type_id,mem_space_id,file_space_id,dxpl)` reads the dataset specified by `dataset_id`. The `mem_type_id` input specifies the memory data type and should usually be `'H5ML_DEFAULT'` to allow MATLAB to determine the appropriate value. `mem_space_id` describes how the data is to be arranged in memory and should usually be `'H5S_ALL'`. The `file_space_id` input describes how the data is to be selected from the file. It also can be given as `'H5S_ALL'`, but this results in the entire dataset being read into memory. `dxpl` is the dataset transfer property list identifier and should usually be `'H5P_DEFAULT'`.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Read an entire dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
data = H5D.read(dset_id);
```

```
H5D.close(dset_id);
H5F.close(fid);
```

Read the 2x3 hyperslab starting in the 4th row and 5th column of the example dataset.

```
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g1/g1.1/dset1.1.1');
dims = fliplr([2 3]);
mem_space_id = H5S.create_simple(2,dims,[]);
file_space_id = H5D.get_space(dset_id);
offset = fliplr([3 4]);
block = fliplr([2 3]);
H5S.select_hyperslab(file_space_id,'H5S_SELECT_SET',offset,[],[],block);
data = H5D.read(dset_id,'H5ML_DEFAULT',mem_space_id,file_space_id,plist);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

H5D.open | H5D.write | H5S.create_simple

H5D.set_extent

Change size of dataset dimensions

Syntax

```
H5D.set_extent(dset_id,h5_extents)
```

Description

`H5D.set_extent(dset_id,h5_extents)` changes the dimensions of the dataset `dset_id` to the sizes specified in `h5_extents`.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_extents` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Extend an unlimited one-dimensional dataset from a length of 10 to a length of 20.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
dset_id = H5D.open(fid,'/g4/time');
H5D.set_extent(dset_id,20);
H5D.close(dset_id);
H5F.close(fid);
```

H5D.vlen_get_buf_size

Determine variable length storage requirements

Syntax

```
size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)
```

Description

`size = H5D.vlen_get_buf_size(dataset_id,type_id,space_id)` determines the number of bytes required to store the VL data from the dataset, using the `space_id` for the selection in the dataset on disk and the `type_id` for the memory representation of the VL data in memory.

H5D.write

Write data to HDF5 dataset

Syntax

```
H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,plist_id,buf)
```

Description

`H5D.write(dataset_id,mem_type_id,mem_space_id,file_space_id,plist_id,buf)` writes the dataset specified by `dataset_id` from the application memory buffer `buf` into the file. `plist_id` specifies the data transfer properties. `mem_type_id` identifies the memory datatype of the dataset. `mem_space_id` and `file_space_id` define the part of the dataset to write. The memory datatype should usually be `'H5ML_DEFAULT'`, which specifies that MATLAB should determine the appropriate memory datatype.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Write to the entire 36-by-19 `/g4/world` example dataset.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g4/world');
dims = [36 19];
data = rand(dims);
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5D.close(dset_id);
H5F.close(fid);
```

Write to the entire two-element `/g3/VLstring` dataset.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
h5disp('myfile.h5','/g3/VLstring');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g3/VLstring');
data = {'dogs'; 'dogs and cats'};
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5D.close(dset_id);
H5F.close(fid);
data_out = h5read('myfile.h5','/g3/VLstring');
```

Write a 10-by-5 block of data to the location starting at row index 15 and column index 5 of the same dataset. Recall that indexing is zero-based.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
plist = 'H5P_DEFAULT';
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
dset_id = H5D.open(fid,'/g4/world');
start = [15 5];
h5_start = fliplr(start);
block = [10 5];
h5_block = fliplr(block);
mem_space_id = H5S.create_simple(2,h5_block,[]);
file_space_id = H5D.get_space(dset_id);
H5S.select_hyperslab(file_space_id,'H5S_SELECT_SET',h5_start,[],[],h5_block);
data = rand(block);
H5D.write(dset_id,'H5ML_DEFAULT',mem_space_id,file_space_id,plist,data);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5D.read`

H5DS.attach_scale

Attach dimension scale to specific dataset dimension

Syntax

```
H5DS.attach_scale(dataset_id,dimscale_id,idx)
```

Description

`H5DS.attach_scale(dataset_id,dimscale_id,idx)` attaches a dimension scale `dimscale_id` to dimension `idx` of the dataset `dataset_id`.

Note: The ordering of the dimension scale indices are the same as the HDF5 library C API.

Examples

Add the `'lon'` and `'lat'` dimension scales to the `'world'` dataset.

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
lat_dset_id = H5D.open(fid,'/g4/lat',plist);
lon_dset_id = H5D.open(fid,'/g4/lon',plist);
H5DS.attach_scale(world_dset_id,lat_dset_id,0);
H5DS.attach_scale(world_dset_id,lon_dset_id,1);
H5D.close(lat_dset_id);
H5D.close(lon_dset_id);
H5D.close(world_dset_id);
H5F.close(fid);
```

See Also

`H5DS.detach_scale`

H5DS.detach_scale

Detach dimension scale from specific dataset dimension

Syntax

```
H5DS.detach_scale(dataset_id,dimscale_id,idx)
```

Description

`H5DS.detach_scale(dataset_id,dimscale_id,idx)` detaches dimension scale `dimscale_id` from dimension `idx` of the dataset `dataset_id`.

Note: The ordering of the dimension scale indices are the same as the HDF5 library C API.

See Also

`H5DS.attach_scale`

H5DS.get_label

Retrieve label from specific dataset dimension

Syntax

```
label = H5DS.get_label(dataset_id,idx)
```

Description

`label = H5DS.get_label(dataset_id,idx)` retrieves the label for dimension `idx` of the dataset `dataset_id`.

Note: The ordering of the dimension scale indices are the same as the HDF5 library C API.

Examples

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid,'/g4/world');
label = H5DS.get_label(world_dset_id,0);
H5D.close(world_dset_id);
H5F.close(fid);
```

See Also

`H5DS.set_label`

H5DS.get_num_scales

Number of scales attached to dataset dimension

Syntax

```
num_scales = H5DS.get_num_scales(dataset_id,idx)
```

Description

`num_scales = H5DS.get_num_scales(dataset_id,idx)` determines the number of dimension scales that are attached to dimension `idx` of the dataset `dataset_id`.

Examples

```
fid = H5F.open('example.h5');
world_dset_id = H5D.open(fid,'/g4/world');
num_scales = H5DS.get_num_scales(world_dset_id,0);
H5D.close(world_dset_id);
H5F.close(fid);
```

H5DS.get_scale_name

Name of dimension scale

Syntax

```
name = H5DS.get_scale_name(dimscale_id)
```

Description

`name = H5DS.get_scale_name(dimscale_id)` retrieves the name of the dimension scale `dimscale_id`.

Examples

```
fid = H5F.open('example.h5');
lat_dset_id = H5D.open(fid,'/g4/lat');
scale_name = H5DS.get_scale_name(lat_dset_id);
H5D.close(lat_dset_id);
H5F.close(fid);
```

See Also

`H5DS.set_scale`

H5DS.is_scale

Determine if dataset is a dimension scale

Syntax

```
bool = H5DS.is_scale(dataset_id)
```

Description

`bool = H5DS.is_scale(dataset_id)` determines whether the dataset `dataset_id` is a dimension scale.

Examples

```
fid = H5F.open('example.h5');
lat_dset_id = H5D.open(fid,'/g4/lat');
if H5DS.is_scale(lat_dset_id)
    fprintf('/g4/lat is a dimension scale.\n');
else
    fprintf('/g4/lat is not a dimension scale.\n');
end
H5D.close(lat_dset_id);
H5F.close(fid);
```

H5DS.iterate_scales

Iterate on scales attached to dataset dimension

Syntax

```
[status,idx_out,opdata_out] =
H5DS.iterate_scales(dset_id,dim,idx_in,iter_func,opdata_in)
```

Description

`[status,idx_out,opdata_out] = H5DS.iterate_scales(dset_id,dim,idx_in,iter_func,opdata_in)` iterates over the scales attached to dimension `dim` of the dataset `dset_id` to perform a common operation whose function handle is `iter_func`.

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed. If `idx_in` is `[]`, then the iterator starts at the first member.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] =
iter_func(dset_id,dim,dimscale_id,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`dimscale_id` specifies the current dimension scale dataset identifier and `dim` is the associated dimension.

status value returned by `iter_func` is interpreted as follows:

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed

positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

H5DS.set_label

Set label for dataset dimension

Syntax

```
H5DS.set_label(dataset_id,idx,label)
```

Description

`H5DS.set_label(dataset_id,idx,label)` sets a label for dimension `idx` of the dataset `dataset_id`.

Note: The ordering of the dimension scale indices are the same as the HDF5 library C API.

Examples

```
plist = 'H5P_DEFAULT';
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR',plist);
world_dset_id = H5D.open(fid,'/g4/world',plist);
H5DS.set_label(world_dset_id,0,'latitude');
H5DS.set_label(world_dset_id,1,'longitude');
H5D.close(world_dset_id);
H5F.close(fid);
```

See Also

`H5DS.get_label`

H5DS.set_scale

Convert dataset to dimension scale

Syntax

```
H5DS.set_scale(dataset_id,dim_name)
```

Description

`H5DS.set_scale(dataset_id,dim_name)` converts the dataset, `dataset_id`, to a dimension scale with name `dim_name`.

Examples

Create a dimension scale with name `'xdim'`. The dataset has the name, `'x'`.

```
fid = H5F.create('myfile.h5');
space_id = H5S.create_simple(1,10,10);
dtype = 'H5T_NATIVE_INT';
dcpl = 'H5P_DEFAULT';
dset_id = H5D.create(fid,'x',dtype,space_id,dcpl);
H5DS.set_scale(dset_id,'xdim');
H5S.close(space_id);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5DS.get_scale_name`

H5E.clear

Clear error stack

Syntax

```
H5E.clear()
```

Description

`H5E.clear()` clears the error stack for the current thread.

H5E.get_major

Description of major error number

Syntax

```
err_string = H5E.get_major(major_number)
```

Description

`err_string = H5E.get_major(major_number)` returns a character string describing an error specified by the major error number, `major_number`.

The HDF5 group has deprecated the use of this function.

See Also

`H5E.get_minor`

H5E.get_minor

Description of minor error number

Syntax

```
err_string = H5E.get_minor(minor_number)
```

Description

`err_string = H5E.get_minor(minor_number)` returns a character string describing an error specified by the minor error number, `minor_number`.

The HDF5 group has deprecated the use of this function.

See Also

`H5E.get_major`

H5E.walk

Walk error stack

Syntax

```
H5E.walk(direction,func)
```

Description

`H5E.walk(direction,func)` walks the error stack for the current thread and calls the specified function for each error along the way. `func` is a function handle. `direction` specifies how the error stack is traversed and can be given by one of the following strings or the numeric equivalent.

```
'H5E_WALK_UPWARD'
'H5E_WALK_DOWNWARD'
```

The specified function must have the following signature:

```
status = func(n,error_struct)
```

where `n` is the indexed position of the error in the stack and `error_struct` is a structure with the following fields:

`maj_num`	Major error number
`min_num`	Minor error number
`func_name`	Function in which the error occurred
`file_name`	File in which the error occurred
`line`	Line in file where error occurs
`desc`	Optional supplied description

This function corresponds to the `H5Ewalk1` function in the HDF5 library C API.

See Also

`H5ML.get_constant_value`

H5F.close

Close HDF5 file

Syntax

```
H5F.close(file_id)
```

Description

`H5F.close(file_id)` terminates access to HDF5 file identified by `file_id`, flushing all data to storage.

See Also

`H5F.open`

H5F.create

Create HDF5 file

Syntax

```
file_id = H5F.create(filename)
file_id = H5F.create(name,flags,fcpl_id,fapl_id)
```

Description

`file_id = H5F.create(filename)` creates the file specified by `filename` with default library properties if the file does not already exist.

`file_id = H5F.create(name,flags,fcpl_id,fapl_id)` creates the file specified by `name`. `flags` specifies whether to truncate the file, if it already exists, or to fail if the file already exists. `flags` can be specified by one of the following strings or the numeric equivalent:

`'H5F_ACC_TRUNC'`	overwrite any existing file by the same name
`'H5F_ACC_EXCL'`	do not overwrite an existing file

`fcpl_id` is the file creation property list identifier. `fapl_id` is the file access property list identifier. A value of `'H5P_DEFAULT'` for either property list indicates that the library should use default values for the appropriate property list.

Examples

Create an HDF5 file called `'myfile.h5'`.

```
fid = H5F.create('myfile.h5');
H5F.close(fid);
```

Create an HDF5 file called `'myfile.h5'`, overwriting any existing file by the same name. Default file access and file creation properties shall apply.

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

H5F.close | H5ML.get_constant_value | H5P.create

H5F.flush

Flush buffers to disk

Syntax

```
H5F.flush(object_id,scope)
```

Description

`H5F.flush(object_id,scope)` causes all buffers associated with a file to be immediately flushed to disk without removing the data from the cache. `object_id` can be any object associated with the file, including the file itself, a dataset, a group, an attribute, or a named data type. `scope` specifies whether the scope of the flushing action is global or local. `scope` may be one of the following strings:

```
'H5F_SCOPE_GLOBAL'
'H5F_SCOPE_LOCAL'
```

H5F.get_access_plist

File access property list

Syntax

```
fapl_id = H5F.get_access_plist(file_id)
```

Description

`fapl_id = H5F.get_access_plist(file_id)` returns the file access property list identifier of the file specified by `file_id`.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5F.get_create_plist`

H5F.get_create_plist

File creation property list

Syntax

```
fcpl_id = H5F.get_create_plist(file_id)
```

Description

`fcpl_id = H5F.get_create_plist(file_id)` returns a file creation property list identifier identifying the creation properties used to create the file specified by `file_id`.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
H5P.close(fcpl);
H5F.close(fid);
```

See Also

`H5F.get_access_plist`

H5F.get_filesize

Size of HDF5 file

Syntax

```
size = H5F.get_filesize(file_id)
```

Description

`size = H5F.get_filesize(file_id)` returns the size of the HDF5 file specified by `file_id`.

H5F.get_freespace

Amount of free space in file

Syntax

```
free_space = H5F.get_freespace(file_id)
```

Description

`free_space = H5F.get_freespace(file_id)` returns the amount of space that is unused by any objects in the file specified by `file_id`.

H5F.get_info

Global information about file

Syntax

```
file_info = H5F.get_info(obj_id)
```

Description

`file_info = H5F.get_info(obj_id)` returns global information for the file associated with the object identifier `obj_id`. For details about the fields of the `file_info` structure, please refer to the HDF5 documentation.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'g2');
info = H5F.get_info(gid);
H5G.close(gid);
H5F.close(fid);
```

H5F.get_mdc_config

Metadata cache configuration

Syntax

```
config_struct = H5F.get_mdc_config(file_id)
```

Description

`config_struct = H5F.get_mdc_config(file_id)` returns the current metadata cache configuration for the target file.

Examples

```
fid = H5F.open('example.h5');
config = H5F.get_mdc_config(fid);
H5F.close(fid);
```

See Also

`H5F.set_mdc_config`

H5F.get_mdc_hit_rate

Metadata cache hit-rate

Syntax

```
hitRate = H5F.get_mdc_hit_rate(file_id)
```

Description

`hitRate = H5F.get_mdc_hit_rate(file_id)` queries the metadata cache of the target file to obtain its hit-rate since the last time hit-rate statistics were reset. If the cache has not been accessed since the last time the hit-rate statistics were reset, the hit-rate is defined to be 0.0. The hit-rate is calculated as

```
(cache hits / (cache hits + cache misses))
```

Examples

```
fid = H5F.open('example.h5');
hit_rate = H5F.get_mdc_hit_rate(fid);
H5F.close(fid);
```

See Also

`H5F.get_mdc_config`

H5F.get_mdc_size

Metadata cache size data

Syntax

```
[max_sz,min_clean_sz,cursz,num_cur_entries] =
H5F.get_mdc_size(fileId)
```

Description

`[max_sz,min_clean_sz,cursz,num_cur_entries] = H5F.get_mdc_size(fileId)` queries the metadata cache of the target file to obtain current metadata cache size information.

Examples

```
fid = H5F.open('example.h5');
[maxsz,minsz,cursz,nent] = H5F.get_mdc_size(fid);
H5F.close(fid);
```

See Also

`H5F.get_mdc_config`

H5F.get_name

Name of HDF5 file

Syntax

```
name = H5F.get_name(obj_id)
```

Description

`name = H5F.get_name(obj_id)` returns the name of the file to which the object `obj_id` belongs. The object can be a group, dataset, attribute, or named data type.

Examples

```
fid = H5F.open('example.h5');
name = H5F.get_name(fid);
H5F.close(fid);
```

See Also

`H5A.get_name` | `H5I.get_name`

H5F.get_obj_count

Number of open objects in HDF5 file

Syntax

```
obj_count = H5F.get_obj_count(file_id,types)
```

Description

`obj_count = H5F.get_obj_count(file_id,types)` returns the number of open object identifiers for the file specified by `file_id` for the specified type. `types` can be one of the following strings.

```
'H5F_OBJ_FILE'
'H5F_OBJ_DATASET'
'H5F_OBJ_GROUP'
'H5F_OBJ_DATATYPE'
'H5F_OBJ_ATTR'
'H5F_OBJ_ALL'
'H5F_OBJ_LOCAL'
```

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
obj_count = H5F.get_obj_count(fid,'H5F_OBJ_GROUP');
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5F.get_obj_ids`

H5F.get_obj_ids

List of open HDF5 file objects

Syntax

```
[num_obj_ids,obj_id_list] = H5F.get_obj_ids(file_id,types,max_objs)
```

Description

`[num_obj_ids,obj_id_list] = H5F.get_obj_ids(file_id,types,max_objs)` returns a list of all open identifiers for HDF5 objects of the type specified by `types` in the file specified by `file_id`. The `max_objs` input specifies the maximum number of object identifiers to return. `num_obj_ids` is the total number of objects in the list. `types` can be one of the following strings.

```
'H5F_OBJ_FILE'
'H5F_OBJ_DATASET'
'H5F_OBJ_GROUP'
'H5F_OBJ_DATATYPE'
'H5F_OBJ_ATTR'
'H5F_OBJ_ALL'
'H5F_OBJ_LOCAL'
```

Examples

```
fid = H5F.open('example.h5');
gid1 = H5G.open(fid,'/g1');
gid2 = H5G.open(fid,'/g2');
gid3 = H5G.open(fid,'/g3');
gid4 = H5G.open(fid,'/g4');
[num_obj_ids,objs] = H5F.get_obj_ids(fid,'H5F_OBJ_GROUP',3);
H5G.close(gid1);
H5G.close(gid2);
```

```
H5G.close(gid3);
H5G.close(gid4);
H5F.close(fid);
```

See Also

H5F.get_obj_count

H5F.is_hdf5

Determine if file is HDF5

Syntax

```
value = H5F.is_hdf5(name)
```

Description

`value = H5F.is_hdf5(name)` returns a positive number if the file specified by `name` is in the HDF5 format, and zero if it is not. A negative return value indicates failure.

Examples

```
value = H5F.is_hdf5('example.tif');
if value > 0
    fprintf('example.tif is an HDF5 file\n');
else
    fprintf('example.tif is not an HDF5 file\n');
end
```

H5F.mount

Mount HDF5 file onto specified location

Syntax

```
H5F.mount(loc_id,name,child_id,plist_id)
```

Description

`H5F.mount(loc_id,name,child_id,plist_id)` mounts the file specified by `child_id` onto the group specified by `loc_id` and `name`, using the mount properties specified by `plist_id`.

Examples

Mount one file with a dataset onto a group in a second file and access the dataset via the second file.

```
plist = 'H5P_DEFAULT';
fid2 = H5F.create('file2.h5','H5F_ACC_TRUNC',plist,plist);
gid2 = H5G.create(fid2,'g2',plist,plist,plist);
fid1 = H5F.create('file1.h5','H5F_ACC_TRUNC','H5P_DEFAULT',...
  'H5P_DEFAULT');
space_id = H5S.create('H5S_SCALAR');
dset_id = H5D.create(fid1,'DS1','H5T_NATIVE_DOUBLE',space_id,plist);
H5S.close(space_id);
H5D.close(dset_id);
H5F.mount(fid2,'g2',fid1,plist);
dset_id1 = H5D.open(fid1,'/g2/DS1',plist);
H5D.close(dset_id1);
H5F.unmount(fid1,'g2');
H5G.close(gid2);
H5F.close(fid1);
H5F.close(fid2);
```

See Also

`H5F.unmount`

H5F.open

Open HDF5 file

Syntax

```
file_id = H5F.open(filename)
file_id = H5F.open(name,flags,fapl_id)
```

Description

`file_id = H5F.open(filename)` opens the file specified by `filename` for read-only access and returns the file identifier, `file_id`.

`file_id = H5F.open(name,flags,fapl_id)` opens the file specified by `name`, returning the file identifier, `file_id`. `flags` specifies file access flags and can be specified by one of the following strings or their numeric equivalents:

`'H5F_ACC_RDWR'`	read-write mode
`'H5F_ACC_RDONLY'`	read-only mode

The file access property list, `fapl_id`, may be specified as `'H5P_DEFAULT'`, in which case the default I/O settings are used.

Examples

Open a file in read-only mode with default file access properties.

```
fid = H5F.open('example.h5');
H5F.close(fid);
```

Open a file in read-write mode.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
```

```
H5F.close(fid);
```

See Also

H5F.close | H5ML.get_constant_value

H5F.reopen

Reopen HDF5 file

Syntax

```
new_file_id = H5F.reopen(file_id)
```

Description

`new_file_id = H5F.reopen(file_id)` returns a new file identifier for the already open HDF5 file specified by `file_id`.

See Also

`H5F.open`

H5F.set_mdc_config

Configure HDF5 file metadata cache

Syntax

```
H5F.set_mdc_config(fileId,config)
```

Description

`H5F.set_mdc_config(fileId,config)` attempts to configure the file's metadata cache according to the supplied configuration structure. Before using this function, you should retrieve the current configuration using `H5F.get_mdc_config`.

See Also

`H5F.get_mdc_config`

H5F.unmount

Unmount file or group from mount point

Syntax

```
H5F.unmount(loc_id,name)
```

Description

`H5F.unmount(loc_id,name)` dissassociates the file or group specified by `loc_id` from the mount point specified by `name`. `loc_id` can be a file or group identifier.

See Also

`H5F.mount`

H5G.close

Close group

Syntax

```
H5G.close(group_id)
```

Description

`H5G.close(group_id)` releases resources used by the group specified by `group_id`. `group_id` was returned by either `H5G.create` or `H5G.open`.

See Also

`H5G.create` | `H5G.open`

H5G.create

Create group

Syntax

```
group_id = H5G.create(loc_id,name,size_hint)
group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)
```

Description

`group_id = H5G.create(loc_id,name,size_hint)` creates a new group with the name specified by `name` at the location specified by `loc_id`. `loc_id` can be a file or group identifier. `size_hint` specifies the number of bytes to reserve for the names that will appear in the group. This interface corresponds to the 1.6 version of `H5Gcreate`.

`group_id = H5G.create(loc_id,name,lcpl_id,gcpl_id,gapl_id)` creates a new group with link creation, group creation, and group access property lists `lcpl_id`, `gcpl_id`, and `gapl_id`. This interface corresponds to the 1.8 version of `H5Gcreate`.

Examples

Create an HDF5 file `'myfile.h5'` with a group `'my_group'` with default property list settings.

```
fid = H5F.create('myfile.h5');
plist = 'H5P_DEFAULT';
gid = H5G.create(fid,'my_group',plist,plist,plist);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5G.close` | `H5G.open`

H5G.get_info

Information about group

Syntax

```
info = H5G.get_info(group_id)
```

Description

`info = H5G.get_info(group_id)` retrieves information about the group specified by `group_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
info = H5G.get_info(gid);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5G.create` | `H5G.open`

H5G.open

Open specified group

Syntax

```
group_id = H5G.open(loc_id,name)
group_id = H5G.open(loc_id,name,gapl_id)
```

Description

`group_id = H5G.open(loc_id,name)` opens the group specified by `name` at the location specified by `loc_id`. `loc_id` is a file or group identifier. This interface corresponds to the 1.6 version of `H5Gopen`.

`group_id = H5G.open(loc_id,name,gapl_id)` opens the group with an additional group access property list, `gapl_id`. This interface corresponds to the 1.8 version of `H5Gopen`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g2');
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5G.close` | `H5P.create`

H5I.dec_ref

Decrement reference count

Syntax

```
ref_count = H5I.dec_ref(obj_id)
```

Description

`ref_count = H5I.dec_ref(obj_id)` decrements the reference count of the object identified by `obj_id` and returns the new count.

See Also

`H5I.get_ref` | `H5I.inc_ref`

H5I.get_file_id

File identifier for specified object

Syntax

```
file_id = H5I.get_file_id(obj_id)
```

Description

`file_id = H5I.get_file_id(obj_id)` returns the identifier of the file associated with the object referenced by `obj_id`.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g4');
fid2 = H5I.get_file_id(gid);
name = H5F.get_name(fid2);
fprintf('The filename is %s.\n',name);
H5G.close(gid);
H5F.close(fid);
H5F.close(fid2);
```

H5I.get_name

Name of object

Syntax

```
name = H5I.get_name(obj_id)
```

Description

`name = H5I.get_name(obj_id)` returns the name of the object specified by `obj_id`. If no name is attached to the object, the empty string is returned.

Examples

Display the names of all the objects in the `/g3` group in the example file by alphabetical order.

```
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_INC';
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g3');
info = H5G.get_info(gid);
for j = 1:info.nlinks
    obj_id = H5O.open_by_idx(fid,'g3',idx_type,order,j-1,'H5P_DEFAULT');
    name = H5I.get_name(obj_id);
    fprintf('Object %d: ''%s''.\n',j-1,name);
    H5O.close(obj_id);
end
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5A.get_name` | `H5F.get_name`

H5I.get_ref

Reference count of object

Syntax

```
refcount = H5I.get_ref(obj_id)
```

Description

`refcount = H5I.get_ref(obj_id)` returns the reference count of the object specified by `obj_id`.

See Also

`H5I.dec_ref` | `H5I.inc_ref`

H5I.get_type

Type of object

Syntax

```
obj_type = H5I.get_type(obj_id)
```

Description

`obj_type = H5I.get_type(obj_id)` returns the type of the object specified by `obj_id`. `obj_type` corresponds to one of the following enumerated values.

```
H5I_FILE
H5I_GROUP
H5I_DATATYPE
H5I_DATASPACE
H5I_DATASET
H5I_ATTR
H5I_BADID
```

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g3');
dset_id = H5D.open(fid,'/g4/world');
[~,objs] = H5F.get_obj_ids(fid,'H5F_OBJ_ALL',3);
for j = 1:numel(objs)
    name = H5I.get_name(objs(j));
    fprintf('object ''%s'':  ==> ',name);
    type = H5I.get_type(objs(j));
    switch(type)
        case H5ML.get_constant_value('H5I_FILE')
            fprintf('FILE identifier.\n');
```

```
        case H5ML.get_constant_value('H5I_GROUP')
            fprintf('GROUP identifier.\n');
        case H5ML.get_constant_value('H5I_DATASET')
            fprintf('DATASET identifier.\n');
        otherwise
            fprintf('unknown identifier type.\n');
    end
end
H5G.close(gid);
H5F.close(fid);
```

See Also

H5ML.get_constant_value

H5I.inc_ref

Increment reference count of specified object

Syntax

```
ref_count = H5I.inc_ref(obj_id)
```

Description

`ref_count = H5I.inc_ref(obj_id)` increments the reference count of the object specified by `obj_id` and returns the new count.

See Also

`H5I.dec_ref` | `H5I.get_ref`

H5I.is_valid

Determine if specified identifier is valid

Syntax

```
tf = H5I.is_valid(obj_id)
```

Description

`tf = H5I.is_valid(obj_id)` determines whether the identifier `obj_id` is valid.

Examples

```
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.close(fapl);
if H5I.is_valid(fapl);
    fprintf('File access property list is valid.\n');
else
    fprintf('File access property list is not valid.\n');
end
```

H5L.copy

Copy link from source location to destination location

Syntax

```
H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)
```

Description

`H5L.copy(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)` copies the link specified by `src_name` from the file or group specified by `src_loc_id` to the destination `dest_loc_id`. The new copy of the link is created with the name `dest_name`.

`dest_loc_id` must refer to either the current file or a group in the current file. If `dest_loc_id` is the file identifier, the copy is placed in the file's root group.

The new link is created with the creation and access property lists specified by `lcpl_id` and `lapl_id`.

Examples

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist_id,plist_id);
g1 = H5G.create(fid,'g1',plist_id);
g2 = H5G.create(fid,'g2',plist_id);
g11 = H5G.create(g1,'g3',plist_id);
H5L.copy(g1,'g3',g2,'g4',plist_id,plist_id);
```

H5L.create_external

Create soft link to external object

Syntax

```
H5L.create_external(filename,objname,link_loc_id,link_name,lcpl_id,lapl_id)
```

Description

`H5L.create_external(filename,objname,link_loc_id,link_name,lcpl_id,lapl_id)` creates a soft link to an object in a different file. `filename` identifies the target file containing the target object. `obj_name` specifies the path to the target object within that file. `obj_name` must start at the target file's root group but is not interpreted until lookup time.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

Examples

```
plist_id = 'H5P_DEFAULT';
fid1 = H5F.create('myfile1.h5');
g1 = H5G.create(fid1,'g1',plist_id,plist_id,plist_id);
H5G.close(g1);
H5F.close(fid1);
fid2 = H5F.create('myfile2.h5');
H5L.create_external('myfile1.h5','g1',fid2,'g2',plist_id,plist_id);
```

H5L.create_hard

Create hard link

Syntax

```
H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,lcpl_id,lapl_id)
```

Description

`H5L.create_hard(obj_loc_id,obj_name,link_loc_id,link_name,lcpl_id,lapl_id)` creates a new hard link to a pre-existing object in an HDF5 file. The new link may be one of many that point to that object. `obj_loc_id` and `obj_name` specify the location and name, respectively, of the target object, i.e., the object to which the new hard link points.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

Examples

```
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid,'/g1',0);
gid2 = H5G.create(gid1,'g2',0);
gid3 = H5G.create(gid2,'g3',0);
lcpl = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_hard(gid2,'g3',gid1,'g4',lcpl,lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```

See Also

`H5L.create_soft`

H5L.create_soft

Create soft link

Syntax

```
H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,lapl_id)
```

Description

`H5L.create_soft(target_path,link_loc_id,link_name,lcpl_id,lapl_id)` creates a new soft link to an object in an HDF5 file. The new link may be one of many that point to that object. `target_path` specifies the path to the target object, i.e., the object that the new soft link points to. `target_path` can be anything and is interpreted at lookup time. This `target_path` may be absolute in the file or relative to `link_loc_id`.

`link_loc_id` and `link_name` specify the location and name, respectively, of the new link. `link_name` is interpreted relative to `link_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

Examples

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5');
gid1 = H5G.create(fid,'/g1',0);
gid3 = H5G.create(gid1,'g3',0);
gid2 = H5G.create(fid,'/g2',0);
lcpl = 'H5P_DEFAULT';
lapl = 'H5P_DEFAULT';
H5L.create_soft('/g1/g3',gid2,'g4',lcpl,lapl);
H5G.close(gid3);
H5G.close(gid2);
H5G.close(gid1);
H5F.close(fid);
```

See Also

`H5L.create_hard`

H5L.delete

Remove link

Syntax

```
H5L.delete(loc_id,name,lapl_id)
```

Description

`H5L.delete(loc_id,name,lapl_id)` removes the link specified by name from the location `loc_id`. `lapl_id` is a link access property list identifier.

Examples

Remove the only link to the `'/g3'` group in `example.h5`.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
H5L.delete(fid,'g3','H5P_DEFAULT');
H5F.close(fid);
```

See Also

`H5L.move`

H5L.exists

Determine if link exists

Syntax

```
bool = H5L.exists(loc_id,name,lapl_id)
```

Description

`bool = H5L.exists(loc_id,name,lapl_id)` checks if a link specified by the pairing of an object id and name exists within a group. `lapl_id` is a link access property list identifier.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.2/g1.2.1');
if H5L.exists(gid,'slink','H5P_DEFAULT')
    fprintf('link exists\n');
else
    fprintf('link does not exist\n');
end
```

H5L.get_info

Information about link

Syntax

```
linkStruct = H5L.get_info(location_id,link_name,lapl_id)
```

Description

`linkStruct = H5L.get_info(location_id,link_name,lapl_id)` returns information about a link.

A file or group identifier, `location_id`, specifies the location of the link. `link_name`, interpreted relative to `link_id`, specifies the link being queried.

Examples

```
fid = H5F.open('example.h5');
info = H5L.get_info(fid,'g3','H5P_DEFAULT');
H5F.close(fid);
```

H5L.get_name_by_idx

Information about link specified by index

Syntax

```
name =
H5L.get_name_by_idx(loc_id,group_name,idx_type,order,n,lapl_id)
```

Description

`name = H5L.get_name_by_idx(loc_id,group_name,idx_type,order,n,lapl_id)` retrieves information about a link at index `n`, present in group `group_name`, at location `loc_id`. The `lapl_id` input specifies the link access property list for querying the group.

`idx_type` is the type of index and valid values include the following.

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

`order` specifies the index traversal order. Valid values include the following.

`'H5_ITER_INC'`	Iteration from beginning to end
`'H5_ITER_DEC'`	Iteration from end to beginning
`'H5_ITER_NATIVE'`	Iteration in the fastest available order

Examples

```
fid = H5F.open('example.h5');
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
lapl_id = 'H5P_DEFAULT';
name = H5L.get_name_by_idx(fid,'g3',idx_type,order,0,lapl_id);
H5F.close(fid);
```

H5L.get_val

Value of symbolic link

Syntax

```
linkval = H5L.get_val(link_loc_id,link_name,lapl_id)
```

Description

`linkval = H5L.get_val(link_loc_id,link_name,lapl_id)` returns the value of a symbolic link.

`link_loc_id` is a file or group identifier. `link_name` identifies a symbolic link and is defined relative to `link_loc_id`. Symbolic links include soft and external links and some user-defined links.

In the case of soft links, `linkval` is a cell array containing the path to which the link points.

In the case of external links, `linkval` is a cell array consisting of the name of the target file and the object name.

This function corresponds to the `H5L.get_val` and `H5Lunpack_elink_val` functions in the HDF5 1.8 C API.

Examples

```
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/g1/g1.2/g1.2.1');
linkval = H5L.get_val(gid,'slink','H5P_DEFAULT');
H5G.close(gid);
H5F.close(fid);
```

H5L.iterate

Iterate over links

Syntax

```
[status,idx_out,opdata_out] =
H5L.iterate(group_id,index_type,order,idx_in,iter_func,opdata_in)
```

Description

`[status,idx_out,opdata_out] = H5L.iterate(group_id,index_type,order,idx_in,iter_func,opdata_in)` iterates through the links in a group, specified by `group_id`, to perform a common function whose function handle is `iter_func`. `H5L.iterate` does not recursively follow links into subgroups of the specified group.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they will first be sorted by that index then the iteration will begin. If the links have been so indexed, the sorting step will be unnecessary, so the iteration may begin more quickly. Valid values include the following:

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following:

`'H5_ITER_INC'`	Increasing order
`'H5_ITER_DEC'`	Decreasing order
`'H5_ITER_NATIVE'`	Fastest available order

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows:

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

H5L.iterate_by_name

Iterate through links in group specified by name

Syntax

```
[status,idx_out,opdata_out] =
H5L.iterate_by_name(loc_id,group_name,index_type,order,idx_in,iter_func,opdata
```

Description

`[status,idx_out,opdata_out] = H5L.iterate_by_name(loc_id,group_name,index_type,order,idx_in,iter_func,opdata` iterates through the links in a group to perform a common function whose function handle is `iter_func`. The starting point of the iteration is pairing of a specified by the location id and a relative group name. `H5L.iterate_by_name` does not recursively follow links into subgroups of the specified group. A link access property list, `lapl_id`, may affect the outcome depending upon the type of link being traversed.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they will first be sorted by that index then the iteration will begin. If the links have been so indexed, the sorting step will be unnecessary, so the iteration may begin more quickly. Valid values include the following:

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following:

`'H5_ITER_INC'`	Increasing order
`'H5_ITER_DEC'`	Decreasing order
`'H5_ITER_NATIVE'`	Fastest available order

`idx_in` specifies the starting point of the iteration. `idx_out` returns the point at which iteration was stopped. This allows an interrupted iteration to be resumed.

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final opdata_out at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows:

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

H5L.move

Rename link

Syntax

```
H5L.move(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)
```

Description

`H5L.move(src_loc_id,src_name,dest_loc_id,dest_name,lcpl_id,lapl_id)` renames a link within an HDF5 file. The original link, `src_name`, is removed from the group graph and the new link, `dest_name`, is inserted; this change is accomplished as an atomic operation.

`src_loc_id` and `src_name` identify the existing link. `src_loc_id` is either a file or group identifier; `src_name` is the path to the link and is interpreted relative to `src_loc_id`.

`dest_loc_id` and `dest_name` identify the new link. `dest_loc_id` is either a file or group identifier; `dest_name` is the path to the link and is interpreted relative to `dest_loc_id`.

`lcpl_id` and `lapl_id` are the link creation and link access property lists, respectively, associated with the new link, `dest_name`.

Examples

Rename the `'/g2'` group to `'/g2/g3'`.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.h5');
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
g2id = H5G.open(fid,'g2');
H5L.move(fid,'g3',g2id,'g3','H5P_DEFAULT','H5P_DEFAULT');
H5G.close(g2id);
```

```
H5F.close(fid);
```

See Also

H5L.delete

H5L.visit

Recursively iterate through links in group specified by group identifier

Syntax

```
[status opdata_out] =
H5L.visit(group_id,index_type,order,iter_func,opdata_in)
```

Description

`[status opdata_out] = H5L.visit(group_id,index_type,order,iter_func,opdata_in)` recursively iterates through all links in and below a group, specified by `group_id`, to perform a common function whose function handle is `iter_func`.

`index_type` and order establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.)

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

`'H5_ITER_INC'`	Increasing order
`'H5_ITER_DEC'`	Decreasing order

`'H5_ITER_NATIVE'`	Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

H5L.visit_by_name

Recursively iterate through links in group specified by location and group name

Syntax

```
[status,opdata_out] =
H5L.visit_by_name(loc_id,group_name,index_type,order,iter_func,opdata_in,lapl_
```

Description

`[status,opdata_out] = H5L.visit_by_name(loc_id,group_name,index_type,order,iter_func,opdata_in,lapl_` recursively iterates though all links in and below a group to perform a common function whose function handle is `iter_func`. The starting point of the iteration is specified by the pairing of a location id and a relative group name. A link access property list, `lapl_id`, may affect the outcome depending upon the type of link being traversed.

`index_type` and `order` establish the iteration. `index_type` specifies the index to be used. If the links have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.)

`order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

`'H5_ITER_INC'`	Increasing order

`'H5_ITER_DEC'`	Decreasing order
`'H5_ITER_NATIVE'`	Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

H5ML.compare_values

Numerically compare two HDF5 values

Syntax

```
bEqual = H5ML.compare_values(value1,value2)
```

Description

`bEqual = H5ML.compare_values(value1,value2)` compares two values, where either or both values may be represented as a string. The values are compared numerically.

Function parameters:

`bEqual`	A logical value indicating whether the two values are equal
`value1`	The first value to be compared
`value2`	The second value to be compared

Examples

```
val = H5ML.get_constant_value('H5T_NATIVE_INT');
H5ML.compare_values(val,'H5T_NATIVE_INT')
```

H5ML.get_constant_names

Constants known by HDF5 library

Syntax

```
names = H5ML.get_constant_names()
```

Description

`names = H5ML.get_constant_names()` returns a list of known library constants, definitions, and enumerations. When these strings are supplied as actual parameters to HDF5 functions, they are automatically be converted to the appropriate numeric value.

Function parameters.

`names`	An alphabetized cell array of names

H5ML.get_constant_value

Value corresponding to a string

Syntax

```
value = H5ML.get_constant_value(constant)
```

Description

`value = H5ML.get_constant_value(constant)` returns the value corresponding to a given string. The string should correspond to an enumeration (for example, `'H5_ENUM_T'`) or a predefined identifier (for example, `'H5T_NATIVE_INT'`). Since the value corresponding to a given string is not guaranteed to remain the same, it is almost always preferable to use the `H5ML.compare_values()` function instead.

Function parameters:

`value`	The value corresponding to the supplied string
`constant`	A string that corresponds to a HDF5 enumeration or defined value.

Examples

```
a = H5ML.get_constant_value('H5T_NATIVE_INT');
```

H5ML.get_function_names

Functions provided by HDF5 library

Syntax

```
names = H5ML.get_function_names()
```

Description

`names = H5ML.get_function_names()` returns a list of supported library functions.

Function parameters:

`names`	An alphabetized cell array of names

H5ML.get_mem_datatype

Data type for dataset ID

Syntax

```
DTYPE_ID = H5ML.get_mem_datatype(LOCATION_ID)
```

Description

`DTYPE_ID = H5ML.get_mem_datatype(LOCATION_ID)` returns the ID of an HDF5 memory datatype for the dataset or attribute identified by `LOCATION_ID`. This HDF5 memory datatype is the default used by `H5D.read` or `H5D.write` when you specify `'H5ML_DEFAULT'` as a value of the memory data type parameter.

The identifier returned by `H5ML.get_mem_datatype` should eventually be closed by calling `H5T.close` to release resources.

Examples

```
file_id = H5F.open('example.h5','H5F_ACC_RDONLY','H5P_DEFAULT');
dset_id = H5D.open(file_id,'/g1/g1.1/dset1.1.1');
datatype_id = H5ML.get_mem_datatype(dset_id)
H5T.close(datatype_id);
H5D.close(dset_id);
H5F.close(file_id);
```

H5ML.hoffset

Determine the offset of a field within a structure

Note: `H5ML.hoffset` is not recommended. Use `H5T` instead.

Syntax

Description

This function is used to determine the offset (in bytes) of a structure, `H5T.insert(file_type,'a', offset(1), dtype(1));`, within a field. It is used when constructing an HDF5 COMPOUND type. It is designed to correspond to the HDF5 HOFFSET macro. For more details about the operation of the HOFFSET macro, please consult the HDF5 documentation.

Function parameters:

`offset`	The byte offset of the field within the structure.
`structure`	The structure which contains the specified fieldname.
`fieldname`	The field for which the offset is determined.

Examples

This function is deprecated. It can only be used in workflows that do not include a field that is itself an HDF5 COMPOUND or of variable length. To handle these cases, the offsets should be computed directly. For example, in the case above, a file dataspace for such a compound could be created with:

```
dtype(1) = H5T.copy('H5T_NATIVE_INT');
```

```
dtype(2) = H5T.copy('H5T_NATIVE_DOUBLE');
dtype(3) = H5T.copy('H5T_NATIVE_FLOAT');

for j = 1:3, sz(j,1) = H5T.get_size(dtype(j)); end

% The first offset would always be zero and the size of the last
% field does not matter.
offset(1) = 0;
offset(2:3) = cumsum(sz(1:2));

file_type = H5T.create('H5T_COMPOUND',sum(sz));

H5T.insert(file_type,'a', offset(1), dtype(1));
H5T.insert(file_type,'b', offset(2), dtype(2));
H5T.insert(file_type,'c', offset(3), dtype(3));
```

See Also

H5T.get_size

H5ML.sizeof

Return the size (in bytes) of a variable as stored on disk

Note: `H5ML.sizeof` is not recommended. Use `H5T` instead.

Syntax

Description

This function is used to determine the size (in bytes) of a structure or other (simple) variable. It is designed to correspond to the C sizeof() operator as it is used during the creation of HDF5 datatypes, especially the HDF5 COMPOUND type.

Function parameters:

`size`	The size (in bytes) of the variable as it would be stored on disk.
`arg`	The variable for which the size is being sought.

Examples

This function is deprecated. It can only be used in workflows that do not include a field that is itself an HDF5 COMPOUND or of variable length. To handle these cases, the offsets should be computed directly. For example, in the case above, a file dataspace for such a compound could be created with:

```
dtype(1) = H5T.copy('H5T_NATIVE_INT');
dtype(2) = H5T.copy('H5T_NATIVE_DOUBLE');
dtype(3) = H5T.copy('H5T_NATIVE_FLOAT');

for j = 1:3, sz(j,1) = H5T.get_size(dtype(j)); end
```

```
% The first offset would always be zero and the size of the last
% field does not matter.
offset(1) = 0;
offset(2:3) = cumsum(sz(1:2));

file_type = H5T.create('H5T_COMPOUND',sum(sz));

H5T.insert(file_type,'a', offset(1), dtype(1));
H5T.insert(file_type,'b', offset(2), dtype(2));
H5T.insert(file_type,'c', offset(3), dtype(3));
```

H5T.get_size

H5O.close

Close object

Syntax

```
H5O.close(obj_id)
```

Description

`H5O.close(obj_id)` closes the object specified by `obj_id`. `obj_id` cannot be a dataspace, attribute, property list, or file.

H5O.copy

Copy object from source location to destination location

Syntax

```
H5O.copy(src_loc_id,src_name,dst_loc_id,dst_name,ocpypl_id,lcpl_id)
```

Description

`H5O.copy(src_loc_id,src_name,dst_loc_id,dst_name,ocpypl_id,lcpl_id)` copies the group, dataset or named datatype specified by `src_name` from the file or group specified by `src_loc_id` to the destination location `dst_loc_id`.

The destination location, as specified in `dst_loc_id`, may be a group in the current file or a location in a different file. If `dst_loc_id` is a file identifier, the copy will be placed in that file's root group.

The new copy will be created with the name `dst_name`. `dst_name` must not pre-exist in the destination location. If `dst_name` already exists at the location `dst_loc_id`, the operation will fail.

The new copy of the object is created with the object creation property and link creation property lists `ocpypl_id` and `lcpl_id`, respectively.

Examples

Copy the group `'/g3'` and all its datasets to a new group `'/g3.5'`.

```
srcFile = [matlabroot '/toolbox/matlab/demos/example.h5'];
copyfile(srcFile,'myfile.h5');
fileattrib('myfile.h5','+w');
ocpl = H5P.create('H5P_OBJECT_COPY');
lcpl = H5P.create('H5P_LINK_CREATE');
H5P.set_create_intermediate_group(lcpl,true);
fid = H5F.open('myfile.h5','H5F_ACC_RDWR','H5P_DEFAULT');
gid = H5G.open(fid,'/');
```

```
H5O.copy(gid,'g3',gid,'g3.5',ocpl,lcpl);
H5G.close(gid);
H5P.close(ocpl);
H5P.close(lcpl);
H5F.close(fid);
```

H5O.get_comment

Get comment for object specified by object identifier

Syntax

```
comment = H5O.get_comment(obj_id)
```

Description

`comment = H5O.get_comment(obj_id)` retrieves the comment for the object specified by `obj_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'g4/world');
comment = H5O.get_comment(dset_id);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5O.get_comment_by_name` | `H5O.set_comment` | `H5O.set_comment_by_name`

H5O.get_comment_by_name

Get comment for object specified by location and object name

Syntax

```
comment = H5O.get_comment_by_name(loc_id,name,lapl_id)
```

Description

`comment = H5O.get_comment_by_name(loc_id,name,lapl_id)` retrieves a comment where a location id and name together specify the object. A link access property list can affect the outcome if a link is traversed to access the object.

Examples

```
fid = H5F.open('example.h5','H5F_ACC_RDONLY','H5P_DEFAULT');
comment = H5O.get_comment_by_name(fid,'g4/world','H5P_DEFAULT');
H5F.close(fid);
```

H5O.get_info

Object metadata

Syntax

```
info = H5O.get_info(obj_id)
```

Description

`info = H5O.get_info(obj_id)` retrieves the metadata for an object specified by `obj_id`. For details about the object metadata, please refer to the HDF5 documentation.

Examples

Determine the number of attributes for a dataset.

```
fid = H5F.open('example.h5','H5F_ACC_RDONLY','H5P_DEFAULT');
dsetId = H5D.open(fid,'/g1/g1.1/dset1.1.1');
info = H5O.get_info(dsetId);
info.num_attrs
```

Determine the type of objects in the root group.

```
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
gid = H5G.open(fid,'/');
root_info = H5G.get_info(gid);
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
for j = 0:root_info.nlinks-1
   obj_id = H5O.open_by_idx(fid,'/',idx_type,order,j,plist);
   obj_info = H5O.get_info(obj_id);
   switch(obj_info.type)
       case H5ML.get_constant_value('H5G_LINK')
           fprintf('Object #%d is a link.\n',j);
       case H5ML.get_constant_value('H5G_GROUP')
           fprintf('Object #%d is a group.\n',j);
```

```
        case H5ML.get_constant_value('H5G_DATASET')
            fprintf('Object #%d is a dataset.\n',j);
        case H5ML.get_constant_value('H5G_TYPE')
            fprintf('Object #%d is a named datatype.\n',j);
    end
    H5O.close(obj_id);
end
H5G.close(gid);
H5F.close(fid);
```

H5D.open | H5F.open | H5G.open | H5T.open

H5O.link

Create hard link to specified object

Syntax

```
H5O.link(obj_id,new_loc_id,new_link_name,lcpl_id,lapl_id)
```

Description

`H5O.link(obj_id,new_loc_id,new_link_name,lcpl_id,lapl_id)` creates a hard link to an object, where `new_loc_id` and `new_link_name` specify the location. `lcpl_id` and `lapl_id` are the link creation and access property lists associated with the new link.

`H5O.link` is designed to add additional structure to an existing file so that, for example, an object can be shared among multiple groups.

Examples

Create a hard link from group `'/g2'` to the dataset `'/g1/ds1'`.

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist_id,plist_id);
gid1 = H5G.create(fid,'/g1',plist_id);
space_id = H5S.create_simple(1,10,[]);
ds1 = H5D.create(gid1,'ds1','H5T_NATIVE_INT',space_id,plist_id);
gid2 = H5G.create(fid,'/g2',plist_id);
H5O.link(ds1,gid2,'ds2',plist_id,plist_id);
H5D.close(ds1);
H5S.close(space_id);
H5G.close(gid2); H5G.close(gid1);
H5F.close(fid);
```

See Also

`H5L.create_hard` | `H5L.create_soft`

H5O.open

Open specified object

Syntax

```
obj_id = H5O.open(loc_id,relname,lapl_id)
```

Description

`obj_id = H5O.open(loc_id,relname,lapl_id)` opens an object specified by location identifier and relative path name. `lapl_id` is the link access property list associated with the link pointing to the object. If default link access properties are appropriate, this can be passed in as `'H5P_DEFAULT'`.

Examples

```
fid = H5F.open('example.h5');
obj_id = H5O.open(fid,'g3','H5P_DEFAULT');
H5O.close(obj_id);
H5F.close(fid);
```

See Also

`H5O.close` | `H5O.open_by_idx`

H5O.open_by_idx

Open object specified by index

Syntax

```
obj_id = H5O.open_by_idx(loc_id, group_name, idx_type, order, n,
lapl_id)
```

Description

`obj_id = H5O.open_by_idx(loc_id, group_name, idx_type, order, n, lapl_id)` opens the `n`-th object in the group specified by `loc_id` and `group_name`. `loc_id` specifies a file or group. `group_name` specifies the group relative to `loc_id` in which the object can be found.

Two parameters are used to establish the iteration: `index_type` and `order`. `index_type` specifies the type of index by which objects are ordered. Valid values include the following:

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

`order` specifies the order in which the links are to be referenced for the purposes of this function. Valid values include the following:

`'H5_ITER_INC'`	Increasing order
`'H5_ITER_DEC'`	Decreasing order
`'H5_ITER_NATIVE'`	Fastest available order

`n` specifies the zero-based position of the object within the index. `lapl_id` specifies the link access property list to be used in accessing the object.

Examples

```
fid = H5F.open('example.h5');
```

```
idx_type = 'H5_INDEX_NAME';
order = 'H5_ITER_DEC';
obj_id = H5O.open_by_idx(fid,'g3',idx_type,order,0,'H5P_DEFAULT');
H5O.close(obj_id);
H5F.close(fid);
```

See Also

H5O.close | H5O.open

H5O.set_comment

Set comment for object specified by object identifier

Syntax

```
H5O.set_comment(obj_id,comment)
```

Description

`H5O.set_comment(obj_id,comment)` sets a comment for the object specified by `obj_id`.

Examples

```
plist = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist,plist);
gid = H5G.create(fid,'/g1',plist);
H5O.set_comment(gid,'This is a group comment.');
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5O.get_comment` | `H5O.get_comment_by_name` | `H5O.set_comment_by_name`

H5O.set_comment_by_name

Set comment for object specified by location and object name

Syntax

```
H5O.set_comment_by_name(loc_id,rel_name,comment,lapl_id)
```

Description

`H5O.set_comment_by_name(loc_id,rel_name,comment,lapl_id)` sets a comment for an object specified by a location ID and a relative name. `lapl_id` is a link access property list identifier that can affect the outcome if links are traversed.

Examples

```
plist = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist,plist);
gid = H5G.create(fid,'/g1',plist);
H5O.set_comment_by_name(fid,'g1','This is a group comment.',plist);
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5O.get_comment` | `H5O.get_comment_by_name` | `H5O.set_comment`

H5O.visit

Visit objects specified by object identifier

Syntax

```
[status,opdata_out] =
H5O.visit(obj_id,index_type,order,iter_func,opdata_in)
```

Description

`[status,opdata_out] = H5O.visit(obj_id,index_type,order,iter_func,opdata_in)` is a recursive iteration function to visit the object `object_id` and, if `object_id` is a group, all objects in and below it in an HDF5 file. This provides a mechanism for an application to perform a common set of operations across all of those objects or a dynamically selected subset.

If `object_id` is a group identifier, that group serves as the root of a recursive iteration. If `object_id` is a file identifier, that file's root group serves as the root of the recursive iteration. If `object_id` is any other type of object, such as a dataset or named data type, there is no iteration.

Two parameters are used to establish the iteration: `index_type` and `order`. The `index_type` parameter specifies the index used. If the links in a group have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin. If the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.) `order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

'H5_ITER_INC'	Increasing order
'H5_ITER_DEC'	Decreasing order
'H5_ITER_NATIVE'	Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

See Also

`H5O.visit_by_name`

H5O.visit_by_name

Visit objects specified by location and object name

Syntax

```
[status,opdata_out] =
H5O.visit_by_name(loc_id,obj_name,index_type,order,iter_func,opdata_in,lapl_id
```

Description

`[status,opdata_out] = H5O.visit_by_name(loc_id,obj_name,index_type,order,iter_func,opdata_in,lapl_id` specifies the object by the pairing of the location identifier and object name. `loc_id` specifies a file or an object in a file and `obj_name` specifies an object in the file with either an absolute name or relative to `loc_id`. A link access property list can affect the outcome if links are involved.

Two parameters are used to establish the iteration: `index_type` and `order`. The `index_type` parameter specifies the index to be used. If the links in a group have not been indexed by the index type, they are first sorted by that index, and then the iteration will begin; if the links have been so indexed, the sorting step is unnecessary, so the iteration can begin more quickly. Valid values include the following.

`'H5_INDEX_NAME'`	Alpha-numeric index on name
`'H5_INDEX_CRT_ORDER'`	Index on creation order

Note that the index type passed in `index_type` is a best effort setting. If the application passes in a value indicating iteration in creation order and a group is encountered that was not tracked in creation order, that group will be iterated over in alpha-numeric order by name, or name order. (Name order is the native order used by the HDF5 Library and is always available.) `order` specifies the order in which objects are to be inspected along the index specified in `index_type`. Valid values include the following.

`'H5_ITER_INC'`	Increasing order
`'H5_ITER_DEC'`	Decreasing order

`'H5_ITER_NATIVE'`	Fastest available order

The callback function `iter_func` must have the following signature:

```
function [status,opdata_out] = iter_func(group_id,name,opdata_in)
```

`opdata_in` is a user-defined value or structure and is passed to the first step of the iteration in the `iter_func` `opdata_in` parameter. The `opdata_out` of an iteration step forms the `opdata_in` for the next iteration step. The final `opdata_out` at the end of the iteration is then returned to the caller as `opdata_out`.

`lapl_id` is a link access property list. When default link access properties are acceptable, `'H5P_DEFAULT'` can be used.

`status` value returned by `iter_func` is interpreted as follows.

zero	Continues with the iteration or returns zero status value to the caller if all members have been processed
positive	Stops the iteration and returns the positive status value to the caller
negative	Stops the iteration and throws an error indicating failure

`H5O.visit`

H5P.close

Close property list

Syntax

```
H5P.close(plist_id)
```

Description

`H5P.close(plist_id)` terminates access to the property list specified by `plist_id`.

See Also

`H5P.create`

H5P.copy

Copy of property list

Syntax

```
plist_copy = H5P.copy(plist_id)
```

Description

`plist_copy = H5P.copy(plist_id)` returns a copy of the property list specified by `plist_id`.

Examples

Make a copy of the file creation property list for `'example.h5'`.

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
fcpl2 = H5P.copy(fcpl);
```

H5P.create

Create new property list

Syntax

```
plist = H5P.create(class_id)
```

Description

`plist = H5P.create(class_id)` creates a new property list as an instance of the property list class specified by `class_id`. The `class_id` input can be one of the following strings or the corresponding constant value.

```
'H5P_ATTRIBUTE_CREATE'
'H5P_DATASET_ACCESS'
'H5P_DATASET_CREATE'
'H5P_DATASET_XFER'
'H5P_DATATYPE_CREATE'
'H5P_DATATYPE_ACCESS'
'H5P_FILE_MOUNT'
'H5P_FILE_CREATE'
'H5P_FILE_ACCESS'
'H5P_GROUP_CREATE'
'H5P_GROUP_ACCESS'
'H5P_LINK_CREATE'
'H5P_LINK_ACCESS'
'H5P_OBJECT_COPY'
'H5P_OBJECT_CREATE'
'H5P_STRING_CREATE'
```

`class_id` can also be an instance of a property list class.

Examples

```
fapl = H5P.create('H5P_FILE_ACCESS');
fid = H5F.open('example.h5','H5F_ACC_RDONLY',fapl);
```

See Also

H5ML.get_constant_value | H5P.close | H5P.get_class

H5P.get_class

Property list class

Syntax

```
plist_class = H5P.get_class(plist_id)
```

Description

`plist_class = H5P.get_class(plist_id)` returns the property list class for the property list specified by `plist_id`.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
pclass = H5P.get_class(fcpl);
name = H5P.get_class_name(pclass);
```

See Also

`H5P.get_class_name`

H5P.close_class

Close property list class

Syntax

```
H5P.close_class(class)
```

Description

`H5P.close_class(class)` closes the property list class specified by `pclass_id`.

H5P.equal

Determine equality of property lists

Syntax

```
value = H5P.equal(plist1_id, plist2_id)
```

Description

`value = H5P.equal(plist1_id, plist2_id)` returns a positive number if the two property lists specified are equal, and zero if they are not. A negative value indicates failure.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
fcpl = H5F.get_create_plist(fid);
if H5P.equal(fapl,fcpl)
    fprintf('property lists are equal\n');
else
    fprintf('property lists are not equal\n');
end
```

H5P.exist

Determine if specified property exists in property list

Syntax

```
value = H5P.exist(prop_id, name)
```

Description

`value = H5P.exist(prop_id, name)` returns a positive value if the property specified by the text string `name` exists within the property list or class specified by `prop_id`.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
if H5P.exist(fapl,'sieve_buf_size')
    fprintf('sieve buffer size property exists\n');
else
    fprintf('sieve buffer size property does not exist\n');
end
```

H5P.get

Value of specified property in property list

Syntax

```
value = H5P.get(plist_id, name)
```

Description

`value = H5P.get(plist_id, name)` retrieves a copy of the value of the property specified by the text string `name` in the property list specified by `plist_id`. The `H5P.get` function returns the property as an array of `uint8` values. You might need to cast the value to an appropriate data type to get a meaningful result.

Examples

```
plist = H5P.create('H5P_FILE_ACCESS');
val = H5P.get(plist, 'rdcc_w0');
rdcc_w0 = typecast(val,'double');
```

It is recommended to use alternative functions like `H5P.get_chunk`, `H5P.get_layout`, `H5P.get_size` etc., where available, to get values for the common property names.

See Also

`H5P.set` | `typecast`

H5P.get_class_name

Name of property list class

Syntax

```
classname = H5P.get_class_name(pclass_id)
```

Description

`classname = H5P.get_class_name(pclass_id)` retrieves the name of the generic property list class. `classname` is a text string. If no class is found, the empty string is returned.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
pclass = H5P.get_class(fcpl);
name = H5P.get_class_name(pclass);
```

See Also

`H5P.get_class`

H5P.get_class_parent

Identifier for parent class

Syntax

```
pclass_obj_id = H5P.get_class_parent(pclass_id)
```

Description

`pclass_obj_id = H5P.get_class_parent(pclass_id)` returns an identifier to the parent class object of the property class specified by `pclass_id`.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
fcpl_class = H5P.get_class(fcpl);
parent_class = H5P.get_class_parent(fcpl_class);
name = H5P.get_class_name(parent_class);
```

See Also

`H5P.get_class` | `H5P.get_class_name`

H5P.get_nprops

Query number of properties in property list or class

Syntax

```
nprops = H5P.get_nprops(id)
```

Description

`nprops = H5P.get_nprops(id)` returns the number of properties in the property list or class specified by `id`.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
nprops = H5P.get_nprops(fcpl);
```

H5P.get_size

Query size of property value in bytes

Syntax

```
sz = H5P.get_size(id,name)
```

Description

`sz = H5P.get_size(id,name)` returns the size, in bytes, of the property specified by the text string `name` in the property list or property class specified by `id`.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_size(fapl,'sieve_buf_size');
```

H5P.isa_class

Determine if property list is member of class

Syntax

```
output = H5P.isa_class(plist_id, pclass_id)
```

Description

`output = H5P.isa_class(plist_id, pclass_id)` returns a positive number if the property list specified by `plist_id` is a member of the class specified by `pclass_id`, zero if it is not, and a negative value to indicate an error.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
if H5P.isa_class(fcpl,'H5P_FILE_ACCESS')
    fprintf('fcpl is a file access property list\n');
else
    fprintf('fcpl is not a file access property list\n');
end
```

See Also

`H5P.get_class`

H5P.iterate

Iterate over properties in property list

Syntax

```
[output,idx_out] = H5P.iterate(id,idx_in,iter_func)
```

Description

`[output,idx_out] = H5P.iterate(id,idx_in,iter_func)` executes the operation `iter_func` on each property in the property object specified in `id`. The `id` input can be a property list or a property class. `idx_in` specifies the index of the next property to be processed. `output` is the value returned by the last call to `iter_func`. `idx_out` is the index of the last property processed. `iter_func` is a function handle.

The iterator function must have the following signature:

```
status = iter_func(id,prop_name)
```

`id` still identifies the property object passed into `H5P.iterate`, but `name` identifies the name of the current property.

H5P.set

Set property list value

Syntax

```
H5P.set(plist_id,name,value)
```

Description

`H5P.set(plist_id,name,value)` sets the value of the property specified by the text string `name` in the property list specified by `plist_id` to the value specified in `value`. The datatype of `value` must be `uint8`.

Examples

```
plist = H5P.create('H5P_FILE_ACCESS');
H5P.set(plist, 'rdcc_w0', typecast(0.8, 'uint8'));
```

It is recommended to use alternative functions like `H5P.set_chunk`, `H5P.set_layout`, `H5P.set_size`, etc., where available, to set values for the common property names.

See Also

`typecast`

H5P.get_btree_ratios

B-tree split ratios

Syntax

```
[left,middle,right] = H5P.get_btree_ratios(plist_id)
```

Description

`[left,middle,right] = H5P.get_btree_ratios(plist_id)` returns the B-tree split ratios for the dataset transfer property list specified by `plist_id`. The `left` output specifies the B-tree split ratio for left-most nodes. `right` corresponds to the right-most nodes and lone nodes, and `middle` corresponds to all other nodes.

Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
[left,middle,right] = H5P.get_btree_ratios(dxpl);
```

See Also

`H5P.set_btree_ratios`

H5P.get_chunk_cache

Raw data chunk cache parameters

Syntax

```
[rdcc_nslots,rdcc_nbytes,rdcc_w0] = H5P.get_chunk_cache(dapl_id)
```

Description

`[rdcc_nslots,rdcc_nbytes,rdcc_w0] = H5P.get_chunk_cache(dapl_id)` retrieves the number of chunk slots in the raw data chunk cache hash table (`rdcc_nslots`), the maximum possible number of bytes in the raw data chunk cache (`rdcc_nbytes`), and the preemption policy value (`rdcc_w0`) on a dataset access property list.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/vlen3D');
dapl = H5D.get_access_plist(dset_id);
[rrdcc_nslots,rdcc_nbytes,rdcc_w0] = H5P.get_chunk_cache(dapl);
H5P.close(dapl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.set_chunk_cache`

H5P.get_dxpl_multi

Data access property lists for multiple files

Note: `H5P.get_dxpl_multi` has been removed.

Syntax

```
memb_dxpl = H5P.get_dxpl_multi(dxpl_id)
```

Description

`memb_dxpl = H5P.get_dxpl_multi(dxpl_id)` returns an array of data access property lists for the multifile data transfer property list specified by `dxpl_id`.

H5P.get_edc_check

Determine if error detection is enabled

Syntax

```
check = H5P.get_edc_check(plist_id)
```

Description

`check = H5P.get_edc_check(plist_id)` queries the dataset transfer property list, specified by `plist_id`, to determine whether error detection is enabled for data read operations. Returns either `H5Z_ENABLE_EDC` or `H5Z_DISABLE_EDC`.

Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
check = H5P.get_edc_check(dxpl);
switch(check)
    case H5ML.get_constant_value('H5Z_ENABLE_EDC')
        fprintf('error detection enabled\n');
    case H5ML.get_constant_value('H5Z_DISABLE_EDC');
        fprintf('error detection disabled\n');
end
```

See Also

`H5P.set_edc_check`

H5P.get_hyper_vector_size

Number of I/O vectors

Syntax

```
sz = H5P.get_hyper_vector_size(dxpl_id)
```

Description

`sz = H5P.get_hyper_vector_size(dxpl_id)` returns the number of I/O vectors to be read/written in hyperslab I/O.

Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
sz = H5P.get_hyper_vector_size(dxpl);
```

See Also

`H5P.set_hyper_vector_size`

H5P.set_btree_ratios

Set B-tree split ratios for dataset transfer

Syntax

```
H5P.set_btree_ratios(plist_id,left,middle,right)
```

Description

`H5P.set_btree_ratios(plist_id,left,middle,right)` sets the B-tree split ratios for the dataset transfer property list specified by `plist_id`. The `left` argument specifies the B-tree split ratio for left-most nodes. `right` specifies the B-tree split ratio for right-most nodes and lone nodes. `middle` specifies the B-tree split ratio for all other nodes.

Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
H5P.set_btree_ratios(dxpl, 0.2, 0.6, 0.95);
```

See Also

`H5P.get_btree_ratios`

H5P.set_chunk_cache

Set raw data chunk cache parameters

Syntax

```
H5P.set_chunk_cache(dapl_id, rdcc_nslots, rdcc_nbytes, rdcc_w0)
```

Description

`H5P.set_chunk_cache(dapl_id, rdcc_nslots, rdcc_nbytes, rdcc_w0)` sets the number of elements (`rdcc_nslots`), the total number of bytes (`rdcc_nbytes`), and the preemption policy value (`rdcc_w0`) in the raw data chunk cache.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/vlen3D');
dapl = H5D.get_access_plist(dset_id);
H5P.set_chunk_cache(dapl,500,1e6,0.7);
H5P.close(dapl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.get_chunk_cache`

H5P.set_dxpl_multi

Set data transfer property list for multifile driver

Note: `H5P.set_dxpl_multi` has been removed.

Syntax

```
H5P.set_dxpl_multi(dxpl_id, memb_dxpl)
```

Description

`H5P.set_dxpl_multi(dxpl_id, memb_dxpl)` sets the data transfer property list `dxpl_id` to use the multifile driver. `memb_dxpl` is an array of data access property lists.

H5P.set_edc_check

Enable error detection for dataset transfer

Syntax

```
H5P.set_edc_check(plist_id,check)
```

Description

`H5P.set_edc_check(plist_id,check)` sets the dataset transfer property list specified by `plist_id` to enable or disable error detection when reading data. `check` can have the value `H5Z_ENABLE_EDC` or `H5Z_DISABLE_EDC`.

Examples

Disable error detection for a default dataset transfer property list.

```
dxpl = H5P.create('H5P_DATASET_XFER');
H5P.set_edc_check(dxpl,'H5Z_DISABLE_EDC');
```

See Also

`H5P.get_edc_check`

H5P.set_hyper_vector_size

Set number of I/O vectors for hyperslab I/O

Syntax

```
H5P.set_hyper_vector_size(dxpl_id,size)
```

Description

`H5P.set_hyper_vector_size(dxpl_id,size)` sets the number of I/O vectors to be accumulated in memory before being issued to the lower levels of the HDF5 library for reading or writing the actual data. `dxpl_id` is a dataset transfer property list identifier. `size` specifies the number of I/O vectors to accumulate in memory for I/O operations.

Examples

```
dxpl = H5P.create('H5P_DATASET_XFER');
H5P.set_hyper_vector_size(dxpl,2048);
```

See Also

`H5P.get_hyper_vector_size`

H5P.all_filters_avail

Determine availability of all filters

Syntax

```
value = H5P.all_filters_avail(dcpl_id)
```

Description

`value = H5P.all_filters_avail(dcpl_id)` returns a positive value if all of the filters set in the dataset creation property list `dcpl_id` are currently available, and zero if they are not. A negative value indicates failure.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/float');
dcpl = H5D.get_create_plist(dset_id);
if H5P.all_filters_avail(dcpl)
    fprintf('all filters available\n');
else
    fprintf('all filters not available\n');
end
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.set_filter`

H5P.fill_value_defined

Determine if fill value is defined

Syntax

```
fvstatus = H5P.fill_value_defined(plist_id)
```

Description

`fvstatus = H5P.fill_value_defined(plist_id)` determines whether a fill value is defined in the dataset creation property list `plist_id`. The `fvstatus` output can have any of the following values: `H5D_FILL_VALUE_UNDEFINED`, `H5D_FILL_VALUE_DEFAULT`, or `H5D_FILL_VALUE_USER_DEFINED`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/float');
dcpl = H5D.get_create_plist(dset_id);
fvstatus = H5P.fill_value_defined(dcpl);
switch(fvstatus)
    case H5ML.get_constant_value('H5D_FILL_VALUE_UNDEFINED')
        fprintf('fill value undefined\n');
    case H5ML.get_constant_value('H5D_FILL_VALUE_DEFAULT')
        fprintf('fill value set to default\n');
    case H5ML.get_constant_value('H5D_FILL_VALUE_USER_DEFINED')
        fprintf('fill value is user defined\n');
end
```

See Also

`H5P.get_fill_value` | `H5P.set_fill_value`

H5P.get_alloc_time

Return timing of storage space allocation

Syntax

```
alloc_time = H5P.get_alloc_time(plist_id)
```

Description

`alloc_time = H5P.get_alloc_time(plist_id)` retrieves the timing for storage space allocation from the dataset creation property list specified by `plist_id`. The `alloc_time` output can have any of the following values: `H5D_ALLOC_TIME_DEFAULT`, `H5D_ALLOC_TIME_EARLY`, `H5D_ALLOC_TIME_INCR`, or `H5D_ALLOC_TIME_LATE`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
alloc_time = H5P.get_alloc_time(dcpl);
switch(alloc_time)
    case H5ML.get_constant_value('H5D_ALLOC_TIME_DEFAULT')
        fprintf('allocation time is default\n');
    case H5ML.get_constant_value('H5D_ALLOC_TIME_EARLY')
        fprintf('allocation time is dataset creation time\n');
    case H5ML.get_constant_value('H5D_ALLOC_TIME_INCR')
        fprintf('allocation time is incremental\n');
    case H5ML.get_constant_value('H5D_ALLOC_TIME_LATE')
        fprintf('allocation time is when data is first written\n');
end
```

H5P.get_chunk

Return size of chunks

Syntax

```
[rank,h5_chunk_dims] = H5P.get_chunk(plist_id)
```

Description

`[rank,h5_chunk_dims] = H5P.get_chunk(plist_id)` retrieves the size of chunks for the raw data of a chunked layout dataset for the dataset creation property list specified by `plist_id`.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_chunk_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g4/time');
dcpl = H5D.get_create_plist(dset_id);
[rank,chunk_dims] = H5P.get_chunk(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.set_chunk`

H5P.get_external

Return information about external file

Syntax

```
[name,offset,size] = H5P.get_external(plist_id,idx)
```

Description

`[name,offset,size] = H5P.get_external(plist_id,idx)` returns information about the external file specified by the dataset creation property list `plist_id`. The `idx` specifies the external file index, which is a number from zero to `N-1`, where `N` is the value returned by `H5P.get_external_count`. The `name` output returns the name of the external file (limited by 2048 characters). The `offset` output returns the location in bytes, from the beginning of the external file, where the data starts. The `size` output returns the size of the external data.

See Also

`H5P.get_external_count`

H5P.get_external_count

Return count of external files

Syntax

```
num_files = H5P.get_external_count(plist_id)
```

Description

`num_files = H5P.get_external_count(plist_id)` returns the number of external files for the dataset creation property list, `plist_id`.

See Also

`H5P.get_external`

H5P.get_fill_time

Return time when fill values are written to dataset

Syntax

```
fill_time = H5P.get_fill_time(plist_id)
```

Description

`fill_time = H5P.get_fill_time(plist_id)` returns the time when fill values are written to the dataset specified by the dataset creation property list `plist_id`. The `fill_time` output is one of the following values: `H5D_FILL_TIME_IFSET`, `H5D_FILL_TIME_ALLOC`, or `H5D_FILL_TIME_NEVER`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
fill_time = H5P.get_fill_time(dcpl);
switch(fill_time)
    case H5ML.get_constant_value('H5D_FILL_TIME_IFSET')
        fprintf('upon allocation if and only if fill value set by user\n');
    case H5ML.get_constant_value('H5D_FILL_TIME_ALLOC')
        fprintf('written when storage space is allocated\n');
    case H5ML.get_constant_value('H5D_FILL_TIME_NEVER')
        fprintf('fill values are never written\n');
end
```

See Also

`H5P.get_fill_time` | `H5P.set_fill_value`

H5P.get_fill_value

Return dataset fill value

Syntax

```
value = H5P.get_fill_value(plist_id,type_id)
```

Description

`value = H5P.get_fill_value(plist_id,type_id)` returns the dataset fill value defined in the dataset creation property list `plist_id`. The `type_id` input specifies the datatype of the returned fill value.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
type_id = H5T.copy('H5T_NATIVE_INT');
fill_value = H5P.get_fill_value(dcpl,type_id);
```

See Also

`H5P.get_fill_time` | `H5P.set_fill_time` | `H5P.set_fill_value`

H5P.get_filter

Return information about filter in pipeline

Syntax

```
[filter,flags,cd_values,name] = H5P.get_filter(plist_id,index)
[filter,flags,cd_values,name,filter_config] =
H5P.get_filter(plist_id,index)
```

Description

`[filter,flags,cd_values,name] = H5P.get_filter(plist_id,index)` returns information about the filter, specified by its filter index, in the filter pipeline, specified by the property list with which it is associated. This interface corresponds to the 1.6 version of `H5Pget_filter` in the HDF5 library.

`[filter,flags,cd_values,name,filter_config] = H5P.get_filter(plist_id,index)` returns information about the filter, specified by its filter index, in the filter pipeline, specified by the property list with which it is associated. It also returns information about the filter. Consult the HDF5 documentation for `H5Zget_filter_info` for information about `filter_config`. This interface corresponds to the 1.8 version of `H5Pget_filter` in the HDF5 library.

See Also

`H5P.get_filter_by_id` | `H5P.get_nfilters` | `H5P.modify_filter` | `H5P.remove_filter`

H5P.get_filter_by_id

Return information about specified filter

Syntax

```
[flags,cd_values,name,filter_config] =
H5P.get_filter_by_id(plist_id,idx)
```

Description

`[flags,cd_values,name,filter_config] = H5P.get_filter_by_id(plist_id,idx)` returns information about the filter specified by the filter id, `idx`.

See Also

`H5P.get_filter` | `H5P.get_nfilters` | `H5P.modify_filter` | `H5P.remove_filter`

H5P.get_layout

Determine layout of raw data for dataset

Syntax

```
layout = H5P.get_layout(dcpl)
```

Description

`layout = H5P.get_layout(dcpl)` returns the layout of the raw data for the dataset specified by the dataset creation property list, `dcpl`. Possible values are: `H5D_COMPACT`, `H5D_CONTIGUOUS`, or `H5D_CHUNKED`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
layout = H5P.get_layout(dcpl);
switch(layout)
    case H5ML.get_constant_value('H5D_COMPACT')
        fprintf('layout is compact\n');
    case H5ML.get_constant_value('H5D_CONTIGUOUS')
        fprintf('layout is contiguous\n');
    case H5ML.get_constant_value('H5D_CHUNKED')
        fprintf('layout is chunked\n');
end
```

See Also

`H5P.set_layout`

H5P.get_nfilters

Return number of filters in pipeline

Syntax

```
num_filters = H5P.get_nfilters(plist_id)
```

Description

`num_filters = H5P.get_nfilters(plist_id)` returns the number of filters defined in the filter pipeline associated with the dataset creation property list, `plist_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g4/world');
dcpl = H5D.get_create_plist(dset_id);
num_filters = H5P.get_nfilters(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.get_filter` | `H5P.get_filter_by_id` | `H5P.modify_filter` | `H5P.remove_filter`

H5P.modify_filter

Modify filter in pipeline

Syntax

```
H5P.modify_filter(plist_id,filter_id,flags,cd_values)
```

Description

`H5P.modify_filter(plist_id,filter_id,flags,cd_values)` modifies the specified filter in the filter pipeline. `plist_id` is a property list identifier. `flags` is a bit vector specifying certain general properties of the filter. `cd_values` specifies auxiliary data for the filter.

See Also

`H5P.get_filter` | `H5P.get_filter_by_id` | `H5P.get_nfilters` | `H5P.remove_filter`

H5P.remove_filter

Remove filter from property list

Syntax

```
H5P.remove_filter(plist_id,filter)
```

Description

`H5P.remove_filter(plist_id,filter)` removes the specified filter from the filter pipeline. `plist_id` is the dataset creation property list identifier.

See Also

`H5P.get_filter` | `H5P.get_filter_by_id` | `H5P.get_nfilters` | `H5P.modify_filter`

H5P.set_alloc_time

Set timing for storage space allocation

Syntax

```
H5P.set_alloc_time(plist_id,alloc_time)
```

Description

`H5P.set_alloc_time(plist_id,alloc_time)` sets the timing for the allocation of storage space for a dataset's raw data. `plist_id` is a dataset creation property list. `alloc_time` can have any of the following values: `H5D_ALLOC_TIME_DEFAULT`, `H5D_ALLOC_TIME_EARLY`, `H5D_ALLOC_TIME_INC`, or `H5D_ALLOC_TIME_LATE`.

Examples

Create a 1000x500 double precision dataset with late allocation time.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [1000 500];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
alloc_time = H5ML.get_constant_value('H5D_ALLOC_TIME_LATE');
H5P.set_alloc_time(dcpl,alloc_time);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.get_alloc_time`

H5P.set_chunk

Set chunk size

Syntax

```
H5P.set_chunk(plist_id,h5_chunk_dims)
```

Description

`H5P.set_chunk(plist_id,h5_chunk_dims)` sets the size of the chunks used to store a chunked layout dataset. `plist_id` is a dataset creation property list identifier. `h5_chunk_dims` is an array specifying the size, in dataset elements, of each chunk.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_chunk_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Create a two dimensional double precision dataset that has an initial size of [512 1024], but is also unlimited in both dimensions and has a chunk size of [512 1024].

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
unlimited = H5ML.get_constant_value('H5S_UNLIMITED');
dims = [512 1024];
h5_dims = fliplr(dims);
h5_maxdims = [unlimited unlimited];
space_id = H5S.create_simple(2,[1024 512],h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [512 1024];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
```

```
H5D.close(dset_id);
H5F.close(fid);
```

See Also

H5P.get_chunk

H5P.set_deflate

Set compression method and compression level

Syntax

```
H5P.set_deflate(plist_id,level)
```

Description

`H5P.set_deflate(plist_id,level)` sets the compression method for the dataset creation property list specified by `plist_id` to `H5D_COMPRESS_DEFLATE`. `level` specifies the compression level as a value from 0 and 9, inclusive. Lower values results in less compression.

Examples

Create a two dimensional double precision dataset that has an initial size of [512 1024], but is also unlimited in both dimensions and has a chunk size of [512 1024] and a compression level of 5.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
unlimited = H5ML.get_constant_value('H5S_UNLIMITED');
dims = [512 1024];
h5_dims = fliplr(dims);
h5_maxdims = [unlimited unlimited];
space_id = H5S.create_simple(2,[1024 512],h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [512 1024];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_deflate(dcpl,5);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

H5P.set_external

Add additional file to external file list

Syntax

```
H5P.set_external(plist_id,name,offset,nbytes)
```

Description

`H5P.set_external(plist_id,name,offset,nbytes)` adds the external file specified by `name` to the list of external files in the dataset creation property list, `plist_id`. The `offset` argument specifies the location, in bytes, where the data starts relative to the beginning of the file. `nbytes` is the number of bytes reserved in the file for the data. `nbytes` may also be given as `'H5F_UNLIMITED'`, in which case the external file may be of unlimited size.

Examples

Create a dataset with an unlimited size external file.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 50];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
H5P.set_external(dcpl,'myexternalfile.dat',0,'H5F_UNLIMITED');
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
data = rand(dims);
dxpl = 'H5P_DEFAULT';
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',dxpl,data);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5ML.get_constant_value` | `H5P.get_external`

H5P.set_fill_time

Set time when fill values are written to dataset

Syntax

```
H5P.set_fill_time(plist_id,fill_time)
```

Description

`H5P.set_fill_time(plist_id,fill_time)` sets the timing for writing fill values to a dataset in the dataset creation property list `plist_id`. The timing can be specified by one of the following values: `H5D_FILL_TIME_IFSET`, `H5D_FILL_TIME_ALLOC`, or `H5D_FILL_TIME_NEVER`.

Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 50];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
fill_time = H5ML.get_constant_value('H5D_FILL_TIME_ALLOC');
H5P.set_fill_time(dcpl,fill_time);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.get_fill_time` | `H5P.get_fill_value` | `H5P.set_fill_value`

H5P.set_fill_value

Set fill value for dataset creation property list

Syntax

```
H5P.set_fill_value(plist_id,type_id,value)
```

Description

`H5P.set_fill_value(plist_id,type_id,value)` sets the fill value for a the dataset creation property list specified by `plist_id`. The `value` argument specifies the fill value. `type_id` specifies the datatype of the fill value. Setting `value` to an empty array indicates that the fill value is to be undefined.

Examples

Create a double precision dataset with a fill value of -999.

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 50];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = H5P.create('H5P_DATASET_CREATE');
fill_time = H5ML.get_constant_value('H5D_FILL_TIME_ALLOC');
H5P.set_fill_time(dcpl,fill_time);
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
H5P.set_fill_value(dcpl,type_id,-999);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

H5P.set_filter

Add filter to filter pipeline

Syntax

```
H5P.set_filter(plist_id,filter,flags,cd_values)
```

Description

`H5P.set_filter(plist_id,filter,flags,cd_values)` adds the specified filter and corresponding properties to the end of an output filter pipeline. `plist_id` is a property list identifier. `filter` is a filter identifier and should correspond to one of the following values:

```
H5P_FILTER_DEFLATE
H5P_FILTER_SHUFFLE
H5P_FILTER_FLETCHER32
```

`flags` is a bit vector specifying properties of the filter. `cd_values` is an array that contains auxiliary data for the filter.

See Also

`H5P.set_deflate` | `H5P.set_fletcher32` | `H5P.set_shuffle`

H5P.set_fletcher32

Set Fletcher32 checksum filter in dataset creation

Syntax

```
H5P.set_fletcher32(plist_id)
```

Description

`H5P.set_fletcher32(plist_id)` sets the Fletcher32 checksum filter in the dataset creation property list specified by `plist_id`. The dataset creation property list must also have chunking enabled.

Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [10 20];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_fletcher32(dcpl);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.set_deflate` | `H5P.set_shuffle`

H5P.set_layout

Set type of storage for dataset

Syntax

```
H5P.set_layout(dcpl,layout)
```

Description

`H5P.set_layout(dcpl,layout)` sets the type of storage used to store the raw data for the dataset creation property list, `dcpl`. The `layout` argument specifies the type of storage layout for raw data: `H5D_COMPACT`, `H5D_CONTIGUOUS`, or `H5D_CHUNKED`.

Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
layout = H5ML.get_constant_value('H5D_CONTIGUOUS');
H5P.set_layout(dcpl,layout);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.get_layout` | `H5P.set_chunk`

H5P.set_nbit

Set N-Bit filter

Syntax

```
H5P.set_nbit(plist_id)
```

Description

`H5P.set_nbit(plist_id)` sets the N-Bit filter, `H5Z_FILTER_NBIT`, in the dataset creation property list `plist_id`.

H5P.set_scaleoffset

Set Scale-Offset filter

Syntax

```
H5P.set_scaleoffset(plistId,scaleType,scaleFactor)
```

Description

`H5P.set_scaleoffset(plistId,scaleType,scaleFactor)` sets the Scale-Offset filter, `H5Z_FILTER_SCALEOFFSET`, for a dataset. For integer data types, the parameter `scaleType` should be set to the enumerated value `H5Z_SO_INT`. For floating-point data types, the `scaleType` should be the enumerated value `H5Z_SO_FLOAT_DSCALE`. Chunking must already be enabled on the dataset creation property list.

See Also

`H5P.set_chunk`

H5P.set_shuffle

Set shuffle filter

Syntax

```
H5P.set_shuffle(plist_id)
```

Description

`H5P.set_shuffle(plist_id)` sets the shuffle filter, `H5Z_FILTER_SHUFFLE`, in the dataset creation property list `plist_id`. Compression must be enabled on the dataset creation property list in order to use the shuffle filter, and best results are usually obtained when the shuffle filter is set immediately prior to setting the deflate filter.

Examples

```
fid = H5F.create('myfile.h5');
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,dims,[]);
dcpl = H5P.create('H5P_DATASET_CREATE');
chunk_dims = [10 20];
h5_chunk_dims = fliplr(chunk_dims);
H5P.set_chunk(dcpl,h5_chunk_dims);
H5P.set_shuffle(dcpl);
H5P.set_deflate(dcpl,5);
dset_id = H5D.create(fid,'DS',type_id,space_id,dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.set_deflate`

H5P.get_alignment

Retrieve alignment properties

Syntax

```
[threshold,alignment] = H5P.get_alignment(plist_id)
```

Description

`[threshold,alignment] = H5P.get_alignment(plist_id)` retrieves the current settings for alignment properties from the file access property list specified by `plist_id`.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
[threshold,alignment] = H5P.get_alignment(fapl);
H5P.close(fapl);
H5F.close(fid);
```

H5P.get_driver

Low-level file driver

Syntax

```
driver_id = H5P.get_driver(plist_id)
```

Description

`driver_id = H5P.get_driver(plist_id)` returns the identifier of the low-level file driver associated with the file access property list or data transfer property list specified by `plist_id`. See HDF5 documentation for a list of valid return values.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
driver_id = H5P.get_driver(fapl);
if ( driver_id == H5ML.get_constant_value('H5FD_SEC2') )
    fprintf('File driver is H5FD_SEC2.\n');
end
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5ML.get_constant_value`

H5P.get_family_offset

Offset for family file driver

Syntax

```
offset = H5P.get_family_offset(fapl_id)
```

Description

`offset = H5P.get_family_offset(fapl_id)` retrieves the value of offset from the file access property list, `fapl_id`. `offset` is the offset of the data in the HDF5 file that is stored on disk in the selected member file in a family of files.

See Also

`H5P.set_family_offset`

H5P.get_fapl_core

Information about core file driver properties

Syntax

```
[increment,backing_store] = H5P.get_fapl_core(fapl_id)
```

Description

`[increment,backing_store] = H5P.get_fapl_core(fapl_id)` queries the `H5FD_CORE` driver properties as set by `H5P.set_fapl_core`. The `fapl_id` argument specifies a file access property list. The return value `increment` specifies the size, in bytes, of memory increments. `backing_store` is a Boolean flag indicating whether to write the file contents to disk when the file is closed.

See Also

`H5P.set_fapl_core`

H5P.get_fapl_family

File access property list information

Syntax

```
[memb_size,memb_fapl_id] = H5P.get_fapl_family(fapl_id)
```

Description

`[memb_size,memb_fapl_id] = H5P.get_fapl_family(fapl_id)` returns the size in bytes of each file member and the identifier of the file access property list for use with the family driver specified by `fapl_id`.

See Also

`H5P.set_fapl_family`

H5P.get_fapl_multi

Information about multifile access property list

Syntax

```
[memb_map,memb_fapl,memb_name,memb_addr,relax] =
H5P.get_fapl_multi(fapl_id)
```

Description

`[memb_map,memb_fapl,memb_name,memb_addr,relax] = H5P.get_fapl_multi(fapl_id)` returns information about the multifile access property list specified by `fapl_id`. The `memb_map` output maps memory usage types to other memory usage types. `memb_fapl` is a property list for each memory usage type. `memb_name` is the name generator for names of member files. `relax` is a Boolean value that, when non-zero, allows read-only access to incomplete file sets.

See Also

`H5P.set_fapl_multi`

H5P.get_fclose_degree

File close degree

Syntax

```
degree = H5P.get_fclose_degree(fapl_id)
```

Description

`degree = H5P.get_fclose_degree(fapl_id)` returns the current setting of the file close degree property `fc_degree` in the file access property list specified by `fapl_id`. Possible return values are: `H5F_CLOSE_DEFAULT`, `H5F_CLOSE_WEAK`, `H5F_CLOSE_SEMI`, or `H5F_CLOSE_STRONG`.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
degree = H5P.get_fclose_degree(fapl);
switch(degree)
    case H5ML.get_constant_value('H5F_CLOSE_DEFAULT')
        fprintf('file close degree is default\n');
    case H5ML.get_constant_value('H5F_CLOSE_WEAK')
        fprintf('file close degree is weak\n');
    case H5ML.get_constant_value('H5F_CLOSE_SEMI')
        fprintf('close degree is semi\n');
    case H5ML.get_constant_value('H5F_CLOSE_STRONG')
        fprintf('close degree is strong\n');
end
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5P.set_fclose_degree`

H5P.get_libver_bounds

Library version bounds settings

Syntax

```
[low,high] = H5P.get_libver_bounds(fapl_id)
```

Description

`[low,high] = H5P.get_libver_bounds(fapl_id)` gets bounds on library version bounds settings that control the format versions used when creating objects in the file with access property list `fapl_id`.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
[low,high] = H5P.get_libver_bounds(fapl);
```

See Also

`H5F.get_access_plist` | `H5P.set_libver_bounds`

H5P.get_gc_references

Garbage collection references setting

Syntax

```
gc_ref = H5P.get_gc_references(fapl_id)
```

Description

`gc_ref = H5P.get_gc_references(fapl_id)` returns the current setting for the garbage collection references property from the file access property list specified by `fapl_id`. If `gc_ref` is `1`, garbage collection is on; if `0`, garbage collection is off.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
gc_ref = H5P.get_gc_references(fapl);
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5P.set_gc_references`

H5P.get_mdc_config

Metadata cache configuration

Syntax

```
config_struct = H5P.get_mdc_config(plist_id)
```

Description

`config_struct = H5P.get_mdc_config(plist_id)` returns the current metadata cache configuration from the indicated file access property list.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
config = H5P.get_mdc_config(fapl);
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5P.set_mdc_config`

H5P.get_meta_block_size

Metadata block size setting

Syntax

```
sz = H5P.get_meta_block_size(fapl_id)
```

Description

`sz = H5P.get_meta_block_size(fapl_id)` returns the current minimum size, in bytes, of new metadata block allocations.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_meta_block_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5P.set_meta_block_size`

H5P.get_multi_type

Type of data property for MULTI driver

Syntax

```
type = H5P.get_multi_type(fapl_id)
```

Description

`type = H5P.get_multi_type(fapl_id)` returns the type of data setting from the file access or data transfer property list, `fapl_id`.

This function should only be used with an HDF5 file written as a set of files with the MULTI file driver.

See Also

`H5P.set_multi_type`

H5P.get_sieve_buf_size

Maximum data sieve buffer size

Syntax

```
sz = H5P.get_sieve_buf_size(fapl_id)
```

Description

`sz = H5P.get_sieve_buf_size(fapl_id)` returns the current maximum size of the data sieve buffer.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_sieve_buf_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5P.set_sieve_buf_size`

H5P.get_small_data_block_size

Small data block size setting

Syntax

```
sz = H5P.get_small_data_block_size(fapl_id)
```

Description

`sz = H5P.get_small_data_block_size(fapl_id)` returns the current setting for the size of the small data block. `fapl_id` is a file access property list identifier.

Examples

```
fid = H5F.open('example.h5');
fapl = H5F.get_access_plist(fid);
sz = H5P.get_small_data_block_size(fapl);
H5P.close(fapl);
H5F.close(fid);
```

See Also

`H5P.set_small_data_block_size`

H5P.set_alignment

Set alignment properties for file access property list

Syntax

```
H5P.set_alignment(fapl_id,threshold,alignment)
```

Description

`H5P.set_alignment(fapl_id,threshold,alignment)` sets the alignment properties of the file access property list specified by `fapl_id` so that any file object greater than or equal in size to threshold (in bytes) is aligned on an address which is a multiple of alignment.

In most cases the default values of threshold and alignment result in the best performance.

See Also

`H5P.get_alignment`

H5P.set_family_offset

Set offset property for family of files

Syntax

```
H5P.set_family_offset(fapl_id,offset)
```

Description

`H5P.set_family_offset(fapl_id,offset)` sets offset property in the file access property list specified by `fapl_id` for low-level access to a file in a family of files. `offset` identifies a user-determined location from the beginning of the HDF5 file in bytes.

See Also

`H5P.get_family_offset`

H5P.set_fapl_core

Modify file access to use H5FD_CORE driver

Syntax

```
H5P.set_fapl_core(fapl_id,increment,backing_store)
```

Description

`H5P.set_fapl_core(fapl_id,increment,backing_store)` modifies the file access property list to use the H5FD_CORE driver. `increment` specifies the increment by which allocated memory is to be increased each time more memory is required. `backing_store` is a Boolean flag that, when non-zero, indicates the file contents should be written to disk when the file is closed.

Examples

Create a file image in memory only.

```
plist = 'H5P_DEFAULT';
ndatasets = 20;
block_size = 1024*1024;
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_core(fapl,2^16,false);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist,fapl);
space_id = H5S.create_simple(1, block_size, []);
type_id = H5T.copy('H5T_IEEE_F64LE');
data = zeros(block_size,1);
for j = 1:ndatasets
 dsname = sprintf( 'dset%02d', j);
 fprintf( 'Writing dataset %s...\n',dsname);
 dsid = H5D.create(fid,dsname,type_id,space_id,'H5P_DEFAULT');
 H5D.write(dsid,'H5ML_DEFAULT',space_id,space_id,plist,data);
 H5D.close(dsid);
end
H5P.close(fapl);
H5S.close(space_id);
```

```
H5T.close(type_id);
H5F.close(fid);
dir('myfile.h5');
```

H5P.get_fapl_core

H5P.set_fapl_family

Set file access to use family driver

Syntax

```
H5P.set_fapl_family(fapl_id,memb_size,memb_fapl_id)
```

Description

`H5P.set_fapl_family(fapl_id,memb_size,memb_fapl_id)` sets the file access property list, specified by `fapl_id`, to use the family driver. `memb_size` is the size in bytes of each file member. `memb_fapl_id` is the identifier of the file access property list to be used for each family member.

Examples

```
plist = 'H5P_DEFAULT';
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_family(fapl, 8192, plist);
fid = H5F.create('family%d.h5','H5F_ACC_TRUNC','H5P_DEFAULT',fapl);
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [50 25];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,[]);
dset_id = H5D.create(fid,'DS',type_id,space_id,plist)
data = reshape(1:prod(dims),dims);
H5D.write(dset_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',plist,data);
H5P.close(fapl);
H5T.close(type_id);
H5S.close(space_id);
H5D.close(dset_id);
dir('*.h5');
h5disp('family%d.h5');
```

See Also

`H5P.get_fapl_family`

H5P.set_fapl_log

Set use of logging driver

Syntax

```
H5P.set_fapl_log(fapl_id,logfile,flags,buf_size)
```

Description

`H5P.set_fapl_log(fapl_id,logfile,flags,buf_size)` modifies the file access property list, `fapl_id`, to use the logging driver H5FD_LOG. `logfile` is the name of the file in which the logging entries are to be recorded. `flags` is a bit mask that specifies the types of activity to log. See the HDF5 documentation for a list of available flag settings. `buf_size` specifies the size of the logging buffer.

H5P.set_fapl_multi

Set use of multifile driver

Syntax

```
H5P.set_fapl_multi(fapl_id,relax)
H5P.set_fapl_multi(fapl_id,memb_map,memb_fapl,memb_name,memb_addr,relax)
```

Description

`H5P.set_fapl_multi(fapl_id,relax)` sets the file access property list, `fapl_id`, to access HDF5 files created with the multi-driver with default values provided by the HDF5 library. `relax` is a Boolean value that allows read-only access to incomplete file sets when set to `1`.

`H5P.set_fapl_multi(fapl_id,memb_map,memb_fapl,memb_name,memb_addr,relax)` sets the file access property list to use the multifile driver. `memb_map` maps memory usage types to other memory usage types. `memb_fapl` contains a property list for each memory usage type. `memb_name` is a name generator for names of member files. `memb_addr` specifies the offsets within the virtual address space at which each type of data storage begins.

See Also

`H5P.get_fapl_multi`

H5P.set_fapl_sec2

Set file access for sec2 driver

Syntax

```
H5P.set_fapl_sec2(fapl_id)
```

Description

`H5P.set_fapl_sec2(fapl_id)` modifies the file access property list, `fapl_id`, to use the H5FD_SEC2 driver.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_sec2(fapl);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

H5P.set_fapl_split

Set file access for emulation of split file driver

Syntax

```
H5P.set_fapl_split(fapl_id,meta_ext,meta_plist_id,raw_ext,raw_plist_id)
```

Description

`H5P.set_fapl_split(fapl_id,meta_ext,meta_plist_id,raw_ext,raw_plist_id)` is a compatibility function that enables the multi-file driver to emulate the split driver from HDF5 Releases 1.0 and 1.2. `meta_ext` is a text string that specifies the metadata filename extension. `meta_plist_id` is a file access property list identifier for the metadata file. `raw_ext` is a text string that specifies the raw data filename extension. `raw_plist_id` is the file access property list identifier for the raw data file.

H5P.set_fapl_stdio

Set file access for standard I/O driver

Syntax

```
H5P.set_fapl_stdio(fapl_id)
```

Description

`H5P.set_fapl_stdio(fapl_id)` modifies the file access property list, `fapl_id`, to use the standard I/O driver, H5FD_STDIO.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fapl_stdio(fapl);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

H5P.set_fclose_degree

Set file access for file close degree

Syntax

```
H5P.set_fclose_degree(fapl_id,degree)
```

Description

`H5P.set_fclose_degree(fapl_id,degree)` sets the file close degree property in the file access property list, `fapl_id`, to the value specified by `degree`. The `degree` argument can have any of the following values:

`'H5F_CLOSE_WEAK'`

`'H5F_CLOSE_SEMI'`

`'H5F_CLOSE_STRONG'`

`'H5F_CLOSE_DEFAULT'`

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_fclose_degree(fapl,'H5F_CLOSE_STRONG');
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_fclose_degree`

H5P.set_gc_references

Set garbage collection references flag

Syntax

```
H5P.set_gc_references(fapl_id,gc_ref)
```

Description

`H5P.set_gc_references(fapl_id,gc_ref)` sets the flag for garbage collecting references for the file specified by the file access property list identifier, `fapl_id`. The `gc_ref` argument is a flag setting reference garbage collection to on (`1`) or off (`0`).

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_gc_references(fapl,1);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_gc_references`

H5P.set_libver_bounds

Set library version bounds for objects

Syntax

```
H5P.set_libver_bounds(fapl_id,low,high)
```

Description

`H5P.set_libver_bounds(fapl_id,low,high)` sets bounds on library versions, and indirectly format versions, to be used when creating objects in the file with access property list `fapl_id`. The `low` argument must be set to either of `'H5F_LIBVER_EARLIEST'`, `'H5F_LIBVER_18'` or `'H5F_LIBVER_LATEST'`. The `high` argument must be set to `'H5F_LIBVER_18'` or `'H5F_LIBVER_LATEST'`.

Examples

Create an HDF5 file where objects are created using the latest available format for each object.

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_libver_bounds(fapl,'H5F_LIBVER_LATEST','H5F_LIBVER_LATEST');
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
```

See Also

`H5ML.get_constant_value` | `H5P.get_libver_bounds`

H5P.set_mdc_config

Set initial metadata cache configuration

Syntax

```
H5P.set_mdc_config(plist_id,config_struct)
```

Description

`H5P.set_mdc_config(plist_id,config_struct)` sets the initial metadata cache configuration in the indicated file access property list to the supplied values. Before using this function, you should retrieve the current configuration using `H5P.get_mdc_config`.

Many of the fields in the structure, `config_struct`, are intended to be used only in close consultation with the HDF5 Group itself.

See Also

`H5P.get_mdc_config`

H5P.set_meta_block_size

Set minimum metadata block size

Syntax

```
H5P.set_meta_block_size(fapl_id,size)
```

Description

`H5P.set_meta_block_size(fapl_id,size)` sets the minimum metadata block size for the file access property list specified by `fapl_id`. The `size` argument specifies minimum size, in bytes, of metadata block allocations.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_meta_block_size(fapl,4096);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_meta_block_size`

H5P.set_multi_type

Specify type of data accessed with MULTI driver

Syntax

```
H5P.set_multi_type(fapl_id,type)
```

Description

`H5P.set_multi_type(fapl_id,type)` sets the type of data property in the file access or data transfer property list `fapl_id`. The `type` argument can have any of the following values: `H5FD_MEM_SUPER`, `H5FD_MEM_BTREE`, `H5FD_MEM_DRAW`, `H5FD_MEM_GHEAP`, `H5FD_MEM_LHEAP`, or `H5FD_MEM_OHDR`.

See Also

`H5P.get_multi_type`

H5P.set_sieve_buf_size

Set maximum size of data sieve buffer

Syntax

```
H5P.set_sieve_buf_size(fapl_id,buffer_size)
```

Description

`H5P.set_sieve_buf_size(fapl_id,buffer_size)` sets `buffer_size`, the maximum size in bytes of the data sieve buffer, which is used by file drivers that are capable of using data sieving. `fapl_id` is a file access property list identifier.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_sieve_buf_size(fapl,131072);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_sieve_buf_size`

H5P.set_small_data_block_size

Set size of block reserved for small data

Syntax

```
H5P.set_small_data_block_size(fapl_id,size)
```

Description

`H5P.set_small_data_block_size(fapl_id,size)` sets the maximum size, in bytes, of a contiguous block reserved for small data. `fapl_id` is a file access property list identifier.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_small_data_block_size(fapl,4096);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_small_data_block_size`

H5P.get_istore_k

Return 1/2 rank of indexed storage B-tree

Syntax

```
ik = H5P.get_istore_k(plist_id)
```

Description

`ik = H5P.get_istore_k(plist_id)` returns the chunked storage B-tree 1/2 rank of the file creation property list specified by `plist_id`.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
ik = H5P.get_istore_k(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

See Also

`H5P.set_istore_k`

H5P.get_sizes

Return size of offsets and lengths

Syntax

```
[sizeof_addr,sizeof_size] = H5P.get_sizes(fcpl)
```

Description

`[sizeof_addr,sizeof_size] = H5P.get_sizes(fcpl)` returns the size of the offsets and lengths used in an HDF5 file. `fcpl` specifies a file creation property list.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[soaddr, sosize] = H5P.get_sizes(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

See Also

`H5P.set_sizes`

H5P.get_sym_k

Return size of B-tree 1/2 rank and leaf node 1/2 size

Syntax

```
[ik,lk] = H5P.get_sym_k(plist_id)
```

Description

`[ik,lk] = H5P.get_sym_k(plist_id)` returns the size of the symbol table B-tree 1/2 rank, `ik`, and the symbol table leaf node 1/2 size, `lk`. The `plist_id` argument is a file creation property list identifier.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[ik, lk] = H5P.get_sym_k(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

See Also

`H5P.set_sym_k`

H5P.get_userblock

Return size of user block

Syntax

```
sz = H5P.get_userblock(plist_id)
```

Description

`sz = H5P.get_userblock(plist_id)` returns the size of a user block in a file creation property list. `plist_id` is a property list identifier.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
sz = H5P.get_userblock(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

See Also

`H5P.set_userblock`

H5P.get_version

Return version information for file creation property list

Syntax

```
[superblock,freelist,stab,shhdr] = H5P.get_version(fcpl)
```

Description

`[superblock,freelist,stab,shhdr] = H5P.get_version(fcpl)` returns the version of the super block, the global freelist, the symbol table, and the shared object header. Retrieving this information requires the file creation property list.

Examples

```
fid = H5F.open('example.h5');
fcpl = H5F.get_create_plist(fid);
[super,freelist,stab,shhdr] = H5P.get_version(fcpl);
H5P.close(fcpl);
H5F.close(fid);
```

H5P.set_istore_k

Set size of parameter for indexing chunked datasets

Syntax

```
H5P.set_istore_k(plist_id,ik)
```

Description

`H5P.set_istore_k(plist_id,ik)` sets the size of the parameter used to control the B-trees for indexing chunked datasets for the file creation property list specified by `plist_id`. The `ik` argument is one half the rank of a tree that stores chunked raw data.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_istore_k(fcpl,64);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_istore_k`

H5P.set_sizes

Set byte size of offsets and lengths

Syntax

```
H5P.set_sizes(plist_id,sizeof_addr,sizeof_size)
```

Description

`H5P.set_sizes(plist_id,sizeof_addr,sizeof_size)` sets the byte size of the offsets and lengths used to address objects in an HDF5 file. `plist_id` is a file creation property list.

See Also

`H5P.get_sizes`

H5P.set_sym_k

Set size of parameters used to control symbol table nodes

Syntax

```
H5P.set_sym_k(plist_id,ik,lk)
```

Description

`H5P.set_sym_k(plist_id,ik,lk)` sets the size of parameters used to control the symbol table nodes for the file access property list, `plist_id`. The `ik` argument is one half the rank of a tree that stores a symbol table for a group. `lk` is one half of the number of symbols that can be stored in a symbol table node.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_sym_k(fcpl,32,8);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_sym_k`

H5P.set_userblock

Set user block size

Syntax

```
H5P.set_userblock(plist_id,size)
```

Description

`H5P.set_userblock(plist_id,size)` sets the user block size of the file creation property list, `plist_id`.

Examples

```
fcpl = H5P.create('H5P_FILE_CREATE');
fapl = H5P.create('H5P_FILE_ACCESS');
H5P.set_userblock(fcpl,4096);
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',fcpl,fapl);
H5F.close(fid);
```

See Also

`H5P.get_userblock`

H5P.get_attr_creation_order

Return tracking order and indexing settings

Syntax

```
crt_order_flags = H5P.get_attr_creation_order(ocpl_id)
```

Description

`crt_order_flags = H5P.get_attr_creation_order(ocpl_id)` retrieves tracking and indexing settings for attribute creation order. If `crt_order_flags` is zero, then the attribute creation order is neither tracked or indexed. Otherwise the creation order flags should be one of the following constant values:

```
H5P_CRT_ORDER_TRACKED
H5P_CRT_ORDER_INDEXED
```

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
flags = H5P.get_attr_creation_order(dcpl);
switch ( flags )
    case 0
        fprintf('neither tracked nor indexed\n');
    case H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED')
        fprintf('tracked\n');
    case H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED')
        fprintf('indexed\n');
end
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5ML.get_constant_value` | `H5P.set_attr_creation_order`

H5P.get_attr_phase_change

Retrieve attribute phase change thresholds

Syntax

```
[max_compact,min_dense] = H5P.get_attr_phase_change(ocpl_id)
```

Description

`[max_compact,min_dense] = H5P.get_attr_phase_change(ocpl_id)` retrieves attribute phase change thresholds for the dataset or group with creation property list `ocpl_id`.

`max_compact` is the maximum number of attributes to be stored in compact storage (default is 8).

`min_dense` is the minimum number of attributes to be stored in dense storage (default is 6).

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
dcpl = H5D.get_create_plist(dset_id);
[max_compact,min_dense] = H5P.get_attr_phase_change(dcpl);
H5P.close(dcpl);
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5P.set_attr_phase_change`

H5P.get_copy_object

Return properties to be used when object is copied

Syntax

```
copy_options = H5P.get_copy_object(ocpl_id)
```

Description

`copy_options = H5P.get_copy_object(ocpl_id)` retrieves the properties currently specified in the object copy property list `ocpl_id`, which will be invoked when a new copy is made of an existing object.

Examples

```
ocpl = H5P.create('H5P_OBJECT_COPY');
options = H5P.get_copy_object(ocpl);
```

See Also

`H5P.set_copy_object`

H5P.set_attr_creation_order

Set tracking of attribute creation order

Syntax

```
H5P.set_attr_creation_order(gcplId,crt_order_flags)
```

Description

`H5P.set_attr_creation_order(gcplId,crt_order_flags)` sets tracking and indexing of attribute creation order. The creation order flags should be either `H5P_CRT_ORDER_TRACKED` or a bitwise-or of `H5P_CRT_ORDER_TRACKED` and `H5P_CRT_ORDER_INDEXED`.

The default behavior is that attribute creation order is neither tracked nor indexed.

Examples

```
dcpl = H5P.create('H5P_DATASET_CREATE');
order = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED');
H5P.set_attr_creation_order(dcpl,order);
```

See Also

`bitor` | `H5ML.get_constant_value` | `H5P.get_attr_creation_order`

H5P.set_attr_phase_change

Set attribute storage phase change thresholds

Syntax

```
H5P.set_attr_phase_change(ocpl_id,max_compact,min_dense)
```

Description

`H5P.set_attr_phase_change(ocpl_id,max_compact,min_dense)` sets attribute storage phase change thresholds for the group or dataset with creation order property list `ocpl_id`.

`max_compact` is the maximum number of attributes to be stored in compact storage (default is 8).

`min_dense` is the minimum number of attributes to be stored in dense storage (default is 6).

See Also

`H5P.get_attr_phase_change`

H5P.set_copy_object

Set properties to be used when objects are copied

Syntax

```
H5P.set_copy_object(ocp_plist_id,copy_options)
```

Description

`H5P.set_copy_object(ocp_plist_id,copy_options)` sets the properties in the object copy property list `ocp_plist_id` that will be invoked when a new copy is made of an existing object. `ocp_plist_id` is the object copy property list and specifies the properties governing the copying of the object.

Several flags, described below, are available for inclusion in the object copy property list:

`H5O_COPY_SHALLOW_HIERARCHY_FLAG`	Copy only immediate members of a group. Default behavior, without flag: Recursively copy all objects below the group.
`H5O_COPY_EXPAND_SOFT_LINK_FLAG`	Expand soft links into new objects. Default behavior, without flag: Keep soft links as they are.
`H5O_COPY_EXPAND_EXT_LINK_FLAG`	Expand external link into new objects. Default behavior, without flag: Keep external links as they are.
`H5O_COPY_EXPAND_REFERENCE_FLAG`	Copy objects that are pointed to by references. Default behavior, without flag: Update only the values of object references.
`H5O_COPY_WITHOUT_ATTR_FLAG`	Copy object without copying attributes. Default behavior, without flag: Copy object along with all its attributes.

Examples

```
ocp_plist_id = H5P.create ('H5P_OBJECT_COPY');
```

```
option1 = H5ML.get_constant_value('H5O_COPY_EXPAND_SOFT_LINK_FLAG');
option2 = H5ML.get_constant_value('H5O_COPY_EXPAND_REFERENCE_FLAG');
copy_options = bitor(option1,option2);
H5P.set_copy_object(ocp_plist_id, copy_options);
```

H5P.get_create_intermediate_group

Determine creation of intermediate groups

Syntax

```
bool = H5P.get_create_intermediate_group(lcpl_id)
```

Description

`bool = H5P.get_create_intermediate_group(lcpl_id)` determines whether the link creation property list `lcpl_id` is set to enable creating missing intermediate groups.

Examples

```
lcpl = H5P.create('H5P_LINK_CREATE');
if H5P.get_create_intermediate_group(lcpl)
    fprintf('set to enable creating intermediate groups\n');
else
    fprintf('not set to enable creating intermediate groups\n');
end
```

See Also

`H5P.set_create_intermediate_group`

H5P.get_link_creation_order

Query if link creation order is tracked

Syntax

```
crt_order_flags = H5P.get_link_creation_order(gcpl_id)
```

Description

`crt_order_flags = H5P.get_link_creation_order(gcpl_id)` queries whether link creation order is tracked or indexed in a group with creation property list identifier `gcpl_id`. The creation order flags should be one of the following constant values:

`H5P_CRT_ORDER_TRACKED`

`H5P_CRT_ORDER_INDEXED`

Examples

```
tracked = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED');
indexed = H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED');
gcpl = H5P.create('H5P_GROUP_CREATE');
order = H5P.get_link_creation_order(gcpl);
if bitand(order,tracked)
    fprintf('order is tracked\n');
end
if bitand(order,indexed)
    fprintf('order is indexed\n');
end
```

See Also

`bitand` | `H5ML.get_constant_value` | `H5P.set_link_creation_order`

H5P.get_link_phase_change

Query settings for conversion between groups

Syntax

```
[max_compact,min_dense] = H5P.get_link_phase_change(gcpl_id)
```

Description

`[max_compact,min_dense] = H5P.get_link_phase_change(gcpl_id)` retrieves the settings for conversion between compact and dense groups.

`max_compact` is the maximum number of links to store as header messages in the group header before converting the group to the dense format. Groups that are in the compact format and exceed this number of links are automatically converted to the dense format.

`min_dense` is the minimum number of links to store in the dense format. Groups which are in dense format and in which the number of links falls below this number are automatically converted back to the compact format.

Examples

```
gcpl = H5P.create('H5P_GROUP_CREATE');
[max_compact, min_dense] = H5P.get_link_phase_change(gcpl);
```

See Also

`H5P.set_link_phase_change`

H5P.set_create_intermediate_group

Set creation of intermediate groups

Syntax

```
H5P.set_create_intermediate_group(lcpl_id,flag)
```

Description

`H5P.set_create_intermediate_group(lcpl_id,flag)` specifies in the link creation property list `lcpl_id` whether to create missing intermediate groups.

Examples

Enable the creation of intermediate groups.

```
fid = H5F.create('myfile.h5');
lcpl = H5P.create('H5P_LINK_CREATE');
H5P.set_create_intermediate_group(lcpl,1);
gid = H5G.create(fid,'/a/b/c/d',lcpl,'H5P_DEFAULT','H5P_DEFAULT');
H5G.close(gid);
H5F.close(fid);
```

See Also

`H5P.get_create_intermediate_group`

H5P.set_link_creation_order

Set creation order tracking and indexing

Syntax

```
H5P.set_link_creation_order(gcplId,crt_order_flags)
```

Description

`H5P.set_link_creation_order(gcplId,crt_order_flags)` sets creation order tracking and indexing for links in the group with group creation property list `gcpl_id`.

The creation order flags should be one of the following constant values:

`H5P_CRT_ORDER_TRACKED`

`H5P_CRT_ORDER_INDEXED`

If only `H5P_CRT_ORDER_TRACKED` is set, HDF5 will track link creation order in any group created with the group creation property list `gcpl_id`. If both `H5P_CRT_ORDER_TRACKED` and `H5P_CRT_ORDER_INDEXED` are set, HDF5 will track link creation order in the group and index links on that property.

Examples

```
tracked = H5ML.get_constant_value('H5P_CRT_ORDER_TRACKED');
indexed = H5ML.get_constant_value('H5P_CRT_ORDER_INDEXED');
order = bitor(tracked,indexed);
gcpl = H5P.create('H5P_GROUP_CREATE');
H5P.set_link_creation_order(gcpl,order);
```

See Also

`H5ML.get_constant_value` | `H5P.get_link_creation_order`

H5P.set_link_phase_change

Set parameters for group conversion

Syntax

```
H5P.set_link_phase_change(gcpl_id,max_compact,min_dense)
```

Description

`H5P.set_link_phase_change(gcpl_id,max_compact,min_dense)` sets the parameters for conversion between compact and dense groups.

`max_compact` is the maximum number of links to store as header messages in the group header before converting the group to the dense format. Groups that are in the compact format and exceed this number of links are automatically converted to the dense format.

`min_dense` is the minimum number of links to store in the dense format. Groups which are in dense format and in which the number of links falls below this number are automatically converted back to the compact format.

Examples

```
gcpl = H5P.create('H5P_GROUP_CREATE');
H5P.set_link_phase_change(gcpl,10,8);
```

See Also

`H5P.get_link_phase_change`

H5P.get_char_encoding

Return character encoding

Syntax

```
encoding = H5P.get_char_encoding(propertyList)
```

Description

`encoding = H5P.get_char_encoding(propertyList)` retrieves the character encoding used to encode strings or object names that are created with the property list `propertyList`. The values returned correspond to either `H5T_CSET_ASCII` or `H5T_CSET_UTF8`.

See Also

`H5ML.get_constant_value` | `H5P.set_char_encoding`

H5P.set_char_encoding

Set character encoding used to encode strings

Syntax

```
H5P.set_char_encoding(propList,encoding)
```

Description

`H5P.set_char_encoding(propList,encoding)` sets the character encoding used to encode strings or object names that are created with the property list `propList`. The values of `encoding` should either be `H5T_CSET_ASCII` or `H5T_CSET_UTF8`.

See Also

`H5ML.get_constant_value` | `H5P.get_char_encoding`

H5R.create

Create reference

Syntax

```
ref = H5R.create(loc_id,name,ref_type,space_id)
```

Description

`ref = H5R.create(loc_id,name,ref_type,space_id)` creates the reference, `ref`, of the type specified in `ref_type`, pointing to the object specified by name located at `loc_id`. The `ref_type` argument can be either `'H5R_OBJECT'`, or `'H5R_DATASET_REGION'`. The `space_id` argument should be `-1`, if `ref_type` is `'H5R_OBJECT'`.

Examples

Create a double-precision dataset and a reference dataset.

```
fid = H5F.create('myfile.h5');
type1_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [10 5];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space1_id = H5S.create_simple(2,h5_dims,h5_maxdims);
dcpl = 'H5P_DEFAULT';
dset1_id = H5D.create(fid,'my_double',type1_id,space1_id,dcpl);
type2_id = 'H5T_STD_REF_OBJ';
space2_id = H5S.create('H5S_SCALAR');
dset2_id = H5D.create(fid,'my_ref',type2_id,space2_id,dcpl);
ref_data = H5R.create(fid,'my_double','H5R_OBJECT',-1);
dxpl = 'H5P_DEFAULT';
H5D.write(dset2_id,'H5ML_DEFAULT','H5S_ALL','H5S_ALL',dxpl,ref_data);
H5D.close(dset1_id);
H5D.close(dset2_id);
H5F.close(fid);
```

See Also

H5D.create

H5R.dereference

Open object specified by reference

Syntax

```
output = H5R.dereference(dataset,ref_type,ref)
```

Description

`output = H5R.dereference(dataset,ref_type,ref)` returns an identifier to the object specified by `ref` in the dataset specified by `dataset`.

Examples

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/reference');
ref_data = H5D.read(dset_id,'H5T_STD_REF_OBJ',space,space,plist);
deref_dset_id = H5R.dereference(dset_id,'H5R_OBJECT',ref_data(:,1));
H5D.close(dset_id);
H5D.close(deref_dset_id);
H5F.close(fid);
```

See Also

`H5I.get_name` | `H5R.create`

H5R.get_name

Name of referenced object

Syntax

```
name = H5R.get_name(loc_id,ref_type,ref)
```

Description

`name = H5R.get_name(loc_id,ref_type,ref)` retrieves the name for the object identified by `ref`. The `loc_id` argument is the identifier for the dataset containing the reference or for the group containing that dataset. `ref_type` specifies the type of the reference `ref`. Valid values for `ref_type` are `'H5R_OBJECT'` or `'H5R_DATASET_REGION'`.

Examples

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/reference');
ref_data = H5D.read(dset_id,'H5T_STD_REF_OBJ',space,space,plist);
name = H5R.get_name(dset_id,'H5R_OBJECT',ref_data(:,1));
H5D.close(dset_id);
H5F.close(fid);
```

See Also

`H5I.get_name`

H5R.get_obj_type

Type of referenced object

Syntax

```
obj_type = H5R.get_obj_type(id,ref_type,ref)
```

Description

`obj_type = H5R.get_obj_type(id,ref_type,ref)` returns the type of object that an object reference points to. Valid values for `ref_type` are: `H5R_OBJECT` or `H5R_DATASET_REGION`. Valid return values correspond to the following values.

`'H5O_TYPE_GROUP'`	Object is a group.
`'H5O_TYPE_DATASET'`	Object is a dataset.
`'H5O_TYPE_NAMED_DATATYPE'`	Object is a named datatype.

This function corresponds to the 1.8 interface version of `H5Rget_obj_type` in the HDF5 library C API.

Examples

```
plist = 'H5P_DEFAULT';
space = 'H5S_ALL';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/reference');
ref_data = H5D.read(dset_id,'H5T_STD_REF_OBJ',space,space,plist);
obj_type = H5R.get_obj_type(fid,'H5R_OBJECT',ref_data(:,1));
switch(obj_type)
    case H5ML.get_constant_value('H5O_TYPE_GROUP')
        fprintf('group\n');
    case H5ML.get_constant_value('H5O_TYPE_DATASET')
        fprintf('dataset\n');
    case H5ML.get_constant_value('H5O_TYPE_NAMED_DATATYPE')
        fprintf('named datatype\n');
```

```
end
H5D.close(dset_id);
H5F.close(fid);
```

See Also

H5ML.get_constant_value

H5R.get_region

Copy of data space of specified region

Syntax

```
space_id = H5R.get_region(dataset,ref_type,ref)
```

Description

`space_id = H5R.get_region(dataset,ref_type,ref)` returns a data space with the specified region selected. `dataset` is used to identify the file containing the referenced region and can be any identifier for any object in the file.

Examples

```
space = 'H5S_ALL';
plist = 'H5P_DEFAULT';
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/region_reference');
ref_data = H5D.read(dset_id,'H5T_STD_REF_DSETREG',space,space,plist);
space_id = H5R.get_region(fid,'H5R_DATASET_REGION',ref_data(:,1));
H5S.close(space_id);
H5D.close(dset_id);
H5F.close(fid);
```

H5S.copy

Create copy of data space

Syntax

```
output = H5S.copy(space_id)
```

Description

`output = H5S.copy(space_id)` creates a new data space, which is an exact copy of the dataspace identified by `space_id`. The `output` argument is a data space identifier.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g2/dset2.1');
space1_id = H5D.get_space(dset_id);
space2_id = H5S.copy(space1_id);
[~,dims1] = H5S.get_simple_extent_dims(space1_id)
[~,dims2] = H5S.get_simple_extent_dims(space2_id)
```

See Also

`H5D.get_space` | `H5S.get_simple_extent_dims`

H5S.create

Create new data space

Syntax

```
space_id = H5S.create(space_type)
```

Description

`space_id = H5S.create(space_type)` creates a new dataspace of the type specified by `space_type`, which can be specified by one of the following strings.

```
'H5S_SCALAR'
'H5S_SIMPLE'
'H5S_NULL'
```

`space_id` is the identifier for the new dataspace.

Examples

Create a scalar dataspace.

```
space_id = H5S.create('H5S_SCALAR');
numpoints = H5S.get_simple_extent_npoints(space_id);
```

See Also

`H5S.get_simple_extent_npoints`

H5S.close

Close data space

Syntax

```
H5S.close(space_id)
```

Description

`H5S.close(space_id)` releases and terminates access to a data space. `space_id` is a data space identifier.

See Also

`H5A.get_space` | `H5D.get_space`

H5S.create_simple

Create new simple data space

Syntax

```
space_id = H5S.create_simple(rank,h5_dims,h5_maxdims)
```

Description

`space_id = H5S.create_simple(rank,h5_dims,h5_maxdims)` creates a new simple data space and opens it for access. `rank` is the number of dimensions used in the data space. `h5_dims` is an array specifying the size of each dimension of the dataset. `h5_maxdims` is an array specifying the upper limit on the size of each dimension. `space_id` is a data space identifier.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Create a data space for a dataset with 10 rows and 5 columns.

```
dims = [10 5];
h5_dims = fliplr(dims);
h5_maxdims = h5_dims;
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
```

Create a data space for a dataset with 10 rows and 5 columns such that the dataset is extendible along the column dimension.

```
dims = [10 5];
h5_dims = fliplr(dims);
maxdims = [10 H5ML.get_constant_value('H5S_UNLIMITED')];
```

```
h5_maxdims = fliplr(maxdims);
space_id = H5S.create_simple(2,h5_dims,h5_maxdims);
```

See Also

H5ML.get_constant_value | H5S.close | H5S.create

H5S.extent_copy

Copy extent from source to destination data space

Syntax

```
H5S.extent_copy(dst_id,src_id)
```

Description

`H5S.extent_copy(dst_id,src_id)` copies the extent from the source data space, `src_id`, to the destination data space, `dst_id`.

Examples

```
space_id1 = H5S.create('H5S_SIMPLE');
dims = [100 200];
h5_dims = fliplr(dims);
maxdims = [100 H5ML.get_constant_value('H5S_UNLIMITED')];
h5_maxdims = fliplr(maxdims);
H5S.set_extent_simple(space_id1,2,h5_dims,h5_maxdims);
space_id2 = H5S.create('H5S_SIMPLE');
H5S.extent_copy(space_id2,space_id1);
```

See Also

`H5S.create` | `H5S.get_simple_extent_dims` | `H5S.set_extent_simple`

H5S.get_select_bounds

Bounding box of data space selection

Syntax

```
[start,finish] = H5S.get_select_bounds(space_id)
```

Description

`[start,finish] = H5S.get_select_bounds(space_id)` returns the coordinates of the bounding box containing the current selection. `start` contains the starting coordinates of the bounding box and `finish` contains the coordinates of the diagonally opposite corner.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
start = fliplr([30 40]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_OR',start,[],[],block);
[start, finish] = H5S.get_select_bounds(space_id);
matlab_start = fliplr(start);
matlab_finish = fliplr(finish);
```

See Also

`H5S.create_simple` | `H5S.select_hyperslab`

H5S.get_select_elem_npoints

Number of element points in selection

Syntax

```
numpoints = H5S.get_select_elem_npoints(space_id)
```

Description

`numpoints = H5S.get_select_elem_npoints(space_id)` returns the number of element points in the current data space selection.

Examples

Select the corner points of a data space.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
coords = fliplr(coords);
coords = coords';
H5S.select_elements(space_id,'H5S_SELECT_SET',coords)
numpoints = H5S.get_select_elem_npoints(space_id);
```

See Also

`H5S.select_elements`

H5S.get_select_elem_pointlist

Element points in data space selection

Syntax

```
points =
H5S.get_select_elem_pointlist(space_id,startpoint,numpoints)
```

Description

`points = H5S.get_select_elem_pointlist(space_id,startpoint,numpoints)` returns the list of element points in the current data space selection. `startpoint` specifies the element point to start with and `numpoints` specifies the total number of points.

`points` is a two-dimensional array of 0-based values specifying the coordinates of the elements. If `m` is the rank of the dataspace, then `points` will have size [`m` x `numpoints`].

Note: The ordering of the coordinate points is the same as the HDF5 library C API.

Examples

Determine the first two points in the current selection.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
coords = fliplr(coords);
coords = coords';
H5S.select_elements(space_id,'H5S_SELECT_SET',coords);
points = H5S.get_select_elem_pointlist(space_id,0,2);
```

H5S.get_select_hyper_blocklist

List of hyperslab blocks

Syntax

```
blocklist =
H5S.get_select_hyper_blocklist(space_id,startblock,numblocks)
```

Description

`blocklist = H5S.get_select_hyper_blocklist(space_id,startblock,numblocks)` returns a list of the hyperslab blocks currently selected. `space_id` is a dataspace identifier. `startblock` specifies the block to start with and `numblocks` specifies the number of hyperslab blocks to retrieve.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
start = fliplr([20 30]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_NOTB',start,[],[],block);
nblocks = H5S.get_select_hyper_nblocks(space_id);
for j = 1:nblocks
    hblocks{j} = H5S.get_select_hyper_blocklist(space_id,j-1,1);
end
```

See Also

`H5S.get_select_hyper_nblocks` | `H5S.select_hyperslab`

H5S.get_select_hyper_nblocks

Number of hyperslab blocks

Syntax

```
num_blocks = H5S.get_select_hyper_nblocks(space_id)
```

Description

`num_blocks = H5S.get_select_hyper_nblocks(space_id)` returns the number of hyperslab blocks in the current data space selection.

Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
start = fliplr([20 30]); block = fliplr([20 25]);
H5S.select_hyperslab(space_id,'H5S_SELECT_NOTB',start,[],[],block);
nblocks = H5S.get_select_hyper_nblocks(space_id);
```

See Also

`H5S.get_select_hyper_blocklist` | `H5S.select_hyperslab`

H5S.get_select_npoints

Number of elements in data space selection

Syntax

```
num_points = H5S.get_select_npoints(space_id)
```

Description

`num_points = H5S.get_select_npoints(space_id)` returns the number of elements in the current data space selection.

Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
op = 'H5S_SELECT_SET';
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
n = H5S.get_select_npoints(space_id);
```

See Also

`H5S.create_simple` | `H5S.select_hyperslab`

H5S.get_select_type

Type of data space selection

Syntax

```
sel_type = H5S.get_select_type(space_id)
```

Description

`sel_type = H5S.get_select_type(space_id)` returns the data space selection type. Valid return values correspond to the following enumerated constants:

```
H5S_SEL_NONE
H5S_SEL_POINTS
H5S_SEL_HYPERSLABS
H5S_SEL_ALL
```

Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
sel_type = H5S.get_select_type(space_id);
switch(sel_type)
    case H5ML.get_constant_value('H5S_SEL_NONE')
        fprintf('no selection\n');
    case H5ML.get_constant_value('H5S_SEL_POINTS');
        fprintf('point selection\n');
    case H5ML.get_constant_value('H5S_SEL_HYPERSLABS');
        fprintf('hyperslab selection\n');
end
```

H5S.get_simple_extent_dims

Data space size and maximum size

Syntax

```
[numdims,h5_dims,h5_maxdims] = H5S.get_simple_extent_dims(space_id)
```

Description

`[numdims,h5_dims,h5_maxdims] = H5S.get_simple_extent_dims(space_id)` returns the number of dimensions in the data space, the size of each dimension, and the maximum size of each dimension.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g2/dset2.2');
space_id = H5D.get_space(dset_id);
[ndims,h5_dims] = H5S.get_simple_extent_dims(space_id);
matlab_dims = fliplr(h5_dims);
```

H5S.get_simple_extent_ndims

Data space rank

Syntax

```
output = H5S.get_simple_extent_ndims(space_id)
```

Description

`output = H5S.get_simple_extent_ndims(space_id)` returns the dimensionality (also called the rank) of a data space.

H5S.get_simple_extent_npoints

Number of elements in data space

Syntax

```
output = H5S.get_simple_extent_npoints(space_id)
```

Description

`output = H5S.get_simple_extent_npoints(space_id)` returns the number of elements in the data space specified by `space_id`.

H5S.get_simple_extent_type

Data space class

Syntax

```
space_type = H5S.get_simple_extent_type(space_id)
```

Description

`space_type = H5S.get_simple_extent_type(space_id)` returns the data space class of the data space specified by `space_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
space_id = H5D.get_space(dset_id);
space_type = H5S.get_simple_extent_type(space_id);
switch(space_type)
    case H5ML.get_constant_value('H5S_SCALAR')
        fprintf('scalar\n');
    case H5ML.get_constant_value('H5S_SIMPLE')
        fprintf('simple\n');
    case H5ML.get_constant_value('H5S_NULL')
        fprintf('none\n');
end
```

See Also

`H5D.get_space` | `H5ML.get_constant_value` | `H5S.create`

H5S.is_simple

Determine if data space is simple

Syntax

```
output = H5S.is_simple(space_id)
```

Description

`output = H5S.is_simple(space_id)` returns a positive value if the data space specified by `space_id` is a simple data space, zero if it is not, and a negative value to indicate failure.

Examples

Create a new data space and verify that it is simple.

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
val = H5S.is_simple(space_id);
```

Create a null data space and verify that it is not simple.

```
space_id = H5S.create('H5S_NULL');
val = H5S.is_simple(space_id);
```

See Also

`H5S.create` | `H5S.create_simple`

H5S.offset_simple

Set offset of simple data space

Syntax

```
H5S.offset_simple(space_id,offset)
```

Description

`H5S.offset_simple(space_id,offset)` specifies the offset of the simple data space specified by `space_id`. This function allows the same shaped selection to be moved to different locations within a data space without requiring it to be redefined.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
offset = fliplr([3 5]);
H5S.offset_simple(space_id,offset)
[start,finish] = H5S.get_select_bounds(space_id);
start = fliplr(start);
finish = fliplr(finish);
```

See Also

`H5S.get_select_bounds` | `H5S.select_hyperslab`

H5S.select_all

Select entire extent of data space

Syntax

```
H5S.select_all(space_id)
```

Description

`H5S.select_all(space_id)` selects the entire extent of the data space specified by `space_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
space_id = H5D.get_space(dset_id);
num_points1 = H5S.get_select_npoints(space_id);
H5S.select_none(space_id);
num_points2 = H5S.get_select_npoints(space_id);
H5S.select_all(space_id);
num_points3 = H5S.get_select_npoints(space_id);
```

H5S.select_elements

Specify coordinates to include in selection

Syntax

```
H5S.select_elements(space_id,op,h5_coord)
```

Description

`H5S.select_elements(space_id,op,h5_coord)` selects the array elements to be included in the selection for the data space specified by `space_id`. The `op` argument determines how the new selection is to be combined with the previously existing selection for the data space and can be specified by one of the following string values.

```
'H5S_SELECT_SET'
'H5S_SELECT_APPEND'
'H5S_SELECT_PREPEND'
```

`h5_coord` is a two-dimensional array of 0-based values specifying the coordinates of the elements being selected. If `m` is the rank of the data space and if n is the number of points, then `h5_coord` should be an `m`-by-`n` array.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_coord` parameter assumes coordinates have C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Select the corner points of a data space. In this case, `h5_coord` should have size 2x4.

```
dims = [100 200];
h5_dims = fliplr(dims);
```

```
space_id = H5S.create_simple(2,h5_dims,h5_dims);
coords = [0 0; 0 199; 99 0; 99 199];
h5_coords = fliplr(coords);
h5_coords = h5_coords';
H5S.select_elements(space_id,'H5S_SELECT_SET',h5_coords);
```

See Also

H5S.create_simple | H5S.get_select_elem_npoints | H5S.get_select_elem_pointlist

H5S.select_hyperslab

Select hyperslab region

Syntax

```
H5S.select_hyperslab(space_id,op,h5_start,h5_stride,h5_count,h5_block)
```

Description

`H5S.select_hyperslab(space_id,op,h5_start,h5_stride,h5_count,h5_block)` selects a hyperslab region to add to the current selected region for the data space specified by `space_id`. The `op` argument determines how the new selection is to be combined with the previously existing selection for the data space. Possible values include: `H5S_SELECT_SET`, `H5S_SELECT_OR`, `H5S_SELECT_AND`, `H5S_SELECT_XOR`, `H5S_SELECT_NOTA`, or `H5S_SELECT_NOTB`.

The `h5_start` array determines the starting coordinates of the hyperslab to select. The `h5_count` array determines how many blocks to select from the data space, in each dimension. The `h5_stride` array specifies how many elements to move in each dimension. The `h5_block` array determines the size of the element block selected from the data space.

If `h5_stride` is specified as `[]`, then a contiguous hyperslab is selected, as if each value in `h5_stride` were set to 1. If `h5_count` is specified as `[]`, the number of blocks selected along each dimension defaults to 1. If `h5_block` is specified as `[]`, then the block size defaults to a single element in each dimension, as if each value in the block array were set to 1.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_start`, `h5_stride`, `h5_count` and `h5_block` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
dims = [100 200];
```

```
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([10 20]); block = fliplr([20 30]);
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],[],block);
```

See Also

H5S.create_simple

H5S.select_none

Reset selection region to include no elements

Syntax

```
H5S.select_none(space_id)
```

Description

`H5S.select_none(space_id)` resets the selection region for the data space `space_id` to include no elements.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
space_id = H5D.get_space(dset_id);
num_points1 = H5S.get_select_npoints(space_id);
H5S.select_none(space_id);
num_points2 = H5S.get_select_npoints(space_id);
```

H5S.select_valid

Determine validity of selection

Syntax

```
output = H5S.select_valid(space_id)
```

Description

`output = H5S.select_valid(space_id)` returns a positive value if the selection of the data space `space_id` is within the extent of that data space, and zero if it is not. A negative value indicates failure.

Examples

```
dims = [100 200];
h5_dims = fliplr(dims);
space_id = H5S.create_simple(2,h5_dims,h5_dims);
start = fliplr([90 190]); count = [11 11];
H5S.select_hyperslab(space_id,'H5S_SELECT_SET',start,[],count,[]);
valid = H5S.select_valid(space_id);
```

See Also

`H5S.create_simple` | `H5S.select_hyperslab`

H5S.set_extent_none

Remove extent from data space

Syntax

```
H5S.set_extent_none(space_id)
```

Description

`H5S.set_extent_none(space_id)` removes the extent from a data space and sets the type to `H5S_NO_CLASS`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer2D');
space_id = H5D.get_space(dset_id);
H5S.set_extent_none(space_id);
extent_type = H5S.get_simple_extent_type(space_id);
switch(extent_type)
    case H5ML.get_constant_value('H5S_SCALAR')
        fprintf('scalar\n');
    case H5ML.get_constant_value('H5S_SIMPLE')
        fprintf('simple\n');
    case H5ML.get_constant_value('H5S_NO_CLASS')
        fprintf('no class\n');
end
```

See Also

`H5S.get_simple_extent_dims`

H5S.set_extent_simple

Set size of data space

Syntax

```
H5S.set_extent_simple(space_id,rank,h5_dims,h5_maxdims)
```

Description

`H5S.set_extent_simple(space_id,rank,h5_dims,h5_maxdims)` sets the size of the data space identified by `space_id`. The `rank` argument is the number of dimensions used in the data space. `h5_dims` is an array specifying the size of each dimension of the dataset. `h5_maxdims` is an array specifying the upper limit on the size of each dimension.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` and `h5_maxdims` parameters assume C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
space_id = H5S.create('H5S_SIMPLE');
dims = [100 200];
h5_dims = fliplr(dims);
maxdims = [100 H5ML.get_constant_value('H5S_UNLIMITED')];
h5_maxdims = fliplr(maxdims);
H5S.set_extent_simple(space_id,2,h5_dims, h5_maxdims);
```

See Also

`H5ML.get_constant_value` | `H5S.create` | `H5S.get_simple_extent_dims`

H5T.close

Close data type

Syntax

```
H5T.close(type_id)
```

Description

`H5T.close(type_id)` releases the data type specified by `type_id`.

See Also

`H5A.get_type` | `H5D.get_type`

H5T.commit

Commit transient data type

Syntax

```
H5T.commit(loc_id,name,type_id)
H5T.commit(loc_id,name,type_id,lcpl_id,tcpl_id,tapl_id)
```

Description

`H5T.commit(loc_id,name,type_id)` commits a transient data type to a file, creating a new named data type. `loc_id` is a file or group identifier. `name` is the name of the data type and `type_id` is the data type id. This interface corresponds to the 1.6.x version of `H5Tcommit`.

`H5T.commit(loc_id,name,type_id,lcpl_id,tcpl_id,tapl_id)` commits a transient data type to a file, creating a new named data type. `loc_id` is a file or group identifier. `name` is the name of the data type and `type_id` is the data type id. `lcpl_id`, `tcpl_id`, and `tapl_id` are link creation, data type creation, and data type access property list identifiers. This interface corresponds to the 1.8.x version of `H5Tcommit`.

Examples

Create a named variable-length data type.

```
plist_id = 'H5P_DEFAULT';
fid = H5F.create('myfile.h5','H5F_ACC_TRUNC',plist_id,plist_id);
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');
vlen_type_id = H5T.vlen_create(base_type_id);
H5T.commit(fid,'MyVlen',vlen_type_id);
H5T.close(vlen_type_id);
H5T.close(base_type_id);
H5F.close(fid);
```

See Also

`H5T.close` | `H5T.committed`

H5T.committed

Determine if data type is committed

Syntax

```
output = H5T.committed(type_id)
```

Description

`output = H5T.committed(type_id)` returns a positive value to indicate that the data type has been committed, and zero to indicate that it has not. A negative value indicates failure.

Examples

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
is_committed = H5T.committed(type_id);
```

See Also

`H5T.commit`

H5T.copy

Copy data type

Syntax

```
output_type_id = H5T.copy(type_id)
```

Description

`output_type_id = H5T.copy(type_id)` copies the existing data type identifier, a dataset identifier specified by `type_id`, or a predefined data type such as `'H5T_NATIVE_DOUBLE'`. `output_type_id` is a data type identifier.

Examples

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
type_size = H5T.get_size(type_id);
```

See Also

`H5T.get_size`

H5T.create

Create new data type

Syntax

```
output = H5T.create(class_id,size)
```

Description

`output = H5T.create(class_id,size)` creates a new data type of the class specified by `class_id`, with the number of bytes specified by `size`. The `output` argument is a data type identifier.

Examples

Create a signed 32-bit enumerated data type.

```
type_id = H5T.create('H5T_ENUM',4);
H5T.set_order(type_id,'H5T_ORDER_LE');
H5T.set_sign(type_id,'H5T_SGN_2');
H5T.enum_insert(type_id,'black',0);
H5T.enum_insert(type_id,'white',1);
```

See Also

`H5T.set_order` | `H5T.set_sign`

H5T.detect_class

Determine of data type contains specific class

Syntax

```
output = H5T.detect_class(type_id,class_id)
```

Description

`output = H5T.detect_class(type_id,class_id)` returns a positive value if the data type specified in `type_id` contains any data types of the data type class specified in `class_id`, or zero to indicate that it does not. A negative value indicates failure.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/vlen');
type_id = H5D.get_type(dset_id);
has_double = H5T.detect_class(type_id,'H5T_FLOAT');
```

See Also

`H5D.get_type`

H5T.equal

Determine equality of data types

Syntax

```
output = H5T.equal(type1_id,type2_id)
```

Description

`output = H5T.equal(type1_id,type2_id)` returns a positive number if the data type identifiers refer to the same data type, and zero to indicate that they do not. A negative value indicates failure. Either of the input values could be a string corresponding to an HDF5 data type.

Examples

Determine if the data type of a dataset is a 32-bit little endian integer.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer2D');
dtype_id = H5D.get_type(dset_id);
if H5T.equal(dtype_id,'H5T_STD_I32LE')
    fprintf('32-bit little endian integer\n');
end
```

See Also

`H5D.get_type`

H5T.get_class

Data type class identifier

Syntax

```
class_id = H5T.get_class(type_id)
```

Description

`class_id = H5T.get_class(type_id)` returns the data type class identifier of the data type specified by `type_id`.

Valid class identifiers include:

```
H5T_INTEGER
H5T_FLOAT
H5T_STRING
H5T_BITFIELD
H5T_OPAQUE
H5T_COMPOUND
H5T_ENUM
H5T_VLEN
H5T_ARRAY
```

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/enum');
type_id = H5D.get_type(dset_id);
class_id = H5T.get_class(type_id);
switch(class_id)
    case H5ML.get_constant_value('H5T_INTEGER')
```

```
        fprintf('Integer\n');
    case H5ML.get_constant_value('H5T_FLOAT')
        fprintf('Floating point\n');
    case H5ML.get_constant_value('H5T_STRING')
        fprintf('String\n');
    case H5ML.get_constant_value('H5T_BITFIELD')
        fprintf('Bitfield\n');
    case H5ML.get_constant_value('H5T_OPAQUE')
        fprintf('Opaque\n');
    case H5ML.get_constant_value('H5T_COMPOUND')
        fprintf('Compound'\n');
    case H5ML.get_constant_value('H5T_ENUM')
        fprintf('Enumerated\n');
    case H5ML.get_constant_value('H5T_VLEN')
        fprintf('Variable length\n');
    case H5ML.get_constant_value('H5T_ARRAY')
        fprintf('Array\n');
end
```

See Also

H5ML.get_constant_value

H5T.get_create_plist

Copy of data type creation property list

Syntax

```
plist_id = H5T.get_create_plist(datatype_id)
```

Description

`plist_id = H5T.get_create_plist(datatype_id)` returns a property list identifier for the data type creation property list associated with the data type specified by `datatype_id`.

See Also

`H5D.get_create_plist` | `H5F.get_create_plist`

H5T.get_native_type

Native data type of dataset data type

Syntax

```
output = H5T.get_native_type(type_id,direction)
```

Description

`output = H5T.get_native_type(type_id,direction)` returns the equivalent native data type for the dataset data type specified in `type_id`. The `direction` argument indicates the order in which the library searches for a native data type match and must be either `'H5T_DIR_ASCEND'` or `'H5T_DIR_DESCEND'`.

H5T.get_size

Size of data type in bytes

Syntax

```
type_size = H5T.get_size(type_id)
```

Description

`type_size = H5T.get_size(type_id)` returns the size of a data type in bytes. `type_id` is a data type identifier.

Examples

Determine the size of the data type for a specific dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/bitfield2D');
type_id = H5D.get_type(dset_id);
type_size = H5T.get_size(type_id);
```

See Also

`H5D.get_type` | `H5T.set_size`

H5T.get_super

Base data type

Syntax

```
super_type_id = H5T.get_super(type_id)
```

Description

`super_type_id = H5T.get_super(type_id)` returns the base data type from which the data type type specified by `type_id` is derived.

Examples

Retrieve the base data type for an enumerated dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/enum');
dtype_id = H5D.get_type(dset_id);
super_type_id = H5T.get_super(dtype_id);
```

H5T.lock

Lock data type

Syntax

```
H5T.lock(type_id)
```

Description

`H5T.lock(type_id)` locks the data type specified by `type_id`, making it read-only and non-destructible.

H5T.open

Open named data type

Syntax

```
type_id = H5T.open(loc_id,name)
```

Description

`type_id = H5T.open(loc_id,name)` opens a named data type at the location specified by `loc_id` and returns an identifier for the data type. `loc_id` is either a file or group identifier.

This function corresponds to the `H5Topen1` function in the HDF5 library C API.

See Also

`H5A.open` | `H5D.open` | `H5G.open` | `H5O.open` | `H5T.close`

H5T.array_create

Create array data type object

Syntax

```
array_type_id = H5T.array_create(base_id,h5_dims)
array_type_id = H5T.array_create(base_id,rank,h5_dims,perms)
```

Description

`array_type_id = H5T.array_create(base_id,h5_dims)` creates a new array data type object. This interface corresponds to the 1.8 library version of `H5Tarray_create`.

`array_type_id = H5T.array_create(base_id,rank,h5_dims,perms)` creates a new array data type object. This interface corresponds to the 1.6 library version of `H5Tarray_create`. The `perms` parameter is not used at this time and can be omitted.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. The `h5_dims` parameter assumes C-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

Create a 100-by-200 double precision array data type.

```
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');
dims = [100 200];
h5_dims = fliplr(dims);
array_type = H5T.array_create(base_type_id,h5_dims);
```

See Also

`H5T.get_array_dims` | `H5T.get_array_ndims`

H5T.get_array_dims

Array dimension extents

Syntax

```
dimsizes = H5T.get_array_dims(type_id)
[ndims,dimsizes,perm] = H5T.get_array_dims(type_id)
```

Description

`dimsizes = H5T.get_array_dims(type_id)` returns the sizes of the dimensions and the dimension permutations of the specified array data type object. This interface corresponds to the 1.8 version of `H5Tget_array_dims`.

`[ndims,dimsizes,perm] = H5T.get_array_dims(type_id)` corresponds to the 1.6 version of the interface. It is strongly deprecated.

Note: The HDF5 library uses C-style ordering for multidimensional arrays, while MATLAB uses FORTRAN-style ordering. Please consult "Using the MATLAB Low-Level HDF5 Functions" in the MATLAB documentation for more information.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/array2D');
type_id = H5D.get_type(dset_id);
h5_dims = H5T.get_array_dims(type_id);
dims = fliplr(h5_dims);
```

See Also

`H5T.array_create` | `H5T.get_array_ndims`

H5T.get_array_ndims

Rank of array data type

Syntax

```
output = H5T.get_array_ndims(type_id)
```

Description

`output = H5T.get_array_ndims(type_id)` returns the rank, the number of dimensions, of an array data type object.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/array2D');
type_id = H5D.get_type(dset_id);
ndims = H5T.get_array_ndims(type_id);
```

See Also

`H5T.get_array_dims`

H5T.get_cset

Character set of string data type

Syntax

```
cset = H5T.get_cset(type_id)
```

Description

`cset = H5T.get_cset(type_id)` returns the character set type of the data type specified by `type_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/string');
type_id = H5D.get_type(dset_id);
cset = H5T.get_cset(type_id);
switch(cset)
  case H5ML.get_constant_value('H5T_CSET_ASCII')
      fprintf('ASCII\n');
  case H5ML.get_constant_value('H5T_CSET_UTF8')
      fprintf('UTF-8\n');
end
```

See Also

`H5T.set_cset`

H5T.get_ebias

Exponent bias of floating-point type

Syntax

```
output = H5T.get_ebias(type_id)
```

Description

`output = H5T.get_ebias(type_id)` returns the exponent bias of a floating-point type. `type_id` is data type identifier.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/float');
type_id = H5D.get_type(dset_id);
ebias = H5T.get_ebias(type_id);
```

See Also

`H5T.set_ebias`

H5T.get_fields

Floating-point data type bit field information

Syntax

```
[spos,epos,esize,mpos,msize] = H5T.get_fields(type_id)
```

Description

`[spos,epos,esize,mpos,msize] = H5T.get_fields(type_id)` returns information about the locations of the various bit fields of a floating point data type. `type_id` is a data type identifier. `spos` is the floating-point sign bit. `epos` is the exponent bit-position. `esize` is the size of the exponent in bits. `mpos` is the mantissa bit-position. `msize` is the size of the mantissa in bits.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/float');
type_id = H5D.get_type(dset_id);
[spos, epos, esize, mpos, msize] = H5T.get_fields(type_id);
```

H5T.get_inpad

Internal padding type for floating-point data types

Syntax

```
pad_type = H5T.get_inpad(type_id)
```

Description

`pad_type = H5T.get_inpad(type_id)` returns the internal padding type for unused bits in floating-point data types. `type_id` is a data type identifier. `pad_type` can be `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/float');
type_id = H5D.get_type(dset_id);
pad_type = H5T.get_inpad(type_id);
switch(pad_type)
    case H5ML.get_constant_value('H5T_PAD_ZERO')
        fprintf('pad zero\n');
    case H5ML.get_constant_value('H5T_PAD_ONE');
        fprintf('pad one\n');
    case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
        fprintf('pad background\n');
end
```

See Also

`H5T.set_inpad`

H5T.get_norm

Mantissa normalization type

Syntax

```
norm_type = H5T.get_norm(type_id)
```

Description

`norm_type = H5T.get_norm(type_id)` returns the mantissa normalization of a floating-point data type. `type_id` is a data type identifier. `norm_type` can be `H5T_NORM_IMPLIED`, `H5T_NORM_MSBSET`, or `H5T_NORM_NONE`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/float');
type_id = H5D.get_type(dset_id);
norm_type = H5T.get_norm(type_id);
switch(norm_type)
    case H5ML.get_constant_value('H5T_NORM_IMPLIED')
        fprintf('MSB of mantissa is not stored, always 1\n');
    case H5ML.get_constant_value('H5T_NORM_MSBSET');
        fprintf('MSB of mantissa is always 1\n');
    case H5ML.get_constant_value('H5T_NORM_NONE')
        fprintf('mantissa is not normalized\n');
end
```

See Also

`H5T.set_norm`

H5T.get_offset

Bit offset of first significant bit

Syntax

```
offset = H5T.get_offset(type_id)
```

Description

`offset = H5T.get_offset(type_id)` returns the offset of the first significant bit. `type_id` is a data type identifier.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/float');
type_id = H5D.get_type(dset_id);
offset = H5T.get_offset(type_id);
```

See Also

`H5T.set_offset`

H5T.get_order

Byte order of atomic data type

Syntax

```
output = H5T.get_order(type_id)
```

Description

`output = H5T.get_order(type_id)` returns the byte order of an atomic data type. `type_id` is a data type identifier. Possible return values are the constant values corresponding to the following strings:

```
'H5T_ORDER_LE'
'H5T_ORDER_BE'
'H5T_ORDER_VAX'
```

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g2/dset2.2');
type_id = H5D.get_type(dset_id);
switch(H5T.get_order(type_id))
    case H5ML.get_constant_value('H5T_ORDER_LE')
        fprintf('little endian\n');
    case H5ML.get_constant_value('H5T_ORDER_BE')
        fprintf('big endian\n');
    case H5ML.get_constant_value('H5T_ORDER_VAX')
        fprintf('vax\n');
end
```

See Also

`H5ML.get_constant_value` | `H5T.set_order`

H5T.get_pad

Padding type of least and most-significant bits

Syntax

```
[lsb,msb] = H5T.get_pad(type_id)
```

Description

`[lsb,msb] = H5T.get_pad(type_id)` returns the padding type of the least and most-significant bit padding. `type_id` is a data type identifier. `lsb` is the least-significant bit padding type. `msb` is the most-significant bit padding type. Values for `lsb` and `msb` can be `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
type_id = H5D.get_type(dset_id);
[lsb,msb] = H5T.get_pad(type_id);
switch(lsb)
    case H5ML.get_constant_value('H5T_PAD_ZERO')
        fprintf('lsb pad type is zeros\n');
    case H5ML.get_constant_value('H5T_PAD_ONE');
        fprintf('lsb pad type is ones\n');
    case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
        fprintf('lsb pad type is background\n');
end
switch(msb)
    case H5ML.get_constant_value('H5T_PAD_ZERO')
        fprintf('msb pad type is zeros\n');
    case H5ML.get_constant_value('H5T_PAD_ONE');
        fprintf('msb pad type is ones\n');
    case H5ML.get_constant_value('H5T_PAD_BACKGROUND')
        fprintf('msb pad type is background\n');
end
```

See Also

H5T.set_pad

H5T.get_precision

Precision of atomic data type

Syntax

```
output = H5T.get_precision(type_id)
```

Description

`output = H5T.get_precision(type_id)` returns the precision of an atomic data type. `type_id` is a data type identifier.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
type_id = H5D.get_type(dset_id);
numbits = H5T.get_precision(type_id);
```

See Also

`H5T.set_precision`

H5T.get_sign

Sign type for integer data type

Syntax

```
sign_type = H5T.get_sign(type_id)
```

Description

`sign_type = H5T.get_sign(type_id)` returns the sign type for an integer type. `type_id` is a data type identifier. Valid types are: `H5T_SGN_NONE` or `H5T_SGN_2`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/integer');
type_id = H5D.get_type(dset_id);
sign_type = H5T.get_sign(type_id);
switch(sign_type)
    case H5ML.get_constant_value('H5T_SGN_NONE')
        fprintf('Unsigned integer type.\n');
    case H5ML.get_constant_value('H5T_SGN_2');
        fprintf('Signed integer type.\n');
end
```

See Also

`H5T.set_sign`

H5T.get_strpad

Storage mechanism for string data type

Syntax

```
output = H5T.get_strpad(type_id)
```

Description

`output = H5T.get_strpad(type_id)` returns the storage mechanism (padding type) for a string data type. Possible values are:

`H5T_STR_NULLPAD`	Pad with zeros
`H5T_STR_NULLTERM`	Null-terminate
`H5T_STR_SPACEPAD`	Pad with spaces

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/string');
type_id = H5D.get_type(dset_id);
padding = H5T.get_strpad(type_id);
switch(padding)
    case H5ML.get_constant_value('H5T_STR_NULLTERM')
        fprintf('null-terminated\n');
    case H5ML.get_constant_value('H5T_STR_NULLPAD')
        fprintf('padded with zeros\n');
    case H5ML.get_constant_value('H5T_STR_SPACEPAD')
        fprintf('padded with spaces\n');
end
```

See Also

`H5T.set_strpad`

H5T.set_cset

Set character dataset for string data type

Syntax

```
H5T.set_cset(type_id, cset)
```

Description

`H5T.set_cset(type_id, cset)` sets the character encoding used to create strings. The only valid type is `H5T_CSET_ASCII`.

Examples

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,10);
encoding = H5ML.get_constant_value('H5T_CSET_ASCII');
H5T.set_cset(type_id,encoding);
```

See Also

`H5T.get_cset`

H5T.set_ebias

Set exponent bias of floating-point data type

Syntax

```
H5T.set_ebias(type_id,ebias)
```

Description

`H5T.set_ebias(type_id,ebias)` sets the exponent bias of a floating-point type. `type_id` is a data type identifier. `ebias` is an exponent bias value.

Examples

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
H5T.set_size(type_id,32);
H5T.set_ebias(type_id,99);
```

See Also

`H5T.get_ebias`

H5T.set_fields

Set sizes and locations of floating-point bit fields

Syntax

```
H5T.set_fields(type_id,spos,epos,esize,mpos,msize)
```

Description

`H5T.set_fields(type_id,spos,epos,esize,mpos,msize)` sets the locations and sizes of the various floating-point bit fields. `spos` is the sign position. `epos` is the exponent in bits. `esize` is the size of exponent in bits. `mpos` is the mantissa bit position. `msize` is the size of the mantissa in bits.

Examples

```
type_id = H5T.copy('H5T_NATIVE_DOUBLE');
H5T.set_fields(type_id,30,24,6,0,2);
```

See Also

`H5T.get_fields`

H5T.set_inpad

Specify how unused internal bits are to be filled

Syntax

```
H5T.set_inpad(type_id,pad)
```

Description

`H5T.set_inpad(type_id,pad)` sets how unused internal bits of a floating point type are filled. `type_id` is the identifier of the data type. `inpad` specifies how to fill the bits: `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND` (leave background alone).

Examples

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
pad_type = H5ML.get_constant_value('H5T_PAD_ZERO');
H5T.set_inpad(type_id,pad_type);
```

See Also

`H5T.get_inpad`

H5T.set_norm

Set mantissa normalization of floating-point data type

Syntax

```
H5T.set_norm(type_id,norm)
```

Description

`H5T.set_norm(type_id,norm)` sets the mantissa normalization of a floating-point data type. Valid normalization types are: `H5T_NORM_IMPLIED`, `H5T_NORM_MSBSET`, or `H5T_NORM_NONE`.

Examples

```
type_id = H5T.copy('H5T_NATIVE_FLOAT');
norm_type = H5ML.get_constant_value('H5T_NORM_MSBSET');
H5T.set_norm(type_id,norm_type);
```

See Also

`H5T.get_norm`

H5T.set_offset

Set bit offset of first significant bit

Syntax

```
H5T.set_offset(type_id,offset)
```

Description

`H5T.set_offset(type_id,offset)` sets the bit offset of the first significant bit. `type_id` is the identifier of the data type. `offset` specifies the number of bits of padding that appear.

Examples

```
type_id = H5T.copy('H5T_NATIVE_INT');
H5T.set_offset(type_id,16);
```

See Also

`H5T.get_offset`

H5T.set_order

Set byte ordering of atomic data type

Syntax

```
H5T.set_order(type_id,type_order)
```

Description

`H5T.set_order(type_id,type_order)` sets the byte ordering of an atomic data type. `type_order` can be one of the following values:

`H5T_ORDER_LE`

`H5T_ORDER_BE`

`H5T_ORDER_VAX`

Examples

Create a big endian 32-bit integer type.

```
type_id = H5T.copy('H5T_NATIVE_INT');
order = H5ML.get_constant_value('H5T_ORDER_BE');
H5T.set_order(type_id,order);
```

See Also

`H5ML.get_constant_value` | `H5T.get_order`

H5T.set_pad

Set padding type for least and most significant bits

Syntax

```
H5T.set_pad(type_id,lsb,msb)
```

Description

`H5T.set_pad(type_id,lsb,msb)` sets the padding type for the least and most-significant bits. `type_id` is the identifier of the data type. `lsb` specifies the padding type for least-significant bits; `msb` for most-significant bits. Valid padding types are `H5T_PAD_ZERO`, `H5T_PAD_ONE`, or `H5T_PAD_BACKGROUND` (leave background alone).

Examples

```
type_id = H5T.copy('H5T_NATIVE_INT');
lsb = H5ML.get_constant_value('H5T_PAD_ONE');
msb = H5ML.get_constant_value('H5T_PAD_ZERO');
H5T.set_pad(type_id,lsb,msb);
```

See Also

`H5T.get_pad`

H5T.set_precision

Set precision of atomic data type

Syntax

```
H5T.set_precision(type_id,prec)
```

Description

`H5T.set_precision(type_id,prec)` sets the precision of an atomic data type. `type_id` is a data type identifier. `prec` specifies the number of bits of precision for the data type.

H5T.set_sign

Set sign property for integer data type

Syntax

```
H5T.set_sign(type_id,sign)
```

Description

`H5T.set_sign(type_id,sign)` sets the sign property for an integer type. `type_id` is a data type identifier. `sign` specifies the sign type. Valid values are `H5T_SGN_NONE` or `H5T_SGN_2`.

Examples

```
type_id = H5T.copy('H5T_NATIVE_LONG');
sgn = H5ML.get_constant_value('H5T_SGN_NONE');
H5T.set_sign(type_id,sgn);
```

See Also

`H5T.get_sign`

H5T.set_size

Set size of data type in bytes

Syntax

```
H5T.set_size(type_id,type_size)
```

Description

`H5T.set_size(type_id,type_size)` sets the total size in bytes for the data type specified by `type_id`. The string `'H5T_VARIABLE'` can also be used if a variable length string is desired.

Examples

Create a variable length string with null termination.

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,'H5T_VARIABLE');
H5T.set_strpad(type_id,'H5T_STR_NULLTERM');
```

See Also

`H5T.get_size`

H5T.set_strpad

Set storage mechanism for string data type

Syntax

```
H5T.set_strpad(type_id,storage_type)
```

Description

`H5T.set_strpad(type_id,storage_type)` defines the storage mechanism for the string data type identified by `type_id`. The storage type may be one of the following values.

`'H5T_STR_NULLTERM'`	Null terminated
`'H5T_STR_NULLPAD'`	Padded with zeros
`'H5T_STR_SPACEPAD'`	Padded with spaces

Examples

Create a ten-character string data type with space padding.

```
type_id = H5T.copy('H5T_C_S1');
H5T.set_size(type_id,10);
H5T.set_strpad(type_id,'H5T_STR_SPACEPAD');
```

See Also

`H5T.get_strpad`

H5T.get_member_class

Data type class for compound data type member

Syntax

```
output = H5T.get_member_class(type_id,membno)
```

Description

`output = H5T.get_member_class(type_id,membno)` returns the data type class of the compound data type member specified by `membno`. The `type_id` argument is the data type identifier of a compound object.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/compound');
type_id = H5D.get_type(dset_id);
member_name = H5T.get_member_name(type_id,0);
member_class = H5T.get_member_class(type_id,0);
```

See Also

`H5T.get_member_name`

H5T.get_member_index

Index of compound or enumeration type member

Syntax

```
idx = H5T.get_member_index(type_id,name)
```

Description

`idx = H5T.get_member_index(type_id,name)` returns the index of a field of a compound data type or an element of an enumeration data type. `type_id` is a data type identifier and name is a text string that identifies the target field or element.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/compound');
type_id = H5D.get_type(dset_id);
idx = H5T.get_member_index(type_id,'b');
```

See Also

`H5T.get_member_name`

H5T.get_member_name

Name of compound or enumeration type member

Syntax

```
name = H5T.get_member_name(type_id,membno)
```

Description

`name = H5T.get_member_name(type_id,membno)` returns the name of a field of a compound data type or an element of an enumeration data type. `type_id` is a data type identifier. `membno` is a zero-based index of the field or element whose name is to be retrieved.

Examples

Determine the name of the first field of a compound dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/compound');
dtype_id = H5D.get_type(dset_id);
member_name = H5T.get_member_name(dtype_id,0);
```

See Also

`H5T.get_member_index`

H5T.get_member_offset

Offset of field of compound data type

Syntax

```
output = H5T.get_member_offset(type_id,membno)
```

Description

`output = H5T.get_member_offset(type_id,membno)` returns the byte offset of the field specified by `membno` in the compound data type specified by `type_id`. Note that zero (0) is a valid offset.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/compound');
type_id = H5D.get_type(dset_id);
idx = H5T.get_member_offset(type_id,1);
```

See Also

`H5T.get_member_name`

H5T.get_member_type

Data type of specified member

Syntax

```
type_id = H5T.get_member_type(type_id,membno)
```

Description

`type_id = H5T.get_member_type(type_id,membno)` returns the data type of the member specified by `membno` in the data type specified by `type_id`.

Examples

Get the size of the data type of the first member of a compound data type.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/compound');
compound_type_id = H5D.get_type(dset_id);
member_type_id = H5T.get_member_type(compound_type_id,0);
type_size = H5T.get_size(member_type_id);
```

See Also

`H5D.get_type`

H5T.get_nmembers

Number of elements in enumeration type

Syntax

```
output = H5T.get_nmembers(type_id)
```

Description

`output = H5T.get_nmembers(type_id)` retrieves the number of fields in a compound data type or the number of members of an enumeration data type. `type_id` is a data type identifier.

Examples

Determine the number of fields in a compound dataset.

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/compound');
dtype_id = H5D.get_type(dset_id);
nmembers = H5T.get_nmembers(dtype_id);
```

H5T.insert

Add member to compound data type

Syntax

```
H5T.insert(type_id,name,offset,member_datatype)
```

Description

`H5T.insert(type_id,name,offset,member_datatype)` adds another member to the compound data type specified by `type_id`. The `name` argument is a text string that specifies the name of the new member, which must be unique in the compound data type. `offset` specifies where you want to insert the new member and `member_datatype` specifies the data type identifier of the new member.

Examples

```
type_id = H5T.create('H5T_COMPOUND',16);
H5T.insert(type_id,'first',0,'H5T_NATIVE_DOUBLE');
H5T.insert(type_id,'second',8,'H5T_NATIVE_INT');
H5T.insert(type_id,'third',12,'H5T_NATIVE_UINT');
```

See Also

`H5T.create`

H5T.pack

Recursively remove padding from compound data type

Syntax

```
H5T.pack(type_id)
```

Description

`H5T.pack(type_id)` recursively removes padding from within a compound data type to make it more efficient (space-wise) to store that data. `type_id` is a data type identifier.

H5T.enum_create

Create new enumeration data type

Syntax

```
output = H5T.enum_create(parent_id)
```

Description

`output = H5T.enum_create(parent_id)` creates a new enumeration data type based on the specified base data type, `parent_id`, which must be an integer type. `output` is a data type identifier for the new enumeration data type.

Examples

```
parent_id = H5T.copy('H5T_NATIVE_UINT');
type_id = H5T.enum_create(parent_id);
H5T.enum_insert(type_id,'red',1);
H5T.enum_insert(type_id,'green',2);
H5T.enum_insert(type_id,'blue',3);
H5T.close(type_id);
H5T.close(parent_id);
```

See Also

`H5T.enum_insert`

H5T.enum_insert

Insert enumeration data type member

Syntax

```
H5T.enum_insert(type_id,name,value)
```

Description

`H5T.enum_insert(type_id,name,value)` inserts a new enumeration data type member into the enumeration data type specified by `type_id`. The `name` argument is a text string that specifies the name of the new member of the enumeration and `value` is the value of the member.

Examples

```
parent_id = H5T.copy('H5T_NATIVE_UINT');
type_id = H5T.enum_create(parent_id);
H5T.enum_insert(type_id,'red',1);
H5T.enum_insert(type_id,'green',2);
H5T.enum_insert(type_id,'blue',3);
H5T.close(type_id);
H5T.close(parent_id);
```

See Also

`H5T.enum_create`

H5T.enum_nameof

Name of enumeration data type member

Syntax

```
name = H5T.enum_nameof(type_id,value)
```

Description

`name = H5T.enum_nameof(type_id,value)` returns the symbol name corresponding to a member of an enumeration data type. `type_id` specifies the enumeration data type. `value` identifies the member of the enumeration.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/enum');
type_id = H5D.get_type(dset_id);
name0 = H5T.enum_nameof(type_id,int32(0));
name1 = H5T.enum_nameof(type_id,int32(1));
```

See Also

`H5T.enum_valueof`

H5T.enum_valueof

Value of enumeration data type member

Syntax

```
value = H5T.enum_valueof(type_id,member_name)
```

Description

`value = H5T.enum_valueof(type_id,member_name)` returns the value corresponding to a specified member of an enumeration data type. `type_id` specifies the enumeration data type and `member_name` specifies the member.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/enum');
type_id = H5D.get_type(dset_id);
num_members = H5T.get_nmembers(type_id);
for j = 1:num_members
    member_name{j} = H5T.get_member_name(type_id,j-1);
    member_value(j) = H5T.enum_valueof(type_id,member_name{j});
end
```

See Also

`H5T.get_member_name` | `H5T.get_nmembers`

H5T.get_member_value

Value of enumeration data type member

Syntax

```
value = H5T.get_member_value(type_id,membno)
```

Description

`value = H5T.get_member_value(type_id,membno)` returns the value of the enumeration data type member specified by `membno`. The `type_id` argument is the data type identifier for the enumeration data type.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/enum');
type_id = H5D.get_type(dset_id);
num_members = H5T.get_nmembers(type_id);
for j = 1:num_members
    member_name{j} = H5T.get_member_name(type_id,j-1);
    member_value(j) = H5T.get_member_value(type_id,j-1);
end
```

See Also

`H5T.get_member_name` | `H5T.get_nmembers`

H5T.get_tag

Tag associated with opaque data type

Syntax

```
tag = H5T.get_tag(type_id)
```

Description

`tag = H5T.get_tag(type_id)` returns the tag associated with the opaque data type specified by `type_id`.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/opaque');
dtype_id = H5D.get_type(dset_id);
tag = H5T.get_tag(dtype_id);
```

See Also

`H5T.set_tag`

H5T.set_tag

Tag opaque data type with description

Syntax

```
H5T.set_tag(type_id,tag)
```

Description

`H5T.set_tag(type_id,tag)` tags the opaque data type specified by `type_id`, with the descriptive ASCII string identifier, `tag`.

Examples

Create an opaque data type with a length of 4 bytes and a particular tag.

```
type_id = H5T.create('H5T_OPAQUE',4);
H5T.set_tag(type_id,'Created by MATLAB.');
```

See Also

`H5T.create` | `H5T.get_tag`

H5T.is_variable_str

Determine if data type is variable-length string

Syntax

```
output = H5T.is_variable_str(type_id)
```

Description

`output = H5T.is_variable_str(type_id)` returns a positive value if the data type specified by `type_id` is a variable-length string and zero if it is not. A negative value indicates failure.

Examples

```
fid = H5F.open('example.h5');
dset_id = H5D.open(fid,'/g3/VLstring2D');
type_id = H5D.get_type(dset_id);
if H5T.is_variable_str(type_id) > 0
    fprintf('variable length string\n');
end
```

See Also

`H5D.get_type` | `H5T.get_size` | `H5T.vlen_create`

H5T.vlen_create

Create new variable-length data type

Syntax

```
vlen_type_id = H5T.vlen_create(base_id)
```

Description

`vlen_type_id = H5T.vlen_create(base_id)` creates a new variable-length (VL) data type. `base_id` specifies the base type of the data type to create.

Examples

Create a variable length data type for 64-bit floating-point numbers.

```
base_type_id = H5T.copy('H5T_NATIVE_DOUBLE');
vlen_type_id = H5T.vlen_create(base_type_id);
```

See Also

`H5T.is_variable_str`

H5Z.filter_avail

Determine if filter is available

Syntax

```
output = H5Z.filter_avail(filter_id)
```

Description

`output = H5Z.filter_avail(filter_id)` determines whether the filter specified by the filter identifier is available to the application. `filter_id` can be specified by one of the following strings or its numeric equivalent.

```
'H5Z_FILTER_DEFLATE'
'H5Z_FILTER_SHUFFLE'
'H5Z_FILTER_FLETCHER32'
'H5Z_FILTER_SZIP'
'H5Z_FILTER_NBIT'
'H5Z_FILTER_SCALEOFFSET'
```

Examples

Determine if the shuffle filter is available.

```
bool = H5Z.filter_avail('H5Z_FILTER_SHUFFLE');
```

See Also

`H5ML.get_constant_value`

H5Z.get_filter_info

Information about filter

Syntax

```
filter_config_flags = H5Z.get_filter_info(filter)
```

Description

`filter_config_flags = H5Z.get_filter_info(filter)` retrieves information about the filter specified by its identifier. At present, the information returned is the filter's configuration flags, indicating whether the filter is configured to decode data, to encode data, neither, or both. `filter_config_flags` should be used with the HDF5 constant values `H5Z_FILTER_CONFIG_ENCODE_ENABLED` and `H5Z_FILTER_CONFIG_DECODE_ENABLED` in a bitwise AND operation. If the resulting value is 0, then the encode or decode functionality is not available.

Examples

Determine if encoding is enabled for the deflate filter.

```
flags = H5Z.get_filter_info('H5Z_FILTER_DEFLATE');
functionality = H5ML.get_constant_value('H5Z_FILTER_CONFIG_ENCODE_ENABLED');
enabled = bitand(flags,functionality) > 0;
```

See Also

`bitand` | `H5ML.get_constant_value` | `H5Z.filter_avail`

hadamard

Hadamard matrix

Syntax

```
H = hadamard(n)
```

Description

`H = hadamard(n)` returns the Hadamard matrix of order `n`.

Definitions

Hadamard matrices are matrices of `1`'s and `-1`'s whose columns are orthogonal,

```
H'*H = n*I
```

where `[n n]=size(H)` and `I = eye(n,n)` ,.

They have applications in several different areas, including combinatorics, signal processing, and numerical analysis, [1], [2].

An `n`-by-`n` Hadamard matrix with `n > 2` exists only if `rem(n,4) = 0`. This function handles only the cases where `n`, `n/12`, or `n/20` is a power of 2.

Examples

The command `hadamard(4)` produces the 4-by-4 matrix:

```
1     1     1     1
1    -1     1    -1
1     1    -1    -1
1    -1    -1     1
```

`compan` | `hankel` | `toeplitz`

Introduced before R2006a

handle class

Abstract class for deriving handle classes

Description

`classdef` *`MyHandleClass`* `<` `handle` makes *`MyHandleClass`* a subclass of the `handle` class.

The `handle` class is the superclass for all classes that follow handle semantics. A *handle* is a reference to an object. If you copy an object's handle variable, MATLAB copies only the handle. Both the original and copy refer to the same object. For example, if a function modifies a handle object passed as an input argument, the modification affects the original input object.

In contrast, nonhandle objects (that is, value objects) are not references. Functions must return modified value objects to change the object outside of the function's workspace.

See “Modifying Objects” for information on passing objects to functions.

If you want to create a class that defines events, you must derive that class from the `handle` class.

The `handle` class is an abstract class, so you cannot create an instance of this class directly. You use the `handle` class to derive other classes, which can be concrete classes whose instances are handle objects. See “Handle Classes” for information on using handle classes.

Methods

addlistener	Create event listener
delete	Delete handle object
findobj	Find handle objects

findprop	Find `meta.property` object
isvalid	Determine valid handles
notify	Notify listeners that event is occurring
relationaloperators	Determine equality or sort handle objects

Events

`ObjectBeingDestroyed`	Triggered when the handle object is about to be destroyed, but before calling the `delete` method. Listener callbacks execute before MATLAB destroys the handle object.

Destroying Handle Objects

MATLAB destroys handle objects when there are no references to the object. You can explicitly remove a handle object by calling its `delete` method. The `handle` class enables you to control what happens when handle objects are destroyed, either implicitly when no references exist or explicitly when you delete the object.

Define `delete` Method in Subclass

Subclasses of `handle` can define their own `delete` method. MATLAB calls this method when deleting an object of the subclass, enabling your subclass to perform any specific actions necessary before deleting an object.

For more information, see “Handle Class Destructor”.

Create Listener for `ObjectBeingDestroyed` Event

Any code can respond to the pending deletion of a handle object by defining a listener for that object’s `ObjectBeingDestroyed` event. MATLAB triggers this event before calling the object’s `delete` method.

For more information on using events and listeners, see “Events and Listeners — Syntax and Techniques”.

Attributes

`Abstract`	`true`
`ConstructOnLoad`	`true`
`HandleCompatible`	`true`

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Derive Class from `handle`

Derive `MyClass` from `handle`:

```
classdef MyClass < handle
   properties
      Prop1
   end
   methods
      function obj = MyClass(arg)
         obj.Prop1 = arg;
      end
   end
end
```

- Class Attributes

- “Handle Classes”
- “Supporting Both Handle and Value Subclasses”
- “Handle Objects”

addlistener

Class: handle

Create event listener

Syntax

```
lh = addlistener(Hsource,EventName,callback)
lh = addlistener(Hsource,property,EventName,callback)
```

Description

`lh = addlistener(Hsource,EventName,callback)` creates a listener for the specified event when triggered on the source object.

If `Hsource` is not scalar, the listener responds to the named event on any object in the `Hsource` array.

`lh = addlistener(Hsource,property,EventName,callback)` creates a listener for one of the predefined property events. There are four predefined property events:

Event Name	Event Occurs
`PreSet`	Immediately before the property value is set, before calling its set access method
`PostSet`	Immediately after the property value is set
`PreGet`	Immediately before a property value query is serviced, before calling its get access method
`PostGet`	Immediately after returning the property value to the query

Tips

- To remove a listener, delete the listener object returned by `addlistener`. For example,

```
delete(lh)
```

calls the handle class delete method to delete the object from the workspace and remove the listener.

- Redefining or clearing the variable containing the handle of the listener (for example, `lh`) does not delete the listener. The event object (`Hsource`) still has a reference to the `event.listener` object. `addlistener` ties the listener's lifecycle to the object that is the source of the event.
- To define a listener that is not tied to the event object, use the `event.listener` constructor directly to create the listener.

Input Arguments

`Hsource` — Event source

handle array

Event source is the object that is source of the event, or an array of source objects, specified as a handle array.

`EventName` — Name of event

character array

Name of event that is triggered on the source objects, specified as a case-sensitive, quoted string. For property events, the event name is one of the four predefined property events.

`property` — Name of property

string

Name of the property whose property event triggers your listener, specified as one of these values:

- A scalar `meta.property` object
- An array or a cell array of `meta.property` objects
- A string or a cell array of strings, where each string is the name of a property defined for the objects in `Hsource`

  You can listen to property events on dynamic properties only If `Hsource` is scalar. If `Hsource` is non-scalar, then the properties must belong to the class of `Hsource` and can not include dynamic properties (which are not part of the class definition).

The class defining the source property must set the `GetObservable` and `SetObservable` property attributes to enable you to listen to the property events.

`callback` — Listener callback
function handle

Listener callback specified as a function handle

Data Types: `function_handle`

Output Arguments

`lh` — listener
`event.listener` or `event.proplistener`

Listener object created by `addlistener`, specified as the handle to an `event.listener` or an `event.proplistener` object.

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Alternatives

When you need the lifecycle of the listener object to be independent of the source object lifecycle, use the `even.listener` or `event.proplistener` to create listeners.

See Also
`handle.notify` | `event.listener`

delete

Class: handle

Delete handle object

Syntax

```
delete(h)
```

Description

`delete(h)` deletes a handle object, but does not clear the handle variable from the workspace. The handle variable is not valid once the handle object has been deleted.

Subclasses of `handle` can implement a method named `delete` to perform cleanup tasks just before MATLAB destroys an object of the class. MATLAB calls the `delete` method of any `handle` object when the object is destroyed when the subclass `delete` method meets certain criteria.

For information on implementing a class destructor for a subclass of `handle`, see "Handle Class Destructor".

Input Arguments

h — Objects to destroy

handle array

Objects to destroy, specified as a handle array.

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

`isvalid`

More About

- “Handle Class Destructor”
- “Handle Objects”

findobj

Class: handle

Find handle objects

Syntax

```
Hmatch = findobj(H)
Hmatch = findobj(H,property,value,...,property,value)
Hmatch = findobj(H,'-not',property,value)
Hmatch = findobj(H,'-regexp',property,value)
Hmatch = findobj(H,property,value,'-logicaloperator',property,value)
Hmatch = findobj(H,'-function',fh)
Hmatch = findobj(H,'-function',property,fh)
Hmatch = findobj(H,'-property',property)
Hmatch = findobj(H,'-method',methodname)
Hmatch = findobj(H,'-event',eventname)
Hmatch = findobj(H,'-depth',d,___)
Hmatch = findobj(H,'flat',___)
```

Description

`Hmatch = findobj(H)` returns the objects listed in `H` and all of their descendants.

`Hmatch = findobj(H,property,value,...,property,value)` finds `handle` objects that have the specified property set to the specified value.

`Hmatch = findobj(H,'-not',property,value)` inverts the expression in the following `property value` pair. That is, find objects whose specified property is not equal to `value`.

`Hmatch = findobj(H,'-regexp',property,value)` treats the content of the `value` argument as regular expressions.

`Hmatch = findobj(H,property,value,'-logicaloperator',property,value)` applies the logical operator to the name/value pairs. Supported logical operators include:

- `'-or'` (default if you do not specify an operator)
- `'-and'`
- `'-xor'`

`Hmatch = findobj(H,'-function',fh)` calls the function handle `fh` on the objects in `H` and returns the objects for which the function returns `true`.

`Hmatch = findobj(H,'-function',property,fh)` calls the function handle `fh` on the specified property's value for the objects in `H` and returns the objects for which the function returns `true`. The function must return a scalar logical value.

`Hmatch = findobj(H,'-property',property)` finds all object in `H` having the named property.

`Hmatch = findobj(H,'-method',methodname)` finds objects that have the specified method name.

`Hmatch = findobj(H,'-event',eventname)` finds objects that have the specified method name.

`Hmatch = findobj(H,'-depth',d, ___ )` specifies how many levels in the instance hierarchies under the objects in `H` to search.

`Hmatch = findobj(H,'flat', ___ )` searches only the level of the objects in array `H`.

Tips

- `findobj` has access only to public properties
- If there are no matches, `findobj` returns an empty array of the same class as the input array `H`.
- Logical operator precedence follows MATLAB precedence rules. For more information, see "Operator Precedence".
- Control precedence by grouping within cell arrays

Input Arguments

`H` — Objects to search from

handle array

Objects to search from, specified as an array of object handles. Unless the you specify the `'-depth'` or `'flat'` options, `findobj` searches the objects in the input array `H` and child objects in the instance hierarchy.

`property` — Property name
string

Property name, specified as a case-sensitive, quoted string.

`value` — Property value
any value

Property value, specified as a value or MATLAB expression.

`methodname` — Method name
string

Method name, specified as a case-sensitive quoted string.

`eventname` — Event name
string

Event name, specified as a case-sensitive quoted string.

`d` — Depth of search
integer >= 0

Depth of search, specified as an integer indicating the number of levels below any given object in the input array `H`.

- `d = n` — Search `n` levels of the hierarchy below each object in `H`
- `d = 0` — Search only the same level as the objects in `H`.
- `d = inf` — Search all levels below objects in `H`. This is the default.

`fh` — Function handle
function handle

Function handle, specifying the function that is evaluated for each object in the input array `H`. This function must return a scalar, logical value indicating whether there is a match (`true`) or not (`false`).

Output Arguments

`Hmatch` — Objects found by search

handle array

Objects found by search, returned as a handle array.

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Object with Specific Property Value

Find the object with a specific property value. Given the `handle` class, `BasicHandle`:

```
classdef BasicHandle < handle
   properties
      Prop1
   end
   methods
      function obj = BasicHandle(val)
         if nargin > 0
            obj.Prop1 = val;
         end
      end
   end
end
```

Create an array of `BasicHandle` objects:

```
h(1) = BasicHandle(7);
h(2) = BasicHandle(11);
h(3) = BasicHandle(27);
```

Find the handle of the object whose `Prop1` property has a value of 7:

```
h7 = findobj(h,'Prop1',7);
h7.Prop1

ans =

     7
```

Object with Specific Property Name

Find the object with a specific dynamic property. Given the `button` class:

```
classdef button < dynamicprops
   properties
      UiHandle
   end
   methods
      function obj = button(pos)
         if nargin > 0
            if length(pos) == 4
               obj.UiHandle = uicontrol('Position',pos,...
                'Style','pushbutton');
            else
               error('Improper position')
            end
         end
      end
   end
end
```

Create an array of button objects, only one element of which defines a dynamic property. Use `findobj` to get the handle of the object with the dynamic property named `ButtonCoord`:

```
b(1) = button([20 40 80 20]);
b(1).addprop('ButtonCoord');
b(1).ButtonCoord = [2,3];
b(2) = button([120 40 80 20]);
b(3) = button([220 40 80 20]);

h =  findobj(b,'-property','ButtonCoord');
h.ButtonCoord

ans =
```

2 3

See Also

handle.findprop

findprop

Class: handle

Find `meta.property` object

Syntax

```
mp = findprop(h,property)
```

Description

`mp = findprop(h,property)` returns the `meta.property` object associated with the named property of the object `h`. `property` can be a property defined by the class of `h` or a dynamic property defined only for the object `h`.

Input Arguments

`h` — handle object

handle

Handle object, specified as a scalar handle.

`property` — Name of property

string

Name of property, specified as a case-sensitive, quoted string.

Output Arguments

`mp` — `meta.property` object

`meta.property`

`meta.property` object that is associated with the named property. If `findprop` does not find the property on the object `h`, `findprop` returns a 0-by-1 empty `meta.property` object.

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

View Property Attribute Settings

Use `findprop` to view property attribute settings:

```
mp = findprop(containers.Map,'Count')
```

```
mp =

  property with properties:

                  Name: 'Count'
           Description: 'Number of pairs in the collection'
    DetailedDescription: ''
              GetAccess: 'public'
              SetAccess: 'private'
              Dependent: 1
               Constant: 0
               Abstract: 0
              Transient: 1
                 Hidden: 0
         GetObservable: 0
         SetObservable: 0
              AbortSet: 0
             GetMethod: []
             SetMethod: []
            HasDefault: 0
         DefiningClass: [1x1 meta.class]
```

See Also

`handle.findobj` | `meta.property`

More About

- "Getting Information About Properties"
- "Dynamic Properties — Adding Properties to an Instance"

isvalid

Class: handle

Determine valid handles

Syntax

```
B = isvalid(H)
```

Description

`B = isvalid(H)` returns a logical array in which each element is `true` if the corresponding element in `H` is a valid handle. A handle variable becomes invalid if the object has been deleted.

You cannot override the `isvalid` method in `handle` subclasses.

Input Arguments

`H` — Input array

handle array

Input array, specified as an array of object handles.

Output Arguments

`B` — Result of validity test

logical

Result of validity test, returned as a logical array the same size as `H` in which each element is `true` if the corresponding element in `H` is a valid handle.

Attributes

`Access`	`public`

```
Sealed                                  true
```

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Test for Valid Handles

This example tests a handle array for valid members:

```
H = plot(rand(5));
delete(H(3:4))
B = isvalid(H)
```

```
B =

     1
     1
     0
     0
     1
```

See Also

`handle.delete` | `isgraphics`

More About

- "Testing Handle Validity"

notify

Class: handle

Notify listeners that event is occurring

Syntax

```
notify(H,EventName)
notify(H,EventName,data)
```

Description

`notify(H,EventName)` notifies listeners that the named event is taking place on the handle objects in `H`.

`notify(H,EventName,data)` includes user-defined event data.

Input Arguments

`H` — Event source

handle array

Event source, specified as a handle array. All of the objects in `H` must defined the named event.

`EventName` — Name of event

string

Name of event, specified as a case-sensitive, quoted string that is defined by the class of `H`.

`data` — User-defined event data

subclass of `event.EventData`

User-defined event data, specified as an object that is a subclass of the `event.EventData` class. For information on defining event data, see "Define Event-Specific Data".

Note: Listener callbacks should not reuse the same event data object in subsequent calls to `notify`. Always create a new event data object to pass to `notify`.

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`handle.addlistener`

More About

- "Events and Listeners — Syntax and Techniques"

relationaloperators

Class: handle

Determine equality or sort handle objects

Syntax

```
tf = eq(H1,H2)
tf = ne(H1,H2)
tf = lt(H1,H2)
tf = le(H1,H2)
tf = gt(H1,H2)
tf = ge(H1,H2)
```

Description

`tf = eq(H1,H2)` Equal. (`H1 == H2`)

`tf = ne(H1,H2)` Not equal. (`H1 ~= H2`)

`tf = lt(H1,H2)` Less than. (`H1 < H2`)

`tf = le(H1,H2)` Less than or equal. (`H1 <= H2`)

`tf = gt(H1,H2)` Greater than. (`H1 > H2`)

`tf = ge(H1,H2)` Greater than or equal. (`H1 >= H2`)

For each pair of input arrays (`H1` and `H2`), the operation returns a logical array of the same size. Each element in the returned array is an element-wise equality or comparison test result. These methods perform scalar expansion in the same way as the MATLAB built-in relational operators. See `relationaloperators` for more information.

The following guidelines apply to handle comparison:

- Copies of a handle variable always compare as equal.
- The repeated comparison of any two handles always yields the same result in the same MATLAB session.

- Different handles are always not equal.
- The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.
- If the input arrays belong to different classes (including the case where one input array belongs to a non-handle class such as `double`) then the comparison is always false.
- If you make a comparison between a handle object and an object of a dominant class, the method of the dominant class is invoked. You should generally test only like objects because a dominant class might not define one of these methods.
- An error occurs if the input arrays are not the same size and neither is scalar.

Use `isequal` when you want to determine if different handle objects have the same data in all object properties.

Input Arguments

`H1` — Left argument to operator

handle array

Left argument to operator, specified as a handle array.

`H2` — Right argument to operator

handle array

Right argument to operator, specified as a handle array.

Output Arguments

`tf` — Result of comparison

logical array

Result of comparison, returned as a logical array of the same size as the input arrays, where each element is an element-wise equality or comparison test result

- `1` — relationship is true
- `0` — relationship if not true

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`isequal`

hankel

Hankel matrix

Syntax

```
H = hankel(c)
H = hankel(c,r)
```

Description

`H = hankel(c)` returns the square Hankel matrix whose first column is `c` and whose elements are zero below the first anti-diagonal.

`H = hankel(c,r)` returns a Hankel matrix whose first column is `c` and whose last row is `r`. If the last element of `c` differs from the first element of `r`, the last element of `c` prevails.

Definitions

A Hankel matrix is a matrix that is symmetric and constant across the anti-diagonals, and has elements `h(i,j) = p(i+j-1)`, where vector `p = [c r(2:end)]` completely determines the Hankel matrix.

Examples

A Hankel matrix with anti-diagonal disagreement is

```
c = 1:3; r = 7:10;
h = hankel(c,r)
h =
    1    2    3    8
    2    3    8    9
    3    8    9   10
```

```
p = [1 2 3 8 9 10]
```

See Also

`hadamard` | `kron` | `toeplitz`

Introduced before R2006a

hasnext

Determine if ValueIterator has one or more values available

Syntax

```
tf = hasnext(ValIter)
```

Description

`tf = hasnext(ValIter)` returns logical `1` (`true`) if `ValueIter` has one or more values available; otherwise, it returns logical `0` (`false`).

Examples

Get Values from ValueIterator in Reduce Function

Use the `hasnext` and `getnext` functions in a `while` loop within the reduce function to iteratively get values from the `ValueIterator` object. For example,

```
function MeanDistReduceFun(sumLenKey, sumLenIter, outKVStore)
    sumLen = [0 0];
    while hasnext(sumLenIter)
        sumLen = sumLen + getnext(sumLenIter);
    end
    add(outKVStore, 'Mean', sumLen(1)/sumLen(2));
end
```

Always call `hasnext` before `getnext` to confirm availability of a value. `mapreduce` returns an error if you call `getnext` with no remaining values in the `ValueIterator` object.

Input Arguments

`ValIter` — Intermediate value iterator

`ValueIterator` object

Intermediate value iterator, specified as a `ValueIterator` object. The `mapreduce` function automatically creates this object during execution. The second input to the reduce function specifies the variable name for the `ValueIterator` object, which is the variable name to use with the `hasnext` and `getnext` functions.

For more information, see Using ValueIterator Objects.

More About

- Using ValueIterator Objects
- "Build Effective Algorithms with MapReduce"

See Also

`getnext` | `mapreduce`

Introduced in R2014b

hasFrame

Class: VideoReader

Determine if frame available to read

Syntax

```
tf = hasFrame(obj)
```

Description

`tf = hasFrame(obj)` returns logical `1` (`true`) if there is a video frame available to read from the file. Otherwise, it returns logical `0` (`false`).

Input Arguments

`obj` — Object associated with video file to read

`VideoReader` object

Object associated with the video file to read, specified as a `VideoReader` object.

Examples

Read and Play Back Movie File

Read and play back the sample movie file, `xylophone.mp4`.

Construct a `VideoReader` object to read data from the sample file. Then, determine the width and height of the video.

```
xyloObj = VideoReader('xylophone.mp4');

vidWidth = xyloObj.Width;
vidHeight = xyloObj.Height;
```

Create a movie structure array, `mov`.

```
mov = struct('cdata',zeros(vidHeight,vidWidth,3,'uint8'),...
    'colormap',[]);
```

Read one frame at a time until the end of the video is reached.

```
k = 1;
while hasFrame(xyloObj)
    mov(k).cdata = readFrame(xyloObj);
    k = k+1;
end
```

Size a figure based on the video's width and height. Then, play back the movie once at the video's frame rate.

```
hf = figure;
set(hf,'position',[150 150 vidWidth vidHeight]);

movie(hf,mov,1,xyloObj.FrameRate);
```

`movie` | `VideoReader`

hdf5info

Information about HDF5 file

Note: `hdf5info` will be removed in a future version. Use `h5info` instead.

Syntax

```
fileinfo = hdf5info(filename)
fileinfo = hdf5info(...,'ReadAttributes',BOOL)
[...] = hdf5info(..., 'V71Dimensions', BOOL)
```

Description

`fileinfo = hdf5info(filename)` returns a structure `fileinfo` whose fields contain information about the contents of the HDF5 file `filename`. `filename` is a string that specifies the name of the HDF5 file.

`fileinfo = hdf5info(...,'ReadAttributes',BOOL)` specifies whether `hdf5info` returns the values of the attributes or just information describing the attributes. By default, `hdf5info` reads in attribute values (`BOOL` = `true`).

`[...] = hdf5info(..., 'V71Dimensions', BOOL)` specifies whether to report the dimensions of data sets and attributes as they were returned in previous versions of `hdf5info` (MATLAB 7.1 [R14SP3] and earlier). If `BOOL` is true, `hdf5info` swaps the first two dimensions of the data set. This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, swapping these dimensions may not correctly reflect the intent of the data in the file and may invalidate metadata. When `BOOL` is false (the default), `hdf5info` returns data dimensions that correctly reflect the data ordering as it is written in the file —each dimension in the output variable matches the same dimension in the file.

Note If you use the `'V71Dimensions'` parameter and intend on passing the `fileinfo` structure returned to the `hdf5read` function, you should also specify the

`'V71Dimensions'` parameters with `hdf5read`. If you do not, `hdf5read` uses the new behavior when reading the data set and certain metadata returned by `hdf5info` does not match the actual data returned by `hdf5read`.

Examples

```
fileinfo = hdf5info('example.h5');
```

To get more information about the contents of the HDF5 file, look at the `GroupHierarchy` field in the `fileinfo` structure returned by `hdf5info`.

```
toplevel = fileinfo.GroupHierarchy

toplevel =

      Filename: [1x64 char]
          Name: '/'
        Groups: [1x2 struct]
      Datasets: []
     Datatypes: []
         Links: []
    Attributes: [1x2 struct]
```

To probe further into the file hierarchy, keep examining the `Groups` field.

See also

`hdf5read`, `hdf5write`

hdf5read

Read HDF5 file

Note: `hdf5read` will be removed in a future version. Use `h5read` instead.

Syntax

```
data = hdf5read(filename,datasetname)
attr = hdf5read(filename,attributename)
[data, attr] = hdf5read(...,'ReadAttributes',BOOL)
data = hdf5read(hinfo)
[...] = hdf5read(..., 'V71Dimensions', BOOL)
```

Description

`data = hdf5read(filename,datasetname)` reads all the data in the data set `datasetname` that is stored in the HDF5 file `filename` and returns it in the variable `data`. To determine the names of data sets in an HDF5 file, use the `hdf5info` function.

The return value, `data`, is a multidimensional array. `hdf5read` maps HDF5 data types to native MATLAB data types, whenever possible. If it cannot represent the data using MATLAB data types, `hdf5read` uses one of the HDF5 data type objects. For example, if an HDF5 file contains a data set made up of an enumerated data type, `hdf5read` uses the `hdf5.h5enum` object to represent the data in the MATLAB workspace. The `hdf5.h5enum` object has data members that store the enumerations (names), their corresponding values, and the enumerated data.

Note: `hdf5read` performs best when reading numeric datasets. If you need to read string, compound, or variable length datasets, MathWorks strongly recommends that you use the low-level HDF5 interface function, `H5D.read`. To read a subset of a dataset, you must use the low-level interface.

`attr = hdf5read(filename,attributename)` reads all the metadata in the attribute `attributename`, stored in the HDF5 file `filename`, and returns it in the variable `attr`. To determine the names of attributes in an HDF5 file, use the `hdf5info` function.

`[data, attr] = hdf5read(...,'ReadAttributes',BOOL)` reads all the data, as well as all of the associated attribute information contained within that data set. By default, `BOOL` is false.

`data = hdf5read(hinfo)` reads all of the data in the data set specified in the structure `hinfo` and returns it in the variable `data`. The `hinfo` structure is extracted from the output returned by `hdf5info`, which specifies an HDF5 file and a specific data set.

`[...] = hdf5read(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets read from the file. If `BOOL` is true, `hdf5read` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data dimensions correctly reflect the data ordering as it is written in the file — each dimension in the output variable matches the same dimension in the file.

Examples

Use `hdf5info` to get information about an HDF5 file and then use `hdf5read` to read a data set, using the information structure (`hinfo`) returned by `hdf5info` to specify the data set.

```
hinfo = hdf5info('example.h5');
dset = hdf5read(hinfo.GroupHierarchy.Groups(2).Datasets(1));
```

`hdf5info` | `hdf5write`

Introduced before R2006a

hdf5write

Write data to file in HDF5 format

Note: `hdf5write` will be removed in a future version. Use `h5write` instead.

Syntax

```
hdf5write(filename,location,dataset)
hdf5write(filename,details,dataset)
hdf5write(filename,details,attribute)
hdf5write(filename, details1, dataset1, details2, dataset2,...)
hdf5write(filename,...,'WriteMode',mode,...)
hdf5write(..., 'V71Dimensions', BOOL)
```

Description

`hdf5write(filename,location,dataset)` writes the data `dataset` to the HDF5 file, `filename`. If `filename` does not exist, `hdf5write` creates it. If `filename` exists, `hdf5write` overwrites the existing file, by default, but you can also append data to an existing file using an optional syntax.

`location` defines where to write the data set in the file. HDF5 files are organized in a hierarchical structure similar to a UNIX directory structure. `location` is a string that resembles a UNIX path.

`hdf5write` maps the data in `dataset` to HDF5 data types according to rules outlined below.

`hdf5write(filename,details,dataset)` writes `dataset` to `filename` using the values in the `details` structure. For a data set, the `details` structure can contain the following fields.

Field Name	Description	Data Type
`Location`	Location of the data set in the file	Character array

Field Name	Description	Data Type
`Name`	Name to attach to the data set	Character array

`hdf5write(filename,details,attribute)` writes the metadata `attribute` to `filename` using the values in the `details` structure. For an attribute, the `details` structure can contain following fields.

Field Name	Description	Data Type
`AttachedTo`	Location of the object this attribute modifies	Structure array
`AttachType`	Identifies what kind of object this attribute modifies; possible values are `'group'` and `'dataset'`	Character array
`Name`	Name to attach to the data set	Character array

`hdf5write(filename, details1, dataset1, details2, dataset2,...)` writes multiple data sets and associated attributes to `filename` in one operation. Each data set and attribute must have an associated `details` structure.

`hdf5write(filename,...,'WriteMode',mode,...)` specifies whether `hdf5write` overwrites the existing file (the default) or appends data sets and attributes to the file. Possible values for mode are `'overwrite'` and `'append'`.

`hdf5write(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets written to the file. If `BOOL` is true, `hdf5write` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data written to the file correctly reflects the data ordering of the data sets — each dimension in the file's data sets matches the same dimension in the corresponding MATLAB variable.

Data Type Mappings

The following table lists how `hdf5write` maps the data type from the workspace into an HDF5 file. If the data in the workspace that is being written to the file is a MATLAB

data type, `hdf5write` uses the following rules when translating MATLAB data into HDF5 data objects.

MATLAB Data Type	HDF5 Data Set or Attribute
Numeric	Corresponding HDF5 native data type. For example, if the workspace data type is `uint8`, the `hdf5write` function writes the data to the file as 8-bit integers. The size of the HDF5 dataspace is the same size as the MATLAB array.
String	Single, null-terminated string
Cell array of strings	Multiple, null-terminated strings, each the same length. Length is determined by the length of the longest string in the cell array. The size of the HDF5 dataspace is the same size as the cell array.
Cell array of numeric data	Numeric array, the same dimensions as the cell array. The elements of the array must all have the same size and type. The data type is determined by the first element in the cell array.
Structure array	HDF5 compound type. Individual fields in the structure employ the same data translation rules for individual data types. For example, a cell array of strings becomes a multiple, null-terminated strings.
HDF5 objects	If the data being written to the file is composed of HDF5 objects, `hdf5write` uses the same data type when writing to the file. For all HDF5 objects, except `HDF5.h5enum` objects, the dataspace has the same dimensions as the array of HDF5 objects passed to the function. For `HDF5.h5enum` objects, the size and dimensions of the data set in the HDF5 file is the same as the object's Data field.

Examples

Write a 5-by-5 data set of `uint8` values to the root group.

```
hdf5write('myfile.h5', '/dataset1', uint8(magic(5)))
```

Write a 2-by-2 string data set in a subgroup.

```
dataset = {'north', 'south'; 'east', 'west'};
hdf5write('myfile2.h5', '/group1/dataset1.1', dataset);
```

Write a data set and attribute to an existing group.

```
dset = single(rand(10,10));
dset_details.Location = '/group1/dataset1.2';
dset_details.Name = 'Random';

attr = 'Some random data';
attr_details.Name = 'Description';
attr_details.AttachedTo = '/group1/dataset1.2/Random';
attr_details.AttachType = 'dataset';

hdf5write('myfile2.h5', dset_details, dset, ...
          attr_details, attr, 'WriteMode', 'append');
```

Write a data set using objects.

```
dset = hdf5.h5array(magic(5));
hdf5write('myfile3.h5', '/g1/objects', dset);
```

Introduced before R2006a

hdfan

Gateway to HDF multifile annotation (AN) interface

Syntax

```
[out1,...,outN] = hdfan(funcstr,input1,...,inputN)
```

Description

`hdfan` is the MATLAB gateway to the HDF multifile annotation (AN) interface.

`[out1,...,outN] = hdfan(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the AN function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between AN functions in the HDF library and valid values for `funcstr`. For example, `hdfan('endaccess',annot_id)` corresponds to the C library call `ANendaccess(annot_id)`.

Access Functions

Access functions initialize the interface and provide and terminate access to annotations.

Value of `funcstr`	Function Syntax	Description
`'start'`	`AN_id = hdfan('start',file_id)`	Initializes the multifile annotation interface.
`'select'`	`annot_id = hdfan('select',AN_id, index,annot_type)`	Selects and returns the identifier for the annotation identified by the given index value and annotation type.
`'end'`	`status = hdfan('end',AN_id)`	Terminates access to the multifile annotation interface.
`'create'`	`annot_id = hdfan('create',AN_id,tag,r`	Creates a data annotation for the object identified by the specified tag and reference number. `annot_type` can be `'data_label'` or `'data_desc'`.

Value of `funcstr`	Function Syntax	Description
`'createf'`	`annot_id = hdfan('createf',AN_id,anno`	Creates a file label or file description annotation. `annot_type` can be `'file_label'` or `'file_desc'`.
`'endaccess'`	`status = hdfan('endaccess',annot_id`	Terminates access to an annotation.

Read/Write Functions

Read/write functions read and write file or object annotations.

Value of `funcstr`	Function Syntax	Description
`'writeann'`	`status = hdfan('writeann',annot_id,`	Writes the annotation corresponding to the given annotation identifier.
`'readann'`	`[annot_string,status] = hdfan('readann',annot_id)`	Reads the annotation corresponding to the given annotation identifier;
	`[annot_string,status] = hdfan('readann',annot_id,m`	Reads the annotation corresponding to the given annotation identifier. `annot_string` will not be longer than `max_str_length`.

General Inquiry Functions

General inquiry functions return information about the annotations in a file.

Value of `funcstr`	Function Syntax	Description
`'numann'`	`num_annot = hdfan('numann',AN_id,annot`	Gets number of annotations of specified type corresponding to given tag/ref pair.
`'annlist'`	`[ann_list,status] = hdfan('annlist',AN_id,anno`	Gets the list of annotations of given type in the file corresponding to a given tag/ref pair.

Value of funcstr	Function Syntax	Description
'annlen'	length = hdfan('annlen',annot_id)	Gets the length of annotation corresponding to the given annotation identifier.
'fileinfo'	[nfl,nfd,ndl,ndd,status] = hdfan('fileinfo',AN_id)	Gets number of file label, file description, data label, and data description annotations in the file corresponding to AN_id.
'get_tagref'	[tag,ref,status] = hdfan('get_tagref',AN_id,i	Gets the tag/ref pair for the specified annotation type and index.
'id2tagref'	[tag,ref,status] = hdfan('id2tagref',annot_id	Gets the tag/ref pair corresponding to the specified annotation identifier.
'tagref2id'	annot_id = hdfan('tagref2id',AN_id,ta	Gets the annotation identifier corresponding to the specified tag/ref pair.
'atype2tag'	tag = hdfan('atype2tag',annot_ty	Gets the tag corresponding to the specified annotation type.
'tag2atype'	annot_type = hdfan('tag2atype',tag)	Gets the annotation type corresponding to the specified tag.

Input/Output Arguments

A status or identifier output of -1 indicates that the operation failed.

In general, the input argument annot_type can be one of these strings:

- 'file_label'
- 'file_desc'
- 'data_label'
- 'data_desc'

AN_id refers to the multifile annotation interface identifier.

annot_id refers to an individual annotation identifier.

You must terminate access to all opened identifiers using either `hdfan('end',AN_id)` or `hdfan('endaccess',annot_id)`. Otherwise, the HDF library might not properly write all data to the file.

hdfdf24

Gateway to HDF 24-bit raster image (DF24) interface

Syntax

```
[out1,...,outN] = hdfdf24(funcstr,input1,...,inputN)
```

Description

`hdfdf24` is the MATLAB gateway to the HDF 24-bit raster image interface.

`[out1,...,outN] = hdfdf24(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the DF24 function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between DF24 functions in the HDF library and valid values for `funcstr`. For example, `hdfdf24('lastref')` corresponds to the C library call `DF24lastref()`.

Write Functions

Write functions create raster image sets and store them in new files or append them to existing files.

Value of `funcstr`	Function Syntax	Description
`'addimage'`	`status = hdfdf24('addimage',filenam`	Appends a 24-bit raster image to a file.
`'putimage'`	`status = hdfdf24('putimage',filenam`	Writes a 24-bit raster image to file by overwriting all existing data.
`'setcompress'`	`status = hdfdf24('setcompress',comp`	Sets the compress method for the next raster image written to the file. `compress_type` can be `'none'`, `'rle'`, `'jpeg'`, or `'imcomp'`. If

Value of `funcstr`	Function Syntax	Description
		`compress_type` is `'jpeg'`, then two additional parameters must be specified: `quality` (a scalar between 0 and 100) and `force_baseline` (either 0 or 1). Other compression types do not have additional parameters.
`'setdims'`	`status = hdfdf24('setdims',width,he`	Sets the dimensions for the next raster image written to the file.
`'setil'`	`status = hdfdf24('setil',interlace)`	Sets the interlace format of the next raster image written to the file. `interlace` can be `'pixel'`, `'line'`, or `'component'`.
`'lastref'`	`ref = hdfdf24('lastref')`	Reports the last reference number assigned to a 24-bit raster image.

Read Functions

Read functions determine the dimensions and interlace format of an image set, read the actual image data, and provide sequential or random read access to any raster image set.

Value of `funcstr`	Function Syntax	Description
`'getdims'`	`[width,height,interlace,st = hdfdf24('getdims',filename`	Retrieves the dimensions before reading the next raster image. `interlace` can be `'pixel'`, `'line'`, or `'component'`.
`'getimage'`	`[RGB,status] = hdfdf24('getimage',filenam`	Reads the next 24-bit raster image.
`'reqil'`	`status = hdfdf24('reqil',interlace)`	Specifies the interlace format before reading the next raster image. `interlace` can be `'pixel'`, `'line'`, or `'component'`.

Value of `funcstr`	Function Syntax	Description
`'readref'`	`status = hdfdf24('readref',filename`	Reads 24-bit raster image with the specified raster number.
`'restart'`	`status = hdfdf24('restart')`	Returns to the first 24-bit raster image in the file.
`'nimages'`	`num_images = hdfdf24('nimages',filename`	Reports the number of 24-bit raster images in a file.

Input/Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

HDF uses C-style ordering of elements, in which elements along the last dimension vary fastest. MATLAB uses FORTRAN-style ordering, in which elements along the first dimension vary fastest. `hdfdf24` does not automatically convert from C-style ordering to MATLAB style ordering, which means that MATLAB image arrays need to be permuted when using `hdfdf24` to read or write from HDF files. The exact permutation depends on the interlace format specified by, for example, `hdfdf24('setil',...)`. The following calls to `permute` converts HDF arrays to MATLAB arrays, according to the specified interlace format.

```
RGB = permute(RGB,[3 2 1]);
```
`'pixel'` interlace

```
RGB = permute(RGB,[3 1 2]);
```
`'line'` interlace

```
RGB = permute(RGB,[2 1 3]);
```
`'component'` interlace

`hdfdf24` | `hdfdfr8` | `hdfh` | `hdfhd` | `hdfhe` | `hdfhx` | `hdfml` | `hdfv` | `hdfvf` | `hdfvh` | `hdfvs` | `matlab.io.hdf4.sd`

hdfdfr8

Gateway to HDF 8-bit raster image (DFR8) interface

Syntax

```
[out1,...,outN] = hdfdfr8(funcstr,input1,...,inputN)
```

Description

`hdfdfr8` is the MATLAB gateway to the HDF 8-bit raster image (DFR8) interface.

`[out1,...,outN] = hdfdfr8(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the DFR8 function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between DFR8 functions in the HDF library and valid values for `funcstr`. For example, `hdfdfr8('setpalette',map)` corresponds to the C library call `DFR8setpalette(map)`.

Write Functions

Write functions create raster image sets and store them in new files or append them to existing files.

Value of `funcstr`	Function Syntax	Description
`'writeref'`	`status = hdfdfr8('writeref',filenam`	Stores the raster image using the specified reference number.
`'setpalette'`	`status = hdfdfr8('setpalette',color`	Sets palette for multiple 8-bit raster images.
`'addimage'`	`status = hdfdfr8('addimage',filenam`	Appends an 8-bit raster image to a file. `compress` can be `'none'`, `'rle'`, `'jpeg'`, or `'imcomp'`.
`'putimage'`	`status = hdfdfr8('putimage',filenam`	Writes an 8-bit raster image to an existing file or creates the file. `compress` can be `'none'`, `'rle'`, `'jpeg'`, or `'imcomp'`.

Value of funcstr	Function Syntax	Description
'setcompress'	status = hdfdfr8('setcompress',comp	Sets the compression type. compress_type can be 'none', 'rle', 'jpeg', or 'imcomp'. If compress_type is 'jpeg', then two additional parameters must be passed in: quality (a scalar between 0 and 100) and force_baseline (either 0 or 1). Other compression types do not have additional parameters.

Read Functions

Read functions determine the dimension and palette assignment for an image set, read the actual image data, and provide sequential or random read access to any raster image set.

Value of funcstr	Function Syntax	Description
'getdims'	[width,height,hasmap,statu = hdfdfr8('getdims',filename	Retrieves dimensions for an 8-bit raster image.
'getimage'	[X,map,status] = hdfdfr8('getimage',filenam	Retrieves an 8-bit raster image and its palette.
'readref'	status = hdfdfr8('readref',filename	Gets the next raster image with the specified reference number.
'restart'	status = hdfdfr8('restart')	Ignores information about last file accessed and restarts from beginning.
'nimages'	num_images = hdfdfr8('nimages',filename	Returns number of raster images in a file.
'lastref'	ref = hdfdfr8('lastref')	Returns reference number of last element accessed.

Input/Output Arguments

A status or identifier output of -1 indicates that the operation failed.

HDF uses C-style ordering of elements, in which elements along the last dimension vary fastest.MATLAB uses FORTRAN-style ordering, in which elements along the first dimension vary fastest. `hdfdfr8` does not automatically convert from C-style ordering to MATLAB style ordering, which means that MATLAB image and colormap matrices must be transposed when using `hdfdfr8` to read or write from HDF files.

Functions in `hdfdfr8` that read and write palette information expect to use `uint8` data in the range [0,255], while MATLAB colormaps contain double-precision values in the range [0,1]. Therefore, HDF palettes must be converted to `double` and scaled to be used as MATLAB colormaps.

hdfh

Gateway to HDF H interface

Syntax

```
[out1,...,outN] = hdfh(funcstr,input1,...,inputN)
```

Description

`hdfh` is the MATLAB gateway to the HDF H interface.

`[out1,...,outN] = hdfh(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the H function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between H functions in the HDF library and valid values for `funcstr`. For example, `hdfh('close',file_id)` corresponds to the C library call `Hclose(file_id)`.

Functions

Value of `funcstr`	Function Syntax	Description
`'appendable'`	`status = hdfh('appendable',access_id)`	Specifies that the element can be appended to.
`'close'`	`status = hdfh('close',file_id)`	Closes the access path to the file.
`'deldd'`	`status = hdfh('deldd',file_id,tag,ref)`	Deletes a tag and reference number from the data descriptor list.
`'dupdd'`	`status = hdfh('dupdd',file_id,tag,ref,`	
`'endaccess'`	`status = hdfh('endaccess',access_id)`	Terminates access to a data object by disposing of the access identifier.
`'fidinquire'`	`[filename,access_mode,attach,` `= hdfh('fidinquire',file_id)`	Returns information about specified file.

Value of `funcstr`	Function Syntax	Description
`'find'`	`[tag,ref,offset,length,status = hdfh('find',file_id,... search_tag,search_ref,search_`	Locates the next object to be searched for in an HDF file. `search_type` can be `'new'` or `'continue'`. The `dir` input can be `'forward'` or `'backward'`.
`'getelement'`	`[data,status] = hdfh('getelement',file_id,tag`	Reads the data element for the specified tag and reference number.
`'getfileversio`	`[major,minor,release,info,sta = hdfh('getfileversion',file_id`	Returns version information for an HDF file.
`'getlibversion`	`[major,minor,release,info,sta = hdfh('getlibversion')`	Returns version information for the current HDF library.
`'inquire'`	`[file_id,tag,ref,length,offse special,status] = hdfh('inquire',access_id)`	Returns access information about a data element.
`'ishdf'`	`tf = hdfh('ishdf',filename)`	Determines if a file is an HDF file.
`'length'`	`length = hdfh('length',file_id,tag,ref`	Returns the length of a data object specified by the tag and reference number.
`'newref'`	`ref = hdfh('newref',file_id)`	Returns a reference number that can be used with any tag to product a unique tag/reference number pair.
`'nextread'`	`status = hdfh('nextread',access_id,tag`	Searches for the next data descriptor that matches the specified tag and reference number. `origin` can be `'start'` or `'current'`.
`'number'`	`num = hdfh('number',file_id,tag)`	Returns the number of instances of a tag in a file.

Value of `funcstr`	Function Syntax	Description
`'offset'`	`offset = hdfh('offset',file_id,tag,ref`	Returns the offset of a data element in the file.
`'open'`	`file_id = hdfh('open',filename,access,r`	Provides an access path to an HDF file by reading all the data descriptor blocks into memory.
`'putelement'`	`count = hdfh('putelement',file_id,tag`	Writes a data element or replaces an existing data element in an HDF file. `X` must be a `uint8` array.
`'read'`	`X = hdfh('read',access_id,length)`	Reads the next segment in a data element.
`'seek'`	`status = hdfh('seek',access_id,offset,`	Sets the access pointer to an offset within a data element. `origin` can be `'start'` or `'current'`.
`'startread'`	`access_id = hdfh('startread',file_id,tag,`	
`'startwrite'`	`access_id = hdfh('startwrite',file_id,tag`	
`'sync'`	`status = hdfh('sync',file_id)`	
`'trunc'`	`length = hdfh('trunc',access_id,trunc_`	Truncates the specified data object to the given length.
`'write'`	`count = hdfh('write',access_id,X)`	Writes the next data segment to a specified data element. `X` must be a `uint8` array.

Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

Limitations

- `hdfh` does not support these functions in the NCSA H interface:
  - `Hcache`
  - `Hendbitaccess`
  - `Hexist`
  - `Hflushdd`
  - `Hgetbit`
  - `Hputbit`
  - `Hsetlength`
  - `Hshutdown`
  - `Htagnewref`

hdfhd

Gateway to HDF HD interface

Syntax

```
[out1,...,outN] = hdfhd(funcstr,input1,...,inputN)
```

Description

`hdfhd` is the MATLAB gateway to the HDF HD interface.

`[out1,...,outN] = hdfhd(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the HD function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between HD functions in the HDF library and valid values for `funcstr`.

Functions

Value of `funcstr`	Function Syntax	Description
`'gettagsname'`	`tag_name = hdfhd('gettagsname',tag)`	Gets the name of the specified tag.

Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

hdfhe

Gateway to HDF HE interface

Syntax

```
[out1,...,outN] = hdfhe(funcstr,input1,...,inputN)
```

Description

`hdfhe` is the MATLAB gateway to the HDF HE interface.

This is a stub page.

`[out1,...,outN] = hdfhe(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the HE function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between HE functions in the HDF library and valid values for `funcstr`.

Functions

Value of `funcstr`	Function Syntax	Description
`'clear'`	`hdfhe('clear')`	Clears all information on reported errors from the error stack.
`'print'`	`hdfhe('print',level)`	Prints information in error stack. If `level` is 0, then the entire error stack is printed.
`'string'`	`error_text = hdfhe('string',error_c`	Returns the error message associated with the specified error code.
`'value'`	`error_code = hdfhe('value',stack_of`	Returns an error code from the specified level of the error stack. A

Value of `funcstr`	Function Syntax	Description
		`stack_offset` value of 1 gets the most recent error code.

Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

Limitations

- `hdfhe` does not support these functions:
  - `HEpush`
  - `HEreport`

hdfhx

Gateway to HDF external data (HX) interface

Syntax

```
[out1,...,outN] = hdfhx(funcstr,input1,...,inputN)
```

Description

`hdfhx` is the MATLAB gateway to the HDF interface for manipulating linked and external data elements.

`[out1,...,outN] = hdfhx(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the HX function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between HX functions in the HDF library and valid values for `funcstr`. For example, `hdfhx('setdir',pathname);` corresponds to the C library call `HXsetdir(pathname)`.

Functions

Value of `funcstr`	Function Syntax	Description
`'create'`	`access_id = hdfhx('create',file_id,ta`	Creates a new external file special data element. `ength)`
`'setcreatedir'`	`status = hdfhx('setcreatedir',path`	Sets the directory location for writing external file.
`'setdir'`	`status = hdfhx('setdir',pathname);`	Sets the directory for locating external files. `pathname` can contain multiple directories separated by vertical bars.

Input/Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

In cases where the HDF C library accepts `NULL` for certain inputs, an empty matrix (`[ ]` or `' '`) can be used.

hdfinfo

Information about HDF4 or HDF-EOS file

Syntax

```
S = hdfinfo(filename)
S = hdfinfo(filename,mode)
```

Description

`S = hdfinfo(filename)` returns a structure `S` whose fields contain information about the contents of an HDF4 or HDF-EOS file. `filename` is a string that specifies the name of the HDF4 file.

`S = hdfinfo(filename,mode)` reads the file as an HDF4 file, if `mode` is `'hdf'`, or as an HDF-EOS file, if `mode` is `'eos'`. If `mode` is `'eos'`, only HDF-EOS data objects are queried. To retrieve information on the entire contents of a file containing both HDF4 and HDF-EOS objects, `mode` must be `'hdf'`.

Note `hdfinfo` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To get information about an HDF5 file, use `hdf5info`.

The set of fields in the returned structure `S` depends on the individual file. Fields that can be present in the `S` structure are shown in the following table.

Mode	Field Name	Description	Return Type
HDF	`Attributes`	Attributes of the data set	Structure array
	`Description`	Annotation description	Cell array
	`Filename`	Name of the file	String
	`Label`	Annotation label	Cell array
	`Raster8`	Description of 8-bit raster images	Structure array

Mode	Field Name	Description	Return Type
	`Raster24`	Description of 24-bit raster images	Structure array
	`SDS`	Description of scientific data sets	Structure array
	`Vdata`	Description of Vdata sets	Structure array
	`Vgroup`	Description of Vgroups	Structure array
`EOS`	`Filename`	Name of the file	String
	`Grid`	Grid data	Structure array
	`Point`	Point data	Structure array
	`Swath`	Swath data	Structure array

Those fields in the table above that contain structure arrays are further described in the tables shown below.

Fields Common to Returned Structure Arrays

Structure arrays returned by `hdfinfo` contain some common fields. These are shown in the table below. Not all structure arrays will contain all of these fields.

Field Name	Description	Data Type
`Attributes`	Data set attributes. Contains fields `Name` and `Value`.	Structure array
`Description`	Annotation description	Cell array
`Filename`	Name of the file	String
`Label`	Annotation label	Cell array
`Name`	Name of the data set	String
`Rank`	Number of dimensions of the data set	Double
`Ref`	Data set reference number	Double
`Type`	Type of HDF or HDF-EOS object	String

Fields Specific to Certain Structures

Structure arrays returned by `hdfinfo` also contain fields that are unique to each structure. These are shown in the tables below.

Fields of the Attribute Structure

Field Name	Description	Data Type
`Name`	Attribute name	String
`Value`	Attribute value or description	Numeric or string

Fields of the Raster8 and Raster24 Structures

Field Name	Description	Data Type
`HasPalette`	`1` (`true`) if the image has an associated palette, otherwise `0` (`false`) (8-bit only)	Logical
`Height`	Height of the image, in pixels	Number
`Interlace`	Interlace mode of the image (24-bit only)	String
`Name`	Name of the image	String
`Width`	Width of the image, in pixels	Number

Fields of the SDS Structure

Field Name	Description	Data Type
`DataType`	Data precision	String
`Dims`	Dimensions of the data set. Contains fields `Name`, `DataType`, `Size`, `Scale`, and `Attributes`. `Scale` is an array of numbers to place along the dimension and demarcate intervals in the data set.	Structure array
`Index`	Index of the SDS	Number

Fields of the Vdata Structure

Field Name	Description	Data Type
`DataAttributes`	Attributes of the entire data set. Contains fields `Name` and `Value`.	Structure array
`Class`	Class name of the data set	String

Field Name	Description	Data Type
`Fields`	Fields of the Vdata. Contains fields `Name` and `Attributes`.	Structure array
`NumRecords`	Number of data set records	Double
`IsAttribute`	`1` (`true`) if Vdata is an attribute, otherwise `0` (`false`)	Logical

Fields of the Vgroup Structure

Field Name	Description	Data Type
`Class`	Class name of the data set	String
`Raster8`	Description of the 8-bit raster image	Structure array
`Raster24`	Description of the 24-bit raster image	Structure array
`SDS`	Description of the Scientific Data sets	Structure array
`Tag`	Tag of this Vgroup	Number
`Vdata`	Description of the Vdata sets	Structure array
`Vgroup`	Description of the Vgroups	Structure array

Fields of the Grid Structure

Field Name	Description	Data Type
`Columns`	Number of columns in the grid	Number
`DataFields`	Description of the data fields in each `Grid` field of the grid. Contains fields `Name`, `Rank`, `Dims`, `NumberType`, `FillValue`, and `TileDims`.	Structure array
`LowerRight`	Lower right corner location, in meters	Number
`Origin Code`	Origin code for the grid	Number
`PixRegCode`	Pixel registration code	Number
`Projection`	Projection code, zone code, sphere code, and projection parameters of	Structure

Field Name	Description	Data Type
	the grid. Contains fields `ProjCode`, `ZoneCode`, `SphereCode`, and `ProjParam`.	
`Rows`	Number of rows in the grid	Number
`UpperLeft`	Upper left corner location, in meters	Number

Fields of the Point Structure

Field Name	Description	Data Type
`Level`	Description of each level of the point. Contains fields `Name`, `NumRecords`, `FieldNames`, `DataType`, and `Index`.	Structure

Fields of the Swath Structure

Field Name	Description	Data Type
`DataFields`	Data fields in the swath. Contains fields `Name`, `Rank`, `Dims`, `NumberType`, and `FillValue`.	Structure array
`GeolocationField`	Geolocation fields in the swath. Contains fields `Name`, `Rank`, `Dims`, `NumberType`, and `FillValue`.	Structure array
`IdxMapInfo`	Relationship between indexed elements of the geolocation mapping. Contains fields `Map` and `Size`.	Structure
`MapInfo`	Relationship between data and geolocation fields. Contains fields `Map`, `Offset`, and `Increment`.	Structure

Examples

To retrieve information about the file `example.hdf`,

```
fileinfo = hdfinfo('example.hdf')
```

```
fileinfo =
    Filename: 'example.hdf'
         SDS: [1x1 struct]
       Vdata: [1x1 struct]
```

And to retrieve information from this about the scientific data set in `example.hdf`,

```
sds_info = fileinfo.SDS

sds_info =
       Filename: 'example.hdf'
           Type: 'Scientific Data Set'
           Name: 'Example SDS'
           Rank: 2
       DataType: 'int16'
     Attributes: []
           Dims: [2x1 struct]
          Label: {}
    Description: {}
          Index: 0
```

`hdfread`

Introduced before R2006a

hdfml

Utilities for working with MATLAB HDF gateway functions

Syntax

```
hdfml('closeall')
hdfml('listinfo')
tag = hdfml('tagnum',tagname)
nbytes = hdfml('sizeof',data_type)
hdfml('defaultchartype',char_type)
```

Description

`hdfml('closeall')` closes all open registered HDF file and data object identifiers.

`hdfml('listinfo')` prints information about all open registered HDF file and data object identifiers.

`tag = hdfml('tagnum',tagname)` returns the tag number corresponding to the tag name specified by `tagname`.

`nbytes = hdfml('sizeof',data_type)` returns size in bytes of specified data type.

`hdfml('defaultchartype',char_type)` defines the HDF data type for MATLAB strings. Valid values for `char_type` are `'char8'` or `'uchar8'`. The change persists until the MATLAB HDF gateway function is cleared from memory. MATLAB strings are mapped to `char8` by default.

The MATLAB HDF gateway functions maintain lists of certain HDF file and data object identifiers so that, for example, HDF objects and files can be properly closed when a user issues the command:

```
clear mex
```

These lists are updated whenever these identifiers are created or closed.

hdfpt

Interface to HDF-EOS Point object

Syntax

```
[out1,...,outN] = hdfpt(funcstr,input1,...,inputN)
```

Description

`hdfpt` is the MATLAB gateway to the Point functions in the HDF-EOS C library, which is developed and maintained by EOSDIS (Earth Observing System Data and Information System). A Point data set comprises a series of data records taken at (possibly) irregular time intervals and at scattered geographic locations. Each data record consists of a set of one or more data values representing the state of a point in time and/or space.

`[out1,...,outN] = hdfpt(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the Point function in the HDF-EOS library specified by `functstr`.

There is a one-to-one correspondence between PT functions in the HDF-EOS C library and valid values for `funcstr`. For example, `hdfpt('detach',point_id)` corresponds to the C library call `PTdetach(point_id)`.

Programming Model

The programming model for accessing a point data set through `hdfpt` is as follows:

1. Open the file and initialize the PT interface by obtaining a file id from a file name.
2. Open or create a point data set by obtaining a point id from a point name.
3. Perform desired operations on the data set.
4. Close the point data set by disposing of the point id.
5. Terminate point access to the file by disposing of the file id.

To access a single point data set that already exists in an HDF-EOS file, use the following MATLAB commands:

```
fileid = hdfpt('open',filename,access);
pointid = hdfpt('attach',fileid,pointname);

% Optional operations on the data set...

status = hdfpt('detach',pointid);
status = hdfpt('close',fileid);
```

To access several files at the same time, obtain a separate file identifier for each file to be opened. To access more than one point data set, obtain a separate point id for each data set.

It is important to properly dispose of point id's and file id's so that buffered operations are written completely to disk. If you quit MATLAB or clear all MEX-files with PT identifiers still open, MATLAB issues a warning and automatically disposes of them.

Note that file identifiers returned by `hdfpt` are not interchangeable with file identifiers returned by any other HDF-EOS or HDF function.

Access Routines

Access routines initialize and terminate access to the PT interface and point data sets (including opening and closing files).

Value of `funcstr`	Function Syntax	Description
`'open'`	`file_id = hdfpt('open',filename,acce`	Given the filename and desired access mode, opens or creates an HDF file in order to create, read, or write a point. `access` can be `'read'`, `'readwrite'`, or `'create'`. `file_id` is -1 if the operation fails.
`'create'`	`point_id = hdfpt('create',file_id,poi`	Creates a point data set with the specified name. `pointname` is a string contain the name of the point data set. `point_id` is -1 if the operation fails.
`'attach'`	`point_id = hdfpt('attach',file_id,poi`	Attaches to an existing point data set within the file.

Value of `funcstr`	Function Syntax	Description
		`point_id` is -1 if the operation fails.
`'detach'`	`status = hdfpt('detach',point_id)`	Detaches from point data set.
`'close'`	`status = hdfpt('close',file_id)`	Closes file.

Definition Routines

Definition routines allow the user to set key features of a point data set.

Value of `funcstr`	Function Syntax	Description
`'deflevel'`	`status = hdfpt('deflevel',point_id, fieldList,fieldTypes,field`	Defines a new level within a point data set. `levelname` is the name of the level to be defined. `fieldList` is a string containing a comma-separated list of field names in the new level. `fieldTypes` is a cell array containing the number type string for each field. Valid number type strings include `'uchar8'`, `'uchar'`, `'char8'`, `'char'`, `'double'`, `'uint8'`, `'uint16'`, `'uint32'`, `'float'`, `'int8'`, `'int16'`, and `'int32'`. `fieldOrders` is a vector containing the order for each field.
`'deflinkage'`	`status = hdfpt('deflinkage',point_i`	Defines a linkfield between two adjacent levels. `parent` is the name of the parent level. `child` is the name of the child level. `linkfield` is the name of a field that is defined at both levels.

Basic I/O Routines

Basic I/O routines read and write data and metadata to a point data set.

Value of `funcstr`	Function Syntax	Description
`'writelevel'`	`status = hdfpt('writelevel',point_i`	Appends new records to the specified level in a point data set. `level` is the desired level index (zero-based). `data` must be a `P`-by-1 cell array where `P` is the number of fields defined for the specified level. Each cell of `data` must contain an `M(k)`-by-`N` matrix of data, where `M(k)` is the order of the `k`-th field (the number of scalar values in the field) and `N` is the number of records. The MATLAB class of the cells must match the HDF data type defined for the corresponding fields. A MATLAB string is automatically converted to match any of the HDF char types. Other data types must match exactly.
`'readlevel'`	`[data,status] = hdfpt('readlevel',point_id level,fieldList,records)`	Reads data from a given level in a point data set. `level` is the index (zero-based) of the desired level. `fieldList` is a string containing a comma-separated list of the fields to read. `records` is a vector containing the indices (zero-based) of the records to read. `data` is a `P`-by-1 cell array where `P` is the number of requested fields. Each cell of `data` contains an `M(k)`-by-`N` matrix of data where `M(k)` is the order of the `k`-

Value of `funcstr`	Function Syntax	Description
		th field and `N` is the number of records, or `length(records)`.
`'updatelevel'`	`status = hdfpt('updatelevel',point_ level,fieldList,records,da`	Updates (corrects) data in a particular level of a point data set. `level` is the index (zero-based) of the desired level. `fieldList` is a string containing a comma-separated list of field names to update. `records` is a vector containing the indices (zero-based) of the records to update. `data` is a `P`-by-1 cell array where `P` is the number of specified fields. Each cell of `data` must contain an `M(k)`-by-`N` matrix of data, where `M(k)` is the order of the `k`-th field (the number of scalar values in the field) and `N` is the number of records, or `length(records)`. The MATLAB class of the cells must match the HDF data type defined for the corresponding fields. A MATLAB string is automatically converted to match any of the HDF char types. Other data types must match exactly.
`'writeattr'`	`status = hdfpt('writeattr',point_id`	Writes or updates the point data set attribute with the specified name. If the attribute does not already exist, it is created.
`'readattr'`	`[data,status] = hdfpt('readattr',point_id,`	Reads the attribute data from the specified attribute.

Inquiry Routines

Inquiry routines return information about data contained in a point data set.

Value of `funcstr`	Function Syntax	Description
`'nlevels'`	`nlevels = hdfpt('nlevels',point_id)`	Returns the number of levels in a point data set. `nlevels` is -1 if the operation fails.
`'nrecs'`	`nrecs = hdfpt('nrecs',point_id,lev`	Returns the number of records in the specified level. `nrecs` is -1 if the operation fails.
`'nfields'`	`[numfields,strbufsize] = hdfpt('nfields',point_id,l`	Returns the number of fields in the specified level. `strbufsize` is the length of the comma-separated field name string. `numfields` is -1 and `strbufsize` is `[]` if the operation fails.
`'levelinfo'`	`[numfields,fieldList,field Type,fieldOrder] = ... hdfpt('levelinfo',point_id`	Returns information on fields for a specified level. `fieldList` is a string containing a comma-separated list of field names. `fieldType` is a cell array of strings that defined the data type for each field. `fieldOrder` is a vector containing the order (number of scalar values) associated with each field. If the operation fails, `numfields` is -1 and the other outputs are empty.
`'levelindx'`	`level = hdfpt('levelindx',point_id`	Returns the level index (zero-based) of the level with the specified name. `level` is -1 if the operation fails.
`'bcklinkinfo'`	`[linkfield,status] = hdfpt('bcklinkinfo',point_`	Returns the linkfield to the previous level. `status` is -1 and `linkfield` is `[]` if the operation fails.

Value of `funcstr`	Function Syntax	Description
`'fwdlinkinfo'`	`[linkfield,status] = hdfpt('fwdlinkinfo',point_`	Returns the linkfield to the following level. `status` is -1 and `linkfield` is `[]` if the operation fails.
`'getlevelname'`	`[levelname,status] = hdfpt('getlevelname',point`	Returns the name of a level given the level index. `status` is -1 and `levelname` is `[]` if the operation fails.
`'sizeof'`	`[byteSize,fieldLevels] = hdfpt('sizeof',point_id,fi`	Returns the size in bytes and field levels of the specified fields. `fieldList` is a string containing a comma-separated list of field names. `byteSize` is the total size of bytes of the specified fields, and `fieldLevels` is a vector containing the level index corresponding to each field. `byteSize` is -1 and `fieldLevels` is `[]` if the operation fails.
`'attrinfo'`	`[numberType,count,status] = ... hdfpt('attrinfo',point_id,`	Returns the number type and size in bytes of the specified attribute. `attrname` is the name of the attribute. `numberType` is a string corresponding to the HDF data type of the attribute. `count` is the number of bytes used by the attribute data. `status` is -1 and `numberType` and `count` are `[]` if the operation fails.

Value of `funcstr`	Function Syntax	Description
`'inqattrs'`	`[nattrs,attrnames] = hdfpt('inqattrs',point_id)`	Retrieve information about attributes defined in a point data set. `nattrs` and `attrnames` are the number and names of all the defined attributes, respectively. If the operation fails, `nattrs` is -1 and `attrnames` is `[]`.
`'inqpoint'`	`[numpoints,pointnames] = hdfpt('inqpoint',filename)`	Retrieve number and names of point data sets defined in an HDF-EOS file. `pointnames` is a string containing a comma-separated list of point names. `numpoints` is -1 and `pointnames` is `[]` if the operation fails.

Utility Routines

Placeholder.

Value of `funcstr`	Function Syntax	Description
`'getrecnums'`	`[outRecords,status] = hdfpt('getrecnums',... point_id,inLevel,outLevel,`	Returns the record numbers in `outLevel` corresponding the group of records specified by `inRecords` in level `inLevel`. The `inLevel` and `outLevel` arguments are zero-based level indices. `inRecords` is a vector of zero-based record indices. `status` is -1 and `outRecords` is `[]` if the operation fails.

Subset Routines

Subset routines allow reading of data from a specified geographic region.

Value of `funcstr`	Function Syntax	Description
`'defboxregion'`	`region_id = hdfpt('defboxregion',point`	Defines a longitude-latitude box region for a point. `cornerLon` is a two-element vector containing the longitudes of opposite box corners. `cornerLat` is a two-element vector containing the latitudes of opposite box corners. `region_id`is -1 if the operation fails.
`'defvrtregion'`	`period_id = hdfpt('defvrtregion',point vert_field,range)`	Defines a vertical region for a point. `vert_field` is the name of the field to subset. `range` is a two-element vector containing the minimum and maximum vertical values. `period_id` is -1 if the operation fails.
`'regioninfo'`	`[byteSize,status] = hdfpt('regioninfo',point_i region_id,level,fieldList)`	Returns the data size in bytes of the subset period of the specified level. `fieldlist` is a string containing a comma-separated list of fields to extract. `status` and `byteSize` are -1 if the operation fails.
`'regionrecs'`	`[numRec,recNumbers,status] = hdfpt('regionrecs',... point_id,region_id,level)`	Returns the records numbers within the subsetted region of the specified level. `status` and `numrec` are -1 and `recNumbers` is `[ ]` if the operation fails.

Value of `funcstr`	Function Syntax	Description
`'extractregion'`	`[data,status] = hdfpt('extractregion',poin region_id,level,fieldList)`	Reads data from the specified subset region. `fieldList` is a string containing a comma-separated list of requested fields. `data` is a `P`-by-1 cell array where `P` is the number of requested fields. Each cell of `data` contains an `M(k)`-by-`N` matrix of data where `M(k)` is the order of the `k`-th field and `N` is the number of records. `status` is -1 and `data` is `[]` if the operation fails.
`'deftimeperiod'`	`period_id = hdfpt('deftimeperiod',poin`	Defines a time period for a point data set. `period_id` is -1 if the operation fails.
`'periodinfo'`	`[byteSize,status] = hdfpt('periodinfo',point_i period_id,level,fieldList)`	Retrieves the size in bytes of the subsetted period. `fieldList` is string containing a comma-separated list of desired field names. `byteSize` and `status` are -1 if the operation fails.
`'periodrecs'`	`[numRec,recNumbers,status] = hdfpt('periodrecs',... point_id,period_id,level)`	Returns the records numbers within the subsetted time period of the specified level. `numRec` and `status` are -1 if the operation fails.

Value of `funcstr`	Function Syntax	Description
`'extractperiod'`	`[data,status] = hdfpt('extractperiod',... point_id,period_id,level,f`	Reads data from the specified subsetted time period. `fieldList` is a string containing a comma-separated list of requested fields. `data` is a `P`-by-1 cell array where `P` is the number of requested fields. Each cell of `data` contains an `M(k)`-by-`N` matrix of data where `M(k)` is the order of the `k`-th field and `N` is the number of records. `status` is -1 and `data` is `[]` if the operation fails.

Input/Output Arguments

Most routines return the flag, `status`, which is 0 when the routine succeeds and -1 when the routine fails. Routines with syntaxes which do not contain `status` return failure information in one of its outputs as notated in the function syntaxes.

`levelName` is a string.

Some of the C library functions accept input values that are defined in terms of C macros. For example, the C `PTopen()` function requires an access mode input that can be DFACC_READ, DFACC_RDWR, or DFACC_CREATE, where these symbols are defined in the appropriate C header file. Where macro definitions are used in the C library, the equivalent MATLAB syntaxes use strings derived from the macro names. You can either use a string containing the entire macro name, or you can omit the common prefix. You can use either upper or lower case. For example, this C function call:

```
status = PTopen("PointFile.hdf",DFACC_CREATE)
```
is equivalent to these MATLAB function calls:

```
status = hdfpt('open','PointFile.hdf','DFACC_CREATE')
status = hdfpt('open','PointFile.hdf','dfacc_create')
status = hdfpt('open','PointFile.hdf','CREATE')
status = hdfpt('open','PointFile.hdf','create')
```

In cases where a C function returns a value with a macro definition, the equivalent MATLAB function returns the value as a string containing the lowercase short form of the macro.

HDF number types are specified by strings, including `'uchar8'`, `'uchar'`, `'char8'`, `'char'`, `'double'`, `'uint8'`, `'uint16'`, `'uint32'`, `'float'`, `'int8'`, `'int16'`, and `'int32'`.

In cases where the HDF-EOS library accepts `NULL`, use an empty matrix (`[ ]`).

`matlab.io.hdfeos.sw`

hdfread

Read data from HDF4 or HDF-EOS file

Syntax

```
data = hdfread(filename, datasetname)
data = hdfread(hinfo)
data = hdfread(...,param,value,...)
data = hdfread(filename,EOSname,param,value,...)
[data,map] = hdfread(...)
```

Description

`data = hdfread(filename, datasetname)` returns all the data in the data set specified by `datasetname` from the HDF4 or HDF-EOS file specified by `filename`. To determine the name of a data set in an HDF4 file, use the `hdfinfo` function.

Note `hdfread` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To read data from an HDF5 file, use `h5read`.

`data = hdfread(hinfo)` returns all the data in the data set specified by the structure`hinfo`, returned by the `hdfinfo` function. Specify the field in the `hinfo` structure that relates to a particular type of data set, and use indexing to specify which data set, when there are more than one. See “Specify data set to read” on page 1-3543 for more information.

`data = hdfread(...,param,value,...)` returns subsets of the data according to the specified parameter and value pairs. See the tables below to find the valid parameters and values for different types of data sets.

`data = hdfread(filename,EOSname,param,value,...)` subsets the data field from the HDF-EOS point, grid, or swath specified by `EOSname`.

`[data,map] = hdfread(...)` returns the image `data` and the colormap `map` for an 8-bit raster image.

Subsetting Parameters

The following tables show the subsetting parameters that can be used with the `hdfread` function for certain types of HDF4 data. These data types are

- HDF Scientific Data (SD)
- HDF Vdata (V)
- HDF-EOS Grid Data
- HDF-EOS Point Data
- HDF-EOS Swath Data

Note the following:

- If a parameter requires multiple values, use a cell array to store the values. For example, the `'Index'` parameter requires three values: `start`, `stride`, and `edge`. Enclose these values in curly braces as a cell array.

  ```
  hdfread(..., 'Index', {start,stride,edge})
  ```
- All values that are indices are 1-based.

Subsetting Parameters for HDF Scientific Data (SD) Data Sets

When you are working with HDF SD files, `hdfread` supports the parameters listed in this table.

Parameter	Description
`'Index'`	Three-element cell array, `{start,stride,edge}`, specifying the location, range, and values to be read from the data set • `start` — A 1-based array specifying the position in the file to begin reading Default: `1`, start at the first element of each dimension. The values specified must not exceed the size of any dimension of the data set. • `stride` — A 1-based array specifying the interval between the values to read Default: `1`, read every element of the data set.

Parameter	Description
	• `edge` — A 1-based array specifying the length of each dimension to read Default: An array containing the lengths of the corresponding dimensions

For example, this code reads the data set `Example SDS` from the HDF file `example.hdf`. The `'Index'` parameter specifies that `hdfread` start reading data at the beginning of each dimension, read until the end of each dimension, but only read every other data value in the first dimension.

```
data = hdfread('example.hdf','Example SDS','Index',{[],[2 1],[]})
```

Subsetting Parameters for HDF Vdata Sets

When you are working with HDF Vdata files, `hdfread` supports these parameters.

Parameter	Description
`'Fields'`	Text string specifying the name of the field to be read. When specifying multiple field names, use a cell array.
`'FirstRecord'`	1-based number specifying the record from which to begin reading
`'NumRecords'`	Number specifying the total number of records to read

For example, this code reads the Vdata set `Example Vdata` from the HDF file `example.hdf`.

```
data = hdfread('example.hdf','Example Vdata','FirstRecord', 2,'NumRecords', 5)
```

Subsetting Parameters for HDF-EOS Grid Data

When you are working with HDF-EOS grid data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive parameters — You can only specify one of these parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

Parameter	Description
Required Parameter	

Parameter	Description
`'Fields'`	String specifying the field to be read. You can specify only one field name for a Grid data set.
Mutually Exclusive Optional Parameters	
`'Index'`	Three-element cell array, `{start,stride,edge}`, specifying the location, range, and values to be read from the data set `start` — An array specifying the position in the file to begin reading Default: `1`, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set. `stride` — An array specifying the interval between the values to read Default: `1`, read every element of the data set. `edge` — An array specifying the length of each dimension to read Default: An array containing the lengths of the corresponding dimensions
`'Interpolate'`	Two-element cell array, `{longitude,latitude}`, specifying the longitude and latitude points that define a region for bilinear interpolation. Each element is an N-length vector specifying longitude and latitude coordinates.
`'Pixels'`	Two-element cell array, `{longitude,latitude}`, specifying the longitude and latitude coordinates that define a region. Each element is an N-length vector specifying longitude and latitude coordinates. This region is converted into pixel rows and columns with the origin in the upper left corner of the grid. Note: This is the pixel equivalent of reading a `'Box'` region.
`'Tile'`	Vector specifying the coordinates of the tile to read, for HDF-EOS Grid files that support tiles
Optional Parameters	
`'Box'`	Two-element cell array, `{longitude,latitude}`, specifying the longitude and latitude coordinates that define a region. `longitude` and `latitude` are each two-element vectors specifying longitude and latitude coordinates.

Parameter	Description
`'Time'`	Two-element cell array, `[start stop]`, where `start` and `stop` are numbers that specify the start and end-point for a period of time
`'Vertical'`	Two-element cell array, `{dimension, range}` `dimension` — String specifying the name of the data set field to be read from. You can specify only one field name for a Grid data set. `range` — Two-element array specifying the minimum and maximum range for the subset. If `dimension` is a dimension name, then `range` specifies the range of elements to extract. If `dimension` is a field name, then `range` specifies the range of values to extract. `'Vertical'` subsetting can be used alone or in conjunction with `'Box'` or `'Time'`. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to `hdfread`.

For example,

```
data = hdfread('grid.hdf','PolarGrid','Fields','ice_temp','Index', {[5 10],[],[15 20]})
```

Subsetting Parameters for HDF-EOS Point Data

When you are working with HDF-EOS Point data, `hdfread` has two required parameters and three optional parameters.

Parameter	Description
Required Parameters	
`'Fields'`	String naming the data set field to be read. For multiple field names, use a comma-separated list.
`'Level'`	1-based number specifying which level to read from in an HDF-EOS Point data set
Mutually Exclusive Optional Parameters	
`'Box'`	Two-element cell array, `{longitude,latitude}`, specifying the longitude and latitude coordinates that define a region. `longitude` and `latitude` are each two-element vectors specifying longitude and latitude coordinates.

Parameter	Description
`'RecordNumbers'`	Vector specifying the record numbers to read
`'Time'`	Two-element cell array, `[start stop]`, where `start` and `stop` are numbers that specify the start and endpoint for a period of time

For example,

```
hdfread(...,'Fields',{field1, field2},...
            'Level',level,'RecordNumbers',[1:50, 200:250])
```

Subsetting Parameters for HDF-EOS Swath Data

When you are working with HDF-EOS Swath data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive

You can only use one of the mutually exclusive parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

Parameter	Description
Required Parameter	
`'Fields'`	String naming the data set field to be read. You can specify only one field name for a Swath data set.
Mutually Exclusive Optional Parameters	
`'Index'`	Three-element cell array, `{start,stride,edge}`, specifying the location, range, and values to be read from the data set • `start` — An array specifying the position in the file to begin reading Default: `1`, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set. • `stride` — An array specifying the interval between the values to read Default: `1`, read every element of the data set. • `edge` — An array specifying the length of each dimension to read

Parameter	Description
	Default: An array containing the lengths of the corresponding dimensions
`'Time'`	Three-element cell array, `{start, stop, mode}`, where `start` and `stop` specify the beginning and the endpoint for a period of time, and `mode` is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met: • Its midpoint is within the box (`mode='midpoint'`). • Either endpoint is within the box (`mode='endpoint'`).
Optional Parameters	
`'Box'`	Three-element cell array, `{longitude, latitude, mode}` specifying the longitude and latitude coordinates that define a region. `longitude` and `latitude` are two-element vectors that specify longitude and latitude coordinates. `mode` is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met: • Its midpoint is within the box (`mode='midpoint'`). • Either endpoint is within the box (`mode='endpoint'`). • Any point is within the box (`mode='anypoint'`).
`'Vertical'`	Two-element cell array, `{dimension, range}` • `dimension` is a string specifying either a dimension name or field name to subset the data by. • `range` is a two-element vector specifying the minimum and maximum range for the subset. If `dimension` is a dimension name, then `range` specifies the range of elements to extract. If `dimension` is a field name, then `range` specifies the range of values to extract. `'Vertical'` subsetting can be used alone or in conjunction with `'Box'` or `'Time'`. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to `hdfread`.

For example,

```
hdfread('swath.hdf', 'Example Swath', 'Fields', 'Temperature', ...
         'Time', {5000, 6000, 'midpoint'})
```

Examples

Read Data Set in HDF File

Specify the name of the HDF file and the name of the data set. This example reads a data set named `temperature` from a sample HDF file.

```
data = hdfread('sd.hdf','temperature');
```

Specify data set to read

Call `hdfinfo` to retrieve information about the contents of the HDF file.

```
fileinfo = hdfinfo('sd.hdf')
```

```
fileinfo =

      Filename: 'B:\matlab\toolbox\matlab\imagesci\sd.hdf'
    Attributes: [1x1 struct]
           SDS: [1x2 struct]
         Vdata: [1x1 struct]
```

Extract the structure containing information about the particular data set you want to import from the data returned by `hdfinfo`. This example uses the structure in the SDS field to retrieve a scientific data set.

```
sds_info = fileinfo.SDS(2)
```

```
sds_info =

       Filename: 'B:\matlab\toolbox\matlab\imagesci\sd.hdf'
           Type: 'Scientific Data Set'
           Name: 'temperature'
           Rank: 2
       DataType: 'double'
     Attributes: [1x11 struct]
           Dims: [2x1 struct]
          Label: {}
```

```
    Description: {}
          Index: 1
```

Pass this structure to `hdfread` to import the data in the data set.

```
data = hdfread(sds_info);
```

Read Data from HDF-EOS Grid Field

Read data from the HDF-EOS global grid field, `TbOceanRain`, in the example file, `example.hdf`.

```
data1 = hdfread('example.hdf','MonthlyRain','Fields','TbOceanRain');
```

Read data for the northern hemisphere for the same field. Use the `Box` parameter to specify the longitude and latitude coordinates for that region.

```
data2 = hdfread('example.hdf','MonthlyRain', ...
'Fields','TbOceanRain', ...
'Box', {[0 360],[0 90]});
```

Read Subset of Data in Data Set

Retrieve info about the example file, `example.hdf`.

```
fileinfo = hdfinfo('example.hdf');
```

Retrieve information about Scientific Data Set in `example.hdf`.

```
data_set_info = fileinfo.SDS;
```

Check the size of the data set.

```
data_set_info.Dims.Size
```

```
ans =

    16

ans =

     5
```

Read a subset of the data in the data set using the `'index'` parameter with `hdfread`. This example specifies a starting index of `[3 3]`, an interval of 1 between values (`[]` meaning the default value of 1), and a length of 10 rows and 2 columns.

```
data = hdfread(data_set_info,'Index',{[3 3],[],[10 2]});
data(:,1)
```

```
ans =

     7
     8
     9
    10
    11
    12
    13
    14
    15
    16
```

```
data(:,2)
```

```
ans =

     8
     9
    10
    11
    12
    13
    14
    15
    16
    17
```

Access Data in Fields of Vdata

Use the `Vdata` field from the information returned by `hdfinfo` to read three fields of the data, `Idx`, `Temp`, and `Dewpt`.

```
s = hdfinfo('example.hdf');
data = hdfread(s.Vdata(1),'Fields',{'Idx','Temp','Dewpt'})

data =

    [1x10 int16]
    [1x10 int16]
    [1x10 int16]
```

`hdfinfo`

Introduced before R2006a

hdftool

Browse and import data from HDF4 or HDF-EOS files

Syntax

```
hdftool
hdftool(filename)
h = hdftool( ___ )
```

Description

`hdftool` starts the HDF Import Tool, a graphical user interface used to browse the contents of HDF4 and HDF-EOS files and import data and subsets of data from these files. To open an HDF4 or HDF-EOS file, select **Open** from the **Home** tab. You can open multiple files in the HDF Import Tool by selecting **Open** from the **Home** tab.

`hdftool(filename)` opens the HDF4 or HDF-EOS file specified by `filename` in the HDF Import Tool.

`h = hdftool( ___ )` returns a handle `h` to the HDF Import Tool. To close the tool from the command line, use `close(h)`.

Examples

```
hdftool('example.hdf');
```

hdfv

Gateway to HDF Vgroup (V) interface

Syntax

```
[out1,...,outN] = hdfv(funcstr,input1,...,inputN)
```

Description

`hdfv` is the MATLAB gateway to the HDF Vgroup (V) interface.

`[out1,...,outN] = hdfv(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the V function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between V functions in the HDF library and valid values for `funcstr`. For example, `hdfv('nattrs',vgroup_id)` corresponds to the C library call `Vnattrs(vgroup_id)`.

Access Functions

Access functions open files, initialize the Vgroup interface, and access individual groups. They also terminate access to vgroups and the Vgroup interface and close HDF files.

Value of `funcstr`	Function Syntax	Description
`'start'`	`status = hdfv('start',file_id)`	Initializes the V interface.
`'attach'`	`vgroup_id = hdfv('attach',file_id,vgr`	Establishes access to a vgroup. `access` can be `'r'` or `'w'`.
`'detach'`	`status = hdfv('detach',vgroup_id)`	Terminates access to a vgroup.
`'end'`	`status = hdfv('end',file_id)`	Terminates access to the V interface.

Create Functions

Create functions organize, label, and add data objects to vgroups.

Value of `funcstr`	Function Syntax	Description
`'setclass'`	`status = hdfv('setclass',vgroup_id`	Assigns a class to a vgroup.
`'setname'`	`status = hdfv('setname',vgroup_id,`	Assigns a name to a vgroup.
`'insert'`	`ref = hdfv('insert',vgroup_id, id)`	Adds a vgroup or vdata to an existing group. `id` can be a vdata id or a vgroup id.
`'addtagref'`	`status = hdfv('addtagref',vgroup_i`	Adds any HDF data object to an existing vgroup.
`'setattr'`	`status = hdfv('setattr',vgroup_id,`	Sets the attribute of a vgroup.

File Inquiry Functions

File inquiry functions return information about how vgroups are stored in a file. They are useful for locating vgroups in a file.

Value of `funcstr`	Function Syntax	Description
`'lone'`	`[refs,count] = hdfv('lone',file_id,maxsi`	Returns the reference numbers of vgroups not included in other vgroups.
`'getid'`	`next_ref = hdfv('getid',file_id,vgro`	Returns the reference number for the next vgroup in the HDF file.
`'find'`	`vgroup_ref = hdfv('find',file_id,vgrou`	Returns the reference number of the vgroup with the specified name if successful and zero otherwise.
`'findclass'`	`vgroup_ref = hdfv('findclass',file_id,`	Returns the reference number of the vgroup with the specified class.

Vgroup Inquiry Functions

Vgroup inquiry functions provide specific information about a specific vgroup. This information includes the class, name, member count, and additional member information.

Value of `funcstr`	Function Syntax	Description
`'getclass'`	`[class_name,status] = hdfv('getclass',vgroup_id`	Returns the name of the class of the specified group.
`'getname'`	`[vgroup_name,status] = hdfv('getname',vgroup_id)`	Returns the name of the specified group.
`'inquire'`	`[num_entries,name,status] = hdfv('inquire',vgroup_id)`	Returns the number of entries and the name of a vgroup.
`'isvg'`	`status = hdfv('isvg',vgroup_id,ref`	Checks if the object specified by ref refers to a child vgroup of the vgroup specified by `vgroup_id`.
`'isvs'`	`status = hdfv('isvs',vgroup_id,vda`	Checks if the object specified by `vdata_ref` refers to a child vdata of the vgroup specified by `vgroup_id`.
`'gettagref'`	`[tag,ref,status] = hdfv('gettagref',vgroup_i`	Retrieves a tag/reference number pair for a data object in the specified vgroup.
`'ntagrefs'`	`count = hdfv('ntagrefs',vgroup_id`	Returns the number of tag/reference number pairs contained in the specified vgroup.
`'gettagrefs'`	`[tag,refs,count] = hdfv('gettagrefs',vgroup_`	Retrieves the tag/reference pairs of all the data objects within a vgroup.
`'inqtagref'`	`tf = hdfv('inqtagref',vgroup_i`	Checks if an object belongs to a vgroup.
`'getversion'`	`version = hdfv('getversion',vgroup_`	Queries the vgroup version of a given vgroup.

Value of `funcstr`	Function Syntax	Description
`'nattrs'`	`count = hdfv('nattrs',vgroup_id)`	Queries the total number of vgroup attributes.
`'attrinfo'`	`[name,data_type,count,nby = hdfv('attrinfo',vgroup_id attr_index)`	Queries information on a given vgroup attribute.
`'getattr'`	`[values,status] = hdfv('getattr',vgroup_id,`	Queries the values of a given attribute.
`'Queryref'`	`ref = hdfv('Queryref',vgroup_id`	Returns the reference number of the specified vgroup.
`'Querytag'`	`tag = hdfv('Querytag',vgroup_id`	Returns the tag of the specified vgroup.
`'flocate'`	`vdata_ref = hdfv('flocate',vgroup_id,`	Returns the reference number of the vdata containing the specified field name in the specified vgroup.
`'nrefs'`	`count = hdfv('nrefs',vgroup_id,ta`	Returns the number of data objects with the specified tag in the specified vgroup.

Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

hdfvf

Gateway to VF functions in HDF Vdata interface

Syntax

```
[out1,...,outN] = hdfvf(funcstr,input1,...,inputN)
```

Description

`hdfvf` is the MATLAB gateway to the VF unctions in the HDF Vdata interface.

`[out1,...,outN] = hdfvf(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the VF function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between VF functions in the HDF library and valid values for `funcstr`. For example, `hdfvf('nfields',vdata_id)` corresponds to the C library call `VFnfields(vdata_id)`.

Field Inquiry Functions

Field inquiry functions provide specific information about the fields in a given vdata, including the field's size, name, order, type, and number of fields in the vdata.

Value of `funcstr`	Function Syntax	Description
`'fieldesize'`	`fsize = hdfvf('fieldesize',vdata_id`	Retrieves the field size (as stored in a file) of a specified field.
`'fieldisize'`	`fsize = hdfvf('fieldisize',vdata_id`	Retrieves the field size (as stored in memory) of a specified field.
`'fieldname'`	`name = hdfvf('fieldname',vdata_id,`	Retrieves the name of the specified field in the given vdata.
`'fieldorder'`	`order = hdfvf('fieldorder',vdata_id`	Retrieves the order of the specified field in the given vdata.

Value of `funcstr`	Function Syntax	Description
`'fieldtype'`	`data_type = hdfvf('fieldtype',vdata_id,`	Retrieves the data type for the specified field in the given vdata.
`'nfields'`	`count = hdfvf('nfields',vdata_id)`	Retrieves the total number of fields in the specified vdata.

Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

hdfvh

Gateway to VH functions in HDF Vdata interface

Syntax

```
[out1,...,outN] = hdfvh(funcstr,input1,...,inputN)
```

Description

`hdfvh` is the MATLAB gateway to VH functions in the HDF Vdata interface.

`[out1,...,outN] = hdfvh(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the VH function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between VH functions in the HDF library and valid values for `funcstr`.

High-level Vdata Functions

High-level Vdata functions write data to single-field vdatas.

Value of `funcstr`	Function Syntax	Description
`'makegroup'`	`vgroup_ref = hdfvh('makegroup',file_id, vgroup_name,vgroup_class)`	Groups a collection of data objects within a vgroup.
`'storedata'`	`count = hdfvh('storedata',file_id, vdata_name,vdata_class)`	Creates vdatas containing records limited to one field with one component per field.
`'storedatam'`	`count = hdfvh('storedatam',file_id vdata_name,vdata_class)`	Creates vdatas containing records with one field containing one or more components.

Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

hdfdf24 | hdfdfr8 | hdfh | hdfhd | hdfhe | hdfhx | hdfml | hdfv | hdfvf | hdfvh | hdfvs | matlab.io.hdf4.sd

hdfvs

Gateway to VS functions in HDF Vdata interface

Syntax

```
[out1,...,outN] = hdfvs(funcstr,input1,...,inputN)
```

Description

`hdfvs` is the MATLAB gateway to the VS functions in the HDF Vdata interface.

`[out1,...,outN] = hdfvs(funcstr,input1,...,inputN)` returns one or more outputs corresponding to the VS function in the HDF library specified by `functstr`.

There is a one-to-one correspondence between VS functions in the HDF library and valid values for `funcstr`. For example, `hdfvs('detach',vdata_id)` corresponds to the C library call `VSdetach(vdata_id)`.

Access Functions

Access functions attach, or allow access, to vdatas. Data transfer can only occur after a vdata has been accessed. These routines also detach from, or properly terminate access to, vdatas when data transfer has been completed.

Value of `funcstr`	Function Syntax	Description
`'attach'`	`vdata_id = hdfvs('attach',file_id,vd`	Establishes access to a specified vdata. `access` can be `'r'` or `'w'`.
`'detach'`	`status = hdfvs('detach',vdata_id)`	Terminates access to a specified vdata.

Read and Write Functions

Read and write functions read and write the contents of a vdata.

Value of `funcstr`	Function Syntax	Description
`'fdefine'`	`status = hdfvs('fdefine',vdata_id,`	Defines a new vdata field. `data_type` is a string specifying the HDF number type. It can be any hese strings: `'uchar8'`, `'uchar'`, `'char8'`, `'char'`, `'double'`, `'uint8'`, `'uint16'`, `'uint32'`, `'float'`, `'int8'`, `'int16'`, or `'int32'`.
`'setclass'`	`status = hdfvs('setclass',vdata_id`	Assigns a class to a vdata.
`'setfields'`	`status = hdfvs('setfields',vdata_i`	Specifies the vdata fields to be written.
`'setinterlace'`	`status = hdfvs('setinterlace',vdat`	Sets the interlace mode for a vdata. `interlace` can be `'full'` or `'no'`.
`'setname'`	`status = hdfvs('setname',vdata_id,`	Assigns a name to a vdata.
`'write'`	`count = hdfvs('write', vdata_id, data)`	Writes to a vdata. data must be an `nfields`-by-1 cell array. Each cell must contain an `order(i)`-by-`n` vector of data where `order(i)` is the number of scalar values in each field. The types of the data must match the field types set via `hdfvs('setfields')` or the fields in an already existing vdata.

Value of `funcstr`	Function Syntax	Description
`'read'`	`[data,count] = hdfvs('read',vdata_id,n)`	Reads from a vdata. Data is returned in a `nfields`-by-1 cell array. Each cell contains a `order(i)`-by-`n` vector of data where `order` is the number of scalar values in each field. The fields are returned in the same order as specified in `hdfvs('setfields',...)`.
`'seek'`	`pos = hdfvs('seek',vdata_id,rec`	Seeks to a specified record in a vdata.
`'setattr'`	`status = hdfvs('setattr',vdata_id,`	Sets the attribute of a vdata field or vdata.
`'setexternalfile'`	`status = hdfvs('setexternalfile',v`	Stores vdata information in an external file.
`'getattr'`	`[value,status] = hdfvs('getattr',vdata_id,`	Reads the value of an attribute attached to a vdata or a vdata field. Set `field_index` to `'vdata'` to retrieve an attribute attached to the field itself. Set `field_index` to the numerical index of the field to retrieve an attribute attached to a vdata field.
`'setattr'`	`status = hdfvs('setattr',vdata_id,`	Sets the attribute of a vdata field or vdata.`field_index` can be an index number or `'vdata'`.

File Inquiry Functions

File inquiry functions provide information about how vdatas are stored in a file. They are useful for locating vdatas in a file.

Value of `funcstr`	Function Syntax	Description
`'find'`	`vdata_ref = hdfvs('find',file_id,vdat`	Searches for a given vdata name in the specified HDF file.

Value of `funcstr`	Function Syntax	Description
`'findclass'`	`vdata_ref = hdfvs('findclass',file_id`	Returns the reference number of the first vdata corresponding to the specified vdata class.
`'getid'`	`next_ref = hdfvs('getid',file_id,vda`	Returns the identifier of the next vdata in the file.
`'lone'`	`[refs,count] = hdfvs('lone',file_id,maxs`	Returns the reference numbers of the vdatas that are not linked into vgroups.

Vdata Inquiry Functions

Vdata inquiry functions provide specific information about a given vdata, including the vdata's name, class, number of fields, number of records, tag and reference pairs, interlace mode, and size.

Value of `funcstr`	Function Syntax	Description
`'fexist'`	`status = hdfvs('fexist',vdata_id,f`	Tests for the existence of fields in the specified vdata.
`'inquire'`	`[n,interlace,fields,nbyte = ... hdfvs('inquire',vdata_id)`	Returns information about the specified vdata.
`'elts'`	`count = hdfvs('elts',vdata_id)`	Returns the number of records in the specified vdata.
`'getclass'`	`[class_name,status] = hdfvs('getclass',vdata_id`	Returns the HDF class of the specified vdata.
`'getfields'`	`[field_names,count] = hdfvs('getfields',vdata_i`	Returns all field names within the specified vdata.
`'getinterlace'`	`[interlace,status] = hdfvs('getinterlace',vdat`	Retrieves the interlace mode of the specified vdata.
`'getname'`	`[vdata_name,status] = hdfvs('getname',vdata_id)`	Retrieves the name of the specified vdata.
`'getversion'`	`version = hdfvs('getversion',vdata_`	Returns the version number of a vdata.

Value of `funcstr`	Function Syntax	Description
`'sizeof'`	`nbytes = hdfvs('sizeof',vdata_id,f`	Returns the fields sizes of the specified vdata.
`'Queryfields'`	`[fields,status] = hdfvs('Queryfields',vdata`	Returns the field names of the specified vdata.
`'Queryname'`	`[name,status] = hdfvs('Queryname',vdata_i`	Returns the name of the specified vdata.
`'Queryref'`	`ref = hdfvs('Queryref',vdata_id`	Retrieves the reference number of the specified vdata.
`'Querytag'`	`tag = hdfvs('Querytag',vdata_id`	Retrieves the tag of the specified vdata.
`'Querycount'`	`[count,status] = hdfvs('Querycount',vdata_`	Returns the number of records in the specified vdata.
`'Queryinterlace'`	`[interlace,status] = hdfvs('Queryinterlace',vd`	Returns the interlace mode of the specified vdata.
`'Queryvsize'`	`vsize = hdfvs('Queryvsize',vdata_`	Retrieves the local size in bytes of the specified vdata record.
`'findex'`	`[field_index,status] = hdfvs('findex',vdata_id,f`	Queries the index of a vdata field given the field name.
`'nattrs'`	`count = hdfvs('nattrs',vdata_id)`	Returns the number of attributes of the specified vdata and the vdata fields contained in it.
`'fnattrs'`	`count = hdfvs('fnattrs',vdata_id,`	Queries the total number of vdata attributes.
`'findattr'`	`attr_index = hdfvs('findattr',vdata_id`	Retrieves the index of an attribute given the attribute name.
`'isattr'`	`tf = hdfvs('isattr',vdata_id)`	Determines if the given vdata is an attribute.

Value of `funcstr`	Function Syntax	Description
`'attrinfo'`	`[name,data_type,count,nby = hdfvs('attrinfo',... vdata_id,field_index,attr`	Returns the name, data type, number of values, and the size of the values of the specified attributes of the specified vdata field or vdata.

Output Arguments

A `status` or identifier output of -1 indicates that the operation failed.

height

Number of table rows

Syntax

```
H = height(T)
```

Description

`H = height(T)` returns the number of rows in the table, `T`.

`height(T)` is equivalent to `size(T,1)`.

Examples

Number of Table Rows

Create a table, `T`.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

T = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
T =

               Age    Height    Weight    BloodPressure
               ___    ______    ______    _____________

    Smith      38     71        176       124          93
    Johnson    43     69        163       109          77
    Williams   38     64        131       125          83
    Jones      40     67        133       117          75
    Brown      49     64        119       122          80
```

Find the number of rows in table `T`.

```
H = height(T)
```

```
H =

     5
```

`T` contains five rows; `height` does not count the variable names.

Input Arguments

`T` — Input table

table

Input table, specified as a table.

See Also

`numel` | `size` | `width`

help

Help for functions in Command Window

Syntax

```
help
help name
```

Description

`help` lists all primary help topics in the Command Window. Each main help topic corresponds to a folder name on the MATLAB search path.

`help name` displays the help text for the functionality specified by `name`, such as a function, method, class, or toolbox.

Input Arguments

`name`

String that specifies an operator symbol (such as +) or the name of a function, class, method, package, toolbox folder, or other functionality.

Some classes and other packaged items require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, such as:

```
help className.name
help packageName.name
help packageName.className.name
```

If `name` is overloaded, that is, appears in multiple folders on the search path, `help` displays the help text for the first instance of `name` found on the search path, and displays a hyperlinked list of the overloaded functions and their folders.

When `name` specifies the name or partial path of a toolbox folder:

- If the folder contains a nonempty `Contents.m` file, the `help` function displays the file. `Contents.m` contains a list of MATLAB program files in the folder and their descriptions. If `Contents.m` exists, but is empty, MATLAB responds with `No help found for` *`name`*.
- If the folder does not contain a `Contents.m` file, the `help` function lists the first line of help text for each program file in the folder.
- If `name` is the name of both a function and a toolbox, `help` displays the associated text for both the toolbox and the function.

Examples

Functions and Overloaded Methods

Display help for the MATLAB `close` function.

```
help close
```

Because `close` refers to the name of a function and to the name of several methods, the help text includes hyperlinks to the overloaded methods.

Request help for the Database Toolbox™ `close` method.

```
help database.close
```

Package, Class, and Method Help

Display help for the `containers` package, `Map` class, and the `isKey` method.

```
help containers
help containers.Map
help containers.Map.isKey
```

Not all packages, classes, and associated methods or events require complete specification. For example, display the help for the `throwAsCaller` method of the `MException` class.

```
help throwAsCaller
```

Functions in Folder

List all of the functions in the folder *`matlabroot`*`/toolbox/matlab/general` by specifying a partial path.

```
help general
```

Alternatives

View more extensive help using the `doc` command or the Function Browser. To open the Function Browser, click its icon,  .

More About

Tips

- Some help text displays the names of functions in uppercase characters to make them stand out from the rest of the text. When typing these function names, use lowercase. For function names that appear in mixed case (such as `javaObject`), type the names as shown.
- To prevent long descriptions from scrolling off the screen before you have time to read them, enter `more on`, and then enter the `help` statement.
- Some classes require that you specify the package name to display the help text. To identify the package name, create an instance of the class, and then call `class(obj)`.

`doc`

Introduced before R2006a

helpdlg

Create help dialog box

Syntax

```
helpdlg
helpdlg('helpstring')
helpdlg('helpstring','dlgname')
h = helpdlg(...)
```

Description

`helpdlg` creates a nonmodal help dialog box or brings the named help dialog box to the front.

Note A nonmodal dialog box enables the user to interact with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

`helpdlg` displays a dialog box named `'Help Dialog'` containing the string `'This is the default help string.'`

`helpdlg('helpstring')` displays a dialog box named `'Help Dialog'` containing the string specified by `'helpstring'`.

`helpdlg('helpstring','dlgname')` displays a dialog box named `'dlgname'` containing the string `'helpstring'`.

`h = helpdlg(...)` returns the handle of the dialog box.

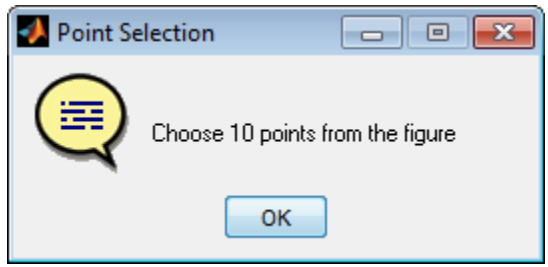
Examples

The statement

```
helpdlg('Choose 10 points from the figure',...
```

```
        'Point Selection');
```

displays this dialog box:



More About

Tips

MATLAB wraps the text in `'helpstring'` to fit the width of the dialog box. The dialog box remains on your screen until you press the **OK** button or the **Enter** key. After either of these actions, the help dialog box disappears.

helpwin

Provide access to help comments for all functions

Note: `helpwin` will be removed in a future release. Use `doc` instead.

Syntax

```
helpwin
helpwin topic
```

Description

`helpwin` lists topics for groups of functions in the MATLAB Help browser. It shows brief descriptions of the topics and provides links to display help comments for the functions. You cannot follow links in the `helpwin` list of functions if the MATLAB software is busy (for example, running a program).

`helpwin topic` displays help information for the topic. If `topic` is a folder, it displays all functions in the folder. If `topic` is a function, `helpwin` displays help for that function. From the page, you can access a list of folders (**Default Topics** link) as well as the reference page help for the function (**Go to online doc** link). You cannot follow links in the `helpwin` list of functions if MATLAB is busy (for example, running a program).

Examples

Typing

```
helpwin datafun
```

displays the functions in the `datafun` folder and a brief description of each.

Typing

```
helpwin fft
```

displays the help for the `fft` function.

`doc` | `help`

Introduced before R2006a

hess

Hessenberg form of matrix

Syntax

```
H = hess(A)
[P,H] = hess(A)
[AA,BB,Q,Z] = hess(A,B)
```

Description

`H = hess(A)` finds `H`, the Hessenberg form of matrix `A`.

`[P,H] = hess(A)` produces a Hessenberg matrix `H` and a unitary matrix `P` so that `A = P*H*P'` and `P'*P = eye(size(A))` .

`[AA,BB,Q,Z] = hess(A,B)` for square matrices `A` and `B`, produces an upper Hessenberg matrix `AA`, an upper triangular matrix `BB`, and unitary matrices `Q` and `Z` such that `Q*A*Z = AA` and `Q*B*Z = BB`.

Definitions

A Hessenberg matrix is zero below the first subdiagonal. If the matrix is symmetric or Hermitian, the form is tridiagonal. This matrix has the same eigenvalues as the original, but less computation is needed to reveal them.

Examples

`H` is a 3-by-3 eigenvalue test matrix:

```
H =
   -149    -50   -154
    537    180    546
    -27     -9    -25
```

Its Hessenberg form introduces a single zero in the (3,1) position:

```
hess(H) =
   -149.0000    42.2037   -156.3165
   -537.6783   152.5511   -554.9272
           0     0.0728      2.4489
```

matlab.mixin.Heterogeneous class

Package: matlab.mixin

Superclass for heterogeneous array formation

Description

`matlab.mixin.Heterogeneous` is an abstract class that provides support for the formation of heterogeneous arrays. A heterogeneous array is an array of objects that differ in their specific class, but are all derived from or are instances of a root class. The root class derives directly from `matlab.mixin.Heterogeneous`.

Heterogeneous Hierarchy

Use `matlab.mixin.Heterogeneous` to define hierarchies of classes whose instances you can combine into heterogeneous arrays.

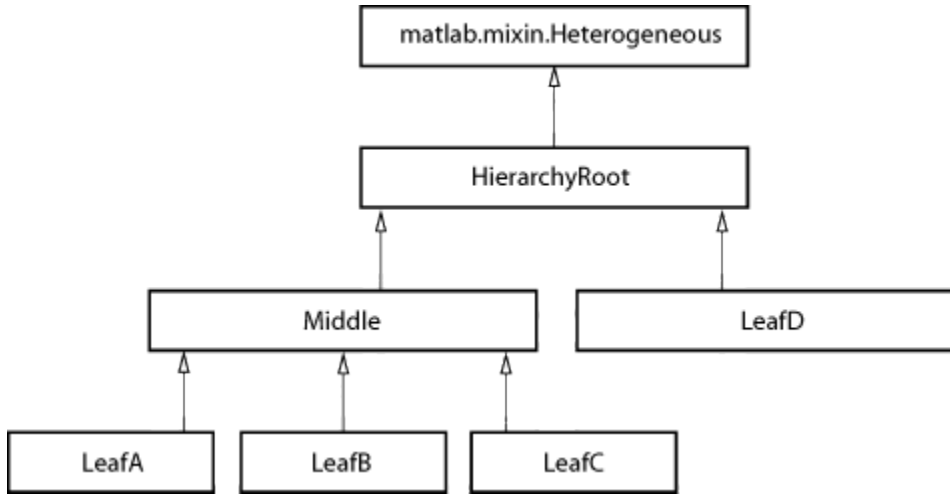
The following class definition enables the formation of heterogeneous arrays that combine instances of any classes derived from `HierarchyRoot`.

```
classdef HierarchyRoot < matlab.mixin.Heterogeneous
% HierarchyRoot is a direct subclass of
% matlab.mixin.Heterogeneous
% HierarchyRoot is the root of this heterogeneous hierarchy
```

Deriving the `HierarchyRoot` class directly from `matlab.mixin.Heterogeneous` enables the `HierarchyRoot` class to become the root of a hierarchy of classes. You can combine instances of the members of this hierarchy into a heterogeneous array. Only instances of classes derived from the same root class can combine to form a valid heterogeneous array.

Class of a Heterogeneous Array

The class of a heterogeneous array is always the class of the most specific superclass common to all objects in the array. For example, suppose you define the following class hierarchy:



Forming an array (`harray`) of an instance of `LeafA` with an instance of `LeafB` creates an array of class `Middle`:

```
harray = [LeafA,LeafB];
class(harray)
ans =
Middle
```

Forming an array (`harray`) of an instance of `LeafC` with an instance of `LeafD` creates an array of class `HierarchyRoot`:

```
harray = [LeafC,LeafD];
class(harray)
ans =
HierarchyRoot
```

Forming an array (`harray`) of an instance of `LeafA` with an other instance of `LeafA` creates a homogeneous array of class `LeafA`:

```
harray = [LeafA,LeafA];
class(harray)
ans =
LeafA
```

Note: You cannot form heterogeneous arrays that include instances of classes that are not derived from the same hierarchy root (that is, the `HierarchyRoot` class in the hierarchy shown previously).

Forming a Heterogeneous Array

Heterogeneous arrays are the result of operations that produces arrays containing instances of two or more classes from the heterogeneous hierarchy. Usually, concatenation or indexed assignment form these arrays. For example, these statements form `harray` using indexed assignment:

```
harray(1) = LeafA;
harray(2) = LeafC;
class(harray)
ans =
Middle
```

Growing the Array Can Change Its Class

Assigning new objects into an array containing objects derived from `matlab.mixin.Heterogeneous` can change the class of the array. For example, given a homogeneous array containing objects only of the `LeafA` class:

```
harray = [LeafA,LeafA,LeafA];
class(harray)
ans =
LeafA
```

Adding an object of another class derived from the same root to `harray` converts the array's class to the most specific superclass:

```
harray(4) = LeafB;
class(harray)
ans =
Middle
```

Method Dispatching

When MATLAB invokes a method for which the dominant argument is a heterogeneous array, the method:

- Must be defined for the class of the heterogeneous array, either directly by the class of the array or inherited from a superclass.

- Must be `Sealed = true` (cannot be overridden by a subclass).

The class of the heterogeneous array determines which class method executes for any given method invocation, as is the case with a homogeneous array. MATLAB does not consider the class of individual elements in the array when dispatching to methods.

Sealing Inherited Methods

The requirement that methods called on a heterogeneous array be `Sealed = true` ensures correct and predictable behavior with all array elements.

You must override methods that are inherited from outside the heterogeneous hierarchy if these methods are not `Sealed = true` and you want to call these methods on heterogeneous arrays.

For example, suppose you define a heterogeneous array by subclassing `matlab.mixin.SetGet`, in addition to `matlab.mixin.Heterogeneous`. Override the `set` method to call the `matlab.mixin.SetGet` superclass method as required by your class design:

```
methods(Sealed)
   function varargout = set(obj,varargin)
      if nargout == 0
         set@matlab.mixin.SetGet(obj, varargin{:});
      else
         varargout{:} = set@matlab.mixin.SetGet(obj,varargin{:});
      end
   end
end
```

Method implementations can take advantage of the fact that, given a heterogeneous array `harray`, and a scalar index `n`, the expression

```
harray(n)
```

is not a heterogeneous array. Therefore, when invoking a method on a single element of a heterogeneous array, special requirements for heterogeneous arrays do not apply.

Defining the Default Object

When working with object arrays (both heterogeneous and homogeneous), MATLAB creates default objects to fill in missing array elements by calling the class constructor

with no arguments. Filling in missing array elements becomes necessary in cases such as:

- Indexed assignment creates an array with gaps. For example, if `harray` is not previously defined:

  ```
  harray(5) = LeafA;
  ```

- Loading a heterogeneous array from a MAT-file when MATLAB cannot find the class definition of a specific object.

The `matlab.mixin.Heterogeneous` class provides a default implementation of a method called `getDefaultScalarElement`. This method returns an instance of the root class of the heterogeneous hierarchy, unless the root class is abstract.

If the root class is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy, you can override the `getDefaultScalarElement` method to return an instance of a class derived from the root class.

Defining the getDefaultScalarElement Method

Specify the class of the default object by overriding the `matlab.mixin.Heterogeneous` method called `getDefaultScalarElement` in the root class of the heterogeneous hierarchy. You can override `getDefaultScalarElement` only in the root class (direct subclasses of `matlab.mixin.Heterogeneous`).

`getDefaultScalarElement` has the following signature:

```
methods (Static, Sealed, Access = protected)
   function default_object = getDefaultScalarElement
   ...
   end
end
```

The `getDefaultScalarElement` method must satisfy these criteria:

- Static — MATLAB calls this method without an object.
- Protected — MATLAB calls this method, object users do not.
- Sealed (not required) — Seal this method to ensure users of the heterogeneous hierarchy do not change the intended behavior of the class.
- It must return a scalar object
- It must pass the `isa` test for the root class, that is:

```
(isa(getDefaultScalarElement,'HierarchyRoot')
```

where *`HierarchyRoot`* is the name of the heterogeneous hierarchy root class. This means the default object can be an instance of any class derived from the root class.

Cannot Redefine Indexing or Concatenation

The use of heterogeneous arrays requires consistent indexing and concatenation behaviors. Therefore, subclasses of `matlab.mixin.Heterogeneous` cannot change their default indexed reference, indexed assignment, or concatenation behavior.

You cannot override the following methods in your subclasses:

- `cat`
- `horzcat`
- `vertcat`
- `subref`
- `subsasign`

In cases involving multiple inheritance in which your subclass inherits from superclasses in addition to `matlab.mixin.Heterogeneous`, the superclasses cannot define any of these methods.

Default Concatenation Behavior

Statements of the form:

```
a = [obj1,obj2,...];
```

create an array, `a`, containing the objects listed in brackets.

Concatenating `Heterogeneous` objects of the same specific class retains the class of the objects and does not form a heterogeneous array.

Concatenating `Heterogeneous` objects derived from the same root superclass, but that are of different specific classes, yields a heterogeneous array. MATLAB does not attempt to convert the class of any array members if all are part of the same root hierarchy.

Indexed Assignment Behavior

Statements of the form:

```
a(m:n) = [objm,...objn];
```

assign the right-hand side objects to the array elements (`m:n`), specified on the left side of the assignment.

Indexed assignment to a heterogeneous array can:

- Increase or decrease the size of the array
- Overwrite existing array elements
- Change property values of objects within the array
- Change the class of the array
- Change whether the array is heterogeneous

Indexed Reference Behavior

Statements of the form:

```
a = harray(m:n);
```

assign the elements of `harray` referenced by indices `m:n`, to array `a`.

Indexed reference on a heterogeneous array returns a sub-range of the original array. Depending on the specific elements within that sub-range (`m:n`), the result might have a different class than the original array, and might not be heterogeneous.

Converting Nonmember Objects

If you attempt to form a heterogeneous array with objects that are not derived from the same root class, MATLAB calls the `convertObject` method, if it exists, to convert objects to the dominant class. Implementing a `convertObject` method enables the formation of heterogeneous arrays containing objects that are not part of the heterogeneous hierarchy.

When Is Conversion Necessary

Suppose there are two classes `A` and `B`, where `B` is not derived from `matlab.mixin.Heterogeneous`, or where `A` and `B` are derived from different root classes that are derived from `matlab.mixin.Heterogeneous`.

MATLAB attempts to call the `convertObject` method implemented by the root class of `A` in the following cases:

- The indexed assignment:

  ```
  A(k) = B
  ```

- Horizontal and vertical concatenations:

  ```
  [A,B] and [A;B]
  ```

Implement a `convertObject` method if you want to support conversion of objects whose class is not defined in your heterogeneous hierarchy. You do not need to implement this method if your class design does not require this conversion.

Implementing convertObject

Only the root class of the heterogeneous hierarchy can implement a `convertObject` method.

The `convertObject` method must have the following signature:

```
Method (Static, Sealed, Access = protected)
   function cobj = convertObject('DomClass',objToConvert)
   ...
   end
end
```

For indexed assignment `A(k) = B` and concatenation `[A,B]`:

- *`DomClass`* — Name of the class of the array `A`
- `objToConvert` — Object to be converted, `B` in this case
- `cobj` — Legal member of the heterogeneous hierarchy to which `A` belongs

You must implement `convertObject` to return a valid object of class `A` or MATLAB issues an error.

Handle Compatibility

The `matlab.mixin.Heterogeneous` class is handle compatible. It can be combined with either handle or value classes when defining a subclass using multiple superclasses. See “Supporting Both Handle and Value Subclasses” for information on handle compatibility.

The `matlab.mixin.Heterogeneous` class is a value class. To learn how value classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

Methods

cat	Concatenation for heterogeneous arrays
getDefaultScalarElement	Return default object for heterogeneous array operations
horzcat	Horizontal concatenation for heterogeneous arrays
vertcat	Vertical concatenation for heterogeneous arrays

`handle`

How To

- Class Attributes
- Property Attributes
- “Creating Subclasses — Syntax and Techniques”

cat

Class: matlab.mixin.Heterogeneous
Package: matlab.mixin

Concatenation for heterogeneous arrays

Syntax

```
C = cat(dim,A,B)
```

Description

`C = cat(dim,A,B)` concatenates objects `A` and `B` along the dimension `dim`.
The class of object arrays `A` and `B` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

- If `A` and `B` are of the same class, the class of the resulting array is unchanged.
- If `A` and `B` are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array and the array's class is that of the most specific superclass shared by `A` and `B`.

The `cat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

Input Arguments

`dim`

Scalar dimension along which to concatenate arrays

Default:

`A`

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as `B`

B

Object array derived from the same root subclass of `matlab.mixin.Heterogeneous` as A

Output Arguments

C

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by A and B.

Attributes

Sealed	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`matlab.mixin.Heterogeneous` | `cat`

matlab.mixin.Heterogeneous.getDefaultScalarElement

Class: matlab.mixin.Heterogeneous
Package: matlab.mixin

Return default object for heterogeneous array operations

Syntax

```
defaultObject = getDefaultScalarElement
```

Description

`defaultObject = getDefaultScalarElement` returns the default object for a heterogeneous hierarchy. Override this method if the "Root Class" on page 1-3587 is abstract or is not an appropriate default object for the classes in the heterogeneous hierarchy. `getDefaultScalarElement` must return an instance of another member of the heterogeneous hierarchy.

The `matlab.mixin.Heterogeneous` class provided a default implementation of this method that returns an instance of the "Root Class" on page 1-3587.

MATLAB calls the `getDefaultScalarElement` method when requiring a default object. See `matlab.mixin.Heterogeneous` for more information on heterogeneous arrays and default objects.

Tips

- Override `getDefaultScalarElement` only if the "Root Class" on page 1-3587 is not suitable as a default object.
- Override `getDefaultScalarElement` only in the "Root Class" on page 1-3587 of the heterogeneous hierarchy.
- `getDefaultScalarElement` must return a scalar object.
- `getDefaultScalarElement` must be a static method with protected access. While not required by MATLAB, you can seal this method to prevent overriding by other classes.

- MATLAB returns an error if the value returned by `getDefaultScalarElement` is not scalar or is not an instance of a class that is a valid member of the hierarchy.

Output Arguments

`defaultObject`

The default object for heterogeneous array operations.

Definitions

Root Class

Root class – The direct subclass of `matlab.mixin.Heterogeneous` that forms the root of a heterogeneous hierarchy. Classes of objects that you can combine into heterogeneous arrays must derive from this root class.

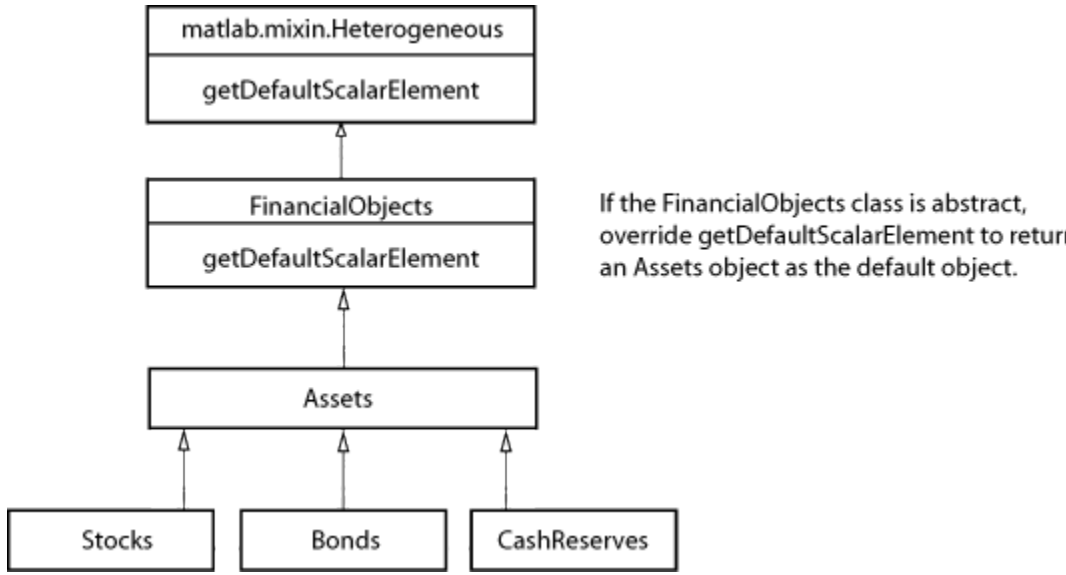
Attributes

`Static`	`true`
`Access`	`Protected`
`Sealed`	`true` not required

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

This example describes a heterogeneous hierarchy with a root class (`FinancialObjects`) that is an abstract class and cannot, therefore, be used for the default object. The `FinancialObjects` class definition includes an override of the `getDefaultScalarElement` method which returns an instance of the `Assets` class as the default object.



The root class can override the `getDefaultScalarElement` method that is defined in `matlab.mixin.Heterogeneous` class and return an `Assets` object as the default object.

```
classdef FinancialObjects < matlab.mixin.Heterogeneous
   methods (Abstract)
      val = determineCurrentValue(obj)
   end
   methods (Static, Sealed, Access = protected)
      function default_object = getDefaultScalarElement
         default_object = Assets;
      end
   end
end
```

See Also

`matlab.mixin.Heterogeneous`

horzcat

Class: matlab.mixin.Heterogeneous
Package: matlab.mixin

Horizontal concatenation for heterogeneous arrays

Syntax

```
C = horzcat(A1,A2,...)
```

Description

`C = horzcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of rows.

The class of object arrays `A1,A2,...` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

```
C = horzcat(A1,A2,...)
```

for the expressions:

```
C = [A1,A2,...]
C = [A1 A2 ...]
```

when `A1` is an array of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

Input Arguments

A1

Object array of class `matlab.mixin.Heterogeneous`

A2

Object array of class `matlab.mixin.Heterogeneous`

Output Arguments

C

Array resulting from the specified concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

Attributes

`Sealed`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`matlab.mixin.Heterogeneous` | `horzcat`

vertcat

Class: matlab.mixin.Heterogeneous
Package: matlab.mixin

Vertical concatenation for heterogeneous arrays

Syntax

```
C = vertcat(A1,A2,...)
```

Description

`C = vertcat(A1,A2,...)` concatenates the `matlab.mixin.Heterogeneous` objects `A1`, `A2`, and so on, to form the array `C`. All input arrays must have the same number of columns.

The class of object arrays `A1,A2,...` must be derived from the same root class of a `matlab.mixin.Heterogeneous` hierarchy.

MATLAB calls:

```
C = vertcat(A1,A2,...)
```

for the expression:

```
C = [A1;A2;...]
```

when `A1` and `A2`, and so on are arrays of `matlab.mixin.Heterogeneous` objects.

If all input arguments are of the same specific class, the class of the resulting array is unchanged. If all input arguments are of different subclasses of a common superclass that is derived from `matlab.mixin.Heterogeneous`, then the result is a heterogeneous array. The array's class is that of the most specific superclass shared by all input arguments.

If all input arguments are not members of the same heterogeneous hierarchy, MATLAB calls the `convertObjects` method, if defined by the dominant root class (the first argument or the left-most element in the concatenation if no other class is dominant).

The `horzcat` method is sealed in the class `matlab.mixin.Heterogeneous` and, therefore, you cannot override it in subclasses.

Input Arguments

`A1`

Object array of class `matlab.mixin.Heterogeneous`

`A2`

Object array of class `matlab.mixin.Heterogeneous`

Output Arguments

`C`

Array resulting from the specified vertical concatenation. The class of this array is that of the most specific superclass shared by the input arguments.

Attributes

`Sealed`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`matlab.mixin.Heterogeneous` | `vertcat`

hex2dec

Convert hexadecimal number string to decimal number

Syntax

```
d = hex2dec('hex_value')
```

Description

`d = hex2dec('hex_value')` converts *`hex_value`* to its floating-point integer representation. The argument *`hex_value`* is a hexadecimal integer stored in a MATLAB string or cell array of strings. If the value of *`hex_value`* is greater than hexadecimal `10,000,000,000,000`, `hex2dec` might not return an exact conversion.

If *`hex_value`* is a cell array of strings, each row is interpreted as a hexadecimal string.

Examples

```
hex2dec('3ff')

ans =

        1023
```

For a character array `S`,

```
S =
0FF
2DE
123
hex2dec(S)

ans =

255
734
291
```

See Also

dec2hex | format | hex2num | sprintf

hex2num

Convert hexadecimal number string to double-precision number

Syntax

```
n = hex2num(S)
```

Description

`n = hex2num(S)`, where `S` is a 16 character string or cell array of strings representing a hexadecimal number, returns the IEEE double-precision floating-point number `n` that it represents. Fewer than 16 characters are padded on the right with zeros. If `S` is a cell array of strings, each row is interpreted as a double-precision number.

`NaN`s, infinities and denorms are handled correctly.

Examples

```
hex2num('400921fb54442d18')
```

returns `Pi`.

```
hex2num('bff')
```

returns

```
ans =

    -1
```

See Also

`num2hex` | `hex2dec` | `sprintf` | `format`

Introduced before R2006a

hgexport

Export figure

Syntax

```
hgexport(h,filename)
hgexport(h,'-clipboard')
```

Description

`hgexport(h,filename)` writes figure `h` to the file `filename`.

`hgexport(h,'-clipboard')` writes figure `h` to the Microsoft Windows clipboard.

The format in which the figure is exported is determined by which renderer you use. The Painters renderer generates a metafile. The OpenGL renderer generate a bitmap.

Alternatives

Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see "Customize Figure Interactively Before Saving" and "Copy Figure to Clipboard From Edit Menu".

See Also

`print`

Introduced before R2006a

hggroup

Create group object

Syntax

```
h = hggroup
h = hggroup(...,'PropertyName',propertyvalue,...)
```

Properties

For a list of properties, see Group Properties.

Description

`h = hggroup` creates a group object as a child of the current axes and returns its handle, `h`.

`h = hggroup(...,'PropertyName',propertyvalue,...)` creates a group object with the property values specified in the argument list.

A group object can be the parent of any axes, as well as other group objects. Use group objects to form a group of child objects that can be treated as a single object.

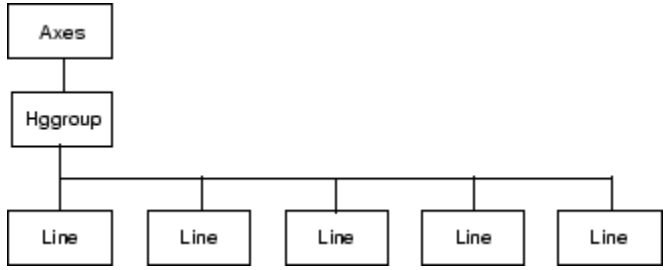
Examples

Plot random data and parented the lines to the group object.

```
hg = hggroup;
plot(randn(5),randn(5),'Parent',hg)
```

Instance Diagram for This Example

The following diagram shows the object hierarchy created by this example.



More About

- “Create Object Groups”

`hgtransform`

Introduced before R2006a

Group Properties

Control group appearance and behavior

Group object properties control the behavior of group objects. By changing property values, you can modify certain aspects of the group object.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = hggroup;
c = h.Children;
h.Visible = 'off';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Visibility

`Visible` — Visibility of group

`'on'` (default) | `'off'`

Visibility of group, specified as one of these values:

- `'on'` — Display all objects in the group.
- `'off'` — Hide all objects in the group. You still can access the properties of invisible group objects. Setting the `Visible` property for the group object does not change the `Visible` property for objects in the group.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces

the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.

- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'hggroup'`

Type of graphics object, returned as `'hggroup'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — Tag to associate with group

`''` (default) | string

Tag to associate with the group, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with group

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the group object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the group.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the group object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the group from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the group object in the legend as one entry (default).
   - `'off'` — Do not include the group object in the legend.
   - `'children'` — Include only children of the group object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of group

axes object | group object | transform object

Parent of group, specified as an axes, group, or transform object.

`Children` — Children of group

empty `GraphicsPlaceholder` array | array of graphics objects

Children of group, returned as an array of graphics objects. Use this property to view a list of the children or to reorder the children by setting the property to a permutation of itself.

You cannot add or remove children using the `Children` property of the group. To add a child to this list, set the `Parent` property of the child graphics object to the group object.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of group object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The group object handle is always visible.
- `'off'` — The group object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the

HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

- `'callback'` — The group object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the group at the command-line, but allows callback functions to access it.

If the group object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the group. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The group object — You can access properties of the group object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the group. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the group when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the group.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Children that can capture mouse clicks

`'visible'` (default) | `'none'`

Children that can capture mouse clicks, specified as one of these values:

- `'visible'` — Any child object can capture a mouse click, depending on the `PickableParts` property value of the child.
- `'none'` — No child objects can capture mouse clicks, regardless of the `PickableParts` property value of the child.

`HitTest` — Response to mouse clicks captured by children

`'on'` (default) | `'off'`

Response to mouse clicks captured by children, specified one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of group. If you have defined the `UIContextMenu` property, then invoke the context menu.
- `'off'` — Do not trigger the callbacks of the group. Instead, trigger the callbacks for the nearest ancestor of the group that has a `HitTest` property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

A group cannot capture mouse clicks. However, if you click a child of the group and if the child has a `HitTest` property set to `'off'`, then the child passes the click to the group.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running

callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the group is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the group tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the group. Setting the `CreateFcn` property on an existing group has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during group creation. MATLAB executes the callback after creating the group and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The group object — You can access properties of the group object from within the callback function. You also can access the group object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the group. MATLAB executes the callback before destroying the group so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The group object — You can access properties of the group object from within the callback function. You also can access the group object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of group

`'off'` (default) | `'on'`

Deletion status of group, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the group begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the group no longer exists.

Check the value of the BeingDeleted property to verify that the group is not about to be deleted before querying or modifying it.

`hggroup`

More About

- “Access Property Values”
- “Graphics Object Properties”

hgload

Load graphics object hierarchy from file

Syntax

```
h = hgload('filename')
[h,old_prop_values] = hgload(...,property_structure)
```

Description

Note: `hgload` is not recommended. Use `openfig` instead.

`h = hgload('filename')` loads graphics object hierarchy from the FIG-file specified by `filename` and returns handles to the top-level objects. If `filename` contains no extension, then MATLAB adds the `.fig` extension.

`[h,old_prop_values] = hgload(...,property_structure)` overrides the properties on the top-level objects stored in the FIG-file with the values in `property_structure`, and returns their previous values in `old_prop_values`.

`property_structure` must be a structure having field names that correspond to property names and values that are the new property values.

`old_prop_values` is a cell array equal in length to `h`, containing the old values of the overridden properties for each object. Each cell contains a structure having field names that are property names, each of which contains the original value of each property that has been changed. Any property specified in `property_structure` that is not a property of a top-level object in the FIG-file is not included in `old_prop_values`.

Nonserializable objects (such as the default toolbars and the default menus) are not saved because they are created when the figure is created. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files.

Alternatives

Use the **File > Open** on the figure window menu to access figure files with the **Open** dialog.

See Also

`hgsave | open`

Introduced before R2006a

hgsave

Save graphics object hierarchy to file

Syntax

```
hgsave('filename')
hgsave(h,'filename')
hgsave(...,'-v6')
hgsave(...,'-v7.3')
```

Description

Note: `hgsave` is not recommended. Use `savefig` instead.

`hgsave('filename')` saves the current figure to a file named `filename`.

`hgsave(h,'filename')` saves the objects identified by the array of handles `h` to a file named `filename`. If you do not specify an extension for `filename`, then the extension `.fig` is appended. If `h` is a vector, none of the handles in `h` may be ancestors or descendents of any other handles in `h`.

`hgsave(...,'-v6')` saves the FIG-file in a format that can be loaded by versions prior to MATLAB 7.

`hgsave(...,'-v7.3')` saves the FIG-file in a format that can be loaded only by MATLAB versions 7.3 and above. This format, based on HDF5 files, is intended for saving FIG-files larger than 2 GB.

Backward Compatibility

When creating a figure you want to save and use in a MATLAB version prior to MATLAB 7, use the `'v6'` option with the plotting function and the `'-v6'` option for `hgsave`. Check the reference page for the plotting function you are using for more information.

In MATLAB release R2014b or later, you cannot open a save FIG-file in earlier versions of MATLAB. Use `savefig` to save figures that are compatible with earlier versions of MATLAB.

Alternatives

Use the **File > Export Setup** dialog. Use **Edit > Copy Figure** to copy the figure's content to the system clipboard. For details, see "Customize Figure Interactively Before Saving" and "Copy Figure to Clipboard From Edit Menu".

See Also

`hgload` | `open` | `save` | `savefig`

Introduced before R2006a

hgsetget

Abstract class used to derive handle class with set and get methods

Note: `hgsetget` will be removed in a future release. Use `matlab.mixin.SetGet` instead.

Syntax

```
classdef myclass < hgsetget
```

Description

`classdef myclass < hgsetget` makes *`myclass`* a subclass of the `hgsetget` class, which is a subclass of the `handle` class.

Use the `hgsetget` class to derive classes that inherit `set` and `get` methods that behave like Handle Graphics `set` and `get` functions.

Methods

When you derive a class from the `hgsetget` class, your class inherits the following methods.

Method	Purpose
set	Assigns values to the specified properties or returns a cell array of possible values for writable properties.
get	Returns value of specified property or a `struct` with all property values.
setdisp	Called when `set` is called with no output arguments and a handle array, but no property name. Override this method to change what set displays.

Method	Purpose
getdisp	Called when `get` is called with no output arguments and handle array, but no property name. Override this method to change what get displays.

More About

- "Implementing a Set/Get Interface for Properties"

hgtransform

Create transform graphics object

Syntax

```
h = hgtransform
h = hgtransform('PropertyName',propertyvalue,...)
```

Properties

For a list of properties, see Transform Properties.

Description

`h = hgtransform` creates a transform object and returns its handle.

`h = hgtransform('PropertyName',propertyvalue,...)` creates a transform object with the property value settings specified in the argument list. For a description of the properties, see Transform Properties.

Transform objects can contain other objects, which lets you treat the transform object and its children as a single entity with respect to visibility, size, orientation, etc. You can group objects by parenting them to a single transform object (i.e., setting the object's `Parent` property to the transform object's handle):

```
h = hgtransform;
surface('Parent',h,...)
```

The primary advantage of parenting objects to an transform object is that you can perform *transforms* (for example, translation, scaling, rotation, etc.) on the child objects in unison.

The parent of a transform object is either an axes object or another transform object.

Although you cannot see a transform object, setting its `Visible` property to `off` makes all its children invisible as well.

Exceptions and Limitations

- A transform object can be the parent of any number of axes child objects belonging to the same axes, except for light objects.
- Transform objects can never be the parent of axes objects and therefore can contain objects only from a single axes.
- Transform objects can be the parent of other transform objects within the same axes.
- You cannot transform image objects because images are not true 3-D objects. Texture mapping the image data to a surface `CData` enables you to produce the effect of transforming an image in 3-D space.
- Transforms do not affect text objects unless the text object uses data units. If a text object has a position specified in data units, then the transform moves the lower left corner of the text. The transform does not affect the font size or orientation. To change the font size and orientation, use text properties.

Note Many plotting functions clear the axes (remove axes children) before drawing the graph. Clearing the axes also deletes any transform objects in the axes.

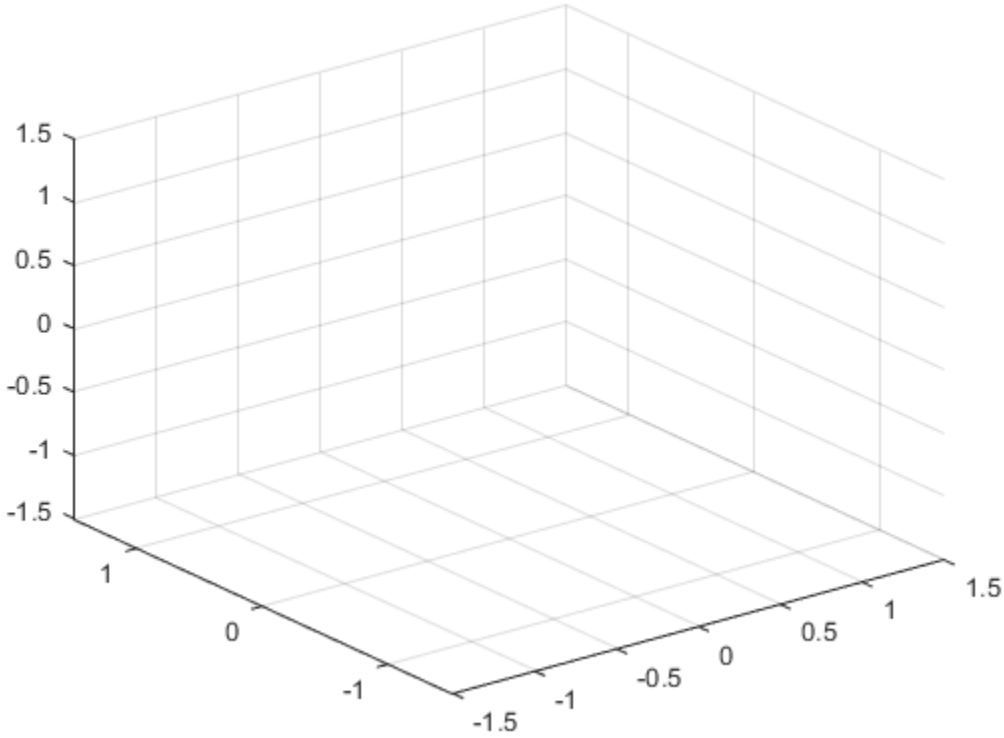
Examples

Transforming a Group of Objects

This example shows how to create a 3-D star with a group of surface objects parented to a single transform object. The transform object then rotates the object about the z-axis while scaling its size.

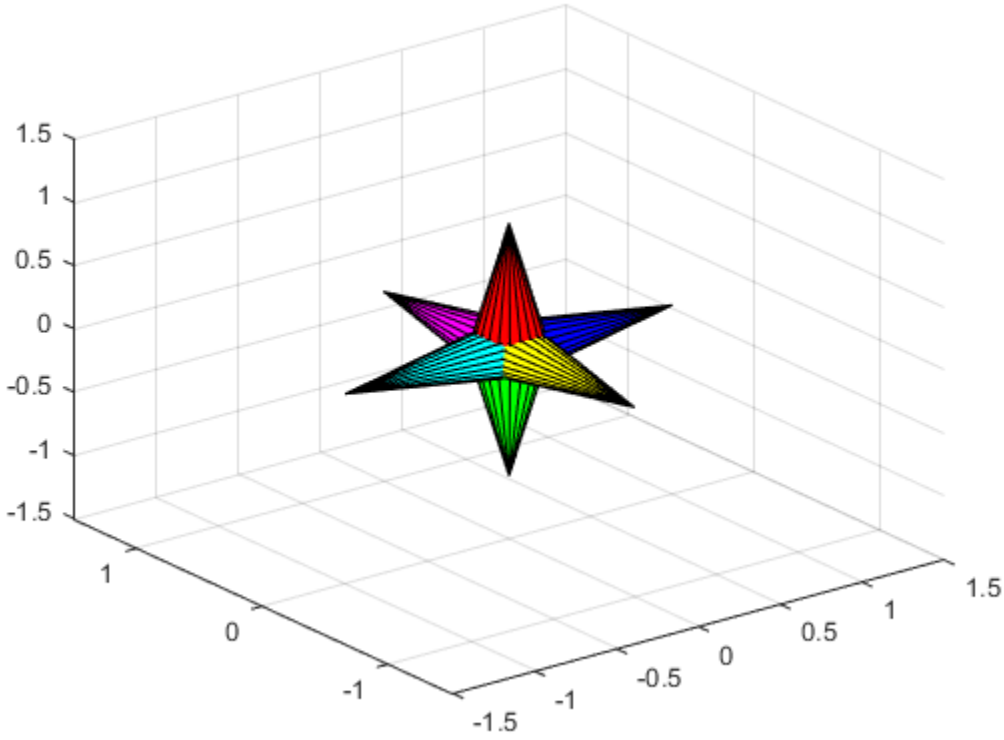
Create an axes and adjust the view. Set the axes limits to prevent auto limit selection during scaling.

```
ax = axes('XLim',[-1.5 1.5],'YLim',[-1.5 1.5],'ZLim',[-1.5 1.5]);
view(3)
grid on
```



Create the objects you want to parent to the transform object.

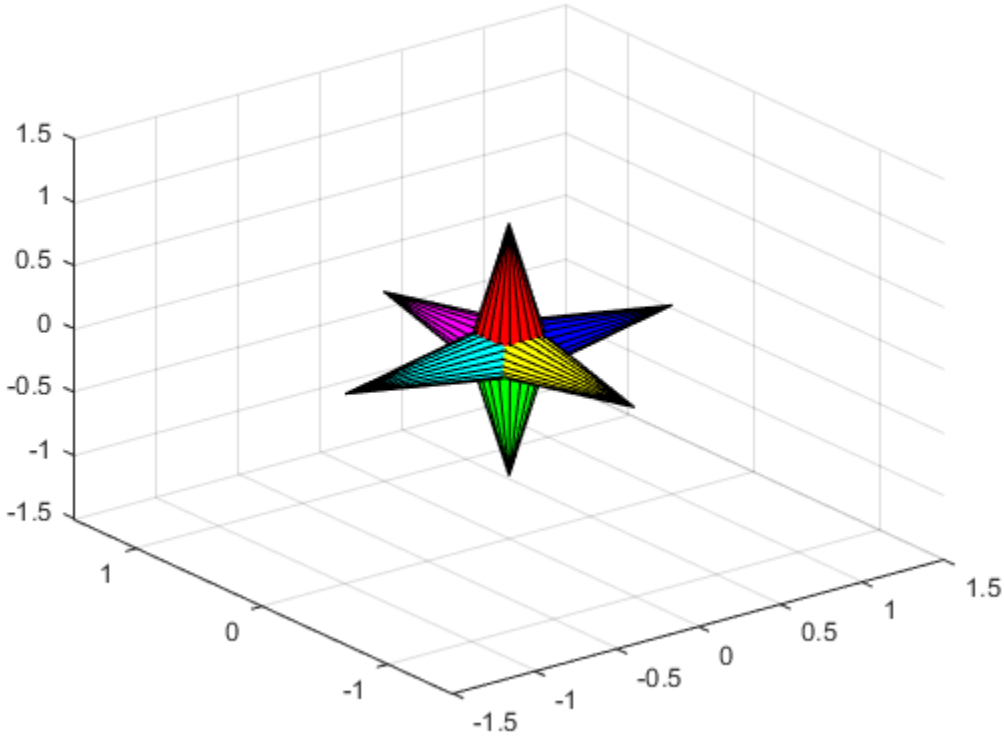
```
[x,y,z] = cylinder([.2 0]);
h(1) = surface(x,y,z,'FaceColor','red');
h(2) = surface(x,y,-z,'FaceColor','green');
h(3) = surface(z,x,y,'FaceColor','blue');
h(4) = surface(-z,x,y,'FaceColor','cyan');
h(5) = surface(y,z,x,'FaceColor','magenta');
h(6) = surface(y,-z,x,'FaceColor','yellow');
```



Create a transform object and parent the surface objects to it. Initialize the rotation and scaling matrix to the identity matrix (eye).

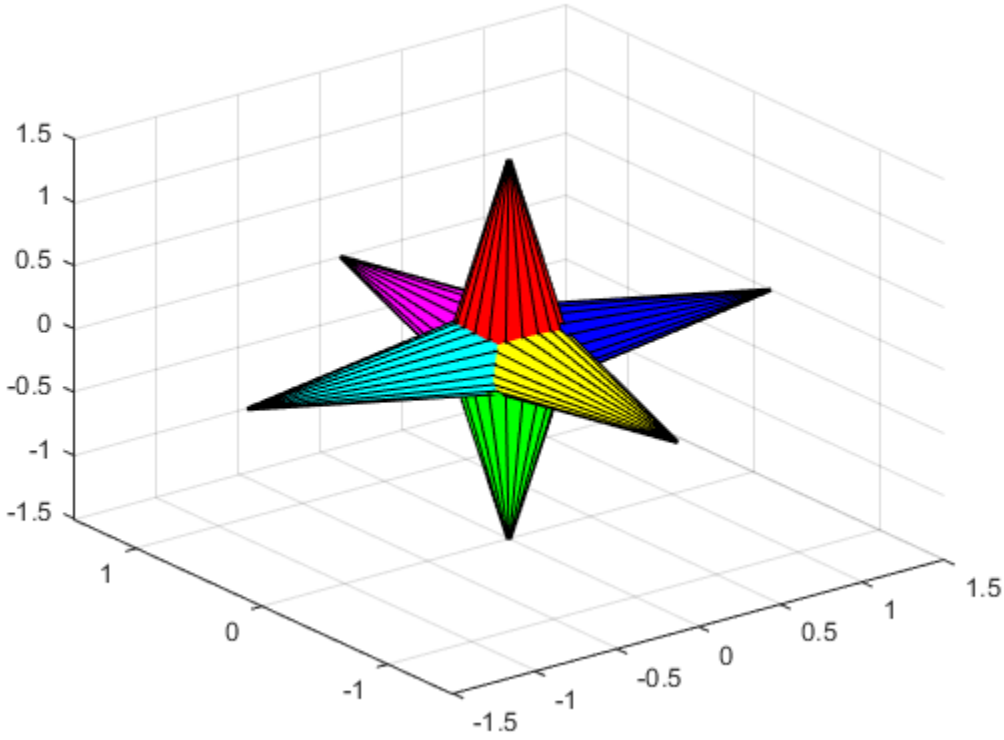
```
t = hgtransform('Parent',ax);
set(h,'Parent',t)

Rz = eye(4);
Sxy = Rz;
```



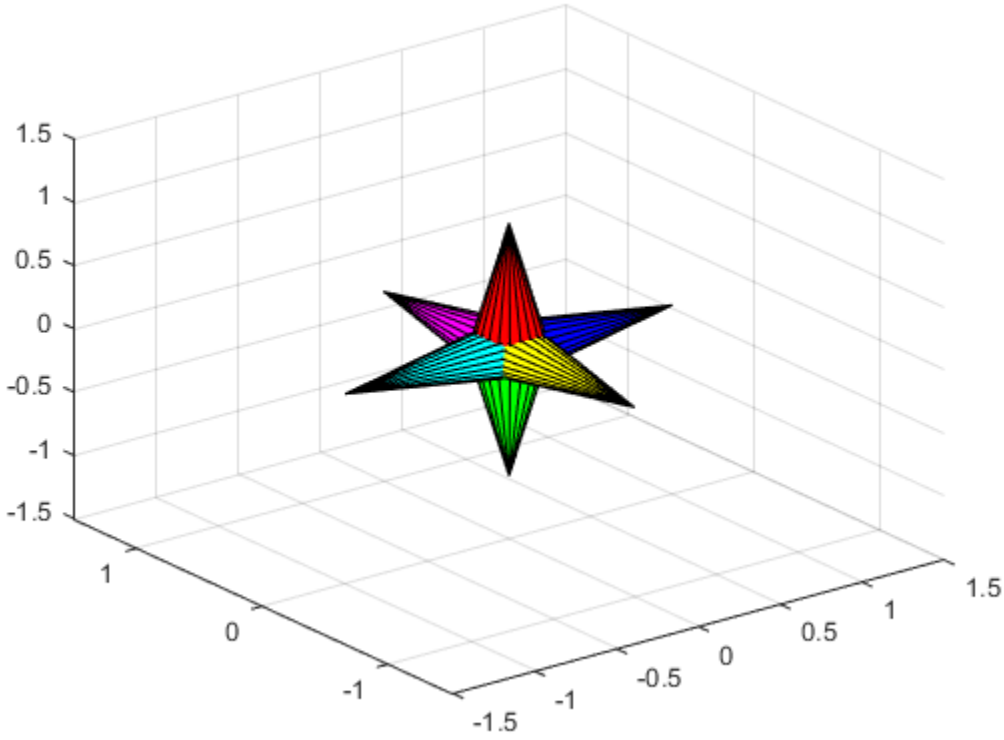
Form the *z*-axis rotation matrix and the scaling matrix. Rotate group and scale by using the increasing values of `r`.

```
for r = 1:.1:2*pi
    % Z-axis rotation matrix
    Rz = makehgtform('zrotate',r);
    % Scaling matrix
    Sxy = makehgtform('scale',r/4);
    % Concatenate the transforms and
    % set the transform Matrix property
    set(t,'Matrix',Rz*Sxy)
    drawnow
end
pause(1)
```



Reset to the original orientation and size using the identity matrix.

```
set(t,'Matrix',eye(4))
```

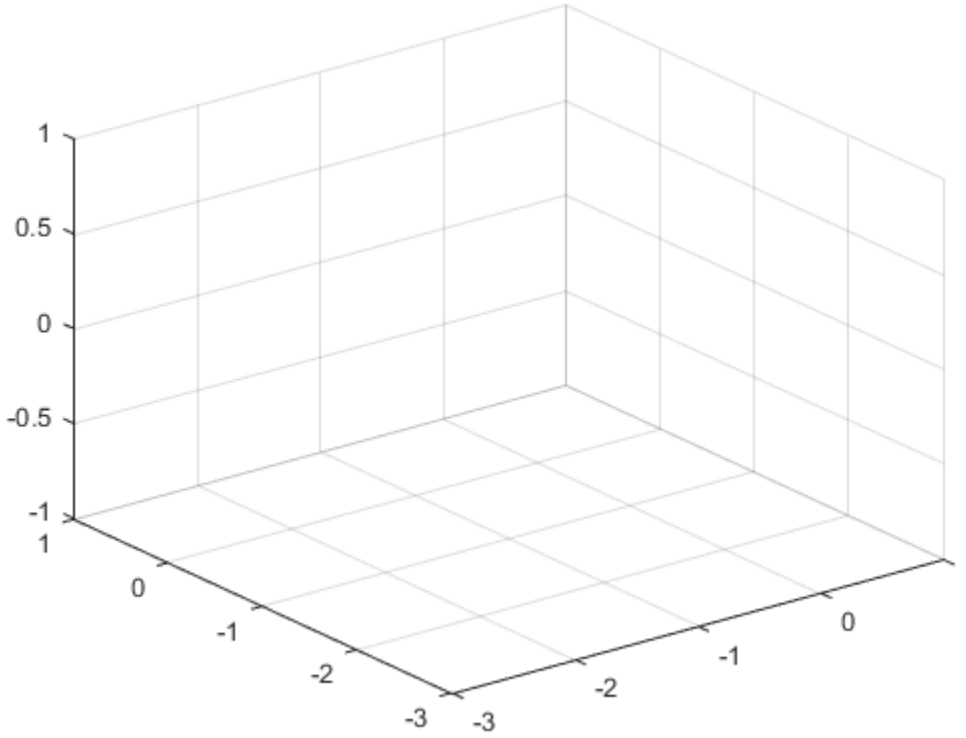


Transforming Objects Independently

This example creates two transform objects to illustrate how to transform each independently within the same axes. A translation transformation moves one transform object away from the origin.

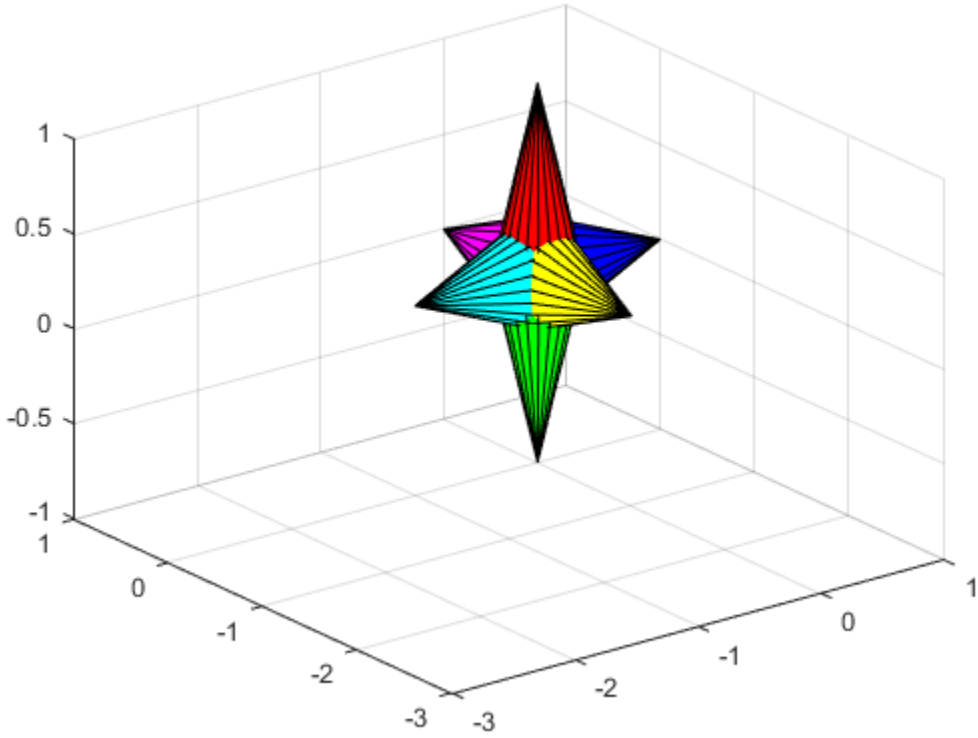
Create and set up the axes object that will be the parent of both transform objects. Set the limits to accommodate the translated object.

```
ax = axes('XLim',[-3 1],'YLim',[-3 1],'ZLim',[-1 1]);
view(3)
grid on
```



Create the surface objects to group.

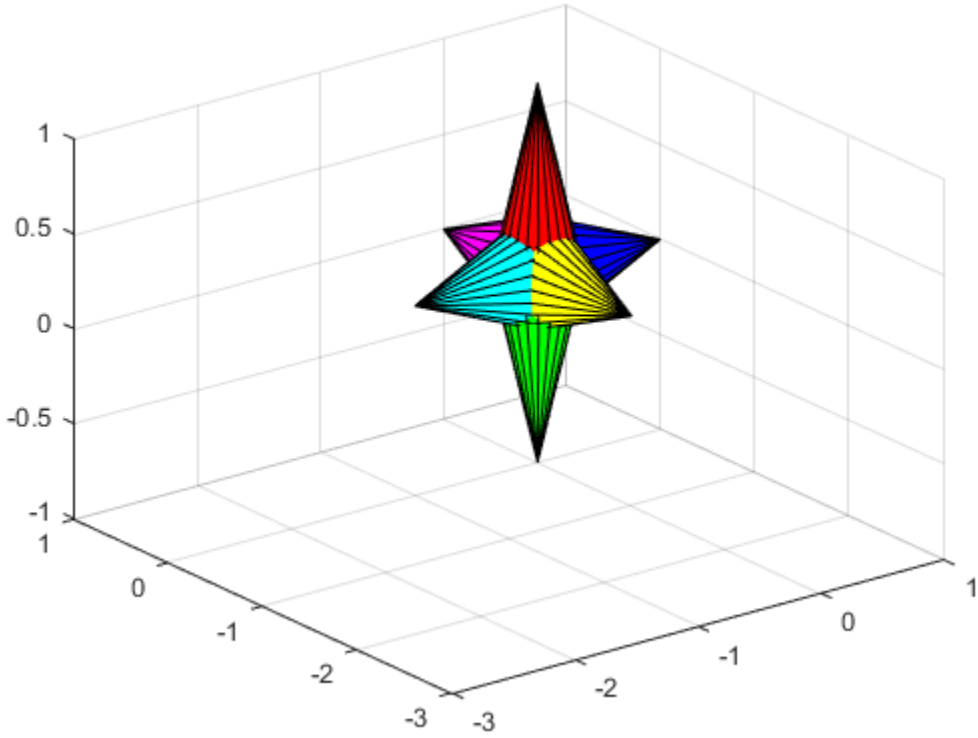
```
[x,y,z] = cylinder([.3 0]);
h(1) = surface(x,y,z,'FaceColor','red');
h(2) = surface(x,y,-z,'FaceColor','green');
h(3) = surface(z,x,y,'FaceColor','blue');
h(4) = surface(-z,x,y,'FaceColor','cyan');
h(5) = surface(y,z,x,'FaceColor','magenta');
h(6) = surface(y,-z,x,'FaceColor','yellow');
```



Create the transform objects and parent them to the same axes. Then, parent the surfaces to transform t1. Copy the surface objects and parent the copies to transform t2. This figure should not change.

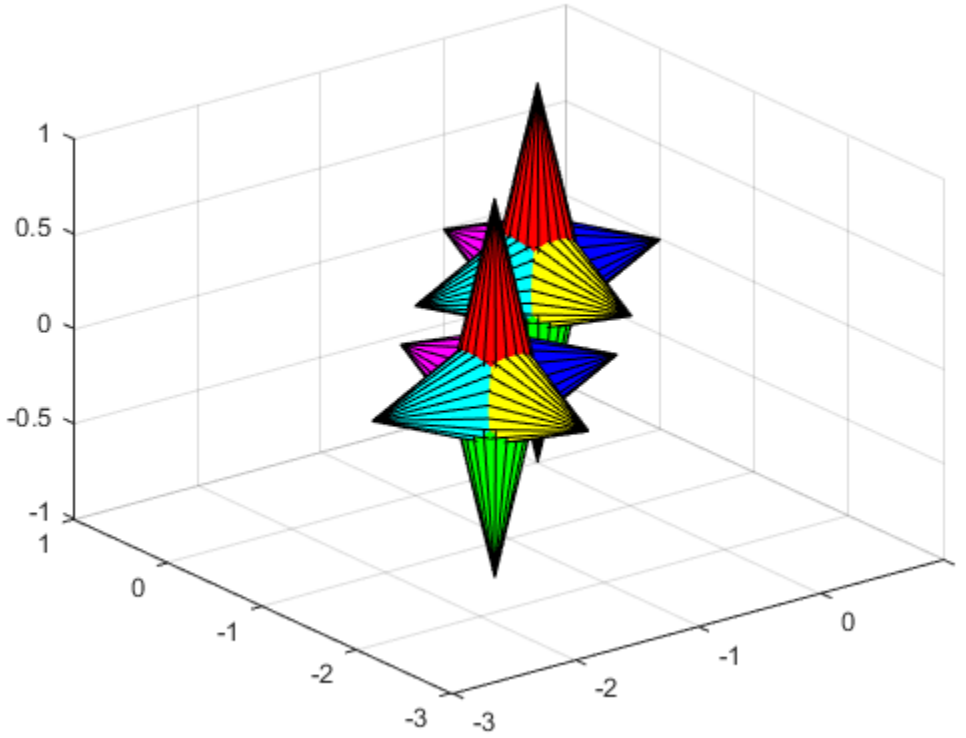
```
t1 = hgtransform('Parent',ax);
t2 = hgtransform('Parent',ax);

set(h,'Parent',t1)
h2 = copyobj(h,t2);
```



Translate the second transform object away from the first transform object and display the result.

```
Txy = makehgtform('translate',[-1.5 -1.5 0]);
set(t2,'Matrix',Txy)
drawnow
```



Rotate both transform objects in opposite directions.

```
% Rotate 10 times (2pi radians = 1 rotation)
for r = 1:.1:20*pi
    % Form z-axis rotation matrix
    Rz = makehgtform('zrotate',r);
    % Set transforms for both transform objects
    set(t1,'Matrix',Rz)
    set(t2,'Matrix',Txy*inv(Rz))
    drawnow
end
```

Transform Properties

Control transform appearance and behavior

Transform properties control the behavior of transform objects. By changing property values, you can modify certain aspects of the transform object.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = hgtransform;
c = h.Children;
h.Matrix = makehgtform('scale',0.5);
```

If you are using an earlier release, use the `get` and `set` functions instead.

Transform Matrix

`Matrix` — Transform matrix

4-by-4 matrix

Transform matrix applied to the transform object and its children, specified as a 4-by-4 matrix. For more information about defining this matrix, see "Transforms Supported by hgtransform".

Data Types: `double`

Visibility

`Visible` — Visibility of transform

`'on'` (default) | `'off'`

Visibility of transform, specified as one of these values:

- `'on'` — Display all objects in the transform.
- `'off'` — Hide all objects in the transform. You still can access the properties of invisible transform objects. Setting the `Visible` property for the transform object does not change the `Visible` property for objects in the transform.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'hgtransform'`

Type of graphics object, returned as `'hgtransform'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — Tag to associate with transform

`''` (default) | string

Tag to associate with the transform, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with transform

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the transform object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the transform.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the transform object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the transform from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the transform object in the legend as one entry (default).
   - `'off'` — Do not include the transform object in the legend.
   - `'children'` — Include only children of the transform object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of transform

axes object | group object | transform object

Parent of transform, specified as an axes, group, or transform object.

`Children` — Children of transform

empty `GraphicsPlaceholder` array | array of graphics objects

Children of transform, returned as an array of graphics objects. Use this property to view a list of the children or to reorder the children by setting the property to a permutation of itself.

You cannot add or remove children using the `Children` property of the transform. To add a child to this list, set the `Parent` property of the child graphics object to the transform object.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of transform object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The transform object handle is always visible.
- `'off'` — The transform object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The transform object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the transform at the command-line, but allows callback functions to access it.

If the transform object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the transform. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The transform object — You can access properties of the transform object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the transform. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the transform when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the transform.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Children that can capture mouse clicks

`'visible'` (default) | `'none'`

Children that can capture mouse clicks, specified as one of these values:

- `'visible'` — Any child object can capture a mouse click, depending on the `PickableParts` property value of the child.
- `'none'` — No child objects can capture mouse clicks, regardless of the `PickableParts` property value of the child.

`HitTest` — Response to mouse clicks captured by children

`'on'` (default) | `'off'`

Response to mouse clicks captured by children, specified one of these values:

- `'on'` — Trigger the `ButtonDownFcn` callback of transform. If you have defined the `UIContextMenu` property, then invoke the context menu.
- `'off'` — Do not trigger the callbacks of the transform. Instead, trigger the callbacks for the nearest ancestor of the transform that has a `HitTest` property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

A transform cannot capture mouse clicks. However, if you click a child of the transform and if the child has a `HitTest` property set to `'off'`, then the child passes the click to the transform.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the transform is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the

`BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the transform tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the transform. Setting the `CreateFcn` property on an existing transform has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during transform creation. MATLAB executes the callback after creating the transform and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The transform object — You can access properties of the transform object from within the callback function. You also can access the transform object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the transform. MATLAB executes the callback before destroying the transform so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The transform object — You can access properties of the transform object from within the callback function. You also can access the transform object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of transform

`'off'` (default) | `'on'`

Deletion status of transform, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the transform begins

execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the transform no longer exists.

Check the value of the BeingDeleted property to verify that the transform is not about to be deleted before querying or modifying it.

hidden

Remove hidden lines from mesh plot

Syntax

```
hidden on
hidden off
hidden
```

Description

Hidden line removal draws only those lines that are not obscured by other objects in a 3-D view. The `hidden` function only applies to surface plot objects that have a uniform `FaceColor`.

`hidden on` turns on hidden line removal for the current mesh plot so lines in the back of a mesh are hidden by those in front. This is the default behavior.

`hidden off` turns off hidden line removal for the current mesh plot.

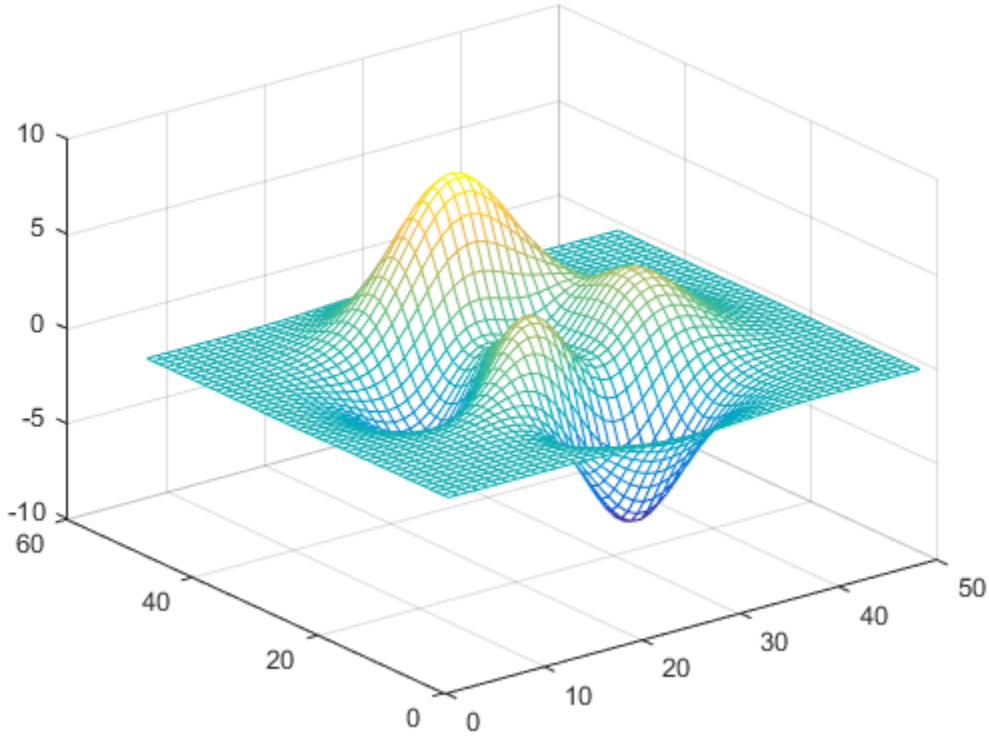
`hidden` toggles the hidden line removal state.

Examples

Show Obscured Lines

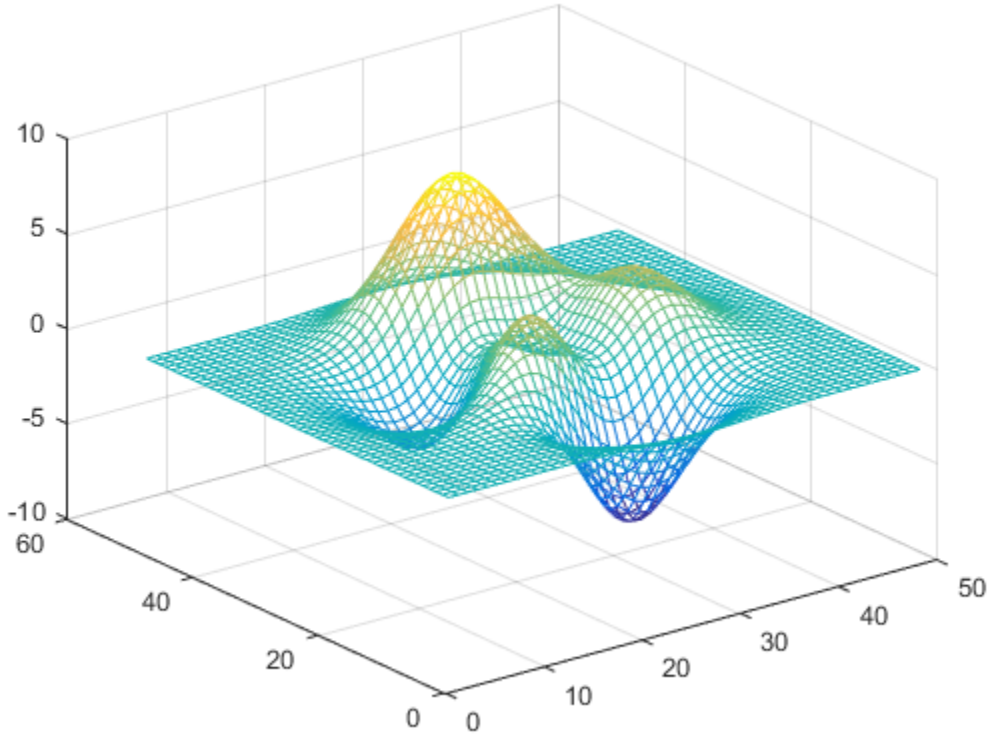
Create a mesh plot of the `peaks` function.

```
figure
mesh(peaks)
```



By default, MATLAB® hides obscured lines from the view. Show the obscured parts of the mesh by setting the hidden line removal to `off`.

```
hidden off
```



More About

Algorithms

When a surface graphics object has a uniform `FaceColor` matching the `Color` property of the axes, `hidden off` sets the `FaceColor` of the surface object to `'none'`.

`hidden on` sets the `FaceColor` property of such surface objects to match the axes `Color` property (or to match that of the figure, if axes `Color` is `'none'`).

Introduced before R2006a

hilb

Hilbert matrix

Syntax

```
H = hilb(n)
```

Description

`H = hilb(n)` returns the Hilbert matrix of order `n`.

Definitions

The Hilbert matrix is a notable example of a poorly conditioned matrix [1]. The elements of the Hilbert matrices are $H(i,j) = 1/(i + j - 1)$.

Examples

Even the fourth-order Hilbert matrix shows signs of poor conditioning.

```
cond(hilb(4)) =
    1.5514e+04
```

Introduced before R2006a

hist

Histogram plot (not recommended; use `histogram`)

Compatibility

`hist` is not recommended for numeric histograms. Use `histogram` instead. Use `hist` to plot categorical histograms.

For more information, including suggestions on updating code, see "Replace Discouraged Instances of hist and histc".

Syntax

```
hist(x)
hist(x,nbins)
hist(x,xbins)

hist(ax, ___ )

counts = hist( ___ )
[counts,centers] = hist( ___ )
```

Description

`hist(x)` creates a histogram bar chart of the elements in vector `x`. The elements in `x` are sorted into 10 equally spaced bins along the *x*-axis between the minimum and maximum values of `x`. `hist` displays bins as rectangles, such that the height of each rectangle indicates the number of elements in the bin.

If the input is a multi-column array, `hist` creates histograms for each column of `x` and overlays them onto a single plot.

If the input is of data type `categorical`, each bin is a category of `x`.

`hist(x,nbins)` sorts x into the number of bins specified by the scalar nbins.

`hist(x,xbins)` sorts `x` into bins with intervals or categories determined by the vector `xbins`.

- If `xbins` is a vector of evenly spaced values, then `hist` uses the values as the bin centers.
- If `xbins` is a vector of unevenly spaced values, then `hist` uses the midpoints between consecutive values as the bin edges.
- If `x` is of data type `categorical`, then `xbins` must be a categorical vector or cell array of strings that specifies categories. `hist` plots bars only for those categories.

The length of the vector `xbins` is equal to the number of bins.

`hist(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

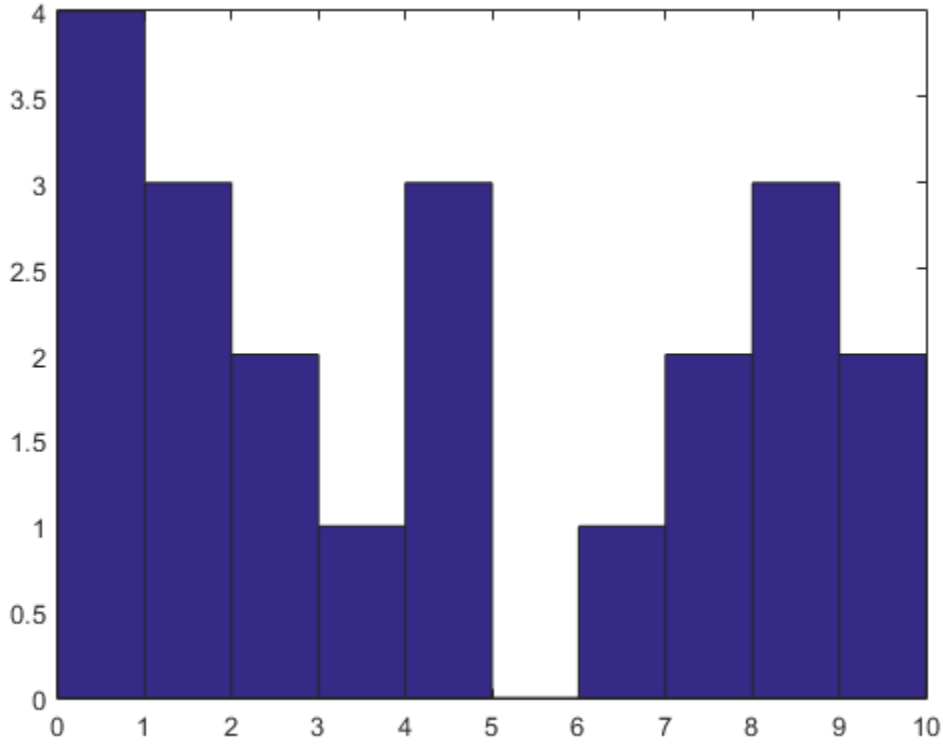
`counts = hist( ___ )` returns a row vector, counts, containing the number of elements in each bin.

`[counts,centers] = hist( ___ )` returns an additional row vector, centers, indicating the location of each bin center on the *x*-axis.

Examples

Histogram of Vector

```
x = [0 2 9 2 5 8 7 3 1 9 4 3 5 8 10 0 1 2 9 5 10];
hist(x)
```

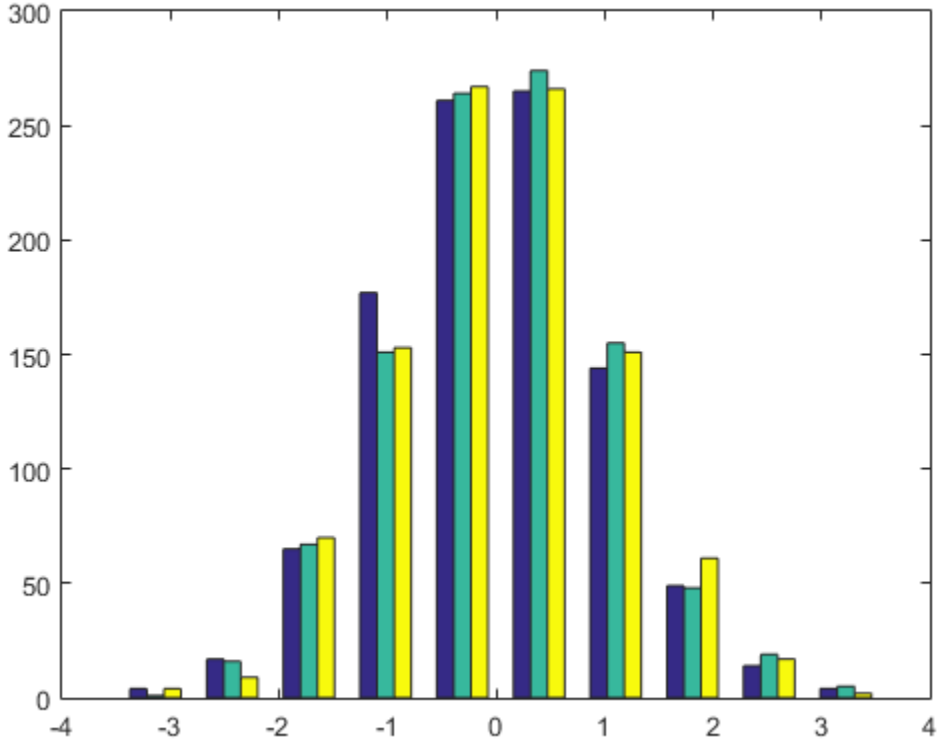


`hist` sorts the values in `x` among 10 equally spaced bins between the minimum and maximum values in the vector, which are 0 and 10 in this example.

Histogram of Multiple Columns

Generate three columns of 1,000 random numbers and plot the three column overlaid histogram.

```
x = randn(1000,3);
hist(x)
```

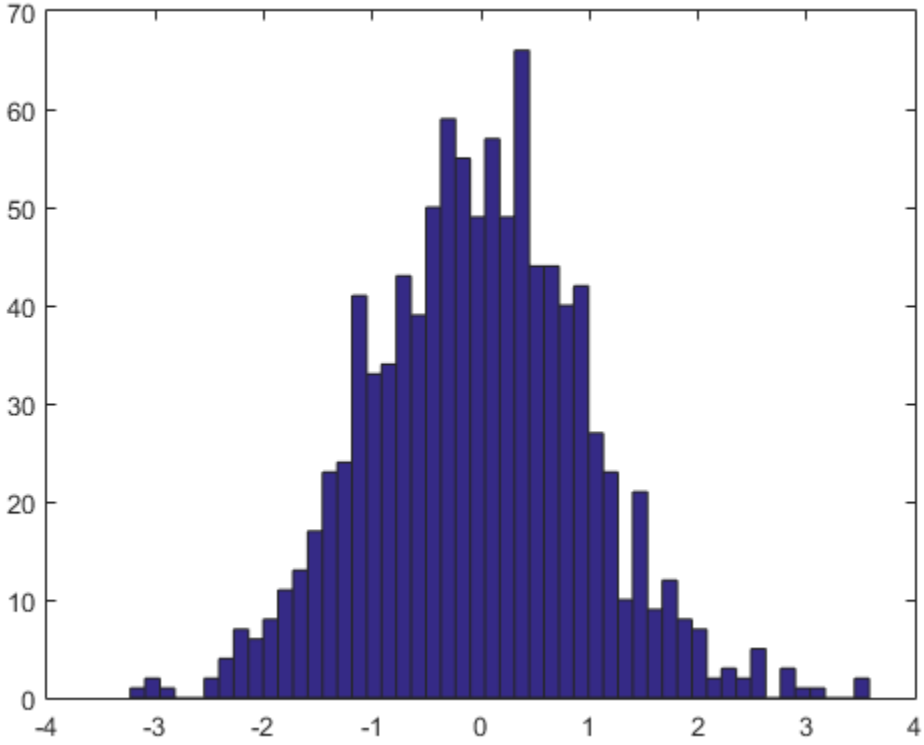


The values in `x` are sorted among 10 equally spaced bins between the minimum and maximum values. `hist` sorts and bins the columns of `x` separately and plots each column with a different color.

Specify Number of Histogram Bins

Plot a histogram of 1,000 random numbers sorted into 50 equally spaced bins.

```
x = randn(1000,1);
nbins = 50;
hist(x,nbins)
```



Specify Histogram Bin Intervals

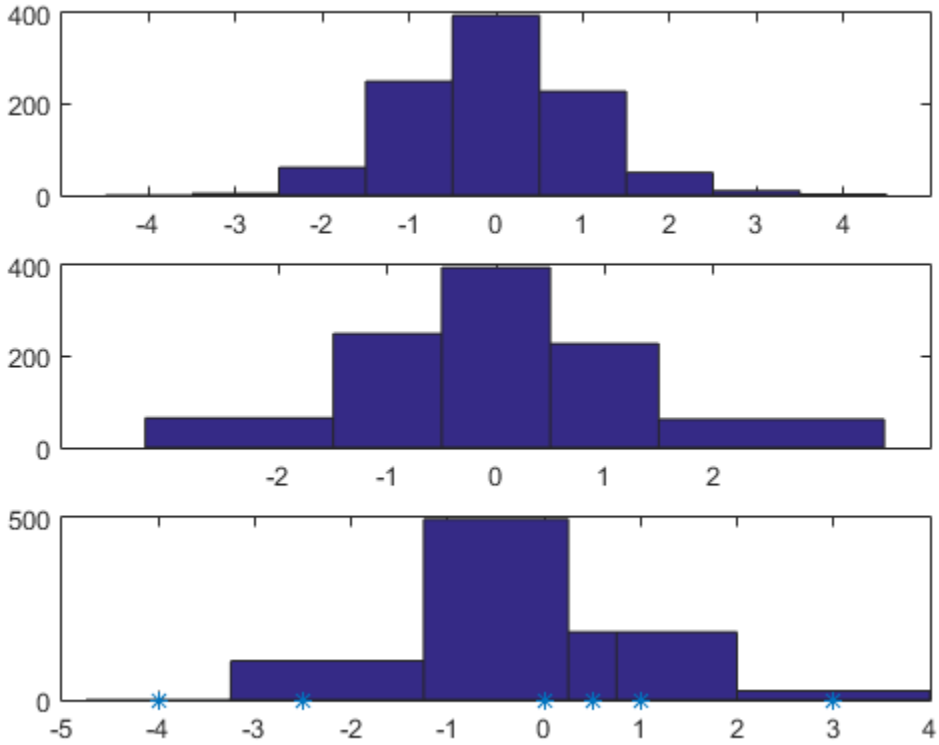
Plot three histograms of the same data using different bin intervals:

- In the upper subplot, specify the bin centers using a vector of evenly spaced values that span the values in `x`.
- In the middle subplot, specify the bin centers using a vector of evenly spaced values that do not span the values in `x`. The first and last bins extend to cover the minimum and maximum values in `x`.
- In the lower subplot, specify the bin intervals using a vector of unevenly spaced values. The `hist` function uses the midpoints between consecutive values as the bin edges and indicates the specified values by markers along the *x*-axis.

```
x = randn(1000,1);
subplot(3,1,1)
xbins1 = -4:4;
hist(x,xbins1)

subplot(3,1,2)
xbins2 = -2:2;
hist(x,xbins2)

subplot(3,1,3)
xbins3 = [-4 -2.5 0 0.5 1 3];
hist(x,xbins3)
```

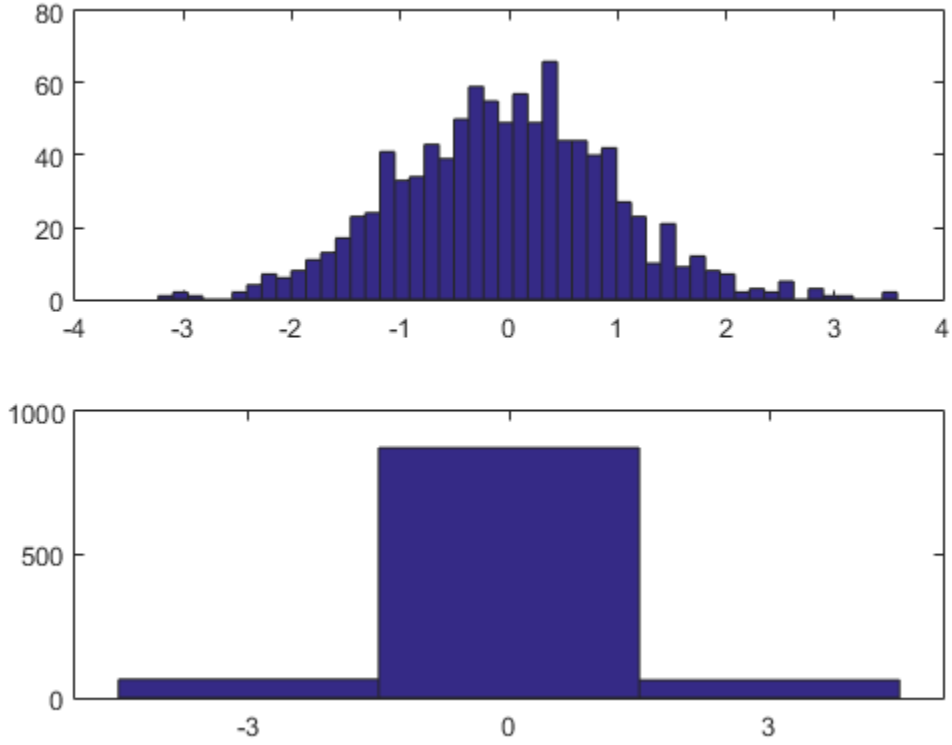


Specify Histogram Axes

Create a figure with two subplots. In the upper subplot, plot a histogram of 1,000 random numbers sorted into 50 equally spaced bins. In the lower subplot, plot a histogram of the same data and use bins with centers at -3, 0, and 3.

```
x = randn(1000,1);
ax1 = subplot(2,1,1);
hist(ax1,x,50)

ax2 = subplot(2,1,2);
xbins = [-3 0 3];
hist(ax2,x,xbins)
```



Use hist to Calculate Only

Generate 1,000 random numbers. Count how many numbers are in each of 10 equally spaced bins. Return the bin counts and bin centers.

```
x = randn(1000,1);
[counts,centers] = hist(x)
```

```
counts =

     4    27    88   190   270   243   123    38    13     4
```

```
centers =

  Columns 1 through 7

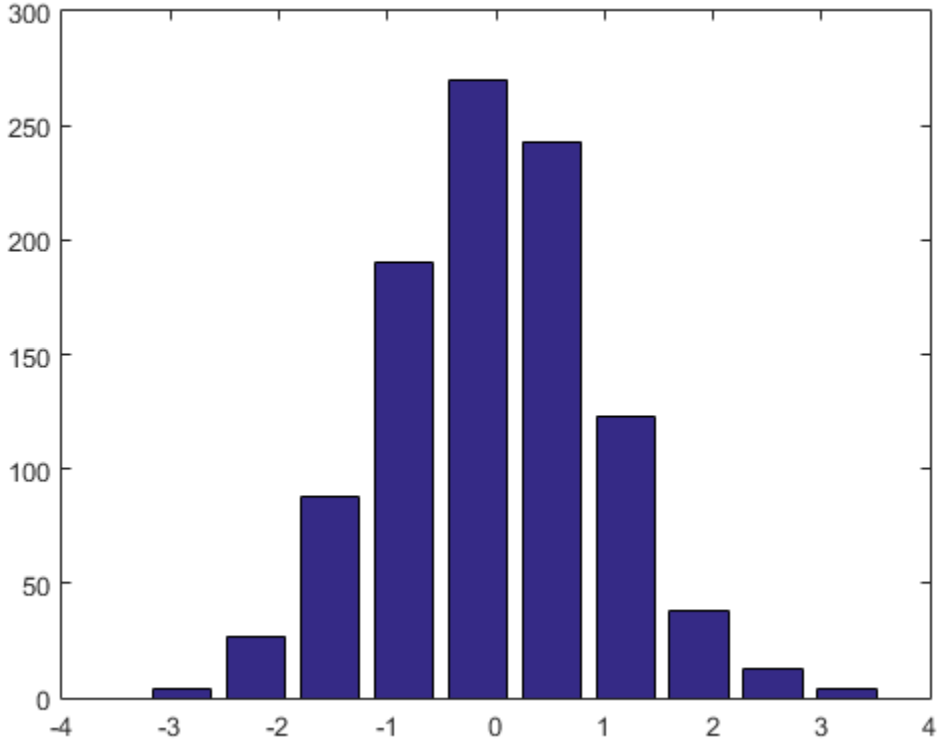
   -2.8915   -2.2105   -1.5294   -0.8484   -0.1673    0.5137    1.1947

  Columns 8 through 10

    1.8758    2.5568    3.2379
```

Use `bar` to plot the histogram.

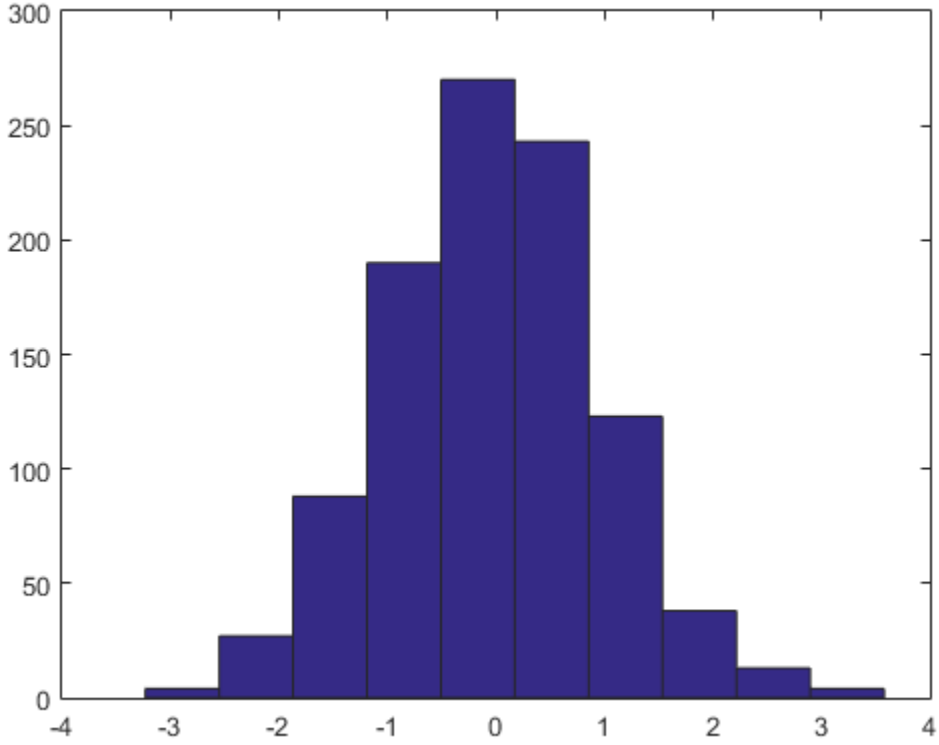
```
bar(centers,counts)
```



Specify Histogram Colors

Generate 1,000 random numbers and create a histogram.

```
data = randn(1000,1);
hist(data)
```

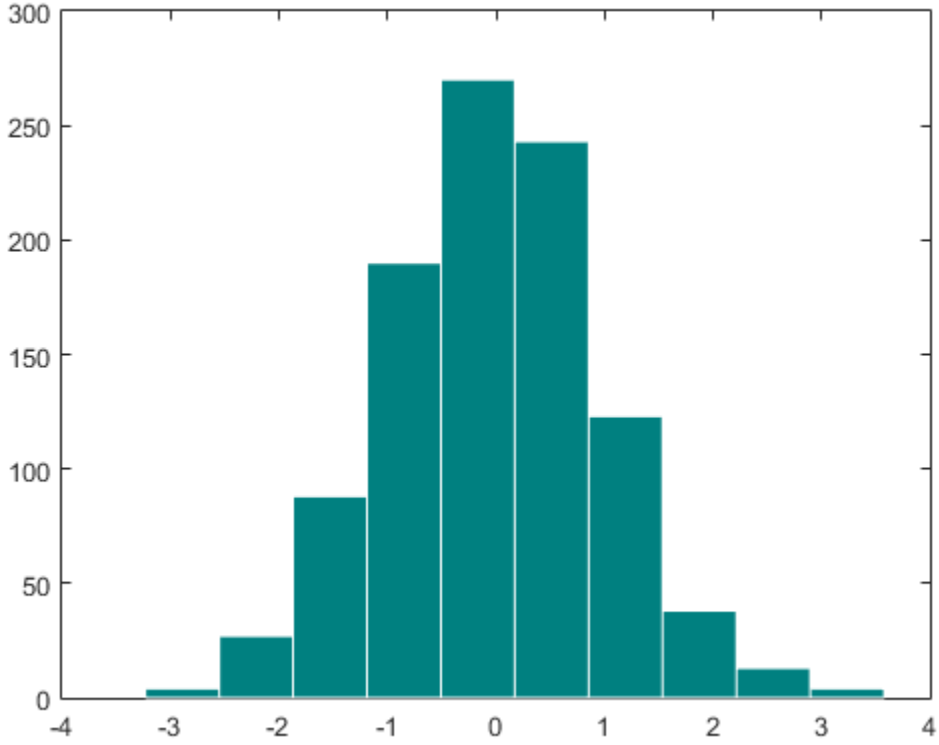


Get the handle to the patch object that creates the histogram plot.

```
h = findobj(gca,'Type','patch');
```

Set the face color of the bars plotted to an RGB triplet value of `[0 0.5 0.5]`. Set the edge color to white.

```
h.FaceColor = [0 0.5 0.5];
h.EdgeColor = 'w';
```



Input Arguments

x — Input array

vector or matrix

Input vector or matrix.

- If x is a vector, then `hist` creates one histogram.
- If x is a matrix, then `hist` creates a separate histogram for each column and plots the histograms using different colors.

If the input array contains `NaN`s or undefined categorical values, `hist` does not include these values in the bin counts.

If the input array contains the infinite values `-Inf` or `Inf`, then `hist` sorts `-Inf` into the first bin and `Inf` into the last bin. If you do not specify the bin intervals, then `hist` calculates the bin intervals using only the finite values in the input array.

Data Types: `single|double|logical|categorical`

`nbins` — Number of bins

10 (default) | scalar

Number of bins. Input `x` must be numeric, not categorical.

Data Types: `single|double|int8|int16|int32|int64|uint8|uint16|uint32|uint64`

`xbins` — Bin locations or categories

vector

Bin locations or categories, specified as a vector.

If x is numeric or logical, then xbins must be of type `single` or `double`.

- If the elements in xbins are equally spaced, then these elements are the bin centers.
- If the elements in xbins are not equally spaced, then these elements are indicated by markers along the *x*-axis, but are not the actual bin centers. Instead, `hist` calculates the bin edges as the midpoints between consecutive elements in vector `xbins`. To specify the bin edges directly, use `histc`.
- xbins must contain only finite values. The first and last bins extend to cover the minimum and maximum values in x.

If x is categorical, then xbins must be a categorical vector or cell array of strings that specifies categories. `hist` plots bars only for those categories specified by xbins.

`ax` — Axes object

axes object

Axes object. Use `ax` to plot the histogram in a specific axes instead of the current axes (`gca`).

Output Arguments

`counts` — Counts of the number of elements in each bin

row vector

Counts of the number of elements in each bin, returned as a row vector.

`centers` — Bin centers or categories

vector

Bin centers or categories, returned as a vector. If used with the syntax `[counts,centers] = hist(x,xbins)`, then the `centers` output has the same elements as the `xbins` input.

- If `x` is numeric or logical, then `centers` is a numeric row vector.
- If `x` is categorical, then `centers` is a cell array of strings.

See Also

`bar` | `histc` | `histcounts` | `histogram` | `mode` | `patch` | `rose` | `stairs`

Introduced before R2006a

histc

Histogram bin counts (not recommended; use `histcounts`)

Compatibility

`histc` is not recommended. Use `histcounts` instead.

For more information, including suggestions on updating code, see "Replace Discouraged Instances of hist and histc".

Syntax

```
bincounts = histc(x,binranges)
bincounts = histc(x,binranges,dim)
[bincounts,ind]= histc( ___ )
```

Description

`bincounts = histc(x,binranges)` counts the number of values in `x` that are within each specified bin range. The input, `binranges`, determines the endpoints for each bin. The output, `bincounts`, contains the number of elements from `x` in each bin.

- If `x` is a vector, then `histc` returns `bincounts` as a vector of histogram bin counts.
- If `x` is a matrix, then `histc` operates along each column of `x` and returns `bincounts` as a matrix of histogram bin counts for each column.

To plot the histogram, use `bar(binranges,bincounts,'histc')`.

`bincounts = histc(x,binranges,dim)` operates along the dimension `dim`.

`[bincounts,ind]= histc( ___ )` returns `ind`, an array the same size as `x` indicating the bin number that each entry in `x` sorts into. Use this syntax with any of the previous input argument combinations.

Examples

Create Histogram Plot

Initialize the random number generator to make the output of `randn` repeatable.

```
rng(0,'twister')
```

Define `x` as 100 normally distributed random numbers. Define bin ranges between -4 and 4. Determine the number of values in `x` that are within each specified bin range. Return the number of elements in each bin in `bincounts`.

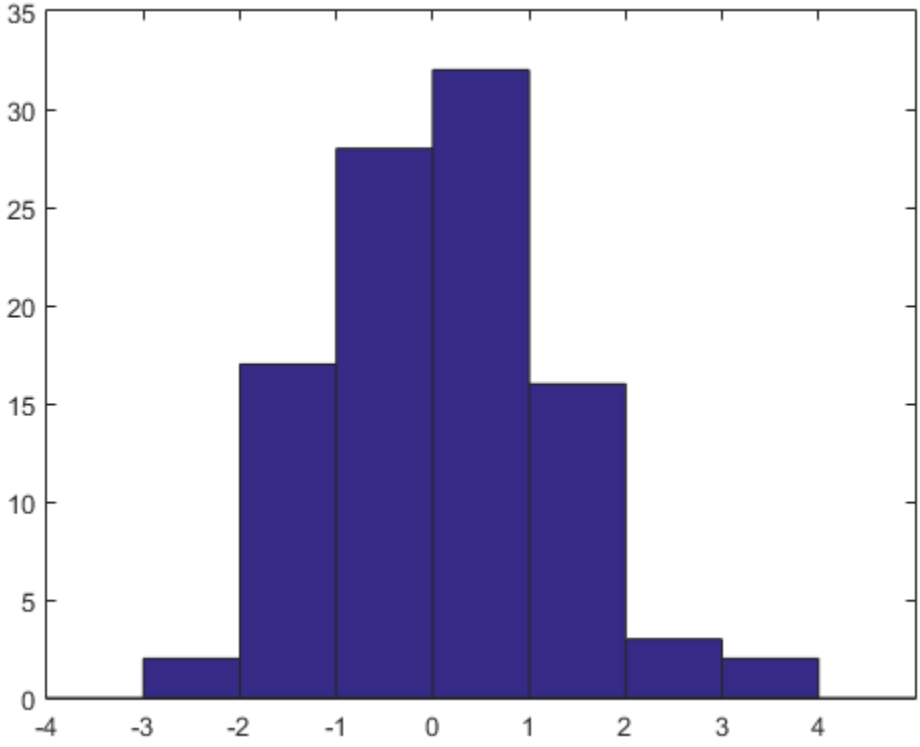
```
x = randn(100,1);
binranges = -4:4;
[bincounts] = histc(x,binranges)
```

```
bincounts =

     0
     2
    17
    28
    32
    16
     3
     2
     0
```

To plot the histogram, use the `bar` function.

```
figure
bar(binranges,bincounts,'histc')
```



Return Bin Numbers for Histogram

Defined `ages` as a vector of ages. Sort `ages` into bins with varying ranges between 0 and 75.

```
ages = [3,12,24,15,5,74,23,54,31,23,64,75];
binranges = [0,10,25,50,75];

[bincounts,ind] = histc(ages,binranges)
```

```
bincounts =

     2     5     1     3     1
```

```
ind =

     1     2     2     2     1     4     2     4     3     2     4     5
```

`bincounts` contains the number of values in each bin. `ind` indicates the bin numbers.

Input Arguments

`x` — Values to be sorted

vector | matrix

Values to be sorted, specified as a vector or a matrix. The bin counts do not include values in `x` that are `NaN` or that lie outside the specified bin ranges. If `x` contains complex values, then `histc` ignores the imaginary parts and uses only the real parts.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`binranges` — Bin ranges

vector | matrix

Bin ranges, specified as a vector of monotonically nondecreasing values or a matrix of monotonically nondecreasing values running down each successive column. The values in `binranges` determine the left and right endpoints for each bin. If `binranges` contains complex values, then `histc` ignores the imaginary parts and uses only the real parts.

If `binranges` is a matrix, then `histc` determines the bin ranges by using values running down successive columns. Each bin includes the left endpoint, but does not include the right endpoint. The last bin consists of the scalar value equal to last value in `binranges`.

For example, if `binranges` equals the vector `[0,5,10,13]`, then `histc` creates four bins. The first bin includes values greater than or equal to 0 and strictly less than 5. The second bin includes values greater than or equal to 5 and less than 10, and so on. The last bin contains the scalar value 13.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`dim` — Dimension along which to operate

scalar

Dimension along which to operate, specified as a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Output Arguments

`bincounts` — Number of elements in each bin

vector | matrix

Number of elements in each bin, returned as a vector or a matrix that is the same size as `x`. The last entry in `bincounts` is the number of values in `x` that equal the last entry in `binranges`.

`ind` — Bin index numbers

vector | matrix

Bin index numbers, returned as a vector or a matrix that is the same size as `x`.

More About

Tips

- If values in `x` lie outside the specified bin ranges, then `histc` does not include these values in the bin counts. Start and end the `binranges` vector with `-inf` and `inf` to ensure that all values in `x` are included in the bin counts.

See Also

`bar` | `hist` | `histcounts` | `histogram` | `mode`

Introduced before R2006a

histogram

Histogram plot

Syntax

```
histogram(X)
histogram(X,nbins)
histogram(X,edges)
histogram( ___ ,Name,Value)
histogram(ax, ___ )
h = histogram( ___ )
```

Description

`histogram(X)` creates a histogram plot of `X`. The `histogram` function uses an automatic binning algorithm that returns bins with a uniform width, chosen to cover the range of elements in `X` and reveal the underlying shape of the distribution. The bins display as rectangles such that the height of each rectangle indicates the number of elements in the bin.

`histogram(X,nbins)` uses a number of bins specified by the scalar, `nbins`.

`histogram(X,edges)` sorts `X` into bins with the bin edges specified by the vector, `edges`. Each bin includes the left edge, but does not include the right edge, except for the last bin which includes both edges.

`histogram( ___ ,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments using any of the previous syntaxes. For example, you can specify `'BinWidth'` and a scalar to adjust the width of the bins, or `'Normalization'` with a valid string (`'count'`, `'probability'`, `'countdensity'`, `'pdf'`, `'cumcount'`, or `'cdf'`) to use a different type of normalization.

`histogram(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = histogram( ___ )` also returns a histogram object. Use this to inspect and adjust the properties of the histogram.

Examples

Histogram of Vector

Generate 10,000 random numbers and create a histogram. The `histogram` function automatically chooses an appropriate number of bins to cover the range of values in `x` and show the shape of the underlying distribution.

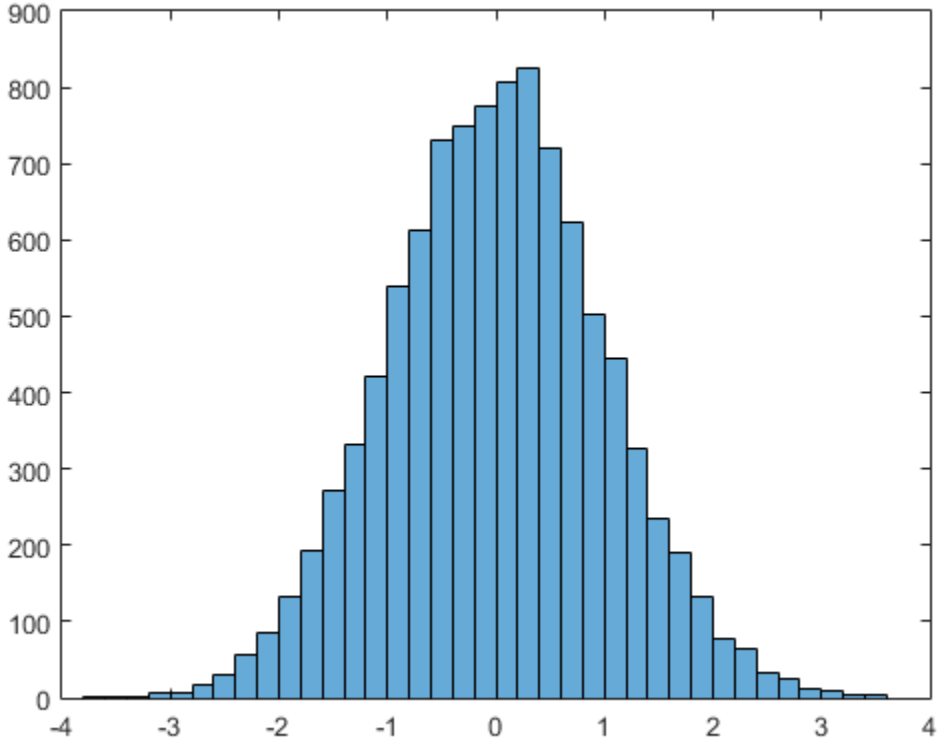
```
x = randn(10000,1);
h = histogram(x)
```

```
h =

  Histogram with properties:

            Data: [10000x1 double]
          Values: [1x37 double]
         NumBins: 37
        BinEdges: [1x38 double]
        BinWidth: 0.2000
       BinLimits: [-3.8000 3.6000]
   Normalization: 'count'
       FaceColor: 'auto'
       EdgeColor: [0 0 0]

  Use GET to show all properties
```



When you specify an output argument to the `histogram` function, it returns a histogram object. You can use this object to inspect the properties of the histogram, such as the number of bins or the width of the bins.

Find the number of histogram bins.

```
nbins = h.NumBins
```

```
nbins =

    37
```

Specify Number of Histogram Bins

Plot a histogram of 1,000 random numbers sorted into 25 equally spaced bins.

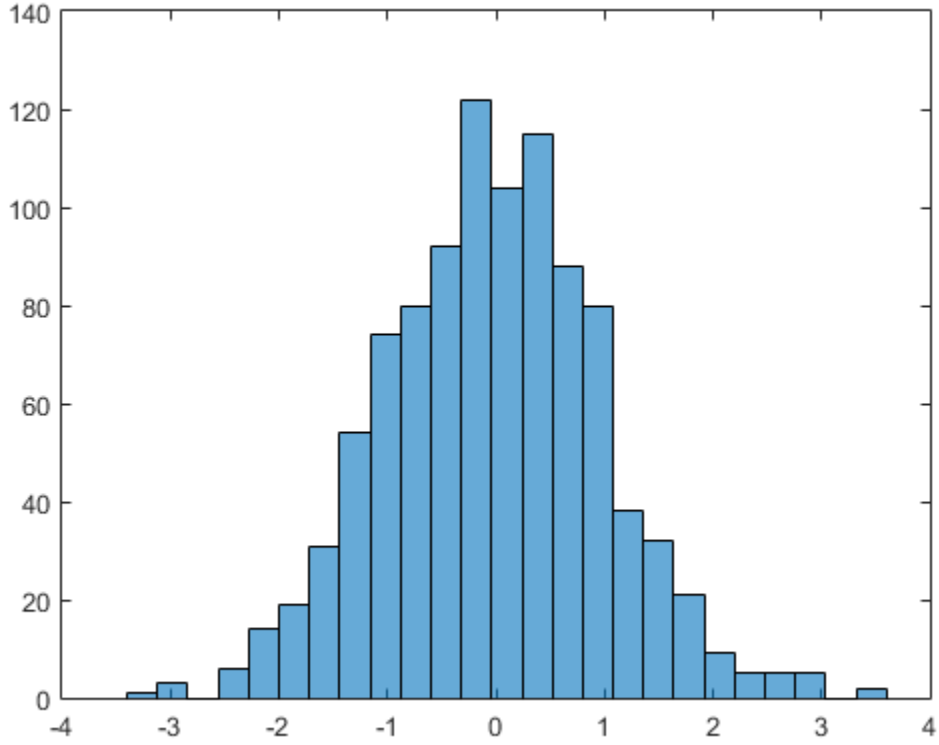
```
x = randn(1000,1);
nbins = 25;
h = histogram(x,nbins)
```

```
h =

  Histogram with properties:

            Data: [1000x1 double]
          Values: [1x25 double]
         NumBins: 25
        BinEdges: [1x26 double]
        BinWidth: 0.2800
       BinLimits: [-3.4000 3.6000]
    Normalization: 'count'
        FaceColor: 'auto'
        EdgeColor: [0 0 0]

  Use GET to show all properties
```



Find the bin counts.

```
counts = h.Values
```

```
counts =

  Columns 1 through 13

     1     3     0     6    14    19    31    54    74    80    92   122   104

  Columns 14 through 25

   115    88    80    38    32    21     9     5     5     5     0     2
```

Change Number of Histogram Bins

Generate 1,000 random numbers and create a histogram.

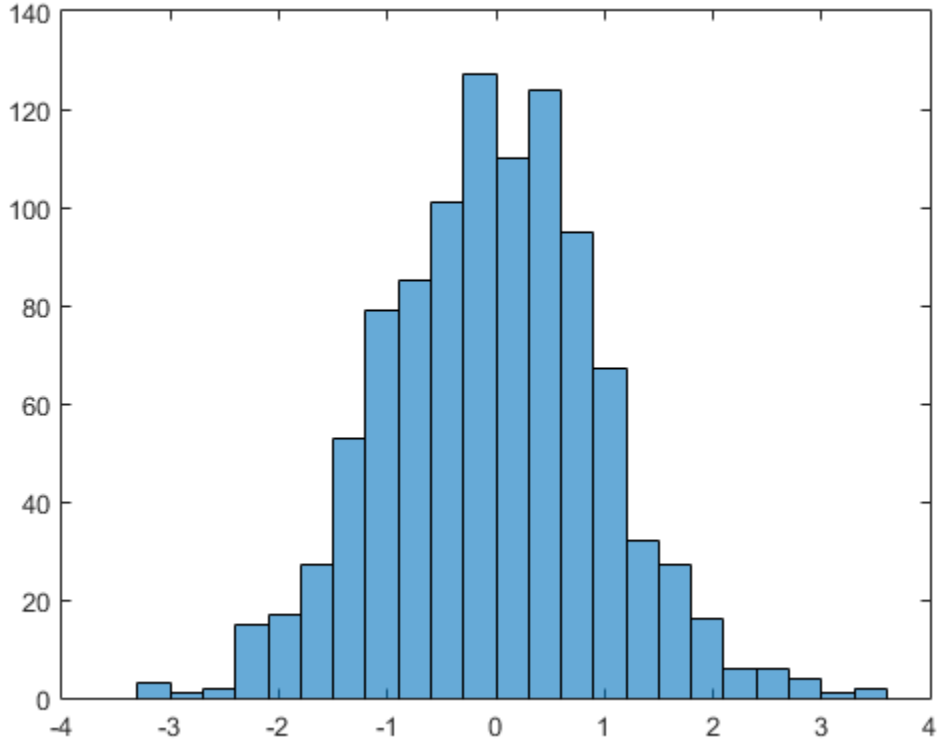
```
X = randn(1000,1);
h = histogram(X)
```

```
h =

  Histogram with properties:

            Data: [1000x1 double]
          Values: [1x23 double]
         NumBins: 23
        BinEdges: [1x24 double]
        BinWidth: 0.3000
       BinLimits: [-3.3000 3.6000]
    Normalization: 'count'
        FaceColor: 'auto'
        EdgeColor: [0 0 0]

  Use GET to show all properties
```

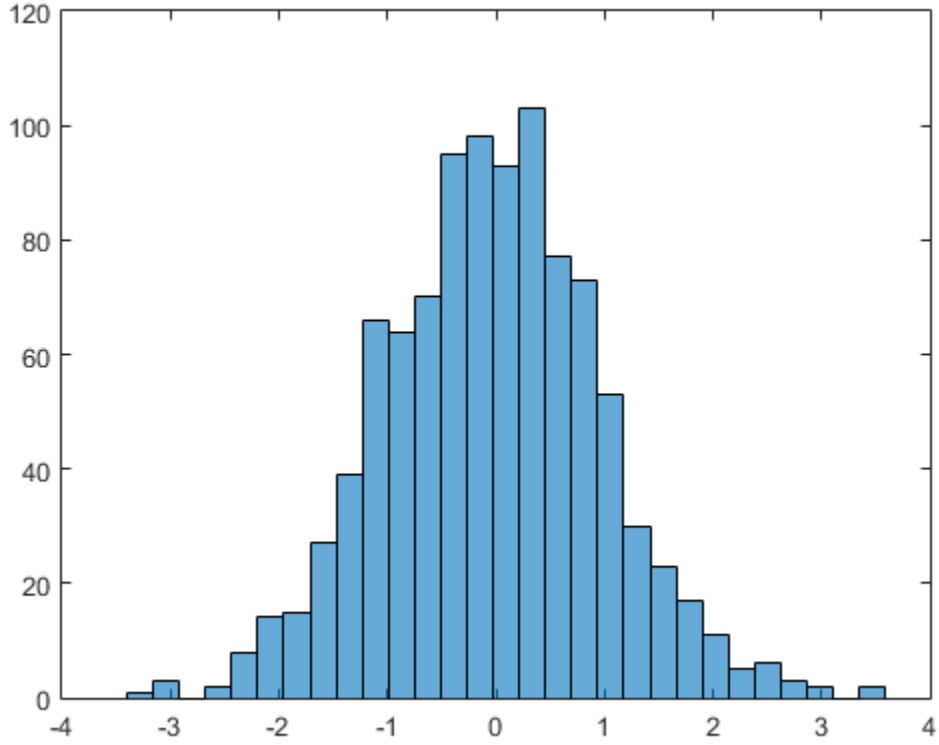


Use the `morebins` function to coarsely adjust the number of bins.

```
Nbins = morebins(h);
Nbins = morebins(h)
```

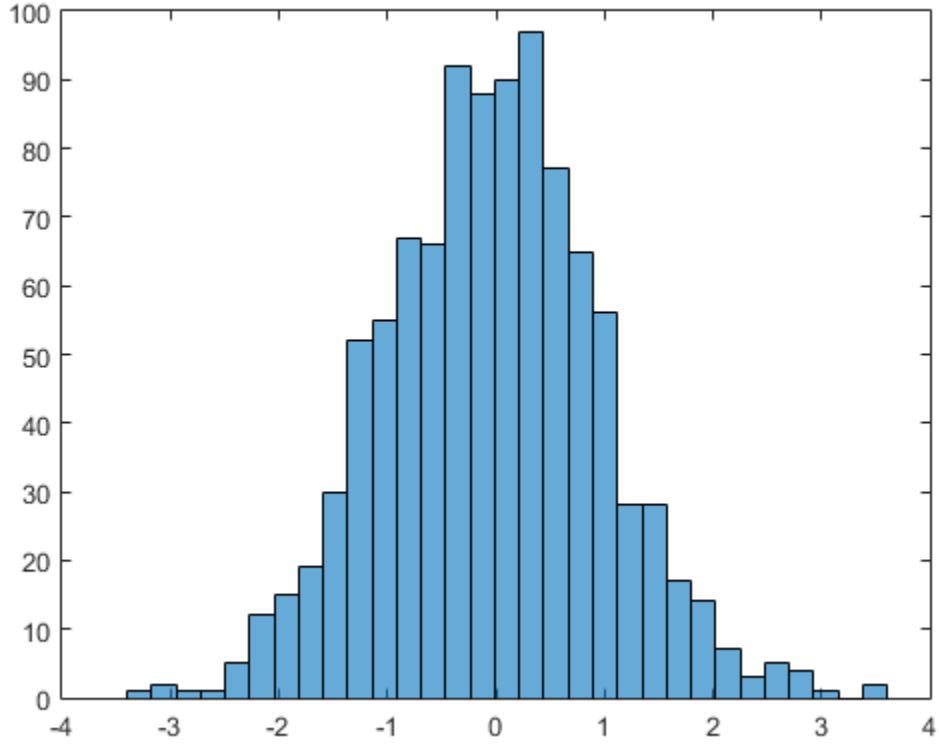
```
Nbins =

    29
```



Adjust the bins at a fine grain level by explicitly setting the number of bins.

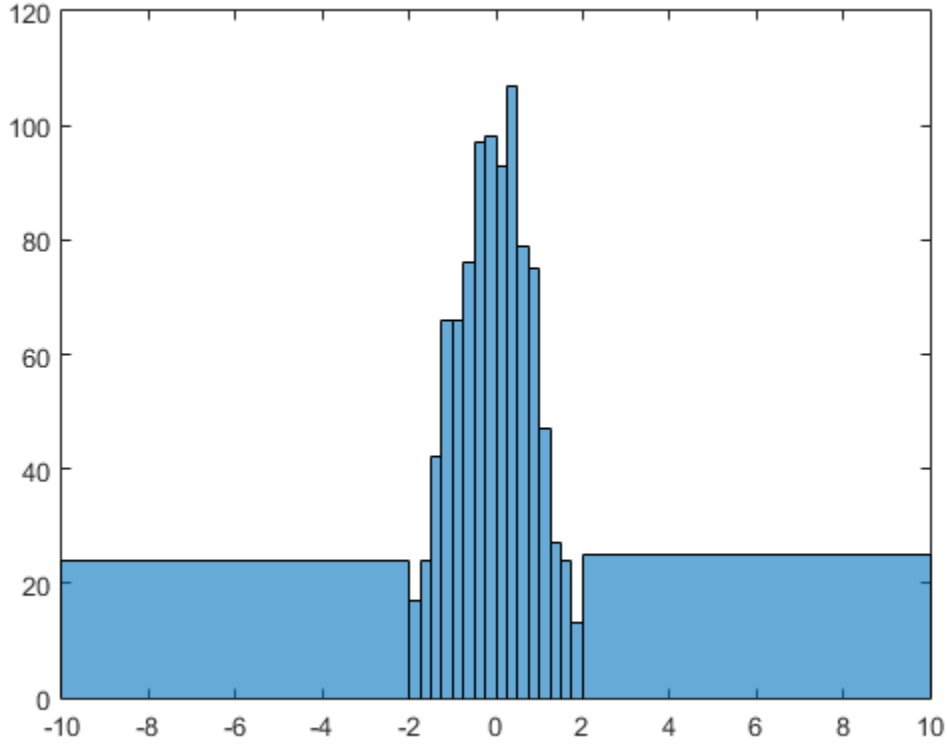
```
h.NumBins = 31;
```



Specify Bin Edges of Histogram

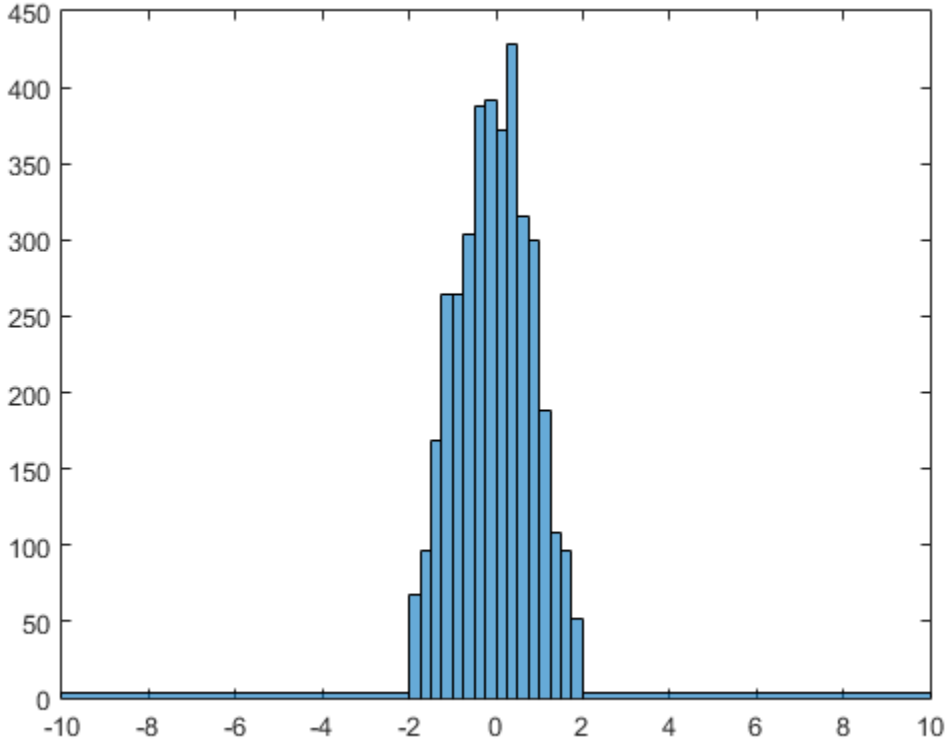
Generate 1,000 random numbers and create a histogram. Specify the bin edges as a vector with wide bins on the edges of the histogram to capture the outliers that do not satisfy $|x| < 2$. The first vector element is the left edge of the first bin, and the last vector element is the right edge of the last bin.

```
x = randn(1000,1);
edges = [-10 -2:0.25:2 10];
h = histogram(x,edges);
```



Specify the `Normalization` property as `'countdensity'` to flatten out the bins containing the outliers. Now, the *area* of each bin (rather than the height) represents the frequency of observations in that interval.

```
h.Normalization = 'countdensity';
```



Histogram with Specified Normalization

Generate 1,000 random numbers and create a histogram using the `'probability'` normalization.

```
x = randn(1000,1);
h = histogram(x,'Normalization','probability')
```

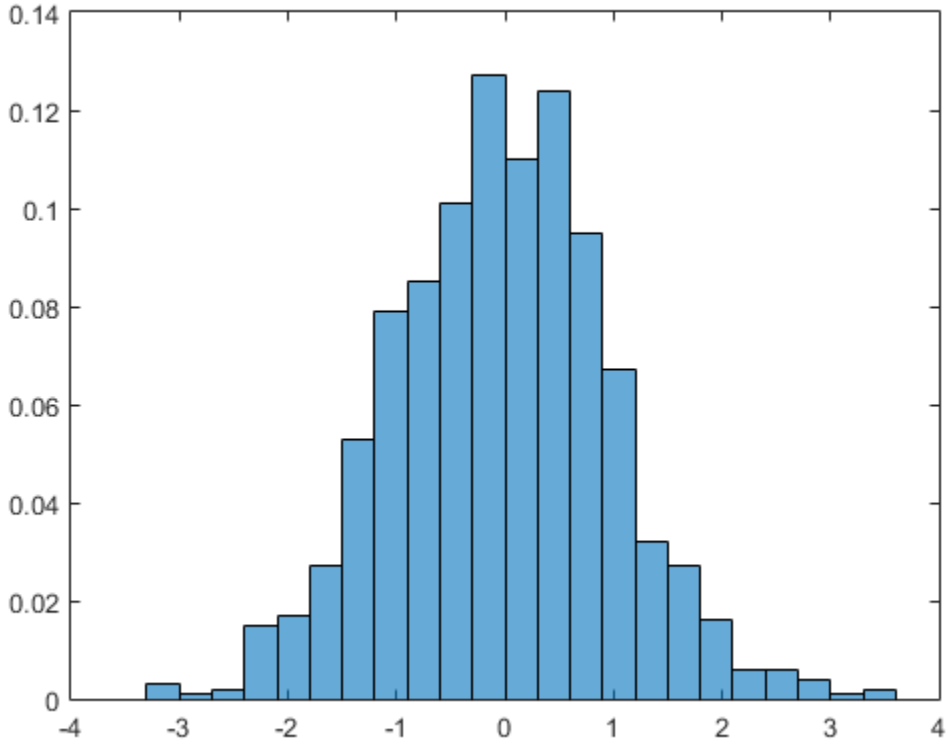
```
h =

  Histogram with properties:

            Data: [1000x1 double]
```

```
          Values: [1x23 double]
         NumBins: 23
       BinEdges: [1x24 double]
       BinWidth: 0.3000
      BinLimits: [-3.3000 3.6000]
  Normalization: 'probability'
      FaceColor: 'auto'
      EdgeColor: [0 0 0]

  Use GET to show all properties
```



Compute the sum of the bar heights. With this normalization, the height of each bar is equal to the probability of selecting an observation within that bin interval, and the height of all of the bars sums to 1.

```
S = sum(h.Values)
```

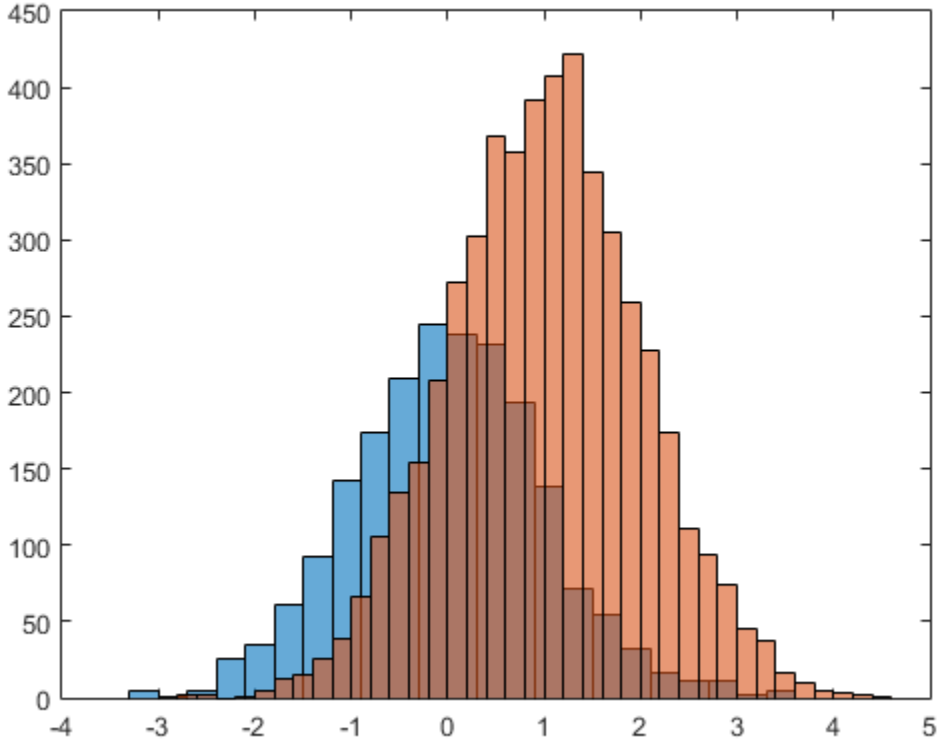
```
S =

     1
```

Plot Multiple Histograms

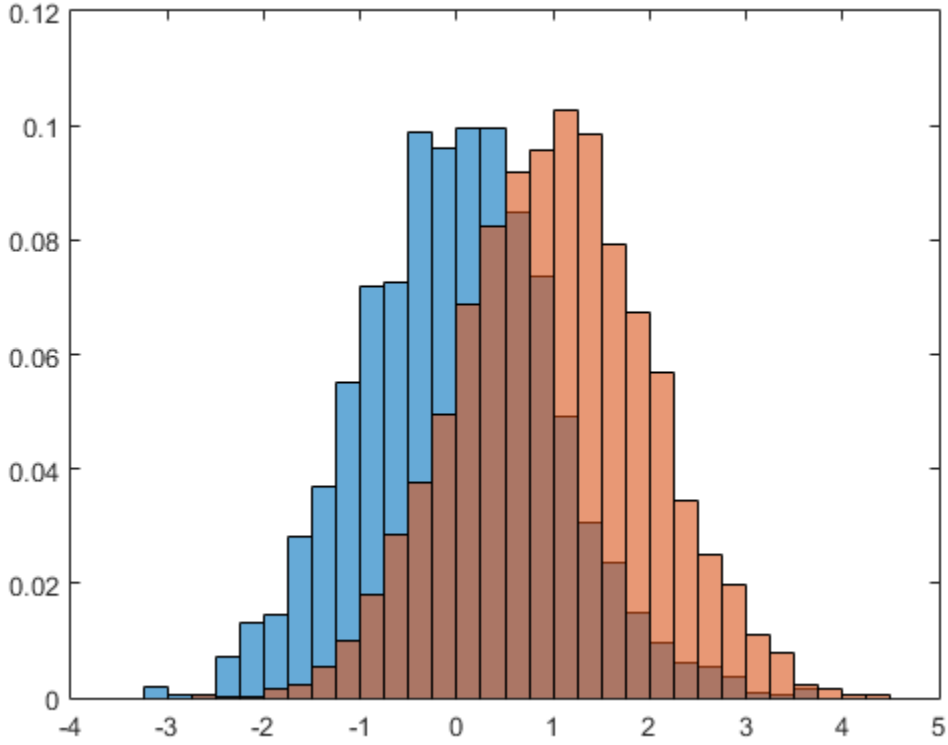
Generate two vectors of random numbers and plot a histogram for each vector in the same figure.

```
x = randn(2000,1);
y = 1 + randn(5000,1);
h1 = histogram(x);
hold on
h2 = histogram(y);
```



Since the sample size and bin width of the histograms are different, it is difficult to compare them. Normalize the histograms so that all of the bar heights add to 1, and use a uniform bin width.

```
h1.Normalization = 'probability';
h1.BinWidth = 0.25;
h2.Normalization = 'probability';
h2.BinWidth = 0.25;
```



Adjust Histogram Properties

Generate 1,000 random numbers and create a histogram. Return the histogram object to adjust the properties of the histogram without recreating the entire plot.

```
x = randn(1000,1);
h = histogram(x)
```

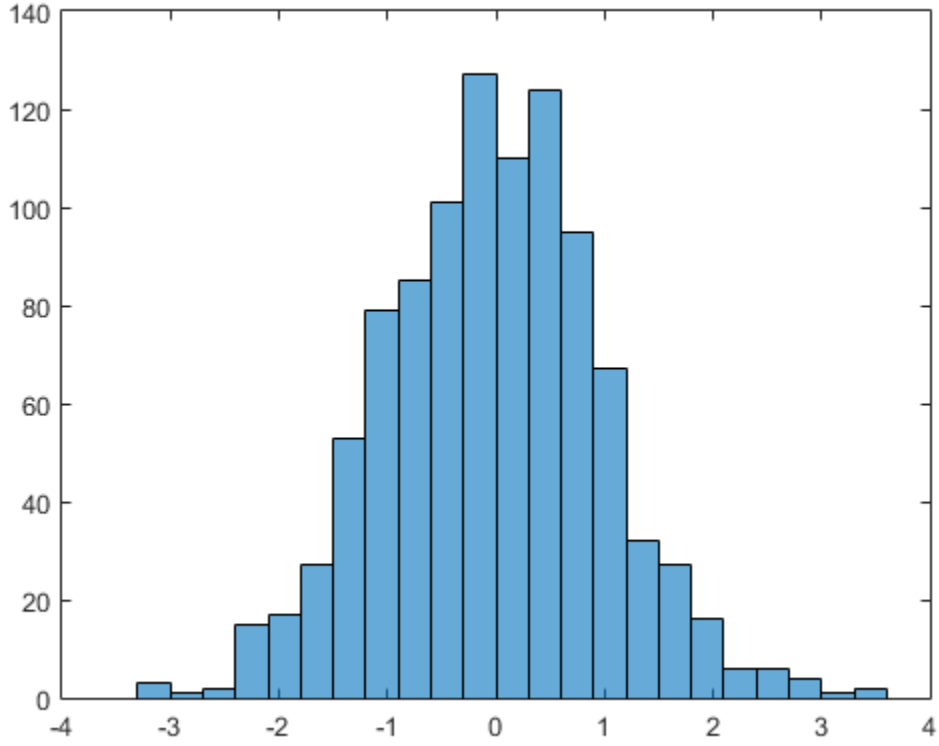
```
h =

  Histogram with properties:

            Data: [1000x1 double]
```

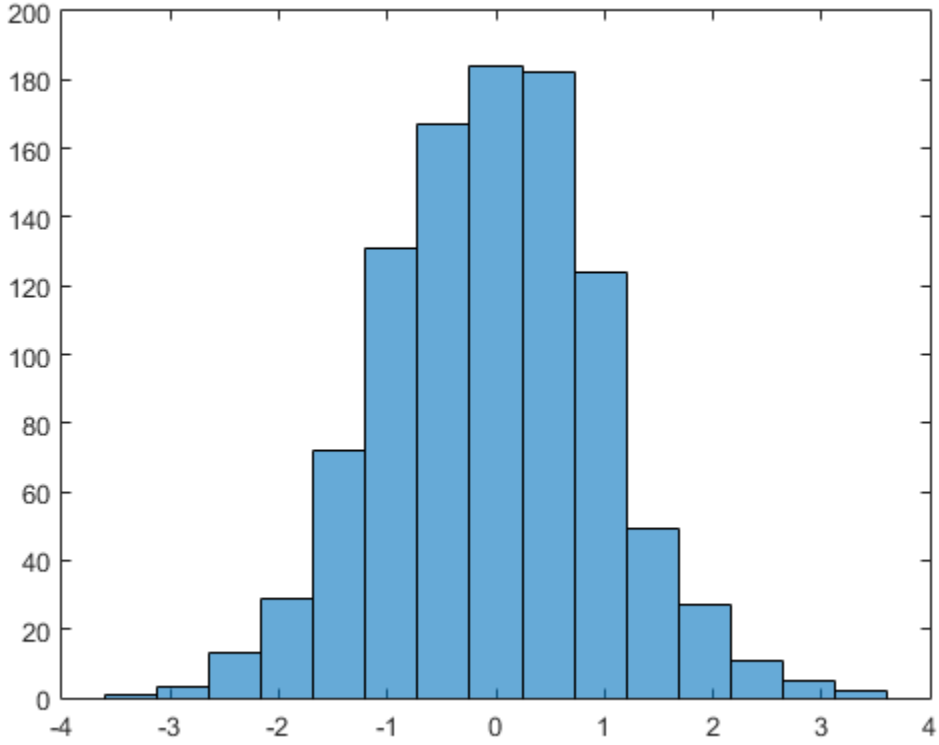
```
          Values: [1x23 double]
         NumBins: 23
        BinEdges: [1x24 double]
        BinWidth: 0.3000
       BinLimits: [-3.3000 3.6000]
   Normalization: 'count'
       FaceColor: 'auto'
       EdgeColor: [0 0 0]

  Use GET to show all properties
```



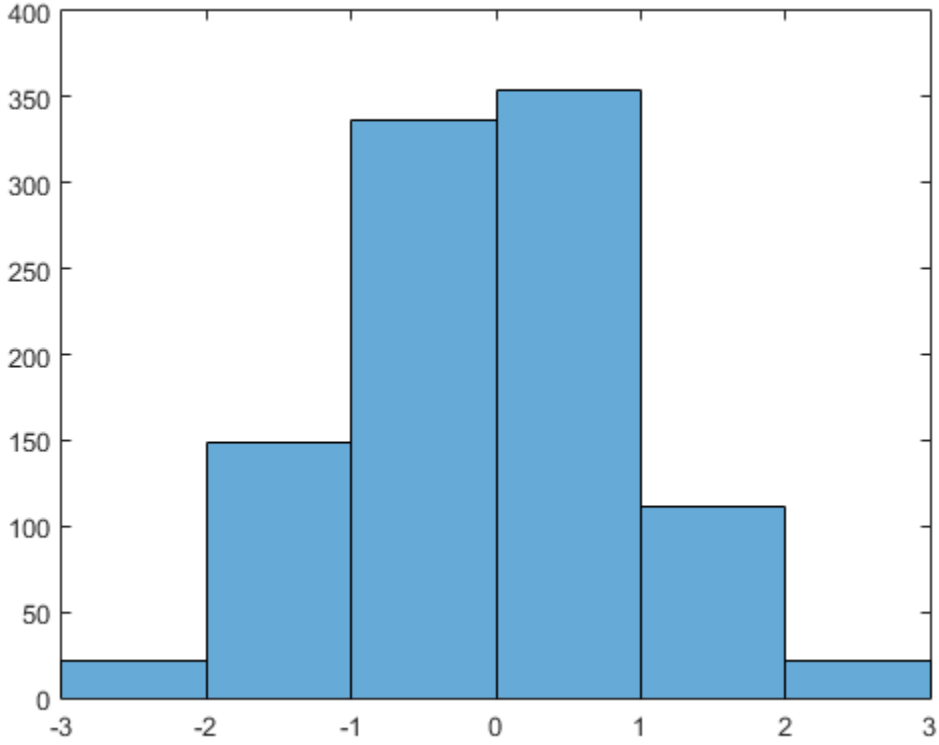
Specify exactly how many bins to use.

```
h.NumBins = 15;
```



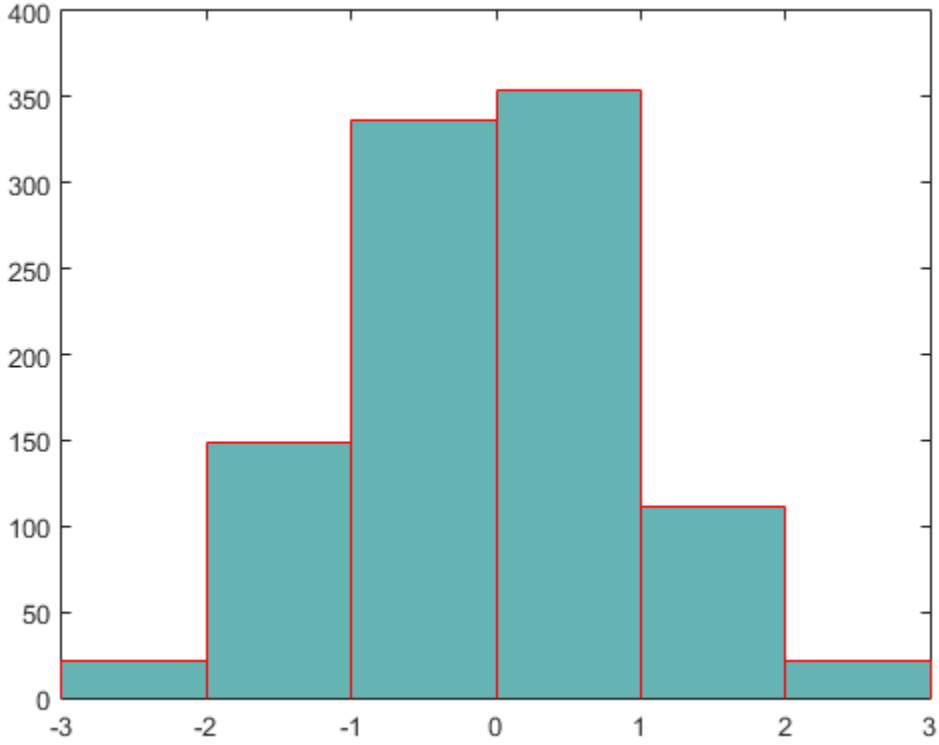
Specify the edges of the bins with a vector. The first value in the vector is the left edge of the first bin. The last value is the right edge of the last bin.

```
h.BinEdges = [-3:3];
```



Change the color of the histogram bars.

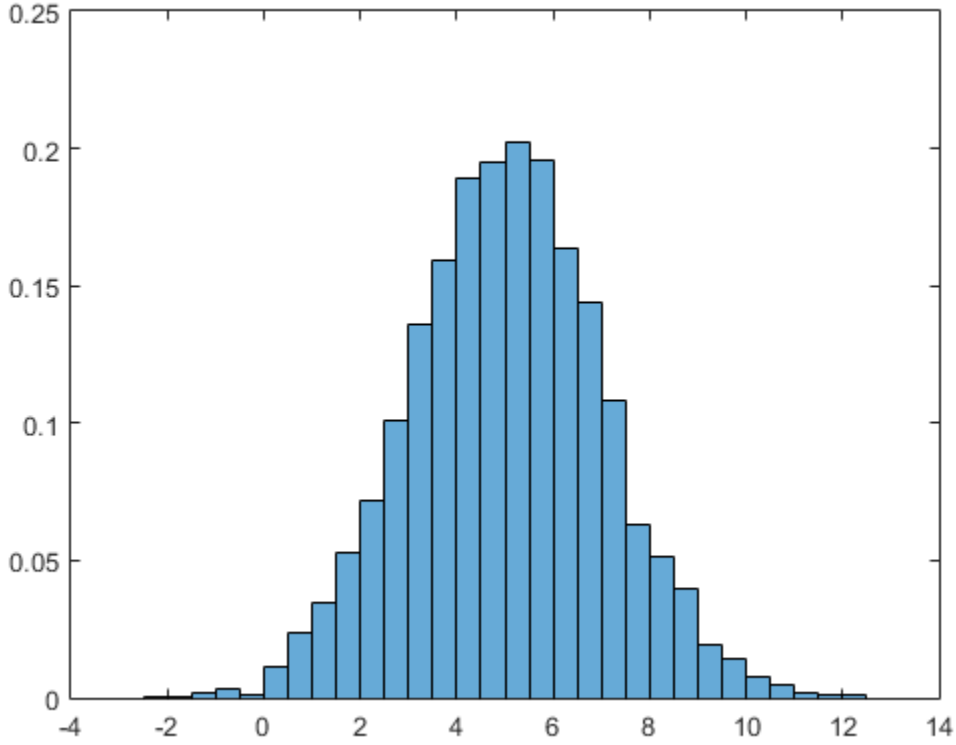
```
h.FaceColor = [0 0.5 0.5];
h.EdgeColor = 'r';
```



Determine Underlying Probability Distribution

Generate 5,000 normally distributed random numbers with a mean of 5 and a standard deviation of 2. Plot a histogram with `Normalization` set to `'pdf'` to produce an estimation of the probability density function.

```
x = 2*randn(5000,1) + 5;
histogram(x,'Normalization','pdf')
```



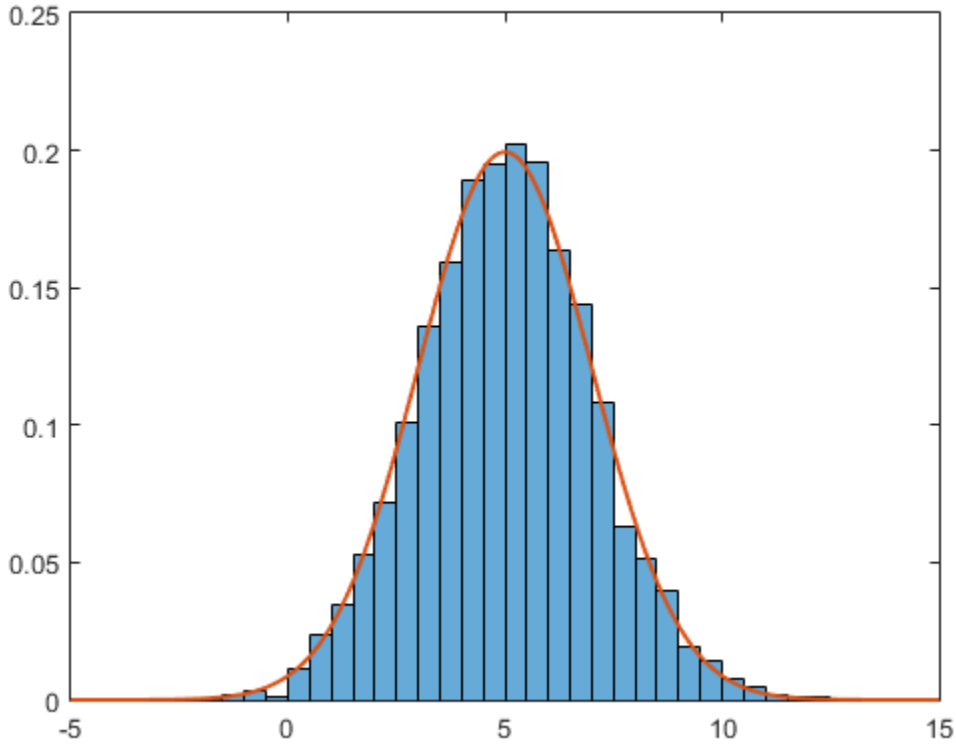
In this example, the underlying distribution for the normally distributed data is known. You can, however, use the `'pdf'` histogram plot to determine the underlying probability distribution of the data by comparing it against a known probability density function.

The probability density function for a normal distribution with mean μ, standard deviation σ, and variance σ^2 is

$$f(x,\mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left[-\frac{(x-\mu)^2}{2\sigma^2}\right].$$

Overlay a plot of the probability density function for a normal distribution with a mean of 5 and a standard deviation of 2.

```
hold on
y = -5:0.1:15;
mu = 5;
sigma = 2;
f = exp(-(y-mu).^2./(2*sigma^2))./(sigma*sqrt(2*pi));
plot(y,f,'LineWidth',1.5)
```



Input Arguments

X — Data to distribute among bins

vector | matrix | multidimensional array

Data to distribute among bins, specified as a vector, matrix, or multidimensional array. If `X` is not a vector, then `histogram` treats it as a single column vector, `X(:)`, and plots a single histogram.

`histogram` ignores all `NaN` values. Similarly, `histogram` ignores `Inf` and `-Inf` values, unless the bin edges explicitly specify `Inf` or `-Inf` as a bin edge.

Note: If `X` contains integers of type `int64` or `uint64` that are larger than `flintmax`, then it is recommended that you explicitly specify the histogram bin edges. `histogram` automatically bins the input data using double precision, which lacks integer precision for numbers greater than `flintmax`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`nbins` — Number of bins

positive integer

Number of bins, specified as a positive integer. If you do not specify `nbins`, then `histogram` automatically calculates how many bins to use based on the values in `X`.

Example: `histogram(X,15)` creates a histogram with 15 bins.

`edges` — Bin edges

vector

Bin edges, specified as a vector. `edges(1)` is the left edge of the first bin, and `edges(end)` is the right edge of the last bin.

The value `X(i)` is in the `k`th bin if `edges(k)` $\le$ `X(i)` < `edges(k+1)`. The last bin also includes the right bin edge, so that it contains `X(i)` if `edges(end-1)` $\le$ `X(i)` $\le$ `edges(end)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ax` — Axes object

axes object

Axes object. If you do not specify an axes, then the histogram function uses the current axes (`gca`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `histogram(X,'BinWidth',5)`

The histogram properties listed here are only a subset. For a complete list, see Histogram Properties.

`'BinLimits'` — Bin limits

two-element vector

Bin limits, specified as a two-element vector, `[bmin,bmax]`. This option plots a histogram using the values in the input array, `X`, that fall between `bmin` and `bmax` inclusive. That is, `X(X>=bmin & X<=bmax)`.

Example: `histogram(X,'BinLimits',[1,10])` plots a histogram using only the values in `X` that are between `1` and `10` inclusive.

`'BinLimitsMode'` — Selection mode for bin limits

`'auto'` (default) | `'manual'`

Selection mode for bin limits, specified as `'auto'` or `'manual'`. The default value is `'auto'`, so that the bin limits automatically adjust to the data.

If you explicitly specify either `BinLimits` or `BinEdges`, then `BinLimitsMode` is automatically set to `'manual'`. In that case, specify `BinLimitsMode` as `'auto'` to rescale the bin limits to the data.

`'BinMethod'` — Binning algorithm

`'auto'` (default) | `'scott'` | `'fd'` | `'integers'` | `'sturges'` | `'sqrt'` | `'manual'`

Binning algorithm, specified as one of the values in this table.

Value	Description
`'auto'`	The default `'auto'` algorithm chooses a bin width to cover the data range

Value	Description
	and reveal the shape of the underlying distribution.
`'scott'`	Scott's rule is optimal if the data is close to being normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin width of `3.49*std(X(:))*numel(X)^(-1/3)`.
`'fd'`	The Freedman-Diaconis rule is less sensitive to outliers in the data, and might be more suitable for data with heavy-tailed distributions. It uses a bin width of `2*IQR(X(:))*numel(X)^(-1/3)`, where `IQR` is the interquartile range of `X`.
`'integers'`	The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins (2^{16}). If the data range is greater than 65536, then the integer rule uses wider bins instead.
`'sturges'`	Sturges' rule is popular due to its simplicity. It chooses the number of bins to be `ceil(1 + log2(numel(X)))`.
`'sqrt'`	The Square Root rule is widely used in other software packages. It chooses the number of bins to be `ceil(sqrt(numel(X)))`.

If you set the `BinLimits`, `NumBins`, `BinEdges`, or `BinWidth` property, then the `BinMethod` property is set to `'manual'`.

Example: `histogram(X,'BinMethod','integers')` creates a histogram with the bins centered on integers.

`'BinWidth'` — Width of bins

scalar

Width of bins, specified as a scalar. When you specify `BinWidth`, then `histogram` can use a maximum of 65,536 bins (or 2^{16}). If instead the specified bin width requires more bins, then `histogram` uses a larger bin width corresponding to the maximum number of bins.

Example: `histogram(X,'BinWidth',5)` uses bins with a width of 5.

`'DisplayStyle'` — Histogram display style

`'bar'` (default) | `'stairs'`

Histogram display style, specified as either `'bar'` or `'stairs'`. Specify `'stairs'` to display a stairstep plot, which displays the outline of the histogram without filling the interior.

The default value of `'bar'` displays a histogram bar plot.

Example: `histogram(X,'DisplayStyle','stairs')` plots the outline of the histogram.

`'EdgeColor'` — Histogram edge color

`[0 0 0]` or black (default) | `'none'` | `'auto'` | RGB triplet or color string

Histogram edge color, specified as one of these values:

- `'none'` — Edges are not drawn.
- `'auto'` — Color of each edge is chosen automatically.
- RGB triplet or a color string — Edges use the specified color.

  An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `histogram(X,'EdgeColor','r')` creates a histogram plot with red bar edges.

'FaceAlpha' — Transparency of histogram bars

`0.6` (default) | scalar value between `0` and `1` inclusive

Transparency of histogram bars, specified as a scalar value between `0` and `1` inclusive. `histogram` uses the same transparency for all the bars of the histogram. A value of `1` means fully opaque and `0` means completely transparent (invisible).

Example: `histogram(X,'FaceAlpha',1)` creates a histogram plot with fully opaque bars.

'FaceColor' — Histogram bar color

`'auto'` (default) | `'none'` | RGB triplet or color string

Histogram bar color, specified as one of these values:

- `'none'` — Bars are not filled.
- `'auto'` — Histogram bar color is chosen automatically (default).
- RGB triplet or a color string — Bars are filled with the specified color.

  An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

If you specify `DisplayStyle` as `'stairs'`, then `histogram` does not use the `FaceColor` property.

Example: `histogram(X,'FaceColor','g')` creates a histogram plot with green bars.

`'Normalization'` — Type of normalization

`'count'` (default) | `'probability'` | `'countdensity'` | `'pdf'` | `'cumcount'` | `'cdf'`

Type of normalization, specified as one of the values in this table.

Value	Description
`'count'`	Default normalization scheme. The height of each bar is the number of observations in each bin. The sum of the bar heights is `numel(X)`.
`'probability'`	The height of each bar is the relative number of observations, (number of observations in bin / total number of observations). The sum of the bar heights is 1.
`'countdensity'`	The height of each bar is, (number of observations in bin / width of bin). The area (height * width) of each bar is the number of observations in the bin. The sum of the bar areas is `numel(X)`.
`'pdf'`	Probability density function estimate. The height of each bar is, (number of observations in the bin) / (total number of observations * width of bin). The area of each bar is the relative number of observations. The sum of the bar areas is 1.

Value	Description
`'cumcount'`	The height of each bar is the cumulative number of observations in each bin and all previous bins. The height of the last bar is `numel(X)`.
`'cdf'`	Cumulative density function estimate. The height of each bar is equal to the cumulative relative number of observations in the bin and all previous bins. The height of the last bar is `1`.

Example: `histogram(X,'Normalization','pdf')` plots an estimate of the probability density function for `X`.

`'Orientation'` — Orientation of bars
`'vertical'` (default) | `'horizontal'`

Orientation of bars, specified as `'vertical'` or `'horizontal'`.

Example: `histogram(X,'Orientation','horizontal')` creates a histogram plot with horizontal bars.

Output Arguments

h — Histogram
object

Histogram, returned as an object. For more information, see Using histogram Objects.

`fewerbins` | `histcounts` | `morebins`

Introduced in R2014b

Using histogram Objects

Histogram bar plot for numeric data

Histograms are a type of bar plot for numeric data that group the data into bins. After you create a histogram object, you can modify aspects of the histogram by changing its property values. This is particularly useful for quickly modifying the properties of the bins or changing the display.

Examples

Adjust Properties of Histogram Object

This example creates a histogram object, and then shows how to adjust the properties of the histogram to affect the output display.

Create a histogram for all of the prime numbers less than 10,000,000. Specify an output argument to return the histogram object, `h`.

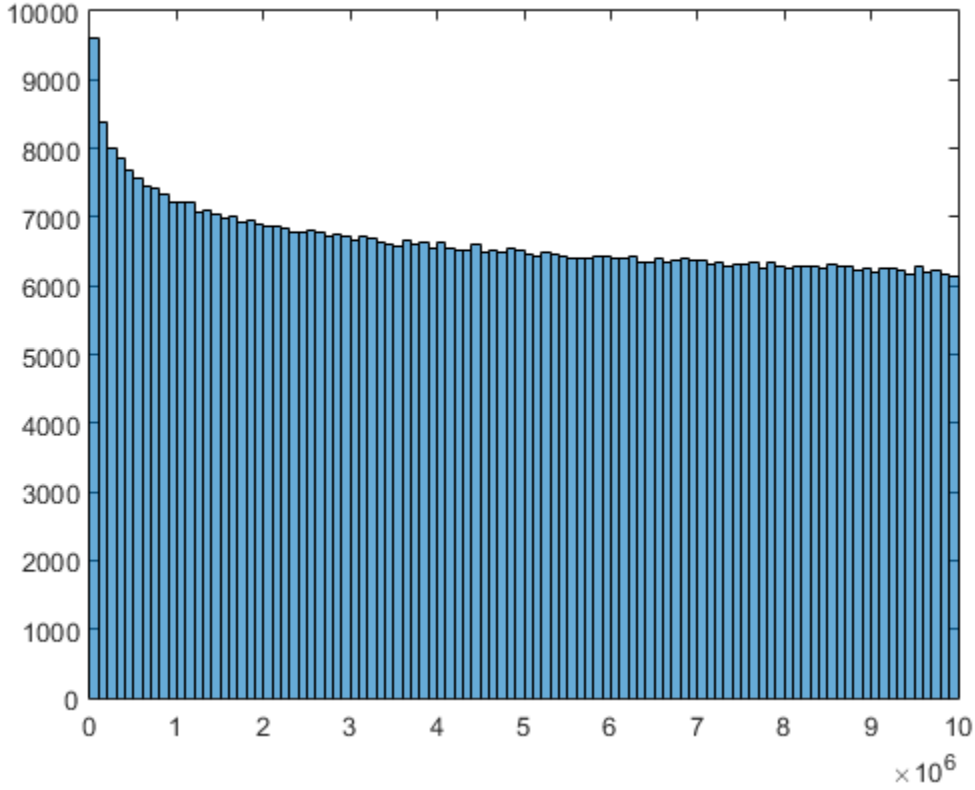
```
x = primes(1e7);
h = histogram(x)
```

```
h =

  Histogram with properties:

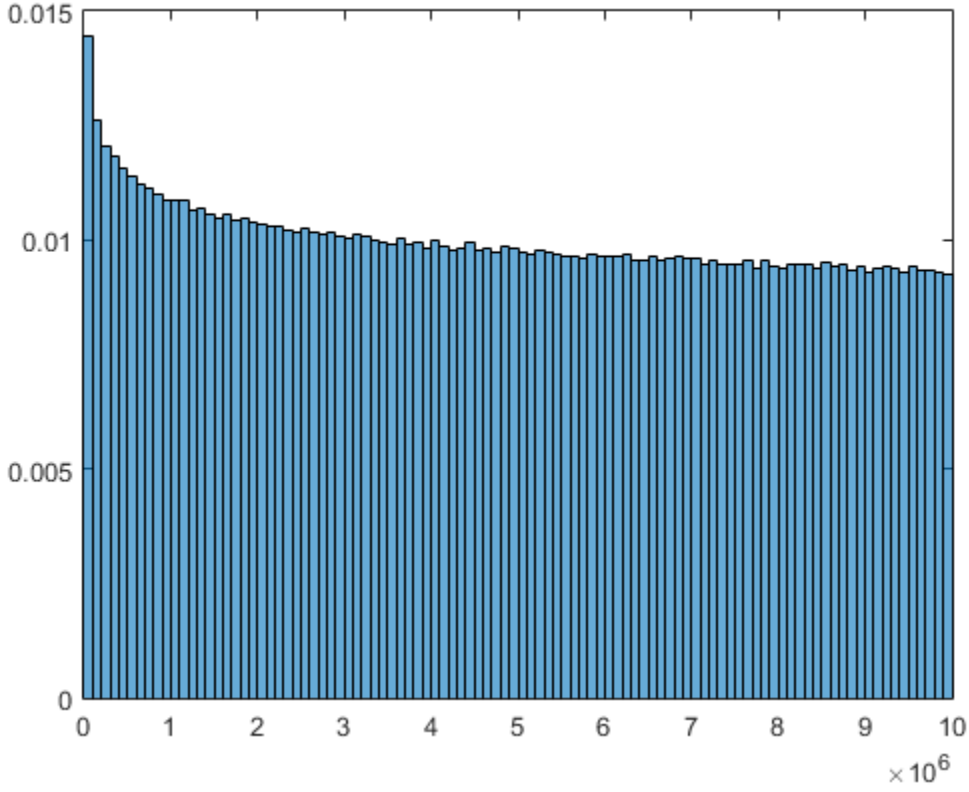
            Data: [1x664579 double]
          Values: [1x100 double]
         NumBins: 100
        BinEdges: [1x101 double]
        BinWidth: 100000
       BinLimits: [0 10000000]
   Normalization: 'count'
       FaceColor: 'auto'
       EdgeColor: [0 0 0]

  Use GET to show all properties
```



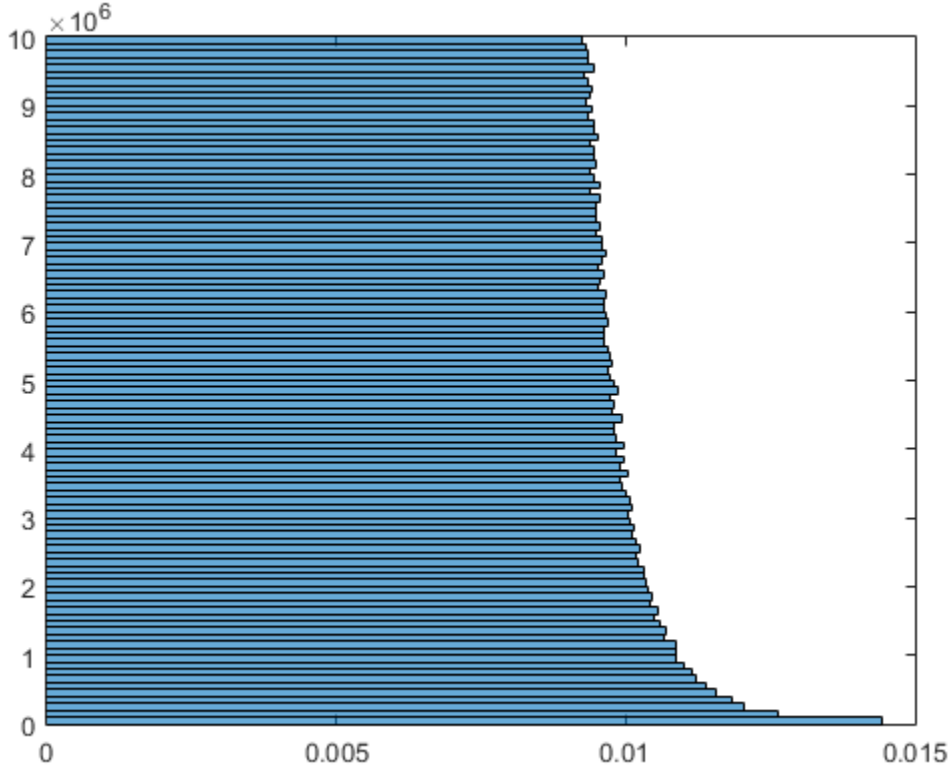
Change the normalization of the histogram by setting the `Normalization` property to `'probability'`.

```
h.Normalization = 'probability';
```



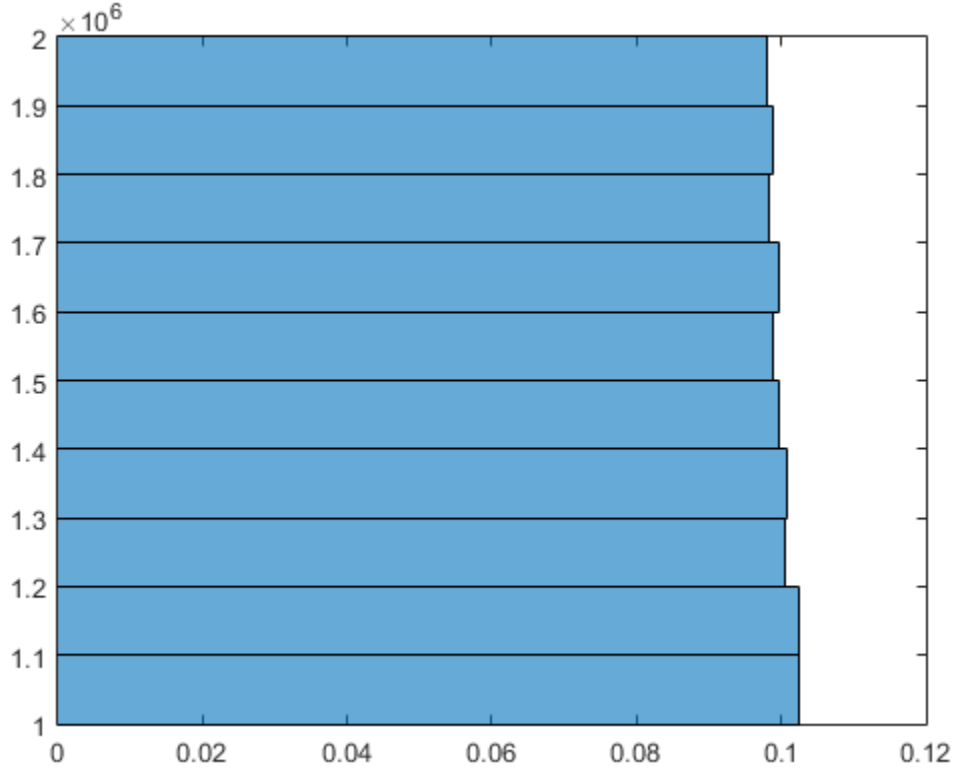
Use horizontal bars for the histogram.

```
h.Orientation = 'horizontal';
```



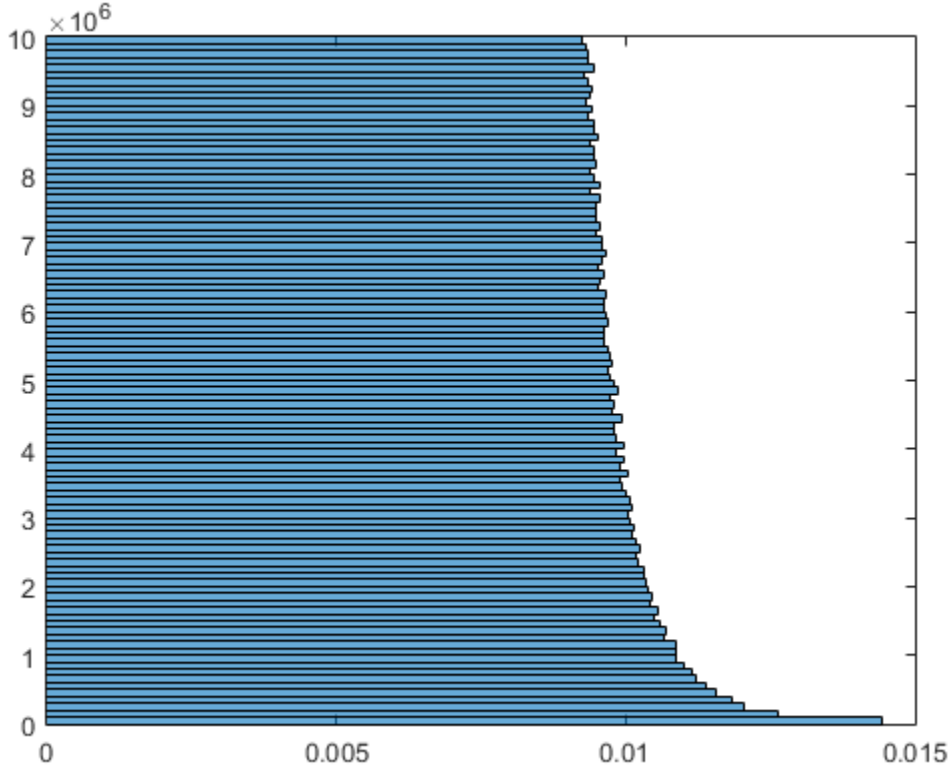
Zoom in to a specific range of bins. When you set `BinLimits`, the `BinLimitsMode` automatically changes to `'manual'`.

```
h.BinLimits = [1e6,2e6];
```



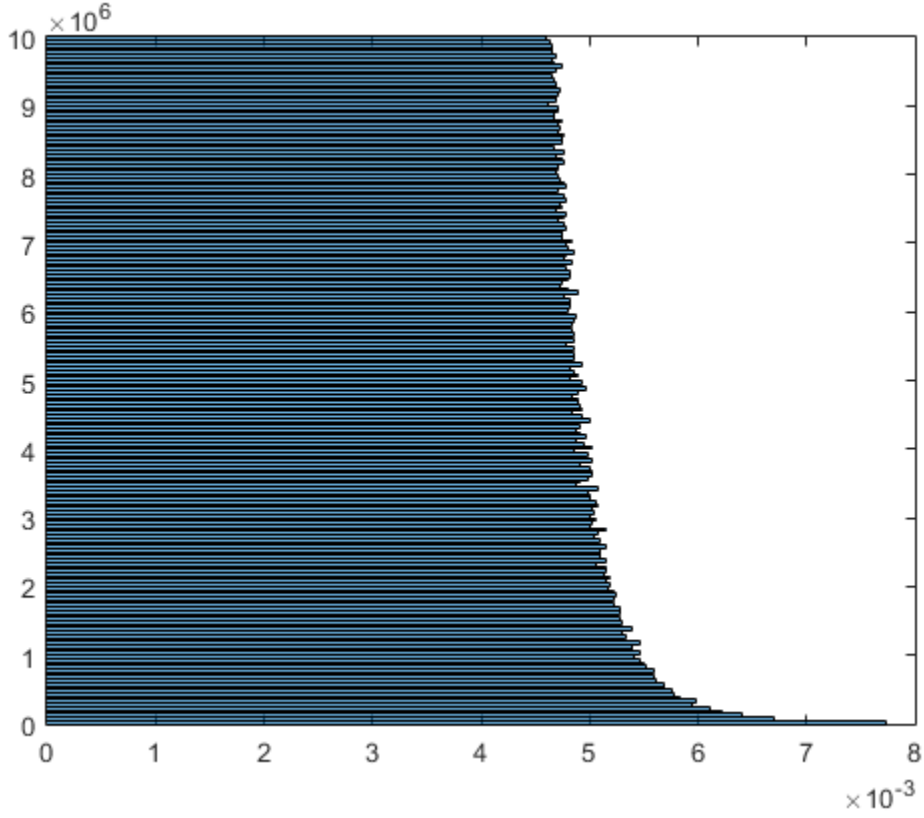
Zoom back out to the original bin scaling by switching `BinLimitsMode` back to `'auto'`.

```
h.BinLimitsMode = 'auto';
```



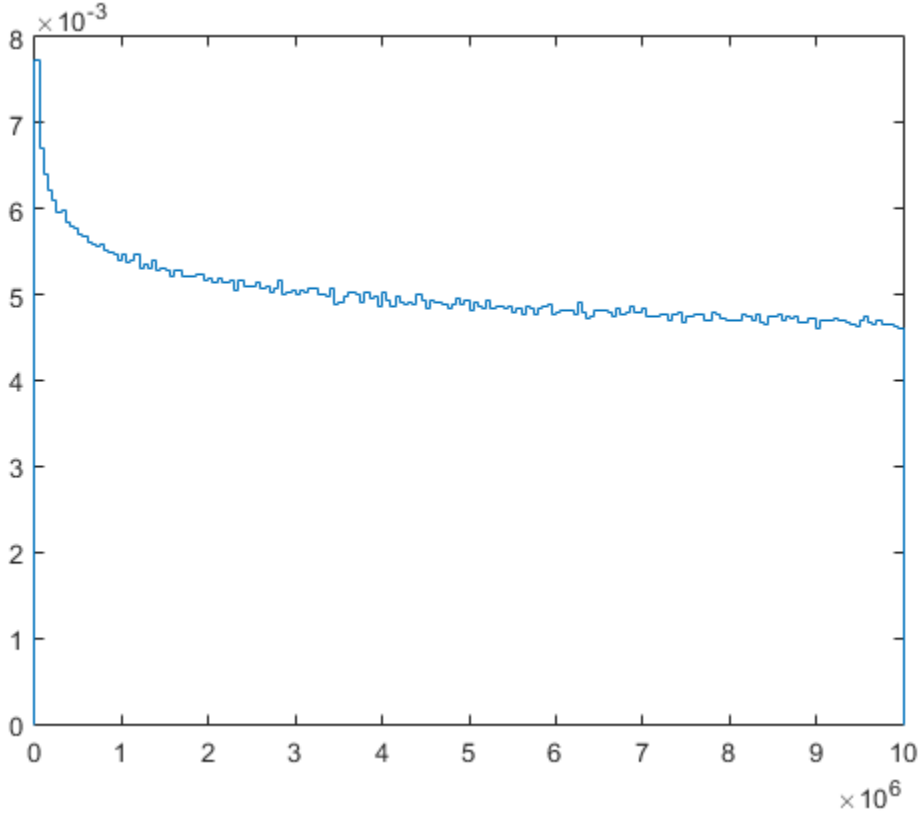
Change the number of bins in the histogram.

```
h.NumBins = 200;
```



Create a vertical stair histogram.

```
h.Orientation = 'vertical';
h.DisplayStyle = 'stairs';
```



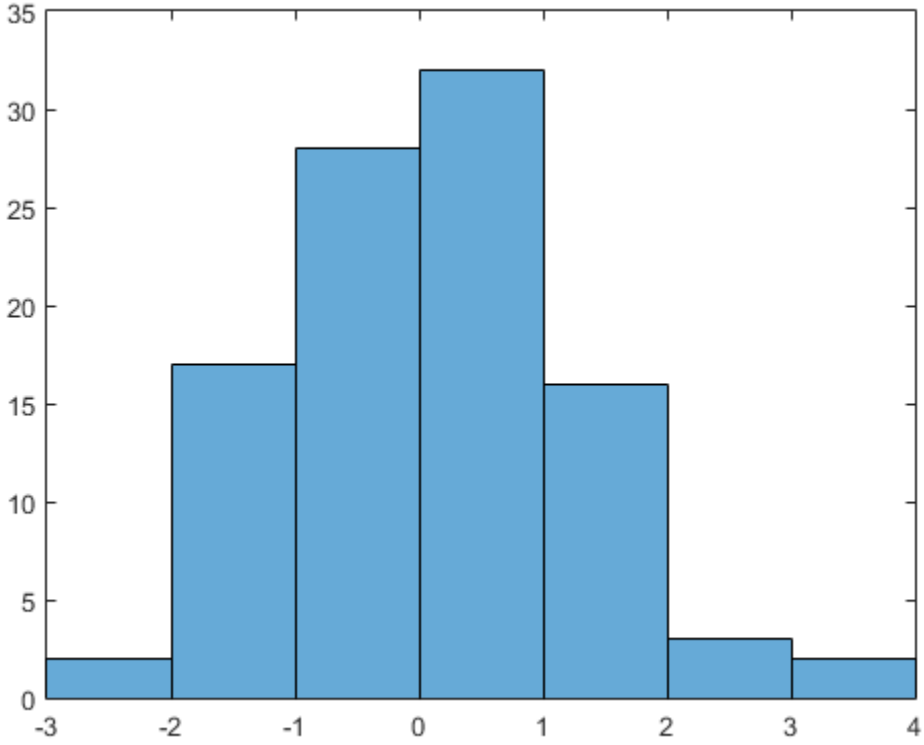
Saving and Loading Histogram Objects

Use the `savefig` function to save a histogram figure.

```
y = histogram(randn(10));
savefig('histogram.fig');
clear all
close all
```

Use `openfig` to load the histogram figure back into MATLAB. `openfig` also returns a handle to the figure, `h`.

```
h = openfig('histogram.fig');
```



Use the `findobj` function to locate the correct object handle from the figure handle. This allows you to continue manipulating the original histogram object used to generate the figure.

```
y = findobj(h, 'type', 'histogram')
```

```
y =

  Histogram with properties:

            Data: [10x10 double]
          Values: [2 17 28 32 16 3 2]
         NumBins: 7
```

```
         BinEdges: [-3 -2 -1 0 1 2 3 4]
         BinWidth: 1
        BinLimits: [-3 4]
    Normalization: 'count'
        FaceColor: 'auto'
        EdgeColor: [0 0 0]

  Use GET to show all properties
```

More About

- Histogram Properties

Histogram Properties

Control histogram appearance and behavior

Histogram properties control the appearance and behavior of the histogram. By changing property values, you can modify aspects of the histogram. Use dot notation to refer to a particular object and property:

```
h = histogram(randn(10,1));
c = h.BinWidth;
h.BinWidth = 2;
```

Bins

`BinEdges` — Edges of bins

numeric vector

Edges of bins, specified as a numeric vector. The first vector element specifies the left edge of the first bin. The last element specifies the right edge of the last bin. If you do not specify the bin edges, then `histogram` automatically determines the location of the bin edges.

`BinLimits` — Bin limits

two-element vector

Bin limits, specified as a two-element vector, `[bmin,bmax]`. This option plots a histogram using the values in the input array, `X`, that fall between `bmin` and `bmax` inclusive. That is, `X(X>=bmin & X<=bmax)`.

Example: `histogram(X,'BinLimits',[1,10])` plots a histogram using only the values in `X` that are between `1` and `10` inclusive.

`BinLimitsMode` — Selection mode for bin limits

`'auto'` (default) | `'manual'`

Selection mode for bin limits, specified as `'auto'` or `'manual'`. The default value is `'auto'`, so that the bin limits automatically adjust to the data.

If you explicitly specify either `BinLimits` or `BinEdges`, then `BinLimitsMode` is automatically set to `'manual'`. In that case, specify `BinLimitsMode` as `'auto'` to rescale the bin limits to the data.

`BinMethod` — Binning algorithm

`'auto'` (default) | `'scott'` | `'fd'` | `'integers'` | `'sturges'` | `'sqrt'` | `'manual'`

Binning algorithm, specified as one of the values in this table.

Value	Description
`'auto'`	The default `'auto'` algorithm chooses a bin width to cover the data range and reveal the shape of the underlying distribution.
`'scott'`	Scott's rule is optimal if the data is close to being normally distributed. This rule is appropriate for most other distributions, as well. It uses a bin width of `3.49*std(X(:))*numel(X)^(-1/3)`.
`'fd'`	The Freedman-Diaconis rule is less sensitive to outliers in the data, and might be more suitable for data with heavy-tailed distributions. It uses a bin width of `2*IQR(X(:))*numel(X)^(-1/3)`, where `IQR` is the interquartile range of `X`.
`'integers'`	The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To avoid accidentally creating too many bins, you can use this rule to create a limit of 65536 bins (2^{16}). If the data range is greater than 65536, then the integer rule uses wider bins instead.
`'sturges'`	Sturges' rule is popular due to its simplicity. It chooses the number of bins to be `ceil(1 + log2(numel(X)))`.
`'sqrt'`	The Square Root rule is widely used in other software packages. It chooses the number of bins to be `ceil(sqrt(numel(X)))`.

If you set the `BinLimits`, `NumBins`, `BinEdges`, or `BinWidth` property, then the `BinMethod` property is set to `'manual'`.

Example: `histogram(X,'BinMethod','integers')` creates a histogram with the bins centered on integers.

`BinWidth` — Width of bins

scalar

Width of bins, specified as a scalar. When you specify `BinWidth`, then `histogram` can use a maximum of 65,536 bins (or 2^{16}). If instead the specified bin width requires more bins, then `histogram` uses a larger bin width corresponding to the maximum number of bins.

Example: `histogram(X,'BinWidth',5)` uses bins with a width of 5.

`Normalization` — Type of normalization

`'count'` (default) | `'probability'` | `'countdensity'` | `'pdf'` | `'cumcount'` | `'cdf'`

Type of normalization, specified as one of the values in this table.

Value	Description
`'count'`	Default normalization scheme. The height of each bar is the number of observations in each bin. The sum of the bar heights is `numel(X)`.
`'probability'`	The height of each bar is the relative number of observations, (number of observations in bin / total number of observations). The sum of the bar heights is 1.
`'countdensity'`	The height of each bar is, (number of observations in bin / width of bin). The area (height * width) of each bar is the number of observations in the bin. The sum of the bar areas is `numel(X)`.
`'pdf'`	Probability density function estimate. The height of each bar is, (number of observations in the bin) / (total number

Value	Description
	of observations * width of bin). The area of each bar is the relative number of observations. The sum of the bar areas is 1.
`'cumcount'`	The height of each bar is the cumulative number of observations in each bin and all previous bins. The height of the last bar is `numel(X)`.
`'cdf'`	Cumulative density function estimate. The height of each bar is equal to the cumulative relative number of observations in the bin and all previous bins. The height of the last bar is `1`.

Example: `histogram(X,'Normalization','pdf')` plots an estimate of the probability density function for `X`.

`NumBins` — Number of bins

positive integer

Number of bins, specified as a positive integer. If you do not specify `NumBins`, then `histogram` automatically calculates how many bins to use based on the values in `Data`.

`EdgeColor` — Histogram edge color

`[0 0 0]` or black (default) | `'none'` | `'auto'` | RGB triplet or color string

Histogram edge color, specified as one of these values:

- `'none'` — Edges are not drawn.
- `'auto'` — The color of each edge is chosen automatically.
- RGB triplet or a color string — Edges use the specified color.

  An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `histogram(X,'EdgeColor','r')` creates a histogram plot with red bar edges.

`FaceColor` — Histogram bar color

`'auto'` (default) | `'none'` | RGB triplet or color string

Histogram bar color, specified as one of these values:

- `'none'` — Bars are not filled.
- `'auto'` — The histogram bar color is chosen automatically (default).
- RGB triplet or a color string — Bars are filled with the specified color.

  An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]

Long Name	Short Name	RGB Triplet
'black	'k'	[0 0 0]

If you specify DisplayStyle as 'stairs', then histogram does not utilize the FaceColor property.

Example: histogram(X,'FaceColor','g') creates a histogram plot with green bars.

FaceAlpha — Transparency of histogram bars

0.6 (default) | scalar value between 0 and 1 inclusive

Transparency of histogram bars, specified as a scalar value between 0 and 1 inclusive. histogram uses the same transparency for all the bars of the histogram. A value of 1 means fully opaque and 0 means completely transparent (invisible).

Example: histogram(X,'FaceAlpha',1) creates a histogram plot with fully opaque bars.

Data

Data — Data to distribute among bins

vector | matrix | multidimensional array

Data to distribute among bins, specified as a vector, matrix, or multidimensional array. If Data is not a vector, then histogram treats it as a single column vector, Data(:), and plots a single histogram.

histogram ignores all NaN values. Similarly, histogram ignores Inf and -Inf values unless the bin edges explicitly specify Inf or -Inf as a bin edge.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Values — Bin values

numeric vector

Bin values, specified as a numeric vector. If Normalization is 'count' (the default), then the kth element in Values specifies how many elements of Data fall in the kth bin interval (bin counts). The last bin includes values that are on *either* bin edge, but all other bins only include values that fall on the left edge.

Depending on the value of `Normalization`, the `Values` property can instead contain a normalized variant of the bin counts.

Histogram Type

`DisplayStyle` — Histogram display style

`'bar'` (default) | `'stairs'`

Histogram display style, specified as either `'bar'` or `'stairs'`. Specify `'stairs'` to display a stairstep plot, which displays the outline of the histogram without filling the interior.

The default value of `'bar'` displays a histogram bar plot.

Example: `histogram(X,'DisplayStyle','stairs')` plots the outline of the histogram.

`Orientation` — Orientation of bars

`'vertical'` (default) | `'horizontal'`

Orientation of bars, specified as `'vertical'` or `'horizontal'`.

Example: `histogram(X,'Orientation','horizontal')` creates a histogram plot with horizontal bars.

Visibility

`Visible` — Visibility of histogram

`'on'` (default) | `'off'`

Visibility of histogram, specified as one of these values:

- `'on'` — Display the histogram.
- `'off'` — Hide the histogram without deleting it. You still can access the properties of an invisible histogram object.

Identifiers

`Type` — Type of graphics object

`'histogram'` (default)

Type of graphics object, returned as `'histogram'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

`Tag` — Tag to associate with histogram

`''` (default) | string

Tag to associate with the histogram, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: `char`

`UserData` — Data to associate with histogram

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the histogram object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the histogram.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property

does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the histogram object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the histogram from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the histogram object in the legend as one entry (default).
   - `'off'` — Do not include the histogram object in the legend.
   - `'children'` — Include only children of the histogram object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of histogram

axes object | group object | transform object

Parent of histogram, specified as an axes, group, or transform object.

`Children` — Children of histogram

empty `GraphicsPlaceholder` array

The histogram has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of histogram object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The histogram object handle is always visible.
- `'off'` — The histogram object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The histogram object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the histogram at the command-line, but allows callback functions to access it.

If the histogram object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the histogram. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram object — You can access properties of the histogram object from within the callback function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the histogram. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the histogram when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the histogram.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.

- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The Visible property must be set to `'on'`. The HitTest property determines if the histogram responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the histogram passes the click to the object below it in the current view of the figure window. The HitTest property of the histogram has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the histogram. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the histogram that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the histogram object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the histogram is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the

`BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the histogram tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the histogram. Setting the `CreateFcn` property on an existing histogram has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during histogram creation. MATLAB executes the callback after creating the histogram and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram object — You can access properties of the histogram object from within the callback function. You also can access the histogram object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the histogram. MATLAB executes the callback before destroying the histogram so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The histogram object — You can access properties of the histogram object from within the callback function. You also can access the histogram object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of histogram

`'off'` (default) | `'on'`

Deletion status of histogram, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the histogram begins

execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the histogram no longer exists.

Check the value of the BeingDeleted property to verify that the histogram is not about to be deleted before querying or modifying it.

histcounts

Histogram bin counts

Syntax

```
[N,edges] = histcounts(X)
[N,edges] = histcounts(X,nbins)
[N,edges] = histcounts(X,edges)
[N,edges] = histcounts(___,Name,Value)
[N,edges,bin] = histcounts(___)
```

Description

`[N,edges] = histcounts(X)` partitions the `X` values into bins, and returns the count in each bin, as well as the bin edges. The `histcounts` function uses an automatic binning algorithm that returns bins with a uniform width, chosen to cover the range of elements in `X` and reveal the underlying shape of the distribution.

`[N,edges] = histcounts(X,nbins)` uses a number of bins specified by the scalar, `nbins`.

`[N,edges] = histcounts(X,edges)` sorts `X` into bins with the bin edges specified by the vector, `edges`. The value `X(i)` is in the `k`th bin if `edges(k)` $\le$ `X(i)` $<$ `edges(k+1)`. The last bin also includes the right bin edge, so that it contains `X(i)` if `edges(end-1)` $\le$ `X(i)` $\le$ `edges(end)`.

`[N,edges] = histcounts(___,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can specify `'BinWidth'` and a scalar to adjust the width of the bins.

`[N,edges,bin] = histcounts(___)` also returns an index array, `bin`, using any of the previous syntaxes. `bin` is an array of the same size as `X` whose elements are the bin indices for the corresponding elements in `X`. The number of elements in the `k`th bin is `nnz(bin==k)`, which is the same as `N(k)`.

Examples

Bin Counts and Bin Edges

Distribute 100 random values into bins. `histcounts` automatically chooses an appropriate bin width to reveal the underlying distribution of the data.

```
X = randn(100,1);
[N,edges] = histcounts(X)
```

```
N =

     2    17    28    32    16     3     2

edges =

    -3    -2    -1     0     1     2     3     4
```

Specify Number of Bins

Distribute 10 numbers into 6 equally spaced bins.

```
X = [2 3 5 7 11 13 17 19 23 29];
[N,edges] = histcounts(X,6)
```

```
N =

     2     2     2     2     1     1

edges =

         0    4.9000    9.8000   14.7000   19.6000   24.5000   29.4000
```

Specify Bin Edges

Distribute 1,000 random numbers into bins. Define the bin edges with a vector, where the first element is the left edge of the first bin, and the last element is the right edge of the last bin.

```
X = randn(1000,1);
```

```
edges = [-5 -4 -2 -1 -0.5 0 0.5 1 2 4 5];
N = histcounts(X,edges)
```

```
N =

     0    24   149   142   195   200   154   111    25     0
```

Normalized Bin Counts

Distribute all of the prime numbers less than 100 into bins. Specify `'Normalization'` as `'probability'` to normalize the bin counts so that `sum(N)` is `1`. That is, each bin count represents the probability that an observation falls within that bin.

```
X = primes(100);
[N,edges] = histcounts(X, 'Normalization', 'probability')
```

```
N =

    0.4000    0.2800    0.2800    0.0400

edges =

     0    30    60    90   120
```

Determine Bin Placement

Distribute 100 random integers between -5 and 5 into bins, and specify `'BinMethod'` as `'integers'` to use unit-width bins centered on integers. Specify a third output for `histcounts` to return a vector representing the bin indices of the data.

```
X = randi([-5,5],100,1);
[N,edges,bin] = histcounts(X,'BinMethod','integers');
```

Find the bin count for the third bin by counting the occurrences of the number `3` in the bin index vector, `bin`. The result is the same as `N(3)`.

```
count = nnz(bin==3)
```

```
count =
```

```
8
```

Input Arguments

`X` — Data to distribute among bins

vector | matrix | multidimensional array

Data to distribute among bins, specified as a vector, matrix, or multidimensional array. If `X` is not a vector, then `histcounts` treats it as a single column vector, `X(:)`.

`histcounts` ignores all `NaN` values. Similarly, `histcounts` ignores `Inf` and `-Inf` values unless the bin edges explicitly specify `Inf` or `-Inf` as a bin edge.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`nbins` — Number of bins

positive integer

Number of bins, specified as a positive integer. If you do not specify `nbins`, then `histcounts` automatically calculates how many bins to use based on the values in `X`.

Example: `[N,edges] = histcounts(X,15)` uses 15 bins.

`edges` — Bin edges

vector

Bin edges, specified as a vector. `edges(1)` is the left edge of the first bin, and `edges(end)` is the right edge of the last bin.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `[N,edges] = histcounts(X,'Normalization','probability')` normalizes the bin counts in `N`, such that `sum(N)` is 1.

`'BinLimits'` — Bin limits

two-element vector

Bin limits, specified as a two-element vector, `[bmin,bmax]`. This option bins only the values in `X` that fall between `bmin` and `bmax` inclusive; that is, `X(X>=bmin & X<=bmax)`.

Example: `[N,edges] = histcounts(X,'BinLimits',[1,10])` bins only the values in `X` that are between `1` and `10` inclusive.

`'BinMethod'` — Binning algorithm

`'auto'` (default) | `'scott'` | `'fd'` | `'integers'` | `'sturges'` | `'sqrt'`

Binning algorithm, specified as one of the values in this table.

Value	Description
`'auto'`	The default `'auto'` algorithm chooses a bin width to cover the data range and reveal the shape of the underlying distribution.
`'scott'`	Scott's rule is optimal if the data is close to being normally distributed, but is also appropriate for most other distributions. It uses a bin width of `3.49*std(X(:))*numel(X)^(-1/3)`.
`'fd'`	The Freedman-Diaconis rule is less sensitive to outliers in the data, and may be more suitable for data with heavy-tailed distributions. It uses a bin width of `2*IQR(X(:))*numel(X)^(-1/3)`, where `IQR` is the interquartile range of `X`.
`'integers'`	The integer rule is useful with integer data, as it creates a bin for each integer. It uses a bin width of 1 and places bin edges halfway between integers. To prevent from accidentally creating too many bins, a limit of 65536 bins (2^{16}) can be created with this rule. If the data range is greater than 65536, then wider bins are used instead.

Value	Description
`'sturges'`	Sturges' rule is a simple rule that is popular due to its simplicity. It chooses the number of bins to be `ceil(1 + log2(numel(X)))`.
`'sqrt'`	The Square Root rule is another simple rule widely used in other software packages. It chooses the number of bins to be `ceil(sqrt(numel(X)))`.

Example: `[N,edges] = histcounts(X,'BinMethod','integers')` uses bins centered on integers.

`'BinWidth'` — Width of bins

scalar

Width of bins, specified as a scalar. When you specify `BinWidth`, `histcounts` can use a maximum of 65,536 bins (or 2^{16}). If the specified bin width requires more bins, then `histcounts` uses a larger bin width corresponding to the maximum number of bins.

Example: `[N,edges] = histcounts(X,'BinWidth',5)` uses bins with a width of 5.

`'Normalization'` — Type of normalization

`'count'` (default) | `'probability'` | `'countdensity'` | `'pdf'` | `'cumcount'` | `'cdf'`

Type of normalization, specified as one of the values in this table.

Value	Description
`'count'`	Default normalization scheme. Each `N` value is equal to the number of observations in the bin, and `sum(N)` is equal to `numel(X)`.
`'probability'`	Each `N` value is equal to the relative number of observations in the bin such that `sum(N)` is `1`.
`'countdensity'`	Each `N` value is equal to the number of observations in the bin divided by the bin width.

Value	Description
`'pdf'`	Probability density function estimate. Each `N` value is equal to the relative number of observations in the bin divided by the bin width.
`'cumcount'`	Each `N` value is equal to the cumulative number of observations in the bin and all previous bins. `N(end)` is equal to `numel(X)`.
`'cdf'`	Cumulative density function estimate. Each `N` value is equal to the cumulative relative number of observations in the bin and all previous bins. `N(end)` is equal to `1`.

Example: `[N,edges] = histcounts(X,'Normalization','pdf')` bins the data using the probability density function estimate.

Output Arguments

`N` — Bin counts

row vector

Bin counts, returned as a row vector.

`edges` — Bin edges

vector

Bin edges, returned as a vector. `edges(1)` is the left edge of the first bin, and `edges(end)` is the right edge of the last bin.

`bin` — Bin indices

array

Bin indices, returned as an array of the same size as `X`. Each element in `bin` describes which numbered bin contains the corresponding element in `X`.

A value of `0` in `bin` indicates an element which does not belong to any of the bins (for example, a `NaN` value).

More About

Tips

- The behavior of `histcounts` is similar to that of the `discretize` function. Use `histcounts` to find the number of elements in each bin. On the other hand, use `discretize` to find which bin each element belongs to (without counting).
- "Replace Discouraged Instances of hist and histc"

See Also

`discretize` | `histogram`

Introduced in R2014b

hms

Hour, minute, and second numbers of duration

Syntax

```
[h,m,s] = hms(t)
```

Description

`[h,m,s] = hms(t)` returns the hour, minute, and second values of the datetime values in `t` as separate numeric arrays. The `h` and `m` outputs contain integer values, and the `s` output can contain a fractional part. `h`, `m`, and `s` are the same size as `t`.

Calling `hms` is equivalent to calling the `hour`, `minute`, and `second` functions.

Examples

Find Hour, Minute, and Second Numbers of datetime Array

```
t1 = datetime('now','Format','HH:mm:ss.SSS');
t = t1 + minutes(0:45:135)

[h,m,s] = hms(t)
```

```
t =

   09:58:49.720   10:43:49.720   11:28:49.720   12:13:49.720

h =

     9    10    11    12

m =
```

```
    58    43    28    13

s =

   49.7200   49.7200   49.7200   49.7200
```

`hms` returns the hour, minute, and second numbers in separate arrays.

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

Output Arguments

`h` — Hour numbers

numeric array

Hour numbers, returned as a numeric array of integer values from 0 to 23. The `h` output is of type `double` and is the same size as `t`.

`m` — Minute numbers

numeric array

Minute numbers, returned as a numeric array of integer values from 0 to 59. The `m` output is of type `double` and is the same size as `t`.

`s` — Second numbers

numeric array

Second numbers, returned as a numeric array of values from 0 to less than 60, and can include a fractional part. For datetime values whose time zone is `UTCLeapSeconds`, the `s` output can contain a value between 60 and 61 for times that fall during a leap second occurrence. The `s` output is of type `double` and is the same size as `t`.

See Also

`hour` | `minute` | `second` | `ymd`

Introduced in R2014b

hold

Retain current plot when adding new plots

Syntax

```
hold on
hold off
hold all
hold

hold(ax,'on')
hold(ax,'off')
hold(ax)
```

Description

`hold on` retains plots in the current axes so that new plots added to the axes do not delete existing plots. New plots use the next colors and line styles based on the `ColorOrder` and `LineStyleOrder` properties of the axes. MATLAB adjusts axes limits, tick marks, and tick labels to display the full range of data.

`hold off` sets the hold state to off so that new plots added to the axes clear existing plots and reset all axes properties. The next plot added to the axes uses the first color and line style based on the `ColorOrder` and `LineStyleOrder` properties of the axes. This is the default behavior.

`hold all` is the same as `hold on`.

Note: This syntax will be removed in a future release. Use `hold on` instead.

`hold` toggles the hold state between on and off.

`hold(ax,'on')` sets the hold state to on for the axes specified by `ax` instead of the current axes.

`hold(ax,'off')` sets the hold state to off for the specified axes.

`hold(ax)` toggles the hold state for the specified axes.

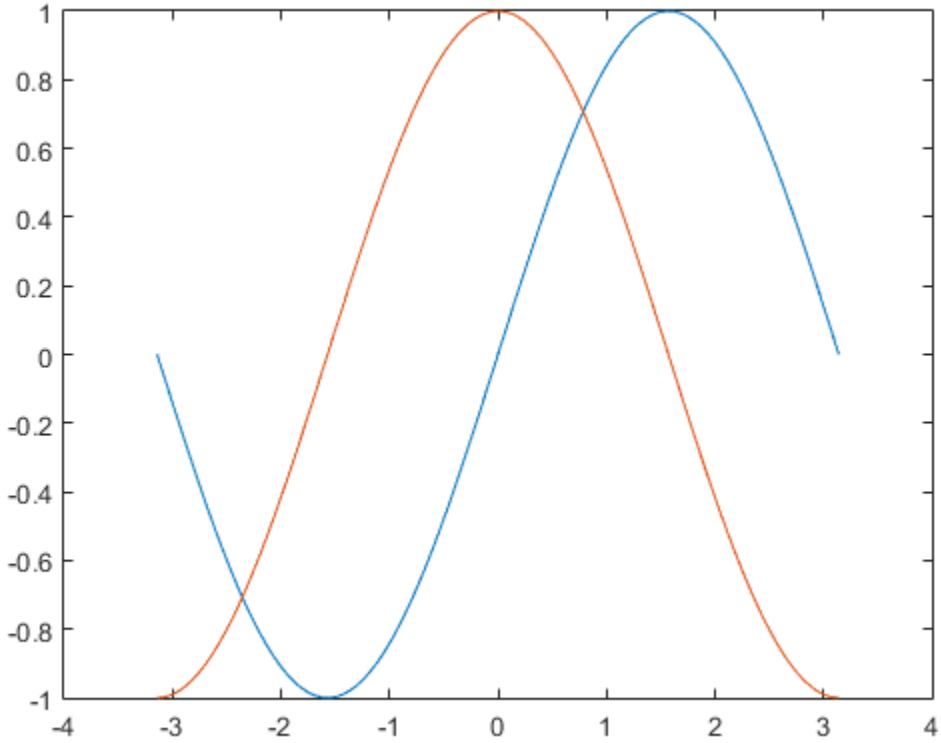
Examples

Add Line Plot to Existing Graph

Create a line plot. Then, use `hold on` to add a second line plot without deleting the existing plot. The new plot uses the next color and line style based on the `ColorOrder` and `LineStyleOrder` properties of the axes.

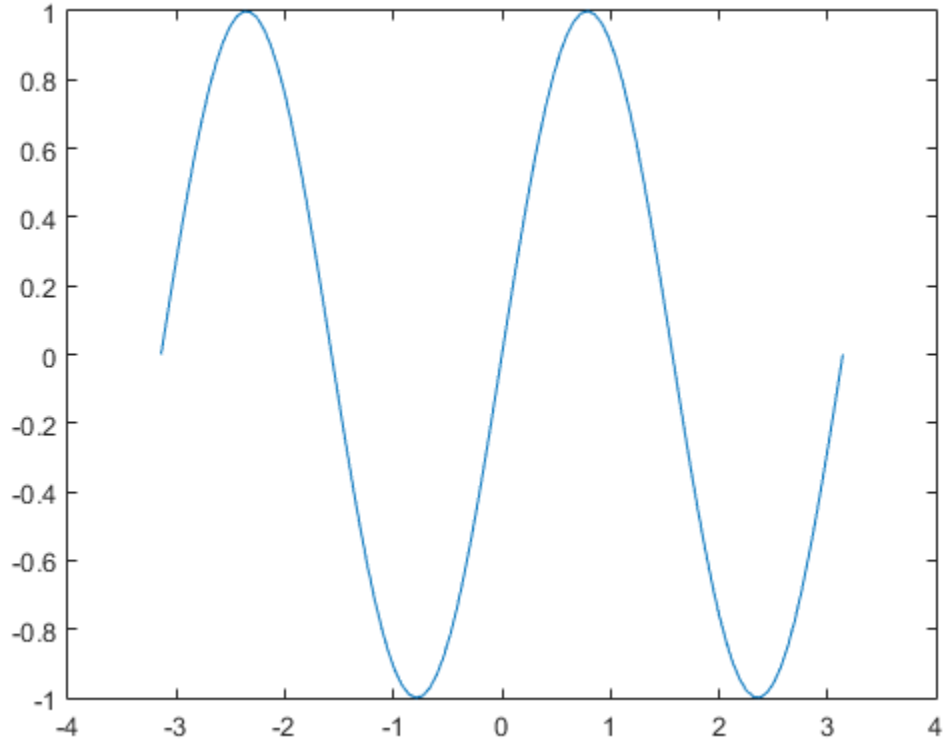
```
x = linspace(-pi,pi);
y1 = sin(x);
y2 = cos(x);

plot(x,y1)
hold on
plot(x,y2)
```



Reset the hold state to off so that new plots delete existing plots. New plots start from the beginning of the color order and line style order.

```
hold off
y3 = sin(2*x);
plot(x,y3)
```

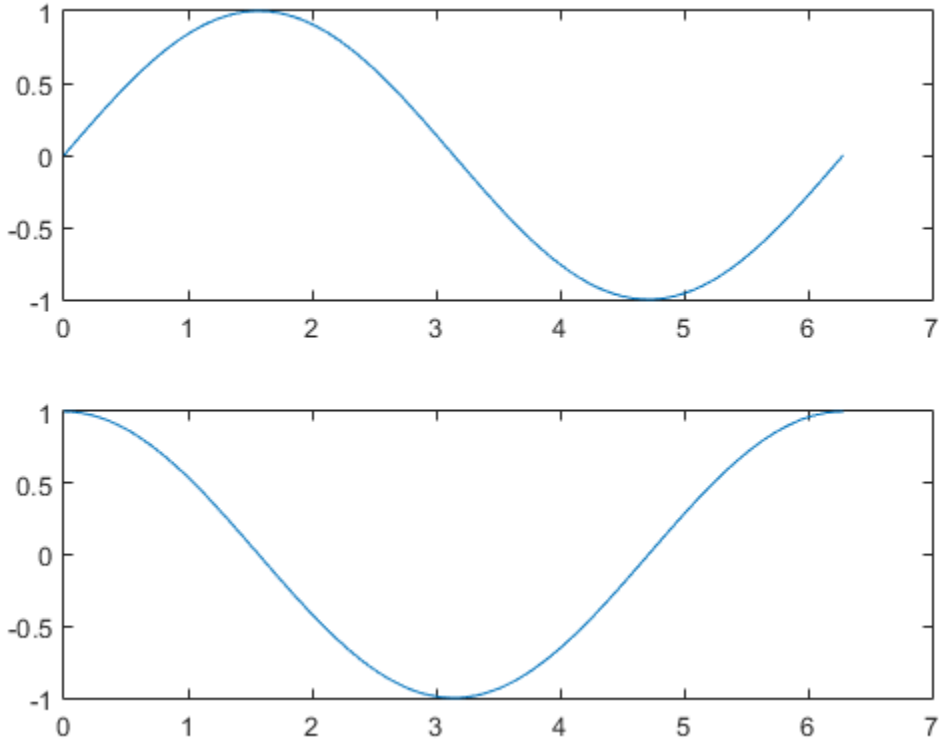


Specify Hold State for Specific Axes

Create a figure with two subplots and add a line plot to each subplot.

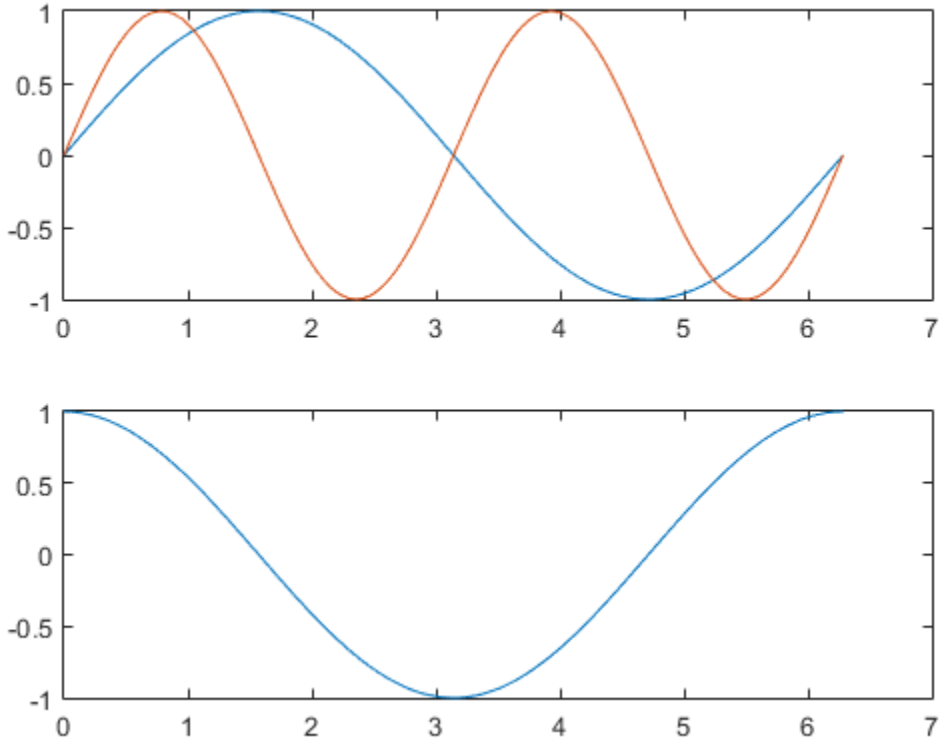
```
ax1 = subplot(2,1,1);
x = linspace(0,2*pi);
y1 = sin(x);
plot(x,y1)

ax2 = subplot(2,1,2);
y2 = cos(x);
plot(x,y2)
```



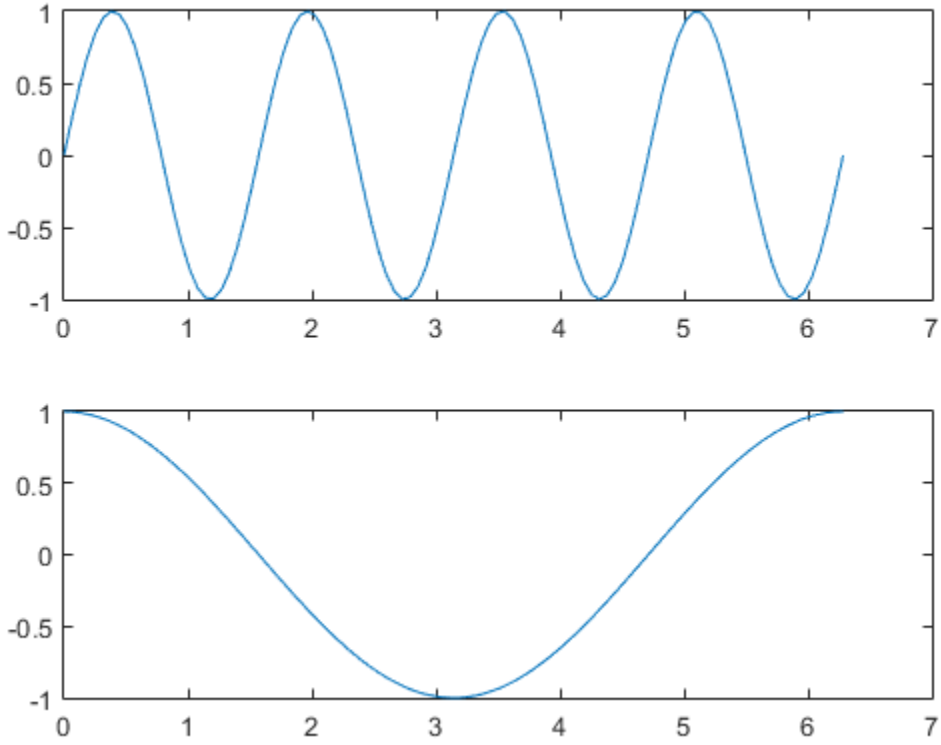
Add a second line plot to the upper subplot.

```
hold(ax1,'on')
y3 = sin(2*x);
plot(ax1,x,y3)
```



Reset the hold state to off for the upper subplot so that new plots replace the existing plots, which is the default behavior.

```
hold(ax1,'off')
y4 = sin(4*x);
plot(ax1,x,y4)
```



Input Arguments

ax — Axes object

axes object

Axes object. Use `ax` to set the hold state for a specific axes, instead of the current axes.

More About

Tips

- Use the `ishold` function to test the hold state.
- The `hold` function toggles the `NextPlot` property of the axes between `'add'` and `'replace'`.
- If an axes does not exist, then the `hold` command creates one.

Introduced before R2006a

home

Send cursor home

Syntax

```
home
```

Description

`home` moves the cursor to the upper-left corner of the window. When using the MATLAB desktop, `home` also scrolls the visible text in the window up and out of view. You can use the scroll bar to see what was previously on the screen.

Examples

Execute a MATLAB command that displays something in the Command Window and then run the `home` function. `home` moves the cursor to the upper-left corner of the screen and clears the screen.

```
magic(5)

ans =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9

home
```

See Also

`clc`

Introduced before R2006a

horzcat

Concatenate arrays horizontally

Syntax

```
C = horzcat(A1,...,AN)
```

Description

`C = horzcat(A1,...,AN)` horizontally concatenates arrays `A1,...,AN`. All arrays in the argument list must have the same number of rows.

- If the inputs are multidimensional arrays, `horzcat` concatenates along the second dimension. The first and remaining dimensions must match.
- If the inputs are tables, `horzcat` concatenates by matching row names when present, or by matching position for tables that do not have row names. All the table inputs must have unique variable names and the row names for all tables that have them must be identical, except for order.

  `horzcat` assigns values for the `Description` and `UserData` properties in `C` using the first nonempty value for the corresponding property in the tables `A1,...,AN`.

MATLAB calls `C = horzcat(A1, A2,...)` for the syntax `C = [A1 A2 ...]` when any of the inputs are an object.

Tips

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

You can concatenate datetime arrays with cell arrays of strings.

You can concatenate duration arrays and calendar duration arrays. The result is a calendar duration array.

You can concatenate duration or calendar duration arrays with numeric arrays. Prior to concatenation, MATLAB converts the numeric array to an array of equivalent days using the `days` function.

For information on combining unlike integer types, integers with nonintegers, or cell arrays with non-cell arrays, see "Valid Combinations of Unlike Classes".

Examples

Horizontally Concatenate Two Matrices

Create a 3-by-5 matrix, `A`.

```
A = magic(5);
A(4:5,:) = []
```

```
A =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
```

Create a 3-by-3 matrix, `B`.

```
B = magic(3)*100
```

```
B =

   800   100   600
   300   500   700
   400   900   200
```

Horizontally concatenate `A` and `B`.

```
C = horzcat(A,B)
```

```
C =
```

```
    17    24     1     8    15   800   100   600
    23     5     7    14    16   300   500   700
     4     6    13    20    22   400   900   200
```

Horizontally Concatenate Two Tables

Create a table, A, with three rows and two variables.

```
A = table([5;6;5],['M';'M';'M'],...
    'VariableNames',{'Age' 'Gender'},...
    'RowNames',{'Thomas' 'Gordon' 'Percy'})
```

```
A =

              Age    Gender
              ---    ------
    Thomas    5      M
    Gordon    6      M
    Percy     5      M
```

Create a table, B, with three rows and three variables.

```
B = table([45;41;40],[45;32;34],{'NY';'CA';'MA'},...
    'VariableNames',{'Height' 'Weight' 'Birthplace'},...
    'RowNames',{'Percy' 'Gordon' 'Thomas'})
```

```
B =

              Height    Weight    Birthplace
              ------    ------    ----------
    Percy     45        45        'NY'
    Gordon    41        32        'CA'
    Thomas    40        34        'MA'
```

Horizontally concatenate A and B.

```
C = horzcat(A,B)
```

```
C =

              Age    Gender    Height    Weight    Birthplace
              ---    ------    ------    ------    ----------
    Thomas    5      M         40        34        'MA'
    Gordon    6      M         41        32        'CA'
    Percy     5      M         45        45        'NY'
```

The order of rows in `C` matches the order in `A`.

Introduced before R2006a

horzcat (tscollection)

Horizontal concatenation for `tscollection` objects

Syntax

```
tsc = horzcat(tsc1,tsc2,...)
```

Description

`tsc = horzcat(tsc1,tsc2,...)` performs horizontal concatenation for `tscollection` objects:

```
tsc = [tsc1 tsc2 ...]
```

This operation combines multiple `tscollection` objects, which must have the same time vectors, into one `tscollection` containing `timeseries` objects from all concatenated collections.

See Also

`tscollection` | `vertcat (tscollection)`

Introduced before R2006a

hour

Hour number

Syntax

```
h = hour(t)
```

Description

`h = hour(t)` returns the hour numbers of the datetime values in `t`. The `h` output is a `double` array the same size as `t` and contains integer values from 0 to 23.

The `hour` function returns the hour numbers of datetime values. To assign hour values to a datetime array, `t`, use `t.Hour` and modify the `Hour` property.

Examples

Find Hour Number of Datetime Values

```
t = datetime('today'):hours(8):datetime('tomorrow');
t.Format = 'MMM dd, HH:mm'
```

```
t =

   Feb 23, 00:00   Feb 23, 08:00   Feb 23, 16:00   Feb 24, 00:00
```

```
h = hour(t)
```

```
h =

     0     8    16     0
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

See Also

`hms` | `minute` | `second` | `timeofday`

Introduced in R2014b

hours

Duration in hours

Syntax

```
H = hours(X)
```

Description

`H = hours(X)` returns an array of hours equivalent to the values in `X`.

- If `X` is a numeric array, then `H` is a `duration` array in units of hours.
- If `X` is a `duration` array, then `H` is a `double` array with each element equal to the number of hours in the corresponding element of `X`.

The `hours` function converts between `duration` and `double` values. To display a duration in units of hours, set its `Format` property to `'h'`.

Examples

Create Duration Array of Hours

```
X = magic(4);
H = hours(X)
```

```
H =

   16 hrs    2 hrs    3 hrs   13 hrs
    5 hrs   11 hrs   10 hrs    8 hrs
    9 hrs    7 hrs    6 hrs   12 hrs
    4 hrs   14 hrs   15 hrs    1 hr
```

Convert Durations to Numeric Array of Hours

Create a `duration` array.

```
X = hours(2:10:38) + minutes(30)

X =

    2.5 hrs   12.5 hrs   22.5 hrs   32.5 hrs
```

Convert each duration in X to a number of hours.

```
H = hours(X)

H =

    2.5000   12.5000   22.5000   32.5000
```

View the data type of H

```
whos H
  Name      Size             Bytes  Class     Attributes

  H         1x4                 32  double
```

Input Arguments

X — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

duration

Introduced in R2014b

hsv2rgb

Convert HSV colormap to RGB colormap

Syntax

```
M = hsv2rgb(H)
rgb_image = hsv2rgb(hsv_image)
```

Description

`M = hsv2rgb(H)` converts a hue-saturation-value (HSV) colormap to a red-green-blue (RGB) colormap. `H` is an *m*-by-3 matrix, where *m* is the number of colors in the colormap. The columns of `H` represent hue, saturation, and value, respectively. `M` is an *m*-by-3 matrix. Its columns are intensities of red, green, and blue, respectively.

`rgb_image = hsv2rgb(hsv_image)` converts the HSV image to the equivalent RGB image. HSV is an *m*-by-*n*-by-3 image array whose three planes contain the hue, saturation, and value components for the image. RGB is returned as an *m*-by-*n*-by-3 image array whose three planes contain the red, green, and blue components for the image.

More About

Tips

As `H(:,1)` varies from 0 to 1, the resulting color varies from red through yellow, green, cyan, blue, and magenta, and returns to red. When `H(:,2)` is 0, the colors are unsaturated (i.e., shades of gray). When `H(:,2)` is 1, the colors are fully saturated (i.e., they contain no white component). As `H(:,3)` varies from 0 to 1, the brightness increases.

The MATLAB `hsv` colormap uses `hsv2rgb([huesaturationvalue])` where `hue` is a linear ramp from 0 to 1, and `saturation` and `value` are all 1's.

See Also

`brighten` | `colormap` | `rgb2hsv`

Introduced before R2006a

hypot

Square root of sum of squares

Syntax

```
c = hypot(a,b)
```

Description

`c = hypot(a,b)` returns the element-wise result of the following equation, computed to avoid underflow and overflow:

```
c = sqrt(abs(a).^2 + abs(b).^2)
```

Inputs `a` and `b` must follow these rules:

- Both `a` and `b` must be single- or double-precision, floating-point arrays.
- The sizes of the `a` and `b` arrays must either be equal, or one a scalar and the other nonscalar. In the latter case, `hypot` expands the scalar input to match the size of the nonscalar input.
- If `a` or `b` is an empty array (0-by-N or N-by-0), the other must be the same size or a scalar. The result `c` is an empty array having the same size as the empty input(s).

`hypot` returns the following in output `c`, depending upon the types of inputs:

- If the inputs to `hypot` are complex (`w+xi` and `y+zi`), then the statement `c = hypot(w+xi,y+zi)` returns the *positive real* result

  ```
  c = sqrt(abs(w).^2+abs(x).^2+abs(y).^2+abs(z).^2)
  ```

- If `a` or `b` is `±Inf`, `hypot` returns `Inf`.
- If neither `a` nor `b` is `Inf`, but one or both inputs is `NaN`, `hypot` returns `NaN`.
- If all inputs are finite, the result is finite. The one exception is when both inputs are very near the value of the MATLAB constant `realmax`. The reason for this is that the equation `c = hypot(realmax,realmax)` is theoretically `sqrt(2)*realmax`, which overflows to `Inf`.

Examples

Example 1

To illustrate the difference between using the `hypot` function and coding the basic `hypot` equation in M-code, create an anonymous function that performs the same function as `hypot`, but without the consideration to underflow and overflow that `hypot` offers:

```
myhypot = @(a,b)sqrt(abs(a).^2+abs(b).^2);
```

Find the upper limit at which your coded function returns a useful value. You can see that this test function reaches its maximum at about `1e154`, returning an infinite result at that point:

```
myhypot(1e153,1e153)
ans =
    1.4142e+153

myhypot(1e154,1e154)
ans =
   Inf
```

Do the same using the `hypot` function, and observe that `hypot` operates on values up to about `1e308`, which is approximately equal to the value for `realmax` on your computer (the largest double-precision floating-point number you can represent on a particular computer):

```
hypot(1e308,1e308)
ans =
  1.4142e+308

hypot(1e309,1e309)
ans =
   Inf
```

Example 2

`hypot(a,a)` theoretically returns `sqrt(2)*abs(a)`, as shown in this example:

```
x = 1.271161e308;

y = x * sqrt(2)
```

```
y =
  1.7977e+308

y = hypot(x,x)
y =
  1.7977e+308
```

See Also

`sqrt` | `abs` | `norm`

Introduced before R2006a

i

Imaginary unit

Syntax

```
1i
z = a + bi
z = x + 1i*y
```

Description

`1i` returns the basic imaginary unit. `i` is equivalent to `sqrt(-1)`.

You can use `i` to enter complex numbers. You also can use the character `j` as the imaginary unit. To create a complex number without using `i` and `j`, use the `complex` function.

`z = a + bi` returns a complex numerical constant, `z`.

`z = x + 1i*y` returns a complex array, `z`.

Examples

Complex Scalar

Create a complex scalar and use the character, `i`, without a multiplication sign as a suffix in forming a complex numerical constant.

```
z = 1+2i
```

```
z =

   1.0000 + 2.0000i
```

Complex Vector

Create a complex vector from two 4-by-1 vectors of real numbers.

```
x = [1:4]';
y = [8:-2:2]';

z = x+1i*y

z =

   1.0000 + 8.0000i
   2.0000 + 6.0000i
   3.0000 + 4.0000i
   4.0000 + 2.0000i
```

`z` is a 4-by-1 complex vector.

Complex Exponential

Create a complex scalar representing a complex vector with radius, `r`, and angle from the origin, `theta`.

```
r = 4;
theta = pi/4;

z = r*exp(1i*theta)

z =

   2.8284 + 2.8284i
```

Input Arguments

a — Real component of complex scalar

scalar

Real component of a complex scalar, specified as a scalar.

Data Types: `single | double`

b — Imaginary component of complex scalar

scalar

Imaginary component of a complex scalar, specified as a scalar.

If `b` is `double`, you can use the character, `i`, without a multiplication sign as a suffix in forming the complex numerical constant.

Example: `7i`

If `b` is `single`, you must use a multiplication sign when forming the complex numerical constant.

Example: `single(7)*i`

Data Types: `single` | `double`

x — Real component of complex array

scalar | vector | matrix | multidimensional array

Real component of a complex array, specified as a scalar, vector, matrix, or mulitdimensional array.

The size of `x` must match the size of `y`, unless one is a scalar. If either `x` or `y` is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

y — Imaginary component of complex array

scalar | vector | matrix | multidimensional array

Imaginary component of a complex array, specified as a scalar, vector, matrix, or mulitdimensional array.

The size of `x` must match the size of `y`, unless one is a scalar. If either `x` or `y` is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

Output Arguments

z — Complex array

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of `z` is the same as the input arguments.

`z` is `single` if at least one input argument is `single`. Otherwise, `z` is `double`.

More About

Tips

- For speed and improved robustness in complex arithmetic, use `1i` and `1j` instead of `i` and `j`.
- Since `i` is a function, it can be overridden and used as a variable. However, it is best to avoid using `i` and `j` for variable names if you intend to use them in complex arithmetic.
- Use the `complex` function to create a complex output in the following cases:
  - When the names `i` and `j` might be used for other variables (and do not equal `sqrt(-1)`)
  - When the inputs are not `double` or `single`
  - When the imaginary component is all zeros

Introduced before R2006a

ichol

Incomplete Cholesky factorization

Syntax

```
L = ichol(A)
L = ichol(A,opts)
```

Description

`L = ichol(A)` performs the incomplete Cholesky factorization of A with zero-fill.

`L = ichol(A,opts)` performs the incomplete Cholesky factorization of A with options specified by opts.

By default, `ichol` references the lower triangle of `A` and produces lower triangular factors.

Input Arguments

`A`

Sparse matrix

`opts`

Structure with up to five fields:

Field Name	Summary	Description
`type`	Type of factorization	String indicating which flavor of incomplete Cholesky to perform. Valid values of this field are `'nofill'` and `'ict'`. The `'nofill'` variant performs *incomplete Cholesky with zero-fill* (`IC(0)`). The `'ict'` variant performs

Field Name	Summary	Description
		incomplete Cholesky with threshold dropping (ICT). The default value is `'nofill'`.
`droptol`	Drop tolerance when type is `'ict'`	Nonnegative scalar used as a drop tolerance when performing ICT. Elements which are smaller in magnitude than a local drop tolerance are dropped from the resulting factor except for the diagonal element which is never dropped. The local drop tolerance at step `j` of the factorization is `norm(A(j:end,j),1)*droptol`. `'droptol'` is ignored if `'type'` is `'nofill'`. The default value is `0`.
`michol`	Indicates whether to perform modified incomplete Cholesky	Indicates whether or not *modified incomplete Cholesky* (MIC) is performed. The field may be `'on'` or `'off'`. When performing MIC, the diagonal is compensated for dropped elements to enforce the relationship `A*e = L*L'*e` where `e = ones(size(A,2),1)`. The default value is `'off'`.
`diagcomp`	Perform compensated incomplete Cholesky with the specified coefficient	Real nonnegative scalar used as a global diagonal shift `alpha` in forming the incomplete Cholesky factor. That is, instead of performing incomplete Cholesky on `A`, the factorization of `A + alpha*diag(diag(A))` is formed. The default value is `0`.

Field Name	Summary	Description
`shape`	Determines which triangle is referenced and returned	Valid values are `'upper'` and `'lower'`. If `'upper'` is specified, only the upper triangle of `A` is referenced and `R` is constructed such that `A` is approximated by `R'*R`. If `'lower'` is specified, only the lower triangle of `A` is referenced and `L` is constructed such that `A` is approximated by `L*L'`. The default value is `'lower'`.

Examples

Incomplete Cholesky Factorization

This example generates an incomplete Cholesky factorization.

Start with a symmetric positive definite matrix, `A`:

```
N = 100;
A = delsq(numgrid('S',N));
```

`A` is the two-dimensional, five-point discrete negative Laplacian on a 100-by-100 square grid with Dirichlet boundary conditions. The size of `A` is `98*98 = 9604` (not 10000 as the borders of the grid are used to impose the Dirichlet conditions).

The no-fill incomplete Cholesky factorization is a factorization which contains only nonzeros in the same position as `A` contains nonzeros. This factorization is extremely cheap to compute. Although the product `L*L'` is typically very different from `A`, the product `L*L'` will match `A` on its pattern up to round-off.

```
L = ichol(A);
norm(A-L*L','fro')./norm(A,'fro')
```

```
ans =

    0.0916
```

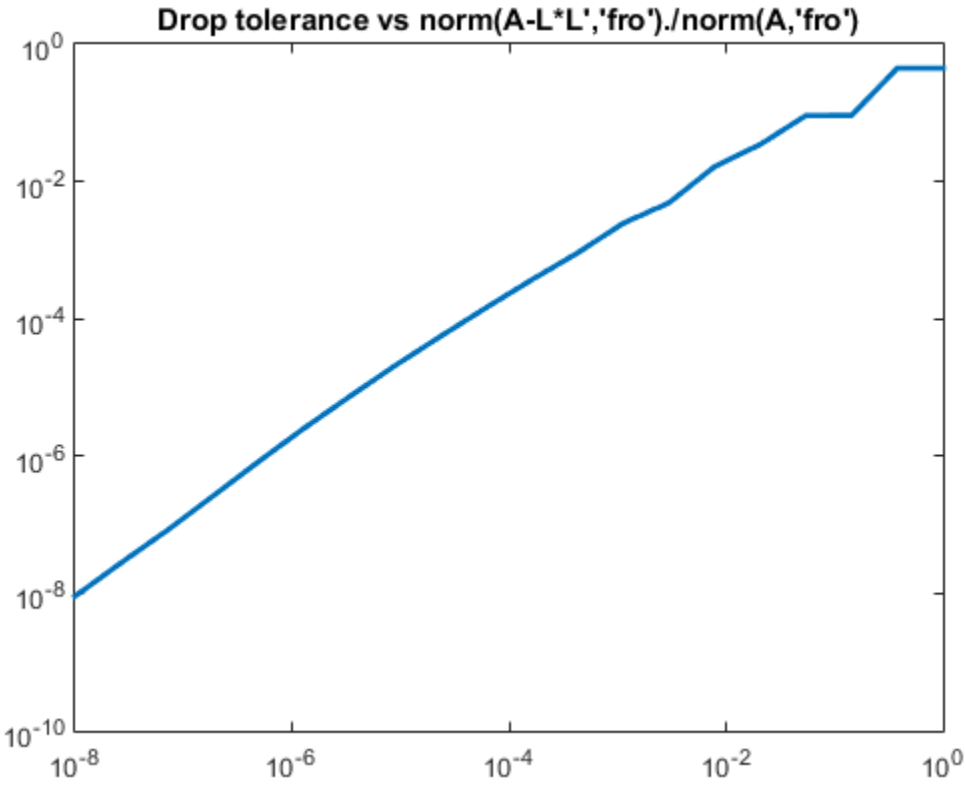
```
norm(A-(L*L').*spones(A),'fro')./norm(A,'fro')
```

```
ans =

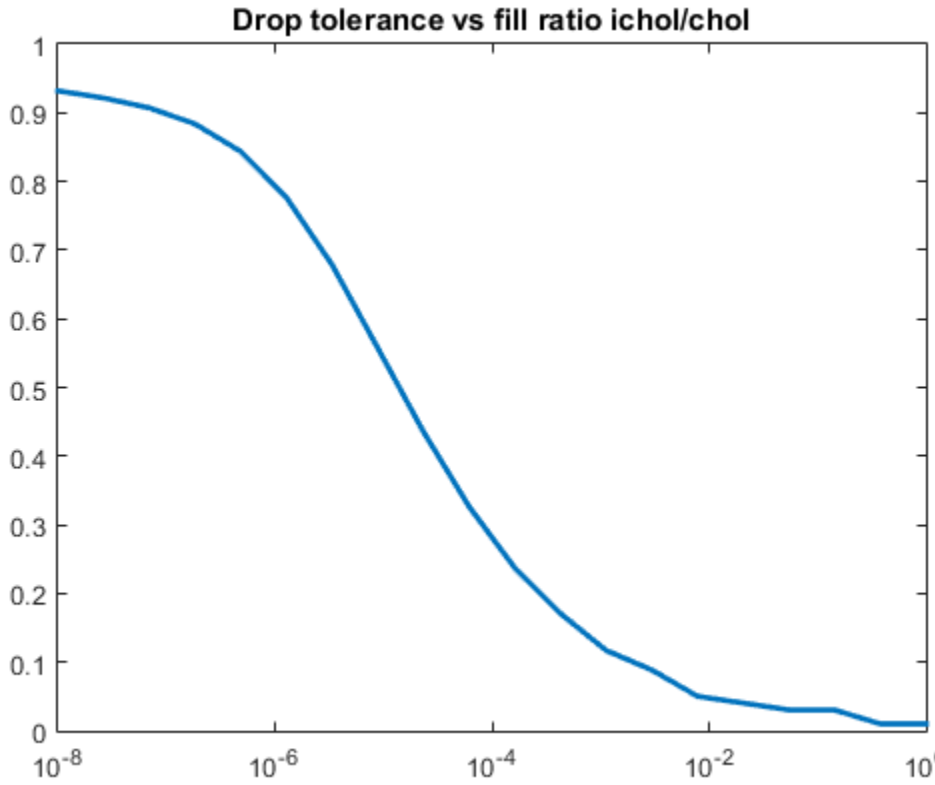
   4.9606e-17
```

`ichol` may also be used to generate incomplete Cholesky factorizations with threshold dropping. As the drop tolerance decreases, the factor tends to get more dense and the product `L*L'` tends to be a better approximation of `A`. The following plots show the relative error of the incomplete factorization plotted against the drop tolerance as well as the ratio of the density of the incomplete factors to the density of the complete Cholesky factor.

```
n = size(A,1);
ntols = 20;
droptol = logspace(-8,0,ntols);
nrm = zeros(1,ntols);
nz = zeros(1,ntols);
nzComplete = nnz(chol(A,'lower'));
for k = 1:ntols
    L = ichol(A,struct('type','ict','droptol',droptol(k)));
    nz(k) = nnz(L);
    nrm(k) = norm(A-L*L','fro')./norm(A,'fro');
end
figure
loglog(droptol,nrm,'LineWidth',2)
title('Drop tolerance vs norm(A-L*L'',''fro'')./norm(A,''fro'')')
figure
semilogx(droptol,nz./nzComplete,'LineWidth',2)
title('Drop tolerance vs fill ratio ichol/chol')
```



Drop tolerance vs norm(A-L*L','fro')./norm(A,'fro')
10^0
10^-2
10^-4
10^-6
10^-8
10^-10
10^-8
10^-6
10^-4
10^-2
10^0



The relative error is typically on the same order as the drop tolerance, although this is not guaranteed.

Using ichol as a Preconditioner

This example shows how to use an incomplete Cholesky factorization as a preconditioner to improve convergence.

Create a symmetric positive definite matrix, A.

```
N = 100;
A = delsq(numgrid('S',N));
```

Create an incomplete Cholesky factorization as a preconditioner for `pcg`. Use a constant vector as the right hand side. As a baseline, execute `pcg` without a preconditioner.

```
b = ones(size(A,1),1);
tol = 1e-6;
maxit = 100;
[x0,fl0,rr0,it0,rv0] = pcg(A,b,tol,maxit);
```

Note that `fl0 = 1` indicating that `pcg` did not drive the relative residual to the requested tolerance in the maximum allowed iterations. Try the no-fill incomplete Cholesky factorization as a preconditioner.

```
L1 = ichol(A);
[x1,fl1,rr1,it1,rv1] = pcg(A,b,tol,maxit,L1,L1');
```

`fl1 = 0`, indicating that `pcg` converged to the requested tolerance and did so in 59 iterations (the value of `it1`). Since this matrix is a discretized Laplacian, however, using modified incomplete Cholesky can create a better preconditioner. A modified incomplete Cholesky factorization constructs an approximate factorization that preserves the action of the operator on the constant vector. That is, `norm(A*e-L*(L'*e))` will be approximately zero for `e = ones(size(A,2),1)` even though `norm(A-L*L','fro')/norm(A,'fro')` is not close to zero. It is not necessary to specify type for this syntax since `nofill` is the default, but it is good practice.

```
opts.type = 'nofill';
opts.michol = 'on';
L2 = ichol(A,opts);
e = ones(size(A,2),1);
norm(A*e-L2*(L2'*e))
[x2,fl2,rr2,it2,rv2] = pcg(A,b,tol,maxit,L2,L2');
```

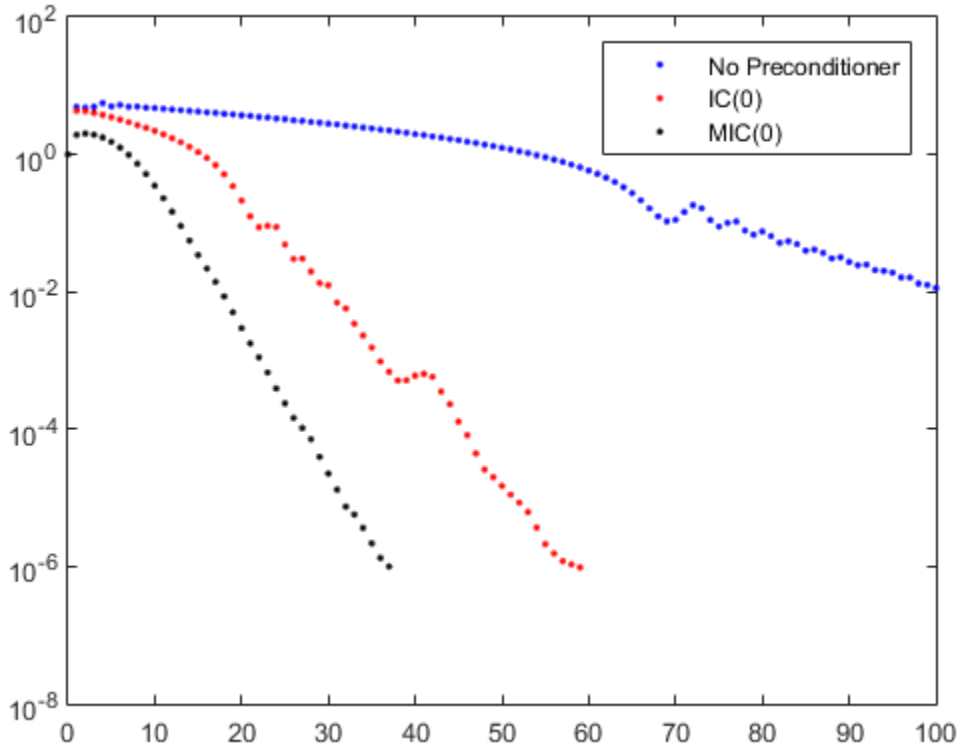
```
ans =

   3.7983e-14
```

`pcg` converges (`fl2 = 0`) but in only 38 iterations. Plotting all three convergence histories shows the convergence.

```
semilogy(0:maxit,rv0./norm(b),'b.');
hold on
semilogy(0:it1,rv1./norm(b),'r.');
semilogy(0:it2,rv2./norm(b),'k.');
```

```
legend('No Preconditioner','IC(0)','MIC(0)');
```



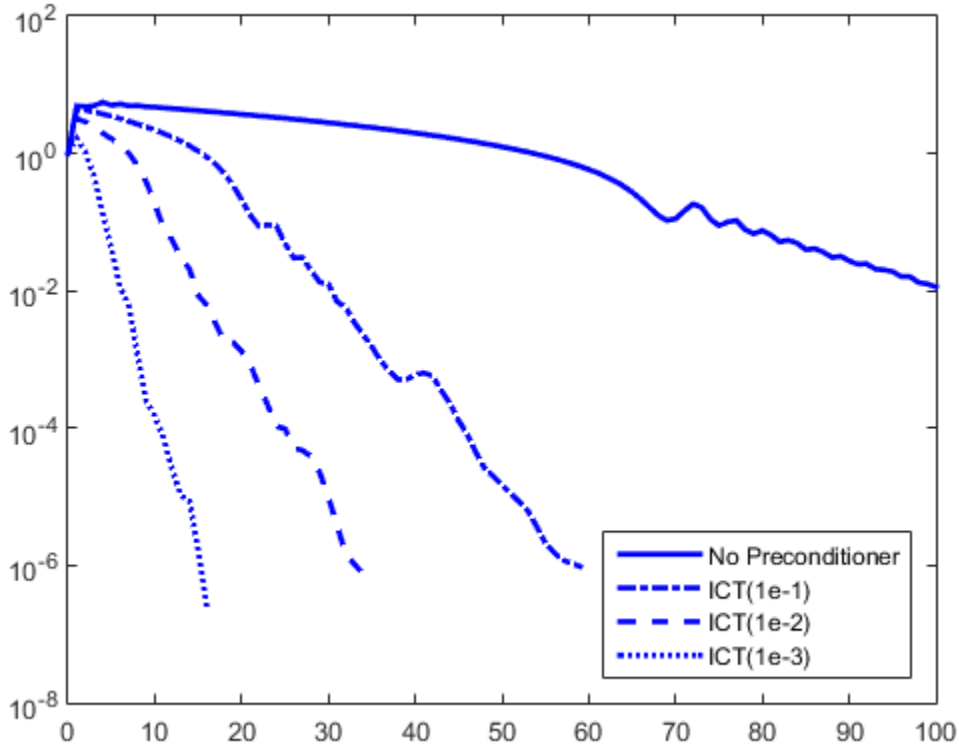
The plot shows that the modified incomplete Cholesky preconditioner creates a much faster convergence.

You can also try incomplete Cholesky factorizations with threshold dropping. The following plot shows convergence of `pcg` with preconditioners constructed with various drop tolerances.

```
L3 = ichol(A, struct('type','ict','droptol',1e-1));
[x3,fl3,rr3,it3,rv3] = pcg(A,b,tol,maxit,L3,L3');
L4 = ichol(A, struct('type','ict','droptol',1e-2));
[x4,fl4,rr4,it4,rv4] = pcg(A,b,tol,maxit,L4,L4');
```

```
L5 = ichol(A, struct('type','ict','droptol',1e-3));
[x5,fl5,rr5,it5,rv5] = pcg(A,b,tol,maxit,L5,L5');

figure
semilogy(0:maxit,rv0./norm(b),'b-','linewidth',2);
hold on
semilogy(0:it3,rv3./norm(b),'b-.','linewidth',2);
semilogy(0:it4,rv4./norm(b),'b--','linewidth',2);
semilogy(0:it5,rv5./norm(b),'b:','linewidth',2);
legend('No Preconditioner','ICT(1e-1)','ICT(1e-2)', ...
   'ICT(1e-3)','Location','SouthEast');
```



Note the incomplete Cholesky preconditioner constructed with drop tolerance `1e-2` is denoted as `ICT(1e-2)`.

As with the zero-fill incomplete Cholesky, the threshold dropping factorization can benefit from modification (i.e. `opts.michol = 'on'`) since the matrix arises from an elliptic partial differential equation. As with `MIC(0)`, the modified threshold based dropping incomplete Cholesky will preserve the action of the preconditioner on constant vectors, that is `norm(A*e-L*(L'*e))` will be approximately zero.

Using the diagcomp Option

This example illustrates the use of the `diagcomp` option of `ichol`.

Incomplete Cholesky factorizations of positive definite matrices do not always exist. The following code constructs a random symmetric positive definite matrix and attempts to solve a linear system using `pcg`.

```
S = rng('default');
A = sprandsym(1000,1e-2,1e-4,1);
rng(S);
b = full(sum(A,2));
[x0,fl0,rr0,it0,rv0] = pcg(A,b,1e-6,100);
```

Since convergence is not attained, try to construct an incomplete Cholesky preconditioner.

```
L = ichol(A,struct('type','ict','droptol',1e-3));
```

```
Error using ichol
Encountered nonpositive pivot.
```

If `ichol` breaks down as above, you can use the `diagcomp` option to construct a shifted incomplete Cholesky factorization. That is, instead of constructing `L` such that `L*L'` approximates `A`, `ichol` with diagonal compensation constructs `L` such that `L*L'` approximates `M = A + alpha*diag(diag(A))` without explicitly forming `M`. As incomplete factorizations always exist for diagonally dominant matrices, `alpha` can be found to make `M` diagonally dominant.

```
alpha = max(sum(abs(A),2)./diag(A))-2
```

```
alpha =

   62.9341
```

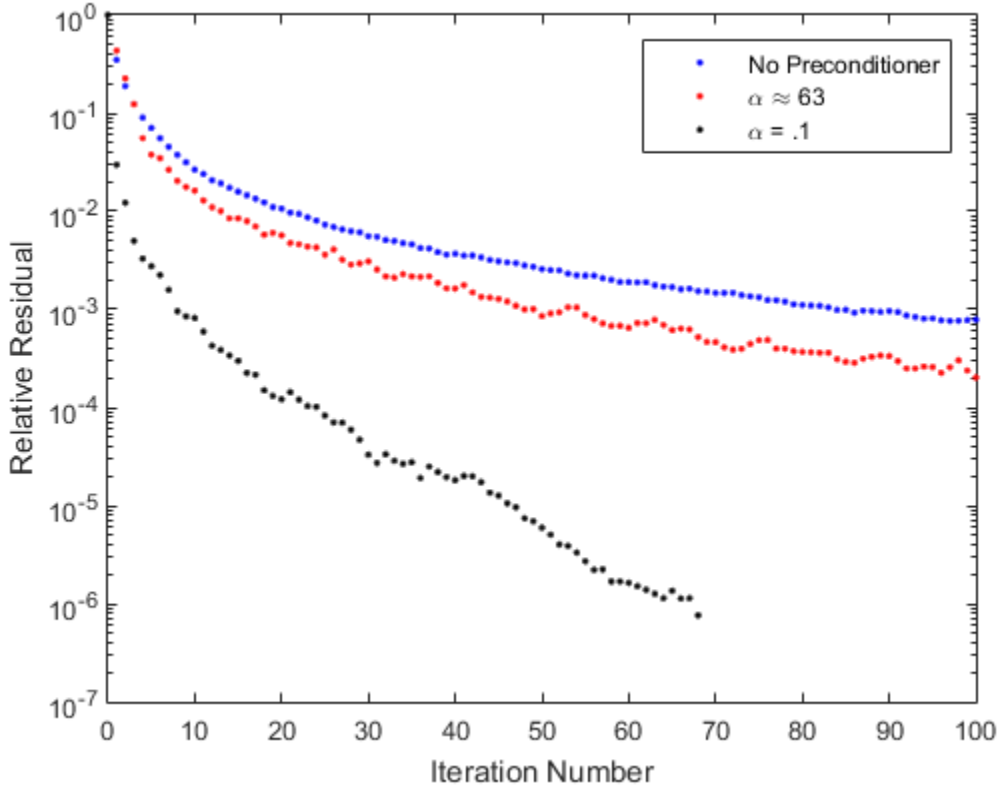
```
L1 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x1,fl1,rr1,it1,rv1] = pcg(A,b,1e-6,100,L1,L1');
```

Here, `pcg` still fails to converge to the desired tolerance within the desired number of iterations, but as the plot below shows, convergence is better for `pcg` with this preconditioner than with no preconditioner. Choosing a smaller `alpha` may help. With some experimentation, we can settle on an appropriate value for `alpha`.

```
alpha = .1;
L2 = ichol(A, struct('type','ict','droptol',1e-3,'diagcomp',alpha));
[x2,fl2,rr2,it2,rv2] = pcg(A,b,1e-6,100,L2,L2');
```

Now, `pcg` converges and a plot can show the convergence histories with each preconditioner.

```
semilogy(0:100,rv0./norm(b),'b.');
hold on;
semilogy(0:100,rv1./norm(b),'r.');
semilogy(0:it2,rv2./norm(b),'k.');
legend('No Preconditioner','\alpha \approx 63','\alpha = .1');
xlabel('Iteration Number');
ylabel('Relative Residual');
```



More About

Tips

- The factor given by this routine may be useful as a preconditioner for a system of linear equations being solved by iterative methods such as `pcg` or `minres`.
- `ichol` works only for sparse square matrices

idivide

Integer division with rounding option

Syntax

```
C = idivide(A, B, opt)
C = idivide(A, B)
C = idivide(A, B, 'fix')
C = idivide(A, B, 'round')
C = idivide(A, B, 'floor')
C = idivide(A, B, 'ceil')
```

Description

`C = idivide(A, B, opt)` is the same as `A./B` for integer classes except that fractional quotients are rounded to integers using the optional rounding mode specified by `opt`. The default rounding mode is `'fix'`. Inputs `A` and `B` must be real and must have the same dimensions unless one is a scalar. The arguments `A` and `B` must belong to the same integer class. Alternatively, one of the arguments can be a scalar double, while the other can be any integer type except `int64` or `uint64`. The result `C` belongs to the integer class of the input arguments.

`C = idivide(A, B)` is the same as `A./B` except that fractional quotients are rounded toward zero to the nearest integers.

`C = idivide(A, B, 'fix')` is the same as the syntax shown immediately above.

`C = idivide(A, B, 'round')` is the same as `A./B` for integer classes. Fractional quotients are rounded to the nearest integers.

`C = idivide(A, B, 'floor')` is the same as `A./B` except that fractional quotients are rounded toward negative infinity to the nearest integers.

`C = idivide(A, B, 'ceil')` is the same as `A./B` except that the fractional quotients are rounded toward infinity to the nearest integers.

Examples

```
a = int32([-2 2]);
b = int32(3);

idivide(a,b)             % Returns [0 0]
idivide(a,b,'floor')     % Returns [-1 0]
idivide(a,b,'ceil')      % Returns [0 1]
idivide(a,b,'round')     % Returns [-1 1]
```

if, elseif, else

Execute statements if condition is true

Syntax

```
if expression
    statements
elseif expression
    statements
else
    statements
end
```

Description

`if` *`expression`*`, `*`statements`*`, end` evaluates an expression, and executes a group of statements when the expression is true. An expression is true when its result is nonempty and contains only nonzero elements (logical or real numeric). Otherwise, the expression is false.

The `elseif` and `else` blocks are optional. The statements execute only if previous expressions in the `if...end` block are false. An `if` block can include multiple `elseif` blocks.

Examples

Use if, elseif, and else for Conditional Assignment

Create a matrix of 1s.

```
nrows = 4;
ncols = 6;
A = ones(nrows,ncols);
```

Loop through the matrix and assign each element a new value. Assign `2` on the main diagonal, `-1` on the adjacent diagonals, and `0` everywhere else.

```
for c = 1:ncols
```

```
    for r = 1:nrows

        if r == c
            A(r,c) = 2;
        elseif abs(r-c) == 1
            A(r,c) = -1;
        else
            A(r,c) = 0;
        end

    end
end
A
```

```
A =

     2    -1     0     0     0     0
    -1     2    -1     0     0     0
     0    -1     2    -1     0     0
     0     0    -1     2    -1     0
```

Compare Arrays

Expressions that include relational operators on arrays, such as `A > 0`, are true only when every element in the result is nonzero.

Test if any results are true using the `any` function.

```
limit = 0.75;
A = rand(10,1)
```

```
A =

    0.8147
    0.9058
    0.1270
    0.9134
    0.6324
    0.0975
    0.2785
    0.5469
    0.9575
```

```
    0.9649
```

```
if any(A > limit)
    disp('There is at least one value above the limit.')
else
    disp('All values are below the limit.')
end
```

```
There is at least one value above the limit.
```

Test Arrays for Equality

Compare arrays using `isequal` rather than the `==` operator to test for equality, because `==` results in an error when the arrays are different sizes.

Create two arrays.

```
A = ones(2,3);
B = rand(3,4,5);
```

If `size(A)` and `size(B)` are the same, concatenate the arrays; otherwise, display a warning and return an empty array.

```
if isequal(size(A),size(B))
   C = [A; B];
else
   disp('A and B are not the same size.')
   C = [];
end
```

```
A and B are not the same size.
```

Determine if Strings Match

Use `strcmp` to compare strings. Using `==` to test for equality results in an error when the strings are different sizes.

```
reply = input('Would you like to see an echo? (y/n): ','s');
if strcmp(reply,'y')
  disp(reply)
end
```

Evaluate Multiple Conditions in Expression

Determine if a value falls within a specified range.

```
x = 10;
minVal = 2;
maxVal = 6;

if (x >= minVal) && (x <= maxVal)
    disp('Value within specified range.')
elseif (x > maxVal)
    disp('Value exceeds maximum value.')
else
    disp('Value is below minimum value.')
end
```

```
Value exceeds maximum value.
```

More About

Expression

An expression can include relational operators (such as < or ==) and logical operators (such as &&, ||, or ~). Use the logical operators `and` and `or` to create compound expressions. MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

Within the conditional expression of an `if...end` block, logical operators & and | behave as short-circuit operators. This behavior is the same as && and ||, respectively. Since && and || consistently short-circuit in conditional expressions and statements, it is good practice to use && and || instead of & and | within the expression. For example,

```
x = 42;
if exist('myfunction.m','file') && (myfunction(x) >= pi)
    disp('Expressions are true')
end
```

The first part of the expression evaluates to false. Therefore, MATLAB does not need to evaluate the second part of the expression, which would result in an undefined function error.

Tips

- You can nest any number of `if` statements. Each `if` statement requires an `end` keyword.

- Avoid adding a space after `else` within the `elseif` keyword (`else if`). The space creates a nested `if` statement that requires its own `end` keyword.

ifft

Inverse fast Fourier transform

Syntax

```
y = ifft(X)
y = ifft(X,n)
y = ifft(X,[],dim)
y = ifft(X,n,dim)
y = ifft(..., 'symmetric')
y = ifft(..., 'nonsymmetric')
```

Description

`y = ifft(X)` returns the inverse discrete Fourier transform (DFT) of vector `X`, computed with a fast Fourier transform (FFT) algorithm. If `X` is a matrix, `ifft` returns the inverse DFT of each column of the matrix.

`ifft` tests `X` to see whether vectors in `X` along the active dimension are *conjugate symmetric*. If so, the computation is faster and the output is real. An `N`-element vector `x` is conjugate symmetric if `x(i) = conj(x(mod(N-i+1,N)+1))` for each element of `x`.

If `X` is a multidimensional array, `ifft` operates on the first non-singleton dimension.

`y = ifft(X,n)` returns the `n`-point inverse DFT of vector `X`.

`y = ifft(X,[],dim)` and `y = ifft(X,n,dim)` return the inverse DFT of `X` across the dimension `dim`.

`y = ifft(..., 'symmetric')` causes `ifft` to treat `X` as conjugate symmetric along the active dimension. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft(..., 'nonsymmetric')` is the same as calling `ifft(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft(fft(X))` equals `X` to within roundoff error.

Data Type Support

`ifft` supports inputs of data types `double` and `single`. If you call `ifft` with the syntax `y = ifft(X, ...)`, the output `y` has the same data type as the input `X`.

More About

Algorithms

The algorithm for `ifft(X)` is the same as the algorithm for `fft(X)`, except for a sign change and a scale factor of `n = length(X)`. As for `fft`, the execution time for `ifft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `ifft` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

`fft` | `fft2` | `ifft2` | `ifftn` | `ifftshift` | `fftw`

Introduced before R2006a

ifft2

2-D inverse fast Fourier transform

Syntax

```
Y = ifft2(X)
Y = ifft2(X,m,n)
y = ifft2(..., 'symmetric')
y = ifft2(..., 'nonsymmetric')
```

Description

`Y = ifft2(X)` returns the two-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifft2` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `M`-by-`N` matrix `X` is conjugate symmetric if `X(i,j) = conj(X(mod(M-i+1, M) + 1, mod(N-j+1, N) + 1))` for each element of `X`.

`Y = ifft2(X,m,n)` returns the `m`-by-`n` inverse fast Fourier transform of matrix `X`.

`y = ifft2(..., 'symmetric')` causes `ifft2` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft2(..., 'nonsymmetric')` is the same as calling `ifft2(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft2(fft2(X))` equals `X` to within roundoff error.

Data Type Support

`ifft2` supports inputs of data types `double` and `single`. If you call `ifft2` with the syntax `y = ifft2(X, ...)`, the output `y` has the same data type as the input `X`.

More About

Algorithms

The algorithm for `ifft2(X)` is the same as the algorithm for `fft2(X)`, except for a sign change and scale factors of `[m,n] = size(X)`. The execution time for `ifft2` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `ifft2` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

Introduced before R2006a

ifftn

N-D inverse fast Fourier transform

Syntax

```
Y = ifftn(X)
Y = ifftn(X,siz)
y = ifftn(..., 'symmetric')
y = ifftn(..., 'nonsymmetric')
```

Description

`Y = ifftn(X)` returns the n-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifftn` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `N1`-by-`N2`-by- ... `Nk` array `X` is conjugate symmetric if

```
X(i1,i2, ...,ik) = conj(X(mod(N1-i1+1,N1)+1, mod(N2-i2+1,N2)+1,
... mod(Nk-ik+1,Nk)+1))
```

for each element of `X`.

`Y = ifftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the inverse transform. The size of the result `Y` is `siz`.

`y = ifftn(..., 'symmetric')` causes `ifftn` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifftn(..., 'nonsymmetric')` is the same as calling `ifftn(...)` without the argument `'nonsymmetric'`.

Data Type Support

`ifftn` supports inputs of data types `double` and `single`. If you call `ifftn` with the syntax `y = ifftn(X, ...)`, the output `y` has the same data type as the input `X`.

More About

Tips

For any `X`, `ifftn(fftn(X))` equals `X` within roundoff error.

Algorithms

`ifftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
    Y = ifft(Y,[],p);
end
```

This computes in-place the one-dimensional inverse DFT along each dimension of `X`.

The execution time for `ifftn` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `ifftn` using the utility function `fftw`, which controls how MATLAB software optimizes the algorithm used to compute an FFT of a particular size and dimension.

Introduced before R2006a

ifftshift

Inverse FFT shift

Syntax

```
ifftshift(X)
ifftshift(X,dim)
```

Description

`ifftshift(X)` swaps the left and right halves of the vector `X`. For matrices, `ifftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth. If `X` is a multidimensional array, `ifftshift(X)` swaps "half-spaces" of `X` along each dimension.

`ifftshift(X,dim)` applies the `ifftshift` operation along the dimension `dim`.

Note: `ifftshift` undoes the results of `fftshift`. If the matrix `X` contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original `X`. Simply performing `fftshift(X)` twice will not produce `X`.

ilu

Sparse incomplete LU factorization

Syntax

```
ilu(A,setup)
[L,U] = ilu(A,setup)
[L,U,P] = ilu(A,setup)
```

Description

`ilu` produces a unit lower triangular matrix, an upper triangular matrix, and a permutation matrix.

`ilu(A,setup)` computes the incomplete LU factorization of `A`. `setup` is an input structure with up to five setup options. The fields must be named exactly as shown in the table below. You can include any number of these fields in the structure and define them in any order. Any additional fields are ignored.

Field Name	Description
`type`	Type of factorization. Values for `type` include: • `'nofill'`(default)—Performs ILU factorization with `0` level of fill in, known as ILU(0). With `type` set to `'nofill'`, only the `milu` setup option is used; all other fields are ignored. • `'crout'`—Performs the Crout version of ILU factorization, known as ILUC. With `type` set to `'crout'`, only the `droptol` and `milu` setup options are used; all other fields are ignored. • `'ilutp'` —Performs ILU factorization with threshold and pivoting. If `type` is not specified, the ILU factorization with `0` level of fill in is performed. Pivoting is only performed with `type` set to `'ilutp'`.
`droptol`	Drop tolerance of the incomplete LU factorization. `droptol` is a non-negative scalar. The default value is `0`, which produces the complete LU factorization.

Field Name	Description

	The nonzero entries of `U` satisfy
	`abs(U(i,j)) >= droptol*norm(A(:,j)),`
	with the exception of the diagonal entries, which are retained regardless of satisfying the criterion. The entries of `L` are tested against the local drop tolerance before being scaled by the pivot, so for nonzeros in `L`
	`abs(L(i,j)) >= droptol*norm(A(:,j))/U(j,j).`

`milu`	Modified incomplete LU factorization. Values for `milu` include: • `'row'`—Produces the row-sum modified incomplete LU factorization. Entries from the newly-formed column of the factors are subtracted from the diagonal of the upper triangular factor, `U`, preserving column sums. That is, `A*e = L*U*e`, where `e` is the vector of ones. • `'col'`—Produces the column-sum modified incomplete LU factorization. Entries from the newly-formed column of the factors are subtracted from the diagonal of the upper triangular factor, `U`, preserving column sums. That is, `e'*A = e'*L*U`. • `'off'` (default)—No modified incomplete LU factorization is produced.
`udiag`	If `udiag` is `1`, any zeros on the diagonal of the upper triangular factor are replaced by the local drop tolerance. The default is `0`.
`thresh`	Pivot threshold between `0` (forces diagonal pivoting) and `1`, the default, which always chooses the maximum magnitude entry in the column to be the pivot.

`ilu(A,setup)` returns `L+U-speye(size(A))`, where `L` is a unit lower triangular matrix and `U` is an upper triangular matrix.

`[L,U] = ilu(A,setup)` returns a unit lower triangular matrix in `L` and an upper triangular matrix in `U`.

`[L,U,P] = ilu(A,setup)` returns a unit lower triangular matrix in `L`, an upper triangular matrix in `U`, and a permutation matrix in `P`.

Limitations

`ilu` works on sparse square matrices only.

Examples

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'crout';
setup.milu = 'row';
setup.droptol = 0.1;
[L,U] = ilu(A,setup);
e = ones(size(A,2),1);
norm(A*e-L*U*e)

ans =

  1.4251e-014
```

This shows that `A` and `L*U`, where `L` and `U` are given by the modified Crout `ILU`, have the same row-sum.

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'nofill';
nnz(A)
ans =

        7840

nnz(lu(A))
ans =

      126478

nnz(ilu(A,setup))
ans =

        7840
```

This shows that A has 7840 nonzeros, the complete LU factorization has 126478 nonzeros, and the incomplete LU factorization, with 0 level of fill-in, has 7840 nonzeros, the same amount as A.

More About

Tips

These incomplete factorizations may be useful as preconditioners for a system of linear equations being solved by iterative methods such as BICG (BiConjugate Gradients), GMRES (Generalized Minimum Residual Method).

im2double

Convert image to double precision

Syntax

```
I2 = im2double(I)
I2 = im2double(I,'indexed')
```

Description

`I2 = im2double(I)` converts the intensity image `I` to double precision, rescaling the data if necessary. `I` can be a grayscale intensity image, a truecolor image, or a binary image.

If the input image is of class `double`, then the output image is identical.

`I2 = im2double(I,'indexed')` converts the indexed image `I` to double precision, offsetting the data if necessary.

Examples

Convert Image to Double Precision

```
I = imread('peppers.png');
whos I
```

```
  Name        Size                Bytes  Class    Attributes

  I         384x512x3            589824  uint8
```

```
I2 = im2double(I);
whos I2
```

```
  Name        Size                Bytes  Class     Attributes

  I2        384x512x3            4718592  double
```

Convert Image to Double Precision on GPU

Convert an array to class `double` on the GPU. This example requires the Parallel Computing Toolbox.

```
I1 = gpuArray(reshape(uint8(linspace(1,255,25)),[5 5]));
I2 = im2double(I1);
```

Input Arguments

`I` — Input image

scalar | vector | matrix | multidimensional array

Input image, specified as a scalar, vector, matrix, or multidimensional array.

- If `I` is an intensity or truecolor image, it can be `uint8`, `uint16`, `double`, `logical`, `single`, or `int16`.
- If `I` is an indexed image, it can be `uint8`, `uint16`, `double` or `logical`.
- If `I` is a binary image, it must be `logical`.

If the Parallel Computing Toolbox is installed, `I` can be a gpuArray and `im2double` converts `I` on a GPU.

Data Types: `single` | `double` | `int16` | `uint8` | `uint16` | `logical`

More About

Tips

- `im2double` supports the generation of efficient, production-quality C/C++ code if you have MATLAB Coder™ installed.

See Also

`double` | `gpuArray` | `im2int16` | `im2single` | `im2uint16` | `im2uint8`

im2frame

Convert image to movie frame

Syntax

```
f = im2frame(X,map)
f = im2frame(X)
```

Description

`f = im2frame(X,map)` converts the indexed image, `X`, and the associated colormap, `map`, into a movie frame `f`.

- If you specify `X` as an m-by-n array of integers, then `im2frame` uses the associated colormap, `map`, where `map` is a three-column array of values in the range [0,1]. Each row of `map` is a three-element RGB triplet that specifies the red, green, and blue components of a single color of the colormap.
- If you specify `X` as an m-by-n-by-3 truecolor image, then `map` is optional and has no effect.

`f = im2frame(X)` converts the indexed image, `X`, into a movie frame `f` using the current colormap if `X` contains an indexed image.

For more information on image types, see "Image Types".

Class Support

`X` must be of class `uint8` or `double`.

Examples

Convert Image Sequence to Movie

Use `im2frame` to convert a sequence of images into a movie.

```
F(1) = im2frame(X1,map);
F(2) = im2frame(X2,map);
 ...
F(n) = im2frame(Xn,map);
movie(F)
```

im2java

Convert image to Java image

Syntax

```
jimage = im2java(I)
jimage = im2java(X,MAP)
jimage = im2java(RGB)
```

Description

To work with a MATLAB image in the Java environment, you must convert the image from its MATLAB representation into an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(I)` converts the intensity image `I` to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(X,MAP)` converts the indexed image `X`, with colormap `MAP`, to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(RGB)` converts the RGB image `RGB` to an instance of the Java image class, `java.awt.Image`.

Class Support

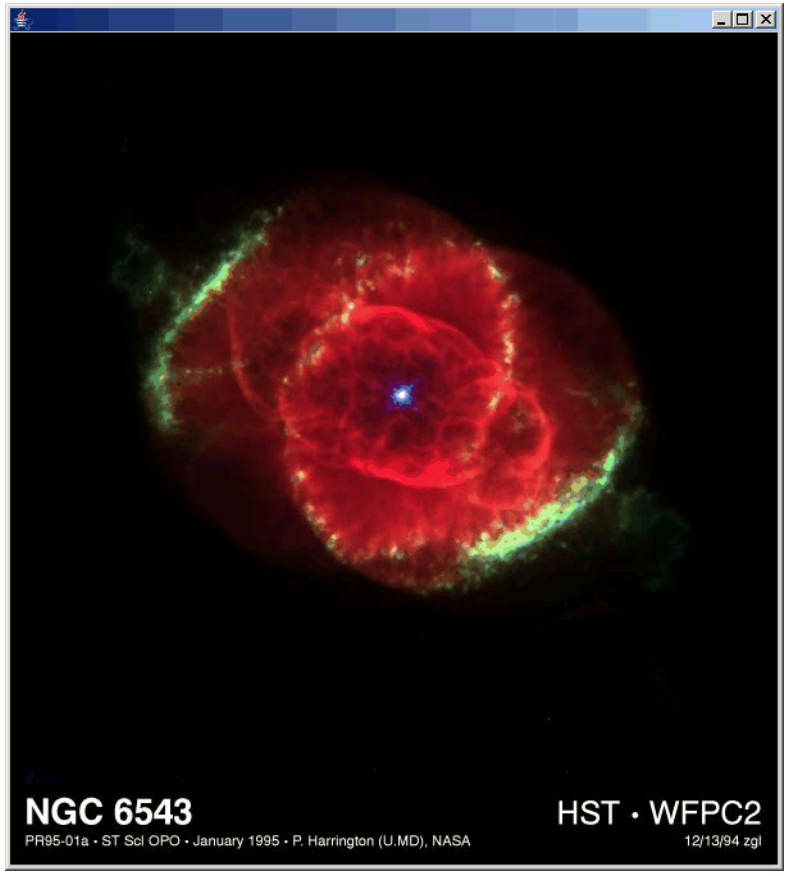
The input image can be of class `uint8`, `uint16`, or `double`.

Note Java requires `uint8` data to create an instance of the Java image class, `java.awt.Image`. If the input image is of class `uint8`, `jimage` contains the same `uint8` data. If the input image is of class `double` or `uint16`, `im2java` makes an equivalent image of class `uint8`, rescaling or offsetting the data as necessary, and then converts this `uint8` representation to an instance of the Java image class, `java.awt.Image`.

Examples

This example reads an image into the MATLAB workspace and then uses `im2java` to convert it into an instance of the Java image class.

```
I = imread('ngc6543a.jpg');
javaImage = im2java(I);
frame = javax.swing.JFrame;
icon = javax.swing.ImageIcon(javaImage);
label = javax.swing.JLabel(icon);
frame.getContentPane.add(label);
frame.pack
frame.show
```



Introduced before R2006a

imag

Imaginary part of complex number

Syntax

```
Y = imag(Z)
```

Description

`Y = imag(Z)` returns the imaginary part of the elements of array `Z`.

Examples

```
imag(2+3i)

ans =

    3
```

See Also

`conj` | `i` | `j` | `real`

Introduced before R2006a

image

Display image from array

Syntax

```
image(C)
image(x,y,C)
image('CData',C)
image('XData',x,'YData',y,'CData',C)

image(___,Name,Value)

im = image(___)
```

Description

`image(C)` displays the data in array C as an image. Each element of C specifies the color for one pixel of the image. The resulting image is an `m`-by-`n` grid of pixels where `m` is the number of columns and `n` is the number of rows in `C`. The row and column indices of the elements determine the centers of the corresponding pixels.

`image(x,y,C)` specifies the image location. Use `x` and `y` to specify the locations of the corners corresponding to `C(1,1)` and `C(m,n)`. To specify both corners, set `x` and `y` as two-element vectors. To specify the first corner and let `image` determine the other, set `x` and `y` as scalar values. The image is stretched and oriented as applicable.

`image('CData',C)` adds the image to the current axes without replacing existing plots. This syntax is the low-level version of `image(C)`. For more information, see "High-Level Versus Low-Level Version of Image" on page 1-3811.

`image('XData',x,'YData',y,'CData',C)` specifies the image location. This syntax is the low-level version of `image(x,y,C)`.

`image(___,Name,Value)` specifies image properties using one or more name-value pair arguments. You can specify image properties with any of the input argument combinations in the previous syntaxes.

`im = image(___)` returns the image object created. Use `im` to set properties of the image after it is created. You can specify this output with any of the input argument

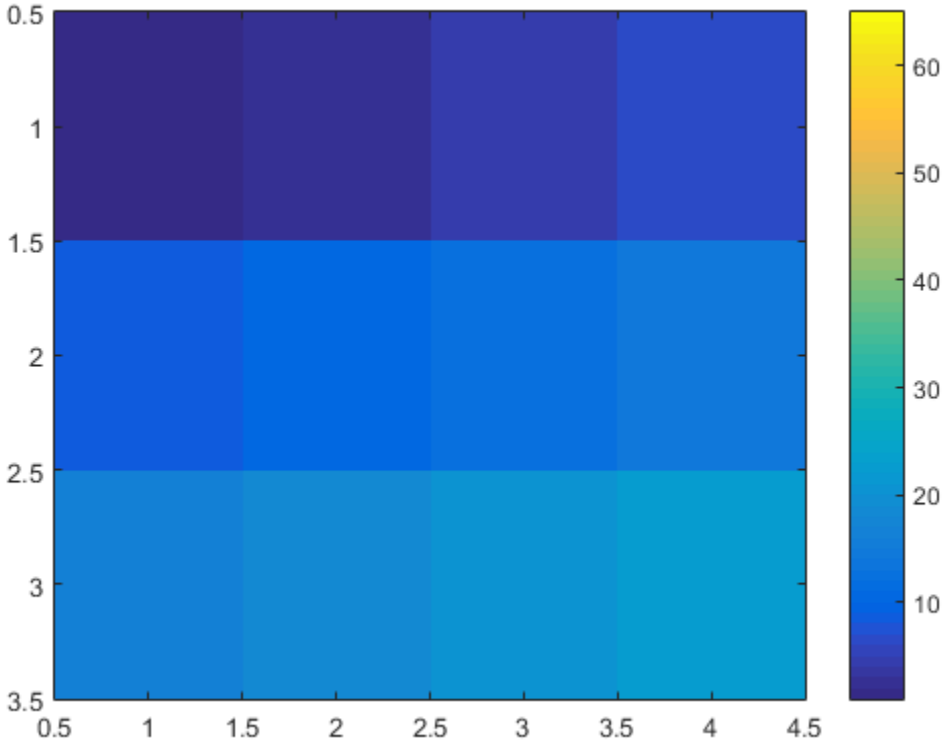
combinations in the previous syntaxes. For a list of image properties and descriptions, see Image Properties.

Examples

Display Image of Matrix Data

Create matrix `C`. Display an image of the data in `C`. Add a colorbar to the graph to show the current colormap.

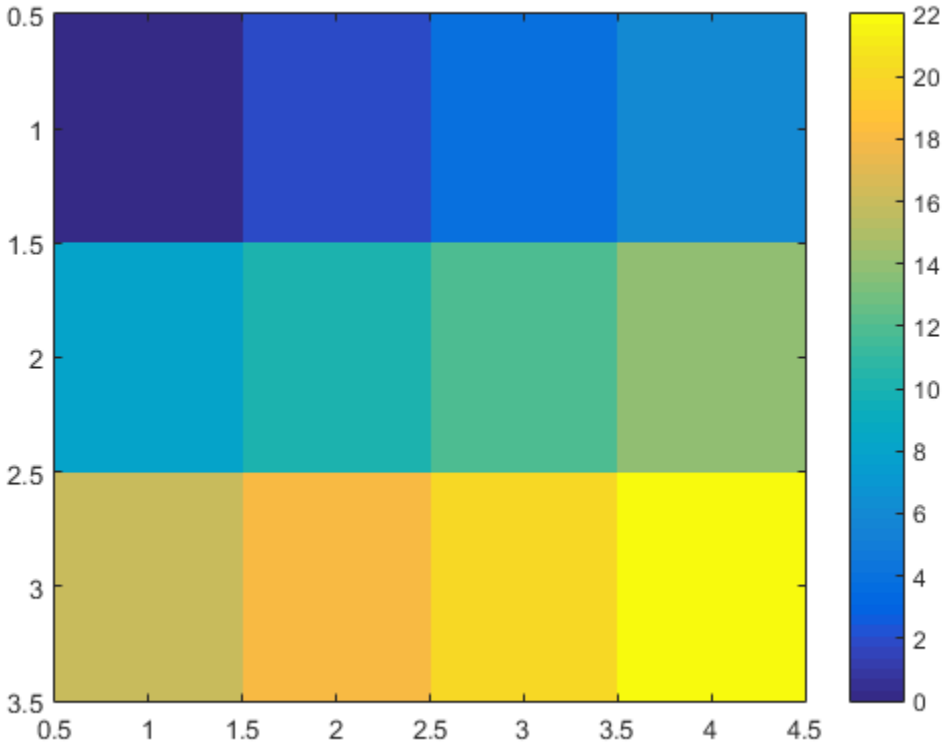
```
C = [0 2 4 6; 8 10 12 14; 16 18 20 22];
image(C)
colorbar
```



By default, the `CDataMapping` property for the image is set to `'direct'` so `image` interprets values in `C` as indices into the colormap. For example, the bottom right pixel corresponding to the last element in `C`, 22, uses the 22nd color of the colormap.

Scale the values to the full range of the current colormap by setting the `CDataMapping` property to `'scaled'` when creating the image.

```
image(C,'CDataMapping','scaled')
colorbar
```

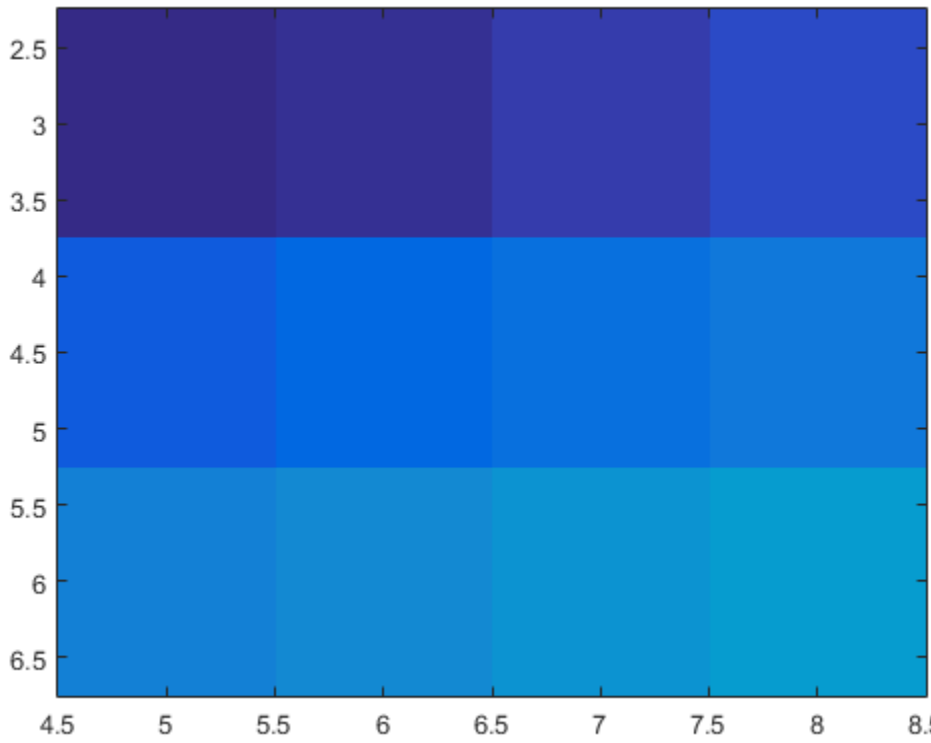


Alternatively, you can use the `imagesc` function to scale the values instead of using `image(C,'CDataMapping','scaled')`. For example, use `imagesc(C)`.

Control Image Placement

Place the image so that it lies between 5 and 8 on the *x*-axis and 3 and 6 on the *y*-axis.

```
x = [5 8];
y = [3 6];
C = [0 2 4 6; 8 10 12 14; 16 18 20 22];
image(x,y,C)
```



Notice that the pixel corresponding to C(1,1) is centered over the point (5,3). The pixel corresponding to C(3,4) is centered over the point (8,6). `image` positions and orients the rest of the image between those two points.

Display Image of 3-D Array of True Colors

Create `C` as a 3-D array of true colors. Use only red colors by setting the last two pages of the array to zeros.

```
C = zeros(3,3,3);
C(:,:,1) = [.1 .2 .3; .4 .5 .6; .7 .8 .9]
```

```
C(:,:,1) =

    0.1000    0.2000    0.3000
    0.4000    0.5000    0.6000
    0.7000    0.8000    0.9000

C(:,:,2) =

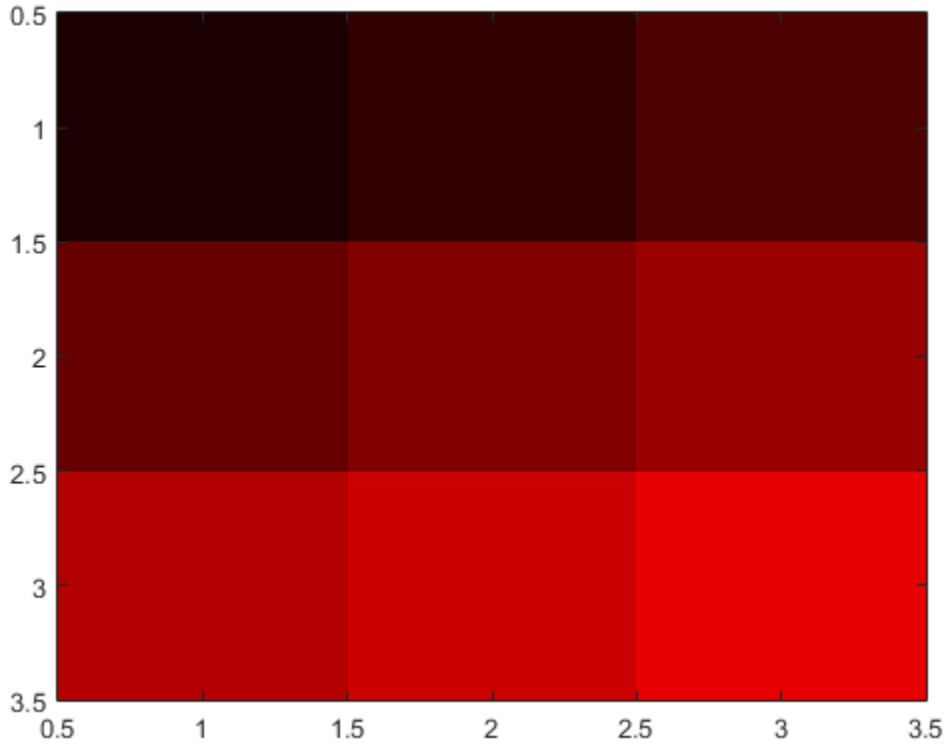
     0     0     0
     0     0     0
     0     0     0

C(:,:,3) =

     0     0     0
     0     0     0
     0     0     0
```

Display an image of the data in `C`.

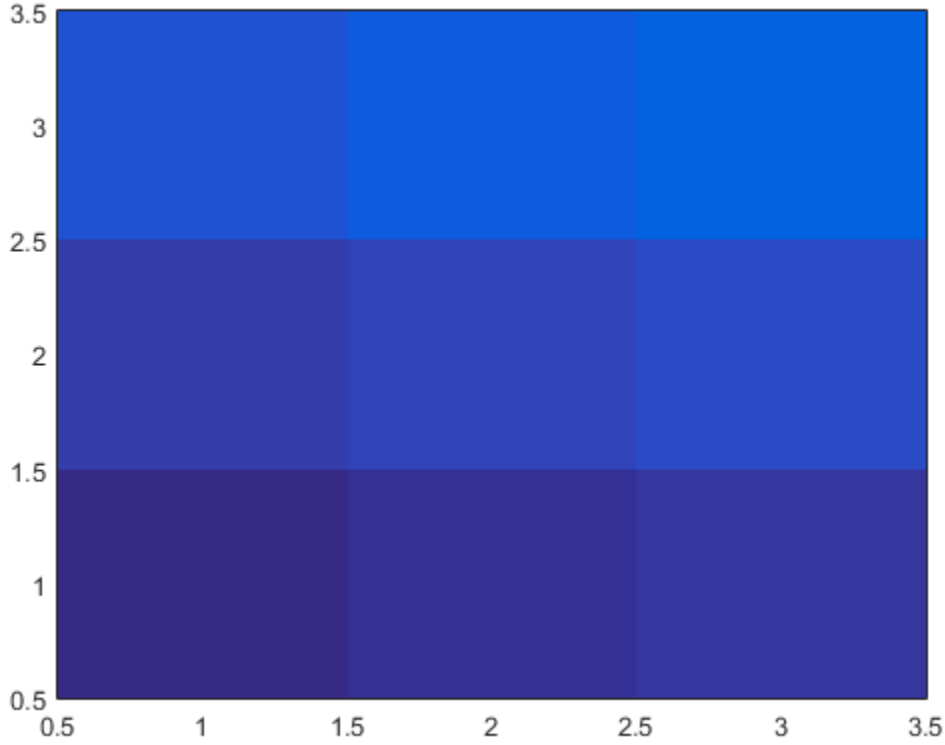
```
image(C)
```



Modify Image After Creation

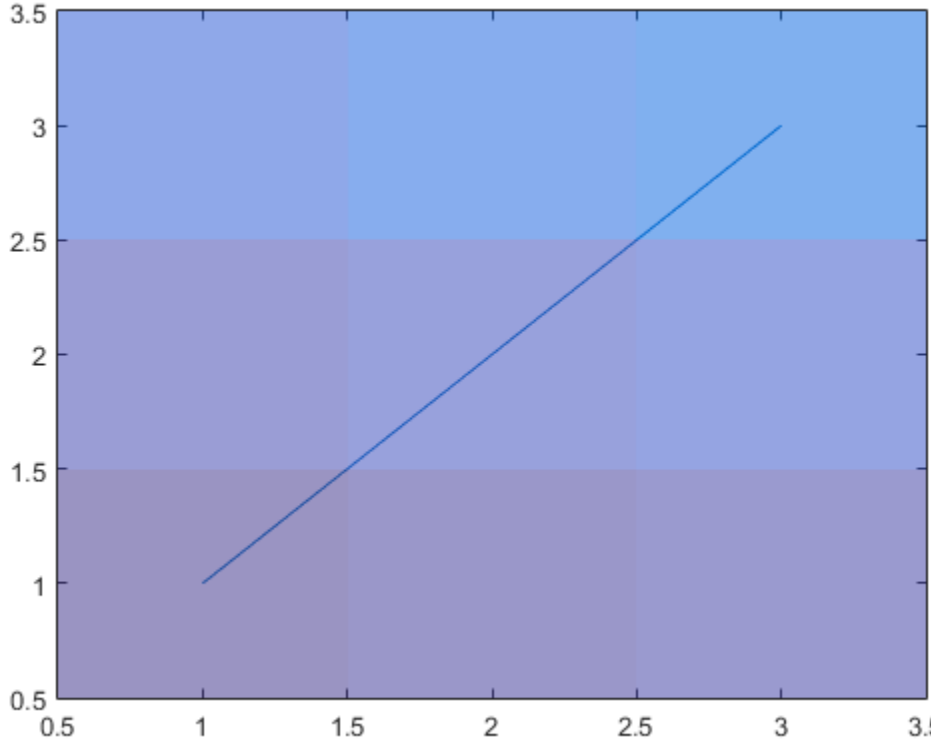
Plot a line, and then create an image on top of the line. Return the image object.

```
plot(1:3)
hold on
C = [1 2 3; 4 5 6; 7 8 9];
im = image(C);
```



Make the image semitransparent so that the line shows through the image.

```
im.AlphaData = 0.5;
```



Read and Display JPEG Image File

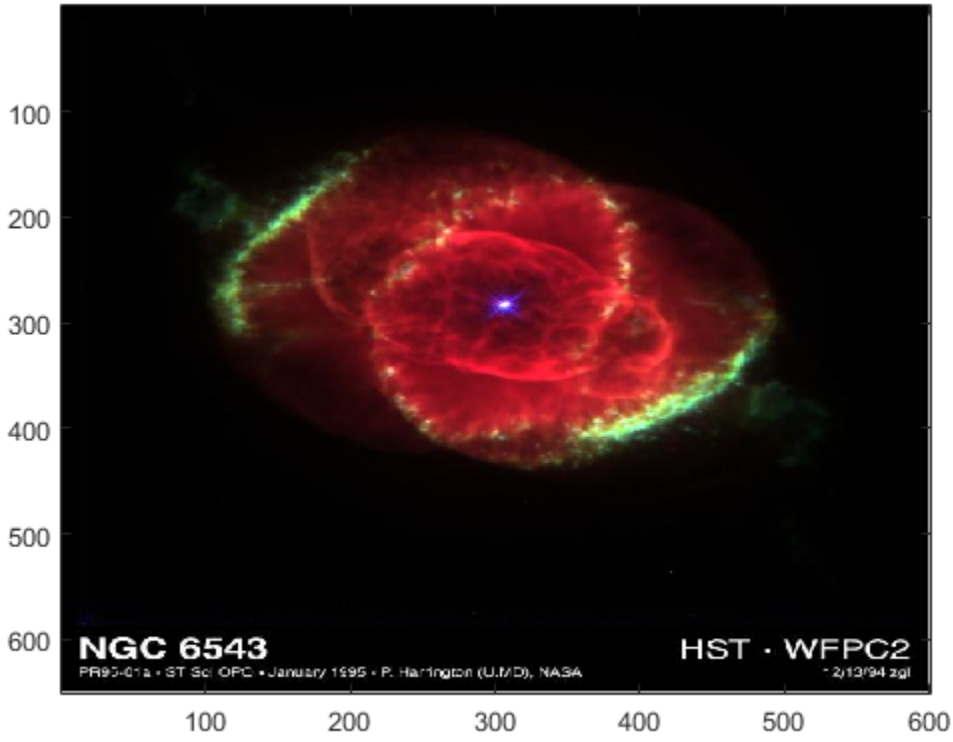
Read a JPEG image file.

```
C = imread('ngc6543a.jpg');
```

`imread` returns a 650-by-600-by-3 array, `C`.

Display the image.

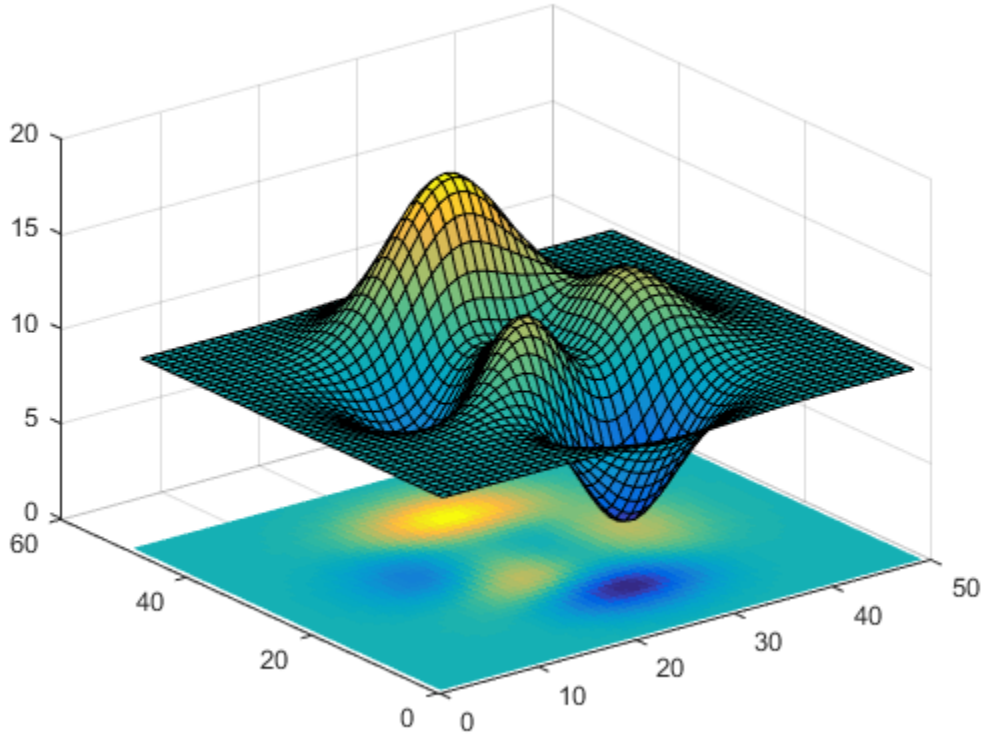
```
image(C)
```



Add Image to Axes in 3-D View

Create a surface plot. Then, add an image under the surface. The image displays in the *xy*-plane.

```
Z = 10 + peaks;
surf(Z)
hold on
image(Z,'CDataMapping','scaled')
```



Input Arguments

`C` — Image color data

vector or matrix | 3-D array of RGB triplets

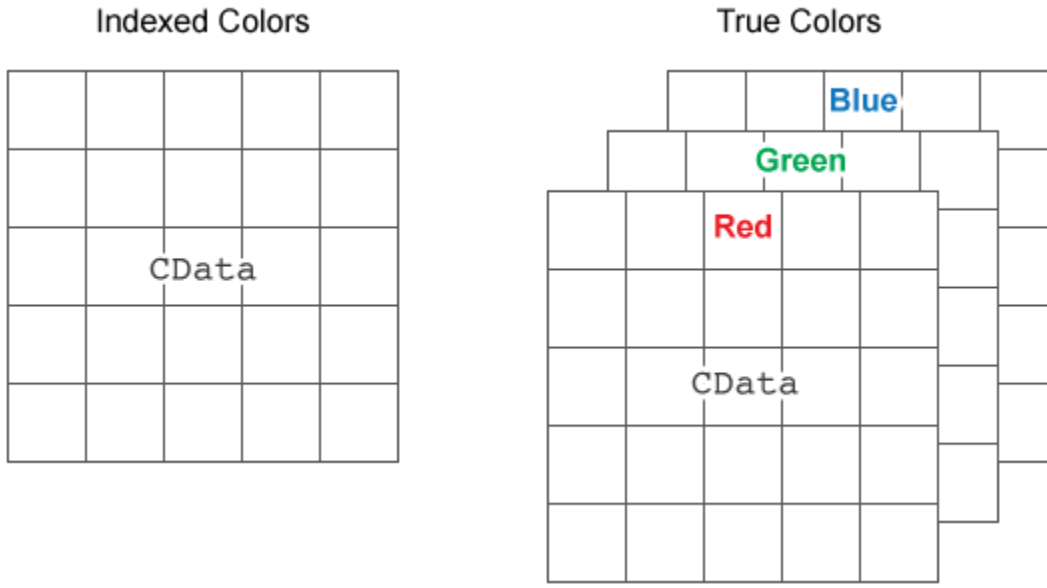
Image color data, specified in one of these forms:

- Vector or matrix — This format defines indexed image data. Each element of `C` defines a color for 1 pixel of the image. For example, `C = [1 2 3; 4 5 6; 7 8 9];`. The elements of `C` map to colors in the colormap. The CDataMapping property controls the mapping method.

- 3-D array of RGB triplets — This format defines true color image data using RGB triplet values. Each RGB triplet defines a color for 1 pixel of the image. An RGB triplet is a three-element vector that specifies the intensities of the red, green, and blue components of the color. The first page of the 3-D array contains the red components, the second page contains the green components, and the third page contains the blue components. Since the image uses true colors instead of colormap colors, the CDataMapping property has no effect.

  - If `C` is of type `double`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.
  - If `C` is an integer type, then the image uses the full range of data to determine the color. For example, if `C` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.
  - If `C` is of type `logical`, then `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.

This illustration shows the relative dimensions of C for the two color models.



The behavior of `NaN` elements is not defined.

To use the low-level version of the `image` function instead, set the `CData` property as a name-value pair. For example, `image('CData',C)`.

Converting Between Data Types

To convert indexed image data from an integer type to type `double`, add 1. For example, if `X8` is indexed image data of type `uint8`, convert it to type `double` using:

```
X64 = double(X8) + 1;
```

To convert indexed image data from type `double` to an integer type, subtract 1 and use `round` to ensure that all the values are integers. For example, if `X64` is indexed image data of type `double`, convert it to `uint8` using:

```
X8 = uint8(round(X64 - 1));
```

To convert true color image data from an integer type to type `double`, rescale the data. For example, if `RGB8` is true color image data of type `uint8`, convert it to `double` using:

```
RGB64 = double(RGB8)/255;
```

To convert true color image data from type `double` to an integer type, rescale the data and use `round` to ensure that all the values are integers. For example, if `RGB64` is image data of type `double`, convert it to `uint8` using:

```
RGB8 = uint8(round(RGB64*255));
```

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

x — Placement along x-axis

`[1 size(C,2)]` (default) | two-element vector | scalar

Placement along the *x*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `C(1,1)` and the second element as the location for the center of `C(m,n)`, where `[m,n] = size(C)`. If `C` is a 3-D array, then `m` and `n` are the first two dimensions. Evenly distribute the centers of the remaining elements of C between those two points.

  The width of each pixel is determined by the expression:

```
(x(2)-x(1))/(size(C,2)-1)
```

If `x(1) > x(2)`, then the image is flipped left-right.

- Scalar — Center `C(1,1)` at this location and each following element one unit apart.

To use the low-level version of the `image` function instead, set the `XData` property as a name-value pair. For example, `image('XData',x,'YData',y,'CData',C)`.

You cannot interactively pan or zoom outside the x-axis limits or y-axis limits of an image, unless the limits are already set outside the bounds of the image. If the limits are already outside the bounds, there is no such restriction. If other objects (such as a line) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

y — Placement along y-axis

`[1 size(C,1)]` (default) | two-element vector | scalar

Placement along *y*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `C(1,1)` and the second element as the location for the center of `C(m,n)`, where `[m,n] = size(C)`. If `C` is a 3-D array, then `m` and `n` are the first two dimensions. Evenly distribute the centers of the remaining elements of C between those two points.

  The height of each pixel is determined by the expression:

  ```
  (y(2)-y(1))/(size(C,1)-1)
  ```

  If `y(1) > y(2)`, then the image is flipped up-down.
- Scalar — Center `C(1,1)` at this location and each following element one unit apart.

To use the low-level version of the `image` function instead, set the `YData` property as a name-value pair. For example, `image('XData',x,'YData',y,'CData',C)`.

You cannot interactively pan or zoom outside the x-axis limits or y-axis limits of an image, unless the limits are already set outside the bounds of the image. If the limits are already outside the bounds, there is no such restriction. If other objects (such as a line) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `image([1 2 3],'AlphaData',0.5)` displays a semitransparent image.

The properties listed here are a subset of image properties. For a complete list, see Image Properties.

`'CDataMapping'` — Color data mapping method

`'direct'` (default) | `'scaled'`

Color data mapping method, specified as `'direct'` or `'scaled'`. Use this property to control the mapping of color data values in CData into the colormap. `CData` must be a vector or a matrix defining indexed colors. This property has no effect if CData is a 3-D array defining true colors.

The methods have these effects:

- `'direct'` — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of `1` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
  - If the values are of type `uint8`, `uint16`, `uint32`, `uint64` , `int8`, `int16`, `int32`, or `int64`, then values of `0` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
  - If the values are of type `logical`, then values of `0` map to the first color in the colormap and values of `1` map to the second color in the colormap.
- `'scaled'` — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

'AlphaData' — Transparency data

1 (default) | scalar | array the same size as CData

Transparency data, specified in one of these forms:

- Scalar — Use a consistent transparency across the entire image.
- Array the same size as CData — Use a different transparency value for each image element.

The AlphaDataMapping property controls how the transparency data values are interpreted.

Example: 0.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

'AlphaDataMapping' — Transparency data mapping method

'none' (default) | 'scaled' | 'direct'

Transparency data mapping method, specified as 'none', 'scaled', or 'direct'. Use this property to control how the transparency values in AlphaData are interpreted.

The methods have these effects:

- 'none' — Clamp the values to the region between 0 and 1. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.
- 'scaled' — Scale the values to range between the minimum and maximum alpha limits of the axes. The ALim property of the axes contains the alpha limits.
- 'direct' — Interpret the values as indices into the figure alphamap. The Alphamap property of the figure contains the alphamap. Values with a decimal portion are fixed to the nearest lower integer.

  - If the values are of type double or single, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap are mapped to the last element in the alphamap.
  - If the values are of type uint8, uint16, uint32, uint64 , int8, int16, int32, or int64 then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap are mapped to the last element in the alphamap (or up to the range limits of the type).

- If the values are of type `logical`, then values of 0 map to the first element in the alphamap and values of 1 map to the second element in the alphamap.

Output Arguments

`im` — Image object

scalar

Image object, returned as a scalar. Use `im` to set properties of the image after it is created. For a list, see Image Properties.

More About

High-Level Versus Low-Level Version of Image

The `image` function has two versions, the high-level version and the low-level version. If you use `image` with `'CData'` as an input argument, then you are using the low-level version. Otherwise, you are using the high-level version.

The high-level version of `image` calls `newplot` before plotting and sets these axes properties:

- `Layer` to `'top'`. The image is shown in front of any tick marks or grid lines.
- `YDir` to `'reverse'`. Values along the *y*-axis decrease from top to bottom. To increase the values from top to bottom, set `YDir` to `'normal'`. This setting reverses both the *y*-axis and the image.
- `View` to `[0 90]`.

The low-level version of the `image` function does not call `newplot` and does not set these axes properties.

Tips

- To read image data into MATLAB from graphics files in various standard formats, such as TIFF, use `imread`. To write MATLAB image data to graphics files, use `imwrite`. The `imread` and `imwrite` functions support a variety of graphics file formats and compression schemes.

Properties
Image Properties

Introduced before R2006a

Image Properties

Control image appearance and behavior

Image properties control the appearance and behavior of image objects. By changing property values, you can modify certain aspects of the image.

Starting in R2014b, you can use dot notation to query and set properties.

```
im = image(rand(20));
C = im.CData;
im.CDataMapping = 'scaled';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Image Data

`CData` — Image color data

64-by-64 array (default) | vector or matrix | 3-D array of RGB triplets

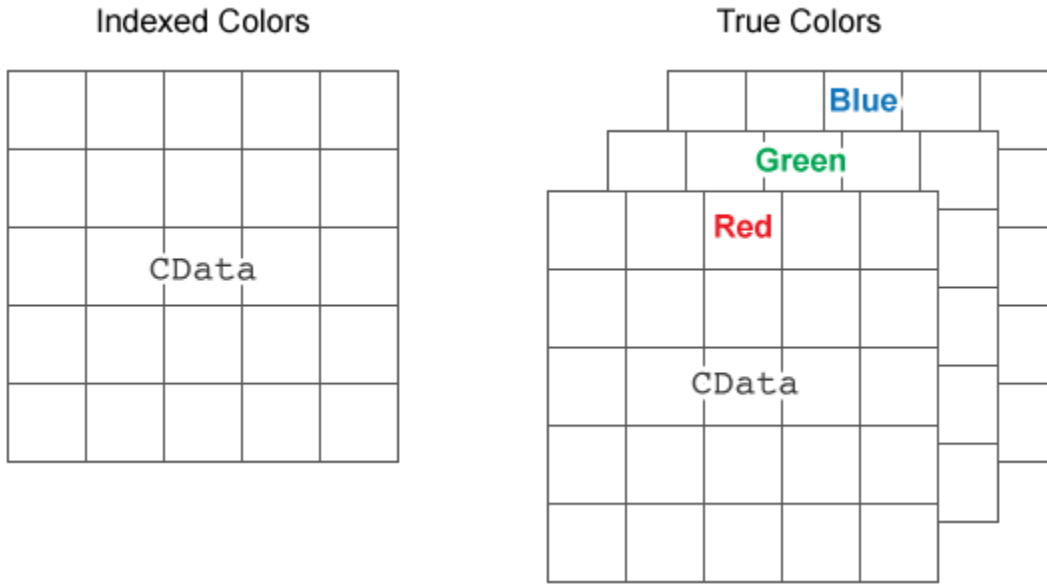
Image color data, specified in one of these forms:

- Vector or matrix — This format defines indexed image data. Each element defines a color for one pixel of the image. The elements map to colors in the colormap. The CDataMapping property controls the mapping method.
- 3-D array of RGB triplets — This format defines true color image data using RGB triplet values. Each RGB triplet defines a color for one pixel of the image. An RGB triplet is a three-element vector that specifies the intensities of the red, green, and blue components of the color. The first page of the 3-D array contains the red components, the second page contains the green components, and the third page contains the blue components. Since the image uses true colors instead of colormap colors, the CDataMapping property has no effect.

  - If `CData` is of type `double`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.
  - If `CData` is an integer type, then the image uses the full range of data to determine the color. For example, if `CData` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.

- If `CData` is of type `logical`, then `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.

This illustration shows the relative dimensions of CData for the two color models.



The behavior of `NaN` elements is not defined.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`CDataMapping` — Color data mapping method

`'direct'` (default) | `'scaled'`

Color data mapping method, specified as `'direct'` or `'scaled'`. Use this property to control the mapping of color data values in CData into the colormap. `CData` must be a vector or a matrix defining indexed colors. This property has no effect if CData is a 3-D array defining true colors.

The methods have these effects:

- `'direct'` — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.

- If the values are of type `double` or `single`, then values of `1` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
- If the values are of type `uint8`, `uint16`, `uint32`, `uint64` , `int8`, `int16`, `int32`, or `int64`, then values of `0` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
- If the values are of type `logical`, then values of `0` map to the first color in the colormap and values of `1` map to the second color in the colormap.

- `'scaled'` — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

Image Position

`XData` — Placement along x-axis

`[1 size(CData,2)]` (default) | two-element vector | scalar

Placement along the *x*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `CData(1,1)` and the second element as the location for the center of `CData(m,n)`, where `[m,n] = size(CData)`. Evenly distribute the centers of the remaining CData elements between those two points.

  The width of each pixel is determined by the expression:

  ```
  (XData(2)-XData(1))/(size(CData,2)-1)
  ```

  If `XData(1)` > `XData(2)`, then the image is flipped left-right.
- Scalar — Center `CData(1,1)` at this location and each following element one unit apart.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`YData` — Placement along y-axis

`[1 size(CData,1)]` (default) | two-element vector | scalar

Placement along *y*-axis, specified in one of these forms:

- Two-element vector — Use the first element as the location for the center of `CData(1,1)` and the second element as the location for the center of `CData(m,n)`, where `[m,n] = size(CData)`. Evenly distribute the centers of the remaining CData elements between those two points.

  The height of each pixel is determined by the expression:

  ```
  (YData(2)-YData(1))/(size(CData,1)-1)
  ```

  If `YData(1)` > `YData(2)`, then the image is flipped up-down.
- Scalar — Center `CData(1,1)` at this location and each following element one unit apart.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Image Transparency

`AlphaData` — Transparency data

1 (default) | scalar | array the same size as `CData`

Transparency data, specified in one of these forms:

- Scalar — Use a consistent transparency across the entire image.
- Array the same size as CData — Use a different transparency value for each image element.

The AlphaDataMapping property controls how the transparency data values are interpreted.

Example: `0.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`AlphaDataMapping` — Transparency data mapping method

`'none'` (default) | `'scaled'` | `'direct'`

Transparency data mapping method, specified as `'none'`, `'scaled'`, or `'direct'`. Use this property to control how the transparency values in AlphaData are interpreted.

The methods have these effects:

- `'none'` — Clamp the values to the region between 0 and 1. A value of 1 or greater is completely opaque, a value of 0 or less is completely transparent, and a value between 0 and 1 is semitransparent.
- `'scaled'` — Scale the values to range between the minimum and maximum alpha limits of the axes. The `ALim` property of the axes contains the alpha limits.
- `'direct'` — Interpret the values as indices into the figure alphamap. The `Alphamap` property of the figure contains the alphamap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of 1 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap are mapped to the last element in the alphamap.
  - If the values are of type `uint8`, `uint16`, `uint32`, `uint64` , `int8`, `int16`, `int32`, or `int64` then values of 0 or less map to the first element in the alphamap. Values equal to or greater than the length of the alphamap are mapped to the last element in the alphamap (or up to the range limits of the type).
  - If the values are of type `logical`, then values of 0 map to the first element in the alphamap and values of 1 map to the second element in the alphamap.

Visibility

`Visible` — Visibility of image

`'on'` (default) | `'off'`

Visibility of image, specified as one of these values:

- `'on'` — Display the image.
- `'off'` — Hide the image without deleting it. You still can access the properties of an invisible image object.

`Clipping` — Clipping of image to axes limits

`'on'` (default) | `'off'`

Clipping of image to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the image that are outside the axes limits.

- `'off'` — Display the entire image, even if parts of it appear outside the axes limits. Parts of the image might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the image that is larger than the original plot.

Identifiers

`Type` — Type of graphics object

`'image'`

Type of graphics object, returned as the string `'image'`.

`Tag` — Tag to associate with image

`''` (default) | string

Tag to associate with the image, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with image

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the image object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent of image

axes object | group object | transform object

Parent of image, specified as an axes, group, or transform object.

`Children` — Children of image

empty `GraphicsPlaceholder` array

The image has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of image object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The image object handle is always visible.
- `'off'` — The image object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The image object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the image at the command-line, but allows callback functions to access it.

If the image object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the image. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The image object — You can access properties of the image object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the image. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the image when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the image.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The Visible property must be set to `'on'`. The HitTest property determines if the image responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the image passes the click to the object below it in the current view of the figure window. The HitTest property of the image has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the image. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the image that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the image object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the image is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the image tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the image. Setting the `CreateFcn` property on an existing image has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during image creation. MATLAB executes the callback after creating the image and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The image object — You can access properties of the image object from within the callback function. You also can access the image object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the image. MATLAB executes the callback before destroying the image so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The image object — You can access properties of the image object from within the callback function. You also can access the image object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of image

`'off'` (default) | `'on'`

Deletion status of image, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the image begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the image no longer exists.

Check the value of the BeingDeleted property to verify that the image is not about to be deleted before querying or modifying it.

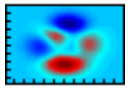
imagesc

Scale data and display image object



Syntax

```
imagesc(C)
imagesc(x,y,C)
imagesc(...,clims)
imagesc('PropertyName',PropertyValue,...)
h = imagesc(...)
```

Description

The `imagesc` function scales image data to the full range of the current colormap and displays the image. (See “Examples” on page 1-3827 for an illustration.)

`imagesc(C)` displays `C` as an image. Each element of `C` corresponds to a rectangular area in the image. The values of the elements of `C` are indices into the current colormap that determine the color of each patch.

`imagesc(x,y,C)` displays `C` as an image and specifies the bounds of the *x*- and *y*-axis with vectors `x` and `y`. If `x(1) > x(2)` or `y(1) > y(2)`, the image is flipped left-right or up-down, respectively. If `x` and `y` are scalars, the image is translated to the specified location `(x,y)` such that the upper left corner of the image starts at `(x,y)`.

`imagesc(...,clims)` normalizes the values in `C` to the range specified by `clims` and displays `C` as an image. `clims` is a two-element vector that limits the range of data values in `C`. These values map to the full range of values in the current colormap.

`imagesc('PropertyName',PropertyValue,...)` is the low-level syntax of the `imagesc` function. It specifies only property name/property value pairs as input arguments. See Image Properties for a list of the property names and their values.

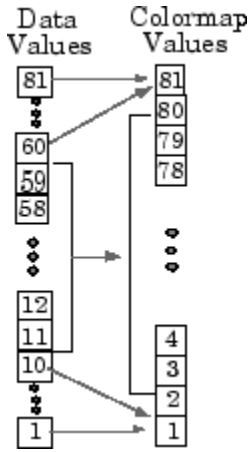
`h = imagesc(...)` returns the handle for an image graphics object.

Examples

You can expand midrange color resolution by mapping low values to the first color and high values to the last color in the colormap by specifying color value limits (`clims`). If the size of the current colormap is 81-by-3, the statements

```
clims = [ 10 60 ]
imagesc(C,clims)
```

map the data values in C to the colormap as shown in this illustration and the code that follows:



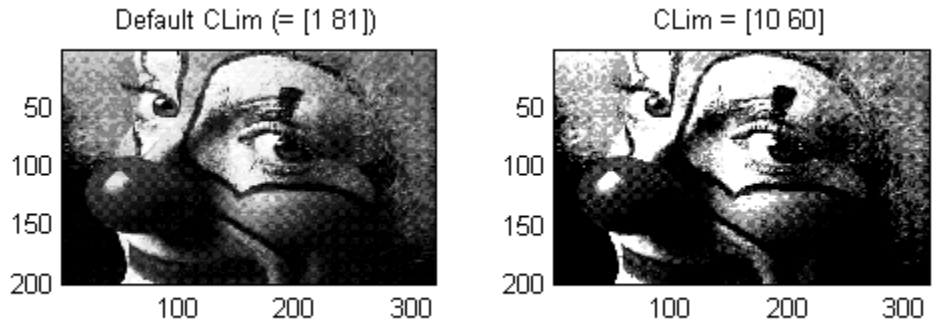
In this example, the left image maps to the `gray` colormap using the statements

```
load clown
figure
subplot(1,2,1)
imagesc(X)
```

```
colormap(gray)
axis image
title('Default CLim (= [1 81])')
```

The right image has values between 10 and 60 scaled to the full range of the gray colormap using the statements

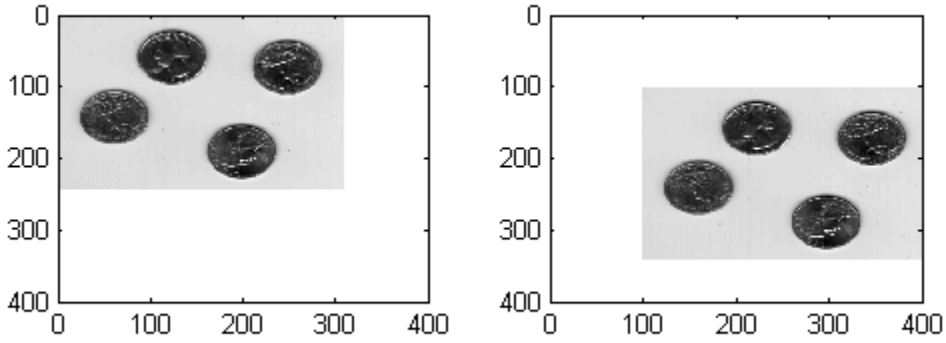
```
subplot(1,2,2)
clims = [10 60];
imagesc(X,clims)
colormap(gray)
axis image
title('CLim = [10 60]')
```



This example shows how to shift the image starting from origin to a position (100, 100),

```
i = imread('eight.tif');
figure; subplot(2,2,1); imagesc(i);
axis([0 400 0 400]);
colormap(gray);
subplot(2,2,2); imagesc(100,100,i);
axis([0 400 0 400]);
colormap(gray);
```

The figure output is as:



The top right corner of the image is now starting from (100,100) instead of the origin.

Passing vector values with the image scales the image to the specified size of 400–by–400.

```
figure; imagesc(1:400,1:400,i);
colormap(gray);
```

More About

Tips

`x` and `y` do not affect the elements in `C`; they only affect the annotation of the axes. If `length(x) > 2` or `length(y) > 2`, `imagesc` ignores all except the first and last elements of the respective vector.

`imagesc` creates an image with CDataMapping set to scaled, and sets the axes CLim property to the value passed in `clims`.

You cannot interactively pan or zoom outside the *x*-limits or *y*-limits of an image.

By default, `imagesc` plots the *y*-axis from lowest to highest value, top to bottom. To reverse this, type `set(gca,'YDir','normal')`. This will reverse both the *y*-axis and the image.

Properties

Image Properties

Introduced before R2006a

imapprox

Approximate indexed image by reducing number of colors

Syntax

```
[Y,newmap] = imapprox(X,map,n)
[Y,newmap] = imapprox(X,map,tol)
Y = imapprox(X,map,newmap)
Y = imapprox(...,dither_option)
```

Description

`[Y,newmap] = imapprox(X,map,n)` approximates the colors in the indexed image `X` and associated colormap `map` by using minimum variance quantization. `imapprox` returns the indexed image `Y` with colormap `newmap`, which has at most `n` colors.

`[Y,newmap] = imapprox(X,map,tol)` approximates the colors in `X` and `map` through uniform quantization. `newmap` contains at most `(floor(1/tol)+1)^3` colors. `tol` must be between 0 and 1.0.

`Y = imapprox(X,map,newmap)` approximates the colors in `map` by using colormap mapping to find the colors in `newmap` that best match the colors in `map`.

`Y = imapprox(...,dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

Value	Description
`{'dither'}`(default)	Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution.
`'nodither'`	Maps each color in the original image to the closest color in the new map. No dithering is performed.

Class Support

The input image `X` can be of class `uint8`, `uint16`, or `double`. The output image `Y` is of class `uint8` if the length of `newmap` is less than or equal to 256. If the length of `newmap` is greater than 256, `Y` is of class `double`.

Examples

Load an indexed image of a mandrill's face. Display image `X` using its associated colormap, `map`, which has 220 colors.

```
load mandrill
figure('color','k')
image(X)
colormap(map)
size(map)         % See that the color map has 220 entries

ans =
   220     3

axis off          % Remove axis ticks and numbers
axis image        % Set aspect ratio to obtain square pixels
```

Reduce the number of colors in the indexed image from 220 to only 16 colors by producing a new image, `Y`, and its associated colormap, `newmap`:

```
figure('color','k')
[Y, newmap] = imapprox(X, map, 16);
size(newmap)   % See that the new color map has 16 entries

ans =
    16     3

image(Y)
colormap(newmap)
axis off       % Remove axis ticks and numbers
axis image     % Set aspect ratio to obtain square pixels
```

More About

Algorithms

`imapprox` uses `rgb2ind` to create a new colormap that uses fewer colors.

`cmunique` | `dither` | `rgb2ind`

imfinfo

Information about graphics file

Syntax

```
info = imfinfo(filename)
info = imfinfo(filename,fmt)
info = imfinfo(URL)
```

Description

`info = imfinfo(filename)` returns a structure whose fields contain information about an image in a graphics file, `filename`.

The format of the file is inferred from its contents.

- If `filename` is a TIFF, HDF, ICO, GIF, or CUR file containing more than one image, then `info` is a structure array with one element for each image in the file. For example, `info(3)` would contain information about the third image in the file.

`info = imfinfo(filename,fmt)` additionally looks for a file named `filename.fmt`, if MATLAB cannot find a file named `filename`.

`info = imfinfo(URL)` returns information about the image at the specified internet resource, `URL`.

Examples

Return Information About Graphics File

Find information about the example image, `ngc6543a.jpg`.

```
info = imfinfo('ngc6543a.jpg')
```

```
info =
```

```
           Filename: 'matlabroot\toolbox\matlab\demos\ngc6543a.jpg'
        FileModDate: '01-Oct-1996 16:19:44'
           FileSize: 27387
             Format: 'jpg'
      FormatVersion: ''
              Width: 600
             Height: 650
           BitDepth: 24
          ColorType: 'truecolor'
    FormatSignature: ''
    NumberOfSamples: 3
       CodingMethod: 'Huffman'
      CodingProcess: 'Sequential'
            Comment: {'CREATOR: XV Version 3.00b  Rev: 6/15/94  Quality = 75, Smoothing
'}
```

Input Arguments

`filename` — Name of graphics file

string

Name of graphics file, specified as a string.

Example: `'myImage.jpg'`

Example: `'C:\myFolder\myImage.jpg'`

Data Types: `char`

`fmt` — Image format

string

Image format, specified as a string. The possible values for `fmt` are contained in the MATLAB file format registry. To view of list of these formats, run the `imformats` command.

Example: `'gif'`

Data Types: `char`

`URL` — Image location

string

Image location, specified as a string. `URL` must include the protocol type (e.g., `http://`).

Data Types: `char`

Output Arguments

`info` — Information about graphics file

structure array

Information about the graphics file, returned as a structure array. The set of fields in `info` depends on the individual file and its format. This table lists the nine fields that always appear, and describes their values.

Field Name	Description	Value
`Filename`	Name of the file or the internet URL specified. If the file is not in the current folder, the string contains the full path name of the file.	string
`FileModDate`	Date when the file was last modified.	string
`FileSize`	Size of the file, in bytes.	integer
`Format`	File format, as specified by *`fmt`*. For formats with more than one possible extension (for example, JPEG and TIFF files), `imfinfo` returns the first variant in the file format registry.	string
`FormatVersion`	File format version.	string or number
`Width`	Image width, in pixels.	integer
`Height`	Image height, in pixels.	integer
`BitDepth`	Number of bits per pixel.	integer
`ColorType`	Image type. `ColorType` includes, but is not limited to, `'truecolor'` for a truecolor (RGB) image, `'grayscale'` for a grayscale intensity image, or `'indexed'` for an indexed image.	string

Additional fields returned by some file formats:

- **JPEG and TIFF only** — If `filename` contains Exchangeable Image File Format (EXIF) tags, then `info` might also contain `'DigitalCamera'` or `'GPSInfo'` (global positioning system information) fields.

- **GIF only** — `imfinfo` returns the value of the `'DelayTime'` field in hundredths of seconds.
- **JPEG2000 only** — The `info` structure contains an m-by-3 cell array, `'ChannelDefinition'`. The first column of `'ChannelDefinition'` reports a channel position as it exists in the file. The second column reports the type of channel, and the third column reports the channel mapping.

`imformats` | `imread` | `imwrite`

Introduced before R2006a

imformats

Manage image file format registry

Syntax

```
imformats

formatStruct = imformats(fmt)

registry = imformats
registry = imformats(formatStruct)
registry = imformats('add',formatStruct)
registry = imformats('remove',fmt)
registry = imformats('update',fmt,formatStruct)
registry = imformats('factory')
```

Description

`imformats` displays a table of information listing all the values in the MATLAB file format registry. This registry determines which file formats the `imfinfo`, `imread`, and `imwrite` functions support.

`formatStruct = imformats(fmt)` searches the known formats in the MATLAB file format registry for the format associated with the file name extension specified by `fmt`. If found, `formatStruct` is a structure containing the characteristics and function names associated with the format. Otherwise, `formatStruct` is an empty structure.

`registry = imformats` returns a structure array, `registry`, containing all the values in the MATLAB file format registry.

`registry = imformats(formatStruct)` sets the MATLAB file format registry for the current MATLAB session to the values in `formatStruct`. The output structure, `registry`, contains the new registry settings. Use this syntax to replace image file format support.

Incorrect use of `imformats` to specify values in the MATLAB file format registry can result in the inability to load any image files. To return the file format registry to a working state, use `imformats` with the `'factory'` input.

`registry = imformats('add',formatStruct)` adds the values in `formatStruct` to the file format registry. Use this syntax to add image file format support.

`registry = imformats('remove',fmt)` removes the format with the extension specified by `fmt` from the file format registry. Use this syntax to remove image file format support.

`registry = imformats('update',fmt,formatStruct)` changes the format registry values for the format with extension `fmt` to have the values specified by `formatStruct`.

`registry = imformats('factory')` resets the MATLAB file format registry to the default format registry values. This removes any user-specified settings.

Examples

Determine if File Format Exists in Registry

Determine if the file format associated with the `.bmp` file extension is in the image file format registry.

```
formatStruct = imformats('bmp')
```

```
formatStruct =

            ext: {'bmp'}
            isa: @isbmp
           info: @imbmpinfo
           read: @readbmp
          write: @writebmp
          alpha: 0
    description: 'Windows Bitmap'
```

`formatStruct` is a non-empty structure, so the BMP file format is in the registry.

Add, Update, or Remove File Format from Registry

Add a hypothetical file format, ABC, to the image file format registry. Update, and then remove the format.

Create a structure with seven fields, defining values for the new format.

```
formatStruct = struct('ext','abc','isa',@isabc,...
    'info',@abcinfo,'read',@readabc,'write','',...
    'alpha',0,'description','My ABC Format')
```

```
formatStruct =

            ext: 'abc'
            isa: @isabc
           info: @abcinfo
           read: @readabc
          write: ''
          alpha: 0
    description: 'My ABC Format'
```

`formatStruct` is a 1-by-1 structure with seven fields. In this example, the `write` field is empty.

Add the new format to the file format registry.

```
registry = imformats('add',formatStruct);
```

Redefine the format associated with the extension, `abc`, by adding a value for the `write` field. Then, update the registry value for the format.

```
formatStruct2 = struct('ext','abc','isa',@isabc,...
    'info',@abcinfo,'read',@readabc,'write',@writeabc,...
    'alpha',0,'description','My ABC Format');

registry = imformats('update','abc',formatStruct2);
```

Remove the format with the extension, `abc`, from the file format registry.

```
registry = imformats('remove','abc');
```

Input Arguments

`formatStruct` — File format registry values

structure array

File format registry values, specified as a structure array with the following 7 fields.

Field	Description	Value
`ext`	File name extensions that are valid for this format.	Cell array of strings
`isa`	Name of the function that determines if a file is of a certain format.	String or function handle
`info`	Name of the function that reads information about a file.	String or function handle
`read`	Name of the function that reads image data in a file.	String or function handle
`write`	Name of the function that writes MATLAB data to a file.	String or function handle
`alpha`	Presence or absence of an alpha channel.	`1` if the format has an alpha channel; otherwise it is `0`.
`description`	Text description of the file format.	String

The values for the `isa`, `info`, `read`, and `write` fields must be either functions on the MATLAB search path or function handles.

Data Types: `struct`

`fmt` — File format extension

string

File format extension, specified as a string.

Example: `'jpg'`

Data Types: `char`

Output Arguments

`registry` — File format registry

structure array

File format registry, returned as a structure array with the following fields.

Field	Description	Value
`ext`	File name extensions that are valid for this format.	Cell array of strings
`isa`	Name of the function that determines if a file is of a certain format.	String or function handle
`info`	Name of the function that reads information about a file.	String or function handle
`read`	Name of the function that reads image data in a file.	String or function handle
`write`	Name of the function that writes MATLAB data to a file.	String or function handle
`alpha`	Presence or absence of an alpha channel.	`1` if the format has an alpha channel; otherwise it is `0`.
`description`	Text description of the file format.	String

Note: Use the `imread`, `imwrite`, and `imfinfo` functions to read, write, or get information about an image file when the file format is in the format registry. Do not directly invoke the functions returned in the fields of the `registry` structure array.

More About

Tips

- Changes to the format registry do not persist between MATLAB sessions. To have a format always available when you start MATLAB, add the appropriate `imformats` command to the MATLAB startup file, `startup.m`, located in `$MATLAB/toolbox/local` on UNIX systems, or `$MATLAB\toolbox\local` on Windows systems.
- "What Is the MATLAB Search Path?"

See Also

`imfinfo` | `imread` | `imwrite` | `path`

Introduced before R2006a

import

Add package or class to current import list

Syntax

```
import package_name.class_name
import package_name.function_name
import package_name.*
import package_name.class_name1 package_name.class_name2...
import package_name1.* package_name2.*...
L = import
import
```

Description

`import package_name.class_name` adds the fully qualified class name to the current import list.

`import package_name.function_name` adds the specified package-based function.

`import package_name.*` adds the specified package name. Note that *`package_name`* must be followed by `.*`.

`import package_name.class_name1 package_name.class_name2...` adds multiple fully qualified class names.

`import package_name1.* package_name2.*...` adds multiple package names.

`L = import` with no input arguments returns a cell array of strings containing the current import list, without adding to it.

`import` with no input arguments displays the current import list, without adding to it.

The `import` function allows your code to refer to an imported class or function using fewer or no package prefixes.

The `import` function only affects the import list of the function within which it is used. When invoked at the command prompt, `import` uses the import list for the MATLAB

command environment. If `import` is used in a script invoked from a function, it affects the import list of the function. If `import` is used in a script that is invoked from the command prompt, it affects the import list for the command environment.

The import list of a function is persistent across calls to that function and is only cleared when the function is cleared.

To clear the current import list, use the following command.

```
clear import
```

This command may only be invoked at the command prompt. Attempting to use `clear import` within a function results in an error.

Importing MATLAB Packages and Classes

You can `import` packages and classes into a MATLAB workspace (from the command line or in a function definition). For example:

```
import packagename.*
```

imports all classes and package functions so that you can reference those classes and functions by their simple names, without the package qualifier.

You can import just a single class from a package:

```
import packagename.ClassName
import Classname
```

You must still use the class name to call static methods:

```
ClassName.staticMethod()
```

For more information on how `import` works with MATLAB classes and packages, see "Importing Classes".

Limitations

- `import` cannot load a Java JAR package created by the MATLAB Compiler SDK™ product.

Examples

To add the `containers.Map` class to the current import list:

```
import containers.Map
myMap = Map('KeyType', 'char', 'ValueType', 'double');
```

To import two Java packages:

```
import java.util.Enumeration java.lang.String
s = String('hello'); % Create java.lang.String object
methods Enumeration % List java.util.Enumeration methods
```

To add the `java.awt` package:

```
import java.awt.*
f = Frame; % Create java.awt.Frame object
```

This example uses `import` in a function to call members of a .NET class in the `System.Drawing` namespace. Create the `getPrinterInfo` function:

```
function ptr = getPrinterInfo
import System.Drawing.Printing.*;
ptr = PrinterSettings;
end
```

To call the function, type:

```
NET.addAssembly('System.Drawing');
printer = getPrinterInfo;
```

For more information about using `import` with .NET assemblies, see "Use import in MATLAB Functions".

More About

Tips

The `import` function allows your code to refer to an imported class by class name only, rather than with the fully qualified class name. `import` is particularly useful in streamlining calls to constructors, where most references to Java classes occur.

If you use the `import` function in a control statement, for example, `if` or `switch`, or in a function, MATLAB limits the scope of the variables to that block of code. If you use the variables outside the function or control block, MATLAB displays an error message.

See Also

`clear` | `load` | `importdata`

Introduced before R2006a

importdata

Load data from file

Syntax

```
A = importdata(filename)
A = importdata('-pastespecial')
A = importdata(___,delimiterIn)
A = importdata(___,delimiterIn,headerlinesIn)
[A,delimiterOut,headerlinesOut] = importdata(___)
```

Description

`A = importdata(filename)` loads data into array `A`.

`A = importdata('-pastespecial')` loads data from the system clipboard rather than from a file.

`A = importdata(___,delimiterIn)` interprets `delimiterIn` as the column separator in ASCII file, `filename`, or the clipboard data. You can use `delimiterIn` with any of the input arguments in the above syntaxes.

`A = importdata(___,delimiterIn,headerlinesIn)` loads data from ASCII file, `filename`, or the clipboard, reading numeric data starting from line `headerlinesIn+1`.

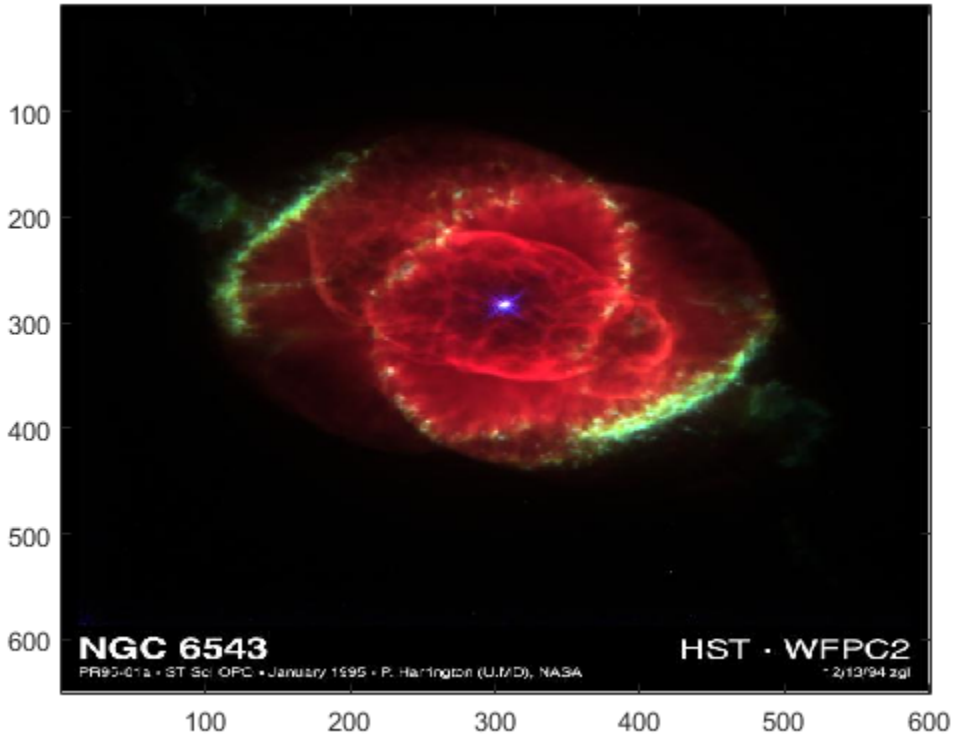
`[A,delimiterOut,headerlinesOut] = importdata(___)` additionally returns the detected delimiter character for the input ASCII file in `delimiterOut` and the detected number of header lines in `headerlinesOut`, using any of the input arguments in the previous syntaxes.

Examples

Import and Display an Image

Import and display the sample image, `ngc6543a.jpg`.

```
A = importdata('ngc6543a.jpg');
image(A)
```



The output, `A`, is class `uint8` because the helper function, `imread`, returns empty results for `colormap` and `alpha`.

Import a Text File and Specify Delimiter and Column Header

Using a text editor, create a space-delimited ASCII file with column headers called `myfile01.txt`.

```
Day1  Day2  Day3  Day4  Day5  Day6  Day7
95.01 76.21 61.54 40.57  5.79 20.28  1.53
23.11 45.65 79.19 93.55 35.29 19.87 74.68
```

```
60.68  1.85 92.18 91.69 81.32 60.38 44.51
48.60 82.14 73.82 41.03  0.99 27.22 93.18
89.13 44.47 17.63 89.36 13.89 19.88 46.60
```

Import the file, specifying the space delimiter and the single column header.

```
filename = 'myfile01.txt';
delimiterIn = ' ';
headerlinesIn = 1;
A = importdata(filename,delimiterIn,headerlinesIn);
```

View columns 3 and 5.

```
for k = [3, 5]
   disp(A.colheaders{1, k})
   disp(A.data(:, k))
   disp(' ')
end
```

```
Day3
   61.5400
   79.1900
   92.1800
   73.8200
   17.6300

Day5
    5.7900
   35.2900
   81.3200
    0.9900
   13.8900
```

Import a Text File and Return Detected Delimiter

Using a text editor, create a comma-delimited ASCII file called `myfile02.txt`.

```
1,2,3
4,5,6
7,8,9
```

Import the file, and display the output data and detected delimiter character.

```
filename = 'myfile02.txt';
[A,delimiterOut]=importdata(filename)
```

```
A =

     1     2     3
     4     5     6
     7     8     9

delimiterOut =

,
```

Import Data from Clipboard

Copy the following lines to the clipboard. Select the text, right-click, and then select **Copy**.

```
1,2,3
4,5,6
7,8,9
```

Import the clipboard data into MATLAB by typing the following.

```
A = importdata('-pastespecial')
```

```
A =

     1     2     3
     4     5     6
     7     8     9
```

Input Arguments

`filename` — Name and extension of file to import

string

Name and extension of the file to import, specified as a string. If `importdata` recognizes the file extension, it calls the MATLAB helper function designed to import the associated file format (such as `load` for MAT-files or `xlsread` for spreadsheets). Otherwise, `importdata` interprets the file as a delimited ASCII file.

For ASCII files and spreadsheets, `importdata` expects to find numeric data in a rectangular form (that is, like a matrix). Text headers can appear above or to the left of the numeric data, as follows:

- Column headers or file description text at the top of the file, above the numeric data.
- Row headers to the left of the numeric data.

Example: `'myFile.jpg'`

Data Types: `char`

`delimiterIn` — Column separator character
string

Column separator character, specified as a string. The default character is interpreted from the file. Use `'\t'` for tab.

Example: `','`

Example: `' '`

Data Types: `char`

`headerlinesIn` — Number of text header lines in ASCII file
nonnegative scalar integer

Number of text header lines in the ASCII file, specified as a nonnegative scalar integer. If you do not specify `headerlinesIn`, the `importdata` function detects this value in the file.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Output Arguments

`A` — Data from the file
matrix | multidimensional array | scalar structure array

Data from the file, returned as a matrix, multidimensional array, or scalar structure array, depending on the characteristics of the file. Based on the file format of the input file, `importdata` calls a helper function to read the data. When the helper function returns more than one nonempty output, `importdata` combines the outputs into a `struct` array.

This table lists the file formats associated with helper functions that can return more than one output, and the possible fields in the structure array, `A`.

File Format	Possible Fields	Class
MAT-files	One field for each variable	Associated with each variable.

ASCII files and Spreadsheets	`data`
	`textdata`
	`colheaders`
	`rowheaders`
		For ASCII files, `data` contains a `double` array. Other fields contain `cell` arrays of strings. `textdata` includes row and column headers.
		For spreadsheets, each field contains a `struct`, with one field for each worksheet.

Images	`cdata`
	`colormap`
	`alpha`
		See `imread`.

Audio files	`data` `fs`	See `audioread`.

The MATLAB helper functions for most other supported file formats return one output. For more information about the class of each output, see the functions listed in "Supported File Formats for Import and Export".

If the ASCII file or spreadsheet contains either column or row headers, but not both, `importdata` returns a `colheaders` or `rowheaders` field in the output structure, where:

- `colheaders` contains only the last line of column header text. `importdata` stores all text in the `textdata` field.
- `rowheaders` is created only when the file or worksheet contains a single column of row headers.

`delimiterOut` — Detected column separator in the input ASCII file
string

Detected column separator in the input ASCII file, returned as a string.

`headerlinesOut` — Detected number of text header lines in the input ASCII file
integer

Detected number of text header lines in the input ASCII file, returned as an integer.

More About

Tips

- To import ASCII files with nonnumeric characters outside of column or row headers, including columns of character data or formatted dates or times, use `textscan` instead of `importdata`.

- "Supported File Formats for Import and Export"
- "Ways to Import Text Files"
- "Ways to Import Spreadsheets"
- "Import or Export a Sequence of Files"

See Also

`imread` | `load` | `readtable` | `save` | `textscan` | `uiimport` | `xlsread`

Introduced before R2006a

imread

Read image from graphics file

Syntax

```
A = imread(filename)
A = imread(filename,fmt)
A = imread( ___ ,idx)
A = imread( ___ ,Name,Value)
[A,map] = imread( ___ )
[A,map,transparency] = imread( ___ )
```

Description

`A = imread(filename)` reads the image from the file specified by `filename`, inferring the format of the file from its contents. If `filename` is a multi-image file, then `imread` reads the first image in the file.

`A = imread(filename,fmt)` additionally specifies the format of the file with the standard file extension indicated by `fmt`. If `imread` cannot find a file with the name specified by `filename`, it looks for a file named *`filename.fmt`*.

`A = imread( ___ ,idx)` reads the specified image or images from a multi-image file. This syntax applies only to GIF, CUR, ICO, and HDF4 files. You must specify a filename input, and you can optionally specify fmt.

`A = imread( ___ ,Name,Value)` specifies format-specific options using one or more name-value pair arguments, in addition to any of the input arguments in the previous syntaxes.

`[A,map] = imread( ___ )` reads the indexed image in `filename` into `A` and reads its associated colormap into `map`. Colormap values in the image file are automatically rescaled into the range `[0,1]`.

`[A,map,transparency] = imread( ___ )` additionally returns the image transparency. This syntax applies only to PNG, CUR, and ICO files. For PNG files,

`transparency` is the alpha channel, if one is present. For CUR and ICO files, it is the AND (opacity) mask.

Examples

Read and Display Image

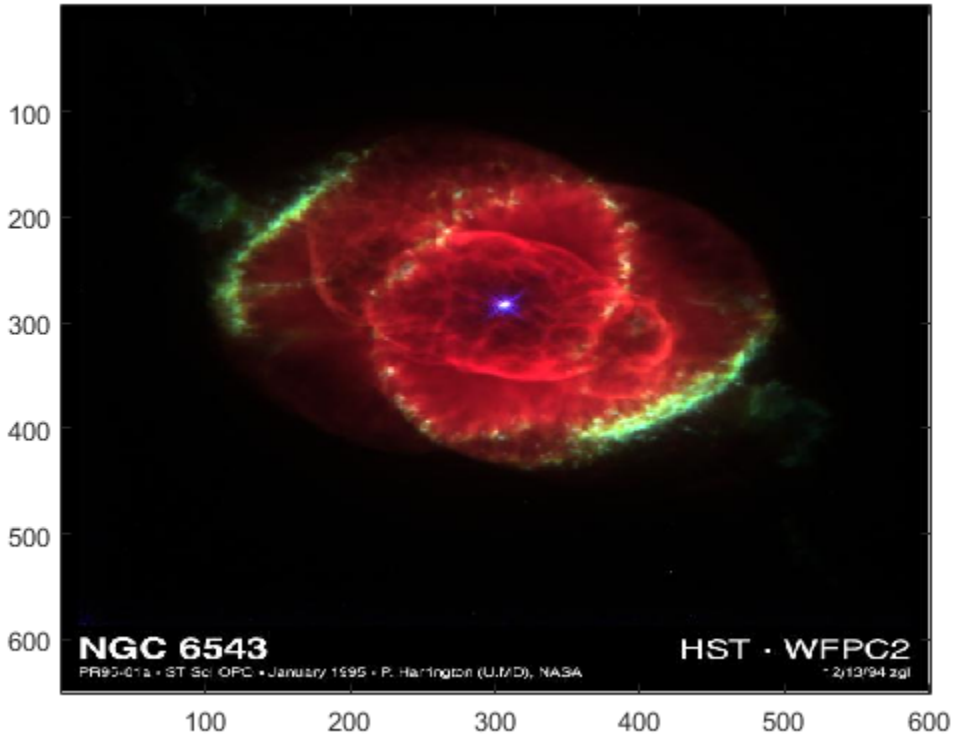
Read a sample image.

```
A = imread('ngc6543a.jpg');
```

`imread` returns a 650-by-600-by-3 array, `A`.

Display the image.

```
image(A)
```



Convert Indexed Image to RGB

Read an image and convert it to an RGB image.

Read the first image in the sample indexed image file, `corn.tif`.

```
[X,map] = imread('corn.tif');
```

`X` is a 415-by-312 array of type `uint8`.

Verify that the colormap, `map`, is not empty, and convert the data in `X` to RGB.

```
if ~isempty(map)
    Im = ind2rgb(X,map);
```

```
end
```

View the size and class of X.

```
whos Im
```

```
  Name        Size                 Bytes  Class     Attributes

  Im        415x312x3            3107520  double
```

X is now a 415-by-312-by-3 array of type `double`.

Read Specific Image in Multipage TIFF File

Read the third image in the sample file, `corn.tif`.

```
[X,map] = imread('corn.tif',3);
```

Return Alpha Channel of PNG Image

Return the alpha channel of the sample image, `peppers.png`.

```
[X,map,alpha] = imread('peppers.png');
alpha
```

```
alpha =

     []
```

No alpha channel is present, so `alpha` is empty.

Read Specified Region of TIFF Image

Read a specific region of pixels of the sample image, `corn.tif`.

Specify the `'PixelRegion'` parameter with a cell array of vectors indicating the boundaries of the region to read. The first vector specifies the range of rows to read, and the second vector specifies the range of columns to read.

```
A = imread('corn.tif','PixelRegion',{[1,2],[2,5]});
```

`imread` reads the image data in rows 1-2 and columns 2-5 from `corn.tif` and returns the 2-by-4 array, `A`.

Input Arguments

`filename` — File name

string

File name, specified as a string. If the file is not in the current folder or in a folder on the MATLAB path, specify the full path name.

`filename` also can be an internet URL specifying an image location. The URL must include the protocol type (for example, `http://`).

For information on the bit depths, compression schemes, and color spaces supported for each file type, see "Algorithms" on page 1-3866.

Example: `'myFile.jpg'`

Example: `'http://www.mathworks.com/myImage.gif'`

Data Types: `char`

`fmt` — Image format

string

Image format, specified as a string indicating the standard file extension. Call `imformats` to see a list of supported formats and their file extensions.

Example: `'png'`

Data Types: `char`

`idx` — Image to read

integer scalar | vector of integers

Image to read, specified as an integer scalar or, for GIF files, a vector of integers. For example, if `idx` is 3, then `imread` returns the third image in the file. For a GIF file, if `idx` is `1:5`, then `imread` returns only the first five frames. The `idx` argument is supported only for multi-image GIF, CUR, ICO, and HDF4 files.

When reading multiple frames from the same GIF file, specify `idx` as a vector of frames or use the `'Frames','all'` name-value pair argument. Because of the way that GIF

files are structured, these syntaxes provide faster performance compared to calling `imread` in a loop.

For HDF4 files, `idx` corresponds to the reference number of the image to read. Reference numbers do not necessarily correspond to the order of the images in the file. You can use `imfinfo` to match image order with reference number.

Example: `3`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Index',5` reads the fifth image of a TIFF file.

GIF Files

`'Frames'` — Frame to read

1 (default) | positive integer | vector of integers | `'all'`

Frames to read, specified as the comma-separated pair consisting of `'Frames'` and a positive integer, a vector of integers, or the string `'all'`. For example, if you specify the value 3, `imread` reads the third frame in the file. If you specify `'all'`, then `imread` reads all frames and returns them in the order in which they appear in the file.

Example: `'frames',5`

JPEG 2000 Files

`'PixelRegion'` — Subimage to read

cell array in the form `{rows,cols}`

Subimage to read, specified as the comma-separated pair consisting of `'PixelRegion'` and a cell array of the form `{rows,cols}`. The `rows` input specifies the range of rows to read. The `cols` input specifies the range of columns to read. Both `rows` and `cols` must

be two-element vectors containing 1-based indices. For example, `'PixelRegion',{[1 2],[3 4]}` reads the subimage bounded by rows 1 and 2 and columns 3 and 4 in the image data. If the `'ReductionLevel'` value is greater than 0, then `rows` and `cols` are coordinates of the subimage.

Example: `'PixelRegion',{[1 100],[4 500]}`

`'ReductionLevel'` — Reduction of image resolution

0 (default) | nonnegative integer

Reduction of the image resolution, specified as the comma-separated pair consisting of `'ReductionLevel'` and a nonnegative integer. For reduction level L, the image resolution is reduced by a factor of 2^L. The reduction level is limited by the total number of decomposition levels as specified by the `'WaveletDecompositionLevels'` field in the output of the `imfinfo` function.

Example: `'ReductionLevel',5`

Data Types: `single` | `double`

`'V79Compatible'` — Compatibility with MATLAB 7.9 (R2009b) and earlier

`false` (default) | `true`

Compatibility with MATLAB 7.9 (R2009b) and earlier, specified as the comma-separated pair consisting of `'V79Compatible'` and either `true` or `false`. If you specify `true`, then the returned grayscale or RGB image is consistent with previous versions of `imread` (MATLAB 7.9 (R2009b) and earlier).

Example: `'V79Compatible',true`

Data Types: `logical`

PNG Files

`'BackgroundColor'` — Background color

`'none'` | integer | 3-element vector of integers

Background color, specified as `'none'`, an integer, or a three-element vector of integers. If `BackgroundColor` is `'none'`, then `imread` does not perform any compositing. Otherwise, `imread` blends transparent pixels with the background color.

- If the input image is indexed, then the value of `BackgroundColor` must be an integer in the range `[1,P]`, where `P` is the colormap length.

- If the input image is grayscale, then the value of `BackgroundColor` must be an integer in the range `[0,1]`.
- If the input image is RGB, then the value of `BackgroundColor` must be a three-element vector with values in the range `[0,1]`.

The default value for `BackgroundColor` depends on the presence of the `transparency` output argument and the image type:

- If you request the `transparency` output argument, then the default value of `BackgroundColor` is `'none'`.
- If you do not request the `transparency` output and the PNG file contains a background color chunk, then that color is the default value for `BackgroundColor`.
- If you do not request the `transparency` output and the file does not contain a background color chunk, then the default value for `BackgroundColor` is `1` for indexed images, `0` for grayscale images, and `[0 0 0]` for truecolor (RGB) images.

TIFF Files

`'Index'` — Image to read

1 (default) | positive integer

Image to read, specified as the comma-separated pair consisting of `'Index'` and a positive integer. For example, if the value of `Index` is 3, then `imread` reads the third image in the file.

Data Types: `single` | `double`

`'Info'` — Information about image

structure array

Information about the image, specified as the comma-separated pair consisting of `'Info'` and a structure array returned by the `imfinfo` function. Use the `Info` name-value pair argument to help `imread` locate the images in a multi-image TIFF file more quickly.

Data Types: `struct`

`'PixelRegion'` — Region boundary

cell array

Region boundary, specified as the comma-separated pair consisting of `'PixelRegion'` and a cell array of the form `{rows,cols}`. The `rows` input specifies the range of rows to read. The `cols` input specifies the range of columns to read. `rows` and `cols` must be either two-element or three-element vectors of 1-based indices. A two-element vector specifies the first and last rows or columns to read. For example, `'PixelRegion',{[1 2],[3 4]}` reads the region bounded by rows 1 and 2 and columns 3 and 4 in the image data.

A three-element vector must be in the form `[start increment stop]`, where `start` is the first row or column to read, `increment` is an incremental value, and `stop` is the last row or column to read. This syntax allows image downsampling. For example, `'PixelRegion',{[1 2 10],[4 3 12]}` reads the region bounded by rows 1 and 10 and columns 4 and 12, and samples data from every 2 pixels in the vertical direction, and every 3 pixels in the horizontal direction.

Example: `'PixelRegion',{[1 100],[4 500]}`

Data Types: `cell`

Output Arguments

A — Image data

array

Image data, returned as an array.

- If the file contains a grayscale image, then A is an `m`-by-`n` array.
- If the file contains an indexed image, then A is an `m`-by-`n` array of index values corresponding to the color at that index in `map`.
- If the file contains a truecolor image, then A is an `m`-by-`n`-by-3 array.
- If the file is a TIFF file containing color images that use the CMYK color space, then A is an `m`-by-`n`-by-4 array.

The class of `A` depends on the image format and the bit depth of the image data. For more information, see “Algorithms” on page 1-3866

map — Colormap

`m`-by-3 matrix

Colormap associated with the indexed image data in `A`, returned as an `m`-by-3 matrix of class `double`.

`transparency` — Transparency information

matrix

Transparency information, returned as a matrix. For PNG files, `transparency` is the alpha channel, if present. If no alpha channel is present, or if you specify the `'BackgroundColor'` name-value pair argument, then `transparency` is `[]`. For CUR and ICO files, `transparency` is the AND mask. For cursor files, this mask sometimes contains the only useful data.

More About

Bit Depth

Bit depth is the number of bits used to represent each image pixel.

Bit depth is calculated by multiplying the bits-per-sample with the samples-per-pixel. Thus, a format that uses 8 bits for each color component (or sample) and three samples per pixel has a bit depth of 24. Sometimes the sample size associated with a bit depth can be ambiguous. For example, does a 48-bit bit depth represent six 8-bit samples, four 12-bit samples, or three 16-bit samples? See “Algorithms” on page 1-3866 for sample size information to avoid this ambiguity.

Algorithms

For most image file formats, `imread` uses 8 or fewer bits per color plane to store image pixels. This table lists the class of the returned image array, `A`, for the bit depths used by the file formats.

Bit Depth in File	Class of Array Returned by `imread`
1 bit per pixel	`logical`
2 to 8 bits per color plane	`uint8`
9 to 16 bits per pixel	`uint16` (`BMP`, `JPEG`, `PNG`, and `TIFF`) For the 16-bit BMP packed format (5-6-5), MATLAB returns `uint8`

The following sections provide information about the support for specific formats, listed in alphabetical order by format name.

BMP — Windows Bitmap

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	No Compression	RLE Compression	Output Class	Notes
1 bit	✓	–	`logical`	
4 bit	✓	✓	`uint8`	
8 bit	✓	✓	`uint8`	
16 bit	✓	–	`uint8`	1 sample/pixel
24 bit	✓	–	`uint8`	3 samples/pixel
32 bit	✓	–	`uint8`	3 samples/pixel (1 byte padding)

CUR — Cursor File

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	No Compression	Compression	Output Class
1 bit	✓	–	`logical`

Supported Bit Depths	No Compression	Compression	Output Class
4 bit	✓	–	`uint8`
8 bit	✓	–	`uint8`

Note By default, Microsoft Windows cursors are 32-by-32 pixels. Since MATLAB pointers must be 16-by-16, you might need to scale your image. If you have Image Processing Toolbox™, you can use the `imresize` function.

GIF — Graphics Interchange Format

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	No Compression	Compression	Output Class
1 bit	✓	–	`logical`
2 bit to 8 bit	✓	–	`uint8`

HDF4 — Hierarchical Data Format

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	Raster Image with colormap	Raster image without colormap	Output Class	Notes
8 bit	✓	✓	`uint8`	
24 bit	–	✓	`uint8`	3 samples/pixel

ICO — Icon File

See “CUR — Cursor File” on page 1-3867

JPEG — Joint Photographic Experts Group

`imread` reads any baseline JPEG image, as well as JPEG images with some commonly used extensions. For information on JPEG 2000 file support, see JPEG 2000.

Supported Bits per Sample	Lossy Compression	Lossless Compression	Output Class	Notes
8 bit	✓	✓	`uint8`	Grayscale or RGB
12 bit	✓	✓	`uint16`	Grayscale or RGB
16 bit	–	✓	`uint16`	Grayscale

JPEG 2000 — Joint Photographic Experts Group 2000

For information about JPEG files, see JPEG.

Note: Indexed JPEG 2000 images are not supported. Only JP2 compatible color spaces are supported for JP2/JPX files. By default, all image channels are returned in the order they are stored in the file.

Supported Bits per Sample	Lossy Compression	Lossless Compression	Output Class	Notes
1 bit	✓	✓	`logical`	Grayscale only
2 bit to 8 bit	✓	✓	`uint8` or `int8`	Grayscale or RGB
9 bit to 16 bit	✓	✓	`uint16` or `int16`	Grayscale or RGB

PBM — Portable Bitmap

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	Raw Binary	ASCII (Plain) Encoded	Output Class
1 bit	✓	✓	`logical`

PCX — Windows Paintbrush

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	Output Class	Notes
1 bit	`logical`	Grayscale only

Supported Bit Depths	Output Class	Notes
8 bit	`uint8`	Grayscale or indexed
24 bit	`uint8`	RGB Three 8-bit samples/pixel

PGM — Portable Graymap

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	Raw Binary	ASCII (Plain) Encoded	Output Class	Notes
8 bit	✓	–	`uint8`	
16 bit	✓	–	`uint16`	
Arbitrary	–	✓	1-bit to 8-bit: `uint8` 9-bit to 16-bit: `uint16`	Values are scaled

PNG — Portable Network Graphics

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	Output Class	Notes
1 bit	`logical`	Grayscale
2 bit	`uint8`	Grayscale
4 bit	`uint8`	Grayscale
8 bit	`uint8`	Grayscale or Indexed
16 bit	`uint16`	Grayscale or Indexed
24 bit	`uint8`	RGB Three 8-bit samples/pixel.
48 bit	`uint16`	RGB Three 16-bit samples/pixel.

PPM — Portable Pixmap

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	Raw Binary	ASCII (Plain) Encoded	Output Class
Up to 16 bit	✓	–	`uint8`
Arbitrary	–	✓	

RAS — Sun Raster

This table lists supported bit depths and the data type of the output image data array.

Supported Bit Depths	Output Class	Notes
1 bit	`logical`	Bitmap
8 bit	`uint8`	Indexed
24 bit	`uint8`	RGB Three 8-bit samples/pixel
32 bit	`uint8`	RGB with Alpha Four 8-bit samples/pixel

TIFF — Tagged Image File Format

`imread` reads most images supported by the TIFF specification or LibTIFF. The `imread` function supports these TIFF capabilities:

- Any number of samples per pixel
- CCITT group 3 and 4 FAX, Packbits, JPEG, LZW, Deflate, ThunderScan compression, and uncompressed images
- Logical, grayscale, indexed color, truecolor and hyperspectral images
- RGB, CMYK, CIELAB, ICCLAB color spaces. If the color image uses the CMYK color space, `A` is an `m`-by-`n`-by-4 array. To determine which color space is used, use `imfinfo` to get information about the graphics file and look at the value of the `PhotometricInterpretation` field. If a file contains CIELAB color data, `imread` converts it to ICCLAB before bringing it into the MATLAB workspace. This conversion is necessary because 8-bit or 16-bit TIFF CIELAB-encoded values use a mixture of signed and unsigned data types that cannot be represented as a single MATLAB array.
- Data organized into tiles or scanlines

`imread` reads and converts TIFF images as follows:

- YCbCr images are converted into the RGB colorspace.
- All grayscale images are read as if black = `0`, white = largest value.
- 1-bit images are returned as class `logical`.
- CIELab images are converted into ICCLab colorspace.

For copyright information, open the `libtiffcopyright.txt` file.

XWD — X Window Dump

This table lists the supported bit depths, compression, and output classes for XWD files.

Supported Bit Depths	ZPixmaps	XYBitmaps	XYPixmaps	Output Class
1 bit	✓	–	✓	`logical`
8 bit	✓	–	–	`uint8`

Introduced before R2006a

imshow

Display image

Syntax

```
imshow(I)
imshow(X,map)
imshow(filename)
imshow(I,[low high])
imshow(___,Name,Value)

himage = imshow( ___ )
```

Description

`imshow(I)` displays image `I` in a Handle Graphics figure, where `I` is a grayscale, RGB (truecolor), or binary image. For binary images, `imshow` displays pixels with the value `0` (zero) as black and `1` as white. `imshow` optimizes figure, axes, and image object properties for image display.

`imshow(X,map)` displays the indexed image `X` with the colormap `map`. A colormap matrix can have any number of rows, but it must have exactly 3 columns. Each row is interpreted as a color, with the first element specifying the intensity of red light, the second green, and the third blue. Color intensity can be specified on the interval 0.0 to 1.0.

`imshow(filename)` displays the image stored in the graphics file specified by `filename`.

`imshow(I,[low high])` displays grayscale image `I`, specifying the display range as a two-element vector, `[low high]`. For more information, see the DisplayRange parameter.

`imshow(___,Name,Value)` displays an image, using name-value pairs to control aspects of the operation.

`himage = imshow( ___ )` returns the handle to the image object created by `imshow`.

Examples

Display Grayscale Image

Display a grayscale image by reading an RGB image into the workspace and converting it to a grayscale image.

Read RGB image into the workspace.

```
RGB = imread('peppers.png');
```

Convert the image to grayscale.

```
I = rgb2gray(RGB);
```

Display the grayscale image.

```
imshow(I)
```

Display Image from File

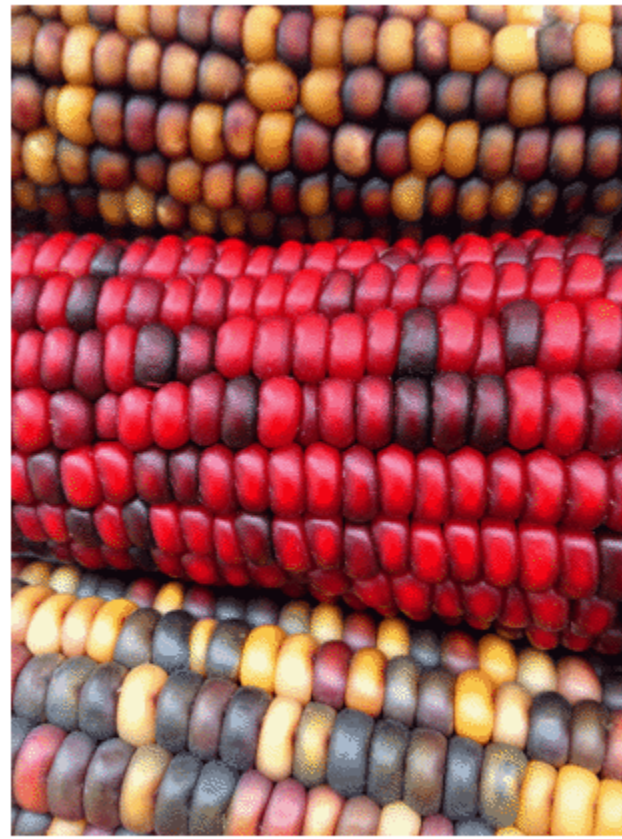
Display an image stored in a file.

```
imshow('peppers.png');
```

Display Indexed Image

Read a sample indexed image, `corn.tif`, into the workspace, and then display it.

```
[X,map] = imread('corn.tif');
imshow(X,map)
```



Input Arguments

`I` — Input image
scalar | vector | matrix | `m`-by-`n`-by-3 array

Input image, specified as a scalar, vector, or matrix representing a grayscale, RGB, or binary image. Multi-plane image inputs must be RGB images of size `m`-by-`n`-by-3. An RGB image can be `uint8`, `uint16`, `single`, or `double`. A grayscale image can be any numeric data type. A binary image is of class `logical`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`X` — Indexed image

2-D array of real numeric values

Indexed image, specified as a 2-D array of real numeric values. The values in X are indices into the colormap specified by map.

Data Types: `single` | `double` | `uint8` | `logical`

`map` — Colormap

m-by-3 array

Colormap, specified as an *m*-by-3 array of type `single` or `double` in the range `[0 1]`, or an *m*-by-3 array of type `uint8`. Each row specifies an RGB color value.

Data Types: `single` | `double` | `uint8`

`filename` — File name

string

File name, specified as a string. The image must be readable by `imread`. The `imshow` function displays the image, but does not store the image data in the MATLAB workspace. If the file contains multiple images, `imshow` displays the first image in the file.

Example: `imshow('peppers.png')`

Data Types: `char`

`[low high]` — Grayscale image display range

two-element vector

Grayscale image display range, specified as a two-element vector. For more information, see the `'DisplayRange'` name-value pair argument.

Example: `[50 250]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `imshow('board.tif','Border','tight')`

`'Border'` — Figure window border space

`'loose'` (default) | `'tight'`

Figure window border space, specified as the comma-separated pair consisting of `'Border'` and either `'tight'` or `'loose'`. When set to `'loose'`, the figure window includes space around the image in the figure. When set to `'tight'`, the figure window does not include any space around the image in the figure.

If the image is very small or if the figure contains other objects besides an image and its axes, `imshow` might use a border regardless of how this parameter is set.

Example: `imshow('board.tif','Border','tight')`

Data Types: `char`

`'Colormap'` — Colormap

m-by-3 matrix

Colormap, specified as the comma-separated pair consisting of `'Colormap'` and an `m`-by-3 matrix. `imshow` uses this to set the figure's `colormap` property. Use this parameter to view grayscale images in false color. If you specify an empty colormap (`[]`), then `imshow` ignores this parameter.

Example: `newmap = copper; imshow('board.tif','Colormap',newmap)`

Data Types: `double`

`'DisplayRange'` — Grayscale image display range

two-element vector

Grayscale image display range, specified as the comma-separated pair consisting of `'DisplayRange'` and a two-element vector of the form `[low high]`. The `imshow` function displays the value `low` (and any value less than `low`) as black, and it displays the value `high` (and any value greater than `high`) as white. Values between `low` and

high are displayed as intermediate shades of gray, using the default number of gray levels.

For uint8, 'DisplayRange' defaults to [0 255]. For all other data types it defaults to [min(I(:)) max(I(:))]. If you specify an empty matrix ([]), imshow uses the default.

Note: Including the parameter name is optional, except when the image is specified by a file name. The syntax imshow(I,[low high]) is equivalent to imshow(I,'DisplayRange',[low high]). If you call imshow with a file name, then you must specify the 'DisplayRange' parameter.

Example: h = imshow(I,'DisplayRange',[0 80]);

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

'InitialMagnification' — Initial magnification of image display

100 (default) | numeric scalar | 'fit'

Initial magnification of image display, specified as the comma-separated pair consisting of 'InitialMagnification' and a numeric scalar or the string, 'fit'. If set to 100, then imshow displays the image at 100% magnification (one screen pixel for each image pixel). If set to 'fit', then imshow scales the entire image to fit in the window.

Initially, imshow always displays the entire image. If the magnification value is so large that the image is too big to display on the screen, imshow warns and displays the image at the largest magnification that fits on the screen.

If the image is displayed in a figure with its 'WindowStyle' property set to 'docked', then imshow warns and displays the image at the largest magnification that fits in the figure.

Note: If you specify the axes position (using subplot or axes), imshow ignores any initial magnification you might have specified and defaults to the 'fit' behavior.

When you use imshow with the 'Reduce' parameter, the initial magnification must be 'fit'.

Example: h = imshow(I,'InitialMagnification','fit');

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

`'Parent'` — Parent axes of image object

handle

Parent axes of image object, specified as the comma-separated pair consisting of `'Parent'` and a handle. Use the `'Parent'` name-value argument to build a UI that gives you control of the figure and axes properties.

Data Types: `function_handle`

`'Reduce'` — Indicator for subsampling

`true` | `false` | `1` | `0`

Indicator for subsampling image, specified as the comma-separated pair consisting of `'Reduce'` and either `true`, `false`, `1`, or `0`. This argument is valid only when you use it with the name of a TIFF file. Use the `Reduce` argument to display overviews of very large images.

Data Types: `logical`

`'Xdata'` — X-axis limits of nondefault coordinate system

two-element vector

X-axis limits of nondefault coordinate system, specified as the comma-separated pair consisting of `'Xdata'` and a two-element vector. This argument establishes a nondefault spatial coordinate system by specifying the image `XData`. The value can have more than two elements, but `imshow` uses only the first and last elements.

Example: `'Xdata',[100 200]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'YData'` — Y-axis limits of nondefault coordinate system

two-element vector

Y-axis limits of nondefault coordinate system, specified as the comma-separated pair consisting of `'Ydata'` and a two-element vector. The value can have more than two elements, but `imshow` uses only the first and last elements.

Example: `'YData',[100 200]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`himage` — Image object

handle

Image object, specified as a handle.

More About

Tips

- If you have Image Processing Toolbox, you can use the Image Viewer app as an integrated environment for displaying images and performing common image processing tasks.
- If you have Image Processing Toolbox, you can use the `iptsetpref` function to set toolbox preferences that modify the behavior of `imshow`.
- The `imshow` function is not supported when you start MATLAB with the `-nojvm` option.

`image` | `imagesc` | `imfinfo` | `imread` | `imwrite` | `iptsetpref`

imwrite

Write image to graphics file

Syntax

```
imwrite(A,filename)
imwrite(A,map,filename)

imwrite( ___ ,fmt)

imwrite( ___ ,Name,Value)
```

Description

`imwrite(A,filename)` writes image data `A` to the file specified by `filename`, inferring the file format from the extension. `imwrite` creates the new file in your current folder. The bit depth of the output image depends on the data type of `A` and the file format. For most formats:

- If `A` is of data type `uint8`, then `imwrite` outputs 8-bit values.
- If `A` is of data type `uint16` and the output file format supports 16-bit data (JPEG, PNG, and TIFF), then `imwrite` outputs 16-bit values. If the output file format does not support 16-bit data, then `imwrite` returns an error.
- If `A` is a grayscale or RGB color image of data type `double` or `single`, then `imwrite` assumes that the dynamic range is [0,1] and automatically scales the data by 255 before writing it to the file as 8-bit values. If the data in `A` is `single`, convert `A` to `double` before writing to a GIF or TIFF file.
- If `A` is of data type `logical`, then `imwrite` assumes that the data is a binary image and writes it to the file with a bit depth of 1, if the format allows it. BMP, PNG, or TIFF formats accept binary images as input arrays.

If `A` contains indexed image data, you should additionally specify the `map` input argument.

`imwrite(A,map,filename)` writes the indexed image in `A` and its associated colormap, `map`, to the file specified by `filename`.

- If A is an indexed image of data type `double` or `single`, then `imwrite` converts the indices to zero-based indices by subtracting 1 from each element, and then writes the data as `uint8`. If the data in A is `single`, convert A to `double` before writing to a GIF or TIFF file.

`imwrite(___,fmt)` writes the image in the format specified by `fmt`, regardless of the file extension in `filename`. You can specify `fmt` after the input arguments in any of the previous syntaxes.

`imwrite(___,Name,Value)` specifies additional parameters for output GIF, HDF, JPEG, PBM, PGM, PNG, PPM, and TIFF files, using one or more name-value pair arguments. You can specify `Name,Value` after the input arguments in any of the previous syntaxes.

Examples

Write Grayscale Image to PNG

Write a 50-by-50 array of grayscale values to a PNG file in the current folder.

```
A = rand(50);
imwrite(A,'myGray.png')
```

Write Indexed Image Data to PNG

Write an indexed image array and its associated colormap to a PNG file.

Load sample image data from the file, `clown.mat`.

```
load clown.mat
```

The image array X and its associated colormap, `map`, are loaded into the MATLAB workspace.

Write the data to a new PNG file.

```
imwrite(X,map,'myclown.png')
```

`imwrite` creates the file, `myclown.png`, in your current folder.

View the new file by opening it outside of MATLAB.

Write Indexed Image with MATLAB Colormap

Write image data to a new PNG file with the built-in MATLAB colormap, `copper`.

Load sample image data from the file `clown.mat`.

```
load clown.mat
```

The image array `X` and its associated colormap, `map`, are loaded into the MATLAB workspace. `map` is a matrix of 81 RGB vectors.

Define a copper-tone colormap with 81 RGB vectors. Then, write the image data to a PNG file using the new colormap.

```
newmap = copper(81);
imwrite(X,newmap,'copperclown.png');
```

`imwrite` creates the file, `copperclown.png`, in your current folder.

View the new file by opening it outside of MATLAB.

Write Truecolor Image to JPEG

Create and write truecolor image data to a JPEG file.

Create a 49-by-49-by-3 array of random RGB values.

```
A = rand(49,49);
A(:,:,2) = rand(49,49);
A(:,:,3) = rand(49,49);
```

Write the image data to a JPEG file, specifying the output format using the string, `'jpg'`. Add a comment to the file using the `'Comment'` name-value pair argument.

```
imwrite(A,'newImage.jpg','jpg','Comment','My JPEG file')
```

View information about the new file.

```
imfinfo('newImage.jpg')
```

```
ans =

           Filename: 'S:\newImage.jpg'
        FileModDate: '25-Jan-2013 16:18:41'
           FileSize: 2339
             Format: 'jpg'
```

```
      FormatVersion: ''
              Width: 49
             Height: 49
           BitDepth: 24
          ColorType: 'truecolor'
    FormatSignature: ''
    NumberOfSamples: 3
       CodingMethod: 'Huffman'
      CodingProcess: 'Sequential'
            Comment: {'My JPEG file'}
```

Write Multiple Images to TIFF File

Write multiple images to a single multipage TIFF file.

Create two sets of random image data, `im1` and `im2`.

```
im1 = rand(50,40,3);
im2 = rand(50,50,3);
```

Write the first image to a new TIFF file. Then, append the second image to the same file.

```
imwrite(im1,'myMultipageFile.tif')
imwrite(im2,'myMultipageFile.tif','WriteMode','append')
```

Write Animated GIF

Animate a series of plots and write the result to a GIF file.

Define the x-axis limits for the plot and specify the output file name.

```
x = 0:0.01:1;
figure
filename = 'testAnimated.gif';
```

Call `frame2im` to get image data from a single movie frame. Because three-dimensional data is not supported for GIF files, call `rgb2ind` to convert the RGB data in the image data, `im`, to an indexed image, `A`, with a colormap, `map`. Call `imwrite` with the name-value pair argument, `'WriteMode','append'`, to append multiple images to the first image.

```
for n = 1:0.5:5
y = x.^n;
plot(x,y)
drawnow
frame = getframe(1);
```

```
im = frame2im(frame);
[A,map] = rgb2ind(im,256);
 if n == 1;
  imwrite(A,map,filename,'gif','LoopCount',Inf,'DelayTime',1);
 else
  imwrite(A,map,filename,'gif','WriteMode','append','DelayTime',1);
 end
end
```

`imwrite` writes the GIF file to your current folder. Name-value pair `'LoopCount',Inf` causes the animation to continuously loop. `'DelayTime',1` specifies a 1-second delay between the display of each image in the animation.

Input Arguments

A — Image data to write

matrix

Image data to write, specified as a full (nonsparse) matrix.

- For grayscale images, `A` can be `m`-by-`n`.
- For indexed images, `A` can be `m`-by-`n`. Specify the associated colormap in the `map` input argument.
- For truecolor images, `A` must be `m`-by-`n`-by-3. `imwrite` does not support writing RGB images to GIF files.

For TIFF files, `A` can be an `m`-by-`n`-by-4 array containing color data that uses the CMYK color space.

For multiframe GIF files, `A` can be an `m`-by-`n`-by-1-by-`p` array containing grayscale or indexed images, where `p` is the number of frames to write. RGB images are not supported in this case.

Data Types: `double` | `single` | `uint8` | `uint16` | `logical`

filename — Name of output file

string

Name of the output file including the file extension, specified as a string. For a list of the image types that `imwrite` can write, see the description for the fmt input argument.

Example: `'myFile.gif'`

Data Types: `char`

`map` — Colormap of indexed image

`m`-by-3 array

Colormap associated with indexed image data in `A`, specified as an `m`-by-3 array. `map` must be a valid MATLAB colormap. See `colormap` for a list of built-in MATLAB colormaps. Most image file formats do not support colormaps with more than 256 entries.

Example: `[0,0,0;0.5,0.5,0.5;1,1,1]`

Example: `jet(60)`

Data Types: `double`

`fmt` — Format of output file

string

Format of the output file, specified as one of the following strings.

This table also summarizes the types of images that `imwrite` can write. The MATLAB file format registry determines which file formats are supported. See `imformats` for more information about this registry.

For certain formats, `imwrite` can accept additional name-value pair arguments. To view these arguments, click the linked format names below.

Value of `fmt`	Format of Output File	Description
`'bmp'`	Windows Bitmap (BMP)	1-bit, 8-bit, and 24-bit uncompressed images
`'gif'`	Graphics Interchange Format (GIF)	8-bit images
`'hdf'`	Hierarchical Data Format (HDF4)	8-bit raster image data sets with or without associated colormap, 24-bit raster image data sets
`'jpg'` or `'jpeg'`	Joint Photographic Experts Group (JPEG)	8-bit, 12-bit, and 16-bit Baseline JPEG images

Value of `fmt`	Format of Output File	Description
		Note: `imwrite` converts indexed images to RGB before writing data to JPEG files, because the JPEG format does not support indexed images.
`'jp2'` or `'jpx'`	JPEG 2000 — Joint Photographic Experts Group 2000	1-bit, 8-bit, and 16-bit JPEG 2000 images
`'pbm'`	Portable Bitmap (PBM)	Any 1-bit PBM image, ASCII (plain) or raw (binary) encoding
`'pcx'`	Windows Paintbrush (PCX)	8-bit images
`'pgm'`	Portable Graymap (PGM)	Any standard PGM image; ASCII (plain) encoded with arbitrary color depth; raw (binary) encoded with up to 16 bits per gray value
`'png'`	Portable Network Graphics (PNG)	1-bit, 2-bit, 4-bit, 8-bit, and 16-bit grayscale images; 8-bit and 16-bit grayscale images with alpha channels; 1-bit, 2-bit, 4-bit, and 8-bit indexed images; 24-bit and 48-bit truecolor images; 24-bit and 48-bit truecolor images with alpha channels
`'pnm'`	Portable Anymap (PNM)	Any of the PPM/PGM/PBM formats, chosen automatically
`'ppm'`	Portable Pixmap (PPM)	Any standard PPM image: ASCII (plain) encoded with arbitrary color depth or raw (binary) encoded with up to 16 bits per color component
`'ras'`	Sun™ Raster (RAS)	Any RAS image, including 1-bit bitmap, 8-bit indexed, 24-bit truecolor, and 32-bit truecolor with alpha

Value of `fmt`	Format of Output File	Description
`'tif'` or `'tiff'`	Tagged Image File Format (TIFF)	Baseline TIFF images, including: • 1-bit, 8-bit, 16-bit, 24-bit, and 48-bit uncompressed images and images with packbits, LZW, or Deflate compression • 1-bit images with CCITT 1D, Group 3, and Group 4 compression • CIELAB, ICCLAB, and CMYK images
`'xwd'`	X Windows Dump (XWD)	8-bit ZPixmaps

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `imwrite(A,'myFile.png','BitDepth',8)` writes the data in `A` using 8 bits to represent each pixel.

GIF — Graphics Interchange Format

`'BackgroundColor'` — Color to use as background color
scalar integer

Color to use as background color for the indexed image, specified as the comma-separated pair consisting of `'BackgroundColor'` and a scalar integer corresponding to the colormap index.

The background color is used for some disposal methods in animated GIFs.

- If image data `A` is `uint8` or `logical`, then the colormap index is zero-based.
- If image data `A` is `double`, then the colormap index is one-based.

The default background color corresponds to the first color in the colormap.

Example: `'BackgroundColor',15`

'Comment' — Comment to add to image

string | cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a string or a 1-by-n cell array of strings. For a cell array of strings, imwrite adds a carriage return after each string.

Example: 'Comment',{'Sample #314','January 5, 2013'}

Data Types: char | cell

'DelayTime' — Delay before displaying next image

0.5 (default) | scalar value in the range [0,655]

Delay before displaying next image, in seconds, specified as the comma-separated pair consisting of 'DelayTime' and a scalar value in the range [0,655]. A value of 0 displays images as fast as your hardware allows.

Example: 'DelayTime',60

'DisposalMethod' — Disposal method of animated GIF

'doNotSpecify' (default) | 'leaveInPlace' | 'restoreBG' | 'restorePrevious'

Disposal method of an animated GIF, specified as the comma-separated pair consisting of 'DisposalMethod' and one of the following strings.

Value of DisposalMethod	Result
'doNotSpecify' (default)	Replace one full-size, nontransparent frame with another.
'leaveInPlace'	Any pixels not covered up by the next frame continue to display.
'restoreBG'	The background color or background tile shows through transparent pixels.
'restorePrevious'	Restore to the state of a previous, undisposed frame.

Example: 'DisposalMethod','restoreBG'

'Location' — Offset of screen relative to image

[0,0] (default) | two-element vector

Offset of the screen relative to the image, measured from the top left corner of each, specified as the comma-separated pair consisting of `'Location'` and a two-element vector. The first vector element specifies the offset from the top, and the second element specifies the offset from the left, in pixels.

Example: `'Location',[10,15]`

Data Types: `double`

`'LoopCount'` — Number of times to repeat animation

`Inf` (default) | integer in the range `[0,65535]`

Number of times to repeat the animation, specified as the comma-separated pair consisting of `'LoopCount'` and either an integer in the range `[0,65535]`, or the value `Inf`. If you specify 0, the animation plays once. If you specify the value 1, the animation plays twice, and so on. A `LoopCount` value of `Inf` causes the animation to continuously loop.

To enable animation within Microsoft PowerPoint®, specify a value for `'LoopCount'` within the range [1,65535]. Some Microsoft applications interpret the value 0 to mean do not loop at all.

Example: `'LoopCount',3`

`'ScreenSize'` — Height and width of frame

height and width of input image (default) | two-element vector

Height and width of the frame, specified as the comma-separated pair consisting of `'ScreenSize'` and a two-element vector. When you use the `ScreenSize` argument with `'Location'`, it provides a way to write frames to the image that are smaller than the whole frame. `'DisposalMethod'` determines the fill value for pixels outside the frame.

Example: `'ScreenSize',[1000 1060]`

Data Types: `double`

`'TransparentColor'` — Color to use as transparent color

scalar integer

Color to use as transparent color for the image, specified as the comma-separated pair consisting of `'TransparentColor'` and a scalar integer corresponding to the colormap index.

- If image data A is `uint8` or `logical`, then indexing begins at `0`.
- If image data A is `double`, then indexing begins at `1`.

Example: `'TransparentColor',20`

`'WriteMode'` — Writing mode

`'overwrite'` (default) | `'append'`

Writing mode, specified as the comma-separated pair consisting of `'WriteMode'` and either `'overwrite'` or `'append'`. In `overwrite` mode, `imwrite` overwrites an existing file,`filename`. In `append` mode, `imwrite` adds a single frame to the existing file.

Example: `'WriteMode','append'`

HDF4 — Hierarchical Data Format

`'Compression'` — Compression scheme

`'none'` (default) | `'jpeg'` | `'rle'`

Compression scheme, specified as the comma-separated pair consisting of `'Compression'` and one of the following strings.

Value of `Compression`	Result
`'none'` (default)	No compression
`'jpeg'`	JPEG compression. Valid only for grayscale and RGB images.
`'rle'`	Run-length encoding. Valid only for grayscale and indexed images.

Example: `'Compression','jpeg'`

`'Quality'` — Quality of JPEG-compressed file

75 (default) | scalar in the range [0,100]

Quality of the JPEG-compressed file, specified as the comma-separated pair consisting of `'Quality'` and a scalar in the range [0,100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression. This parameter applies only if `'Compression'` is `'jpeg'`.

Example: `'Quality',25`

'WriteMode' — Writing mode

'overwrite' (default) | 'append'

Writing mode, specified as the comma-separated pair consisting of 'WriteMode' and either 'overwrite' or 'append'. In overwrite mode, imwrite overwrites an existing file,filename. In append mode, imwrite adds a single frame to the existing file.

Example: 'WriteMode','append'

JPEG — Joint Photographic Experts Group

'BitDepth' — Number of bits per pixel

8 (default) | scalar

Number of bits per pixel, specified as the comma-separated pair consisting of 'BitDepth' and a scalar.

- For grayscale images, the BitDepth value can be 8, 12, or 16. The default value is 8. For 16-bit images, the 'Mode' name-value pair argument must be 'lossless'.
- For color images, the BitDepth value is the number of bits per plane, and can be 8 or 12. The default is 8 bits per plane.

Example: 'BitDepth',12

'Comment' — Comment to add to image

string | character array | n-by-1 cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of 'Comment' and a single string, a character array, or an n-by-1 cell array of strings. imwrite writes each row of input as a comment in the JPEG file.

Example: 'Comment',{'First line';'second line';'third line'}

Data Types: char | cell

'Mode' — Type of compression

'lossy' (default) | 'lossless'

Type of compression, specified as the comma-separated pair consisting of 'Mode' and one of the following strings:

- 'lossy'
- 'lossless'

Example: `'Mode','lossless'`

`'Quality'` — Quality of output file

75 (default) | scalar in the range [0,100]

Quality of the output file, specified as the comma-separated pair consisting of `'Quality'` and a scalar in the range [0,100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression. A `Quality` value of 100 does not write a lossless JPEG image. Instead, use the `'Mode','lossless'` name-value pair argument.

Example: `'Quality',100`

JPEG 2000— Joint Photographic Experts Group 2000

`'Comment'` — Comment to add to image

string | character array | cell array of strings

Comment to add to the image, specified as the comma-separated pair consisting of `'Comment'` and a single string, a character array, or a cell array of strings. `imwrite` writes each row of input as a comment in the JPEG 2000 file.

Example: `'Comment',{'First line';'second line';'third line'}`

Example: `'Comment',{'First line','second line','third line'}`

Data Types: `cell` | `char`

`'CompressionRatio'` — Target compression ratio

1 (default) | scalar

Target compression ratio, specified as the comma-separated pair consisting of `'CompressionRatio'` and a real scalar greater than or equal to 1. The compression ratio is the ratio of the input image size to the output compressed size. For example, a value of 2.0 implies that the output image size is half of the input image size or less. A higher value implies a smaller file size and reduced image quality. The compression ratio does not take into account the header size.

Specifying `CompressionRatio` is valid only when `'Mode'` is `'lossy'`.

Example: `'CompressionRatio',3`

`'Mode'` — Type of compression

`'lossy'` (default) | `'lossless'`

Type of compression, specified as the comma-separated pair consisting of `'Mode'` and one of the following strings:

- `'lossy'`
- `'lossless'`

Example: `'Mode','lossless'`

`'ProgressionOrder'` — Order of packets in code stream

`'LRCP'` (default) | `'RLCP'` | `'RPCL'` | `'PCRL'` | `'CPRL'`

Order of packets in the code stream, specified as the comma-separated pair consisting of `'ProgressionOrder'` and one of the following strings:

- `'LRCP'`
- `'RLCP'`
- `'RPCL'`
- `'PCRL'`
- `'CPRL'`

The characters in the text strings represent the following: `L` = layer, `R` = resolution, `C` = component and `P` = position.

Example: `'ProgressionOrder','RLCP'`

`'QualityLayers'` — Number of quality layers

1 (default) | integer in the range [1,20]

Number of quality layers, specified as the comma-separated pair consisting of `'QualityLayers'` and an integer in the range [1,20].

Example: `'QualityLayers',8`

`'ReductionLevels'` — Number of reduction levels

4 (default) | integer in the range [1,8]

Number of reduction levels, or wavelet decomposition levels, specified as the comma-separated pair consisting of `'ReductionLevels'` and an integer in the range [1,8].

Example: `'ReductionLevels',6`

`'TileSize'` — Tile height and width

image size (default) | two-element vector

Tile height and width, specified as the comma-separated pair consisting of `'TileSize'` and a two-element vector. The minimum size you can specify is `[128 128]`.

Example: `'TileSize',[130 130]`

PBM-, PGM-, and PPM — Portable Bitmap, Graymap, Pixmap

`'Encoding'` — Encoding
`'rawbits'` (default) | `'ASCII'`

Encoding, specified as the comma-separated pair consisting of `'Encoding'` and either `'rawbits'` for binary encoding, or `'ASCII'` for plain encoding.

Example: `'Encoding','ASCII'`

`'MaxValue'` — Maximum gray or color value
scalar

Maximum gray or color value, specified as the comma-separated pair consisting of `'MaxValue'` and a scalar.

Available only for PGM and PPM files. For PBM files, this value is always 1.

If the image array is `uint16`, then the default value for `MaxValue` is `65535`. Otherwise, the default value is `255`.

Example: `'MaxValue',510`

PNG — Portable Network Graphics

In addition to the following name-value pair arguments, you can use any parameter name that satisfies the PNG specification for keywords. That is, the name uses only printable characters, contains 80 or fewer characters, and does not contain leading or trailing spaces. The value corresponding to these user-specified names must be a string that contains no control characters other than linefeed.

`'Alpha'` — Transparency of each pixel
matrix of values in the range [0,1]

Transparency of each pixel, specified as the comma-separated pair consisting of `'Alpha'` and a matrix of values in the range [0,1]. The row and column dimensions of the `Alpha` matrix must be the same as those of the image data array. You can specify `Alpha` only for grayscale (`m`-by-`n`) and truecolor (`m`-by-`n`-by-3) image data.

Note: You cannot specify both `'Alpha'` and `'Transparency'` at the same time.

Data Types: `double` | `uint8` | `uint16`

`'Author'` — Author information

string

Author information, specified as the comma-separated pair consisting of `'Author'` and a string.

Example: `"Author','Ann Smith'`

Data Types: `char`

`'Background'` — Background color when compositing transparent pixels

scalar in the range `[0,1]` | integer in the range `[1,P]` | 3-element vector in the range `[0,1]`

Background color when compositing transparent pixels, specified as the comma-separated pair consisting of `'Background'` and a value dependent on the image data, as follows.

Image Type	Form of `Background` Value
Grayscale images	Scalar in the range `[0,1]`.
Indexed images	Integer in the range `[1,P]`, where `P` is the colormap length. For example, `'Background',50` sets the background color to the color specified by the 50th index in the colormap.
Truecolor images	Three-element vector of RGB intensities in the range `[0,1]`. For example, `'Background',[0 1 1]` sets the background color to cyan.

Data Types: `double`

`'BitDepth'` — Number of bits per pixel

scalar

Number of bits per pixel, specified as the comma-separated pair consisting of `'BitDepth'` and a scalar. Depending on the output image, the scalar can be one of the following values.

Image Type	Allowed Values for `BitDepth`
Grayscale images	1, 2, 4, 8, or 16
Grayscale images with an alpha channel	8 or 16
Indexed images	1, 2, 4, or 8
Truecolor images	8 or 16

- If the image is of class `double` or `uint8`, then the default bit depth is 8 bits per pixel.
- If the image is `uint16`, then the default is 16 bits per pixel.
- If the image is `logical`, then the default is 1 bit per pixel.

Example: `'BitDepth',4`

`'Chromaticities'` — Reference white point and primary chromaticities

8-element vector

Reference white point and primary chromaticities, specified as the comma-separated pair consisting of `'Chromaticities'` and an 8-element vector, `[wx wy rx ry gx gy bx by]`. The elements `wx` and `wy` are the chromaticity coordinates of the white point, and the elements `rx`, `ry`, `gx`, `gy`, `bx`, and `by` are the chromaticity coordinates of the three primary colors.

If you specify `Chromaticities`, you should also specify the `Gamma` name-value pair argument.

Example: `'Chromaticities', [0.312,0.329,0.002,0.002,0.001,0.001,0.115,0.312]`

Data Types: `double`

`'Comment'` — Comment to add to image

string

Comment to add to the image, specified as the comma-separated pair consisting of `'Comment'` and a string.

`'Copyright'` — Copyright notice

string

Copyright notice, specified as the comma-separated pair consisting of `'Copyright'` and a string.

`'CreationTime'` — Time of original image creation

string

Time of original image creation, specified as a string.

`'Description'` — Description of image

string

Description of the image, specified as the comma-separated pair consisting of `'Description'` and a string.

`'Disclaimer'` — Legal disclaimer

string

Legal disclaimer, specified as the comma-separated pair consisting of `'Disclaimer'` and a string.

`'Gamma'` — File gamma

scalar

File gamma, specified as the comma-separated pair consisting of `'Gamma'` and a scalar.

Example: `'Gamma',2.2`

`'ImageModTime'` — Time of last image modification

serial date number | date string

Time of the last image modification, specified as the comma-separated pair consisting of `'ImageModTime'` and a MATLAB serial date number or a date string that can be converted to a date vector using the `datevec` function. Values should be in Coordinated Universal Time (UTC).

The default `ImageModTime` value is the time when you call `imwrite`.

Example: `'ImageModTime','17-Jan-2013 11:23:10'`

Data Types: `double | char`

'InterlaceType' — Interlacing scheme

'none' (default) | 'adam7'

Interlacing scheme, specified as the comma-separated pair consisting of 'InterlaceType' and either 'none' for no interlacing, or 'adam7' to use the Adam7 algorithm.

Example: 'InterlaceType','adam7'

'ResolutionUnit' — Unit for image resolution

'unknown' (default) | 'meter'

Unit for image resolution, specified as the comma-separated pair consisting of 'ResolutionUnit' and either 'unknown' or 'meter'. If you specify ResolutionUnit, you must include at least one of the XResolution and YResolution name-value pair arguments. When the value of ResolutionUnit is 'meter', the XResolution and YResolution values are interpreted in pixels per meter.

Example: 'ResolutionUnit','meter','XResolution',1000

'SignificantBits' — Number of bits to regard as significant

[ ] (default) | scalar | vector

Number of bits in the data array to regard as significant, specified as the comma-separated pair consisting of 'SignificantBits' and a scalar or a vector in the range [1,BitDepth]. Depending on the output image type, the value must be in the following form.

Image Type	Form of SignificantBits Value
Grayscale image without an alpha channel	Scalar
Grayscale image with an alpha channel	2-element vector
Indexed image	3-element vector
Truecolor image without an alpha channel	3-element vector
Truecolor image with an alpha channel	4-element vector

Example: 'SignificantBits',[2,3]

'Software' — Software used to create the image

string

Software used to create the image, specified as the comma-separated pair consisting of `'Software'` and a string.

`'Source'` — Device used to create the image

string

Device used to create the image, specified as the comma-separated pair consisting of `'Source'` and a string.

`'Transparency'` — Pixels to consider transparent

[ ] (default) | scalar in the range [0,1] | vector

Pixels to consider transparent when no alpha channel is used, specified as the comma-separated pair consisting of `'Transparency'` and a scalar or a vector. Depending on the output image, the value must be in the following form.

Image Type	Form of `Transparency` Value
Grayscale images	Scalar in the range [0,1], indicating the grayscale color to be considered transparent.
Indexed images	`Q`-element vector of values in the range [0,1], where `Q` is no larger than the colormap length and each value indicates the transparency associated with the corresponding colormap entry. In most cases, `Q = 1`.
Truecolor images	3-element vector of RGB intensities in the range [0,1], indicating the truecolor color to consider transparent.

Note: You cannot specify both `'Transparency'` and `'Alpha'` at the same time.

Example: `'Transparency',[1 1 1]`

Data Types: `double`

`'Warning'` — Warning of nature of content

string

Warning of nature of content, specified as the comma-separated pair consisting of `'Warning'` and a string.

`'XResolution'` — Image resolution in horizontal direction

scalar

Image resolution in the horizontal direction, in pixels/unit, specified as the comma-separated pair consisting of `'XResolution'` and a scalar. Define the unit by specifying the `ResolutionUnit` name-value pair argument.

If you do not also specify `YResolution`, then the `XResolution` value applies to both the horizontal and vertical directions.

Example: `'XResolution',900`

`'YResolution'` — Image resolution in vertical direction

scalar

Image resolution in the vertical direction, in pixels/unit, specified as the comma-separated pair consisting of `'XResolution'` and a scalar. Define the unit by specifying the `ResolutionUnit` name-value pair argument.

If you do not also specify `XResolution`, then the `YResolution` value applies to both the horizontal and vertical directions.

Example: `'YResolution',900`

RAS — Sun Raster Graphic

`'Alpha'` — Transparency of each pixel

[ ] (default) | matrix

Transparency of each pixel, specified as the comma-separated pair consisting of `'Alpha'` and a matrix with row and column dimensions the same as those of the image data array.

Valid only for truecolor (`m`-by-`n`-by-3) image data.

Data Types: `double` | `single` | `uint8` | `uint16`

`'Type'` — Image type

`'standard'` (default) | `'rgb'` | `'rle'`

Image type, specified as the comma-separated pair consisting of `'Type'` and one of the following strings.

Value of `Type`	Description
`'standard'` (default)	Uncompressed, B-G-R color order for truecolor images
`'rgb'`	Uncompressed, R-G-B color order for truecolor images
`'rle`	Run-length encoding of 1-bit and 8-bit images

Example: `'Type','rgb'`

TIFF — Tagged Image File Format

`'ColorSpace'` — Color space representing color data
`'rgb'` (default) | `'cielab'` | `'icclab'`

Color space representing the color data, specified as the comma-separated pair consisting of `'ColorSpace'` and one of the following strings:

- `'rgb'`
- `'cielab'`
- `'icclab'`

Valid only when the image data array, `A`, is truecolor (`m`-by-`n`-by-3). To use the CMYK color space in a TIFF file, do not use the `'ColorSpace'` name-value pair argument. Instead, specify an `m`-by-`n`-by-4 image data array.

`imwrite` can write color image data that uses the *L*a*b** color space to TIFF files. The 1976 CIE *L*a*b** specification defines numeric values that represent luminance (*L**) and chrominance (*a** and *b**) information. To store *L*a*b** color data in a TIFF file, the values must be encoded to fit into either 8-bit or 16-bit storage. `imwrite` can store *L*a*b** color data in a TIFF file using the following encodings:

- CIELAB encodings — 8-bit and 16-bit encodings defined by the TIFF specification
- ICCLAB encodings — 8-bit and 16-bit encodings defined by the International Color Consortium

The output class and encoding used by `imwrite` depends on the class of the input image data array and the `ColorSpace` value, as shown in the following table. (The 8-bit and 16-bit CIELAB encodings cannot be input arrays because they use a mixture of signed and unsigned values and cannot be represented as a single MATLAB array.)

Input Class and Encoding	Value of `ColorSpace`	Output Class and Encoding
8-bit ICCLAB Values are integers in the range [0 255]. L^* values are multiplied by `255/100`. `128` is added to both the a^* and b^* values.	`'icclab'`	8-bit ICCLAB
	`'cielab'`	8-bit CIELAB
16-bit ICCLAB Values are integers in the range [0, 65280]. L^* values are multiplied by `65280/100`. `32768` is added to both the a^* and b^* values, which are represented as integers in the range [0,65535].	`'icclab'`	16-bit ICCLAB
	`'cielab'`	16-bit CIELAB
Double-precision 1976 CIE $L^*a^*b^*$ values L^* is in the dynamic range [0, 100]. a^* and b^* can take any value. Setting a^* and b^* to 0 (zero) produces a neutral color (gray).	`'icclab'`	8-bit ICCLAB
	`'cielab'`	8-bit CIELAB

Example: `'ColorSpace','cielab'`

`'Compression'` — Compression scheme

`'packbits' | 'none' | 'lzw' | 'deflate' | 'jpeg' | 'ccitt' | 'fax3' | 'fax4'`

Compression scheme, specified as the comma-separated pair consisting of `'Compression'` and one of the following strings:

- `'packbits'` (default for nonbinary images)
- `'none'`
- `'lzw'`
- `'deflate'`
- `'jpeg'`
- `'ccitt'` (binary images only, and the default for such images)
- `'fax3'` (binary images only)
- `'fax4'` (binary images only)

`'jpeg'` is a lossy compression scheme; other compression modes are lossless. Also, if you specify `'jpeg'` compression, you must specify the `'RowsPerStrip'` parameter and the value must be a multiple of 8.

Example: `'Compression','none'`

`'Description'` — Image description

string

Image description, specified by the comma-separated pair consisting of `'Description'` and a string. This is the text that `imfinfo` returns in the `ImageDescription` field for the output image.

Example: `'Description','Sample 2A301'`

`'Resolution'` — X- and Y-resolution

72 (default) | scalar | two-element vector

X- and Y-resolution, specified as the comma-separated pair consisting of `'Resolution'` and a scalar indicating both resolution, or a two-element vector containing the X-Resolution and Y-Resolution.

Example: `'Resolution',80`

Example: `'Resolution',[320,72]`

Data Types: `double`

`'RowsPerStrip'` — Number of rows to include in each strip

scalar

Number of rows to include in each strip, specified as the comma-separated pair consisting of `'RowsPerStrip'` and a scalar. The default value is such that each strip is about 8 kilobytes.

You must specify `RowsPerStrip` if you specify `'jpeg'` compression. The value must be a multiple of 8.

Example: `'RowsPerStrip',16`

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'WriteMode'` — Writing mode

`'overwrite'` (default) | `'append'`

Writing mode, specified as the comma-separated pair consisting of `'WriteMode'` and either `'overwrite'` or `'append'`. In `overwrite` mode, `imwrite` overwrites an existing file. In `append` mode, `imwrite` adds a page to the existing file.

Example: `'WriteMode','append'`

Introduced before R2006a

incenters

Class: TriRep

(Will be removed) Incenters of specified simplices

Note: `incenters(TriRep)` will be removed in a future release. Use `incenter(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
IC = incenters(TR,SI)
[IC RIC] = incenters(TR, SI)
```

Description

`IC = incenters(TR,SI)` returns the coordinates of the incenter of each specified simplex `SI`.

`[IC RIC] = incenters(TR, SI)` returns the incenters and the corresponding radius of the inscribed circle/sphere.

Input Arguments

`TR`	Triangulation representation.
`SI`	Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`. If `SI` is not specified the incenter information for the entire triangulation is returned, where the incenter associated with simplex `i` is the `i`'th row of `IC`.

Output Arguments

`IC`	`m`-by-`n` matrix, where `m = length(SI)`, the number of specified simplices, and `n` is the dimension of the space where the triangulation resides. Each row `IC(i,:)` represents the coordinates of the incenter of simplex `SI(i)`.
`RIC`	Vector of length `length(SI)`, the number of specified simplices.

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

Examples

Example 1

Load a 3-D triangulation:

```
load tetmesh
```

Use `TriRep` to compute the incenters of the first five tetrahedra.

```
trep = TriRep(tet, X)
ic = incenters(trep, [1:5]')
```

Example 2

Query a 2-D triangulation created with `DelaunayTri`.

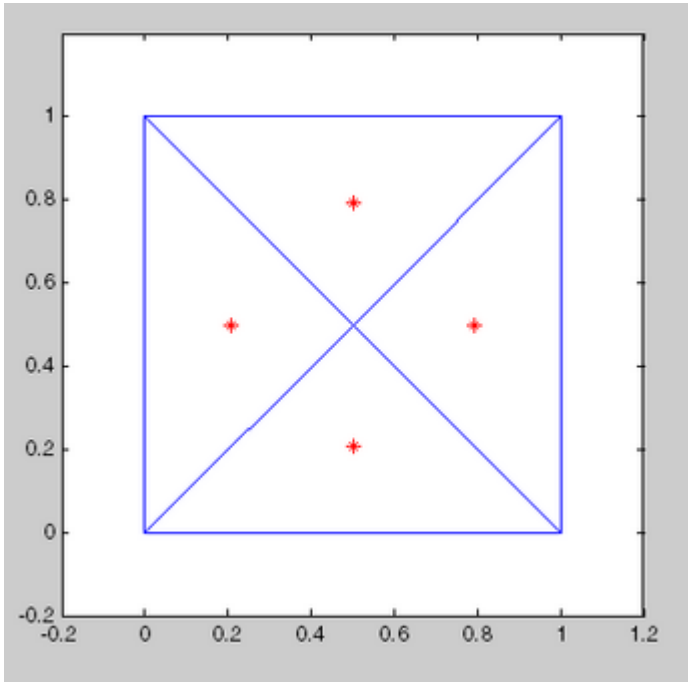
```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
dt = DelaunayTri(x,y);
```

Compute incenters of the triangles:

```
ic = incenters(dt);
```

Plot the triangles and incenters:

```
triplot(dt);
axis equal;
axis([-0.2 1.2 -0.2 1.2]);
hold on;
plot(ic(:,1),ic(:,2),'*r');
hold off;
```



See Also

`triangulation` | `delaunayTriangulation` | `circumcenter`

inOutStatus

Class: DelaunayTri

(Will be removed) Status of triangles in 2-D constrained Delaunay triangulation

---

Note: `inOutStatus(DelaunayTri)` will be removed in a future release. Use `isInterior(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
IN = inOutStatus(DT)
```

Description

`IN = inOutStatus(DT)` returns the in/out status of the triangles in a 2-D constrained Delaunay triangulation of a geometric domain. Given a Delaunay triangulation that has a set of constrained edges that define a bounded geometric domain. The `i`'th triangle in the triangulation is classified as inside the domain if `IN(i) = 1` and outside otherwise.

Note: `inOutStatus` is only relevant for 2-D constrained Delaunay triangulations where the imposed edge constraints bound a closed geometric domain.

Input Arguments

`DT`	Delaunay triangulation.

Output Arguments

`IN`	Logical array of length equal to the number of triangles in the triangulation. The constrained edges in the triangulation define the boundaries of a valid geometric domain.

Examples

Create a geometric domain that consists of a square with a square hole:

```
outerprofile = [-5 -5; -3 -5; -1 -5; 1 -5; 3 -5; ...
 5 -5; 5 -3; 5 -1; 5 1; 5 3;...
 5 5; 3 5; 1 5; -1 5; -3 5; ...
 -5 5; -5 3; -5 1; -5 -1; -5 -3; ];
innerprofile = outerprofile.*0.5;
profile = [outerprofile; innerprofile];
outercons = [(1:19)' (2:20)'; 20 1;];
innercons = [(21:39)' (22:40)'; 40 21];
edgeconstraints = [outercons; innercons];
```

Create a constrained Delaunay triangulation of the domain:

```
dt = DelaunayTri(profile, edgeconstraints)
subplot(1,2,1);
triplot(dt);
hold on;
plot(dt.X(outercons',1), dt.X(outercons',2), ...
     '-r', 'LineWidth', 2);
plot(dt.X(innercons',1), dt.X(innercons',2), ...
     '-r', 'LineWidth', 2);
axis equal;
% Plot showing interior and exterior
% triangles with respect to the domain.
hold off;
subplot(1,2,2);
inside = inOutStatus(dt);
triplot(dt(inside, :), dt.X(:,1), dt.X(:,2));
hold on;
plot(dt.X(outercons',1), dt.X(outercons',2), ...
     '-r', 'LineWidth', 2);
plot(dt.X(innercons',1), dt.X(innercons',2), ...
     '-r', 'LineWidth', 2);
axis equal;
```

```
% Plot showing interior triangles only
hold off;
```

ind2rgb

Convert indexed image to RGB image

Syntax

```
RGB = ind2rgb(X,map)
```

Description

`RGB = ind2rgb(X,map)` converts the indexed image, `X`, and the corresponding colormap, `map`, to the truecolor image, `RGB`. The indexed image, `X`, is an m-by-n array of integers. The colormap, `map`, is a three-column array of values in the range [0,1]. Each row of `map` is a three-element RGB triplet that specifies the red, green, and blue components of a single color of the colormap.

- If you specify `X` as an array of class `uint8` or `uint16`, then the value 0 corresponds to the first color in the colormap.
- If you specify `X` as an array of class `single` or `double`, then the value 1 corresponds to the first color in the colormap.

The truecolor image output, `RGB`, is an m-by-n-by-3 array. For more information on image types, see “Image Types”.

Class Support

`X` can be of class `uint8`, `uint16`, `single`, or `double`. `RGB` is an m-by-n-by-3 array of class `double`.

ind2sub

Subscripts from linear index

Syntax

```
[I,J] = ind2sub(siz,IND)
[I1,I2,I3,...,In] = ind2sub(siz,IND)
```

Description

The `ind2sub` command determines the equivalent subscript values corresponding to a single index into an array.

`[I,J] = ind2sub(siz,IND)` returns the matrices `I` and `J` containing the equivalent row and column subscripts corresponding to each linear index in the matrix `IND` for a matrix of size `siz`. `siz` is a vector with `ndim(A)` elements (in this case, 2), where `siz(1)` is the number of rows and `siz(2)` is the number of columns.

Note For matrices, `[I,J] = ind2sub(size(A),find(A>5))` returns the same values as `[I,J] = find(A>5)`.

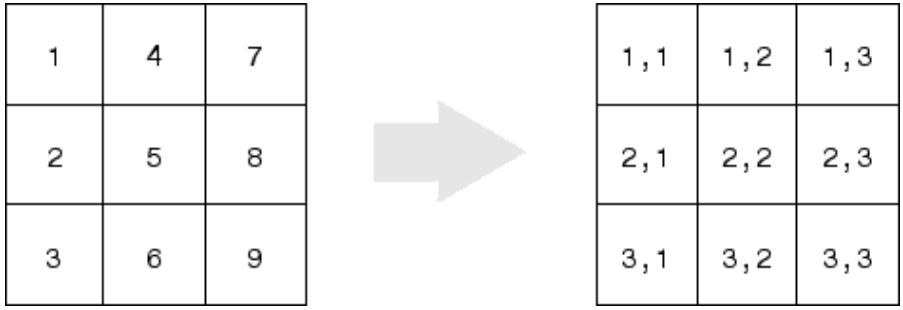
`[I1,I2,I3,...,In] = ind2sub(siz,IND)` returns `n` subscript arrays `I1,I2,...,In` containing the equivalent multidimensional array subscripts equivalent to `IND` for an array of size `siz`. `siz` is an `n`-element vector that specifies the size of each array dimension.

The `IND` input can be `single`, `double`, or any integer type. The outputs are always of class `double`.

Examples

Example 1 — Two-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 3-by-3 matrix is



This code determines the row and column subscripts in a 3-by-3 matrix, of elements with linear indices 3, 4, 5, 6.

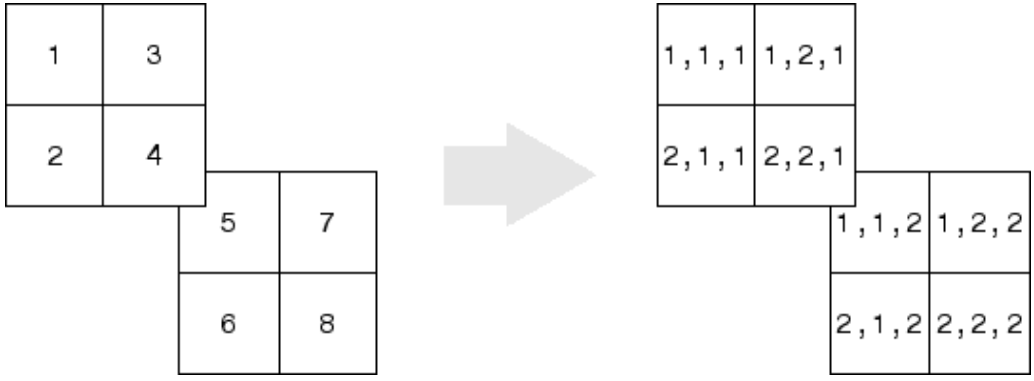
```
IND = [3 4 5 6]
s = [3,3];
[I,J] = ind2sub(s,IND)

I =
     3     1     2     3

J =
     1     2     2     2
```

Example 2 — Three-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 2-by-2-by-2 array is



This code determines the subscript equivalents in a 2-by-2-by-2 array, of elements whose linear indices 3, 4, 5, 6 are specified in the `IND` matrix.

```
IND = [3 4;5 6];
s = [2,2,2];
[I,J,K] = ind2sub(s,IND)

I =
     1     2
     1     2

J =
     2     2
     1     1

K =
     1     1
     2     2
```

Example 3 — Effects of Returning Fewer Outputs

When calling `ind2sub` for an N-dimensional matrix, you would typically supply N output arguments in the call: one for each dimension of the matrix. This example shows what happens when you return three, two, and one output when calling `ind2sub` on a 3-dimensional matrix.

The matrix is 2-by-2-by-2 and the linear indices are 1 through 8:

```
dims = [2 2 2];
indices = [1 2 3 4 5 6 7 8];
```

The 3-output call to `ind2sub` returns the expected subscripts for the 2-by-2-by-2 matrix:

```
[rowsub colsub pagsub] = ind2sub(dims, indices)
rowsub =
     1     2     1     2     1     2     1     2
colsub =
     1     1     2     2     1     1     2     2
pagsub =
     1     1     1     1     2     2     2     2
```

If you specify only two outputs (row and column), `ind2sub` still returns a subscript for each specified index, but drops the third dimension from the matrix, returning subscripts for a 2-dimensional, 2-by-4 matrix instead:

```
[rowsub colsub] = ind2sub(dims, indices)
rowsub =
     1     2     1     2     1     2     1     2
colsub =
     1     1     2     2     3     3     4     4
```

If you specify one output (row), `ind2sub` drops both the second and third dimensions from the matrix, and returns subscripts for a 1-dimensional, 1-by-8 matrix instead:

```
[rowsub] = ind2sub(dims, indices)
rowsub =
     1     2     3     4     5     6     7     8
```

Introduced before R2006a

Inf

Infinity

Syntax

```
Inf
I = Inf(n)
I = Inf(sz1,...,szN)
I = Inf(sz)

I = Inf(classname)
I = Inf(n,classname)
I = Inf(sz1,...,szN,classname)
I = Inf(sz,classname)

I = Inf('like',p)
I = Inf(n,'like',p)
I = Inf(sz1,...szN,'like',p)
I = Inf(sz,'like',p)
```

Description

`Inf` returns the IEEE arithmetic representation for positive infinity. Infinity values result from operations like division by zero and overflow, which lead to results too large to represent as conventional floating-point values.

`I = Inf(n)` is an `n`-by-`n` matrix of `Inf` values.

`I = Inf(sz1,...,szN)` is a `sz1`-by-...-by-`szN` array of `Inf` values where `sz1,...,szN` indicates the size of each dimension. For example, `Inf(3,4)` returns a 3-by-4 array of `Inf` values.

`I = Inf(sz)` is an array of `Inf` values where the size vector, `sz`, defines `size(I)`. For example, `Inf([3,4])` returns a 3-by-4 array of `Inf` values.

Note The size inputs `sz1,...,szN`, as well as the elements of the size vector `sz`, should be nonnegative integers. Negative integers are treated as 0.

`I = Inf(classname)` returns an `Inf` value where the string, `classname`, specifies the data type. `classname` can be either `'single'` or `'double'`.

`I = Inf(n,classname)` returns an `n`-by-`n` array of `Inf` values of data type `classname`.

`I = Inf(sz1,...,szN,classname)` returns a `sz1`-by-...-by-`szN` array of `Inf` values of data type `classname`.

`I = Inf(sz,classname)` returns an array of `Inf` values where the size vector, `sz`, defines `size(I)` and `classname` defines `class(I)`.

`I = Inf('like',p)` returns an array of `Inf`s of the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`I = Inf(n,'like',p)` returns an `n`-by-`n` array of `Inf` values like `p`.

`I = Inf(sz1,...szN,'like',p)` returns a `sz1`-by-...-by-`szN` array of `Inf` values like `p`.

`I = Inf(sz,'like',p)` returns an array of `Inf` values like `p` where the size vector, `sz`, defines `size(I)`.

Examples

`1/0`, `1.e1000`, `2^2000`, and `exp(1000)` all produce `Inf`.

`log(0)` produces `-Inf`.

`Inf-Inf` and `Inf/Inf` both produce `NaN` (Not-a-Number).

`isfinite` | `isfloat` | `isinf` | `nan`

Introduced before R2006a

inferiorto

Specify inferior class relationship

Syntax

```
inferiorto('class1','class2',...)
```

Description

`inferiorto('class1','class2',...)` establishes that the class invoking this function in its constructor has lower precedence than the classes in the argument list. MATLAB uses this precedence to determines which method or function MATLAB calls in any given situation.

Use this function only from a constructor that calls the `class` function to create objects (classes defined before MATLAB 7.6).

Examples

Specify class precedence.

Suppose `a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. Suppose the constructor method of `class_c` contains the statement:

```
inferiorto('class_a')
```

This function call establishes `class_a` as taking precedence over `class_c` for function dispatching. Therefore, either of the following two statements:

```
e = fun(a,c);
e = fun(c,a);
```

Invoke `class_a/fun`.

If you call a function with two objects having an unspecified relationship, the two objects have equal precedence. In this case, MATLAB calls the method of the left-most object. So `fun(b, c)` calls `class_b/fun`, while `fun(c, b)` calls `class_c/fun`.

See Also

`superiorto`

Introduced before R2006a

info

Information about contacting MathWorks

Note: `info` will be removed in a future release.

Syntax

```
info
```

Description

`info` displays in the Command Window, information about contacting MathWorks.

See Also

`help` | `version`

Introduced before R2006a

inline

Construct inline object

Compatibility

`inline` will be removed in a future release. Use “Anonymous Functions” instead.

Syntax

```
inline(expr)
inline(expr,arg1,arg2,...)
inline(expr,n)
```

Description

`inline(expr)` constructs an inline function object from the MATLAB expression contained in the string `expr`. The input argument to the inline function is automatically determined by searching `expr` for an isolated lower case alphabetic character, other than `i` or `j`, that is not part of a word formed from several alphabetic characters. If no such character exists, `x` is used. If the character is not unique, the one closest to `x` is used. If two characters are found, the one later in the alphabet is chosen.

`inline(expr,arg1,arg2,...)` constructs an inline function whose input arguments are specified by the strings `arg1`, `arg2`,`...`. Multicharacter symbol names may be used.

`inline(expr,n)` where `n` is a scalar, constructs an inline function whose input arguments are `x`, `P1`, `P2`, ...

Examples

Example 1

This example creates a simple inline function to square a number.

```
g = inline('t^2')
g =

     Inline function:
     g(t) = t^2
```

You can convert the result to a string using the `char` function.

```
char(g)

ans =

t^2
```

Example 2

This example creates an inline function to represent the formula $f = 3\sin(2x^2)$. The resulting inline function can be evaluated with the `argnames` and `formula` functions.

```
f = inline('3*sin(2*x.^2)')

f =
     Inline function:
     f(x) = 3*sin(2*x.^2)

argnames(f)

ans =
    'x'

formula(f)
ans =

3*sin(2*x.^2)
```

Example 3

This call to `inline` defines the function `f` to be dependent on two variables, `alpha` and `x`:

```
f = inline('sin(alpha*x)')

f =
```

```
     Inline function:
     f(alpha,x) = sin(alpha*x)
```

If `inline` does not return the desired function variables or if the function variables are in the wrong order, you can specify the desired variables explicitly with the `inline` argument list.

```
g = inline('sin(alpha*x)','x','alpha')

g =

     Inline function:
     g(x,alpha) = sin(alpha*x)
```

More About

Tips

Three commands related to `inline` allow you to examine an inline function object and determine how it was created.

`char(fun)` converts the inline function into a character array. This is identical to `formula(fun)`.

`argnames(fun)` returns the names of the input arguments of the inline object `fun` as a cell array of strings.

`formula(fun)` returns the formula for the inline object `fun`.

A fourth command `vectorize(fun)` inserts a `.` before any `^`, `*` or `/` in the formula for `fun`. The result is a vectorized version of the inline function.

Introduced before R2006a

inmem

Names of functions, MEX-files, classes in memory

Syntax

```
M = inmem
[M,X] = inmem
[M,X,C] = inmem
[...] = inmem('-completenames')
```

Description

`M = inmem` returns a cell array of strings containing the names of the functions that are currently loaded.

`[M,X] = inmem` returns an additional cell array `X` containing the names of the MEX-files that are currently loaded.

`[M,X,C] = inmem` also returns a cell array `C` containing the names of the classes that are currently loaded.

`[...] = inmem('-completenames')` returns not only the names of the currently loaded function and MEX-files, but the path and filename extension for each as well. No additional information is returned for loaded classes.

Examples

Functions in Memory

List the functions that remain in memory after calling the `magic` function.

```
clear all
magic(10);

M = inmem
```

```
M =
```

```
    'workspacefunc'
    'magic'
```

The function list includes `magic` and additional functions that are in memory in your current session.

MEX-Files in Memory

Call a sample MEX-function named `arrayProduct`, and then verify that the MEX-function is in memory. You must have a supported C compiler installed on your system to run this example.

```
clear all
sampleFolder = fullfile(matlabroot,'extern','examples','mex');
addpath(sampleFolder)
mex arrayProduct.c

s = 5;
A = [1.5, 2, 9];
B = arrayProduct(s,A);

[M,X] = inmem('-completenames');
X
```

```
X =
    'matlabroot\extern\examples\mex\arrayProduct.mexw64'
```

`clear`

Introduced before R2006a

innerjoin

Inner join between two tables

Syntax

```
C = innerjoin(A,B)
C = innerjoin(A,B,Name,Value)
[C,ia,ib] = innerjoin( ___ )
```

Description

`C = innerjoin(A,B)` creates the table, `C`, as the inner join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The inner join retains only the rows that match between `A` and `B` with respect to the key variables. `C` contains all nonkey variables from `A` and `B`.

`C = innerjoin(A,B,Name,Value)` performs the inner-join operation with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the variables to use as key variables.

`[C,ia,ib] = innerjoin( ___ )` also returns index vectors, ia and ib indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

Examples

Inner-Join Operation of Tables with One Variable in Common

Create a table, `A`.

```
A = table([5;12;23;2;6],...
    {'cereal';'pizza';'salmon';'cookies';'pizza'},...
    'VariableNames',{'Age','FavoriteFood'})
```

```
A =

    Age    FavoriteFood
```

```
    ___    ____________

     5     'cereal'
    12     'pizza'
    23     'salmon'
     2     'cookies'
     6     'pizza'
```

Create a table, `B`, with one variable in common with `A`.

```
B = table({'cereal';'cookies';'pizza';'salmon';'cake'},...
    [110;160;140;367;243],...
    {'A-';'D';'B';'B';'C-'},...
    'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

```
B =

    FavoriteFood    Calories    NutritionGrade
    ____________    ________    ______________

    'cereal'        110         'A-'
    'cookies'       160         'D'
    'pizza'         140         'B'
    'salmon'        367         'B'
    'cake'          243         'C-'
```

Use the`innerjoin` function to create a new table, `C`, with data from tables `A` and `B`.

```
C = innerjoin(A,B)
```

```
C =

    Age    FavoriteFood    Calories    NutritionGrade
    ___    ____________    ________    ______________

     5     'cereal'        110         'A-'
     2     'cookies'       160         'D'
    12     'pizza'         140         'B'
     6     'pizza'         140         'B'
    23     'salmon'        367         'B'
```

Table `C` is sorted by the key variable, `FavoriteFood`.

Inner-Join Operation of Tables and Indices to Values

Create a table, `A`.

```
A = table({'a' 'b' 'c' 'e' 'h'}',[1 2 3 11 17]',...
    'VariableNames',{'Key1' 'Var1'})
```

```
A =

    Key1    Var1
    ____    ____

    'a'      1
    'b'      2
    'c'      3
    'e'     11
    'h'     17
```

Create a table, `B`, with common values in the variable `Key1` between tables `A` and `B`, but also containing rows with values of `Key1` not present in `A`.

```
B = table({'a' 'b' 'd' 'e'}',[4 5 6 7]',...
    'VariableNames',{'Key1' 'Var2'})
```

```
B =

    Key1    Var2
    ____    ____

    'a'     4
    'b'     5
    'd'     6
    'e'     7
```

Use the `innerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Retain only rows whose values in the variable `Key1` match.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = innerjoin(A,B)
```

```
 C =

    Key1    Var1    Var2
    ____    ____    ____

    'a'      1      4
    'b'      2      5
    'e'     11      7
```

```
ia =

     1
     2
     4

ib =

     1
     2
     4
```

Table `C` is sorted by the values in the key variable, `Key1`, and contains the horizontal concatenation of `A(ia,:)` and `B(ib,'Var2')` .

Inner-Join Operation of Tables Using Left and Right Keys

Create a table, `A`.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

```
A =

    Var1    Var2    Var3
    ____    ____    ____

    10      5       10
     4      4        3
     2      9        8
     3      6        8
     7      1        4
```

Create a table, `B`, with common values in the second variable as the first variable of table `A`.

```
B = table([6;1;1;6;8],[2;3;4;5;6])
```

```
B =

    Var1    Var2
    ____    ____
```

```
    6       2
    1       3
    1       4
    6       5
    8       6
```

Use the `innerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Use the first variable of `A` and the second variable of `B` as key variables.

```
[C,ia,ib] = innerjoin(A,B,'LeftKeys',1,'RightKeys',2)
```

```
C =

    Var1_A    Var2    Var3    Var1_B
    ______    ____    ____    ______

    2         9       8       6
    3         6       8       1
    4         4       3       1

ia =

     3
     4
     2

ib =

     1
     2
     3
```

Table `C` retains only the rows that match between `A` and `B` with respect to the key variables.

Table `C` contains the horizontal concatenation of `A(ia,:)` and `B(ib,'Var1')`.

Input Arguments

`A,B` — Input tables

tables

Input tables, specified as tables.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Keys',2` uses the second variable in `A` and the second variable in `B` as key variables.

`'Keys'` — Variables to use as keys

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of `'Keys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the `'Keys'` name-value pair argument with the `'LeftKeys'` and `'RightKeys'` name-value pair arguments.

Example: `'Keys',[1 3]` uses the first and third variables in `A` and `B` as a key variables.

`'LeftKeys'` — Variables to use as keys in `A`

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in `A`, specified as the comma-separated pair consisting of `'LeftKeys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the `'LeftKeys'` name-value pair argument in conjunction with the `'RightKeys'` name-value pair argument. `'LeftKeys'` and `'RightKeys'` both must specify the same number of key variables. `innnerjoin` pairs key values based on their order.

Example: `'LeftKeys',1` uses only the first variable in `A` as a key variable.

`'RightKeys'` — Variables to use as keys in `B`

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of 'RightKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'RightKeys' name-value pair argument in conjunction with the 'LeftKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. innerjoin pairs key values based on their order.

Example: 'RightKeys',3 uses only the third variable in B as a key variable.

'LeftVariables' — Variables from A to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of 'LeftVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'LeftVariables' to include or exclude key variables, as well as nonkey variables from the output, C.

By default, innerjoin includes all variables from A.

'RightVariables' — Variables from B to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from B to include in C, specified as the comma-separated pair consisting of 'RightVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'RightVariables' to include or exclude key variables, as well as nonkey variables from the output, C.

By default, innerjoin includes all the variables from B except the key variables.

Output Arguments

C — Inner join from A and B

table

Inner join from A and B, returned as a table. The output table, C, contains one row for each pair of rows in tables A and B that share the same combination of values in the key variables. If A and B contain variables with the same name, innerjoin adds a unique suffix to the corresponding variable names in C.

In general, if there are m rows in table A and n rows in table B that all contain the same combination of values in the key variables, table C contains m*n rows for that combination.

C is sorted by the values in the key variables and contains the horizontal concatenation of A(ia,LeftVars) and B(ib,RightVars). By default, LeftVars consists of all the variables of A, and RightVars consists of all the nonkey variables from B. Otherwise, LefttVars consists of the variables specified by the 'LeftVariables' name-value pair argument, and RightVars is the variables specified by the 'RightVariables' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the output table, C. For more information, see Table Properties.

ia — Index to A
column vector

Index to A, returned as a column vector. Each element of ia identifies the row in table A that corresponds to that row in the output table, C.

ib — Index to B
column vector

Index to B, returned as a column vector. Each element of ib identifies the row in table B that corresponds to that row in the output table, C.

More About

Key Variable

Variable used to match and combine data between the input tables, A and B.

join | outerjoin

inpolygon

Points located inside or on edge of polygonal region

Syntax

```
in = inpolygon(xq,yq,xv,yv)
[in,on] = inpolygon(xq,yq,xv,yv)
```

Description

`in = inpolygon(xq,yq,xv,yv)` returns `in` indicating if the query points specified by `xq` and `yq` are inside or on the edge of the polygon area defined by `xv` and `yv`.

`[in,on] = inpolygon(xq,yq,xv,yv)` also returns `on` indicating if the query points are on the edge of the polygon area.

Examples

Points Inside Convex Polygon

Define a pentagon and a set of points. Then, determine which points lie inside (or on the edge) of the pentagon.

Define the x and y coordinates of polygon vertices to create a pentagon.

```
L = linspace(0,2.*pi,6);
xv = cos(L)';
yv = sin(L)';
```

Define x and y coordinates of 250 random query points. Initialize the random-number generator to make the output of `randn` repeatable.

```
rng default
xq = randn(250,1);
```

```
yq = randn(250,1);
```

Determine whether each point lies inside or on the edge of the polygon area. Also determine whether any of the points lie on the edge of the polygon area.

```
[in,on] = inpolygon(xq,yq,xv,yv);
```

Determine the number of points lying inside or on the edge of the polygon area.

```
numel(xq(in))
```

```
ans =

    80
```

Determine the number of points lying on the edge of the polygon area.

```
numel(xq(on))
```

```
ans =

     0
```

Since there are no points lying on the edge of the polygon area, all 80 points identified by `xq(in)`, `yq(in)` are strictly inside the polygon area.

Determine the number of points lying outside the polygon area (not inside or on the edge).

```
numel(xq(~in))
```

```
ans =

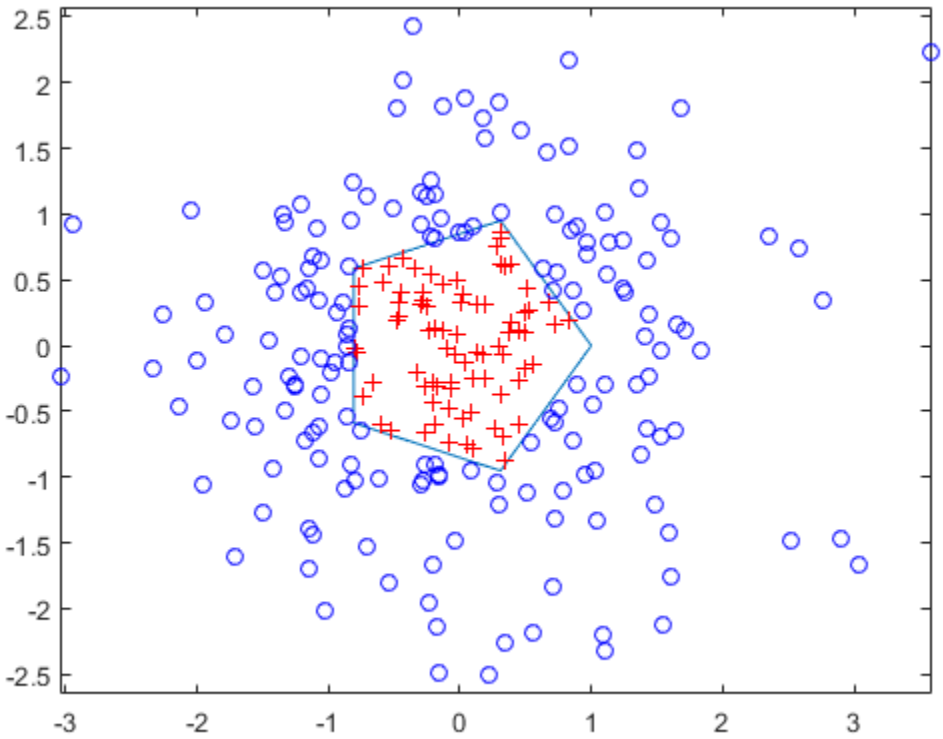
   170
```

Plot the polygon and the query points. Display the points inside the polygon with a red plus. Display the points outside the polygon with a blue circle.

```
figure

plot(xv,yv) % polygon
axis equal

hold on
plot(xq(in),yq(in),'r+') % points inside
plot(xq(~in),yq(~in),'bo') % points outside
hold off
```



Points Inside Multiply Connected Polygon

Find the points inside a square with a square hole.

Define a square region with a square hole. Specify the vertices of the outer loop in a counterclockwise direction, and specify the vertices for the inner loop in a clockwise direction. Use `NaN` to separate the coordinates for the outer and inner loops.

```
xv = [1 4 4 1 1 NaN 2 2 3 3 2];
yv = [1 1 4 4 1 NaN 2 3 3 2 2];
```

Define x and y coordinates of 500 random points. Initialize the random-number generator to make the output of `randn` repeatable.

```
rng default
xq = rand(500,1)*5;
yq = rand(500,1)*5;
```

Determine whether each point lies inside or on the edge of the polygon area.

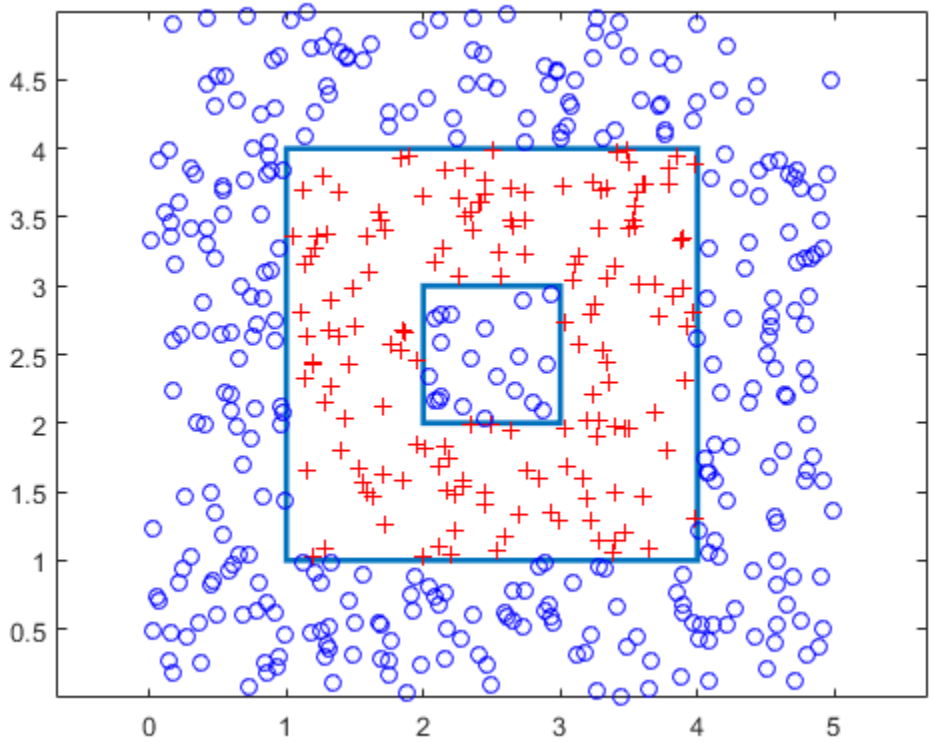
```
in = inpolygon(xq,yq,xv,yv);
```

Plot the polygon and the query points. Display the points inside the polygon with a red plus. Display the points outside the polygon with a blue circle.

```
figure

plot(xv,yv,'LineWidth',2) % polygon
axis equal

hold on
plot(xq(in),yq(in),'r+') % points inside
plot(xq(~in),yq(~in),'bo') % points outside
hold off
```



Query points in the square hole are outside the polygon.

Points Inside Self-Intersecting Polygon

Define the x and y coordinates for a pentagram.

```
xv = [0.5;0.2;1.0;0;0.8;0.5];
yv = [1.0;0.1;0.7;0.7;0.1;1];
```

Define the x and y coordinates of 12 query points.

```
xq = [0.1;0.5;0.9;0.2;0.4;0.5;0.5;0.9;0.6;0.8;0.7;0.2];
yq = [0.4;0.6;0.9;0.7;0.3;0.8;0.2;0.4;0.4;0.6;0.2;0.6];
```

Determine whether each point lies inside or on the edge of the polygon area. Also determine whether any of the points lie on the edge of the polygon area.

```
[in,on] = inpolygon(xq,yq,xv,yv);
```

Determine the number of points lying inside or on the edge of the polygon area.

```
numel(xq(in))
```

```
ans =

     8
```

Determine the number of points lying on the edge of the polygon area.

```
numel(xq(on))
```

```
ans =

     2
```

Determine the number of points lying outside the polygon area (not inside or on the edge).

```
numel(xq(~in))
```

```
ans =

     4
```

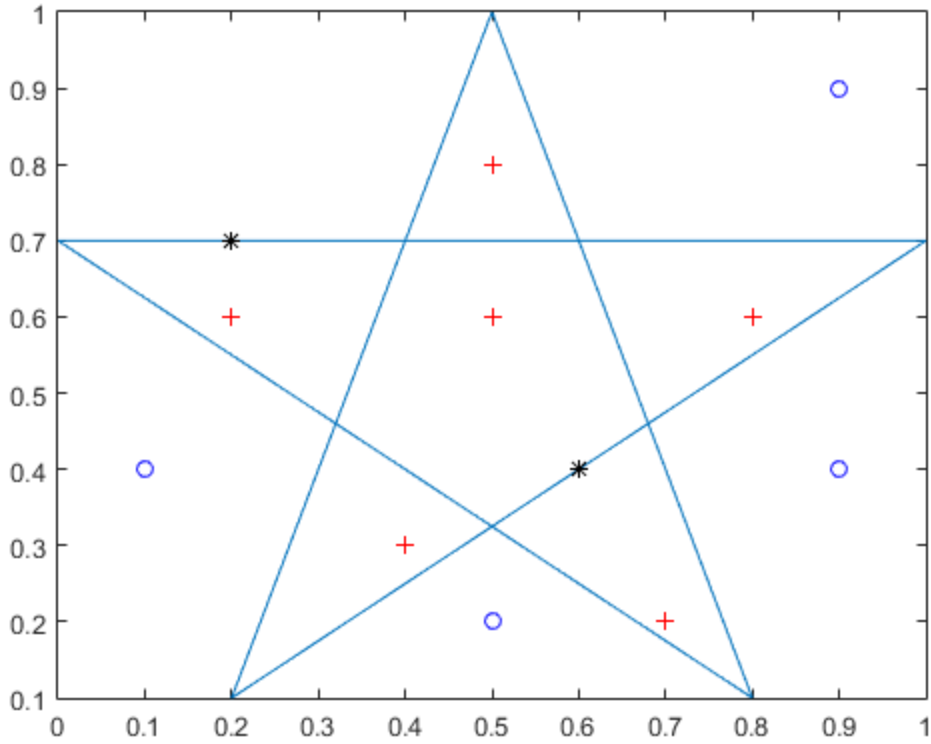
Plot the polygon and the points. Display the points strictly inside the polygon with a red plus. Display the points on the edge with a black asterisk. Display the points outside the polygon with a blue circle.

```
figure

plot(xv,yv) % polygon

hold on
```

```
plot(xq(in&~on),yq(in&~on),'r+') % points strictly inside
plot(xq(on),yq(on),'k*') % points on edge
plot(xq(~in),yq(~in),'bo') % points outside
hold off
```



Six points lie inside the polygon. Two points lie on the edge of the polygon. Four points lie outside the polygon.

Input Arguments

xq — x-coordinates of query points

scalar | vector | matrix | multidimensional array

x-coordinates of query points, specified as a scalar, vector, matrix, or multidimensional array.

The size of `xq` must match the size of `yq`.

Data Types: `double | single`

yq — y-coordinates of query points

scalar | vector | matrix | multidimensional array

y-coordinates of query points, specified as a scalar, vector, matrix, or multidimensional array.

The size of `yq` must match the size of `xq`.

Data Types: `double | single`

xv — x-coordinates of polygon vertices

vector

x-coordinates of polygon vertices, specified as a vector.

The size of `xv` must match the size of `yv`.

To specify vertices of multiply connected or disjoint polygons, separate the coordinates for distinct loops with `NaN`. Additionally for multiply connected polygons, you must orient the vertices for external and internal loops in opposite directions.

The polygon cannot be self-intersecting and multiply connected due to the ambiguity associated with self-intersections and loop orientations.

Data Types: `double | single`

yv — y-coordinates of polygon vertices

vector

y-coordinates of polygon vertices, specified as a vector.

The size of `yv` must match the size of `xv`.

To specify vertices of multiply connected or disjoint polygons, separate the coordinates for distinct loops with `NaN`. Additionally for multiply connected polygons, you must orient the vertices for external and internal loops in opposite directions.

The polygon cannot be self-intersecting and multiply connected due to the ambiguity associated with self-intersections and loop orientations.

Data Types: `double | single`

Output Arguments

`in` — Indicator for points inside or on edge of polygon area

logical array

Indicator for the points inside or on the edge of the polygon area, returned as a logical array. `in` is the same size as `xq` and `yq`.

- A logical `1` (`true`) indicates that the corresponding query point is inside the polygonal region or on the edge of the polygon boundary.
- A logical `0` (`false`) indicates that the corresponding query point is outside the polygonal region.

Therefore, you can use `in` to index into `xq` and `yq` to identify query points of interest.

`xq(in)`, `yq(in)`	Query points inside or on the edge of the polygon area
`xq(~in)`, `yq(~in)`	Query points outside the polygonal region

`on` — Indicator for points on edge of polygon area

logical array

Indicator for the points on the edge of the polygon area, returned as a logical array. `on` is the same size as `xq` and `yq`.

- A logical `1` (`true`) indicates that the corresponding query point is on the polygon boundary.
- A logical `0` (`false`) indicates that the corresponding query point is inside or outside the polygon boundary.

Therefore, you can use `on` and `in` to index into `xq` and `yq` identify query points of interest.

`xq(on)`, `yq(on)`	Query points on the polygon boundary

`xq(~on)`, `yq(~on)`	Query points inside or outside the polygon boundary
`xq(in&~on)`, `yq(in&~on)`	Query points strictly inside the polygonal region

See Also

`delaunay`

Introduced before R2006a

input

Request user input

Syntax

```
x = input(prompt)
str = input(prompt,'s')
```

Description

`x = input(prompt)` displays the text in prompt and waits for the user to input a value and press the **Return** key. The user can enter expressions, like `pi/4` or `rand(3)`, and can use variables in the workspace.

- If the user presses the **Return** key without entering anything, then `input` returns an empty matrix.
- If the user enters an invalid expression at the prompt, then MATLAB displays the relevant error message, and then redisplays the prompt.

`str = input(prompt,'s')` returns the entered text as a string, without evaluating the input as an expression.

Examples

Request Numeric Input or Expression

Request a numeric input, and then multiply the input by 10.

```
prompt = 'What is the original value? ';
x = input(prompt)
y = x*10
```

At the prompt, enter a numeric value or array, such as `42`.

```
x =
```

```
    42

y =
   420
```

The `input` function also accepts expressions. For example, rerun the code.

```
prompt = 'What is the original value? ';
x = input(prompt)
y = x*10
```

At the prompt, enter `magic(3)`.

```
x =
     8     1     6
     3     5     7
     4     9     2

y =
    80    10    60
    30    50    70
    40    90    20
```

The expression does not need to return a numeric result. For example:

```
prompt = 'What color is the sun? ';
s = input(prompt)
```

At the prompt, type `upper('yellow')`.

```
s =
YELLOW
```

Request Unprocessed Text Input

Request a simple text response that requires no evaluation.

```
prompt = 'Do you want more? Y/N [Y]: ';
str = input(prompt,'s');
if isempty(str)
    str = 'Y';
end
```

The `input` function returns the text exactly as typed. If the input is empty, this code assigns a default value, `'Y'`, to the output string, `str`.

Input Arguments

`prompt` — Text displayed to the user

string

Text displayed to the user, specified as a string.

To create a prompt that spans several lines, use `'\n'` to indicate each new line. To include a backslash (`'\'`) in the prompt, use `'\\'`.

Output Arguments

`x` — Result calculated from input

array

Result calculated from input, returned as an array. The type and dimensions of the array depend upon the response to the prompt.

`str` — Exact text of input

string

Exact text of the input, returned as a string.

`ginput` | `inputdlg` | `keyboard` | `menu` | `uicontrol`

Introduced before R2006a

inputdlg

Create dialog box that gathers user input

Syntax

```
answer = inputdlg(prompt)
answer = inputdlg(prompt,dlg_title)
answer = inputdlg(prompt,dlg_title,num_lines)
answer = inputdlg(prompt,dlg_title,num_lines,defAns)
answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)
```

Description

`answer = inputdlg(prompt)` creates a modal dialog box and returns user input for multiple prompts in the cell array. `prompt` is a cell array containing prompt strings.

Note A modal dialog box prevents the user from interacting with other windows before responding. For more information, see WindowStyle in Figure Properties.

`answer = inputdlg(prompt,dlg_title)` `dlg_title` specifies a title for the dialog box.

`answer = inputdlg(prompt,dlg_title,num_lines)` `num_lines` specifies the number of lines for each user-entered value. `num_lines` can be a scalar, column vector, or a m x 2 array.

- If `num_lines` is a scalar, it applies to all prompts.
- If `num_lines` is a column vector, each element specifies the number of lines of input for a prompt.
- If `num_lines` is an array, it must be size m-by-2, where m is the number of prompts on the dialog box. Each row refers to a prompt. The first column specifies the number of lines of input for a prompt. The second column specifies the width of the field in characters.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns)` `defAns` specifies the default value to display for each prompt. `defAns` must contain the same number of elements as `prompt` and all elements must be strings.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)` If `options` is the string `'on'`, the dialog is made resizable in the horizontal direction. If options is a structure, the fields shown in the following table are recognized:

Field	Description
`Resize`	Can be `'on'` or `'off'` (default). If `'on'`, the window is resizable horizontally.
`WindowStyle`	Can be either `'normal'` or `'modal'` (default).
`Interpreter`	Can be either `'none'` (default) or `'tex'`. If the value is `'tex'`, the prompt strings are rendered using LaTeX.

If the user clicks the **Cancel** button to close an `inputdlg` box, the dialog returns an empty cell array:

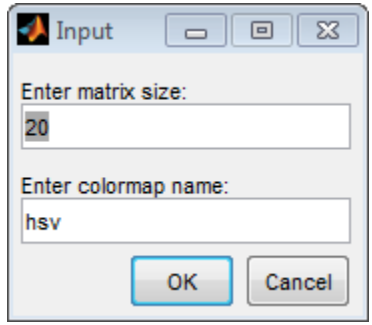
```
answer =
     {}
```

Examples

Example 1

Create a dialog box to input an integer and colormap name. Allow one line for each value.

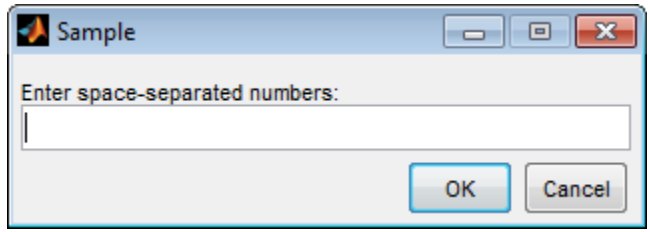
```
prompt = {'Enter matrix size:','Enter colormap name:'};
dlg_title = 'Input';
num_lines = 1;
def = {'20','hsv'};
answer = inputdlg(prompt,dlg_title,num_lines,def);
```



Example 2

Create a dialog box named to accept comma-separated numbers. MATLAB stores accepts the input as a string, so convert the string to numbers using `str2num`.

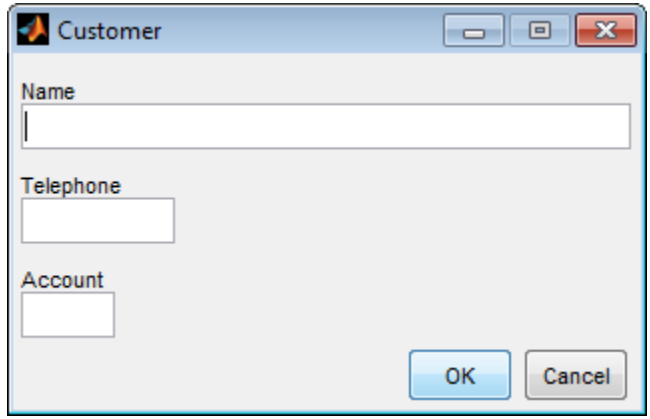
```
x = inputdlg('Enter space-separated numbers:',...
             'Sample', [1 50]);
data = str2num(x{:});
```



Example 3

Create a dialog box to display input fields of different widths.

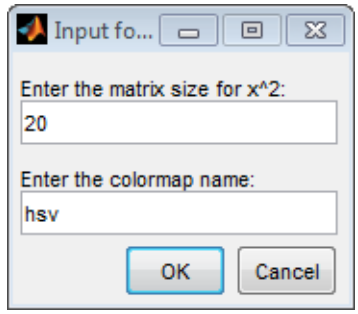
```
x = inputdlg({'Name','Telephone','Account'},...
             'Customer', [1 50; 1 12; 1 7]);
```



Example 4

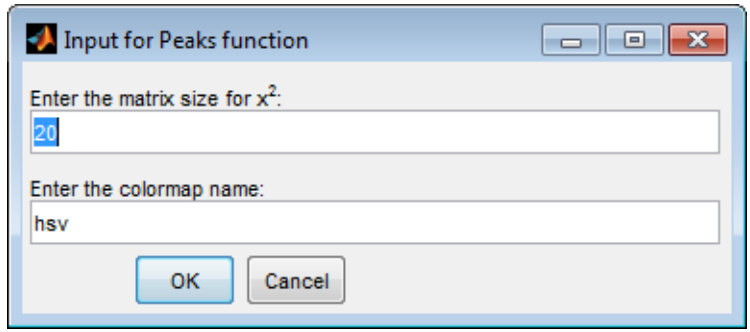
Create a dialog box using the default options. Then, use the options to make it resizable and not modal, and to interpret the text using LaTeX.

```
prompt={'Enter the matrix size for x^2:',...
        'Enter the colormap name:'};
name='Input for Peaks function';
numlines=1;
defaultanswer={'20','hsv'};
answer=inputdlg(prompt,name,numlines,defaultanswer);
```



```
options.Resize='on';
options.WindowStyle='normal';
options.Interpreter='tex';
answer=inputdlg(prompt,name,numlines,...
```

```
                defaultanswer,options);
```



More About

Tips

`inputdlg` uses the `uiwait` function to suspend execution until the user responds.

The returned variable `answer` is a cell array containing strings, one string per text entry field, starting from the top of the dialog box.

To convert a member of the cell array to a number, use `str2num`. To do this, you can add the following code to the end of any of the examples below:

```
% Use curly bracket for subscript
[val status] = str2num(answer{1});
if ~status
    % Handle empty value returned
    % for unsuccessful conversion
    % ...
end
% val is a scalar or matrix converted from the first input
```

Users can enter scalar or vector values into `inputdlg` fields; `str2num` converts space- and comma-delimited strings into row vectors, and semicolon-delimited strings into column vectors. For example, if `answer{1}` contains `'1 2 3;4 -5 6+7i'`, the conversion produces:

```
val = str2num(answer{1})
val =
   1.0000     2.0000     3.0000
```

```
   4.0000    -5.0000     6.0000 + 7.0000i
```

Introduced before R2006a

inputname

Variable name of function input

Syntax

```
inputname(argnum)
```

Description

This command can be used only inside the body of a function.

`inputname(argnum)` returns the workspace variable name corresponding to the argument number *`argnum`*. If the input argument has no name (for example, if it is an expression instead of a variable), the `inputname` command returns the empty string (`''`).

Examples

Suppose the function `myfun.m` is defined as

```
function c = myfun(a,b)
fprintf('First calling variable is "%s"\n.', inputname(1))
```

Then

```
x = 5;  y = 3;  myfun(x,y)
```

produces

```
First calling variable is "x".
```

But

```
myfun(pi+1, pi-1)
```

produces

```
First calling variable is "".
```

Introduced before R2006a

inputParser class

Parse function inputs

Description

The `inputParser` object allows you to manage inputs to a function by creating an input scheme. To check the input, you can define validation functions for required arguments, optional arguments, and name-value pair arguments. Optionally, you can set properties to adjust the parsing behavior, such as handling case sensitivity, structure array inputs, and inputs that are not in the input scheme.

After calling the `parse` method to parse the inputs, the `inputParser` saves names and values of inputs that match the input scheme (stored in `Results`), names of inputs that are not passed to the function and, therefore, are assigned default values (stored in `UsingDefaults`), and names and values of inputs that do not match the input scheme (stored in `Unmatched`).

Construction

`p = inputParser` creates `inputParser` object `p`.

Properties

`CaseSensitive`

Scalar logical value that indicates whether to match case when checking argument names.

Possible values:

`false` (0)	Names are not sensitive to case: `'a'` matches `'A'`.
`true` (1)	Names are case sensitive: `'a'` does not match `'A'`.

Default: `false`

FunctionName

String that specifies the name of the function to include in error messages. By specifying the `FunctionName`, the `parse` method of the `inputParser` will throw error messages as if it were that function. This allows the error to be attributed to the correct function and allows easy access to function documentation through the error message.

Default: The default value is an empty string, `''`.

KeepUnmatched

Scalar logical value that indicates how to handle parameter name and value inputs that are not in the input scheme.

Possible values:

`false` (0)	Throw an error whenever inputs are not in the scheme.
`true` (1)	Store the parameter names and values of unmatched inputs in the `Unmatched` property of the `inputParser` object, and suppress the error.

Default: `false`

PartialMatching

Scalar logical value that indicates whether partial matching of parameter names will be accepted. Partial parameter matching is supported by the `addParameter` method. If the value of `StructExpand` is `true`, then `PartialMatching` is not supported for structure field names corresponding to input parameter names.

Possible values:

`true` (1)	Inputs that are leading substrings of parameter names will be accepted and the value matched to that parameter. If there are multiple possible matches to the input string, MATLAB throws an error.
`false` (0)	Input names are required to match a parameter name exactly (with respect to the `CaseSensitive` property.)

Default: `true`

StructExpand

Scalar logical value that specifies whether to interpret a structure array as a single input or as a set of parameter name and value pairs.

`true` (1)	Expand structures into separate inputs. Each field name corresponds to an input parameter name.
`false` (0)	Regard a structure array as a single input argument.

Default: `true`

Read Only Properties

Parameters

Cell array of strings that contains the names of arguments currently defined in the input scheme.

Each method that adds an input argument to the scheme (`addRequired`, `addOptional`, `addParameter`) updates the `Parameters` property.

Results

Structure containing names and values of inputs that match the function input scheme, populated by the `parse` method.

Each field of the `Results` structure corresponds to the name of an input.

Unmatched

Structure array containing the names and values of inputs that do not match the function input scheme, populated by the `parse` method.

If `KeepUnmatched` is `false` (default) or all inputs match the scheme, then `Unmatched` is a 1-by-1 structure with no fields. Otherwise, each field of the structure corresponds to the name of an input that did not match the scheme.

UsingDefaults

Cell array containing the names of inputs not passed explicitly to the function and assigned default values, populated by the `parse` method.

Methods

addOptional	Add optional positional argument to input parser scheme
addParameter	Add optional parameter name-value pair argument to input parser scheme
addParamValue	(Not recommended) Add parameter name and value argument to Input Parser scheme
addRequired	Add required positional argument to input parser scheme
parse	Parse function inputs

You can define your scheme by calling `addRequired`, `addOptional`, and `addParameter` in any order, but when you call your function that uses the input parser, you should pass in required inputs first, followed by any optional positional inputs, and, finally, any name-value pairs.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

The `copy` method creates another scheme with the same properties as an existing `inputParser` object:

```
pNew = copy(pOld);
```

Examples

Input Validation

Check the validity of required and optional function inputs.

Create a custom function with required and optional inputs in the file `findArea.m`.

```
function a = findArea(width,varargin)
   p = inputParser;
   defaultHeight = 1;
   defaultUnits = 'inches';
   defaultShape = 'rectangle';
   expectedShapes = {'square','rectangle','parallelogram'};

   addRequired(p,'width',@isnumeric);
   addOptional(p,'height',defaultHeight,@isnumeric);
   addParameter(p,'units',defaultUnits);
   addParameter(p,'shape',defaultShape,...
                @(x) any(validatestring(x,expectedShapes)));

   parse(p,width,varargin{:});
   a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```
Error using findArea (line 14)
The value of 'width' is invalid. It must satisfy the function: isnumeric.
```

Specify an unsupported value for `shape`:

```
findArea(4,'shape','circle')
```

```
Error using findArea (line 14)
The value of 'shape' is invalid. Expected input to match one of these strings:

square, rectangle, parallelogram

The input, ''circle'', did not match any of the valid strings.
```

Extra Parameter Value Inputs

Store parameter name and value inputs that are not in the input scheme instead of throwing an error.

```
default = 0;
value = 1;
```

```
p = inputParser;
p.KeepUnmatched = true;
addOptional(p,'expectedInputName',default)
parse(p,'extraInput',value);
```

View the unmatched parameter name and value:

```
p.Unmatched
```

```
ans =

    extraInput: 1
```

Case Sensitivity

Enforce case sensitivity when checking function inputs.

```
p = inputParser;
p.CaseSensitive = true;
defaultValue = 0;
addParameter(p,'InputName',defaultValue)

parse(p,'inputname',10)
```

```
'inputname' is not a recognized parameter. For a list of valid name-value pair arguments, see the documentation for this f
```

Structure Array Inputs

Parse structure array inputs with the `StructExpand` property set to `true` (default) or `false`.

Expand a structure array input into parameter name and value pairs using the default `true` value of the `StructExpand` property.

```
s.input1 = 10;
s.input2 = 20;
default = 0;

p = inputParser;
addParameter(p,'input1',default)
addParameter(p,'input2',default)
parse(p,s)
```

```
p.Results
```

```
ans =

    input1: 10
    input2: 20
```

Explicitly specifying a parameter name and value pair overrides values in the structure.

```
parse(p,s,'input2',300)
p.Results
```

```
ans =

    input1: 10
    input2: 300
```

Accept a structure array input as a single argument by setting the `StructExpand` property to `false`.

```
s2.first = 1;
s2.random = rand(3,4,2);
s2.mytext = 'some text';

p = inputParser;
p.StructExpand = false;
addRequired(p,'structInput')
parse(p,s2)

results = p.Results
fieldList = fieldnames(p.Results.structInput)
```

```
results =

    structInput: [1x1 struct]

fieldList =
```

```
    'first'
    'random'
    'mytext'
```

Parse Inputs Using `validateattributes`

Create a function that parses information about people and, if parsing passes, adds the information to a cell array.

Create a function, `addPerson`, that sets up an `inputParser` scheme using `validateAttributes`. The function should accept the list of people, modify the list if necessary and return the list. Use a persistent `inputParser` to avoid construction of a new object with every function call. If this is the first call to the function, add a titles row to the cell array.

```
function mlist = addPerson(mlist,varargin)

persistent p
if isempty(p)
    p = inputParser;
    p.FunctionName = 'addPerson';
    addRequired(p,'name',@(x)validateattributes(x,{'char'},...
        {'nonempty'}))
    addRequired(p,'id',@(x)validateattributes(x,{'numeric'},...
        {'nonempty','integer','positive'}))
    addOptional(p,'birthyear',9999,@(x)validateattributes(x,...
        {'numeric'},{'nonempty'}))
    addParameter(p,'nickname','-',@(x)validateattributes(x,...
        {'char'},{'nonempty'}))
    addParameter(p,'favColor','-',@(x)validateattributes(x,...
        {'char'},{'nonempty'}))
end

parse(p,varargin{:})

if isempty(mlist)
    mlist = fieldnames(p.Results)';
end
mlist = [mlist; struct2cell(p.Results)'];

end
```

Create an empty list, and add a person to it.

```
pList = {};
pList = addPerson(pList,78,'Joe');

Error using addPerson
The value of 'name' is invalid. Expected input to be one of these types:

char

Instead its type was double.
Error in addPerson (line 17)
```

```
parse(p,mlist,name,id,varargin{:});
```

The parsing failed because the function received the inputs in the incorrect order and tried to assign `name` a value of `78`. This entry was not added to `pList`.

Add several more people to the list.

```
pList = addPerson(pList,'Joe',78);
pList = addPerson(pList,'Mary',3,1942,'favColor','red');
pList = addPerson(pList,'James',182,1970,'nickname','Jimmy')
```

```
pList =

    'birthyear'    'favColor'    'id'     'name'     'nickname'
    [     9999]    '-'           [ 78]    'Joe'      '-'
    [     1942]    'red'         [  3]    'Mary'     '-'
    [     1970]    '-'           [182]    'James'    'Jimmy'
```

More About

- “Input Parser Validation Functions”

inspect

Open Property Inspector

Syntax

```
inspect
inspect(h)
inspect([h1,h2,...])
```

Description

`inspect` creates a separate Property Inspector window to enable the display and modification of the properties of any object you select in the figure window or Layout Editor. If no object is selected, the Property Inspector is blank.

`inspect(h)` creates a Property Inspector window for the object whose handle is `h`.

`inspect([h1,h2,...])` displays properties that objects `h1` and `h2` have in common, or a blank window if there are no such properties; any number of objects can be inspected and edited in this way (for example, handles returned by the `bar` command).

The Property Inspector has the following behaviors:

- Only one Property Inspector window is active at any given time; when you inspect a new object, its properties replace those of the object last inspected.
- When the Property Inspector is open and plot edit mode is on, clicking any object in the figure window displays the properties of that object (or set of objects) in the Property Inspector.
- When you select and inspect two or more objects of different types, the Property Inspector only shows the properties that all objects have in common.
- To change the value of any property, click on the property name shown at the left side of the window, and then enter the new value in the field at the right.

The Property Inspector provides two different views:

- List view — properties are ordered alphabetically (default); this is the only view available for annotation objects.
- Group view — properties are grouped under classified headings (Handle Graphics objects only)

To view alphabetically, click the "AZ" Icon  in the Property Inspector toolbar. To see properties in groups, click

the "++" icon  . When properties are grouped, the "-" and "+" icons are enabled; click  to expand all categories and click  to collapse all categories. You can also expand and collapse individual categories by clicking on the "+" next to the category name. Some properties expand and collapse

---

Notes To see a complete description of any property, right-click on its name or value and select **What's This**; a help window opens that displays the reference page entry for it.

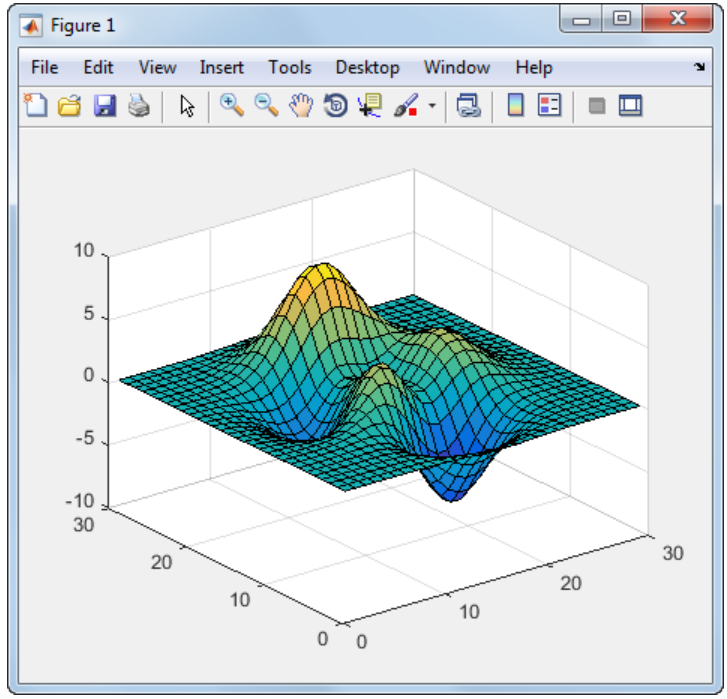
The Property Inspector displays most, but not all, properties of Handle Graphics objects. For example, the `parent` and `children` of HG objects are not shown.
`inspect h` displays a Property Inspector window that enables modification of the string `'h'`, not the object whose handle is `h`.
If you modify properties at the MATLAB command line, you must refresh the Property Inspector window to see the change reflected there. Refresh the Property Inspector by reinvoking `inspect` on the object.

Examples

Example 1

Create a surface mesh plot and view its properties with the Property Inspector.

```
Z = peaks(30);
f = surf(Z);
inspect(f);
```



In the Property Inspector, change the `FaceAlpha` property from `1.0` to `0.4`. Setting this value in the Property Inspector is equivalent to the command, `f.FaceAlpha = 0.4`, which changes the transparency of the surface faces to 40%.

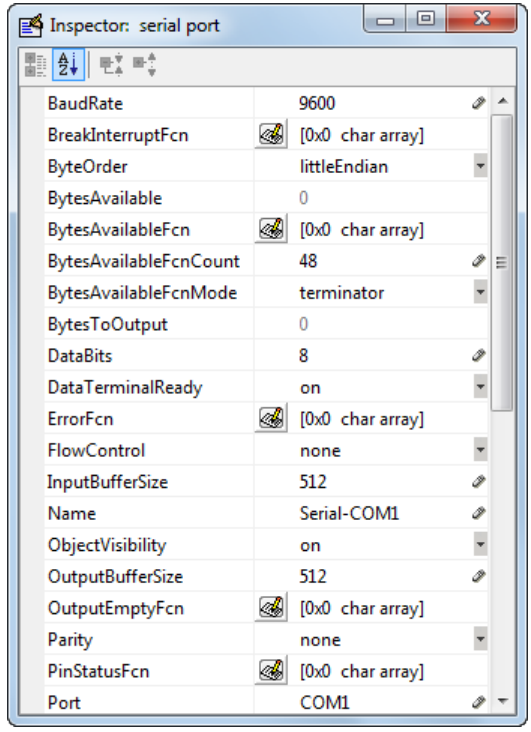
Example 2

Create a serial port object for `COM1` on a Windows platform and use the Property Inspector to peruse its properties:

```
s = serial('COM1');
inspect(s);
```



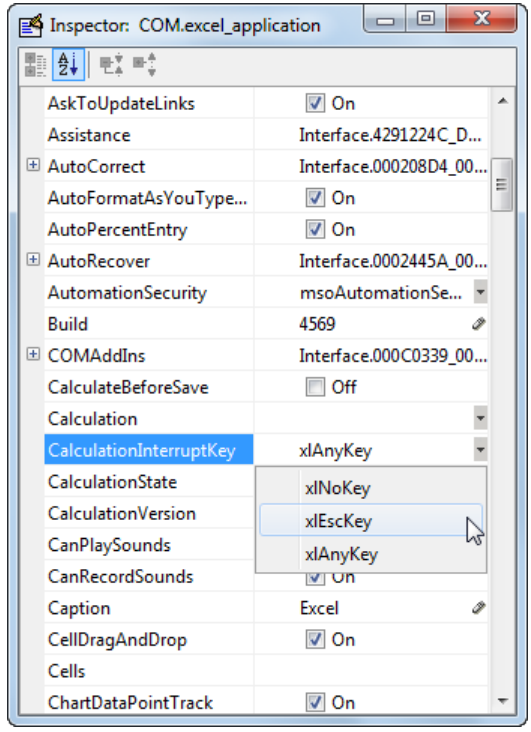
Because COM objects do not define property groupings, the Property Inspector enables only the alphabetical list view of COM object properties.

Example 3

Create a COM Excel server and open a Property Inspector window with `inspect`.

```
h = actxserver('excel.application');
inspect(h);
```

Scroll down until you see the `CalculationInterruptKey` property, which by default is `xlAnyKey`. Click on the down-arrow in the right margin of the Property Inspector, and then select `xlEscKey` from the drop-down menu.



Check this property in the MATLAB Command Window using `get` to confirm that the property value changed.

```
get(h,'CalculationInterruptKey')

ans =
xlEscKey
```

Introduced before R2006a

instrcallback

Event information when event occurs

Syntax

```
instrcallback(obj,event)
```

Description

`instrcallback(obj,event)` displays a message that contains the event type, `event`, the time the event occurred, and the name of the serial port object, `obj`, that caused the event to occur.

For error events, the error message is also displayed. For pin status events, the pin that changed value and its value are also displayed.

Examples

The following example creates the serial port object, `s`, on a Windows platform. It configures `s` to execute `instrcallback` when an output-empty event occurs. The event occurs after the `*IDN?` command is written to the instrument.

```
s = serial('COM1');
set(s,'OutputEmptyFcn',@instrcallback)
fopen(s)
fprintf(s,'*IDN?','async')
```

```
OutputEmpty event occurred at 08:37:49 for the object:
Serial-COM1.
```

Read the identification information from the input buffer and end the serial port session.

```
idn = fscanf(s);
fclose(s)
delete(s)
clear s
```

More About

Tips

Use `instrcallback` as a template to create callback functions that suit your specific application needs.

Introduced before R2006a

instrfind

Read serial port objects from memory to MATLAB workspace

Syntax

```
out = instrfind
out = instrfind('PropertyName',PropertyValue,...)
out = instrfind(S)
out = instrfind(obj,'PropertyName',PropertyValue,...)
```

Description

`out = instrfind` returns all valid serial port objects as an array to `out`.

`out = instrfind('PropertyName',PropertyValue,...)` returns an array of serial port objects whose property names and property values match those specified.

`out = instrfind(S)` returns an array of serial port objects whose property names and property values match those defined in the structure `S`. The field names of `S` are the property names, while the field values are the associated property values.

`out = instrfind(obj,'PropertyName',PropertyValue,...)` restricts the search for matching property name/property value pairs to the serial port objects listed in `obj`.

Examples

Suppose you create the following two serial port objects on a Windows platform.

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s2,'BaudRate',4800)
fopen([s1 s2])
```

You can use `instrfind` to return serial port objects based on property values.

```
out1 = instrfind('Port','COM1');
```

```
out2 = instrfind({'Port','BaudRate'},{'COM2',4800});
```

You can also use `instrfind` to return cleared serial port objects to the MATLAB workspace.

```
clear s1 s2
newobjs = instrfind
```

```
   Instrument Object Array
   Index:   Type:          Status:     Name:
   1        serial         open        Serial-COM1
   2        serial         open        Serial-COM2
```

To close both `s1` and `s2`

```
fclose(newobjs)
```

More About

Tips

Refer to "Displaying Property Names and Property Values" for a list of serial port object properties that you can use with `instrfind`.

You must specify property values using the same format as the `get` function returns. For example, if `get` returns the `Name` property value as `MyObject`, `instrfind` will not find an object with a `Name` property value of `myobject`. However, this is not the case for properties that have a finite set of string values. For example, `instrfind` will find an object with a `Parity` property value of `Even` or `even`.

You can use property name/property value string pairs, structures, and cell array pairs in the same call to `instrfind`.

See Also

`clear` | `get`

Introduced before R2006a

instrfindall

Find visible and hidden serial port objects

Syntax

```
out = instrfindall
out = instrfindall('P1',V1,...)
out = instrfindall(s)
out = instrfindall(objs,'P1',V1,...)
```

Description

`out = instrfindall` finds all serial port objects, regardless of the value of the object's `ObjectVisibility` property. The object or objects are returned to `out`.

`out = instrfindall('P1',V1,...)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified as arguments.

`out = instrfindall(s)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified in the structure `s`, where the field names correspond to property names and the field values correspond to the current value of the respective property.

`out = instrfindall(objs,'P1',V1,...)` restricts the search for objects with matching property name/value pairs to the serial port objects listed in `objs`.

Note that you can use string property name/property value pairs, structures, and cell array property name/property value pairs in the same call to `instrfindall`.

Examples

Suppose you create the following serial port objects on a Windows platform:

```
s1 = serial('COM1');
s2 = serial('COM2');
```

```
set(s2,'ObjectVisibility','off')
```

Because object `s2` has its `ObjectVisibility` set to `'off'`, it is not visible to commands like `instrfind`:

```
instrfind
```

```
   Serial Port Object : Serial-COM1
```

However, `instrfindall` finds all objects regardless of the value of `ObjectVisibility`:

```
instrfindall
```

```
 Instrument Object Array
 Index:   Type:          Status:     Name:
 1        serial         closed      Serial-COM1
 2        serial         closed      Serial-COM2
```

The following statements use `instrfindall` to return objects with specific property settings, which are passed as cell arrays:

```
props = {'PrimaryAddress','SecondaryAddress};
vals = {2,0};
obj = instrfindall(props,vals);
```

You can use `instrfindall` as an argument when you want to apply the command to all objects, visible and invisible. For example, the following statement makes all objects visible:

```
set(instrfindall,'ObjectVisibility','on')
```

More About

Tips

`instrfindall` differs from `instrfind` in that it finds objects whose `ObjectVisibility` property is set to `off`.

Property values are case sensitive. You must specify property values using the same format as that returned by the `get` function. For example, if `get` returns the `Name` property value as `'MyObject'`, `instrfindall` will not find an object with a `Name` property value of `'myobject'`. However, this is not the case for properties that have a

finite set of string values. For example, `instrfindall` will find an object with a `Parity` property value of `'Even'` or `'even'`.

See Also

`get` | `instrfind` | `ObjectVisibility`

int2str

Convert integer to string

Syntax

```
str = int2str(N)
```

Description

`str = int2str(N)` converts an integer to a string with integer format. The input `N` can be a single integer or a vector or matrix of integers. Noninteger inputs are rounded before conversion.

Examples

`int2str(2+3)` is the string `'5'`.

One way to label a plot is

```
title(['case number ' int2str(n)])
```

For matrix or vector inputs, `int2str` returns a string matrix:

```
int2str(eye(3))

ans =

1  0  0
0  1  0
0  0  1
```

See Also

`fprintf` | `num2str` | `sprintf` | `cast`

Introduced before R2006a

int8

Convert to 8-bit signed integer

Syntax

```
intArray = int8(array)
```

Description

`intArray = int8(array)` converts the elements of an array into signed 8-bit (1-byte) integers of class `int8`.

Input Arguments

`array`

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int8`, the `int8` function has no effect.

Output Arguments

`intArray`

Array of class `int8`. Values range from -2^7 to $2^7 - 1$.

The `int8` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int8(2^7)   % 2^7 = 128
```

returns

```
ans =
    127
```

Examples

Convert a `double` array to `int8`:

```
mydata = int8(magic(10));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int8(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int8');   % Preferred
```

Introduced before R2006a

int16

Convert to 16-bit signed integer

Syntax

```
intArray = int16(array)
```

Description

`intArray = int16(array)` converts the elements of an array into signed 16-bit (2-byte) integers of class `int16`.

Input Arguments

`array`

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int16`, the `int16` function has no effect.

Output Arguments

`intArray`

Array of class `int16`. Values range from -2^{15} to $2^{15} - 1$.

The `int16` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int16(2^15)   % 2^15 = 32768
```

returns

```
ans =
    32767
```

Examples

Convert a `double` array to `int16`:

```
mydata = int16(magic(100));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int16(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int16');   % Preferred
```

See Also

Introduced before R2006a

int32

Convert to 32-bit signed integer

Syntax

```
intArray = int32(array)
```

Description

`intArray = int32(array)` converts the elements of an array into signed 32-bit (4-byte) integers of class `int32`.

Input Arguments

`array`

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int32`, the `int32` function has no effect.

Output Arguments

`intArray`

Array of class `int32`. Values range from -2^{31} to $2^{31} - 1$.

The `int32` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int32(2^31)    % 2^31 = 2147483648
```

returns

```
ans =
    2147483647
```

Examples

Convert a `double` array to `int32`:

```
mydata = int32(magic(1000));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int32(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int32');   % Preferred
```

See Also

`double` | `single` | `int8` | `int16` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `intmax` | `intmin`

Introduced before R2006a

int64

Convert to 64-bit signed integer

Syntax

```
intArray = int64(array)
```

Description

`intArray = int64(array)` converts the elements of an array into signed 64-bit (8-byte) integers of class `int64`.

Input Arguments

array

Array of any numeric class, such as `single` or `double`. If `array` is already of class `int64`, the `int64` function has no effect.

Output Arguments

intArray

Array of class `int64`. Values range from -2^{63} to $2^{63} - 1$.

The `int64` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
int64(2^63)   % 2^63 = 9223372036854775808
```

returns

```
ans =
    9223372036854775807
```

Examples

Convert a literal value to `int64`:

```
x = int64(9007199254740993);
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = int64(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'int64');   % Preferred
```

More About

Tips

Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, `double` values cannot represent all integers greater than 2^{53} correctly. Before performing arithmetic operations on values larger than 2^{53} in magnitude, convert the values to 64-bit integers. For example,

```
x = int64(2^53+1);     % Floating-point arithmetic, loses precision
```

is not as accurate as the 64-bit integer arithmetic operation:

```
x = int64(2^53) + 1;   % Preferred
```

See Also

Introduced before R2006a

integral

Numerical integration

Syntax

```
q = integral(fun,xmin,xmax)
q = integral(fun,xmin,xmax,Name,Value)
```

Description

`q = integral(fun,xmin,xmax)` numerically integrates function `fun` from `xmin` to `xmax` using global adaptive quadrature and default error tolerances.

`q = integral(fun,xmin,xmax,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments. For example, specify `'WayPoints'` followed by a vector of real or complex numbers to indicate specific points for the integrator to use.

Examples

Improper Integral

Create the function $f(x) = e^{-x^2}(\ln x)^2$.

```
fun = @(x) exp(-x.^2).*log(x).^2;
```

Evaluate the integral from `x=0` to `x=Inf`.

```
q = integral(fun,0,Inf)
```

```
q =

    1.9475
```

Parameterized Function

Create the function $f(x) = 1/(x^3 - 2x - c)$ with one parameter, c.

```
fun = @(x,c) 1./(x.^3-2*x-c);
```

Evaluate the integral from `x=0` to `x=2` at `c=5`.

```
q = integral(@(x)fun(x,5),0,2)
```

```
q =

   -0.4605
```

Singularity at Lower Limit

Create the function $f(x) = \ln(x)$.

```
fun = @(x)log(x);
```

Evaluate the integral from `x=0` to `x=1` with the default error tolerances.

```
format long
q1 = integral(fun,0,1)
```

```
q1 =

  -1.000000010959678
```

Evaluate the integral again, specifying 12 decimal places of accuracy.

```
q2 = integral(fun,0,1,'RelTol',0,'AbsTol',1e-12)
```

```
q2 =

  -1.000000000000010
```

Complex Contour Integration Using Waypoints

Create the function $f(z) = 1/(2z - 1)$.

```
fun = @(z) 1./(2*z-1);
```

Integrate in the complex plane over the triangular path from `0` to `1+1i` to `1-1i` to `0` by specifying waypoints.

```
q = integral(fun,0,0,'Waypoints',[1+1i,1-1i])
```

```
q =
```

```
        0 - 3.1416i
```

Vector-Valued Function

Create the vector-valued function $f(x) = [\sin x, \sin 2x, \sin 3x, \sin 4x, \sin 5x]$ and integrate from `x=0` to `x=1`. Specify `'ArrayValued',true` to evaluate the integral of an array-valued or vector-valued function.

```
fun = @(x)sin((1:5)*x);
q = integral(fun,0,1,'ArrayValued',true)
```

```
q =

    0.4597    0.7081    0.6633    0.4134    0.1433
```

Improper Integral of Oscillatory Function

Create the function $f(x) = x^5 e^{-x} \sin x$.

```
fun = @(x)x.^5.*exp(-x).*sin(x);
```

Evaluate the integral from `x=0` to `x=Inf` , adjusting the absolute and relative tolerances.

```
format long
q = integral(fun,0,Inf,'RelTol',1e-8,'AbsTol',1e-13)
```

```
q =

 -14.999999999998364
```

Input Arguments

`fun` — Integrand

function handle

Integrand, specified as a function handle, which defines the function to be integrated from `xmin` to `xmax`.

For scalar-valued problems, the function `y = fun(x)` must accept a vector argument, `x`, and return a vector result, `y`. This generally means that `fun` must use array operators

instead of matrix operators. For example, use `.*` (times) rather than `*` (mtimes). If you set the `'ArrayValued'` option to `true`, then `fun` must accept a scalar and return an array of fixed size.

`xmin` — Lower limit of *x*

real number | complex number

Lower limit of *x*, specified as a real (finite or infinite) scalar value or a complex (finite) scalar value. If either `xmin` or `xmax` are complex, then `integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

Data Types: `double | single`
Complex Number Support: Yes

`xmax` — Upper limit of *x*

real number | complex number

Upper limit of *x*, specified as a real number (finite or infinite) or a complex number (finite). If either `xmin` or `xmax` are complex, `integral` approximates the path integral from `xmin` to `xmax` over a straight line path.

Data Types: `double | single`
Complex Number Support: Yes

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

`'AbsTol'` — Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral` uses the absolute error tolerance to limit an estimate of the absolute error, $|q - Q|$, where q is the computed value of the integral and Q is the (unknown) exact value. `integral` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

Note: `AbsTol` and `RelTol` work together. `integral` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the "Tips" on page 1-3997 section.

Example: `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

Data Types: `single` | `double`

`'RelTol'` — Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of `'RelTol'` and a nonnegative real number. `integral` uses the relative error tolerance to limit an estimate of the relative error, $|q - Q|/|Q|$, where q is the computed value of the integral and Q is the (unknown) exact value. `integral` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is `1e-6`.

Note: `RelTol` and `AbsTol` work together. `integral` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the Tips section.

Example: `'RelTol',1e-9` sets the relative error tolerance to approximately 9 significant digits.

Data Types: `single` | `double`

`'ArrayValued'` — Array-valued function flag

`false` (default) | `true` | `0` | `1`

Array-valued function flag, specified as the comma-separated pair consisting of `'ArrayValued'` and either `false`, `true`, `0`, or `1`. Set this flag to `true` to indicate that `fun` is a function that accepts a scalar input and returns a vector, matrix, or N-D array output.

The default value of `'false'` indicates that `fun` is a function that accepts a vector input and returns a vector output.

Example: `'ArrayValued',true` indicates that the integrand is an array-valued function.

`'Waypoints'` — Integration waypoints

vector

Integration waypoints, specified as the comma-separated pair consisting of `'Waypoints'` and a vector of real or complex numbers. Use waypoints to indicate any points in the integration interval that you would like the integrator to use. You can use waypoints to integrate efficiently across discontinuities of the integrand. Specify the locations of the discontinuities in the vector you supply.

You can specify waypoints when you want to perform complex contour integration. If `xmin`, `xmax`, or any entry of the waypoints vector is complex, the integration is performed over a sequence of straight line paths in the complex plane.

Example: `'Waypoints',[1+1i,1-1i]` specifies two complex waypoints along the interval of integration.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Tips

- Do not use waypoints to specify singularities. Instead, split the interval and add the results of separate integrations with the singularities at the endpoints.
- The `integral` function attempts to satisfy:

  ```
  abs(q - Q) <= max(AbsTol,RelTol*abs(q))
  ```

  where `q` is the computed value of the integral and `Q` is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.
- If you specify a complex value for `xmin`, `xmax`, or any waypoint, all of your limits and waypoints must be finite.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.

`function_handle` | `integral2` | `integral3` | `trapz`

Introduced in R2012a

integral2

Numerically evaluate double integral

Syntax

```
q = integral2(fun,xmin,xmax,ymin,ymax)
q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)
```

Description

`q = integral2(fun,xmin,xmax,ymin,ymax)` approximates the integral of the function `z = fun(x,y)` over the planar region `xmin` ≤ `x` ≤ `xmax` and `ymin(x)` ≤ `y` ≤ `ymax(x)`.

`q = integral2(fun,xmin,xmax,ymin,ymax,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

Examples

Integrate Triangular Region with Singularity at the Boundary

The function

$$f(x,y) = \frac{1}{(\sqrt{x+y})\ (1+x+y)}$$

is undefined when x and y are zero. `integral2` performs best when singularities are on the integration boundary.

Create the anonymous function.

```
fun = @(x,y) 1./( sqrt(x + y) .* (1 + x + y).^2 )
```

Integrate over the triangular region bounded by $0 \le x \le 1$ and $0 \le y \le 1 - x$.

```
ymax = @(x) 1 - x
q = integral2(fun,0,1,0,ymax)

q =

    0.2854
```

Evaluate Double Integral in Polar Coordinates

Define the function

$$f(\theta,r) = \frac{r}{\sqrt{r\cos\theta + r\sin\theta}\ (1 + r\cos\theta + r\sin\theta)^2}$$

```
fun = @(x,y) 1./( sqrt(x + y) .* (1 + x + y).^2 );
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
```

Define a function for the upper limit of r.

```
rmax = @(theta) 1./(sin(theta) + cos(theta));
```

Integrate over the region bounded by $0 \le \theta \le \pi/2$ and $0 \le r \le$ rmax.

```
q = integral2(polarfun,0,pi/2,0,rmax)

q =

    0.2854
```

Evaluate Double Integral of Parameterized Function with Specific Method and Error Tolerance

Create the anonymous parameterized function $f(x,y) = ax^2 + by^2$ with parameters a=3 and b=5.

```
a = 3; b = 5;
fun = @(x,y) a*x.^2 + b*y.^2;
```

Evaluate the integral over the region $0 \le x \le 5$ and $-5 \le y \le 0$. Specify the `'iterated'` method and approximately 10 significant digits of accuracy.

```
format long
q = integral2(fun,0,5,-5,0,'Method','iterated',...
```

```
'AbsTol',0,'RelTol',1e-10)

q =

     1.666666666666666e+03
```

Input Arguments

`fun` — Integrand
function handle

Integrand, specified as a function handle, defines the function to be integrated over the planar region `xmin` ≤ `x` ≤ `xmax` and `ymin`(`x`) ≤ `y` ≤ `ymax`(`x`). The function `fun` must accept two arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

Data Types: `function_handle`

`xmin` — Lower limit of *x*
real number

Lower limit of *x*, specified as a real scalar value that is either finite or infinite.

Data Types: `double` | `single`

`xmax` — Upper limit of *x*
real number

Upper limit of *x*, specified as a real scalar value that is either finite or infinite.

Data Types: `double` | `single`

`ymin` — Lower limit of *y*
real number | function handle

Lower limit of *y*, specified as a real scalar value that is either finite or infinite. You can specify `ymin` to be a function handle (a function of *x*) when integrating over a nonrectangular region.

Data Types: `double` | `function_handle` | `single`

`ymax` — Upper limit of *y*
real number | function handle

Upper limit of y, specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of x) when integrating over a nonrectangular region.

Data Types: `double | function_handle | single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

`'AbsTol'` — Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral2` uses the absolute error tolerance to limit an estimate of the absolute error, $|q - Q|$, where q is the computed value of the integral and Q is the (unknown) exact value. `integral2` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

Note: `AbsTol` and `RelTol` work together. `integral2` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the "Tips" on page 1-4004 section.

Example: `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

Data Types: `double | single`

`'RelTol'` — Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of `'RelTol'` and a nonnegative real number. `integral2` uses the relative error tolerance to limit an estimate of the relative error, $|q - Q|/|Q|$, where q is the computed value of the integral

and Q is the (unknown) exact value. `integral2` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is `1e-6`.

Note: `RelTol` and `AbsTol` work together. `integral2` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the "Tips" on page 1-4004 section.

Example: `'RelTol',1e-9` sets the relative error tolerance to approximately 9 significant digits.

Data Types: `double` | `single`

`'Method'` — Integration method

`'auto'` (default) | `'tiled'` | `'iterated'`

Integration method, specified as the comma-separated pair consisting of `'Method'` and one of the methods described below.

Integration Method	Description
`'auto'`	For most cases, `integral2` uses the `'tiled'` method. It uses the `'iterated'` method when any of the integration limits are infinite. This is the default method.
`'tiled'`	`integral2` transforms the region of integration to a rectangular shape and subdivides it into smaller rectangular regions as needed. The integration limits must be finite.
`'iterated'`	`integral2` calls `integral` to perform an iterated integral. The outer integral is evaluated over `xmin` ≤ `x` ≤ `xmax`. The inner integral is evaluated over `ymin(x)` ≤ `y` ≤ `ymax(x)`. The integration limits can be infinite.

Example: `'Method','tiled'` specifies the tiled integration method.

Output Arguments

`q` — Computed integral

numeric value

Computed integral of `fun(x,y)` over the specified region, returned as a numeric value.

More About

Tips

- The `integral2` function attempts to satisfy:

  ```
  abs(q - Q) <= max(AbsTol,RelTol*abs(q))
  ```

  where `q` is the computed value of the integral and `Q` is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.
- The `'iterated'` method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integral at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when `ymin`, `ymax`, (or both) are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify `'iterated'` method.
- Use the `'iterated'` method when `ymin`, `ymax`, (or both) are unbounded functions.
- When paramaterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y) x + y + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.
- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you might need to specify larger absolute and relative error tolerances.

- “Parameterizing Functions”

integral3

Numerically evaluate triple integral

Syntax

```
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)
```

Description

`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax)` approximates the integral of the function `z = fun(x,y,z)` over the region `xmin` $\le$ `x` $\le$ `xmax`, `ymin(x)` $\le$ `y` $\le$ `ymax(x)` and `zmin(x,y)` $\le$ `z` $\le$ `zmax(x,y)`.

`q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

Examples

Triple Integral with Finite Limits

Define the anonymous function $f(x,y,z) = y \sin x + z \cos x$.

```
fun = @(x,y,z) y.*sin(x)+z.*cos(x)
```

Integrate over the region $0 \le x \le \pi$, $0 \le y \le 1$, and $-1 \le z \le 1$.

```
q = integral3(fun,0,pi,0,1,-1,1)
```

```
q =

    2.0000
```

Integral Over the Unit Sphere in Cartesian Coordinates

Define the anonymous function $f(x,y,z) = x \cos y + x^2 \cos z$.

```
fun = @(x,y,z) x.*cos(y) + x.^2.*cos(z)
```

Define the limits of integration.

```
xmin = -1;
xmax = 1;
ymin = @(x)-sqrt(1 - x.^2);
ymax = @(x) sqrt(1 - x.^2);
zmin = @(x,y)-sqrt(1 - x.^2 - y.^2);
zmax = @(x,y) sqrt(1 - x.^2 - y.^2);
```

Evaluate the definite integral with the `'tiled'` method.

```
q = integral3(fun,xmin,xmax,ymin,ymax,zmin,zmax,'Method','tiled')
```

```
q =

    0.7796
```

Evaluate Improper Triple Integral of Parameterized Function

Define the anonymous parameterized function $f(x,y,z) = 10/(x^2 + y^2 + z^2 + a)$.

```
a = 2;
f = @(x,y,z) 10./(x.^2 + y.^2 + z.^2 + a);
```

Evaluate the triple integral over the region `-Inf` $\le x \le 0$, $-100 \le y \le 0$, and $-100 \le z \le 0$.

```
format long
q1 = integral3(f,-Inf,0,-100,0,-100,0)
```

```
q1 =

     2.734244598320928e+03
```

Evaluate the integral again and specify accuracy to approximately 9 significant digits.

```
q2 = integral3(f,-Inf,0,-100,0,-100,0,'AbsTol', 0,'RelTol',1e-9)
```

```
q2 =

     2.734244599944285e+03
```

Input Arguments

`fun` — Integrand

function handle

Integrand, specified as a function handle, defines the function to be integrated over the region `xmin` ≤ `x` ≤ `xmax`, `ymin`(`x`) ≤ `y` ≤ `ymax`(`x`), and `zmin`(`x`,`y`) ≤ `z` ≤ `zmax`(`x`,`y`). The function `fun` must accept three arrays of the same size and return an array of corresponding values. It must perform element-wise operations.

Data Types: `function_handle`

`xmin` — Lower limit of *x*

real number

Lower limit of *x*, specified as a real scalar value that is either finite or infinite.

Example:

Data Types: `double` | `single`

`xmax` — Upper limit of *x*

real number

Upper limit of *x*, specified as a real scalar value that is either finite or infinite.

Data Types: `double` | `single`

`ymin` — Lower limit of *y*

real number | function handle

Lower limit of *y*, specified as a real scalar value that is either finite or infinite. You also can specify `ymin` to be a function handle (a function of *x*) when integrating over a nonrectangular region.

Example:

Data Types: `double` | `function_handle` | `single`

`ymax` — Upper limit of *y*

real number | function handle

Upper limit of *y*, specified as a real scalar value that is either finite or infinite. You also can specify `ymax` to be a function handle (a function of *x*) when integrating over a nonrectangular region.

Example:

Data Types: `double` | `function_handle` | `single`

`zmin` — Lower limit of *z*

real number | function handle

Lower limit of *z*, specified as a real scalar value that is either finite or infinite. You also can specify `zmin` to be a function handle (a function of *x*,*y*) when integrating over a nonrectangular region.

Data Types: `double` | `function_handle` | `single`

`zmax` — Upper limit of *z*

real number | function handle

Upper limit of *z*, specified as a real scalar value that is either finite or infinite. You also can specify `zmax` to be a function handle (a function of *x*,*y*) when integrating over a nonrectangular region.

Data Types: `double` | `function_handle` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

`'AbsTol'` — Absolute error tolerance

nonnegative real number

Absolute error tolerance, specified as the comma-separated pair consisting of `'AbsTol'` and a nonnegative real number. `integral3` uses the absolute error tolerance to limit an estimate of the absolute error, $|q - Q|$, where q is the computed value of the integral and Q is the (unknown) exact value. `integral3` might provide more decimal places of precision if you decrease the absolute error tolerance. The default value is `1e-10`.

Note: `AbsTol` and `RelTol` work together. `integral3` might satisfy the absolute error tolerance or the relative error tolerance, but not necessarily both. For more information on using these tolerances, see the "Tips" on page 1-4010 section.

Example: `'AbsTol',1e-12` sets the absolute error tolerance to approximately 12 decimal places of accuracy.

Data Types: `double` | `single`

`'RelTol'` — Relative error tolerance

nonnegative real number

Relative error tolerance, specified as the comma-separated pair consisting of `'RelTol'` and a nonnegative real number. `integral3` uses the relative error tolerance to limit an estimate of the relative error, $|q - Q|/|Q|$, where q is the computed value of the integral and Q is the (unknown) exact value. `integral3` might provide more significant digits of precision if you decrease the relative error tolerance. The default value is `1e-6`.

Note: `RelTol` and `AbsTol` work together. `integral3` might satisfy the relative error tolerance or the absolute error tolerance, but not necessarily both. For more information on using these tolerances, see the "Tips" on page 1-4010 section.

Example: `'RelTol',1e-9` sets the relative error tolerance to approximately 9 significant digits.

Data Types: `double` | `single`

`'Method'` — Integration method

`'auto'` (default) | `'tiled'` | `'iterated'`

Integration method, specified as the comma-separated pair consisting of `'Method'` and one of the methods described below.

Integration Method	Description
`'auto'`	For most cases, `integral3` uses the `'tiled'` method. It uses the `'iterated'` method when any of the integration limits are infinite. This is the default method.
`'tiled'`	`integral3` calls `integral` to integrate over `xmin` ≤ `x` ≤ `xmax`. It calls `integral2` with the `'tiled'` method to evaluate the double integral over `ymin(x)` ≤ `y` ≤ `ymax(x)` and `zmin(x,y)` ≤ `z` ≤ `zmax(x,y)`.
`'iterated'`	`integral3` calls `integral` to integrate over `xmin` ≤ `x` ≤ `xmax`. It calls `integral2` with the `'iterated'` method to evaluate the double integral over `ymin(x)` ≤ `y` ≤ `ymax(x)` and `zmin(x,y)` ≤ `z` ≤ `zmax(x,y)`. The integration limits can be infinite.

Example: `'Method','tiled'` specifies the tiled integration method.

Output Arguments

q — Computed integral

numeric value

Computed integral of `fun(x,y,z)` over the specified region, returned as a numeric value.

More About

Tips

- The `integral3` function attempts to satisfy:

  ```
  abs(q - Q) <= max(AbsTol,RelTol*abs(q))
  ```

  where `q` is the computed value of the integral and `Q` is the (unknown) exact value. The absolute and relative tolerances provide a way of trading off accuracy and computation time. Usually, the relative tolerance determines the accuracy of the integration. However if `abs(q)` is sufficiently small, the absolute tolerance determines the accuracy of the integration. You should generally specify both absolute and relative tolerances together.
- The `'iterated'` method can be more effective when your function has discontinuities within the integration region. However, the best performance and accuracy occurs when you split the integral at the points of discontinuity and sum the results of multiple integrations.
- When integrating over nonrectangular regions, the best performance and accuracy occurs when any or all of the limits: `ymin`, `ymax`, `zmin`, `zmax` are function handles. Avoid setting integrand function values to zero to integrate over a nonrectangular region. If you must do this, specify `'iterated'` method.
- Use the `'iterated'` method when any or all of the limits: `ymin(x)`, `ymax(x)`, `zmin(x,y)`, `zmax(x,y)` are unbounded functions.
- When paramaterizing anonymous functions, be aware that parameter values persist for the life of the function handle. For example, the function `fun = @(x,y,z) x + y + z + a` uses the value of `a` at the time `fun` was created. If you later decide to change the value of `a`, you must redefine the anonymous function with the new value.

- If you are specifying single-precision limits of integration, or if `fun` returns single-precision results, you may need to specify larger absolute and relative error tolerances.

interfaces

List custom interfaces exposed by COM server object

Syntax

```
customlist = interfaces(h)
```

Description

`customlist = interfaces(h)` returns cell array of strings `customlist` listing all custom interfaces implemented by the component in a specific COM server object. The server is designated by input argument `h`, the handle returned by the `actxcontrol` or `actxserver` function when creating that server.

The `interfaces` function only lists the custom interfaces exposed by the object; it does not return interfaces. Use the `invoke` function to return a handle to a specific custom interface.

COM functions are available on Microsoft Windows systems only.

More About

- "Custom Interfaces"

`actxcontrol` | `invoke` | `actxserver` | `get (COM)`

Introduced before R2006a

interp1

1-D data interpolation (table lookup)

Compatibility

If you pass nonuniformly spaced points and specify the `'v5cubic'` method, `interp1` issues a warning. In addition, the following syntaxes will be removed or changed in a future release:

- `interp1(...,'cubic')`
- `pp = interp1(...'pp')`
- `interp1(X,Y,Xq,[],...)`

For more information, and recommendations for updating your code, see "Functionality being removed or changed".

Syntax

```
vq = interp1(x,v,xq)
vq = interp1(x,v,xq,method)
vq = interp1(x,v,xq,method,extrapolation)

vq = interp1(v,xq)
vq = interp1(v,xq,method)
vq = interp1(v,xq,method,extrapolation)

pp = interp1(x,v,method,'pp')
```

Description

`vq = interp1(x,v,xq)` returns interpolated values of a 1-D function at specific query points using linear interpolation. Vector `x` contains the sample points, and `v` contains the corresponding values, $v(x)$. Vector `xq` contains the coordinates of the query points.

If you have multiple sets of data that are sampled at the same point coordinates, then you can pass `v` as an array. Each column of array `v` contains a different set of 1-D sample values.

`vq = interp1(x,v,xq,method)` specifies a string for choosing an alternative interpolation method: `'nearest'`, `'next'`, `'previous'`, `'linear'`,`'spline'`,`'pchip'`, or `'cubic'`. The default method is `'linear'`.

`vq = interp1(x,v,xq,method,extrapolation)` specifies a strategy for evaluating points that lie outside the domain of `x`. Set `extrapolation` to the string, `'extrap'`, when you want to use the method algorithm for extrapolation. Alternatively, you can specify a scalar value, in which case, `interp1` returns that value for all points outside the domain of `x`.

`vq = interp1(v,xq)` returns interpolated values and assumes a default set of sample point coordinates. The default points are the sequence of numbers from `1` to `n`, where `n` depends on the shape of `v`:

- When v is a vector, the default points are `1:length(v)`.
- When v is an array, the default points are `1:size(v,1)`.

Use this syntax when you are not concerned about the absolute distances between points.

`vq = interp1(v,xq,method)` specifies any of the alternative interpolation methods and uses the default sample points.

`vq = interp1(v,xq,method,extrapolation)` specifies an extrapolation strategy and uses the default sample points.

`pp = interp1(x,v,method,'pp')` returns the piece-wise polynomial form of $v(x)$ using the method algorithm.

Examples

Interpolation of Coarsely Sampled Sine Function

Define the sample points, `x`, and corresponding sample values, `v`.

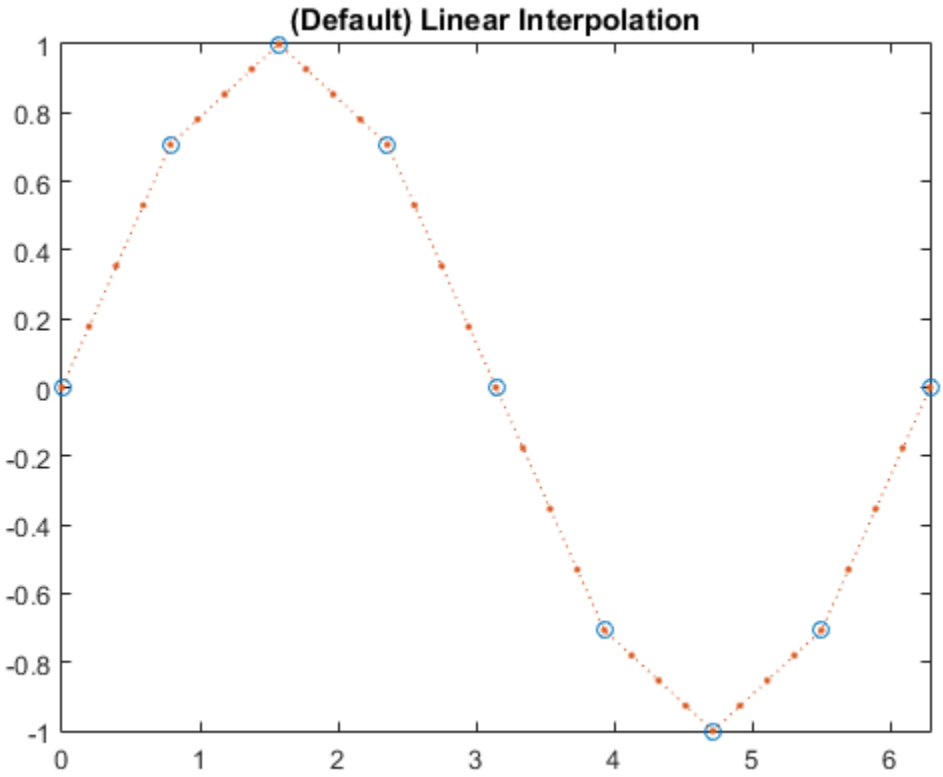
```
x = 0:pi/4:2*pi;
v = sin(x);
```

Define the query points to be a finer sampling over the range of `x`.

```
xq = 0:pi/16:2*pi;
```

Interpolate the function at the query points and plot the result.

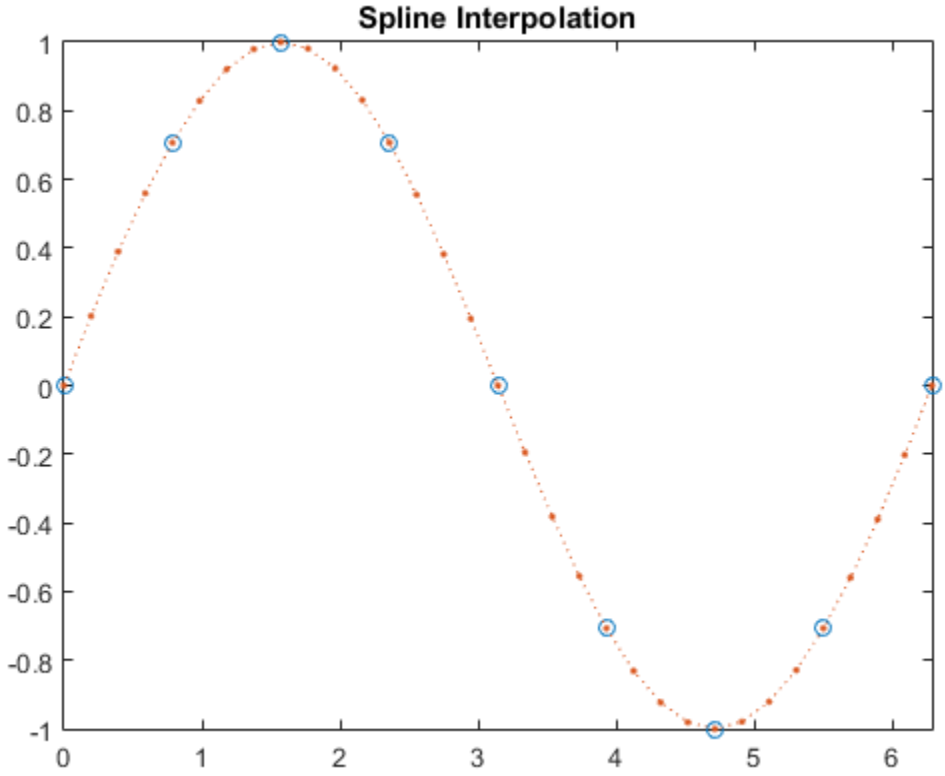
```
figure
vq1 = interp1(x,v,xq);
plot(x,v,'o',xq,vq1,':.');
xlim([0 2*pi]);
title('(Default) Linear Interpolation');
```



Now evaluate `v` at the same points using the `'spline'` method.

```
figure
```

```
vq2 = interp1(x,v,xq,'spline');
plot(x,v,'o',xq,vq2,':.');
xlim([0 2*pi]);
title('Spline Interpolation');
```



Interpolation Without Specifying Points

Define a set of function values.

```
v = [0  1.41  2  1.41  0  -1.41  -2  -1.41 0];
```

Define a set of query points that fall between the default points, `1:9`. In this case, the default points are `1:9` because `v` contains `9` values.

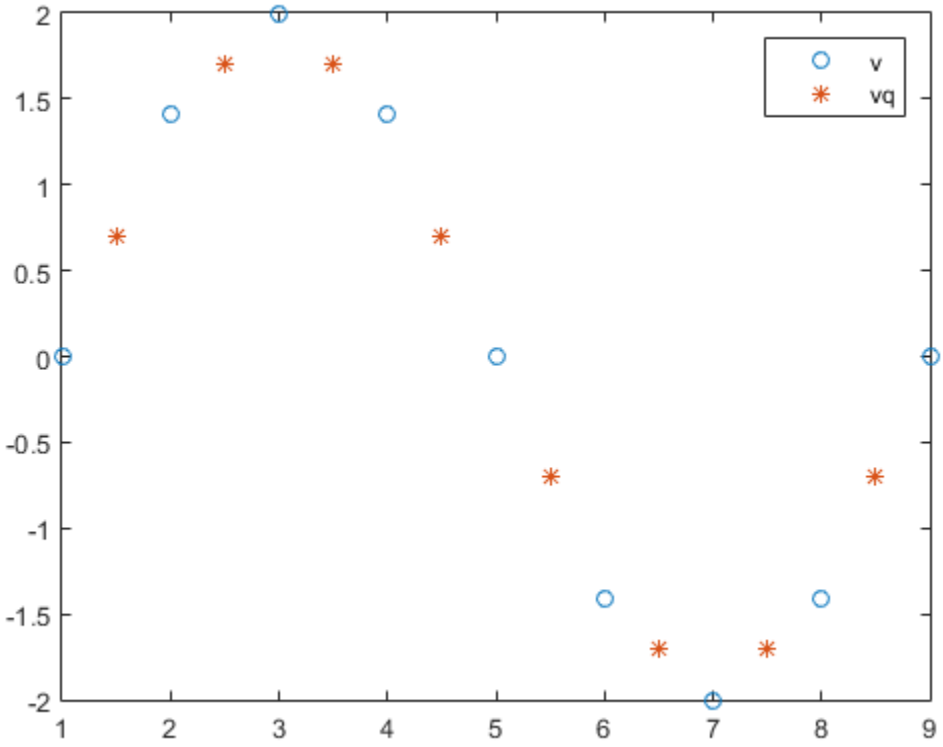
```
xq = 1.5:8.5;
```

Evaluate `v` at `xq`.

```
vq = interp1(v,xq);
```

Plot the result.

```
figure
plot((1:9),v,'o',xq,vq,'*');
legend('v','vq');
```



Interpolation of Complex Values

Define a set of sample points.

```
x = 1:10;
```

Define the values of the function, $v(x) = 5x + x^2 i$, at the sample points.

```
v = (5*x)+(x.^2*1i);
```

Define the query points to be a finer sampling over the range of `x`.

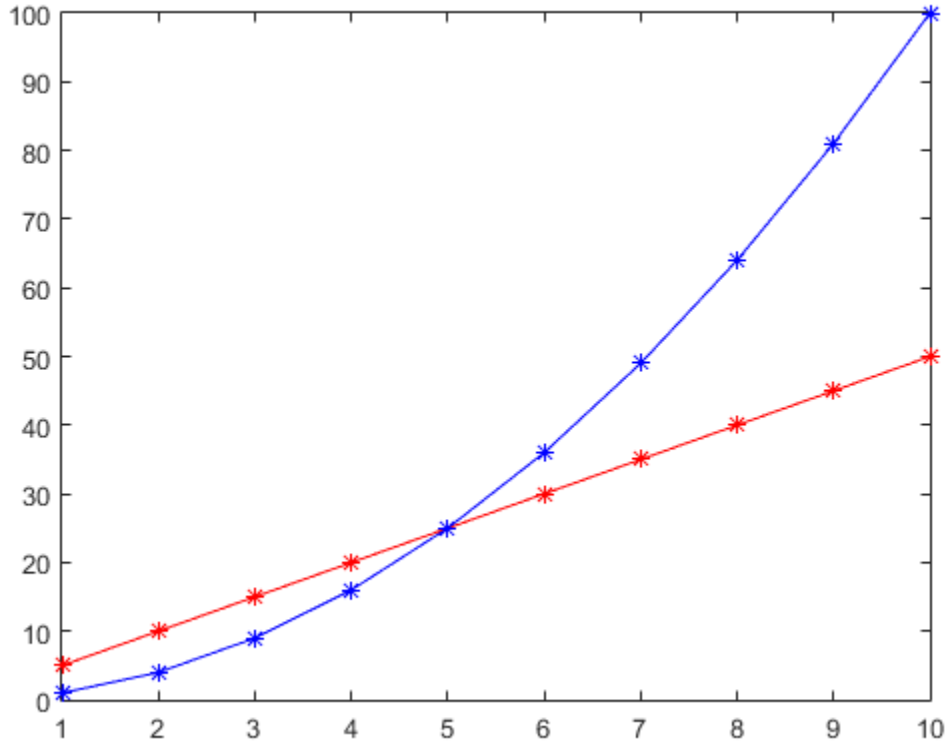
```
xq = 1:0.25:10;
```

Interpolate `v` at the query points.

```
vq = interp1(x,v,xq);
```

Plot the real part of the result in red and the imaginary part in blue.

```
figure
plot(x,real(v),'*r',xq,real(vq),'-r');
hold on
plot(x,imag(v),'*b',xq,imag(vq),'-b');
```



Extrapolation Using Two Different Methods

Define the sample points, `x`, and corresponding sample values, `v`.

```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
```

Specify the query points, `xq`, that extend beyond the domain of `x`.

```
xq = [0 0.5 1.5 5.5 6];
```

Evaluate `v` at `xq` using the `'pchip'` method.

```
vq1 = interp1(x,v,xq,'pchip')
```

```
vq1 =

   19.3684   13.6316   13.2105    7.4800   12.5600
```

Next, evaluate `v` at `xq` using the `'linear'` method.

```
vq2 = interp1(x,v,xq,'linear')
```

```
vq2 =

   NaN   NaN    14   NaN   NaN
```

Now, use the `'linear'` method with the `'extrap'` option.

```
vq3 = interp1(x,v,xq,'linear','extrap')
```

```
vq3 =

     8    10    14     4     2
```

`'pchip'` extrapolates by default, but `'linear'` does not.

Designate Constant Value for All Queries Outside the Domain of x

Define the sample points, `x`, and corresponding sample values, `v`.

```
x = [-3 -2 -1 0 1 2 3];
v = 3*x.^2;
```

Specify the query points, `xq`, that extend beyond the domain of `x`.

```
xq = [-4 -2.5 -0.5 0.5 2.5 4];
```

Now evaluate `v` at `xq` using the `'pchip'` method and assign any values outside the domain of `x` to the value, `27`.

```
vq = interp1(x,v,xq,'pchip',27)
```

```
vq =

   27.0000   18.6563    0.9375    0.9375   18.6563   27.0000
```

Interpolate Multiple Sets of Data in One Pass

Define the sample points.

```
x = (-5:5)';
```

Sample three different parabolic functions at the points defined in `x`.

```
v1 = x.^2;
v2 = 2*x.^2 + 2;
v3 = 3*x.^2 + 4;
```

Create matrix `v`, whose columns are the vectors, `v1`, `v2`, and `v3`.

```
v = [v1 v2 v3];
```

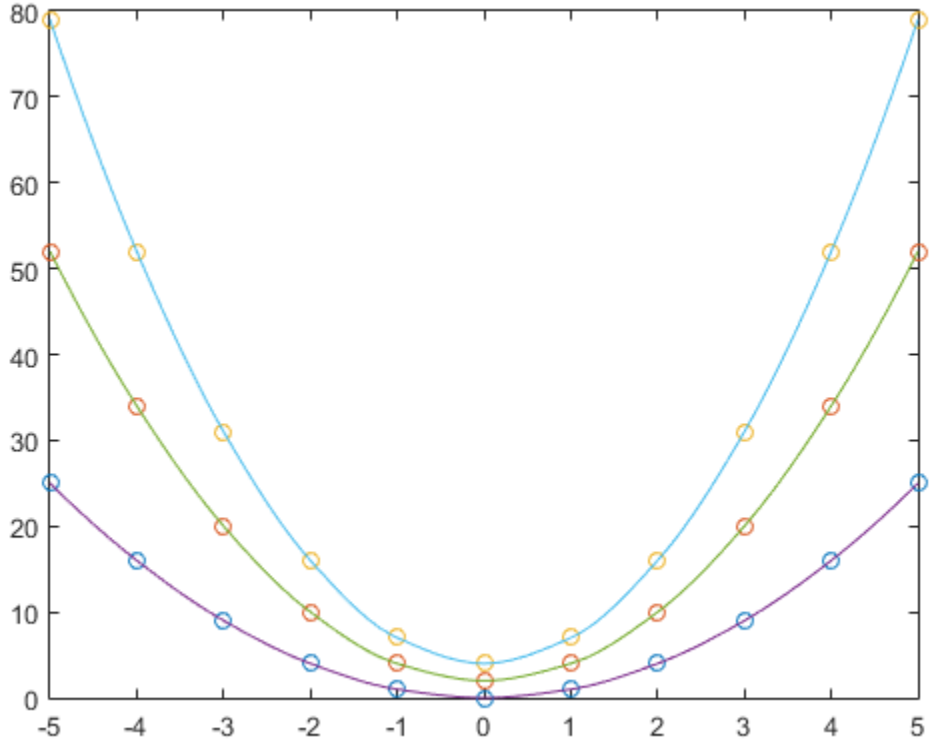
Define a set of query points, `xq`, to be a finer sampling over the range of `x`.

```
xq = -5:0.1:5;
```

Evaluate all three functions at `xq` and plot the results.

```
vq = interp1(x,v,xq,'pchip');
figure
plot(x,v,'o',xq,vq);

h = gca;
h.XTick = -5:5;
```



The circles in the plot represent `v`, and the solid lines represent `vq`.

Input Arguments

x — Sample points

vector

Sample points, specified as a row or column vector of real numbers. The length of `x` must conform to one of the following requirements:

- If `v` is a vector, then `length(x)` must equal `length(v)`.
- If `v` is an array, then `length(x)` must equal `size(v,1)`.

Example: `[1 2 3 4 5 6 7 8 9 10]`

Example: `1:10`

Example: `[3 7 11 15 19 23 27 31]'`

Data Types: `single` | `double`

v — Sample values

vector | matrix | array

Sample values, specified as a vector, matrix, or array of real or complex numbers. If `v` is a matrix or an array, then each column contains a separate set of 1-D values.

Example: `rand(1,10)`

Example: `rand(10,1)`

Example: `rand(10,3)`

Data Types: `single` | `double`
Complex Number Support: Yes

xq — Query points

scalar | vector | matrix | array

Query points, specified as a scalar, vector, matrix, or array of real numbers.

Example: `5`

Example: `1:0.05:10`

Example: `(1:0.05:10)'`

Example: `[0 1 2 7.5 10]`

Data Types: `single` | `double`

method — Interpolation method

`'linear'` (default) | `'nearest'` | `'next'` | `'previous'` | `'spline'` | `'pchip'` | `'cubic'`

Interpolation method, specified as a string from the table below.

method string	Description	Continuity	Comments
`'linear'`	Linear interpolation. The interpolated value at a	C^0	• Requires at least 2 points.

method string	Description	Continuity	Comments
	query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.		• Requires more memory and computation time than nearest neighbor.
`'nearest'`	Nearest neighbor interpolation. The interpolated value at a query point is the value at the nearest sample grid point.	Discontinuous	• Requires at least 2 points. • Modest memory requirements • Fastest computation time
`'next'`	Next neighbor interpolation. The interpolated value at a query point is the value at the next sample grid point.	Discontinuous	• Requires at least 2 points. • Same memory requirements and computation time as `'nearest'`.
`'previous'`	Previous neighbor interpolation. The interpolated value at a query point is the value at the previous sample grid point.	Discontinuous	• Requires at least 2 points. • Same memory requirements and computation time as `'nearest'`.
`'pchip'`	Shape-preserving piecewise cubic interpolation. The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points.	C^1	• Requires at least 4 points. • Requires more memory and computation time than linear.
`'cubic'`	Same as `'pchip'`.	C^1	This method currently returns the same result as `'pchip'`. In a future release, this method will perform cubic convolution.

method string	Description	Continuity	Comments
`'v5cubic'`	Cubic convolution used in MATLAB 5.	C^1	Points must be uniformly spaced. `'cubic'` will replace `'v5cubic'` in a future release.
`'spline'`	Spline interpolation using not-a-knot end conditions. The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension.	C^2	• Requires at least 4 points. • Requires more memory and computation time than `'pchip'`.

`extrapolation` — Extrapolation strategy

`'extrap'` | scalar value

Extrapolation strategy, specified as the string, `'extrap'`, or a real scalar value.

- Specify `'extrap'` when you want `interp1` to evaluate points outside the domain using the same method it uses for interpolation.
- Specify a scalar value when you want `interp1` to return a specific constant value for points outside the domain.

The default behavior depends on the input arguments:

- If you specify the `'pchip'` or `'spline'` interpolation methods, then the default behavior is `'extrap'`.
- All other interpolation methods return `NaN` by default for query points outside the domain.

Example: `'extrap'`

Example: `5`

Data Types: `char` | `single` | `double`

Output Arguments

vq — Interpolated values

scalar | vector | matrix | array

Interpolated values, returned as a scalar, vector, matrix, or array. The size of `vq` depends on the shape of `v` and `xq`.

Shape of v	Shape of xq	Size of Vq	Example
Vector	Vector	`size(xq)`	If `size(v) = [1 100]` and `size(xq) = [1 500]`, then `size(vq) = [1 500]`.
Vector	Matrix or N-D Array	`size(xq)`	If `size(v) = [1 100]` and `size(xq) = [50 30]`, then `size(vq) = [50 30]`.
Matrix or N-D Array	Vector	`[length(xq) size(v,2),...,size(v,n`	If `size(v) = [100 3]` and `size(xq) = [1 500]`, then `size(vq) = [500 3]`.
Matrix or N-D Array	Matrix or N-D Array	`[size(xq,1),...,size(x` `size(v,2),...,size(v,m`	If `size(v) = [4 5 6]` and `size(xq) = [2 3 7]`, then `size(vq) = [2 3 7 5 6]`.

pp — Piecewise polynomial

structure

Piecewise polynomial, returned as a structure that you can pass to the `ppval` function for evaluation.

See Also

`griddedInterpolant` | `interp2` | `interp3` | `interpn`

Introduced before R2006a

interp1q

Quick 1-D linear interpolation

Note: `interp1q` is not recommended. Use `interp1` instead.

Syntax

```
yi = interp1q(x,Y,xi)
```

Description

`yi = interp1q(x,Y,xi)` returns the value of the 1-D function `Y` at the points of column vector `xi` using linear interpolation. The vector `x` specifies the coordinates of the underlying interval. The length of output `yi` is equal to the length of `xi`.

`interp1q` is quicker than `interp1` on non-uniformly spaced data because it does no input checking.

For `interp1q` to work properly,

- `x` must be a monotonically increasing column vector.
- `Y` must be a column vector or matrix with `length(x)` rows.
- `xi` must be a column vector

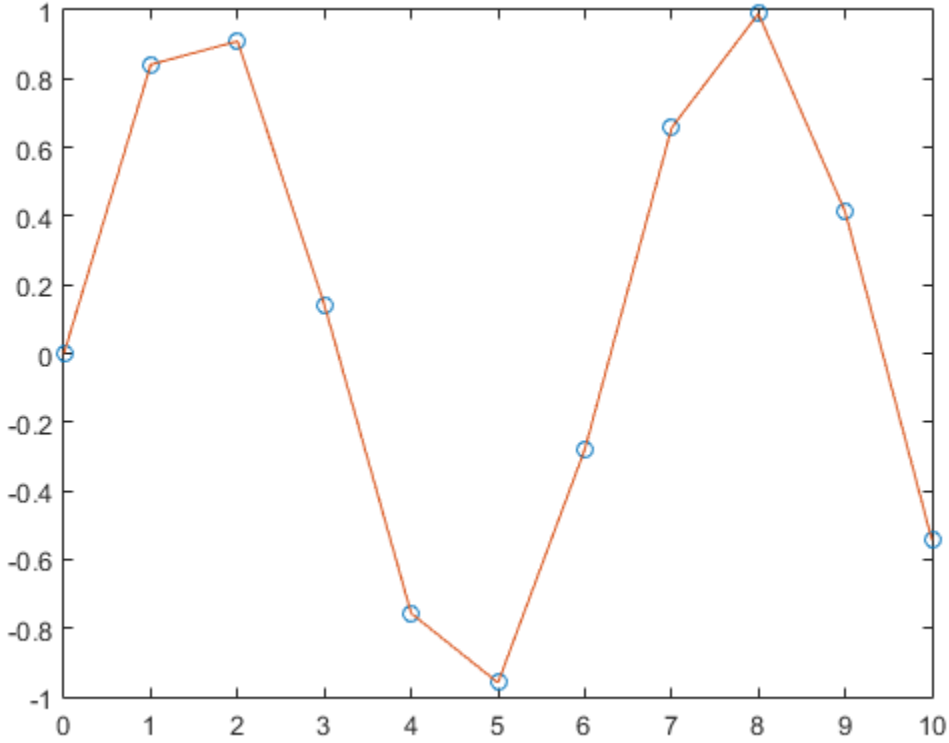
`interp1q` returns NaN for any values of `xi` that lie outside the coordinates in `x`. If `Y` is a matrix, then the interpolation is performed for each column of `Y`, in which case `yi` is `length(xi)-by-size(Y,2)`.

Examples

Linear Interpolation Using `interp1q`

Generate a coarse sine curve and interpolate over a finer abscissa.

```
x = (0:10)';
y = sin(x);
xi = (0:.25:10)';
yi = interp1q(x,y,xi);
plot(x,y,'o',xi,yi)
```



See Also

`interp1` | `interp2` | `interp3` | `interpn`

interp2

Interpolation for 2-D gridded data in meshgrid format

Compatibility

In a future release, `interp2` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

Syntax

```
Vq = interp2(X,Y,V,Xq,Yq)
Vq = interp2(V,Xq,Yq)
Vq = interp2(V)
Vq = interp2(V,k)

Vq = interp2( ___ ,method)
Vq = interp2( ___ ,method,extrapval)
```

Description

`Vq = interp2(X,Y,V,Xq,Yq)` returns interpolated values of a function of two variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X` and `Y` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq` and `Yq` contain the coordinates of the query points.

`Vq = interp2(V,Xq,Yq)` assumes a default grid of sample points. The default grid points cover the rectangular region, `X=1:n` and `Y=1:m`, where `[m,n] = size(V)`. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp2(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interp2(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interp2(___,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interp2(___,method,extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interp2` returns one of the following:

- The extrapolated values for the `'spline'` method
- `NaN` values for interpolation methods other than `'spline'`

Examples

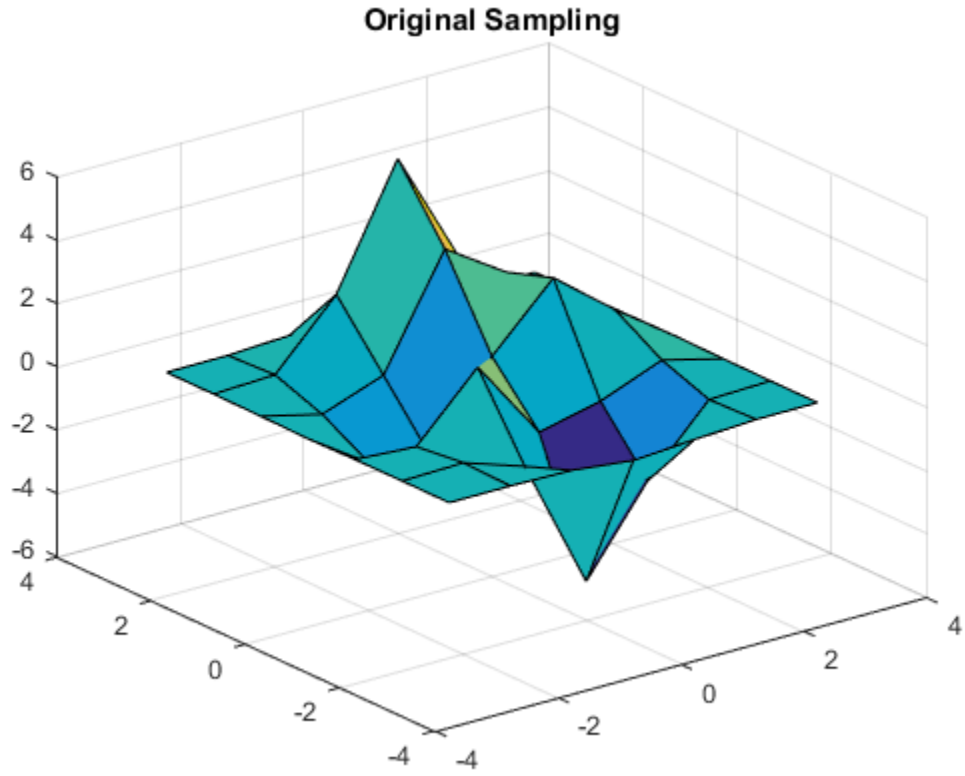
Interpolate Over a Grid Using Default Method

Coarsely sample the `peaks` function.

```
[X,Y] = meshgrid(-3:3);
V = peaks(X,Y);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
title('Original Sampling');
```



Create the query grid with spacing of 0.25.

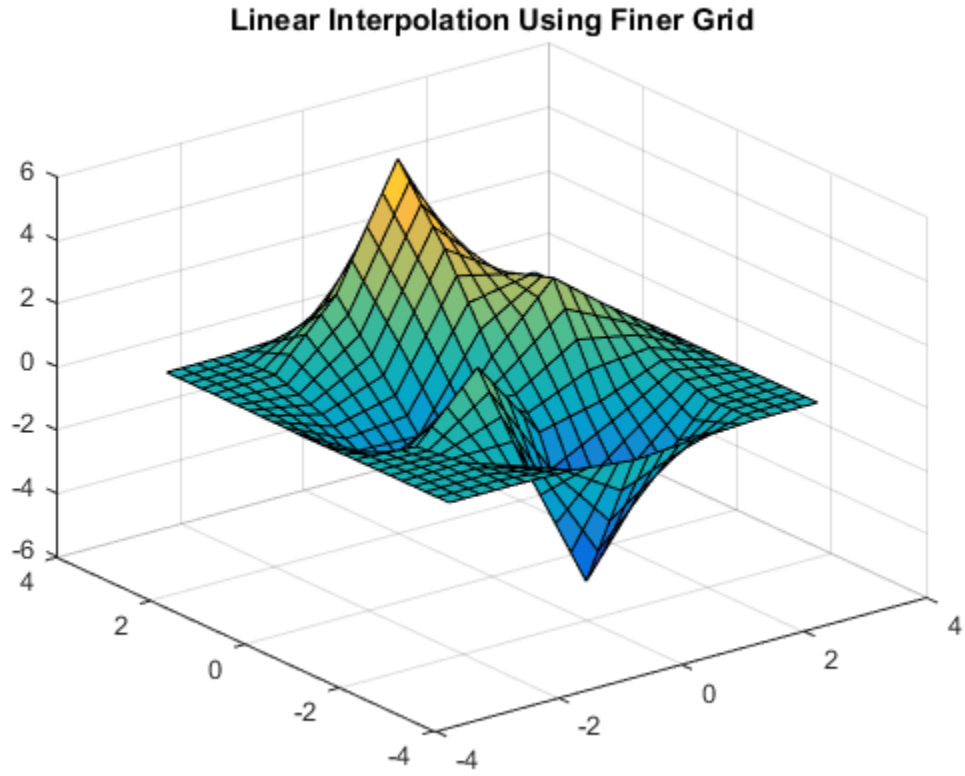
```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points.

```
Vq = interp2(X,Y,V,Xq,Yq);
```

Plot the result.

```
figure
surf(Xq,Yq,Vq);
title('Linear Interpolation Using Finer Grid');
```



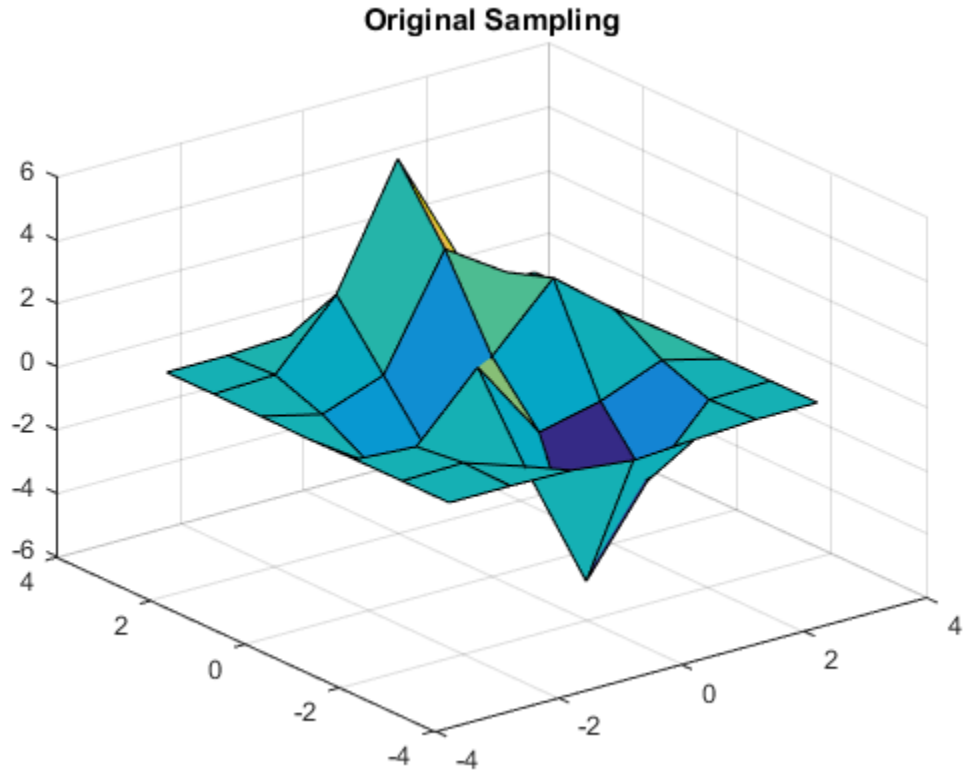
Interpolate Over a Grid Using Cubic Method

Coarsely sample the peaks function.

```
[X,Y] = meshgrid(-3:3);
V = peaks(7);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
title('Original Sampling');
```



Create the query grid with spacing of 0.25.

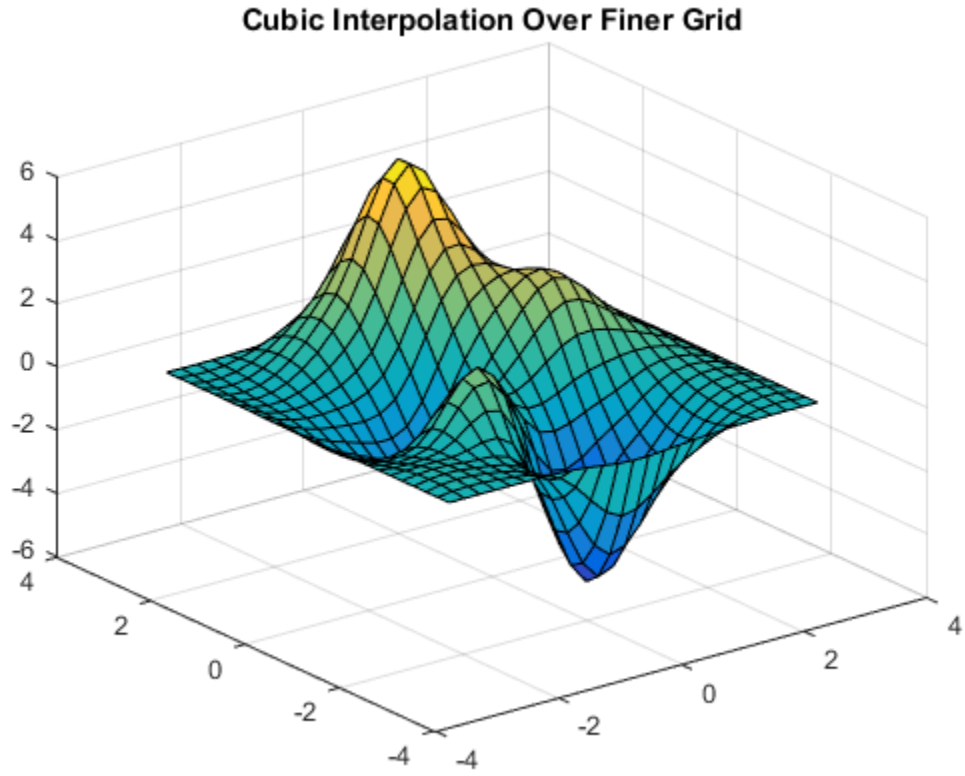
```
[Xq,Yq] = meshgrid(-3:0.25:3);
```

Interpolate at the query points, and specify cubic interpolation.

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic');
```

Plot the result.

```
figure
surf(Xq,Yq,Vq);
title('Cubic Interpolation Over Finer Grid');
```



Refine Grayscale Image

Load some image data into the workspace.

```
load clown
```

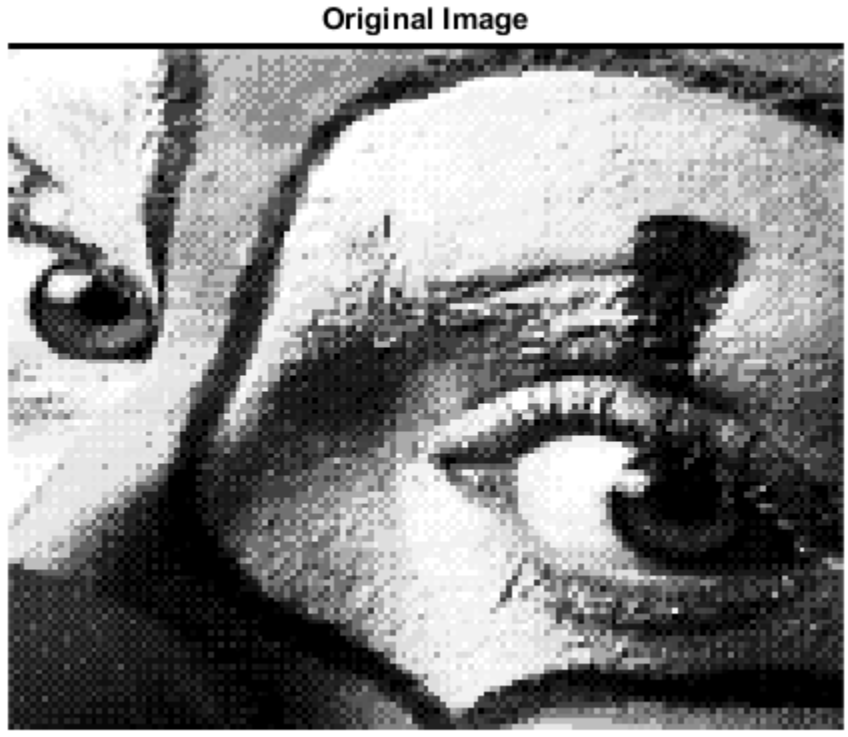
Isolate a small region of the image and cast it to single.

```
V = single(X(1:124,75:225));
```

Display the image.

```
figure
imagesc(V);
```

```
colormap gray
axis image
axis off
title('Original Image');
```



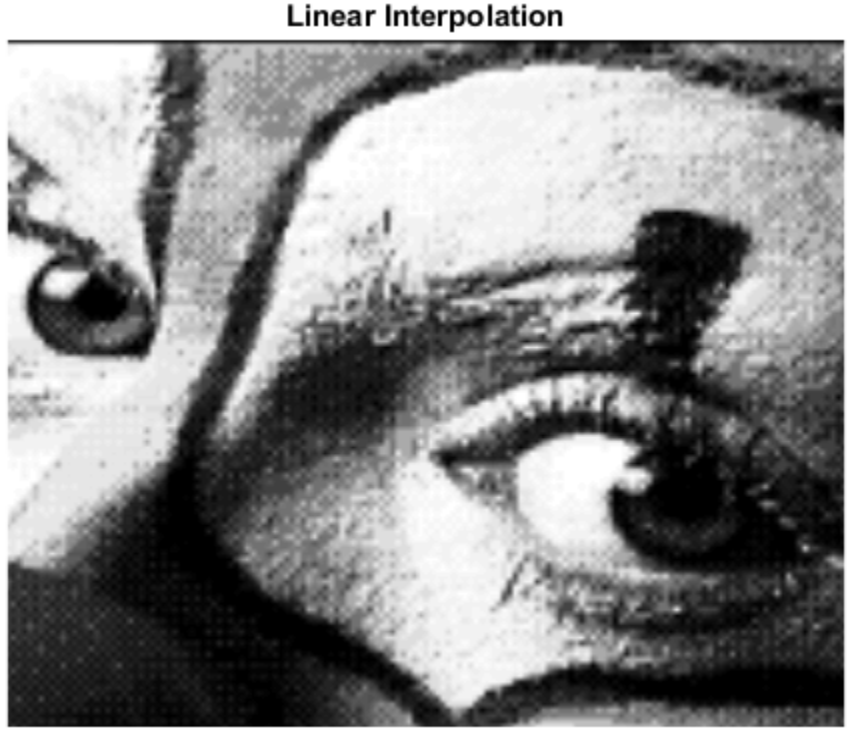
Insert interpolated values by repeatedly dividing the intervals between points of the refined grid five times in each dimension.

```
Vq = interp2(V,5);
```

Display the result.

```
figure
```

```
imagesc(Vq);
colormap gray
axis image
axis off
title('Linear Interpolation');
```



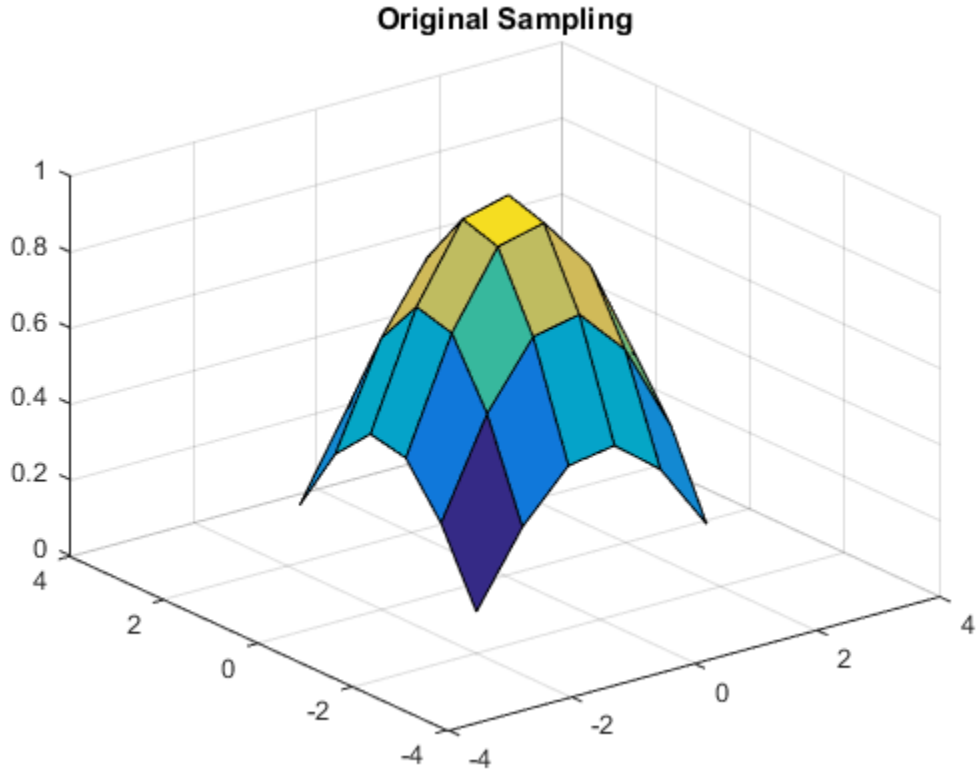
Evaluate Outside the Domain of X and Y

Coarsely sample a function over the range, `[-2, 2]` in both dimensions.

```
[X,Y] = meshgrid(-2:0.75:2);
R = sqrt(X.^2 + Y.^2)+ eps;
V = sin(R)./(R);
```

Plot the coarse sampling.

```
figure
surf(X,Y,V)
xlim([-4 4])
ylim([-4 4])
title('Original Sampling')
```



Create the query grid that extends beyond the domain of `X` and `Y`.

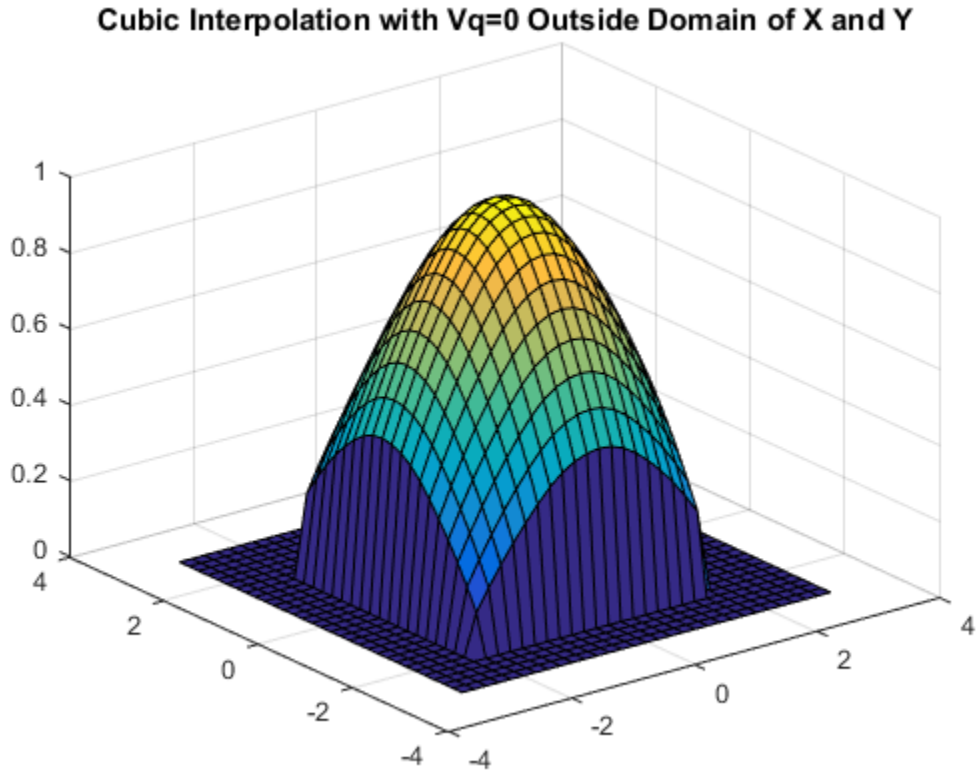
```
[Xq,Yq] = meshgrid(-3:0.2:3);
```

Perform cubic interpolation within the domain of `X` and `Y`, and assign all queries that fall outside to zero.

```
Vq = interp2(X,Y,V,Xq,Yq,'cubic',0);
```

Plot the result.

```
figure
surf(Xq,Yq,Vq)
title('Cubic Interpolation with Vq=0 Outside Domain of X and Y');
```



Input Arguments

X,Y — Sample grid points

matrices | vectors

Sample grid points, specified as real matrices or vectors.

- If `X` and `Y` are matrices, then they contain the coordinates of a full grid (in meshgrid format). Use the `meshgrid` function to create the `X` and `Y` matrices together. Both matrices must be the same size.
- If `X` and `Y` are vectors, then they are treated as a grid vectors. The values in both vectors must be strictly monotonic and increasing.

Example: `[X,Y] = meshgrid(1:30,-10:10)`

Data Types: `single` | `double`

`V` — Sample values

matrix

Sample values, specified as a real or complex matrix. The size requirements for `V` depend on the size of `X` and `Y`.

- If `X` and `Y` are matrices representing a full grid (in `meshgrid` format), then `V` must be the same size as `X` and `Y`.
- If `X` and `Y` are grid vectors, then `V` must be a matrix containing `length(Y)` rows and `length(X)` columns.

Example: `rand(10,10)`

Data Types: `single` | `double`
Complex Number Support: Yes

`Xq,Yq` — Query points

scalars | vectors | matrices | arrays

Query points, specified as a real scalars, vectors, matrices, or arrays.

- If `Xq` and `Yq` are scalars, then they are the coordinates of a single query point.
- If `Xq` and `Yq` are vectors of different orientations, then `Xq` and `Yq` are treated as grid vectors.
- If `Xq` and `Yq` are vectors of the same size and orientation, then `Xq` and `Yq` are treated as scattered points in 2-D space.
- If `Xq` and `Yq` are matrices, then they represent either a full grid of query points (in `meshgrid` format) or scattered points.

- If `Xq` and `Yq` are N-D arrays, then they represent scattered points in 2-D space.

Example: `[Xq,Yq] = meshgrid((1:0.1:10),(-5:0.1:0))`

Data Types: `single` | `double`

k — Refinement factor

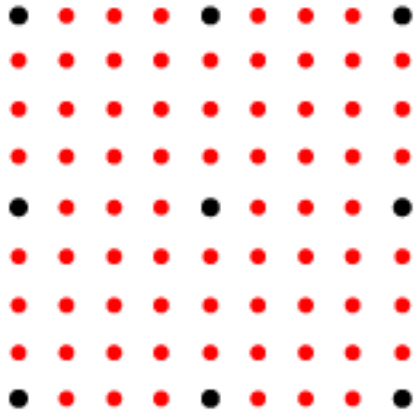
1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in `2^k-1` interpolated points between sample values.

If `k` is `0`, then `Vq` is the same as `V`.

`interp2(V,1)` is the same as `interp2(V)`.

The following illustration shows the placement of interpolated values (in red) among nine sample values (in black) for `k=2`.



Example: `interp2(V,2)`

Data Types: `single` | `double`

method — Interpolation method

`'linear'` (default) | `'nearest'` | `'cubic'` | `'spline'`

Interpolation method, specified as a string from this table.

Method	Description	Continuity	Comments
`'linear'`	The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.	C^0	• Requires at least two grid points in each dimension • Requires more memory than `'nearest'`
`'nearest'`	The interpolated value at a query point is the value at the nearest sample grid point.	Discontinuous	• Requires two grid points in each dimension. • Fastest computation with modest memory requirements
`'cubic'`	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.	C^1	• Grid must have uniform spacing in each dimension, but the spacing does not have to be the same for all dimensions • Requires at least four points in each dimension • Requires more memory and computation time than `'linear'`
`'spline'`	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline using not-a-knot end conditions.	C^2	• Requires four points in each dimension • Requires more memory and computation time than `'cubic'`

`extrapval` — Function value outside domain of `X` and `Y`

scalar

Function value outside domain of `X` and `Y`, specified as a real or complex scalar. `interp2` returns this constant value for all points outside the domain of `X` and `Y`.

Example: `5`

Example: `5+1i`

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

`Vq` — Interpolated values

scalar | vector | matrix

Interpolated values, returned as a real or complex scalar, vector, or matrix. The size and shape of `Vq` depends on the syntax you use and, in some cases, the size and value of the input arguments.

Syntaxes	Special Conditions	Size of Vq	Example
`interp2(X,Y,V,Xq,Yq)` `interp2(V,Xq,Yq)` and variations of these syntaxes that include `method` or `extrapval`	`Xq`, `Yq` are scalars	Scalar	`size(Vq) = [1 1]` when you pass `Xq` and `Yq` as scalars.
Same as above	`Xq`, `Yq` are vectors of the same size and orientation	Vector of same size and orientation as `Xq` and `Yq`	If `size(Xq) = [100 1]` and `size(Yq) = [100 1]`, then `size(Vq) = [100 1]`.
Same as above	`Xq`, `Yq` are vectors of mixed orientation	Matrix in which the number of rows is `length(Yq)`, and the number of columns is `length(Xq)`	If `size(Xq) = [1 100]` and `size(Yq) = [50 1]`, then `size(Vq) = [50 100]`.
Same as above	`Xq`, `Yq` are matrices or arrays of the same size	Matrix or array of the same size as `Xq` and `Yq`	If `size(Xq) = [50 25]` and `size(Yq) = [50 25]`, then `size(Vq) = [50 25]`.

Syntaxes	Special Conditions	Size of Vq	Example
`interp2(V,k)` and variations of this syntax that include `method` or `extrapval`	None	Matrix in which the number of rows is: `2^k * (size(V,1)-1)+1`, and the number of columns is: `2^k * (size(V,2)-1)+1`	If `size(V) = [10 20]` and `k = 2`, then `size(Vq) = [37 77]`.

More About

Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence, `a = [2 4 6 8]` is strictly monotonic and increasing. The sequence, `b = [2 4 4 6 8]` is not strictly monotonic because there is no change in value between `b(2)` and `b(3)`. The sequence, `c = [2 4 6 8 6]` contains a reversal between `c(4)` and `c(5)`, so it is not monotonic at all.

Full Grid (in meshgrid Format)

For `interp2`, the full grid is a pair of matrices whose elements represent a grid of points over a rectangular region. One matrix contains the x-coordinates, and the other matrix contains the y-coordinates. The values in the x-matrix are strictly monotonic and increasing along the rows. The values along its columns are constant. The values in the y-matrix are strictly monotonic and increasing along the columns. The values along its rows are constant. Use the `meshgrid` function to create a full grid that you can pass to `interp2`.

For example, the following code creates a full grid for the region, $-1 \le x \le 3$ and $1 \le y \le 4$:

```
[X,Y] = meshgrid(-1:3,(1:4))
```

```
X =

    -1     0     1     2     3
    -1     0     1     2     3
    -1     0     1     2     3
```

```
    -1     0     1     2     3

Y =

     1     1     1     1     1
     2     2     2     2     2
     3     3     3     3     3
     4     4     4     4     4
```

Grid Vectors

For `interp2`, grid vectors consist of a pair of mixed-orientation vectors that define the *x*- and *y*-coordinates in a grid. One vector is a row vector, and the other is a column vector.

For example, the following code creates the grid vectors that specify the region, $-1 \le x \le 3$ and $1 \le y \le 4$:

```
x = -1:3;
y = (1:4)';
```

Scattered Points

For `interp2`, scattered points consist of a pair of arrays that define a collection of points scattered in 2-D space. One array contains the *x*-coordinates, and the other contains the *y*-coordinates.

For example, the following code specifies the points, (2,7), (5,3), (4,1), and (10,9):

```
x = [2 5; 4 10];
y = [7 3; 1 9];
```

Introduced before R2006a

interp3

Interpolation for 3-D gridded data in meshgrid format

Compatibility

In a future release, `interp3` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see “Functionality being removed or changed”.

Syntax

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)
Vq = interp3(V,Xq,Yq,Zq)
Vq = interp3(V)
Vq = interp3(V,k)

Vq = interp3(___,method)
Vq = interp3(___,method,extrapval)
```

Description

`Vq = interp3(X,Y,Z,V,Xq,Yq,Zq)` returns interpolated values of a function of three variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X`, `Y`, and `Z` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq`, `Yq`, and `Zq` contain the coordinates of the query points.

`Vq = interp3(V,Xq,Yq,Zq)` assumes a default grid of sample points. The default grid points cover the region, `X=1:n`, `Y=1:m`, `Z=1:p`, where `[m,n,p] = size(V)`. Use this syntax when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interp3(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interp3(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interp3(___,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interp3(___,method,extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interp3` returns one of the following:

- The extrapolated values for the `'spline'` method
- `NaN` values for interpolation methods other than `'spline'`

Examples

Interpolate Using Default Method

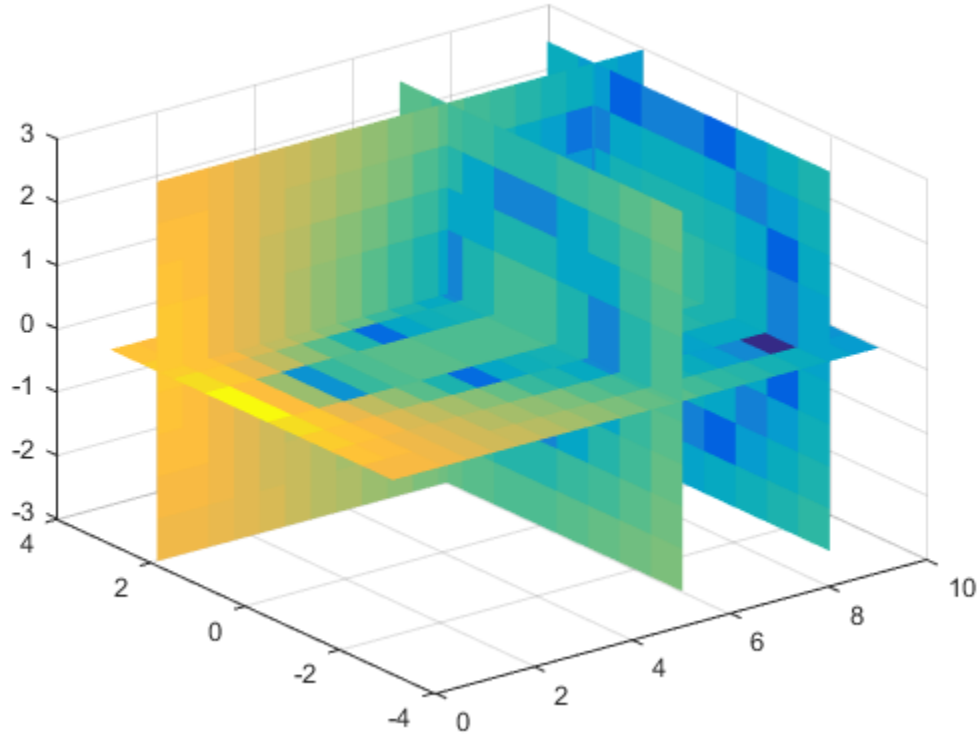
Load the points and values of the flow function, sampled at 10 points in each dimension.

```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays, `X`, `Y`, `Z`. The grid covers the region, $0.1 \le X \le 10$, $-3 \le Y \le 3$, $-3 \le Z \le 3$, and the spacing is $\Delta X = 0.5$, $\Delta Y = 0.7$, and $\Delta Z = 0.7$.

Now, plot slices through the volume of the sample at: `X=6`, `X=9`, `Y=2`, and `Z=0`.

```
figure
slice(X,Y,Z,V,[6 9],2,0);
shading flat
```

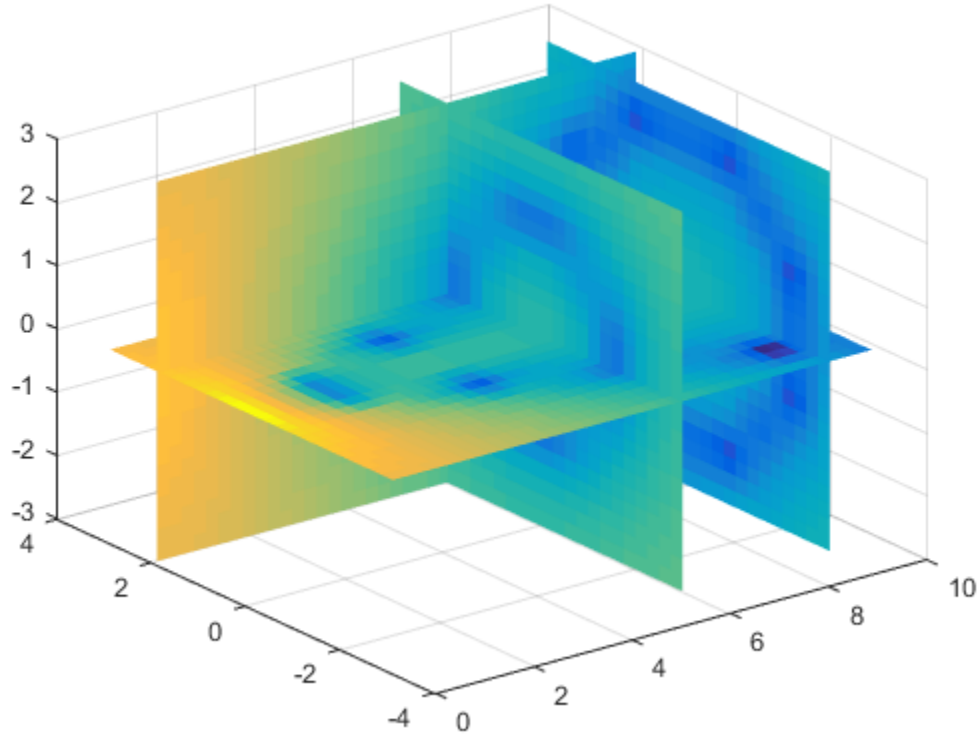


Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10,-3:.25:3,-3:.25:3);
```

Interpolate at the points in the query grid and plot the results using the same slice planes.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq);
figure
slice(Xq,Yq,Zq,Vq,[6 9],2,0);
shading flat
```



Interpolate Using Cubic Method

Load the points and values of the flow function, sampled at 10 points in each dimension.

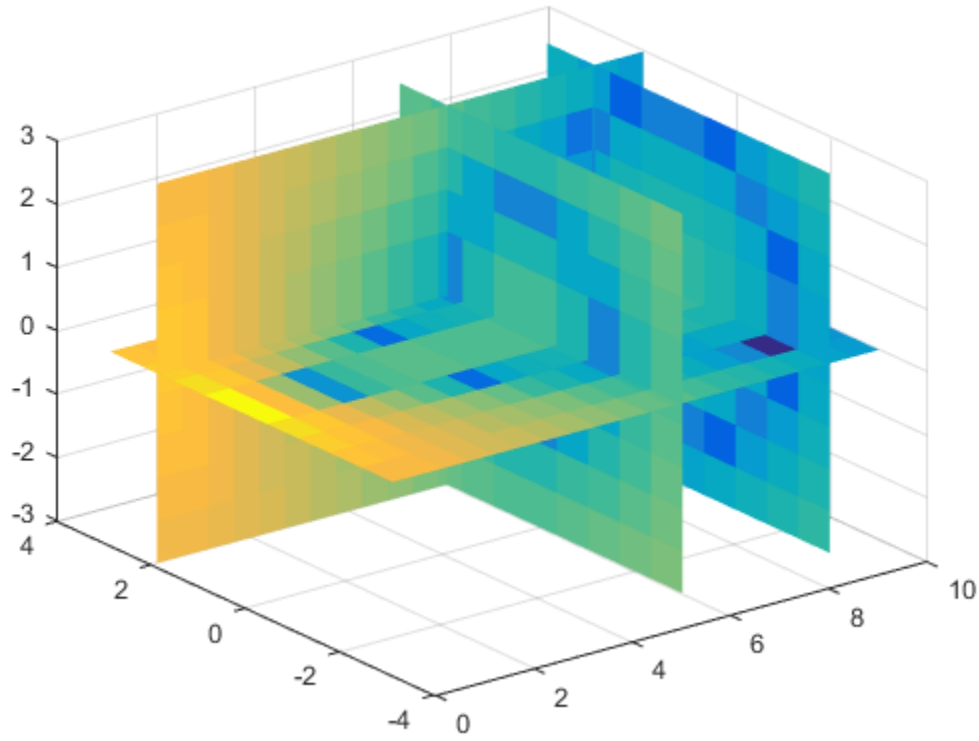
```
[X,Y,Z,V] = flow(10);
```

The `flow` function returns the grid in the arrays, `X`, `Y`, `Z`. The grid covers the region, $0.1 \le X \le 10$, $-3 \le Y \le 3$, $-3 \le Z \le 3$, and the spacing is $\Delta X = 0.5$, $\Delta Y = 0.7$, and $\Delta Z = 0.7$.

Plot slices through the volume of the sample at: `X=6`, `X=9`, `Y=2`, and `Z =0`.

```
figure
```

```
slice(X,Y,Z,V,[6 9],2,0);
shading flat
```



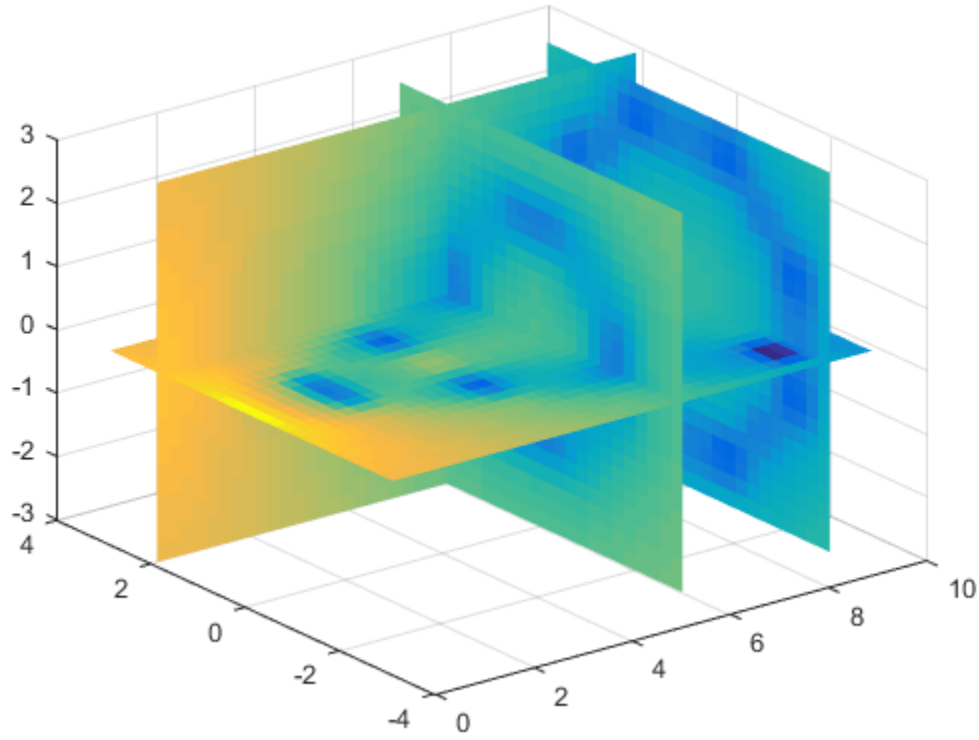
Create a query grid with spacing of 0.25.

```
[Xq,Yq,Zq] = meshgrid(.1:.25:10,-3:.25:3,-3:.25:3);
```

Interpolate at the points in the query grid using the `'cubic'` interpolation method. Then plot the results.

```
Vq = interp3(X,Y,Z,V,Xq,Yq,Zq,'cubic');
figure
slice(Xq,Yq,Zq,Vq,[6 9],2,0);
```

```
shading flat
```



Evaluate Outside the Domain of X, Y, and Z

Create the grid vectors, `x`, `y`, and `z`. These vectors define the points associated with values in `V`.

```
x = 1:100;
y = (1:50)';
z = 1:30;
```

Define the sample values to be a 50-by-100-by-30 random number array, `V`. Use the `gallery` function to create the array.

```
V = gallery('uniformdata',50,100,30,0);
```

Evaluate V at three points outside the domain of x, y, and z. Specify `extrapval = -1`.

```
xq = [0 0 0];
yq = [0 0 51];
zq = [0 101 102];
vq = interp3(x,y,z,V,xq,yq,zq,'linear',-1)
```

```
vq =

    -1    -1    -1
```

All three points evaluate to `-1` because they are outside the domain of x, y, and z.

Input Arguments

X,Y,Z — Sample grid points

arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If X, Y, and Z are arrays, then they contain the coordinates of a full grid (in meshgrid format). Use the `meshgrid` function to create the X, Y, and Z arrays together. These arrays must be the same size.
- If X, Y, and Z are vectors, then they are treated as a grid vectors. The values in these vectors must be strictly monotonic and increasing.

Example: `[X,Y,Z] = meshgrid(1:30,-10:10,1:5)`

Data Types: `single | double`

V — Sample values

array

Sample values, specified as a real or complex array. The size requirements for V depend on the size of X, Y, and Z.

- If X, Y, and Z are arrays representing a full grid (in `meshgrid` format), then the size of V matches the size of X, Y, or Z .

- If `X`, `Y`, and `Z` are grid vectors, then `size(V) = [length(Y) length(X) length(Z)]`.

Example: `rand(10,10,10)`

Data Types: `single` | `double`
Complex Number Support: Yes

`Xq,Yq,Zq` — Query points

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If `Xq`, `Yq`, and `Zq` are scalars, then they are the coordinates of a single query point in R^3.
- If `Xq`, `Yq`, and `Zq` are vectors of different orientations, then `Xq`, `Yq`, and `Zq` are treated as grid vectors in R^3.
- If `Xq`, `Yq`, and `Zq` are vectors of the same size and orientation, then `Xq`, `Yq`, and `Zq` are treated as scattered points in R^3.
- If `Xq`, `Yq`, and `Zq` are arrays of the same size, then they represent either a full grid of query points (in `meshgrid` format) or scattered points in R^3.

Example: `[Xq,Yq,Zq] = meshgrid((1:0.1:10),(-5:0.1:0),3:5)`

Data Types: `single` | `double`

`k` — Refinement factor

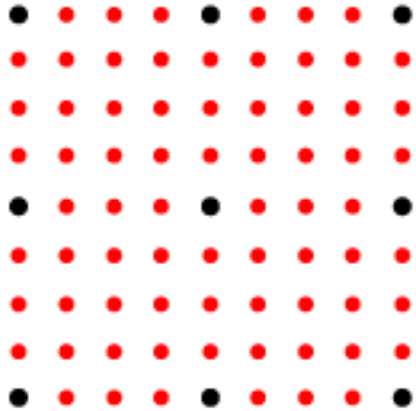
1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in `2^k-1` interpolated points between sample values.

If `k` is `0`, then `Vq` is the same as `V`.

`interp3(V,1)` is the same as `interp3(V)`.

The following illustration depicts `k=2` in one plane of R^3. There are 72 interpolated values in red and 9 sample values in black.



Example: `interp3(V,2)`

Data Types: `single` | `double`

`method` — Interpolation method

`'linear'` (default) | `'nearest'` | `'cubic'` | `'spline'`

Interpolation method, specified as a string from this table.

Method	Description	Continuity	Comments
`'linear'`	The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.	C^0	• Requires at least two grid points in each dimension • Requires more memory than `'nearest'`
`'nearest'`	The interpolated value at a query point is the value at the nearest sample grid point.	Discontinuous	• Requires two grid points in each dimension • Fastest computation with modest memory requirements
`'cubic'`	The interpolated value at a query point is based on a cubic	C^1	• Grid must have uniform spacing in each dimension,

Method	Description	Continuity	Comments
	interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.		but the spacing does not have to be the same for all dimensions • Requires at least four points in each dimension • Requires more memory and computation time than `'linear'`
`'spline'`	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic spline using not-a-knot end conditions.	C^2	• Requires four points in each dimension • Requires more memory and computation time than `'cubic'`

`extrapval` — Function value outside domain of `X`, `Y`, and `Z`
scalar

Function value outside domain of `X`, `Y`, and `Z`, specified as a real or complex scalar. `interp3` returns this constant value for all points outside the domain of `X`, `Y`, and `Z`.

Example: `5`

Example: `5+1i`

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

`Vq` — Interpolated values
scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of `Vq` depends on the syntax you use and, in some cases, the size and value of the input arguments.

Syntaxes	Special Conditions	Size of Vq	Example

`interp3(X,Y,Z,V,Xq,Yq)`
`interp3(V,Xq,Yq,Zq)`
and variations of these syntaxes that include `method` or `extrapval`
	`Xq`, `Yq`, and `Zq` are scalars.	Scalar	`size(Vq) = [1 1]` when you pass `Xq`, `Yq`, and `Zq` as scalars.

Same as above	`Xq`, `Yq`, and `Zq` are vectors of the same size and orientation.	Vector of same size and orientation as `Xq`, `Yq`, and `Zq`	If `size(Xq) = [100 1]`, and `size(Yq) = [100 1]`, and `size(Zq) = [100 1]`, then `size(Vq) = [100 1]`.
Same as above	`Xq`, `Yq`, and `Zq` are vectors of mixed orientation.	`size(Vq) = [length(Y) length(X) length(Z)]`	If `size(Xq) = [1 100]`, and `size(Yq) = [50 1]`, and `size(Zq) = [1 5]`, then `size(Vq) = [50 100 5]`.
Same as above	`Xq`, `Yq`, and `Zq` are arrays of the same size.	Array of the same size as `Xq`, `Yq`, and `Zq`	If `size(Xq) = [50 25]`, and `size(Yq) = [50 25]`, and `size(Zq) = [50 25]`, then `size(Vq) = [50 25]`.
`interp3(V,k)` and variations of this syntax that include `method` or `extrapval`	None	Array in which the length of the `i`th dimension is `2^k * (size(V,i)-1)+1`	If `size(V) = [10 12 5]`, and `k = 3`, then `size(Vq) = [73 89 33]`.

More About

Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence, `a = [2 4 6 8]` is strictly monotonic and increasing. The sequence, `b`

= [2 4 4 6 8] is not strictly monotonic because there is no change in value between b(2) and b(3). The sequence, c = [2 4 6 8 6] contains a reversal between c(4) and c(5), so it is not monotonic at all.

Full Grid (in meshgrid Format)

For interp3, a full grid consists of three arrays whose elements represent a grid of points that define a region in R^3. The first array contains the x-coordinates, the second array contains the y-coordinates, and the third array contains the z-coordinates. The values in each array vary along a single dimension and are constant along the other dimensions.

The values in the x-array are strictly monotonic, increasing, and vary along the second dimension. The values in the y-array are strictly monotonic, increasing, and vary along the first dimension. The values in the z-array are strictly monotonic, increasing, and vary along the third dimension. Use the meshgrid function to create a full grid that you can pass to interp3.

Grid Vectors

For interp3, grid vectors consist of three vectors of mixed-orientation that define the points on a grid in R^3.

For example, the following code creates the grid vectors for the region, $1 \le x \le 3$, $4 \le y \le 5$, and $6 \le z \le 8$:

```
x = 1:3;
y = (4:5)';
z = 6:8;
```

Scattered Points

For interp3, scattered points consist of three arrays or vectors, Xq, Yq, and Zq, that define a collection of points scattered in R^3. The ith array contains the coordinates in the ith dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13).

```
Xq = [1 6; 15 0];
Yq = [19 40; 33 61];
Zq = [10 1; 22 13];
```

See Also

`interp1` | `interp2` | `interpn` | `meshgrid`

Introduced before R2006a

interpft

1-D interpolation using FFT method

Syntax

```
y = interpft(x,n)
y = interpft(x,n,dim)
```

Description

`y = interpft(x,n)` returns the vector `y` that contains the value of the periodic function `x` resampled to `n` equally spaced points.

If `length(x) = m`, and `x` has sample interval `dx`, then the new sample interval for `y` is `dy = dx*m/n`. Note that `n` cannot be smaller than `m`.

If `X` is a matrix, `interpft` operates on the columns of `X`, returning a matrix `Y` with the same number of columns as `X`, but with `n` rows.

`y = interpft(x,n,dim)` operates along the specified dimension.

Examples

Interpolate a triangle-like signal using an interpolation factor of 5. First, set up signal to be interpolated:

```
y = [0 .5 1 1.5 2 1.5 1 .5 0 -.5 -1 -1.5 -2 -1.5 -1 -.5 0];
N = length(y);
```

Perform the interpolation:

```
L = 5;
M = N*L;
x = 0:L:L*N-1;
xi = 0:M-1;
yi = interpft(y,M);
```

```
plot(x,y,'o',xi,yi,'*')
legend('Original data','Interpolated data')
```

More About

Algorithms

The `interpft` command uses the FFT method. The original vector `x` is transformed to the Fourier domain using `fft` and then transformed back with more points.

See Also

`interp1`

Introduced before R2006a

interpn

Interpolation for 1-D, 2-D, 3-D, and N-D gridded data in ndgrid format

Compatibility

In a future release, `interpn` will not accept mixed combinations of row and column vectors for the sample and query grids. For more information, and recommendations for updating your code, see "Functionality being removed or changed".

Syntax

```
Vq = interpn(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)
Vq = interpn(V,Xq1,Xq2,...,Xqn)
Vq = interpn(V)
Vq = interpn(V,k)

Vq = interpn( ___ ,method)
Vq = interpn( ___ ,method,extrapval)
```

Description

`Vq = interpn(X1,X2,...,Xn,V,Xq1,Xq2,...,Xqn)` returns interpolated values of a function of n variables at specific query points using linear interpolation. The results always pass through the original sampling of the function. `X1,X2,...,Xn` contain the coordinates of the sample points. `V` contains the corresponding function values at each sample point. `Xq1,Xq2,...,Xqn` contain the coordinates of the query points.

`Vq = interpn(V,Xq1,Xq2,...,Xqn)` assumes a default grid of sample points. The default grid consists of the points, 1,2,3,...n_i in each dimension. The value of n_i is the length of the ith dimension in `V`. Use this syntax to when you want to conserve memory and are not concerned about the absolute distances between points.

`Vq = interpn(V)` returns the interpolated values on a refined grid formed by dividing the interval between sample values once in each dimension.

`Vq = interpn(V,k)` returns the interpolated values on a refined grid formed by repeatedly dividing the intervals `k` times in each dimension.

`Vq = interpn(___,method)` specifies an optional, trailing input argument that you can pass with any of the previous syntaxes. The `method` argument can be any of the following strings that specify alternative interpolation methods: `'linear'`, `'nearest'`, `'pchip'`,`'cubic'`, or `'spline'`. The default method is `'linear'`.

`Vq = interpn(___,method,extrapval)` also specifies `extrapval`, a scalar value that is assigned to all queries that lie outside the domain of the sample points.

If you omit the `extrapval` argument for queries outside the domain of the sample points, then based on the `method` argument `interpn` returns one of the following:

- The extrapolated values for the `'spline'` method
- `NaN` values for interpolation methods other than `'spline'`

Examples

1-D Interpolation

Define the sample points and values.

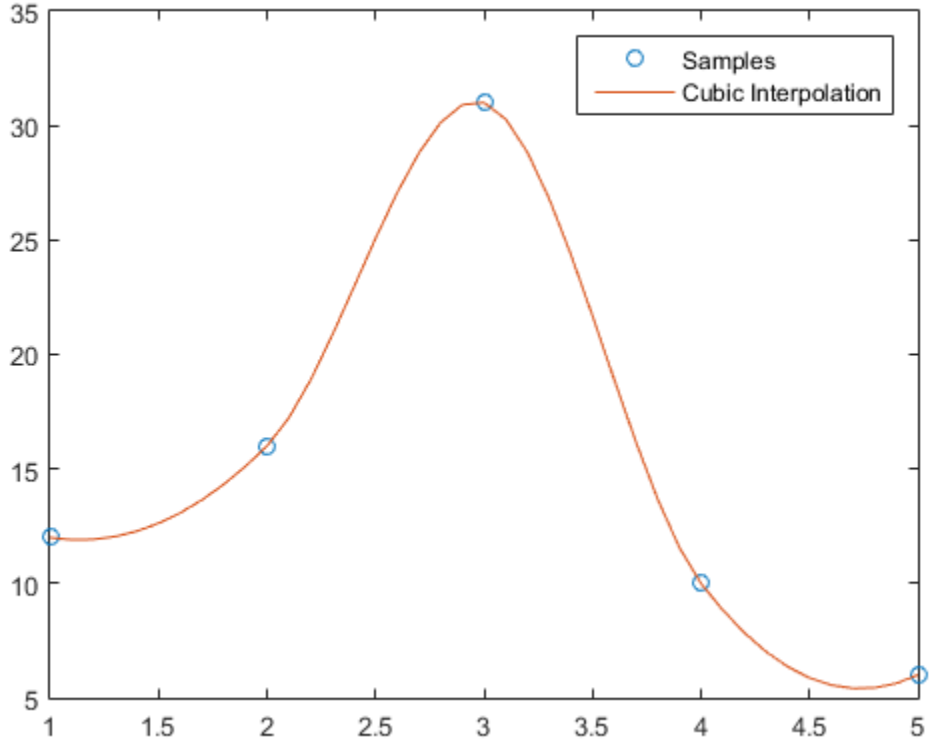
```
x = [1 2 3 4 5];
v = [12 16 31 10 6];
```

Define the query points, `xq`, and interpolate.

```
xq = (1:0.1:5);
vq = interpn(x,v,xq,'cubic');
```

Plot the result.

```
figure
plot(x,v,'o',xq,vq,'-');
legend('Samples','Cubic Interpolation');
```



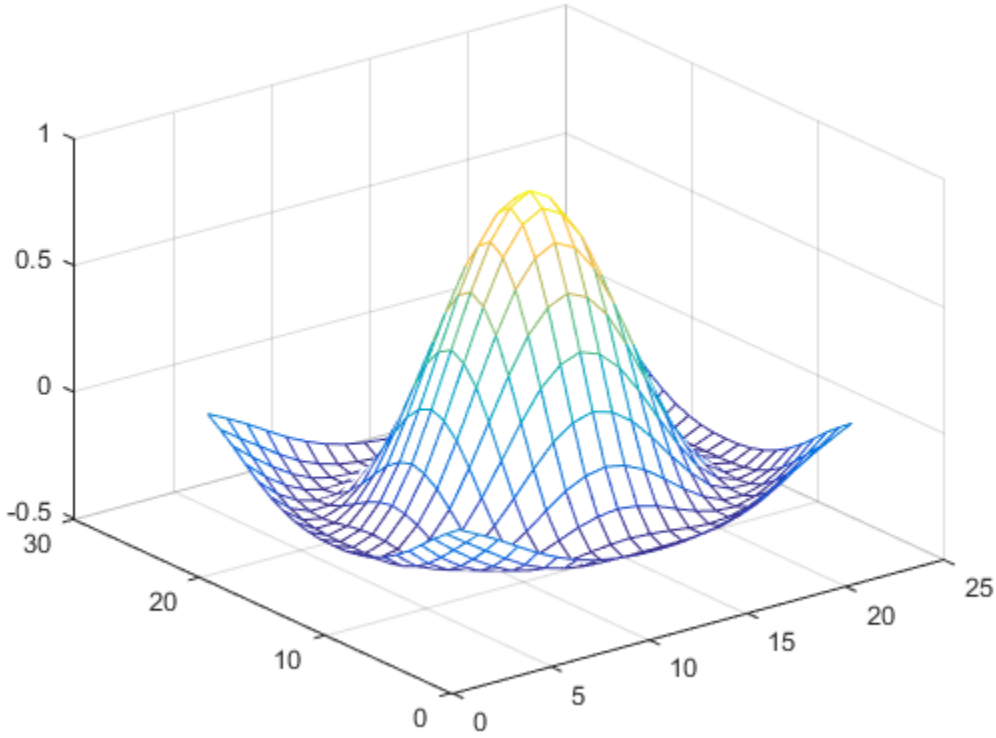
2-D Interpolation

Create a set of grid points and corresponding sample values.

```
[X1,X2] = ndgrid((-5:1:5));
R = sqrt(X1.^2 + X2.^2)+ eps;
V = sin(R)./(R);
```

Interpolate over a finer grid using `ntimes=1`.

```
Vq = interpn(V,'cubic');
mesh(Vq);
```



Evaluate Outside Domain of 3-D Function

Create the grid vectors, `x1`, `x2`, and `x3`. These vectors define the points associated with the values in `V`.

```
x1 = 1:100;
x2 = (1:50)';
x3 = 1:30;
```

Define the sample values to be a 100-by-50-by-30 random number array, `V`. Use the `gallery` function to create the array.

```
V = gallery('uniformdata',100,50,30,0);
```

Evaluate V at three points outside the domain of x1, x2, and x3. Specify extrapval = -1.

```
xq1 = [0 0 0];
xq2 = [0 0 51];
xq3 = [0 101 102];
vq = interpn(x1,x2,x3,V,xq1,xq2,xq3,'linear',-1)
```

```
vq =

    -1    -1    -1
```

All three points evaluate to -1 because they are outside the domain of x1, x2, and x3.

4-D Interpolation

Define an anonymous function that represents $f = te^{-x^2-y^2-z^2}$.

```
f = @(x,y,z,t) t.*exp(-x.^2 - y.^2 - z.^2);
```

Create a grid of points in R^4. Then, pass the points through the function to create the sample values, V.

```
[x,y,z,t] = ndgrid(-1:0.2:1,-1:0.2:1,-1:0.2:1,0:2:10);
V = f(x,y,z,t);
```

Now, create the query grid.

```
[xq,yq,zq,tq] = ...
ndgrid(-1:0.05:1,-1:0.08:1,-1:0.05:1,0:0.5:10);
```

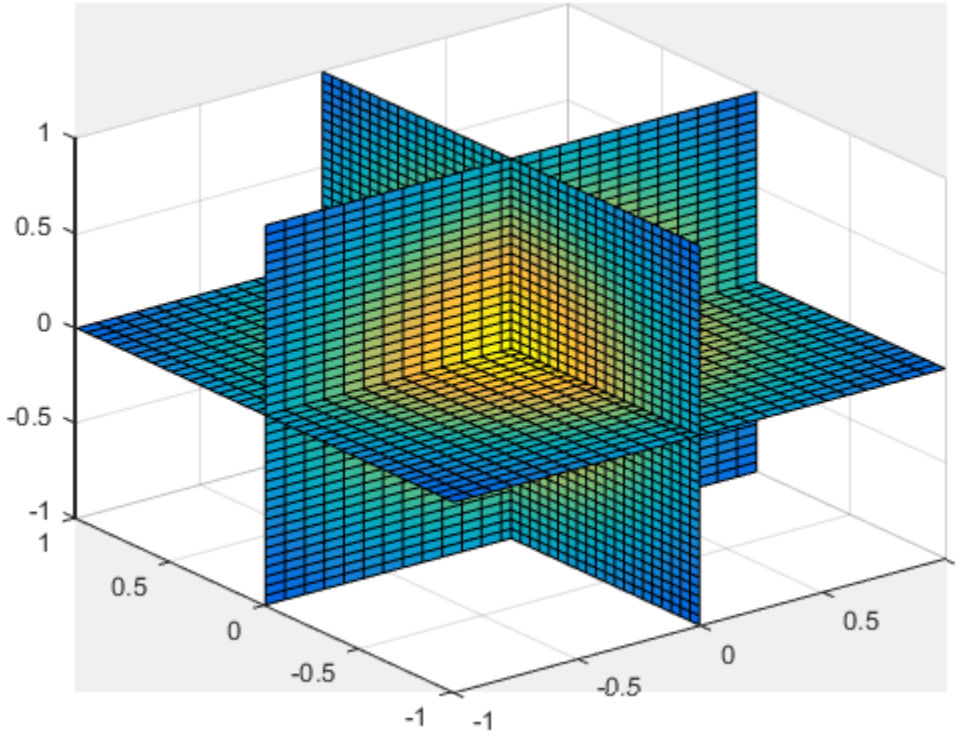
Interpolate V at the query points.

```
Vq = interpn(x,y,z,t,V,xq,yq,zq,tq);
```

Create a movie to show the results.

```
figure('renderer','zbuffer');
nframes = size(tq, 4);
for j = 1:nframes
   slice(yq(:,:,:,j),xq(:,:,:,j),zq(:,:,:,j),...
```

```
        Vq(:,:,:,j),0,0,0);
   caxis([0 10]);
   M(j) = getframe;
end
movie(M);
```



Input Arguments

X1,X2,...,Xn — Sample grid points

arrays | vectors

Sample grid points, specified as real arrays or vectors.

- If `X1,X2,...,Xn` are arrays, then they contain the coordinates of a full grid (in ndgrid format). Use the `ndgrid` function to create the `X1,X2,...,Xn` arrays together. These arrays must be the same size.
- If `X1,X2,...,Xn` are vectors, then they are treated as grid vectors. The values in these vectors must be strictly monotonic and increasing.

Example: `[X1,X2,X3] = ndgrid(1:30,-10:10,1:5)`

Data Types: `single | double`

`V` — Sample values

array

Sample values, specified as a real or complex array. The size requirements for `V` depend on the size of `X1,X2,...,Xn`.

- If `X1,X2,...,Xn` are arrays representing a full grid (in `ndgrid` format), then the size of `V` matches the size of any array, `X1,X2,...,Xn`.
- If `X1,X2,...,Xn` are grid vectors, then `V` is an array whose `i`th dimension is the same length as grid vector `Xi`, where `i= 1,2,...n`.

Example: `rand(10,5,3,2)`

Data Types: `single | double`
Complex Number Support: Yes

`Xq1,Xq2,...,Xqn` — Query points

scalars | vectors | arrays

Query points, specified as a real scalars, vectors, or arrays.

- If `Xq1,Xq2,...,Xqn` are scalars, then they are the coordinates of a single query point in R^n.
- If `Xq1,Xq2,...,Xqn` are vectors of different orientations, then `Xq1,Xq2,...,Xqn` are treated as grid vectors in R^n.
- If `Xq1,Xq2,...,Xqn` are vectors of the same size and orientation, then `Xq1,Xq2,...,Xqn` are treated as scattered points in R^n.
- If `Xq1,Xq2,...,Xqn` are arrays of the same size, then they represent either a full grid of query points (in `ndgrid` format) or scattered points in R^n.

Example: `[X1,X2,X3,X4] = ndgrid(1:10,1:5,7:9,10:11)`

Data Types: `single` | `double`

`k` — Refinement factor

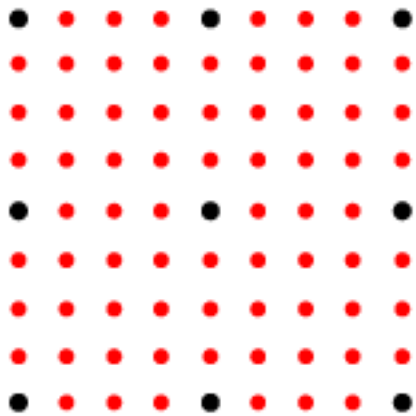
1 (default) | real, nonnegative, integer scalar

Refinement factor, specified as a real, nonnegative, integer scalar. This value specifies the number of times to repeatedly divide the intervals of the refined grid in each dimension. This results in `2^k-1` interpolated points between sample values.

If `k` is `0`, then `Vq` is the same as `V`.

`interpn(V,1)` is the same as `interpn(V)`.

The following illustration depicts `k=2` in R^2. There are 72 interpolated values in red and 9 sample values in black.



Example: `interpn(V,2)`

Data Types: `single` | `double`

`method` — Interpolation method

`'linear'` (default) | `'nearest'` | `'pchip'` | `'cubic'` | `'spline'`

Interpolation method, specified as a string from this table.

Method	Description	Continuity	Comments
`'linear'`	The interpolated value at a query point is based on linear interpolation of the values at neighboring grid points in each respective dimension. This is the default interpolation method.	C^0	• Requires at least two grid points in each dimension • Requires more memory than `'nearest'`
`'nearest'`	The interpolated value at a query point is the value at the nearest sample grid point.	Discontinuous	• Requires two grid points in each dimension. • Fastest computation with modest memory requirements
`'pchip'`	Shape-preserving piecewise cubic interpolation (for 1-D only). The interpolated value at a query point is based on a shape-preserving piecewise cubic interpolation of the values at neighboring grid points.	C^1	• Requires at least four points • Requires more memory and computation time than `'linear'`
`'cubic'`	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic convolution.	C^1	• Grid must have uniform spacing in each dimension, but the spacing does not have to be the same for all dimensions • Requires at least four points in each dimension • Requires more memory and computation time than `'linear'`
`'spline'`	The interpolated value at a query point is based on a cubic interpolation of the values at neighboring grid points in each respective dimension. The interpolation is based on a cubic	C^2	• Requires four points in each dimension • Requires more memory and computation time than `'cubic'`

Method	Description	Continuity	Comments
	spline using not-a-knot end conditions.		

`extrapval` — Function value outside domain of `X1,X2,...,Xn`

scalar

Function value outside domain of `X1,X2,...,Xn`, specified as a real or complex scalar. `interpn` returns this constant value for all points outside the domain of `X1,X2,...,Xn`.

Example: `5`

Example: `5+1i`

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

`Vq` — Interpolated values

scalar | vector | array

Interpolated values, returned as a real or complex scalar, vector, or array. The size and shape of `Vq` depends on the syntax you use and, in some cases, the size and value of the input arguments.

Syntaxes	Special Conditions	Size of Vq	Example
`interpn(X1,...,Xn,V,X` `interpn(V,Xq1,...,Xqn` and variations of these syntaxes that include `method` or `extrapval`	`Xq1,...,Xqn` are scalars	Scalar	`size(Vq) = [1 1]` when you pass `Xq1,...,Xqn` as scalars.
Same as above	`Xq1,...,Xqn` are vectors of the same size and orientation	Vector of same size and orientation as `Xq1,...,Xqn`	In 3-D, if `size(Xq1) = [100 1]`, and `size(Xq2) = [100 1]`, and `size(Xq3) = [100 1]`,

Syntaxes	Special Conditions	Size of Vq	Example
			then `size(Vq) = [100 1]`.
Same as above	`Xq1,...,Xqn` are vectors of mixed orientation	`size(Vq) = [length(Xq1),...,leng`	In 3-D, if `size(Xq1) = [1 100]`, and `size(Xq2) = [50 1]`, and `size(Xq3) = [1 5]`, then `size(Vq) = [100 50 5]`.
Same as above	`Xq1,...,Xqn` are arrays of the same size	Array of the same size as `Xq1,...,Xqn`	In 3-D, if `size(Xq1) = [50 25]`, and `size(Xq2) = [50 25]`, and `size(Xq3) = [50 25]`, then `size(Vq) = [50 25]`.
`interpn(V,k)` and variations of this syntax that include `method` or `extrapval`	None	Array in which the length of the `i`th dimension is `2^k * (size(V,i)-1)+1`,	In 3-D, if `size(V) = [10 12 5]`, and `k = 3`, then `size(Vq) = [73 89 33]`.

More About

Strictly Monotonic

A set of values that are always increasing or decreasing, without reversals. For example, the sequence, `a = [2 4 6 8]` is strictly monotonic and increasing. The sequence, `b = [2 4 4 6 8]` is not strictly monotonic because there is no change in value between `b(2)` and `b(3)`. The sequence, `c = [2 4 6 8 6]` contains a reversal between `c(4)` and `c(5)`, so it is not monotonic at all.

Full Grid (in ndgrid Format)

For `interpn`, the full grid consists of n arrays, `X1,X2,...,Xn`, whose elements represent a grid of points in R^n. The ith array, X_i, contains strictly monotonic, increasing values that vary most rapidly along the ith dimension.

Use the `ndgrid` function to create a full grid that you can pass to `interpn`. For example, the following code creates a full grid in R^2 for the region, $1 \le X1 \le 3$, $1 \le X2 \le 4$.

```
[X1,X2] = ndgrid(-1:3,(1:4))
```

```
X1 =

    -1    -1    -1    -1
     0     0     0     0
     1     1     1     1
     2     2     2     2
     3     3     3     3

X2 =

     1     2     3     4
     1     2     3     4
     1     2     3     4
     1     2     3     4
     1     2     3     4
```

Grid Vectors

For `interpn`, grid vectors consist of n vectors of mixed-orientation that define the points of a grid in R^n.

For example, the following code creates the grid vectors in R^3 for the region, $1 \le x1 \le 3$, $4 \le x2 \le 5$, and $6 \le x3 \le 8$:

```
x1 = 1:3;
x2 = (4:5)';
x3 = 6:8;
```

Scattered Points

For `interpn`, scattered points consist of n arrays or vectors, `Xq1,Xq2,...,Xqn`, that define a collection of points scattered in R^n. The `i`th array, `Xi`, contains the coordinates in the `i`th dimension.

For example, the following code specifies the points, (1, 19, 10), (6, 40, 1), (15, 33, 22), and (0, 61, 13) in R^3.

```
Xq1 = [1 6; 15 0];
Xq2 = [19 40; 33 61];
Xq3 = [10 1; 22 13];
```

Introduced before R2006a

interpstreamspeed

Interpolate stream-line vertices from flow speed

Syntax

```
interpstreamspeed(X,Y,Z,U,V,W,vertices)
interpstreamspeed(U,V,W,vertices)
interpstreamspeed(X,Y,Z,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(X,Y,U,V,vertices)
interpstreamspeed(U,V,vertices)
interpstreamspeed(X,Y,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(...,sf)
vertsout = interpstreamspeed(...)
```

Description

`interpstreamspeed(X,Y,Z,U,V,W,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,W,vertices)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(U)`.

`interpstreamspeed(X,Y,Z,speed,vertices)` uses the 3-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p]=size(speed)`.

`interpstreamspeed(X,Y,U,V,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U`, `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`interpstreamspeed(U,V,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M N]=size(U)`.

`interpstreamspeed(X,Y,speed,vertices)` uses the 2-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M,N]= size(speed)`.

`interpstreamspeed(...,sf)` uses `sf` to scale the magnitude of the vector data and therefore controls the number of interpolated vertices. For example, if `sf` is 3, then `interpstreamspeed` creates only one-third of the vertices.

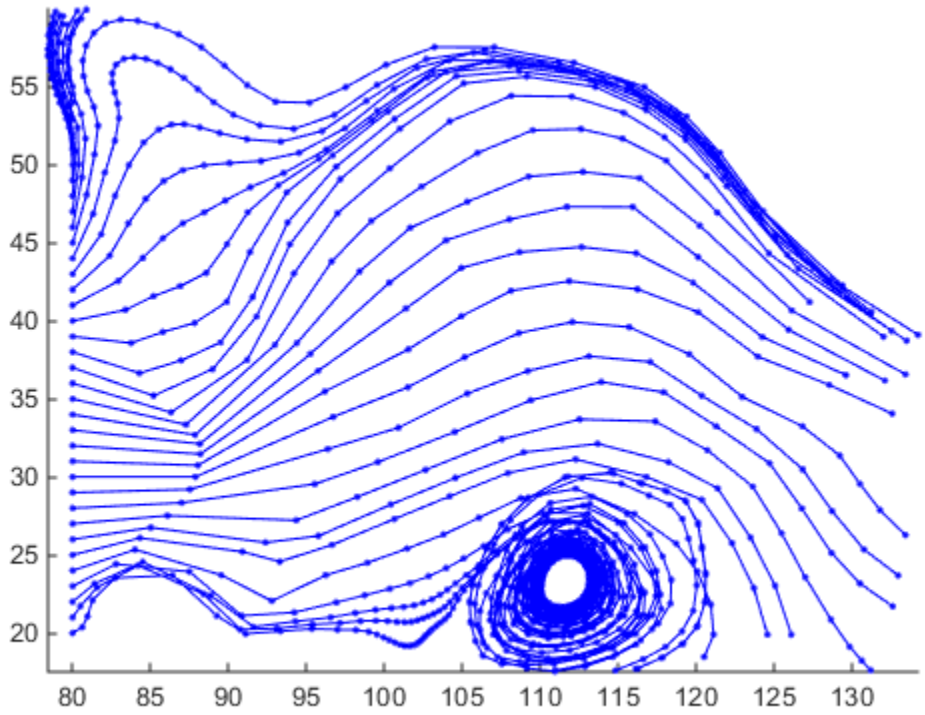
`vertsout = interpstreamspeed(...)` returns a cell array of vertex arrays.

Examples

This example draws streamlines using the vertices returned by `interpstreamspeed`. Dot markers indicate the location of each vertex. This example enables you to visualize the relative speeds of the flow data. Streamlines having widely spaced vertices indicate faster flow; those with closely spaced vertices indicate slower flow.

```
load wind
```

```
[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,0.2);
sl = streamline(iverts);
set(sl,'Marker','.')
axis tight; view(2); daspect([1 1 1])
```



This example plots streamlines whose vertex spacing indicates the value of the gradient along the streamline.

```
figure
z = membrane(6,30);
[u v] = gradient(z);
pcolor(z)
```

```
hold on
[verts averts] = streamslice(u,v);
iverts = interpstreamspeed(u,v,verts,15);
sl = streamline(iverts);
set(sl,'Marker','.')
shading interp
axis tight
view(2)
daspect([1,1,1])
hold off
```

stream2 | stream3 | streamline | streamslice | streamparticles

Introduced before R2006a

intersect

Set intersection of two arrays

Syntax

```
C = intersect(A,B)
C = intersect(A,B,'rows')
[C,ia,ib] = intersect(A,B)
[C,ia,ib] = intersect(A,B,'rows')

[C,ia,ib] = intersect( ___ ,setOrder)

[C,ia,ib] = intersect(A,B,'legacy')
[C,ia,ib] = intersect(A,B,'rows','legacy')
```

Description

`C = intersect(A,B)` returns the data common to both `A` and `B` with no repetitions.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `intersect` returns the values common to both `A` and `B`. The values of `C` are in sorted order.
- If `A` and `B` are tables, then `intersect` returns the set of rows common to both tables. The rows of table `C` are in sorted order.

`C = intersect(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the rows common to both `A` and `B`. The rows of `C` are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia,ib] = intersect(A,B)` also returns index vectors `ia` and `ib`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `C = A(ia)` and `C = B(ib)`.

- If `A` and `B` are tables, then `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect(A,B,'rows')` also returns index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

`[C,ia,ib] = intersect( ___ ,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`, and then `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = intersect(A,B,'legacy')` and `[C,ia,ib] = intersect( A,B,'rows','legacy')` preserve the behavior of the `intersect` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays, tables, datetime arrays, or duration arrays.

Examples

Intersection of Two Vectors

Define two vectors with values in common.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
```

Find the values common to both `A` and `B`.

```
C = intersect(A,B)
```

```
C =

     4     7
```

Intersection of Two Tables

Define two tables with rows in common.

```
A = table([1:5]',['A';'B';'C';'D';'E'],logical([0;1;0;1;0]))
B = table([1:2:10]',['A';'C';'E';'G';'I'],logical(zeros(5,1)))
```

```
A =
```

```
    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    2       B       true
    3       C       false
    4       D       true
    5       E       false

B =

    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    3       C       false
    5       E       false
    7       G       false
    9       I       false
```

Find the rows common to both `A` and `B`.

```
C = intersect(A,B)
```

```
C =

    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    3       C       false
    5       E       false
```

Intersection of Two Vectors and Their Indices

Define two vectors with values in common.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
```

Find the values common to both `A` and `B`, as well as the index vectors `ia` and `ib`, such that `C = A(ia)` and `C = B(ib)`.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
     4     7

ia =

     5
     1

ib =

     3
     1
```

Intersection of Two Tables and Their Indices

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =

             Gender    Age    Height
             ------    ---    ------
    Ted      M         27     74
    Fred     M         52     68
    Betty    F         31     64
    Bob      M         46     61
    Judy     F         35     64
```

Define a table, B, with rows in common with A.

```
B = table(['F';'M';'F';'F'],[31;47;35;23],[64;68;62;58],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Meg' 'Joe' 'Beth' 'Amy'})
```

```
B =

             Gender    Age    Height
             ------    ---    ------
    Meg      F         31     64
    Joe      M         47     68
    Beth     F         35     62
```

```
    Amy      F          23      58
```

Find the rows common to both `A` and `B`, as well as the index vectors ia and ib, such that `C = A(ia,:)` and `C = B(ib,:)`.

```
[C,ia,ib] = intersect(A,B)
```

```
C =

              Gender    Age    Height
              ------    ---    ------
    Betty     F         31     64

ia =

     3

ib =

     1
```

Two rows that have the same values, but different names, are considered equal. Therefore, we discover that Betty, `A(3,:)`, and Meg, `B(1,:)` have the same gender, age, and height.

Intersection of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [2 2 2; 0 0 1; 1 2 3; 1 1 1];
B = [1 2 3; 2 2 2; 2 2 0];
```

Find the rows common to both `A` and `B` as well as the index vectors `ia` and `ib`, such that `C = A(ia,:)` and `C = B(ib,:)`.

```
[C,ia,ib] = intersect(A,B,'rows')
```

```
C =

     1     2     3
     2     2     2
```

```
ia =

     3
     1

ib =

     1
     2
```

A and B do not need to have the same number of rows, but they must have the same number of columns.

Intersection with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as in A.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C,ia,ib] = intersect(A,B,'stable')
```

```
C =

     7     4

ia =

     1
     5

ib =

     1
     3
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia,ib] = intersect(A,B,'sorted')
```

```
C =
```

```
     4     7

ia =

     5
     1

ib =

     3
     1
```

Intersection of Vectors Containing NaNs

Define two vectors containing `NaN`.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the values common to both `A` and `B`.

```
C = intersect(A,B)
```

```
C =

     5
```

`intersect` treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, `A`.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, `B`, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings common to both `A` and `B`.

```
[C,ia,ib] = intersect(A,B)
```

```
C =
```

```
    'cat'    'horse'

ia =

     2
     4

ib =

     2
     4
```

`intersect` treats trailing white space in cell arrays of strings as distinct characters.

Intersection of Arrays of Different Classes and Shapes

Create a column vector character array.

```
A = ['A';'B';'C'], class(A)
```

```
A =

A
B
C

ans =

char
```

Create a 2-by-3 matrix containing elements of numeric type `double`.

```
B = [65 66 67;68 69 70], class(B)
```

```
B =

    65    66    67
    68    69    70
```

```
ans =

double
```

Find the values common to both A and B.

```
[C,ia,ib] = intersect(A,B)
```

```
C =

A
B
C

ia =

     1
     2
     3

ib =

     1
     3
     5
```

`intersect` interprets B as a character array and returns a character array, C.

```
class(C)
```

```
ans =

char
```

Intersection of Char and Cell Array of Strings

Create a character array containing animal names that have three letters.

```
A = ['dog';'cat';'fox';'pig'];
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings containing animal names of varying lengths.

```
B = {'cat','dog','fish','horse'};
class(B)
```

```
ans =

cell
```

Find the strings common to both `A` and `B`.

```
C = intersect(A,B)
```

```
C =

    'cat'
    'dog'
```

The result, `C`, is a cell array of strings.

```
class(C)
```

```
ans =

cell
```

Preserve Legacy Behavior of `intersect`

Use the `'legacy'` flag to preserve the behavior of `intersect` from R2012b and prior releases in your code.

Find the intersection of `A` and `B` with the current behavior.

```
A = [7 1 7 7 4]; B = [7 0 4 4 0];
[C1,ia1,ib1] = intersect(A,B)
```

```
C1 =

     4     7

ia1 =
```

```
     5
     1

ib1 =

     3
     1
```

Find the unique elements of A and preserve the legacy behavior.

```
[C2,ia2,ib2] = intersect(A,B,'legacy')
```

```
C2 =

     4     7

ia2 =

     5     4

ib2 =

     4     1
```

Input Arguments

A,B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays | duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.

- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the `'rows'` option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If A and B are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, A and B can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

`setOrder` — Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in C.

Order Flag	Meaning
`'sorted'`	The values (or rows) in C return in sorted order. For example: `C = intersect([7 0 5],[7 1 5],'sorted')` returns `C = [5 7]`.
`'stable'`	The values (or rows) in C return in the same order as they appear in A and B. For example: `C = intersect([7 0 5],[7 1 5],'stable')` returns `C = [7 5]`.

Output Arguments

C — Data common to A and B

vector | matrix | table

Data common to A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of C when the inputs are vectors or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then C is a column vector unless both A and B are row vectors.
- If the 'rows' flag is not specified and both A and B are row vectors, then C is a row vector.
- If the 'rows' flag is specified, then C is a matrix containing the rows in common from A and B.
- If A and B have no values (or rows) in common, then C is an empty matrix.

The class of the inputs A and B determines the class of C:

- If the class of A and B are the same, then C is the same class.
- If you combine a char or nondouble numeric class with double, then C is the same class as the nondouble input.
- If you combine a logical class with double, then C is double.
- If you combine a cell array of strings with char, then C is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then C is a categorical array.
- If you combine a datetime array with a cell array of date strings or single date string, then C is a datetime array.

ia — Index to A

column vector

Index to A, returned as a column vector when the 'legacy' flag is not specified. ia identifies the values (or rows) in A that are common to B. If there is a repeated value (or row) in A, then ia contains the index to the first occurrence of the value (or row).

`ib` — Index to `B`

column vector

Index to `B`, returned as a column vector when the `'legacy'` flag is not specified. `ib` identifies the values (or rows) in `B` that are common to `A`. If there is a repeated value (or row) in `B`, then `ib` contains the index to the first occurrence of the value (or row).

More About

Tips

- To find the intersection with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `intersect(A(:,vars),B(:,vars))`, where *`vars`* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.
- "Combine Categorical Arrays"

Introduced before R2006a

intmax

Largest value of specified integer type

Syntax

```
v = intmax
v = intmax('classname')
```

Description

`v = intmax` is the largest positive value that can be represented in the MATLAB software with a 32-bit integer. Any value larger than the value returned by `intmax` saturates to the `intmax` value when cast to a 32-bit integer.

`v = intmax('classname')` is the largest positive value in the integer class `classname`. Valid values for the string `classname` are

`'int8'`	`'int16'`	`'int32'`	`'int64'`
`'uint8'`	`'uint16'`	`'uint32'`	`'uint64'`

`intmax('int32')` is the same as `intmax` with no arguments.

Examples

Find the maximum value for a 64-bit signed integer:

```
v = intmax('int64')
v =
  9223372036854775807
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
  2147483647
```

Compare the result with the default value returned by `intmax`:

```
isequal(x, intmax)
ans =
     1
```

See Also

`intmin` | `realmax` | `int8` | `uint8` | `isa` | `class` | `realmin`

Introduced before R2006a

intmin

Smallest value of specified integer type

Syntax

```
v = intmin
v = intmin('classname')
```

Description

`v = intmin` is the smallest value that can be represented in the MATLAB software with a 32-bit integer. Any value smaller than the value returned by `intmin` saturates to the `intmin` value when cast to a 32-bit integer.

`v = intmin('classname')` is the smallest positive value in the integer class `classname`. Valid values for the string `classname` are

`'int8'`	`'int16'`	`'int32'`	`'int64'`
`'uint8'`	`'uint16'`	`'uint32'`	`'uint64'`

`intmin('int32')` is the same as `intmin` with no arguments.

Examples

Find the minimum value for a 64-bit signed integer:

```
v = intmin('int64')
v =

 -9223372036854775808
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
```

```
 -2147483648
```

Compare the result with the default value returned by `intmin`:

```
isequal(x, intmin)
ans =

     1
```

`intmax` | `realmin` | `int8` | `uint8` | `isa` | `class` | `realmax`

Introduced before R2006a

inv

Matrix inverse

Syntax

```
Y = inv(X)
```

Description

`Y = inv(X)` returns the inverse of the square matrix `X`. A warning message is printed if `X` is badly scaled or nearly singular.

In practice, it is seldom necessary to form the explicit inverse of a matrix. A frequent misuse of `inv` arises when solving the system of linear equations $Ax = b$. One way to solve this is with `x = inv(A)*b`. A better way, from both an execution time and numerical accuracy standpoint, is to use the matrix division operator `x = A\b`. This produces the solution using Gaussian elimination, without forming the inverse. See `mldivide` (\) for further information.

Note: MATLAB computes `X^(-1)` and `inv(X)` in the same manner, and both are subject to the same limitations.

Examples

Here is an example demonstrating the difference between solving a linear system by inverting the matrix with `inv(A)*b` and solving it directly with `A\b`. A random matrix `A` of order 500 is constructed so that its condition number, `cond(A)`, is `1.e10`, and its norm, `norm(A)`, is `1`. The exact solution `x` is a random vector of length 500 and the right-hand side is `b = A*x`. Thus the system of linear equations is badly conditioned, but consistent.

On a 300 MHz, laptop computer the statements

```
n = 500;
Q = orth(randn(n,n));
d = logspace(0,-10,n);
```

```
A = Q*diag(d)*Q';
x = randn(n,1);
b = A*x;
tic, y = inv(A)*b; toc
err = norm(y-x)
res = norm(A*y-b)
```

produce

```
elapsed_time =
    1.4320
err =
    7.3260e-006
res =
    4.7511e-007
```

while the statements

```
tic, z = A\b, toc
err = norm(z-x)
res = norm(A*z-b)
```

produce

```
elapsed_time =
    0.6410
err =
    7.1209e-006
res =
    4.4509e-015
```

It takes almost two and one half times as long to compute the solution with `y = inv(A)*b` as with `z = A\b`. Both produce computed solutions with about the same error, `1.e-6`, reflecting the condition number of the matrix. But the size of the residuals, obtained by plugging the computed solution back into the original equations, differs by several orders of magnitude. The direct solution produces residuals on the order of the machine accuracy, even though the system is badly conditioned.

The behavior of this example is typical. Using `A\b` instead of `inv(A)*b` is two to three times as fast and produces residuals on the order of machine accuracy, relative to the magnitude of the data.

Introduced before R2006a

invhilb

Inverse of Hilbert matrix

Syntax

```
H = invhilb(n)
```

Description

`H = invhilb(n)` generates the exact inverse of the exact Hilbert matrix for `n` less than about 15. For larger `n`, `invhilb(n)` generates an approximation to the inverse Hilbert matrix.

Limitations

The exact inverse of the exact Hilbert matrix is a matrix whose elements are large integers. These integers may be represented as floating-point numbers without roundoff error as long as the order of the matrix, `n`, is less than 15.

Comparing `invhilb(n)` with `inv(hilb(n))` involves the effects of two or three sets of roundoff errors:

- The errors caused by representing `hilb(n)`
- The errors in the matrix inversion process
- The errors, if any, in representing `invhilb(n)`

It turns out that the first of these, which involves representing fractions like 1/3 and 1/5 in floating-point, is the most significant.

Examples

`invhilb(4)` is

```
     16    -120     240    -140
```

```
  -120     1200    -2700     1680
   240    -2700     6480    -4200
  -140     1680    -4200     2800
```

`hilb`

Introduced before R2006a

invoke

Invoke method on COM object or interface, or display methods

Syntax

```
S = invoke(h)
S = invoke(h,'methodname')
S = invoke(h,'methodname',arg1,arg2, ...)
S = invoke(h,'custominterfacename')
```

Description

`S = invoke(h)` returns structure array, `S`, containing a list of all methods supported by the object or interface, `h`, along with the prototypes for these methods. If `S` is empty, either there are no properties or methods in the object, or MATLAB cannot read the object's type library. Refer to the COM vendor documentation.

`S = invoke(h,'methodname')` invokes the method specified in the string `methodname`, and returns an output value, if any, in `S`. The data type of the return value depends on the invoked method, which is determined by the control or server.

`S = invoke(h,'methodname',arg1,arg2, ...)` invokes the method specified in the string `methodname` with input arguments `arg1`, `arg2`, etc.

`S = invoke(h,'custominterfacename')` returns an `Interface` object `S`, which is a handle to a custom interface implemented by the COM component. The `h` argument is a handle to the COM object. The `custominterfacename` argument is a string returned by the `interfaces` function.

If the method returns a COM interface, then `invoke` returns a new MATLAB COM object that represents the interface returned. For a description of how MATLAB converts COM types, see "Handling COM Data in MATLAB Software".

COM functions are available on Microsoft Windows systems only.

Examples

Invoke the `Redraw` method in the `mwsamp` control.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);
h.Radius = 100;
invoke(h,'Redraw');
```

Alternatively, call the method directly.

```
Redraw(h);
```

Display all `mwsamp` methods.

```
invoke(h)
```

```
ans =
   AboutBox = void AboutBox(handle)
   Beep = void Beep(handle)
   FireClickEvent = void FireClickEvent(handle)
            .
            .
```

Getting a Custom Interface Example

Once you have created a COM server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces:

```
h = actxserver('mytestenv.calculator');
customlist = interfaces(h)
```

```
customlist =
   ICalc1
   ICalc2
   ICalc3
```

To get a handle to the custom interface you want, use the `invoke` function.

```
c1 = invoke(h,'ICalc1')
```

```
c1 =
   Interface.Calc_1.0_Type_Library.ICalc_Interface
```

filUse this handle with COM client functions to access the properties and methods of the object through the selected custom interface.

`methods` | `ismethod` | `interfaces`

Introduced before R2006a

ipermute

Inverse permute dimensions of N-D array

Syntax

```
A = ipermute(B,order)
```

Description

`A = ipermute(B,order)` is the inverse of `permute`. `ipermute` rearranges the dimensions of `B` so that `permute(A,order)` will produce `B`. `B` has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. All the elements of `order` must be unique.

Examples

Consider the 2-by-2-by-3 array `a`:

```
a = cat(3,eye(2),2*eye(2),3*eye(2))

a(:,:,1) =              a(:,:,2) =
     1     0                   2     0
     0     1                   0     2

a(:,:,3) =
     3     0
     0     3
```

Permuting and inverse permuting `a` in the same fashion restores the array to its original form:

```
B = permute(a,[3 2 1]);
C = ipermute(B,[3 2 1]);
isequal(a,C)
ans=

   1
```

More About

Tips

`permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

`permute`

Introduced before R2006a

is*

Detect state

Description

These functions detect the state of MATLAB entities:

`isa`	Detect object of given MATLAB class or Java class
`isappdata`	Determine if object has specific application-defined data
`isbetween`	Array elements occurring within date and time interval
`iscalendarduration`	Determine if input is duration array
`iscategorical`	Determine whether input is categorical array
`iscategory`	Test for categorical array categories
`iscell`	Determine if input is cell array
`iscellstr`	Determine if input is cell array of strings
`ischar`	Determine if input is character array
`iscolumn`	Determine whether input is column vector
`iscom`	Determine if input is Component Object Model (COM) object
`isdatetime`	Determine if input is datetime array
`isdir`	Determine if input is folder
`isdst`	Datetime values occurring during daylight saving time
`isduration`	Determine if input is duration array
`isempty`	Determine if input is empty array
`isequal`	Determine if arrays are numerically equal
`isequaln`	Determine if arrays are numerically equal, treating `NaN`s as equal
`isevent`	Determine if input is Component Object Model (COM) object event
`isfield`	Determine if input is MATLAB structure array field
`isfinite`	Detect finite elements of array

isfloat	Determine if input is floating-point array
ishandle	Detect valid graphics object handles
ishold	Determine if graphics hold state is on
isinf	Detect infinite elements of array
isinteger	Determine if input is integer array
isinterface	Determine if input is Component Object Model (COM) interface
isjava	Determine if input is Java object
iskeyword	Determine if input is MATLAB keyword
isletter	Detect elements that are alphabetic letters
islogical	Determine if input is logical array
ismac	Determine if running MATLAB for Macintosh OS X platform
ismatrix	Determine whether input is matrix
ismember	Detect members of specific set
ismethod	Determine if input is object method
ismissing	Find table elements with missing values
isnan	Detect elements of array that are not a number (NaN)
isnumeric	Determine if input is numeric array
isobject	Determine if input is MATLAB object
isordinal	Determine whether input is ordinal categorical array
ispc	Determine if running MATLAB for PC (Windows) platform
isprime	Detect prime elements of array
isprop	Determine if input is object property
isprotected	Determine whether categories of categorical array are protected
isreal	Determine if all array elements are real numbers
isrow	Determine whether input is row vector
isscalar	Determine if input is scalar
issorted	Determine if set elements are in sorted order

`isspace`	Detect space characters in array
`issparse`	Determine if input is sparse array
`isstrprop`	Determine if string is of specified category
`isstruct`	Determine if input is MATLAB structure array
`isstudent`	Determine if Student Version of MATLAB
`istable`	Determine whether input is table
`isundefined`	Find undefined elements in categorical array
`isunix`	Determine if running MATLAB for UNIX[a] platform.
`isvarname`	Determine if input is valid variable name
`isvector`	Determine if input is vector
`isweekend`	Datetime values occurring during weekend

a. UNIX is a registered trademark of The Open Group in the United States and other countries.

See Also

`isa` | `exist`

isa

Determine if input is object of specified class

Syntax

```
tf = isa(obj,ClassName)
tf = isa(obj,classCategory)
```

Description

`tf = isa(obj,ClassName)` returns `true` if `obj` is an instance of the class specified by *`ClassName`*, and `false` otherwise. `isa` also returns true if `obj` is an instance of a class that is derived from *`ClassName`*.

`obj` can be any MATLAB variable.

`ClassName` can be any of the following:

- Name of any MATLAB class or fundamental type
- Name of a Java, or .NET class

MATLAB Fundamental Types

`'single'`	Single-precision number
`'double'`	Double-precision number
`'int8'`	Signed 8-bit integer
`'int16'`	Signed 16-bit integer
`'int32'`	Signed 32-bit integer
`'int64'`	Signed 64-bit integer
`'uint8'`	Unsigned 8-bit integer
`'uint16'`	Unsigned 16-bit integer
`'uint32'`	Unsigned 32-bit integer
`'uint64'`	Unsigned 64-bit integer

`'logical'`	Logical `true` or `false`
`'char'`	Character or string
`'struct'`	Structure array
`'cell'`	Cell array
`'function_handle'`	function handle

`tf = isa(obj,classCategory)` returns `true` if `obj` is an instance of any of the classes in the specified *`classCategory`*, and `false` otherwise. `isa` also returns true if `obj` is an instance of a class that is derived from any of the classes in *`classCategory`*.

`classCategory` can be `'numeric'`, `'float'`, or `'integer'`, representing a category of numeric types:

Categories of Numeric Types

`'numeric'`	Integer or floating-point array (`double`, `single`, `int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `int64`, `uint64`)
`'float'`	Single- or double-precision floating-point array (`double`, `single`)
`'integer'`	Signed or unsigned integer array (`int8`, `uint8`, `int16`, `uint16`, `int32`, `uint32`, `int64`, `uint64`)

To test for a sparse array, use `issparse`. To test for a complex array, use `~isreal`.

Examples

These examples show the values returned by `isa` when passed different types:

Determine if the value returned by the `pi` function is of class `double`:

```
isa(pi,'double')
```

```
ans =

     1
```

More generally, determine if the value returned by the `pi` function is a numeric value:

```
isa(pi,'numeric')
```

```
ans =

     1
```

`isa` also returns `true` for the `float` category because the class `double` is a floating-point type. However, `pi` does not return an integer type:

```
isa(pi,'integer')

ans =

     0
```

Determine if the 2-by-3 array returned by `true` is of type logical:

```
isa(true(2,3),'logical')

ans =

     1
```

Identify an instance of the MATLAB `containers.Map` class:

```
colorcodes = containers.Map({'Color','RGB'},...
    {'Yellow',uint8([255,255,0])});
isa(colorcodes,'containers.Map')

ans =

     1
```

The map key, `RGB`, references a `uint8` array:

```
isa(colorcodes('RGB'),'integer')

ans =

     1
```

Specifying a particular integer class provides more specific testing:

```
if strcmp(colorcodes('Color'),'Yellow') && ...
        isa(colorcodes('RGB'),'uint8')
    disp '''The Color is Yellow and the RGB numbers are uint8 values'''
```

```
end
'The Color is Yellow and the RGB numbers are uint8 values'
```

See Also

`class` | `is*` | `isnumeric` | `isfloat` | `isinteger` | `exist`

Introduced before R2006a

isappdata

True if application-defined data exists

Syntax

```
tf = isappdata(h,name)
```

Description

`tf = isappdata(h,name)` returns `logical(1)` if application-defined data exists and these conditions are met:

- The application data has the specified `name` value.
- The application data is associated with the UI component, `h`.

Otherwise, `isappdata` returns `logical(0)`

See Also

`getappdata` | `rmappdata` | `setappdata`

Introduced before R2006a

isbanded

Determine if matrix is within specific bandwidth

Syntax

```
tf = isbanded(A,lower,upper)
```

Description

`tf = isbanded(A,lower,upper)` returns logical `1` (`true`) if matrix A is within the specified lower bandwidth, `lower`, and upper bandwidth, `upper`; otherwise, it returns logical `0` (`false`).

Examples

Test Square Matrix

Create a 5-by-5 square matrix.

```
A = [2 3 0 0 0 ; 1 -2 -3 0 0; 0 -1 2 3 0 ; 0 0 1 -2 -3; 0 0 0 -1 2]
```

```
A =

     2     3     0     0     0
     1    -2    -3     0     0
     0    -1     2     3     0
     0     0     1    -2    -3
     0     0     0    -1     2
```

The result is a square matrix with nonzero diagonals above and below the main diagonal.

Specify both bandwidths, `lower` and `upper`, as `1` to test if `A` is tridiagonal.

```
isbanded(A,1,1)
```

```
ans =

     1
```

The result is logical `1` (`true`).

Test if `A` has nonzero elements below the main diagonal by specifying `lower` as `0`.

```
isbanded(A,0,1)
```

```
ans =

     0
```

The result is logical `0` (`false`) because `A` has nonzero elements below the main diagonal.

Test Nonsquare Matrix

Create a 3-by-5 matrix.

```
A = [1 0 0 0 0; 2 1 0 0 0; 3 2 1 0 0]
```

```
A =

     1     0     0     0     0
     2     1     0     0     0
     3     2     1     0     0
```

The result is a rectangular matrix.

Test if `A` has nonzero elements above the main diagonal.

```
isbanded(A,2,0)
```

```
ans =

     1
```

The result is logical `1` (`true`) because the elements above the main diagonal are all zero.

Test Sparse Block Matrix

Create a 100-by-100 sparse block matrix.

```
B = kron(speye(25),ones(4));
```

Test if `B` has a lower and upper bandwidth of `1`.

```
isbanded(B,1,1)
```

```
ans =

     0
```

The result is logical `0` (`false`) because the nonzero blocks centered on the main diagonal are larger than 2-by-2.

Test if `B` has a lower and upper bandwidth of `3`.

```
isbanded(B,3,3)
```

```
ans =

     1
```

The result is logical `1` (`true`). The matrix, `B`, has an upper and lower bandwidth of `3` since the nonzero diagonal blocks are 4-by-4.

Input Arguments

`A` — Input array

numeric array

Input array, specified as a numeric array. `isbanded` returns logical `0` (`false`) if `A` has more than two dimensions.

Data Types: `single` | `double`
Complex Number Support: Yes

`lower` — Lower bandwidth

nonnegative integer scalar

Lower bandwidth, specified as a nonnegative integer scalar. The lower bandwidth is the number of nonzero diagonals below the main diagonal. `isbanded` returns logical `0` (`false`) if there are nonzero elements below the boundary diagonal, `diag(A,-lower)`.

`upper` — Upper bandwidth

nonnegative integer scalar

Upper bandwidth, specified as a nonnegative integer scalar. The upper bandwidth is the number of nonzero diagonals above the main diagonal. `isbanded` returns logical `0` (`false`) if there are nonzero elements above the boundary diagonal, `diag(A,upper)`.

More About

Tips

- Use the `bandwidth` function to find the upper and lower bandwidths of a given matrix.
- Use `isbanded` to test for several different matrix structures by specifying appropriate upper and lower bandwidths. The table below lists some common tests.

Lower Bandwidth	Upper Bandwidth	Function Call	Tests for
`0`	`0`	`isbanded(A,0,0)`	Diagonal matrix
`1`	`1`	`isbanded(A,1,1)`	Tridiagonal matrix
`0`	`size(A,2)`	`isbanded(A,0,size(A,`	Upper triangular matrix
`size(A,1)`	`0`	`isbanded(A,size(A,1)`	Lower triangular matrix
`1`	`size(A,2)`	`isbanded(A,1,size(A,`	Upper Hessenberg matrix
`size(A,1)`	`1`	`isbanded(A,size(A,1)`	Lower Hessenberg matrix

See Also

`bandwidth` | `diag` | `isdiag` | `istril` | `istriu`

Introduced in R2014a

isbetween

Determine elements within date and time interval

Syntax

```
tf = isbetween(t,tlower,tupper)
```

Description

`tf = isbetween(t,tlower,tupper)` returns an array the same size as `t` containing logical `1` (true) where the corresponding element of `t` is a datetime that lies within the closed interval specified by the corresponding elements of `tlower` and `tupper`. The output `tf` indicates which elements of `t` satisfy:

```
tlower <= t <= tupper
```

Examples

Determine if Dates Occur Within Interval

Define a lower bound and an upper bound for dates.

```
tlower = datetime(2014,05,16)
```

```
tlower =

   16-May-2014
```

```
tupper = '23-May-2014'
```

```
tupper =

23-May-2014
```

`tlower` and `tupper` can be `datetime` arrays or strings. Here, `tlower` is a `datetime` array and `tupper` is a single string.

Create an array of datetime values and determine if each datetime lies within the interval bounded by `tlower` and `tupper`.

```
t = tlower + caldays(2:2:10)
```

```
t =

   18-May-2014   20-May-2014   22-May-2014   24-May-2014   26-May-2014
```

```
tf = isbetween(t,tlower,tupper)
```

```
tf =

     1     1     1     0     0
```

Input Arguments

`t` — Input date and time

`datetime` array | cell array of datetime strings | datetime string

Input date and time, specified as a `datetime` array, a cell array of datetime strings, or a single datetime string.

`tlower` — Lower bound of date and time interval

`datetime` array | cell array of datetime strings | datetime string

Lower bound of date and time interval, specified as a `datetime` array, a cell array of datetime strings, or a single datetime string.

`tupper` — Upper bound of date and time interval

`datetime` array | cell array of date strings | datetime string

Upper bound of date and time interval, specified as a `datetime` array, a cell array of datetime strings, or a single datetime string.

See Also

`ge` | `gt` | `ismember` | `le` | `lt`

Introduced in R2014b

iscalendarduration

Determine if input is calendar duration array

Syntax

```
tf = iscalendarduration(t)
```

Description

`tf = iscalendarduration(t)` returns logical `1` (`true`) if `t` is a `calendarDuration` array. Otherwise, it returns logical `0` (`false`).

Examples

Determine if Array Contains Calendar Duration Values

Determine if the output of an arithmetic calculation is a `calendarDuration` array.

Add two `calendarDuration` arrays.

```
d1 = calyears(1:4);
d2 = caldays(1:4);
d = d1 + d2
```

```
d =

   1y 1d   2y 2d   3y 3d   4y 4d
```

Determine if the output is a `calendarDuration` array.

```
tf = iscalendarduration(d)
```

```
tf =
```

```
1
```

Input Arguments

`t` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `t` can be any data type.

See Also

`calendarDuration` | `isdatetime` | `isduration`

Introduced in R2014b

iscategorical

Determine whether input is categorical array

Syntax

```
tf = iscategorical(A)
```

Description

`tf = iscategorical(A)` returns logical `1` (`true`) if `A` is a categorical array. Otherwise, `iscategorical` returns logical `0` (`false`).

Examples

Determine Whether Workspace Variable Is Categorical Array

Create a workspace variable, `A`.

```
A = categorical({'red' 'green' 'violet'; 'orange' 'red' 'yellow'})
```

```
A =

     red          green      violet
     orange       red        yellow
```

Verify that the workspace variable, `A`, is a categorical array.

```
tf = iscategorical(A)
```

```
tf =

     1
```

A is a 2-by-3 categorical array.

Input Arguments

A — Input variable

workspace variable

Input variable, specified as a workspace variable. A can be any data type.

See Also

`categorical` | `iscell` | `islogical` | `isnumeric` | `isobject` | `isstruct` | `istable`

iscategory

Test for categorical array categories

Syntax

```
tf = iscategory(A,catnames)
```

Description

`tf = iscategory(A,catnames)` returns an array containing logical `1` (`true`) where the data in catnames is a category of A. Otherwise, `iscategory` returns logical `0` (`false`).

`tf` is the same size as `catnames`.

Examples

Test for Categories

Create an ordinal categorical array, `A`.

```
A = categorical({'shirt' 'pants'; 'pants' 'hat'; 'shirt' 'pants'})
```

```
A =

     shirt      pants
     pants      hat
     shirt      pants
```

`A` is a 3-by-2 categorical array.

Test if the articles of clothing, `shirt`, `pants`, `socks`, and `shoes`, are categories of `A`.

```
catnames = {'shirt' 'pants' 'socks' 'shoes'};
tf = iscategory(A,catnames)
```

```
tf =
```

```
     1     1     0     0
```

`shirt` and `pants` are categories of `A`, but `socks`, and `shoes` are not.

`iscategory` does not tell us anything about the category, `hat`, which we did not include in `catnames`.

Test for Category with No Corresponding Data

Create a categorical array, `A`.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'},...
    {'boat' 'car' 'plane' 'train'})
```

```
A =

     plane      car      train      car      plane
```

`A` is a 1-by-5 categorical array.

Test to see if `boat` is a category in `A`.

```
tf = iscategory(A,'boat')
```

```
tf =

     1
```

`iscategory` returns true, even though `A` does not contain any values from the category `boat`.

Input Arguments

`A` — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

`catnames` — Category names

string | cell array of strings | categorical array

Category names, specified as a string, cell array of strings, or categorical array.

See Also

iscell

Determine whether input is cell array

Syntax

```
tf = iscell(A)
```

Description

`tf = iscell(A)` returns logical `1` (`true`) if `A` is a cell array and logical `0` (`false`) otherwise.

Examples

```
A{1,1} = [1 4 3; 0 5 8; 7 2 9];
A{1,2} = 'Anne Smith';
A{2,1} = 3+7i;
A{2,2} = -pi:pi/10:pi;

iscell(A)

ans =

     1
```

See Also

`cell` | `istable` | `iscellstr` | `isstruct` | `isnumeric` | `islogical` | `isobject` | `isa` | `is*`

Introduced before R2006a

iscellstr

Determine whether input is cell array of strings

Syntax

```
tf = iscellstr(A)
```

Description

`tf = iscellstr(A)` returns logical `1` (`true`) if `A` is a cell array of strings (or an empty cell array), and logical `0` (`false`) otherwise. A cell array of strings is a cell array where every element is a character array.

Examples

```
A{1,1} = 'Thomas Lee';
A{1,2} = 'Marketing';
A{2,1} = 'Allison Jones';
A{2,2} = 'Development';

iscellstr(A)

ans =

     1
```

See Also

`cellstr` | `istable` | `iscategorical` | `iscell` | `isstrprop` | `strings` | `char` | `isstruct` | `isa` | `is*`

Introduced before R2006a

ischar

Determine whether item is character array

Syntax

```
tf = ischar(A)
```

Description

`tf = ischar(A)` returns logical `1` (`true`) if `A` is a character array and logical `0` (`false`) otherwise.

Examples

Given the following cell array,

```
C{1,1} = magic(3);           % double array
C{1,2} = 'John Doe';         % char array
C{1,3} = 2 + 4i              % complex double

C =

    [3x3 double]    'John Doe'    [2.0000+ 4.0000i]
```

`ischar` shows that only `C{1,2}` is a character array.

```
for k = 1:3
x(k) = ischar(C{1,k});
end

x

x =

     0     1     0
```

See Also

`char` | `strings` | `isletter` | `isspace` | `isstrprop` | `iscellstr` | `isnumeric` | `isa` | `is*`

Introduced before R2006a

iscolumn

Determine whether input is column vector

Syntax

```
iscolumn(V)
```

Description

`iscolumn(V)` returns logical 1 (`true`) if `size`(V) returns `[n 1]` with a nonnegative integer value `n`, and logical 0 (`false`) otherwise.

Examples

Determine if a vector is a column. This example is a row so `iscolumn` returns 0:

```
V = rand(1,5);
iscolumn(V)
ans =
     0
```

Transpose the vector to make it a column. `iscolumn` returns 1:

```
V1 = V';
iscolumn(V1)
ans =
     1
```

See Also

`ismatrix` | `isrow` | `isscalar` | `isvector`

iscom

Determine whether input is COM or ActiveX object

Syntax

```
tf = iscom(h)
```

Description

`tf = iscom(h)` returns logical `1` (`true`) if handle `h` is a COM or Microsoft ActiveX object. Otherwise, returns logical `0` (`false`).

COM functions are available on Microsoft Windows systems only.

Examples

Test an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
iscom(h)
```

MATLAB displays `true`, indicating object `h` is a COM object.

Test an Excel interface:

```
h = actxserver('Excel.Application');
% Create a workbooks object
w = get(h,workbooks');
iscom(w)
```

MATLAB displays `false`, indicating object `w` is not a COM object.

More About

- "MATLAB COM Integration"

Introduced before R2006a

isdatetime

Determine if input is datetime array

Syntax

```
tf = isdatetime(t)
```

Description

`tf = isdatetime(t)` returns logical `1` (`true`) if `t` is a datetime array. Otherwise, it returns logical `0` (`false`).

Examples

Determine if Array Contains Datetime Values

Define an array.

```
A = [datetime('now');datetime('tomorrow');'January 15, 2015']
```

```
A =

   23-Feb-2015 09:54:40
   24-Feb-2015 00:00:00
   15-Jan-2015 00:00:00
```

Determine if the array is a `datetime` array.

```
tf = isdatetime(A)
```

```
tf =

     1
```

Input Arguments

`t` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `t` can be any data type.

See Also

`datetime` | `iscalendarduration` | `isduration`

Introduced in R2014b

isdiag

Determine if matrix is diagonal

Syntax

```
tf = isdiag(A)
```

Description

`tf = isdiag(A)` returns logical `1` (`true`) if `A` is a diagonal matrix; otherwise, it returns logical `0` (`false`).

Examples

Test Diagonal Matrix

Create a 4-by-4 identity matrix.

```
I = eye(4)
```

```
I =

     1     0     0     0
     0     1     0     0
     0     0     1     0
     0     0     0     1
```

Test to see if the matrix is diagonal.

```
isdiag(I)
```

```
ans =

     1
```

The result is logical 1 (`true`) because all of the nonzero elements in `I` are on the main diagonal.

Test Banded Matrix

Create a matrix with nonzero elements on the main and first diagonals.

```
A = 3*eye(4) + diag([2 2 2],1)
```

```
A =

     3     2     0     0
     0     3     2     0
     0     0     3     2
     0     0     0     3
```

Test to see if the matrix is diagonal.

```
isdiag(A)
```

```
ans =

     0
```

The matrix is not diagonal since there are nonzero elements above the main diagonal.

Create a new matrix, `B`, from the main diagonal elements of `A`.

```
B = diag(diag(A));
```

Test to see if `B` is a diagonal matrix.

```
isdiag(B)
```

```
ans =

     1
```

The result is logical 1 (`true`) because there are no nonzero elements above or below the main diagonal of `B`.

Input Arguments

`A` — Input array

numeric array

Input array, specified as a numeric array. `isdiag` returns logical `0` (`false`) if `A` has more than two dimensions.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Diagonal Matrix

A matrix is diagonal if all elements above and below the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the 4-by-4 identity matrix,

$$I_4 = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

is a diagonal matrix. Diagonal matrices are typically, but not always, square.

Tips

- Use the `diag` function to produce diagonal matrices for which `isdiag` returns logical `1` (`true`).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `isdiag(A) == isbanded(A,0,0)`.

See Also

`diag` | `istril` | `istriu` | `tril` | `triu`

Introduced in R2014a

isdir

Determine whether input is folder

Syntax

```
tf = isdir('A')
```

Description

`tf = isdir('A')` returns logical `1` (`true`) if `A` is a folder. Otherwise, it returns logical `0` (`false`).

Examples

Run:

```
tf=isdir('myfiles/results')
```

MATLAB returns

```
tf =
 1
```

indicating that `myfiles/results` is a folder.

See Also

`dir` | `is*`

Introduced before R2006a

isdst

Determine daylight saving time elements

Syntax

```
tf = isdst(t)
```

Description

`tf = isdst(t)` returns an array the same size as `t` containing logical 1 (`true`) where the corresponding element of `t` is a datetime that occurs during Daylight Saving Time, and logical 0 (`false`) otherwise. `isdst` returns `false` for all elements when the `TimeZone` property of `t` is empty (`''`).

Examples

Determine If Datetime Occurs During Daylight Saving Time

```
t = datetime(2014,3,7:11,'TimeZone','America/New_York')
```

```
t =

   07-Mar-2014   08-Mar-2014   09-Mar-2014   10-Mar-2014   11-Mar-2014
```

```
tf = isdst(t)
```

```
tf =

     0     0     0     1     1
```

March 10 and March 11, 2014 in the `America/New_York` time zone occur during daylight saving time.

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

See Also

datetime Properties | `isweekend` | `tzoffset`

Introduced in R2014b

isduration

Determine if input is duration array

Syntax

```
tf = isduration(t)
```

Description

`tf = isduration(t)` returns logical `1` (`true`) if `t` is a `duration` array. Otherwise, it returns logical `0` (`false`).

Examples

Determine if Array Contains Duration Values

Determine if the output of an arithmetic calculation is a `duration` array.

Subtract a `datetime` array from another.

```
t1 = datetime(2014,03,16:17);
t2 = datetime(2014,03,20);
dt = t2 - t1
```

```
dt =

   96:00:00   72:00:00
```

Determine if the output is a `duration` array.

```
tf = isduration(dt)
```

```
tf =
```

1

Input Arguments

`t` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `t` can be any data type.

See Also

`duration` | `iscalendarduration` | `isdatetime`

Introduced in R2014b

isEdge

Class: TriRep

(Will be removed) Test if vertices are joined by edge

Note: `isEdge(TriRep)` will be removed in a future release. Use `isConnected(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
TF = isEdge(TR, V1, V2)
TF = isEdge(TR, EDGE)
```

Description

`TF = isEdge(TR, V1, V2)` returns an array of 1/0 (true/false) flags, where each entry `TF(i)` is true if `V1(i)`, `V2(i)` is an edge in the triangulation. `V1`, `V2` are column vectors representing the indices of the vertices in the mesh, that is, indices into the vertex coordinate arrays.

`TF = isEdge(TR, EDGE)` specifies the edge start and end indices in matrix format.

Input Arguments

`TR`	Triangulation representation.
`V1, V2`	Column vectors of mesh vertices.
`EDGE`	Matrix of size `n`-by-2 where `n` is the number of query edges.

Output Arguments

`TF`	Array of 1/0 (true/false) flags, where each entry `TF(i)` is true if `V1(i)`, `V2(i)` is an edge in the triangulation.

Examples

Example 1

Load a 2-D triangulation and use `TriRep` to query the presence of an edge between pairs of points.

```
load trimesh2d
trep = TriRep(tri, x,y);
```

Test if vertices 3 and 117 are connected by an edge

```
isEdge(trep, 3, 117)
```

Test if vertices 3 and 164 are connected by an edge

```
isEdge(trep, 3, 164)
```

Example 2

Direct query of a 3-D Delaunay triangulation created using `DelaunayTri`.

```
X = rand(10,3)
dt = DelaunayTri(X)
```

Test if vertices 2 and 7 are connected by an edge

```
isEdge(dt, 2, 7);
```

See Also

`triangulation` | `delaunayTriangulation`

isempty

Determine whether array is empty

Syntax

```
TF = isempty(A)
```

Description

`TF = isempty(A)` returns logical 1 (`true`) if `A` is an empty array and logical 0 (`false`) otherwise. An empty array has at least one dimension of size zero, for example, 0-by-0 or 0-by-5.

Examples

```
B = rand(2,2,2);
B(:,:,:) = [];

isempty(B)

ans = 1
```

See Also

`is*`

Introduced before R2006a

isempty (tscollection)

Determine whether `tscollection` object is empty

Syntax

```
isempty(tsc)
```

Description

`isempty(tsc)` returns a logical value for `tscollection` object `tsc`, as follows:

- `1` — When `tsc` contains neither `timeseries` members nor a time vector
- `0` — When `tsc` contains either `timeseries` members or a time vector

See Also

`timeseries` | `length (tscollection)` | `size (tscollection)` | `tscollection`

Introduced before R2006a

isequal

Determine array equality

Syntax

```
tf = isequal(A,B)
tf = isequal(A1,A2,...,An)
```

Description

`tf = isequal(A,B)` returns logical `1` (`true`) if `A` and `B` are the same size and their contents are of equal value; otherwise, it returns logical `0` (`false`). The test compares both real and imaginary parts of numeric arrays. `isequal` ignores the data type of the values in determining whether they are equal. For cell arrays, categorical arrays, tables, or structures, the function returns logical `1` (`true`) only when all elements and properties are equal. Undefined categorical elements, `NaN` (Not a Number), or `NaT` (Not a Time) values are considered to be unequal to other elements, as well as themselves.

`tf = isequal(A1,A2,...,An)` returns logical `1` (`true`) if all the inputs are numerically equal.

Examples

Compare Two Numeric Matrices

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
B = zeros(3,3);
tf = isequal(A,B)
```

```
tf =

     0
```

The function returns logical `0` (`false`) because the matrices differ by a very small amount and are not *exactly* equal.

Compare Two Structures

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)
```

```
tf =

     1
```

Even though the ordering of the fields in each structure is different, `isequal` treats them as the same because the values are equal.

Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value `true` to the double integer `1`.

```
isequal(true,1)
```

```
ans =

     1
```

Notice that `isequal` does not consider data type when it tests for equality.

Similarly, compare `'A'` to the ASCII-equivalent integer, `65`.

```
isequal('A',65)
```

```
ans =

     1
```

The result is logical `1` (`true`) since `double('A')` equals `65`.

Compare Vectors Containing NaN Values

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
A2 = [1 NaN NaN];
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequal(A1,A2,A3)
```

```
tf =

     0
```

The result is logical `0` (`false`) because `isequal` does not treat NaN values as equal to each other.

Compare Two Datetime Values

Determine if midnight on January 13, 2013 in Anchorage, Alaska is equal to 11 AM on the same date in Cairo.

```
t1 = datetime(2013,1,13,0,0,0,'TimeZone','America/Anchorage');
t2 = datetime(2013,1,13,11,0,0,'TimeZone','Africa/Cairo');
tf = isequal(t1,t2)
```

```
tf =

     1
```

Add 8 months to the date, and compare the datetime values for equality.

```
t1 = datetime(2013,9,13,0,0,0,'TimeZone','America/Anchorage');
t2 = datetime(2013,9,13,11,0,0,'TimeZone','Africa/Cairo');
tf = isequal(t1,t2)
```

```
tf =

     0
```

The datetime values are no longer equal since Cairo does not observe daylight saving time.

Input Arguments

`A,B` — Inputs to be compared

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of `A` and `B` do not have to match.

You can compare a categorical array to a cell array of strings of the same size, or a single categorical element to a single string.

You can compare a datetime array to a cell array of date strings or a single date string.

If inputs `A` and `B` are *both*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequal` returns logical `0` (`false`). This applies even when the objects have the same properties and their values match.

`A1,A2,...,An` — Series of inputs to be compared

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

You can compare a datetime array to a cell array of date strings or a single date string.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequal` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequal` returns logical `0` (`false`). This applies even when the objects have the same properties and their values match.

More About

Tips

- When comparing handle objects, use `==` to test whether objects have the same handle. Use `isequal` to determine if objects with different handles have equal property values.
- Use `isequaln` if you want to test for equality and treat `NaN` or `NaT` values as equal.

See Also

`eq` | `is*` | `isa*` | `isequaln` | `relational operators` | `strcmp`

Introduced before R2006a

isenum

Determine if variable is enumeration

Syntax

```
tf = isenum(e)
```

Description

`tf = isenum(e)` returns logical 1 (`true`) if `e` is an enumeration. Otherwise, it returns logical 0 (`false`). Empty enumeration objects return `true`.

If `e` is a heterogeneous array, `isenum` always returns `false`.

Examples

Test for Enumeration

Determine if a variable is an enumeration.

The `PPM` class defines enumerations for three levels:

```
classdef PPM < int32
   enumeration
      High (1000)
      Medium (100)
      Low (10)
   end
end
```

Create a variable representing a level. Use `isenum` to determine if the variable an enumeration:

```
currentLevel = PPM.High;
isenum(currentLevel)
```

```
ans =
```

1

Input Arguments

e — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as any MATLAB variable.

More About

- "Working with Enumerations"

See Also

`islogical` | `isnumeric` | `isobject` | `isstruct`

Introduced in R2015a

isequaln

Determine array equality, treating NaN values as equal

Syntax

```
tf = isequaln(A,B)
tf = isequaln(A1,A2,...,An)
```

Description

`tf = isequaln(A,B)` returns logical `1` (`true`) if `A` and `B` are the same size and their contents are of equal value; otherwise, it returns logical `0` (`false`). The test compares both real and imaginary parts of numeric arrays. `isequaln` ignores the data type of the values in determining whether they are equal. For cell arrays, categorical arrays, tables, or structures, the function returns logical `1` (`true`) only when all elements and properties are equal. Undefined categorical elements, `NaN` (Not a Number), or `NaT` (Not a Time) values are considered to be equal to other such values.

`tf = isequaln(A1,A2,...,An)` returns logical `1` (`true`) if all the inputs are numerically equal.

Examples

Compare Two Numeric Matrices

Create two numeric matrices and compare them for equality.

```
A = zeros(3,3)+1e-20;
B = zeros(3,3);
tf = isequaln(A,B)
```

```
tf =

     0
```

The function returns logical `0` (`false`) because the matrices differ by a very small amount and are not *exactly* equal.

Compare Two Structures

Create two structures and specify the fields in a different order.

```
A = struct('field1',0.005,'field2',2500);
B = struct('field2',2500,'field1',0.005);
```

Compare the structures for equality.

```
tf = isequaln(A,B)
```

```
tf =

     1
```

Even though the ordering of the fields in each structure is different, `isequaln` treats them as the same because the values are equal.

Comparing Numeric Values with Special Nonnumeric Values

Compare the logical value `true` to the double integer `1`.

```
isequaln(true,1)
```

```
ans =

     1
```

Notice that `isequaln` does not consider data type when it tests for equality.

Similarly, compare `'A'` to the ASCII-equivalent integer, `65`.

```
isequaln('A',65)
```

```
ans =

     1
```

The result is logical `1` (`true`) since `double('A')` equals `65`.

Compare Vectors Containing NaN Values

Create three vectors containing NaN values.

```
A1 = [1 NaN NaN];
A2 = [1 NaN NaN];
A3 = [1 NaN NaN];
```

Compare the vectors for equality.

```
tf = isequaln(A1,A2,A3)
```

```
tf =

     1
```

The result is logical `1` (`true`) because `isequaln` treats the NaN values as equal to each other.

Input Arguments

`A,B` — Inputs to be compared

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of `A` and `B` do not have to match.

You can compare a categorical array to a cell array of strings of the same size, or a single categorical element to a single string.

You can compare a datetime array to a cell array of date strings or a single date string.

If inputs `A` and `B` are *both*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Datetime arrays -- `isequal` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequaln` returns logical `0` (`false`). This applies even when the objects have the same properties and their values match.

`A1,A2,...,An` — Series of inputs to be compared

numeric arrays | categorical arrays | cell arrays | tables | structures | ...

Series of inputs to be compared, specified as numeric arrays, categorical arrays, cell arrays, tables, or structures. Also, you can specify the inputs as logical arrays, character arrays, datetime arrays, duration arrays, calendarDuration arrays, or objects. The numeric types of the inputs do not have to match.

You can compare categorical arrays to cell arrays of strings of the same size, or single categorical elements to single strings.

You can compare a datetime array to a cell array of date strings or a single date string.

If the inputs are *all*

- Structures -- Fields need not be in the same order as long as the contents are equal.
- Ordinal categorical arrays -- Must have the same sets of categories, including their order.
- Categorical arrays that are not ordinal -- Can have different sets of categories, and `isequaln` compares the category names of each pair of elements.
- Datetime arrays -- `isequaln` ignores time zone and display format when it compares points in time.
- Objects of different classes -- `isequaln` returns logical `0` (`false`). This applies even when the objects have the same properties and their values match.

More About

Tips

- When comparing handle objects, use == to test whether objects have the same handle. Use `isequaln` to treat NaN values as equal and determine if objects with different handles have equal property values.
- Use `isequal` if you want to test for equality and treat `NaN` or `NaT` values as unequal.

See Also

`eq` | `is*` | `isa*` | `isequal` | `relational operators` | `strcmp`

isequalwithequalnans

Test arrays for equality, treating NaNs as equal

Note: `isequalwithequalnans` is not recommended. Use `isequaln` instead.

Syntax

```
tf = isequalwithequalnans(A, B, ...)
```

Description

`tf = isequalwithequalnans(A, B, ...)` returns logical `1` (`true`) if the input arrays are the same type and size and hold the same contents, and logical `0` (`false`) otherwise. `NaN` (Not a Number) values are considered to be equal to each other. Numeric data types and structure field order do not have to match.

Examples

Arrays containing `NaN`s are handled differently by `isequal` and `isequalwithequalnans`. `isequal` does not consider `NaN`s to be equal, while `isequalwithequalnans` does.

```
A = [32 8 -29 NaN 0 5.7];
B = A;
isequal(A, B)
ans =
     0

isequalwithequalnans(A, B)
ans =
     1
```

The position of `NaN` elements in the array does matter. If they are not in the same position in the arrays being compared, then `isequalwithequalnans` returns zero.

```
A = [2 4 6 NaN 8];   B = [2 4 NaN 6 8];
isequalwithequalnans(A, B)
ans =
     0
```

More About

Tips

`isequalwithequalnans` is the same as `isequal`, except `isequalwithequalnans` considers `NaN` (Not a Number) values to be equal, and `isequal` does not.

`isequalwithequalnans` recursively compares the contents of cell arrays and structures. If all the elements of a cell array or structure are numerically equal, `isequalwithequalnans` returns logical `1`.

See Also

`isequal` | `strcmp` | `isa` | `is*` | `relational operators` | `isequaln`

Introduced before R2006a

isevent

Determine whether input is COM object event

Syntax

```
tf = isevent(h,'eventname')
```

Description

`tf = isevent(h,'eventname')` returns logical `1` (`true`) if `eventname` is an event recognized by COM object `h`. Otherwise, returns logical `0` (`false`). The `eventname` argument is not case-sensitive.

COM functions are available on Microsoft Windows systems only.

Examples

This example tests events in a MATLAB sample control object.

1. Create an instance of the `mwsamp` control and test `DblClick`.

   ```
   f = figure('position',[100 200 200 200]);
   h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
   isevent(h,'DblClick')
   ```

   MATLAB displays `true`, indicating `DblClick` is an event.

2. Try the same test on`Redraw`.

   ```
   isevent(h,'Redraw')
   ```

   MATLAB displays `false`, indicating `Redraw` is not an event; it is a method.

Test events in a Microsoft Excel workbook object.

1. Create a `Workbook` object `wb`

   ```
   myApp = actxserver('Excel.Application');
   ```

```
wbs = myApp.Workbooks;
wb = Add(wbs);
```

2 Test `Activate`.

```
isevent(wb,'Activate')
```

MATLAB displays `true`, indicating `Activate` is an event.

3 Test `Save`

```
isevent(wb,'Save')
```

MATLAB displays `false`, indicating `Save` is not an event; it is a method.

`events (COM)` | `eventlisteners` | `registerevent`

Introduced before R2006a

isfield

Determine whether input is structure array field

Syntax

```
tf = isfield(S, 'fieldname')
tf = isfield(S, C)
```

Description

`tf = isfield(S, 'fieldname')` examines structure `S` to see if it includes the field specified by the quoted string `'fieldname'`. Output `tf` is set to logical `1` (`true`) if `S` contains the field, or logical `0` (`false`) if not. If `S` is not a structure array, `isfield` returns `false`.

`tf = isfield(S, C)` examines structure `S` for multiple fieldnames as specified in cell array of strings `C`, and returns an array of logical values to indicate which of these fields are part of the structure. Elements of output array `tf` are set to a logical 1 (`true`) if the corresponding element of `C` holds a fieldname that belongs to structure `S`. Otherwise, logical 0 (`false`) is returned in that element. In other words, if structure `S` contains the field specified in `C{m,n}`, `isfield` returns a logical 1 (`true`) in `tf(m,n)`.

Note `isfield` returns `false` if the `field` or `fieldnames` input is empty.

Examples

Example 1 — Single Fieldname Syntax

Given the following MATLAB structure,

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

`isfield` identifies `billing` as a field of that structure.

```
isfield(patient,'billing')
ans =
     1
```

Example 2 — Multiple Fieldname Syntax

Check structure `S` for any of four possible fieldnames. Only the first is found, so the first element of the return value is set to `true`:

```
S = struct('one', 1, 'two', 2);

fields = isfield(S, {'two', 'pi', 'One', 3.14})
fields =
     1     0     0     0
```

More About

- dynamic field names

See Also

`fieldnames` | `setfield` | `getfield` | `orderfields` | `rmfield` | `struct` | `isstruct` | `iscell` | `isa` | `is*`

Introduced before R2006a

isfinite

Array elements that are finite

Syntax

```
TF = isfinite(A)
```

Description

`TF = isfinite(A)` returns an array the same size as `A` containing logical 1 (`true`) where the elements of the array `A` are finite and logical 0 (`false`) where they are infinite or `NaN`. For a complex number `z`, `isfinite(z)` returns `1` if both the real and imaginary parts of `z` are finite, and `0` if either the real or the imaginary part is infinite or `NaN`.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

Examples

```
a = [-2  -1  0  1  2];
isfinite(1./a)
ans =
     1     1     0     1     1
isfinite(0./a)
ans =
     1     1     0     1     1
```

See Also

`isinf` | `isnan` | `is*`

Introduced before R2006a

isfloat

Determine if input is floating-point array

Syntax

```
tf = isfloat(A)
```

Description

`tf = isfloat(A)` returns `true` if `A` is a floating-point array and `false` otherwise. The floating-point types are `single` and `double`, and subclasses of `single` and `double`.

Examples

These examples show the values `isfloat` returns when passed specific types:

```
% pi returns a floating-point value
isfloat(pi)
ans =
     1
% Complex numbers are floating-point values
isfloat(3+7i)
ans =
     1
% Single-precision numbers are floating-point values
isfloat(realmax('single'))
ans =
     1
% isfloat returns a logical value
isfloat(isfloat(pi))
ans =
     0
```

See Also

`isa` | `isinteger` | `double` | `single` | `isnumeric`

Introduced before R2006a

isglobal

(To be removed) Determine if input is global variable

Note `isglobal` has been removed. Avoid conditions in your code that check variable scope. If you need to convert your code quickly in the short term, replace `isglobal` with `~isempty(whos('global','variable'))`. However, you should refactor your code to avoid conditional checks on variable scope.

Syntax

```
tf = isglobal(A)
```

Description

`tf = isglobal(A)` returns logical `1` (`true`) if `A` has been declared to be a global variable in the context from which `isglobal` is called, and logical `0` (`false`) otherwise.

More About

Tips

`isglobal` is most commonly used in conjunction with conditional global declaration. An alternate approach is to use a pair of variables, one local and one declared global.

Instead of using

```
if condition
   global x
end

x = some_value

if isglobal(x)
```

```
   do_something
end
```

You can use

```
global gx
if condition
   gx = some_value
else
   x = some_value
end

if condition
   do_something
end
```

If no other workaround is possible, you can replace the command

```
isglobal(variable)
```

with

```
~isempty(whos('global','variable'))
```

See Also

`global` | `isvarname` | `isa` | `is*`

Introduced before R2006a

isgraphics

True for valid graphics object handles

Syntax

```
tf = isgraphics(H)
tf = isgraphics(H,type)
```

Description

`tf = isgraphics(H)` returns `true` for elements of `H` that are valid graphics object and `false` where elements are not valid graphics objects.

`tf = isgraphics(H,type)` returns `true` for elements of `H` that are valid graphics objects of the type specified by the `type` argument. An object type is the string contained in the object's `Type` property.

Examples

Test for Valid Handles

Create a plot and return the handle array. Test array for valid handles

```
H = plot(rand(5));
isgraphics(H)
```

```
ans =

     1
     1
     1
     1
     1
```

Test for Handle Types

Create a plot and return the handle array. Concatenate with other graphics objects and test for handles that are of type line.

```
H = plot(rand(5));
a = [H;gca;gcf];
isgraphics(a,'line')
```

```
ans =

     1
     1
     1
     1
     1
     0
     0
```

Input Arguments

`H` — Input variable or expression

graphics object array

Input variable or expression that evaluates to graphics object handles.

`type` — The object type

char

The object type, specified as a quoted string. An object's type is contained in its `Type` property.

Output Arguments

`tf` — true or false

logical array

Logical array of `1`s and `0`s indicating the elements of the input array that are valid object handles or valid handles of a specific type if you specify a type argument.

More About

- “Graphics Object Handles”

See Also

Functions

`isa` | `ishghandle`

ishandle

Test for valid graphics or Java object handle

Syntax

```
ishandle(H)
```

Description

`ishandle(H)` returns an array whose elements are `1` where the elements of `H` are graphics or Java object handles, and `0` where they are not.

Note: Use the most specific function for your application instead of `ishandle`, as described in the following sections.

MATLAB Handle Objects

Use the `isa` function to determine the class of MATLAB objects.

Use the `handle` class `isvalid` method to determine the validity of handle objects. See "Testing Handle Validity" for information on testing for MATLAB handle objects.

Graphics Object Handles

Use `isgraphics` for graphics objects.

Java Object Handles

Use `isjava` for Java objects.

See Also

`isa` | `isjava` | `isgraphics`

Introduced before R2006a

ishermitian

Determine if matrix is Hermitian or skew-Hermitian

Syntax

```
tf = ishermitian(A)
tf = ishermitian(A,skewOption)
```

Description

`tf = ishermitian(A)` returns logical `1` (`true`) if square matrix `A` is Hermitian; otherwise, it returns logical `0` (`false`).

`tf = ishermitian(A,skewOption)` specifies the type of the test. Specify `skewOption` as `'skew'` to determine if `A` is skew-Hermitian.

Examples

Test if Symmetric Matrix Is Hermitian

Create a 3-by-3 matrix.

```
A = [1 0 1i; 0 1 0; 1i 0 1]
```

```
A =

   1.0000 + 0.0000i   0.0000 + 0.0000i   0.0000 + 1.0000i
   0.0000 + 0.0000i   1.0000 + 0.0000i   0.0000 + 0.0000i
   0.0000 + 1.0000i   0.0000 + 0.0000i   1.0000 + 0.0000i
```

The matrix is symmetric with respect to its real-valued diagonal.

Test whether the matrix is Hermitian.

```
tf = ishermitian(A)
```

```
tf =

     0
```

The result is logical `0` (`false`) because `A` is not Hermitian. In this case, `A` is equal to its transpose, `A.'`, but not its complex conjugate transpose, `A'`.

Change the element in `A(3,1)` to be `-1i`.

```
A(3,1) = -1i;
```

Determine if the modified matrix is Hermitian.

```
tf = ishermitian(A)
```

```
tf =

     1
```

The matrix, `A`, is now Hermitian because it is equal to its complex conjugate transpose, `A'`.

Test if Matrix Is Skew-Hermitian

Create a 3-by-3 matrix.

```
A = [-1i -1 1-i;1 -1i -1;-1-i 1 -1i]
```

```
A =

   0.0000 - 1.0000i  -1.0000 + 0.0000i   1.0000 - 1.0000i
   1.0000 + 0.0000i   0.0000 - 1.0000i  -1.0000 + 0.0000i
  -1.0000 - 1.0000i   1.0000 + 0.0000i   0.0000 - 1.0000i
```

The matrix has pure imaginary numbers on the main diagonal.

Specify `skewOption` as `'skew'` to determine whether the matrix is skew-Hermitian.

```
tf = ishermitian(A,'skew')
```

```
tf =

     1
```

The matrix, `A`, is skew-Hermitian since it is equal to the negation of its complex conjugate transpose, `-A'`.

Input Arguments

`A` — Input matrix

numeric matrix

Input matrix, specified as a numeric matrix. If `A` is not square, then `ishermitian` returns logical `0` (`false`).

Data Types: `single` | `double`
Complex Number Support: Yes

`skewOption` — Test type

`'nonskew'` (default) | `'skew'`

Test type, specified as `'nonskew'` (default) or `'skew'`. Specify `'skew'` to test whether `A` is skew-Hermitian. Specifying `ishermitian(A,'nonskew')` is equivalent to `ishermitian(A)`.

Data Types: `char`

More About

Hermitian Matrix

- A square matrix, `A`, is Hermitian if it is equal to its complex conjugate transpose, `A = A'`.

  In terms of the matrix elements, this means that

  $$a_{i,j} = \overline{a}_{j,i} .$$

- The entries on the diagonal of a Hermitian matrix are always real. Since real matrices are unaffected by complex conjugation, a real matrix that is symmetric is also Hermitian. For example, the matrix

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

is both symmetric and Hermitian.

- The eigenvalues of a Hermitian matrix are real.

Skew-Hermitian Matrix

- A square matrix, `A`, is skew-Hermitian if it is equal to the negation of its complex conjugate transpose, `A = -A'`.

  In terms of the matrix elements, this means that

  $a_{i,j} = -\overline{a}_{j,i}$.

- The entries on the diagonal of a skew-Hermitian matrix are always pure imaginary or zero. Since real matrices are unaffected by complex conjugation, a real matrix that is skew-symmetric is also skew-Hermitian. For example, the matrix

  $$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

  is both skew-Hermitian and skew-symmetric.
- The eigenvalues of a skew-Hermitian matrix are purely imaginary or zero.

`ctranspose` | `eig` | `isreal` | `issymmetric` | `transpose`

Introduced in R2014a

ishghandle

True for graphics object handles

Syntax

```
ishghandle(h)
```

Description

`ishghandle(h)` returns an array that contains 1's where the elements of `h` are handles to existing graphic objects and 0's where they are not. Differs from `ishandle` in that Simulink objects handles return false.

Examples

Create a plot and find the valid handles:

```
x = [1:10];
y = [1:10];
p = plot(x,y);
ishghandle(p)
```

```
ans =

     1
```

More About

- “Graphics Object Handles”

See Also

`isa` | `isgraphics` | `gca`

ishold

Current hold state

Syntax

```
tf = ishold
```

Description

`tf = ishold` returns `1` if `hold` is `on`, and `0` if it is `off`. When `hold` is `on`, the current plot and most axis properties are held so that subsequent graphing commands add to the existing graph.

A state of `hold on` implies that both figure and axes `NextPlot` properties are set to `add`.

More About

- "Control Graph Display"

See Also

`hold` | `newplot`

Introduced before R2006a

isinf

Array elements that are infinite

Syntax

```
TF = isinf(A)
```

Description

`TF = isinf(A)` returns an array the same size as `A` containing logical 1 (`true`) where the elements of `A` are `+Inf` or `-Inf` and logical 0 (`false`) where they are not. For a complex number `z`, `isinf(z)` returns `1` if either the real or imaginary part of `z` is infinite, and `0` if both the real and imaginary parts are finite or `NaN`.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

Examples

```
a = [-2  -1  0  1  2];

isinf(1./a)

ans =
     0     0     1     0     0

isinf(0./a)

ans =
     0     0     0     0     0
```

See Also

`isfinite` | `isnan` | `is*`

Introduced before R2006a

isinteger

Determine if input is integer array

Syntax

```
tf = isinteger(A)
```

Description

`tf = isinteger(A)` returns `true` if the array `A` is an integer type and `false` otherwise.

An integer array is any of the following integer types and any subclasses of those types:

MATLAB Integer Types

`int8`	8-bit signed integer array
`uint8`	8-bit unsigned integer array
`int16`	16-bit signed integer array
`uint16`	16-bit unsigned integer array
`int32`	32-bit signed integer array
`uint32`	32-bit unsigned integer array
`int64`	64-bit signed integer array
`uint64`	64-bit unsigned integer array

Examples

These examples show the values `isinteger` returns when passed specific types:

```
% uint8 is one of the integer types
isinteger(uint8(1:255))
ans =
     1
```

```
% pi returns a double-precision value
isinteger(pi)
ans =
     0
% Constants are double-precision by default
isinteger(3)
ans =
     0
% isinteger returns a logical value
isinteger(isinteger(uint8(3)))
ans =
     0
```

See Also

isa | isnumeric | isfloat

Introduced before R2006a

isinterface

Determine whether input is COM interface

Syntax

```
tf = isinterface(h)
```

Description

`tf = isinterface(h)` returns logical `1` (`true`) if handle `h` is a COM interface. Otherwise, returns logical `0` (`false`).

COM functions are available on Microsoft Windows systems only.

Examples

Test an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
isinterface(h)
```

MATLAB displays `false`, indicating object `h` is not an interface.

Test a `workbooks` object

```
w = get(h,'workbooks');
isinterface(w)
```

MATLAB displays `true`, indicating object `w` is an interface.

More About

- “Exploring Interfaces”

See Also

`iscom` | `interfaces`

isjava

Determine if input is Java object

Syntax

```
tf = isjava(A)
```

Description

`tf = isjava(A)` returns logical `1` (`true`) if object A is a Java object. Otherwise, it returns logical `0` (`false`).

Examples

Test if java.util.Date Is Java Object

Create an instance of the Java Date class.

```
myDate = java.util.Date;
isjava(myDate)
```

```
ans =

     1
```

`myDate` is a Java object.

However, `myDate` is not a MATLAB object.

```
isobject(myDate)
```

```
ans =

     0
```

See Also

`is*` | `isa` | `isobject` | `javaArray` | `javaMethod` | `javaObject`

Introduced before R2006a

isKey

Class: containers.Map
Package: containers

Determine if `containers.Map` object contains key

Syntax

```
tf = isKey(mapObj,keySet)
```

Description

`tf = isKey(mapObj,keySet)` looks for the specified keys in `mapObj`, and returns logical `true` (`1`) for the keys that it finds, and logical `false` (`0`) for those it does not. `keySet` is a scalar key or a cell array of keys.

Input Arguments

`mapObj`

Object of class `containers.Map`.

`keySet`

Scalar value, string, or cell array that specifies keys to find in `mapObj`.

Output Arguments

`tf`

Array of logical values. If `keySet` is a scalar or a string, `tf` is a scalar. Otherwise, `tf` has the same size and dimensions as `keySet`.

Examples

Find Keys in a Map

Construct a map that contains rainfall data for several months:

```
months =   {'Jan', 'Feb', 'Mar', 'Apr'};
rainfall = [327.2, 368.2, 197.6, 178.4];
mapObj = containers.Map(months,rainfall);
```

Determine if keys `Apr`, `May`, and `Jun` are in the map:

```
keySet = {'Apr','May','Jun'};
tf = isKey(mapObj,keySet)
```

This code returns 1-by-3 vector `tf`:

```
tf =
     1     0     0
```

Find a Single Key

Determine if `mapObj` from the previous example contains key `Feb`:

```
keySet = 'Feb';
tf = isKey(mapObj,keySet)
```

This code returns scalar `tf`:

```
tf =
     1
```

See Also

`keys` | `values` | `containers.Map` | `remove`

iskeyword

Determine whether input is MATLAB keyword

Syntax

```
tf = iskeyword('str')
iskeyword str
iskeyword
```

Description

`tf = iskeyword('str')` returns logical `1` (`true`) if the string `str` is a keyword in the MATLAB language and logical `0` (`false`) otherwise. MATLAB keywords cannot be used as variable names.

`iskeyword str` uses the MATLAB command format.

`iskeyword` returns a list of all MATLAB keywords.

Examples

To test if the word `while` is a MATLAB keyword,

```
iskeyword while
ans =
    1
```

To obtain a list of all MATLAB keywords,

```
iskeyword
    'break'
    'case'
    'catch'
    'classdef'
    'continue'
    'else'
    'elseif'
```

```
'end'
'for'
'function'
'global'
'if'
'otherwise'
'parfor'
'persistent'
'return'
'spmd'
'switch'
'try'
'while'
```

See Also

`isvarname` | `matlab.lang.makeValidName` | `matlab.lang.makeUniqueStrings` | `is*`

Introduced before R2006a

isletter

Array elements that are alphabetic letters

Syntax

```
tf = isletter('str')
```

Description

`tf = isletter('str')` returns an array the same size as `str` containing logical `1` (`true`) where the elements of `str` are letters of the alphabet and logical `0` (`false`) where they are not.

Examples

Find the letters in character array `s`.

```
s = 'A1,B2,C3';

isletter(s)
ans =
     1     0     0     1     0     0     1     0
```

See Also

`ischar` | `isspace` | `isstrprop` | `iscellstr` | `isnumeric` | `char` | `strings` | `isa` | `is*`

Introduced before R2006a

islogical

Determine if input is logical array

Syntax

```
tf = islogical(A)
```

Description

`tf = islogical(A)` returns `true` if `A` is a logical array and `false` otherwise. `islogical` also returns `true` if `A` is an instance of a class that is derived from the `logical` class.

Examples

These examples show the values `islogical` returns when passed specific types:

```
% Relational operators return logical values
islogical(5<7)
ans =
     1

% true and false return logical values
islogical(true) & islogical(false)
ans =
     1

% Constants are double-precision by default
islogical(1)
ans =
     0

% logical creates logical values
islogical(logical(1))
ans =
     1
```

More About

- "Determine if Arrays Are Logical"

See Also

`is*` | `isa` | `logical`

Introduced before R2006a

ismac

Determine if version is for Mac OS X platform

Syntax

```
tf = ismac
```

Description

`tf = ismac` returns logical `1` (`true`) if the version of MATLAB software is for the Apple Mac OS X platform. Otherwise, it returns logical `0` (`false`).

More About

Tips

- The `isunix` function also determines if version is for Mac OS X platforms.

See Also

`computer` | `is*` | `ispc` | `isstudent` | `isunix`

ismatrix

Determine whether input is matrix

Syntax

```
ismatrix(V)
```

Description

`ismatrix(V)` returns logical 1 (`true`) if `size`(V) returns `[m n]` with nonnegative integer values `m` and `n`, and logical 0 (`false`) otherwise.

Examples

Create three vectors:

```
V1 = rand(5,1);
V2 = rand(5,1);
V3 = rand(5,1);
```

Concatenate the vectors and check that the result is a matrix. `ismatrix` returns 1:

```
M = cat(2,V1,V2,V3);
ismatrix(M)
ans =
     1
```

See Also

`iscolumn` | `isrow` | `isscalar` | `isvector`

ismember

Array elements that are members of set array

Syntax

```
Lia = ismember(A,B)
Lia = ismember(A,B,'rows')
[Lia,Locb] = ismember(A,B)
[Lia,Locb] = ismember(A,B,'rows')

[Lia,Locb] = ismember( ___ ,'legacy')
```

Description

`Lia = ismember(A,B)` returns an array containing `1` (`true`) where the data in `A` is found in `B`. Elsewhere, it returns `0` (`false`).

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `ismember` returns a logical value for each element of `A`. The output, `Lia`, is an array of the same size as `A`.
- If `A` and `B` are tables, then `ismember` returns a logical value for each row of `A`. The output, `Lia`, is a column vector with the same number of rows as `A`.

`Lia = ismember(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns a column vector containing `1` (`true`) where the rows of `A` are also rows of `B`. Elsewhere, it returns `0` (`false`).

`A` and `B` must have the same number of columns when you use the `'rows'` option. Furthermore, the `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[Lia,Locb] = ismember(A,B)` also returns an array, `Locb`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `Locb` contains the lowest index in `B` for each value in `A` that is a member of `B`. The output array, `Locb`, contains `0` wherever `A` is not a member of `B`.

- If `A` and `B` are tables, then `Locb` contains the lowest index in `B` for each row in `A` that is also a row in `B`. The output vector, `Locb`, contains `0` whenever `A` is not a row of `B`.

`[Lia,Locb] = ismember(A,B,'rows')` also returns a column vector, `Locb`, containing the lowest index in `B` for each row in `A` that is also a row in `B`. The output vector, `Locb`, contains `0` wherever `A` is not a row of `B`.

`[Lia,Locb] = ismember( ___ ,'legacy')` preserves the behavior of the `ismember` function from R2012b and prior releases using any of the input arguments in previous syntaxes.

The `'legacy'` option does not support categorical arrays, tables, datetime arrays, or duration arrays.

Examples

Values That Are Members of Set

Create two vectors with values in common.

```
A = [5 3 4 2];
B = [2 4 4 4 6 8];
```

Determine which elements of `A` are also in `B`.

```
Lia = ismember(A,B)
```

```
Lia =

     0     0     1     1
```

`A(3)` and `A(4)` are found in `B`.

Table Rows Found in Another Table

Create two tables with rows in common.

```
A = table([1:5]',['A';'B';'C';'D';'E'],logical([0;1;0;1;0]))
B = table([1:2:10]',['A';'C';'E';'G';'I'],logical(zeros(5,1)))
```

```
A =

    Var1    Var2    Var3
    ____    ____    _____

    1       A       false
    2       B       true
    3       C       false
    4       D       true
    5       E       false

B =

    Var1    Var2    Var3
    ____    ____    _____

    1       A       false
    3       C       false
    5       E       false
    7       G       false
    9       I       false
```

Determine which rows of `A` are also in `B`.

```
Lia = ismember(A,B)
```

```
Lia =

     1
     0
     1
     0
     1
```

`A(1,:)`, `A(3,:)`, and `A(5,:)` are found in `B`.

Members of Set and Indices to Values

Create two vectors with values in common.

```
A = [5 3 4 2];
B = [2 4 4 4 6 8];
```

Determine which elements of A are also in B as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =

     0     0     1     1

Locb =

     0     0     2     1
```

The lowest index to `A(3)` is `B(2)`, and `A(4)` is found in `B(1)`.

Rows of Another Table and Their Location

Create a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =

              Gender    Age    Height
              ______    ___    ______

    Ted       M         27     74
    Fred      M         52     68
    Betty     F         31     64
    Bob       M         46     61
    Judy      F         35     64
```

Create another table, B, with rows in common with A.

```
B = table(['M';'F';'F';'F'],[47;31;35;23],[68;64;62;58],...
```

```
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Joe' 'Meg' 'Beth' 'Amy'})

B =

            Gender    Age    Height
            ______    ___    ______

    Joe     M         47     68
    Meg     F         31     64
    Beth    F         35     62
    Amy     F         23     58
```

Determine which rows of `A` are also in `B`, as well as their corresponding locations in `B`.

```
[Lia,Locb] = ismember(A,B)

Lia =

     0
     0
     1
     0
     0

Locb =

     0
     0
     2
     0
     0
```

Two rows that have the same values, but different names, are considered equal. The same data for `Betty` is found in `B(2,:)`, which corresponds to `Meg`.

Rows That Belong to a Set

Create two matrices with a row in common.

```
A = [1 3 5 6; 2 4 6 8];
B = [2 4 6 8; 1 3 5 7; 2 4 6 8];
```

Determine which rows of A are also in B as well as their corresponding locations in B.

```
[Lia, Locb] = ismember(A,B, 'rows')
```

```
Lia =

     0
     1

Locb =

     0
     1
```

The lowest index to `A(2,:)` is `B(1,:)`.

Members of Set Containing NaN Values

Create two vectors containing NaN.

```
A = [5 NaN NaN];
B = [5 NaN NaN];
```

Determine which elements of A are also in B, as well as their corresponding locations in B.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =

     1     0     0

Locb =

     1     0     0
```

`ismember` treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, `A`.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, `B`, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Determine which strings of `A` are also in `B`.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =

     0     1     0     1

Locb =

     0     2     0     4
```

`ismember` treats trailing white space in cell arrays of strings as distinct characters.

Members of Char and Cell Array of Strings

Create a character array, `A`, and a cell array of strings, `B`.

```
A = ['cat';'dog';'fox';'pig'];
B = {'dog','cat','fish','horse'};
```

Determine which strings of `A` are also in `B`.

```
[Lia,Locb] = ismember(A,B)
```

```
Lia =

     1
     1
     0
```

```
     0

Locb =

     2
     1
     0
     0
```

Preserve Legacy Behavior of ismember

Use the `'legacy'` flag to preserve the behavior of `ismember` from R2012b and prior releases in your code.

Find the members of `B` with the current behavior.

```
A = [5 3 4 2];
B = [2 4 4 4 6 8];
[Lia1,Locb1] = ismember(A,B)
```

```
Lia1 =

     0     0     1     1

Locb1 =

     0     0     2     1
```

Find the members of `B`, and preserve the legacy behavior.

```
[Lia2,Locb2] = ismember(A,B,'legacy')
```

```
Lia2 =

     0     0     1     1

Locb2 =
```

```
     0     0     4     1
```

Input Arguments

A — Query array

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Query array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or a table.

`A` must belong to the same class as `B` with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the `'rows'` option, `A` must have the same number of columns as `B`.

If `A` is a table, it must have the same variable names as `B`. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If `A` and `B` are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, `A` can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

B — Set array

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Set array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or a table.

`B` must belong to the same class as `A` with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names.

If you specify the `'rows'` option, `B` must have the same number of columns as `A`.

If `B` is a table, it must have the same variable names as `A`. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If `A` and `B` are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, `B` can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

Output Arguments

Lia — Logical index to A

vector | matrix | N-D array

Logical index to `A`, returned as a vector, matrix or N-D array containing `1` (`true`) wherever the values (or rows) in `A` are members of `B`. Elsewhere, it returns `0` (`false`).

`Lia` is an array of the same size as `A`, unless you specify the `'rows'` flag.

If the `'rows'` flag is specified or if `A` is a table, `Lia` is a column vector with the same number of rows as `A`.

`Locb` — Locations in `B`

vector | matrix | N-D array

Locations in `B`, returned as a vector, matrix, or N-D array. If the `'legacy'` flag is not specified, `Locb` contains the lowest indices to the values (or rows) in `B` that are found in `A`. `Locb` contains `0` wherever `A` is not a member of `B`.

`Locb` is an array of the same size as `A` unless you specify the `'rows'` flag.

If the `'rows'` flag is specified or if `A` is a table, `Locb` is a column vector with the same number of rows as `A`.

More About

Tips

- To find the rows from table `A` that are found in `B` with respect to a subset of variables, you can use column subscripting. For example, you can use `ismember(A(:,vars),B(:,vars))`, where *`vars`* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

Introduced before R2006a

ismembertol

Set ismember within tolerance

`ismembertol` is similar to `ismember`. Whereas `ismember` performs exact comparisons, `ismembertol` performs comparisons using a tolerance.

Syntax

```
LIA = ismembertol(A,B,tol)
LIA = ismembertol(A,B)
[LIA,LocB] = ismembertol( ___ )
[ ___ ] = ismembertol( ___ ,Name,Value)
```

Description

`LIA = ismembertol(A,B,tol)` returns an array containing logical `1` (`true`) where the elements of `A` are within tolerance of the elements in `B`. Otherwise, the array contains logical `0` (`false`). Two values, `u` and `v`, are within tolerance if

```
abs(u-v) <= tol*max(abs([A(:);B(:)]))
```

That is, `ismembertol` scales the `tol` input based on the magnitude of the data.

`LIA = ismembertol(A,B)` uses a default tolerance of `1e-6` for single-precision inputs and `1e-12` for double-precision inputs.

`[LIA,LocB] = ismembertol( ___ )` also returns an array, `LocB`, that contains the index location in `B` for each element in `A` that is a member of `B`. You can use any of the input arguments in previous syntaxes.

`[ ___ ] = ismembertol( ___ ,Name,Value)` uses additional options specified by one or more Name-Value pair arguments using any of the input or output argument combinations in previous syntaxes. For example, `ismembertol(A,B,'ByRows',true)` compares the rows of `A` and `B` and returns a logical column vector.

Examples

Set Members in Presence of Numerical Error

Create a vector, `x`. Obtain a second vector, `y`, by transforming and untransforming `x`. This transformation introduces round-off differences to `y`.

```
x = (1:6)'*pi;
y = 10.^log10(x);
```

Verify that `x` and `y` are not identical by taking the difference.

```
x-y
```

```
ans =

   1.0e-14 *

    0.0444
         0
         0
         0
         0
   -0.3553
```

Use `ismember` to find the elements of `x` that are in `y`. The `ismember` function performs exact comparisons and determines that some of the matrix elements in `x` are not members of `y`.

```
lia = ismember(x,y)
```

```
lia =

     0
     1
     1
     1
     1
     0
```

Use `ismembertol` to perform the comparison using a small tolerance. `ismembertol` treats elements that are within tolerance as equal and determines that all of the elements in `x` are members of `y`.

```
LIA = ismembertol(x,y)
```

```
LIA =

     1
     1
     1
     1
     1
     1
```

Determine Set Members by Rows

By default, `ismembertol` looks for *elements* that are within tolerance, but it also can find *rows* of a matrix that are within tolerance.

Create a numeric matrix, `A`. Obtain a second matrix, `B`, by transforming and untransforming `A`. This transformation introduces round-off differences to `B`.

```
A = [0.05 0.11 0.18; 0.18 0.21 0.29; 0.34 0.36 0.41; ...
    0.46 0.52 0.76; 0.82 0.91 1.00];
B = log10(10.^A);
```

Use `ismember` to find the rows of `A` that are in `B`. `ismember` performs exact comparisons and thus determines that most of the rows in `A` are not members of `B`, even though some of the rows differ by only a small amount.

```
lia = ismember(A,B,'rows')
```

```
lia =

     0
     0
     0
     0
     1
```

Use `ismembertol` to perform the row comparison using a small tolerance. `ismembertol` treats rows that are within tolerance as equal and thus determines that all of the rows in `A` are members of `B`.

```
LIA = ismembertol(A,B,'ByRows',true)
```

```
LIA =

     1
     1
     1
     1
     1
```

Average Similar Values in Vectors

Create two vectors of random numbers and determine which values in `A` are also members of `B`, using a tolerance. Specify `OutputAllIndices` as `true` to return all of the indices for the elements in `B` that are within tolerance of the corresponding elements in `A`.

```
rng(5)
A = rand(1,15);
B = rand(1,5);
[LIA,LocAllB] = ismembertol(A,B,0.2,'OutputAllIndices',true)
```

```
LIA =

  Columns 1 through 13

     1     0     1     0     1     1     1     1     1     1     0     1     1

  Columns 14 through 15

     1     0

LocAllB =

  Columns 1 through 6
```

```
    [2x1 double]    [0]    [2x1 double]    [0]    [3x1 double]    [2x1 double]

  Columns 7 through 12

    [4]    [3x1 double]    [3x1 double]    [2x1 double]    [0]    [2x1 double]

  Columns 13 through 15

    [4x1 double]    [2x1 double]    [0]
```

Find the average value of the elements in `B` that are within tolerance of the value `A(13)`. The cell `LocAllB{13}` contains all the indices for elements in `B` that are within tolerance of `A(13)`.

```
A(13)
allB = B(LocAllB{13})
aveB = mean(allB)

ans =

    0.4413

allB =

    0.2741    0.4142    0.2961    0.5798

aveB =

    0.3911
```

Specify Absolute Tolerance

By default, `ismembertol` uses a tolerance test of the form `abs(u-v) <= tol*DS`, where `DS` automatically scales based on the magnitude of the input data. You can specify a different `DS` value to use with the `DataScale` option. However, absolute tolerances (where `DS` is a scalar) do not scale based on the magnitude of the input data.

First, compare two small values that are a distance `eps` apart. Specify `tol` and `DS` to make the within tolerance equation `abs(u-v) <= 10^-6`.

```
x = 0.1;
ismembertol(x, exp(log(x)), 10^-6, 'DataScale', 1)
```

```
ans =

     1
```

Next, increase the magnitude of the values. The round-off error in the calculation `exp(log(x))` is proportional to the magnitude of the values, specifically to `eps(x)`. Even though the two large values are a distance `eps` from one another, `eps(x)` is now much larger. Therefore, `10^-6` is no longer a suitable tolerance.

```
x = 10^10;
ismembertol(x, exp(log(x)), 10^-6, 'DataScale', 1)
```

```
ans =

     0
```

Correct this issue by using the default (scaled) value of `DS`.

```
Y = [0.1 10^10];
ismembertol(Y, exp(log(Y)))
```

```
ans =

     1     1
```

Specify DataScale by Column

Create a set of random 2-D points, and then use `ismembertol` to group the points into vertical bands that have a similar (within-tolerance) x-coordinate to a small set of query points, `B`. Use these options with `ismembertol`:

- Specify `ByRows` as `true`, since the point coordinates are in the rows of `A` and `B`.
- Specify `OutputAllIndices` as `true` to return the indices for all points in `A` that have an x-coordinate within tolerance of the query points in `B`.

- Specify DataScale as `[1 Inf]` to use an absolute tolerance for the x-coordinate, while ignoring the y-coordinate.

```
A = rand(1000,2);
B = [(0:.2:1)',0.5*ones(6,1)];
[LIA,LocAllB] = ismembertol(B, A, 0.1, 'ByRows', true, ...
    'OutputAllIndices', true, 'DataScale', [1,Inf])
```

```
LIA =

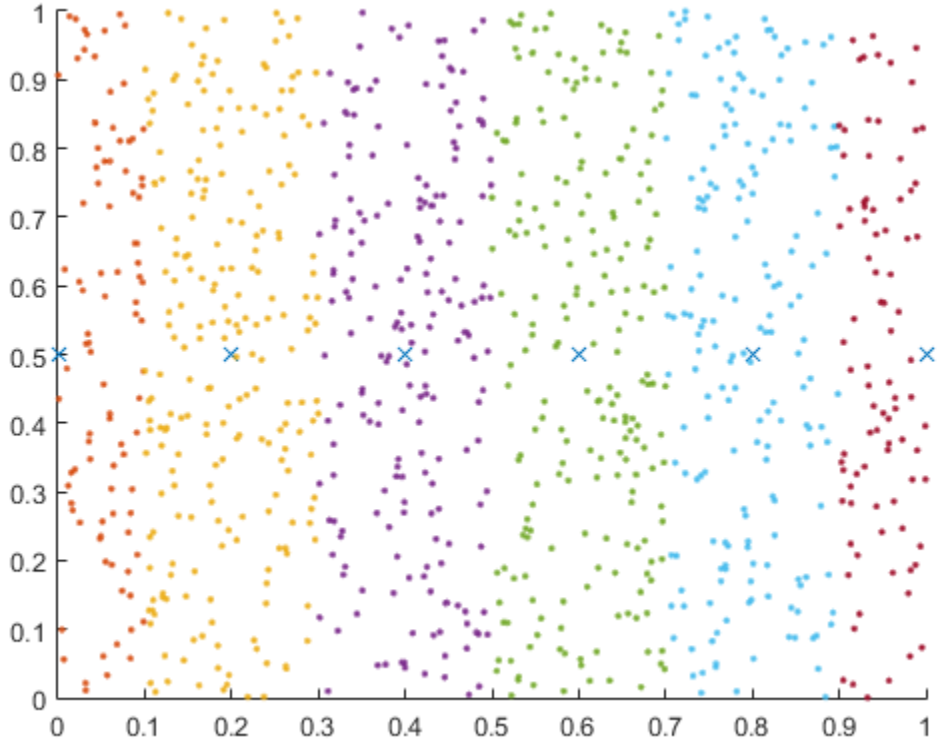
     1
     1
     1
     1
     1
     1

LocAllB =

    [ 94x1 double]
    [223x1 double]
    [195x1 double]
    [212x1 double]
    [187x1 double]
    [ 89x1 double]
```

Plot the points in A that are within tolerance of each query point in B.

```
hold on
plot(B(:,1),B(:,2),'x')
for i=1:length(LocAllB)
    plot(A(LocAllB{i},1), A(LocAllB{i},2),'.')
end
```



- “Group Scattered Data Using a Tolerance”

Input Arguments

A — Query array

scalar | vector | matrix

Query array, specified as a scalar, vector, or matrix. Inputs `A` and `B` must be full.

If you specify the `ByRows` option, then `A` and `B` must have the same number of columns.

Data Types: `single` | `double`

`B` — Query array

scalar | vector | matrix

Query array, specified as a scalar, vector, or matrix. Inputs `A` and `B` must be full.

If you specify the `ByRows` option, then `A` and `B` must have the same number of columns.

Data Types: `single` | `double`

`tol` — Comparison tolerance

positive real scalar

Comparison tolerance, specified as a positive real scalar. `ismembertol` scales the `tol` input using the maximum absolute values in the input arrays `A` and `B`. Then `ismembertol` uses the resulting scaled comparison tolerance to determine which elements in `A` are also a member of `B`. If two elements are within tolerance of each other, then `ismembertol` considers them to be equal.

Two values, `u` and `v`, are within tolerance if `abs(u-v) <= tol*max(abs([A(:);B(:)]))`.

To specify an absolute tolerance, specify both `tol` and the `'DataScale'` Name-Value pair.

Example: `tol = 0.05`

Example: `tol = 1e-8`

Example: `tol = eps`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `LIA = ismembertol(A,B,'ByRows',true)`

`'OutputAllIndices'` — Output index type

`false` (default) | `true` | `0` | `1`

Output index type, specified as the comma-separated pair consisting of `'OutputAllIndices'` and either `false` (default), `true`, `0`, or `1`. `ismembertol` interprets numeric `0` as `false` and numeric `1` as `true`.

When `OutputAllIndices` is `true`, the `ismembertol` function returns the second output, `LocB`, as a cell array. The cell array contains the indices for *all* elements in `B` that are within tolerance of the corresponding value in `A`. That is, each cell in `LocB` corresponds to a value in `A`, and the values in each cell correspond to locations in `B`.

Example: `[LIA,LocAllB] = ismembertol(A,B,tol,'OutputAllIndices',true)`

`'ByRows'` — Row comparison toggle

`false` (default) | `true` | `0` | `1`

Row comparison toggle, specified as the comma-separated pair consisting of `'ByRows'` and either `false` (default), `true`, `0`, or `1`. `ismembertol` interprets numeric `0` as `false` and numeric `1` as `true`. Use this option to find rows in `A` and `B` that are within tolerance.

When `ByRows` is `true`:

- `ismembertol` compares the rows of `A` and `B` by considering each column separately. Thus, `A` and `B` must have the same number of columns.
- If the corresponding row in `A` is within tolerance of a row in `B`, then `LIA` contains logical `1` (`true`). Otherwise, it contains logical `0` (`false`).

Two rows, `u` and `v`, are within tolerance if `abs(u-v) <= tol*max(abs([A;B]))`.

Example: `LIA = ismembertol(A,B,tol,'ByRows',true)`

`'DataScale'` — Scale of data

scalar | vector

Scale of data, specified as the comma-separated pair consisting of `'DataScale'` and either a scalar or vector. Specify `DataScale` as a numeric scalar, `DS`, to change the tolerance test to be, `abs(u-v) <= tol*DS`.

When used together with the `ByRows` option, the `DataScale` value also can be a vector. In this case, each element of the vector specifies `DS` for a corresponding column in `A`. If a value in the `DataScale` vector is `Inf`, then `ismembertol` ignores the corresponding column in `A`.

Example: `LIA = ismembertol(A,B,'DataScale',1)`

Example: `[LIA,LocB] = ismembertol(A,B,'ByRows',true,'DataScale', [eps(1) eps(10) eps(100)])`

Data Types: `single` | `double`

Output Arguments

`LIA` — Logical index to `A`

vector | matrix

Logical index to `A`, returned as a vector or matrix containing logical `1` (`true`) wherever the elements (or rows) in `A` are members of `B` (within tolerance). Elsewhere, `LIA` contains logical `0` (`false`).

`LIA` is the same size as `A`, unless you specify the `ByRows` option. In that case, `LIA` is a column vector with the same number of rows as `A`.

`LocB` — Locations in `B`

vector | matrix | cell array

Locations in `B`, returned as a vector, matrix, or cell array. `LocB` contains the indices to the elements (or rows) in `B` that are found in `A` (within tolerance). `LocB` contains `0` wherever an element in `A` is not a member of `B`.

If `OutputAllIndices` is `true`, then `ismembertol` returns `LocB` as a cell array. The cell array contains the indices for *all* elements in `B` that are within tolerance of the corresponding value in `A`. That is, each cell in `LocB` corresponds to a value in `A`, and the values in each cell correspond to locations in `B`.

`LocB` is the same size as `A`, unless you specify the `ByRows` option. In that case, `LocB` is a column vector with the same number of rows as `A`.

`eps` | `ismember` | `unique` | `uniquetol`

Introduced in R2015a

ismethod

Determine if method of object

Syntax

```
tf = ismethod(obj,'methodName')
```

Description

`tf = ismethod(obj,'methodName')` returns logical `1` (`true`) if the specified `methodName` is a public method of object `obj`. Otherwise, returns logical `0` (`false`).

Examples

Determine if objects support equality testing:

```
if ismethod(obj1,'eq') && ismethod(obj2,'eq')
   tf = obj1 == obj2;
end
```

See Also

`methods` | `class` | `isprop` | `isobject`

Introduced before R2006a

ismethod (COM)

Determine whether input is COM object method

Syntax

```
tf = ismethod(h,'methodname')
```

Description

`tf = ismethod(h,'methodname')` returns logical `1` (`true`) if the specified `methodname` is a method you can call on COM object `h`. Otherwise, returns logical `0` (`false`).

COM functions are available on Microsoft Windows systems only.

Examples

Test members of an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
ismethod(h,'SaveWorkspace')
```

MATLAB returns `true`, `SaveWorkspace` is a method.

Try the same test on `UsableWidth`.

```
ismethod(h,'UsableWidth')
```

MATLAB returns `false`, `UsableWidth` is not a method; it is a property.

ismissing

Find table elements with missing values

Syntax

```
TF = ismissing(A)
TF = ismissing(A,id)
```

Description

`TF = ismissing(A)` returns a logical array, `TF`, that indicates which elements in the table `A` contain a missing value. The size of `TF` is the same as the size of `A`.

Indicators for missing data depend on the data type:

- `NaN` for numeric arrays
- `<undefined>` for categorical arrays
- empty string, `{''}`, for cell arrays of strings
- blank string, `[' ']`, for character arrays

`ismissing` ignores other data types.

`TF = ismissing(A,id)` treats the values in id as missing value indicators. You must include `NaN` (for floating-point variables), the empty string (for variables that are cell arrays of strings or character arrays), or the string `'<undefined>'` (for categorical variables) to have `ismissing` recognize them as missing value indicators.

Examples

Missing Values in Table with Various Data Types

Create a table with variables of different data types where each contains a missing value.

```
dblVar = [NaN;3;5;7;9];
singleVar = single([1;NaN;5;7;9]);
cellstrVar = {'one';'three';'';'seven';'nine'};
```

```
charVar = ['A';'C';'E';' ';'I'];
categoryVar = categorical({'red';'yellow';'blue';'violet';''});

A = table(dblVar,singleVar,cellstrVar,charVar,categoryVar)
```

```
A =

    dblVar    singleVar    cellstrVar    charVar    categoryVar
    ______    _________    __________    _______    ___________

    NaN         1          'one'         A          red
      3       NaN          'three'       C          yellow
      5         5          ''            E          blue
      7         7          'seven'                  violet
      9         9          'nine'        I          <undefined>
```

Find the table elements with missing values.

```
TF = ismissing(A)
```

```
TF =

     1     0     0     0     0
     0     1     0     0     0
     0     0     1     0     0
     0     0     0     1     0
     0     0     0     0     1
```

The size of `TF` is the same as the size of `A`.

Specify Indicators for Missing Values in Table

Create a table where `'NA'`, `''`-`99`, `NaN`, and `Inf` represent missing values.

```
dblVar = [NaN;3;Inf;7;9];
int8Var = int8([1;3;5;7;-99]);
cellstrVar = {'one';'three';'';'NA';'nine'};
charVar = ['A';'C';'E';' ';'I'];

A = table(dblVar,int8Var,cellstrVar,charVar)
```

```
A =

    dblVar    int8Var    cellstrVar    charVar
    ______    _______    __________    _______
```

```
    NaN         1        'one'         A
      3         3        'three'       C
    Inf         5        ''            E
      7         7        'NA'
      9       -99        'nine'        I
```

Find the missing values in the table `A`.

```
id = {'NA' '' -99 NaN Inf};
TF = ismissing(A,id)
```

```
TF =

     1     0     0     0
     0     0     0     0
     1     0     1     0
     0     0     1     1
     0     1     0     0
```

`ismissing` recognizes data in the each variable of the table, `A` as missing values. `ismissing` ignores trailing white space in character arrays. Therefore, since the empty string, `''`, is specified as a missing value indicator, `ismissing` identifies the empty string in the cell arrays of strings, `A.cellstrVar`, as well as the blank space in character array, `A.charVar` as missing values.

Input Arguments

`A` — Input table

table

Input table, specified as a table.

`id` — Missing value indicators

numeric vector | string | cell array containing numeric values and strings

Missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings. Use strings to identify categories in categorical variables that you want to treat as missing values.

You must include `NaN` (for floating-point variables), the empty string (for variables that are cell arrays of strings or character arrays), or the string `'<undefined>'` (for categorical variables) to have `ismissing` recognize them as missing value indicators.

Example: `TF = ismissing(A,-99)` recognizes only `-99` as a missing value.

Data Types: `double` | `char` | `cell`

More About

Tips

- You can use `A(~any(TF,2),:)` to return only complete rows from `A` and `A(:,~any(TF,1))` to return only the variables from `A` with no missing values.
- Integer variables cannot store `NaN`; therefore, you must use a special integer value (otherwise unused) to indicate missing integer data. For example, `-99`.

Algorithms

`ismissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `ismissing` does not ignore white space. All strings must match exactly.
- For character arrays, `ismissing` ignores trailing white space. Therefore, when you specify the empty string, `''`, as a missing value indicator, `ismissing` identifies the empty string in cell arrays of strings, `''`, and the blank space in character arrays, `' '`, as missing values.
- For categorical arrays, `ismissing` ignores leading and trailing white space.

See Also

`isempty` | `isnan` | `isundefined` | `standardizeMissing` | `table`

isnan

Array elements that are NaN

Syntax

```
TF = isnan(A)
```

Description

`TF = isnan(A)` returns an array the same size as `A` containing logical 1 (`true`) where the elements of `A` are `NaN`s and logical 0 (`false`) where they are not. For a complex number `z`, `isnan(z)` returns `1` if either the real or imaginary part of `z` is `NaN`, and `0` if both the real and imaginary parts are finite or `Inf`.

For any real `A`, exactly one of the three quantities `isfinite(A)`, `isinf(A)`, and `isnan(A)` is equal to one.

Examples

```
A = [-2  -1  0  1  2];

isnan(1./A)
ans =
     0     0     0     0     0

isnan(0./A)
ans =
     0     0     1     0     0
```

See Also

`isfinite` | `nan` | `isinf` | `is*`

Introduced before R2006a

isnat

Determine NaT (Not-a-Time) elements

Syntax

```
tf = isnat(A)
```

Description

`tf = isnat(A)` returns an array the same size as the datetime array, `A`, containing logical 1 (`true`) where the elements of `A` are Not-a-Time (`NaT`s) and logical 0 (`false`) where they are not. `NaT` represents a datetime that is undefined.

Examples

Determine If Array Elements are NaT

Create a datetime array from numeric values containing `NaN`.

```
d = datetime(2014,[1 2 NaN 4],1)
```

```
d =

   01-Jan-2014   01-Feb-2014   NaT           01-Apr-2014
```

Determine if any elements of `d` are `NaT` (Not-a-Time).

```
isnat(d)
```

```
ans =

     0     0     1     0
```

Input Arguments

A — Input array

datetime array

Input array, specified as a datetime array.

See Also

`isfinite` | `isinf`

Introduced in R2014b

isnumeric

Determine if input is numeric array

Syntax

```
tf = isnumeric(A)
```

Description

`tf = isnumeric(A)` returns `true` if `A` is a numeric array and `false` otherwise.

A numeric array is any of the following numeric types and any subclasses of those types:

MATLAB Numeric Types

`single`	Single-precision floating-point array
`double`	Double-precision floating-point array
`int8`	8-bit signed integer array
`uint8`	8-bit unsigned integer array
`int16`	16-bit signed integer array
`uint16`	16-bit unsigned integer array
`int32`	32-bit signed integer array
`uint32`	32-bit unsigned integer array
`int64`	64-bit signed integer array
`uint64`	64-bit unsigned integer array

Examples

These examples show the values `isnumeric` returns when passed specific types:

```
% pi returns a numeric value
isnumeric(pi)
```

```
ans =
     1
% Complex numbers are numeric
isnumeric(3+7i)
ans =
     1
% Integers are numeric
isnumeric(uint8(1:255))
ans =
     1
% isnumeric returns a logical value
isnumeric(isnumeric(pi))
ans =
     0
```

See Also

isfloat | isnan | isreal | isinteger | isprime | isfinite | isinf | isa | is*

Introduced before R2006a

isobject

Determine if input is MATLAB object

Syntax

```
tf = isobject(A)
```

Description

`tf = isobject(A)` returns `true` if `A` is an object of a MATLAB class. Otherwise, it returns `false`.

Handle Graphics objects return `false`. Use `ishghandle` to test for Handle Graphics objects.

Instances of MATLAB fundamental classes return `false`. Use `isa` to test for any of these types. See "Fundamental MATLAB Classes" for more on these classes.

Examples

These examples show the values `isobject` returns when passed specific types:

Define the following MATLAB class:

```
classdef button < handle
   properties
      UiHandle
   end
   methods
      function obj = button(pos)
         obj.UiHandle = uicontrol('Position',pos,...
            'Style','pushbutton');
      end
   end
end
```

Determine which objects are MATLAB objects. For example:

```
h = button([20 20 60 60]);
isobject(h)
ans =
     1
isobject(h.UiHandle)
ans =
     0
```

Use `isjava` to test for Java objects in MATLAB, where it returns `false` for MATLAB objects:

```
isjava(h)
ans =
     0
```

Create an object that is a MATLAB numeric type:

```
a = pi;
isa(a,'double')
ans =
     1
isobject(a)
ans =
     0
```

See Also

`class` | `isa` | `is*`

Introduced before R2006a

isocaps

Compute isosurface end-cap geometry

Syntax

```
fvc = isocaps(X,Y,Z,V,isovalue)
fvc = isocaps(V,isovalue)
fvc = isocaps(...,'enclose')
fvc = isocaps(...,'whichplane')
[f,v,c] = isocaps(...)
isocaps(...)
```

Description

`fvc = isocaps(X,Y,Z,V,isovalue)` computes isosurface end-cap geometry for the volume data `V` at isosurface value `isovalue`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`.

The struct `fvc` contains the face, vertex, and color data for the end-caps and can be passed directly to the `patch` command.

`fvc = isocaps(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isocaps(...,'enclose')` specifies whether the end-caps enclose data values above or below the value specified in `isovalue`. The string *`enclose`* can be either `above` (default) or `below`.

`fvc = isocaps(...,'whichplane')` specifies on which planes to draw the end-caps. Possible values for *`whichplane`* are `all` (default), `xmin`, `xmax`, `ymin`, `ymax`, `zmin`, or `zmax`.

`[f,v,c] = isocaps(...)` returns the face, vertex, and color data for the end-caps in three arrays instead of the struct `fvc`.

`isocaps(...)` without output arguments draws a patch with the computed faces, vertices, and colors.

Examples

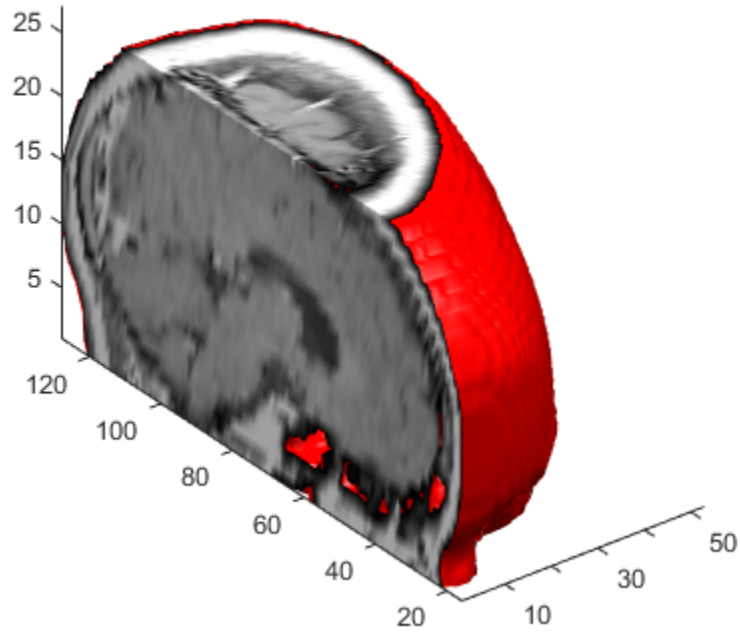
Compute Isosurface End-Cap Geometry

This example uses a data set that is a collection of MRI slices of a human skull. It illustrates the use of isocaps to draw the end-caps on this cutaway volume.

The red isosurface shows the outline of the volume (skull) and the end-caps show what is inside of the volume.

The patch created from the end-cap data (`p2`) uses interpolated face coloring, which means the gray colormap and the light sources determine how it is colored. The isosurface patch (`p1`) used a flat red face color, which is affected by the lights, but does not use the colormap.

```
load mri
D = squeeze(D);
D(:,1:60,:) = [];
p1 = patch(isosurface(D, 5),'FaceColor','red',...
 'EdgeColor','none');
p2 = patch(isocaps(D, 5),'FaceColor','interp',...
 'EdgeColor','none');
view(3)
axis tight
daspect([1,1,.4])
colormap(gray(100))
camlight left
camlight
lighting gouraud
isonormals(D,p1)
```



More About

- "Isocaps Add Context to Visualizations"

See Also

`isosurface` | `isonormals` | `smooth3` | `subvolume` | `reducevolume` | `reducepatch`

Introduced before R2006a

isocolors

Calculate isosurface and patch colors

Syntax

```
nc = isocolors(X,Y,Z,C,vertices)
nc = isocolors(X,Y,Z,R,G,B,vertices)
nc = isocolors(C,vertices)
nc = isocolors(R,G,B,vertices)
nc = isocolors(...,PatchHandle)
isocolors(...,PatchHandle)
```

Description

`nc = isocolors(X,Y,Z,C,vertices)` computes the colors of isosurface (patch object) vertices (`vertices`) using color values `C`. Arrays `X`, `Y`, `Z` define the coordinates for the color data in `C` and must be monotonic vectors that represent a Cartesian, axis-aligned grid (as if produced by `meshgrid`). The colors are returned in `nc`. `C` must be 3-D (index colors).

`nc = isocolors(X,Y,Z,R,G,B,vertices)` uses `R`, `G`, `B` as the red, green, and blue color arrays (true color).

`nc = isocolors(C,vertices)`, and `nc = isocolors(R,G,B,vertices)` assume `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(C)`.

`nc = isocolors(...,PatchHandle)` uses the vertices from the patch identified by `PatchHandle`.

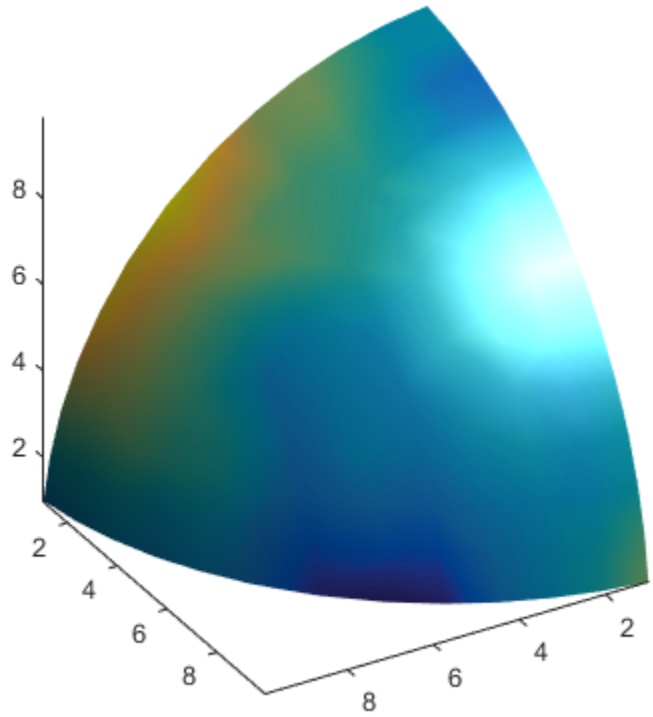
`isocolors(...,PatchHandle)` sets the `FaceVertexCData` property of the patch specified by `PatchHandle` to the computed colors.

Examples

Indexed Color Data

This example displays an isosurface and colors it with random data using indexed color.

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
cdata = smooth3(rand(size(data)),'box',7);
p = patch(isosurface(x,y,z,data,10));
isonormals(x,y,z,data,p)
isocolors(x,y,z,cdata,p)
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
axis tight
camlight
lighting gouraud
```

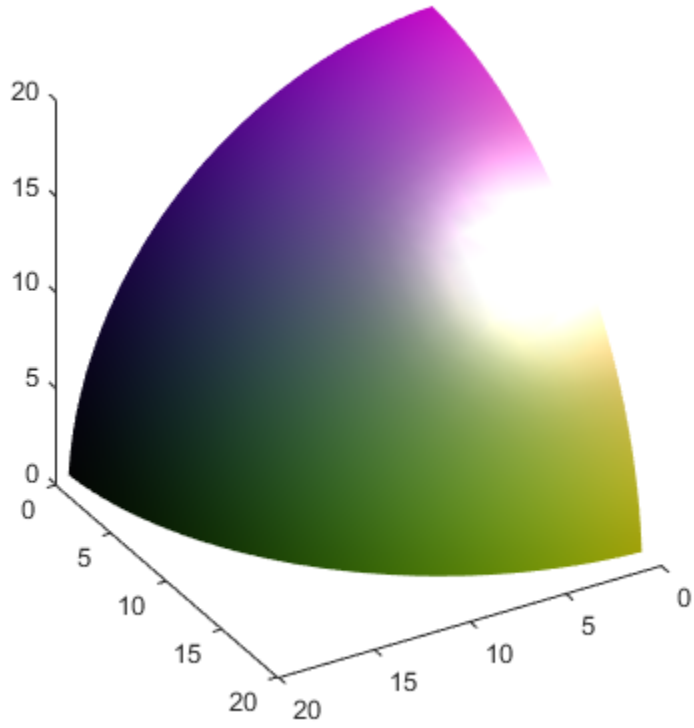


True Color Data

This example displays an isosurface and colors it with true color (RGB) data.

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(x,y,z,data,20));
isonormals(x,y,z,data,p)
[r,g,b] = meshgrid(20:-1:1,1:20,1:20);
isocolors(x,y,z,r/20,g/20,b/20,p)
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
```

```
camlight
lighting gouraud
```

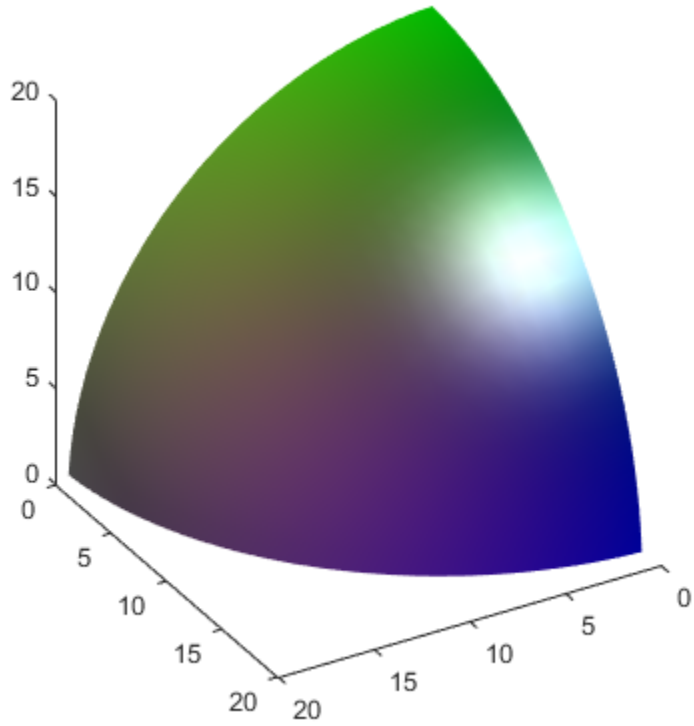


Modified True Color Data

This example uses `isocolors` to calculate the true color data using the isosurface's (patch object's) vertices, but then returns the color data in a variable (`c`) in order to modify the values. It then explicitly sets the isosurface's FaceVertexCData to the new data (`1-c`).

```
[x,y,z] = meshgrid(1:20,1:20,1:20);
data = sqrt(x.^2 + y.^2 + z.^2);
p = patch(isosurface(data,20));
isonormals(data,p)
```

```
[r,g,b] = meshgrid(20:-1:1,1:20,1:20);
c = isocolors(r/20,g/20,b/20,p);
p.FaceVertexCData = 1-c;
p.FaceColor = 'interp';
p.EdgeColor = 'none';
view(150,30)
daspect([1 1 1])
camlight
lighting gouraud
```



More About

- “Interpolating in Indexed Color Versus Truecolor”

See Also

isocaps | isonormals | isosurface | reducepatch | reducevolume | smooth3 | subvolume

Introduced before R2006a

isonormals

Compute normals of isosurface vertices

Syntax

```
n = isonormals(X,Y,Z,V,vertices)
n = isonormals(V,vertices)
n = isonormals(V,p)
n = isonormals(X,Y,Z,V,p)
n = isonormals(...,'negate')
isonormals(V,p)
isonormals(X,Y,Z,V,p)
```

Description

`n = isonormals(X,Y,Z,V,vertices)` computes the normals of the isosurface vertices from the vertex list, `vertices`, using the gradient of the data `V`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The computed normals are returned in `n`.

`n = isonormals(V,vertices)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`n = isonormals(V,p)` and `n = isonormals(X,Y,Z,V,p)` compute normals from the vertices of the patch identified by the handle `p`.

`n = isonormals(...,'negate')` negates (reverses the direction of) the normals.

`isonormals(V,p)` and `isonormals(X,Y,Z,V,p)` set the `VertexNormals` property of the patch identified by the handle `p` to the computed normals rather than returning the values.

Examples

Isosurface Using Different Types of Surface Normals

Compare the effect of different surface normals on the visual appearance of lit isosurfaces. In one case, the triangles used to draw the isosurface define the normals. In

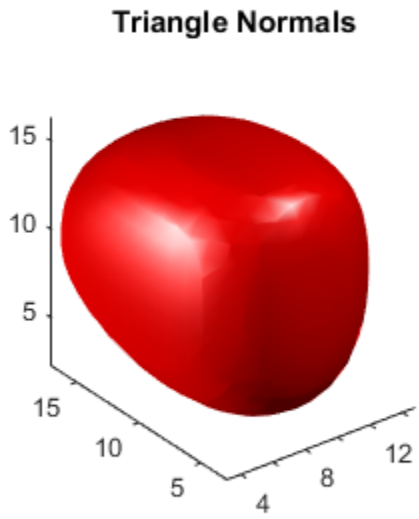
the other, the isonormals function uses the volume data to calculate the vertex normals based on the gradient of the data points. The latter approach generally produces a smoother-appearing isosurface.

Define a 3-D array of volume data.

```
data = cat(3,[0 .2 0; 0 .3 0; 0 0 0],...
    [.1 .2 0; 0 1 0; .2 .7 0],...
    [0 .4 .2; .2 .4 0;.1 .1 0]);
data = interp3(data,3,'cubic');
```

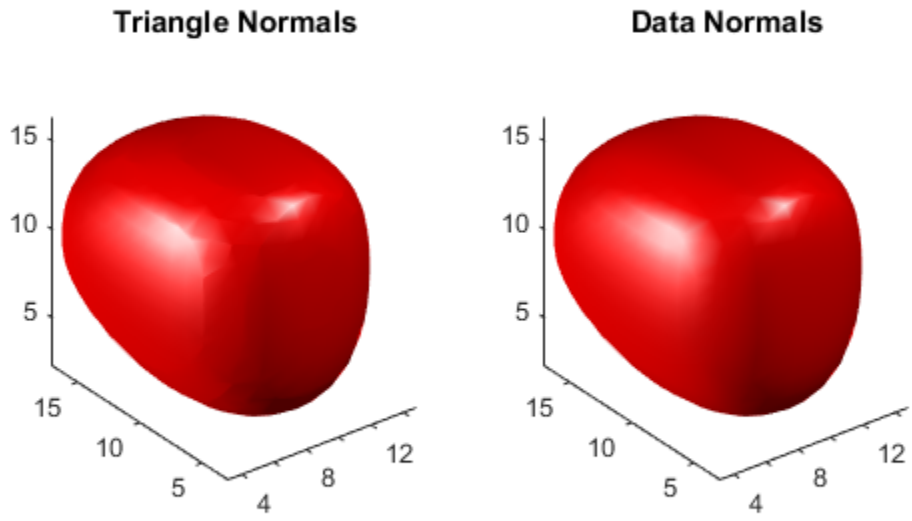
Draw an isosurface from the volume data and add lights. This isosurface uses triangle normals.

```
figure
subplot(1,2,1)
fv = isosurface(data,.5);
p1 = patch(fv,'FaceColor','red','EdgeColor','none');
view(3)
daspect([1,1,1])
axis tight
camlight
camlight(-80,-10)
lighting gouraud
title('Triangle Normals')
```



Draw the same lit isosurface using normals calculated from the volume data.

```
subplot(1,2,2)
fv = isosurface(data,.5);
p2 = patch(fv,'FaceColor','red','EdgeColor','none');
isonormals(data,p2)
view(3)
daspect([1 1 1])
axis tight
camlight
camlight(-80,-10)
lighting gouraud
title('Data Normals')
```



These isosurfaces illustrate the difference between triangle and data normals.

`interp3` | `isosurface` | `isocaps` | `smooth3` | `subvolume` | `reducevolume` | `reducepatch`

Introduced before R2006a

isordinal

Determine whether input is ordinal categorical array

Syntax

```
tf = isordinal(A)
```

Description

`tf = isordinal(A)` returns logical `1` (`true`) if `A` is an ordinal categorical array. Otherwise, `isordinal` returns logical `0` (`false`).

If a categorical array is ordinal, you can use relational operations for inequality comparisons, such as greater and less than, in addition to tests for equality.

Examples

Determine Whether Categorical Array Is Ordinal

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values `'S'`, `'M'`, and `'L'`.

```
A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...
    {'S','M','L'},{'small','medium','large'})
```

```
A =

     medium
     large
     small
     small
     medium
     large
     medium
     large
     medium
     small
```

Determine if the categories of A have a mathematical ordering.

```
isordinal(A)
```

```
ans =

     0
```

A is not ordinal. You must use the `'Ordinal',true` name-value pair argument in the function `categorical` to create an ordinal categorical array.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

More About

Tips

- To convert a categorical array, A, from nonordinal to ordinal, use `A = categorical(A,'Ordinal',true)`.
- To convert a categorical array, A, from ordinal to nonordinal, use `A = categorical(A,'Ordinal',false)`.
- "Ordinal Categorical Arrays"

`categorical` | `categories`

isosurface

Extract isosurface data from volume data

Syntax

```
fv = isosurface(X,Y,Z,V,isovalue)
fv = isosurface(V,isovalue)
fvc = isosurface(...,colors)
fv = isosurface(...,'noshare')
fv = isosurface(...,'verbose')
[f,v] = isosurface(...)
[f,v,c] = isosurface(...)
isosurface(...)
```

Description

`fv = isosurface(X,Y,Z,V,isovalue)` computes isosurface data from the volume data `V` at the isosurface value specified in `isovalue`. That is, the isosurface connects points that have the specified value much the way contour lines connect points of equal elevation.

The arrays `X`, `Y`, and `Z` represent a Cartesian, axis-aligned grid. `V` contains the corresponding values at these grid points. The coordinate arrays (`X`, `Y`, and `Z`) must be monotonic and conform to the format produced by `meshgrid`. `V` must be a 3D volume array of the same size as `X`, `Y`, and `Z`.

The `struct` `fv` contains the faces and vertices of the isosurface, which you can pass directly to the `patch` command.

`fv = isosurface(V,isovalue)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)` where `[m,n,p] = size(V)`.

`fvc = isosurface(...,colors)` interpolates the array `colors` onto the scalar field and returns the interpolated values in the `facevertexcdata` field of the `fvc` structure. The size of the `colors` array must be the same as `V`. The `colors` argument enables you to control the color mapping of the isosurface with data different from that

used to calculate the isosurface (e.g., temperature data superimposed on a wind current isosurface).

`fv = isosurface(...,'noshare')` does not create shared vertices. This is faster, but produces a larger set of vertices.

`fv = isosurface(...,'verbose')` prints progress messages to the command window as the computation progresses.

`[f,v] = isosurface(...)` or `[f,v,c] = isosurface(...)` returns the faces and vertices (and `faceVertexcCData`) in separate arrays instead of a struct.

`isosurface(...)` with no output arguments, creates a patch in the current axes with the computed faces and vertices. If no current axes exists, a new axes is created with a 3-D view.

Special Case Behavior — isosurface Called with No Output Arguments

If there is no current axes and you call `isosurface` with without assigning output arguments, MATLAB creates a new axes, sets it to a 3-D view, and adds lighting to the isosurface graph.

Examples

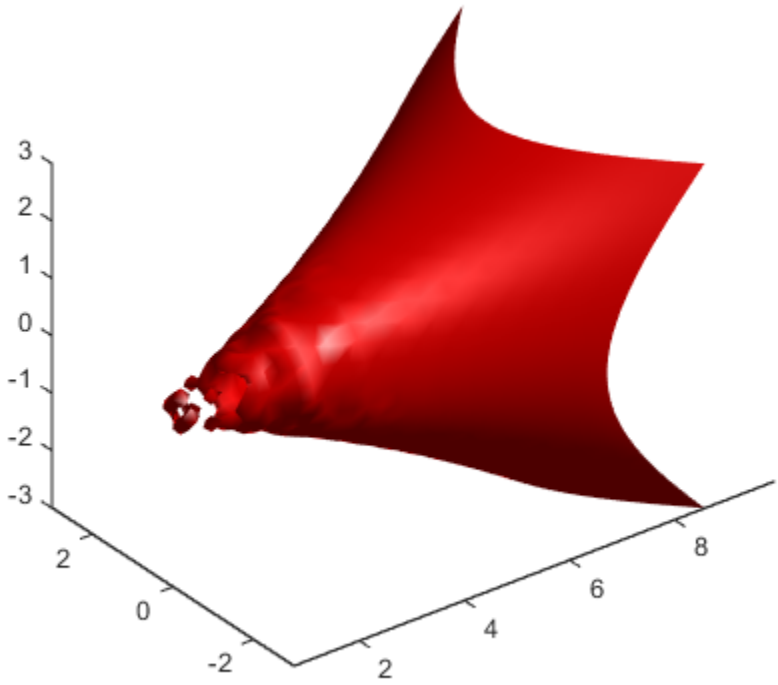
Example 1

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). The isosurface is drawn at the data value of -3. The statements that follow the `patch` command prepare the isosurface for lighting by

- Recalculating the isosurface normals based on the volume data (`isonormals`)
- Setting the face and edge color (`set`, `FaceColor`, `EdgeColor`)
- Specifying the view (`daspect`, `view`)
- Adding lights (`camlight`, `lighting`)

```
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
```

```
isonormals(x,y,z,v,p)
p.FaceColor = 'red';
p.EdgeColor = 'none';
daspect([1,1,1])
view(3); axis tight
camlight
lighting gouraud
```

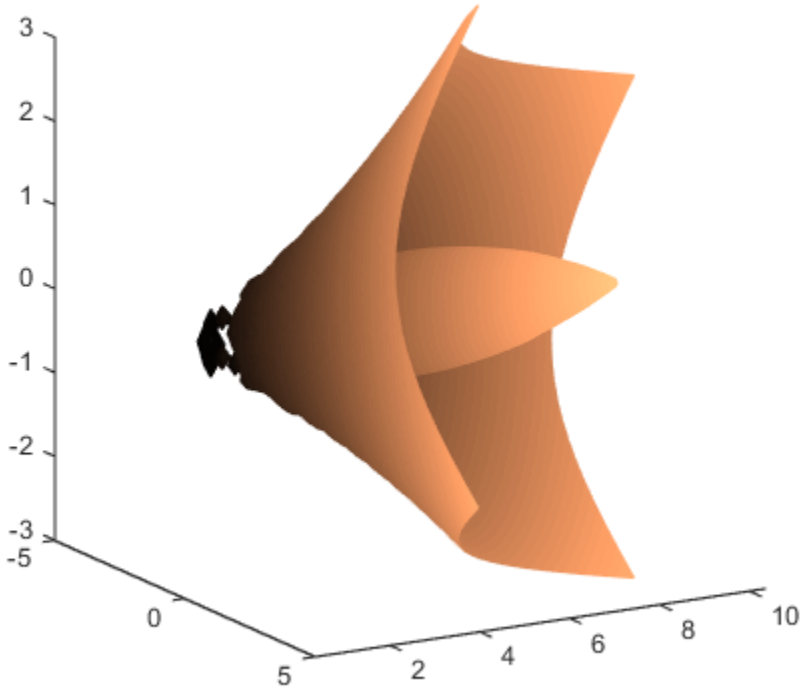


Example 2

Visualize the same flow data as above, but color-code the surface to indicate magnitude along the X-axis. Use a sixth argument to `isosurface`, which provides a means to overlay another data set by coloring the resulting isosurface. The `colors` variable is a

vector containing a scalar value for each vertex in the isosurface, to be portrayed with the current color map. In this case, it is one of the variables that define the surface, but it could be entirely independent. You can apply a different color scheme by changing the current figure color map.

```
[x,y,z,v] = flow;
[faces,verts,colors] = isosurface(x,y,z,v,-3,x);
patch('Vertices', verts, 'Faces', faces, ...
    'FaceVertexCData', colors, ...
    'FaceColor','interp', ...
    'edgecolor', 'interp');
view(30,-15);
axis vis3d;
colormap copper
```



More About

Tips

You can pass the `fv` structure created by `isosurface` directly to the `patch` command, but you cannot pass the individual faces and vertices arrays (`f`, `v`) to `patch` without specifying property names. For example,

```
patch(isosurface(X,Y,Z,V,isovalue))
```

or

```
[f,v] = isosurface(X,Y,Z,V,isovalue);
patch('Faces',f,'Vertices',v)
```

- "Connecting Equal Values with Isosurfaces"

`isonormals` | `shrinkfaces` | `smooth3` | `subvolume`

Introduced before R2006a

ispc

Determine if version is for Windows (PC) platform

Syntax

```
tf = ispc
```

Description

`tf = ispc` returns logical `1` (`true`) if the version of MATLAB software is for the Microsoft Windows platform. Otherwise, it returns logical `0` (`false`).

See Also

`computer` | `is*` | `ismac` | `isstudent` | `isunix`

Introduced before R2006a

ispref

Test for existence of preference

Syntax

```
ispref('group','pref')
ispref('group')
ispref('group',{'pref1','pref2',...'prefn'})
```

Description

`ispref('group','pref')` returns `1` if the preference specified by `group` and `pref` exists, and `0` otherwise.

`ispref('group')` returns `1` if the GROUP exists, and `0` otherwise.

`ispref('group',{'pref1','pref2',...'prefn'})` returns a logical array the same length as the cell array of preference names, containing `1` where each preference exists, and `0` elsewhere.

Examples

```
addpref('mytoolbox','version','1.0')
ispref('mytoolbox','version')

ans =
     1.0
```

See Also

`addpref` | `rmpref` | `getpref` | `setpref` | `uigetpref` | `uisetpref`

Introduced before R2006a

isprime

Determine which array elements are prime

Syntax

```
TF = isprime(X)
```

Description

`TF = isprime(X)` returns a logical array the same size as `X`. The value at `TF(i)` is `true` when `X(i)` is a prime number. Otherwise, the value is `false`.

Examples

Determine if Double Integer Values Are Prime

```
tf = isprime([2 3 0 6 10])
```

```
tf =

     1     1     0     0     0
```

2 and 3 are prime, but 0, 6, and 10 are not.

Determine if Unsigned Integer Values Are Prime

```
x = uint16([333 71 99]);
tf = isprime(x)
```

```
tf =

     0     1     0
```

71 is prime, but 333 and 99 are not.

Input Arguments

X — Input values

scalar, vector, or array of real, nonnegative integer values

Input values, specified as a scalar, vector, or array of real, nonnegative integer values.

Example: `17`

Example: `[1 2 3 4]`

Example: `int16([127 255 4095])`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

See Also

`is*` | `primes`

Introduced before R2006a

isprop

Determine if property of object

Syntax

```
tf = isprop(obj,'PropertyName')
```

Description

`tf = isprop(obj,'PropertyName')` returns `true` if the specified `PropertyName` is a property of object `obj`. Otherwise, `isprop` returns logical `false`.

If `obj` is an array, `isprop` returns a logical array the same size as `obj`. Each true element of `tf` corresponds to an element of `obj` that has the property, `PropertyName`.

Note: If `obj` is an empty object or an array of empty objects, `isprop` returns an empty logical array, even if `PropertyName` is a property of `obj`.

While `isprop` returns `true` if the class of an object defines a property of that name, classes can control access to property values by defining property attributes. Property access can be defined as:

- Readable and writable
- Read only
- Write only
- Accessible only to certain class methods

Therefore, `isprop` might indicate that a property exists, but you might not be able to access that property. For more information, see “Getting Information About Properties”.

Examples

This example uses `isprop` to determine if `XDataSource` is a property of object `h` before attempting to set the property value:

```
h = plot(1:10);
if isprop(h,'XDataSource')
   set(h,'XDataSource','x')
else
   error(['XDataSource not a property of class ',class(h)])
end
```

Since `XDataSource` is a property of `h`, its value is set to `'x'`.

See Also

`properties` | `ismethod`

Introduced before R2006a

isprop (COM)

Determine whether input is COM object property

Syntax

```
tf = isprop(h,'propertyname')
```

Description

`tf = isprop(h,'propertyname')` returns logical `1` (`true`) if the specified `name` is a property of COM object `h`. Otherwise, returns logical `0` (`false`).

COM functions are available on Microsoft Windows systems only.

Examples

Test a property of an instance of a Microsoft Excel application.

```
h = actxserver('Excel.Application');
isprop(h,'UsableWidth')
```

MATLAB returns `true`, `UsableWidth` is a property.

Try the same test on `SaveWorkspace`.

```
isprop(h,'SaveWorkspace')
```

MATLAB returns `false`. `SaveWorkspace` is not a property; it is a method.

`inspect` | `ismethod` | `isevent`

isprotected

Determine whether categories of categorical array are protected

Syntax

```
tf = isprotected(A)
```

Description

`tf = isprotected(A)` returns logical `1` (`true`) if the categories of `A` are protected. Otherwise, `isprotected` returns logical `0` (`false`).

- `true` — When you assign new values to `B`, the values must belong to one of the existing categories. Therefore, you only can combine arrays that have the same categories. To add new categories to `B`, you must use the `addcats` function.
- `false` — When you assign new values to `B`, the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update to include the categories from both arrays.

Examples

Determine Whether Categories Are Protected

Create a categorical array containing the sizes of 10 objects. Use the names `small`, `medium`, and `large` for the values `'S'`, `'M'`, and `'L'`.

```
valueset = {'S','M','L'};
catnames = {'small','medium','large'};

A = categorical({'M';'L';'S';'S';'M';'L';'M';'L';'M';'S'},...
    valueset,catnames,'Ordinal',true)
```

```
A =

     medium
     large
```

```
     small
     small
     medium
     large
     medium
     large
     medium
     small
```

A is a 10-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =

    'small'
    'medium'
    'large'
```

Determine whether the categories of A are protected.

```
tf = isprotected(A)
```

```
tf =

     1
```

Since A is an ordinal categorical array, the categories are protected. If you try to add a new value that does not belong to one of the existing categories, for example `A(11) = 'xlarge'`, then MATLAB returns an error.

First, use `addcats` to add a new category for `xlarge`.

```
A = addcats(A,'xlarge','After','large');
```

Since A is protected, you can now add a value for `xlarge` since it has an existing category.

```
A(11) = 'xlarge'
```

```
A =

     medium
```

```
large
small
small
medium
large
medium
large
medium
small
xlarge
```

A is now a 11-by-1 categorical array with four categories, such that `small < medium < large < xlarge`.

- "Work with Protected Categorical Arrays"

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

The categories of ordinal categorical arrays are always protected.

See Also

`categorical` | `categories`

isreal

Determine whether array is real

Syntax

```
tf = isreal(A)
```

Description

`tf = isreal(A)` returns logical `1` (`true`) when `A` does not have an imaginary part. Otherwise, it returns logical `0` (`false`).

If `A` has a stored imaginary part with value `0`, then `isreal(A)` returns logical `0` (`false`).

Examples

Determine Whether Matrix Contains All Real Values

Define a 3-by-4 matrix, `A`.

```
A = [7 3+4i 2 5i;...
     2i 1+3i 12 345;...
     52 108 78 3];
```

Determine whether the array is real.

```
tf = isreal(A)
```

```
tf =

     0
```

Since `A` contains complex elements, `isreal` returns false.

Define Complex Number with Zero-Valued Imaginary Part

Use the `complex` function to create a scalar, `A`, with zero-valued imaginary part.

```
A = complex(12)

A =

  12.0000 + 0.0000i
```

Determine whether A is real.

```
tf = isreal(A)

tf =

     0
```

A is not real because it has an imaginary part, even though the value of the imaginary part is 0.

Determine whether A contains any elements with zero-valued imaginary part.

```
~any(imag(A))

ans =

     1
```

A contains elements with zero-valued imaginary part.

Computation Resulting in Zero-Valued Imaginary Part

Define two complex scalars, x and y.

```
x=3+4i;
y=5-4i;
```

Determine whether the addition of two complex scalars, x and y, is real.

```
A = x+y

A =

     8
```

MATLAB drops the zero imaginary part.

```
isreal(A)
```

```
ans =

     1
```

A is real since it does not have an imaginary part.

Find Real Elements in Cell Array

Create a cell array.

```
C{1,1} = pi;                % double
C{2,1} = 'John Doe';        % char array
C{3,1} = 2 + 4i;            % complex double
C{4,1} = ispc;              % logical
C{5,1} = magic(3);          % double array
C{6,1} = complex(5,0)       % complex double
```

```
C =

    [          3.1416]
    'John Doe'
    [2.0000 + 4.0000i]
    [               1]
    [3x3 double]
    [5.0000 + 0.0000i]
```

C is a 1-by-6 cell array.

Loop over the elements of a cell array to distinguish between real and complex elements.

```
for k = 1:6
x(k,1) = isreal(C{k,1});
end

x
```

```
x =

     1
     1
     0
     1
     1
     0
```

All but `C{3,1}` and `C{6,1}` are real arrays.

Input Arguments

A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

- For numeric data types, if `A` does not have an imaginary part, `isreal` returns `true`; if `A` does have an imaginary part `isreal` returns `false`.
- For `logical` and `char` data types, `isreal` always returns `true`.
- For `table`, `cell`, `struct`, `datetime`, `function_handle`, and `object` data types, `isreal` always returns `false`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `function_handle`
Complex Number Support: Yes

More About

Tips

- `isreal(complex(A))` always returns `false`, even when the imaginary part is all zeros.
- `~isreal(x)` detects arrays that have an imaginary part, even if it is all zeros.
- “Complex Numbers”

Introduced before R2006a

isrow

Determine whether input is row vector

Syntax

```
isrow(V)
```

Description

`isrow(V)` returns logical 1 (`true`) if `size`(V) returns `[1 n]` with a nonnegative integer value `n`, and logical 0 (`false`) otherwise.

Examples

Determine if a vector is a row. This example is a column so `isrow` returns 0:

```
V = rand(5,1);
isrow(V)
ans =
     0
```

Transpose the vector to make it a row. `isrow` returns 1:

```
V1 = V';
isrow(V1)
ans =
     1
```

See Also

`iscolumn` | `ismatrix` | `isscalar` | `isvector`

isscalar

Determine whether input is scalar

Syntax

```
isscalar(A)
```

Description

`isscalar(A)` returns logical `1` (`true`) if `size(A)` returns [1 1], and logical `0` (`false`) otherwise.

Examples

Test matrix `A` and one element of the matrix:

```
A = rand(5);

isscalar(A)
ans =
     0

isscalar(A(3,2))
ans =
     1
```

See Also

`isvector` | `isrow` | `ismatrix` | `iscolumn` | `islogical` | `ischar` | `isa` | `is*`

Introduced before R2006a

issorted

Determine whether set elements are in sorted order

Syntax

```
TF = issorted(A)
TF = issorted(A, 'rows')
```

Description

`TF = issorted(A)` returns logical `1` (`true`) if the elements of `A` are in sorted order, and logical `0` (`false`) otherwise. Input `A` can be a vector or an N-by-1 or 1-by-N cell array of strings. `A` is considered to be sorted if `A` and the output of `sort(A)` are equal.

`TF = issorted(A, 'rows')` returns logical `1` (`true`) if the rows of two-dimensional matrix `A` are in sorted order, and logical `0` (`false`) otherwise. Matrix `A` is considered to be sorted if `A` and the output of `sortrows(A)` are equal.

Note Only the `issorted(A)` syntax supports `A` as a cell array of strings.

The `issorted(A,'rows')` syntax supports `A` as a categorical array, but not as a cell array of strings.

Examples

Example 1 — Using issorted on a vector

```
A = [5 12 33 39 78 90 95 107 128 131];

issorted(A)
ans =
     1
```

Example 2 — Using issorted on a matrix

```
A = magic(5)
A =
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9

issorted(A, 'rows')
ans =
     0

B = sortrows(A)
B =
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
    17    24     1     8    15
    23     5     7    14    16

issorted(B)
ans =
     1
```

Example 3 — Using issorted on a cell array

```
x = {'one'; 'two'; 'three'; 'four'; 'five'};
issorted(x)
ans =
     0

y = sort(x)
y =
    'five'
    'four'
    'one'
    'three'
    'two'

issorted(y)
```

More About

Tips

For character arrays, `issorted` uses ASCII, rather than alphabetical, order.

You cannot use `issorted` on arrays of greater than two dimensions.

See Also

Introduced before R2006a

isspace

Array elements that are space characters

Syntax

```
tf = isspace('str')
```

Description

`tf = isspace('str')` returns an array the same size as `'str'` containing logical `1` (`true`) where the elements of `str` are Unicode-represented whitespace characters, and logical `0` (`false`) where they are not.

Whitespace characters for which `isspace` returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which `isspace` returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isspace(char(1):char(intmax('uint16'))))
```

Examples

```
isspace('  Find spa ces ')
  Columns 1 through 13
     1   1   0   0   0   0   1   0   0   0   1   0   0
  Columns 14 through 15
     0   1
```

issparse

Determine whether input is sparse

Syntax

```
TF = issparse(S)
```

Description

`TF = issparse(S)` returns logical 1 (`true`) if the storage class of `S` is sparse and logical 0 (`false`) otherwise.

See Also

`is*` | `sparse` | `full`

Introduced before R2006a

isstr

Determine whether input is character array

Note: `isstr` is not recommended. Use `ischar` instead.

See Also

`ischar` | `isa` | `is*`

Introduced before R2006a

isstrprop

Determine whether string is of specified category

Syntax

```
tf = isstrprop('str', 'category')
```

Description

`tf = isstrprop('str', 'category')` returns a logical array the same size as `str` containing logical `1` (`true`) where the elements of `str` belong to the specified *`category`*, and logical `0` (`false`) where they do not.

The `str` input can be a character array, cell array, or any MATLAB numeric type. If `str` is a cell array, then the return value is a cell array of the same shape as `str`.

The *`category`* input can be any of the strings shown in the left column below:

Category	Description
`alpha`	`True` for those elements of `str` that are alphabetic
`alphanum`	`True` for those elements of `str` that are alphanumeric
`cntrl`	`True` for those elements of `str` that are control characters (for example, `char(0:20)`)
`digit`	`True` for those elements of `str` that are numeric digits

`graphic`	True for those elements of str that are graphic characters. These are all values that represent any characters except for the following:
	
	`unassigned, space, line separator,`
	`paragraph separator, control characters,`
	`Unicode format control characters,`
	`private user-defined characters,`
	`Unicode surrogate characters,`
	`Unicode other characters`

`lower`	`True` for those elements of `str` that are lowercase letters

Category	Description
`print`	`True` for those elements of `str` that are graphic characters, plus `char(32)`
`punct`	`True` for those elements of `str` that are punctuation characters
`wspace`	`True` for those elements of `str` that are white-space characters. This range includes the ANSI® C definition of white space, `{' ','\t','\n','\r','\v','\f'}`, in addition to a number of other Unicode characters.
`upper`	`True` for those elements of `str` that are uppercase letters
`xdigit`	`True` for those elements of `str` that are valid hexadecimal digits

Examples

Test for alphabetic characters in a string:

```
A = isstrprop('abc123def', 'alpha')
A =
   1 1 1 0 0 0 1 1 1
```

Test for numeric digits in a string:

```
A = isstrprop('abc123def', 'digit')
A =
   0 0 0 1 1 1 0 0 0
```

Test for hexadecimal digits in a string:

```
A = isstrprop('abcd1234efgh', 'xdigit')
A =
   1 1 1 1 1 1 1 1 1 1 0 0
```

Test for numeric digits in a character array:

```
A = isstrprop(char([97 98 99 49 50 51 101 102 103]), ...
              'digit')
A =
   0 0 0 1 1 1 0 0 0
```

Test for alphabetic characters in a two-dimensional cell array:

```
A = isstrprop({'abc123def';'456ghi789'}, 'alpha')
```

```
A =
   [1x9 logical]
   [1x9 logical]

A{:,:}
ans =
   1 1 1 0 0 0 1 1 1
   0 0 0 1 1 1 0 0 0
```

Test for white-space characters in a string:

```
A = isstrprop(sprintf('a bc\n'), 'wspace')
A =
   0 1 0 0 1
```

More About

Tips

Numbers of type `double` are converted to `int32` according to MATLAB rules of double-to-integer conversion. Numbers of type `int64` and `uint64` bigger than `int32(inf)` saturate to `int32(inf)`.

MATLAB classifies the elements of the `str` input according to the Unicode definition of the specified category. If the numeric value of an element in the input array falls within the range that defines a Unicode character category, then this element is classified as being of that category. The set of Unicode character codes includes the set of ASCII character codes, but also covers a large number of languages beyond the scope of the ASCII set. The classification of characters is dependent on the global location of the platform on which MATLAB is installed.

Whitespace characters for which the `wspace` option returns `true` include tab, line feed, vertical tab, form feed, carriage return, and space, in addition to a number of other Unicode characters. To see all characters for which the `wspace` option returns `true`, enter the following command, and then look up the returned decimal codes in a Unicode reference:

```
find(isstrprop(char(1):char(intmax('uint16')), 'wspace'))
```

Introduced before R2006a

isstruct

Determine whether input is structure array

Syntax

```
tf = isstruct(A)
```

Description

`tf = isstruct(A)` returns logical `1` (`true`) if `A` is a MATLAB structure and logical `0` (`false`) otherwise.

Examples

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];

isstruct(patient)

ans =

     1
```

More About

- dynamic field names

`struct` | `istable` | `iscell` | `ischar` | `isfield` | `isobject` | `isnumeric` | `islogical` | `isa` | `is*`

Introduced before R2006a

isstudent

Determine if version is Student Version

Syntax

```
tf = isstudent
```

Description

`tf = isstudent` returns logical `1` (`true`) if the version of MATLAB software is the Student Version, and returns logical `0` (`false`) for commercial versions.

See Also

`ver` | `version` | `license` | `ispc` | `isunix` | `is*`

Introduced before R2006a

issymmetric

Determine if matrix is symmetric or skew-symmetric

Syntax

```
tf = issymmetric(A)
tf = issymmetric(A,skewOption)
```

Description

`tf = issymmetric(A)` returns logical `1` (`true`) if square matrix `A` is symmetric; otherwise, it returns logical `0` (`false`).

`tf = issymmetric(A,skewOption)` specifies the type of the test. Specify `skewOption` as `'skew'` to determine if `A` is skew-symmetric.

Examples

Test if Hermitian Matrix Is Symmetric

Create a 3-by-3 matrix.

```
A = [1 0 1i; 0 1 0;-1i 0 1]
```

```
A =

   1.0000 + 0.0000i   0.0000 + 0.0000i   0.0000 + 1.0000i
   0.0000 + 0.0000i   1.0000 + 0.0000i   0.0000 + 0.0000i
   0.0000 - 1.0000i   0.0000 + 0.0000i   1.0000 + 0.0000i
```

The matrix is Hermitian and has a real-valued diagonal.

Test whether the matrix is symmetric.

```
tf = issymmetric(A)
```

```
tf =

     0
```

The result is logical `0` (`false`) because `A` is not symmetric. In this case, `A` is equal to its complex conjugate transpose, `A'`, but not its nonconjugate transpose, `A.'`.

Change the element in `A(3,1)` to be `1i`.

```
A(3,1) = 1i;
```

Determine whether the modified matrix is symmetric.

```
tf = issymmetric(A)
```

```
tf =

     1
```

The matrix, `A`, is now symmetric because it is equal to its nonconjugate transpose, `A.'`.

Test if Matrix Is Skew-Symmetric

Create a 4-by-4 matrix.

```
A = [0 1 -2 5; -1 0 3 -4; 2 -3 0 6; -5 4 -6 0]
```

```
A =

     0     1    -2     5
    -1     0     3    -4
     2    -3     0     6
    -5     4    -6     0
```

The matrix is real and has a diagonal of zeros.

Specify `skewOption` as `'skew'` to determine whether the matrix is skew-symmetric.

```
tf = issymmetric(A,'skew')
```

```
tf =

     1
```

The matrix, A, is skew-symmetric since it is equal to the negation of its nonconjugate transpose, `-A.'`.

Input Arguments

A — Input matrix

numeric matrix

Input matrix, specified as a numeric matrix. If A is not square, then `issymmetric` returns logical `0` (`false`).

Data Types: `single` | `double`
Complex Number Support: Yes

skewOption — Test type

`'nonskew'` (default) | `'skew'`

Test type, specified as `'nonskew'` (default) or `'skew'`. Specify `'skew'` to test whether A is skew-symmetric. Specifying `issymmetric(A,'nonskew')` is equivalent to `issymmetric(A)`.

Data Types: `char`

More About

Symmetric Matrix

- A square matrix, A, is symmetric if it is equal to its nonconjugate transpose, `A = A.'`.

  In terms of the matrix elements, this means that

  $$a_{i,j} = a_{j,i} .$$

- Since real matrices are unaffected by complex conjugation, a real matrix that is symmetric is also Hermitian. For example, the matrix

  $$A = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{bmatrix}$$

is both symmetric and Hermitian.

Skew-Symmetric Matrix

- A square matrix, `A`, is skew-symmetric if it is equal to the negation of its nonconjugate transpose, `A = -A.'`.

  In terms of the matrix elements, this means that

  $$a_{i,j} = -a_{j,i} .$$

- Since real matrices are unaffected by complex conjugation, a real matrix that is skew-symmetric is also skew-Hermitian. For example, the matrix

  $$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}$$

  is both skew-symmetric and skew-Hermitian.

See Also

`ctranspose` | `ishermitian` | `isreal` | `transpose`

Introduced in R2014a

isTiled

Class: Tiff

Determine if tiled image

Syntax

```
tf = isTiled(tiffobj)
```

Description

`tf = isTiled(tiffobj)` returns `true` if the image has a tiled organization and `false` if the image has a stripped organization.

Examples

Determine if Image Has Tiled Organization

Open a `Tiff` object and check if the image in the TIFF file has a tiled or stripped organization.

```
t = Tiff('example.tif','r');
tf = isTiled(t)
```

```
tf =

     1
```

The image has a tiled organization.

Close the `Tiff` object.

```
close(t)
```

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

References

This method corresponds to the `TIFFIsTiled` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

istable

Determine whether input is table

Syntax

```
tf = istable(T)
```

Description

`tf = istable(T)` returns logical `1` (`true`) if `T` is a table. Otherwise, it returns logical `0` (`false`) otherwise.

Examples

Determine if Workspace Variable Is Table

Create a workspace variable, `T`.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
    {'NY';'CA';'MA'},[true;false;false])
```

```
T =

    Var1          Var2          Var3    Var4
    ____    ________________    ____    _____

    M       45          45    'NY'    true
    F       41          32    'CA'    false
    M       40          34    'MA'    false
```

Verify that the workspace variable, `T`, is a table.

```
istable(T)
```

```
ans =

     1
```

T is a table.

Determine if Subset of Table Is Table

Create a table, T.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
    {'NY';'CA';'MA'},[true;false;false])
```

```
T =

    Var1          Var2          Var3    Var4
    ____    ______________    ____    _____

    M       45            45    'NY'    true
    F       41            32    'CA'    false
    M       40            34    'MA'    false
```

Determine if the subset of table T that contains only the second and fourth variables is a table.

```
istable(T{:,[2 4]})
```

```
ans =

     0
```

Conversely, accessing data with curly braces, `T{:,[2 4]}`, returns a matrix and not a table.

Input Arguments

T — Input variable

workspace variable

Input variable, specified as a workspace variable. T can be any data type.

See Also

`iscell` | `islogical` | `isnumeric` | `isobject` | `isstruct` | `table`

istril

Determine if matrix is lower triangular

Syntax

```
tf = istril(A)
```

Description

`tf = istril(A)` returns logical `1` (`true`) if `A` is a lower triangular matrix; otherwise, it returns logical `0` (`false`).

Examples

Test Lower Triangular Matrix

Create a 5-by-5 matrix.

```
D = tril(magic(5))
```

```
D =

    17     0     0     0     0
    23     5     0     0     0
     4     6    13     0     0
    10    12    19    21     0
    11    18    25     2     9
```

Test `D` to see if it is lower triangular.

```
istril(D)
```

```
ans =

     1
```

The result is logical 1 (`true`) because all elements above the main diagonal are zero.

Test Matrix of Zeros

Create a 5-by-5 matrix of zeros.

```
Z = zeros(5);
```

Test `Z` to see if it is lower triangular.

```
istril(Z)
```

```
ans =

     1
```

The result is logical 1 (`true`) because a lower triangular matrix can have any number of zeros on its main diagonal.

Input Arguments

A — Input array

numeric array

Input array, specified as a numeric array. `istril` returns logical `0` (`false`) if `A` has more than two dimensions.

Data Types: `single | double`
Complex Number Support: Yes

More About

Lower Triangular Matrix

A matrix is lower triangular if all elements above the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the matrix

$$A = \begin{pmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ -2 & -2 & 1 & 0 \\ -3 & -3 & -3 & 1 \end{pmatrix}$$

is lower triangular. A diagonal matrix is both upper and lower triangular.

Tips

- Use the `tril` function to produce lower triangular matrices for which `istril` returns logical `1` (`true`).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `istril(A) == isbanded(A,size(A,1),0)`.

See Also

`diag` | `isdiag` | `istriu` | `tril` | `triu`

Introduced in R2014a

istriu

Determine if matrix is upper triangular

Syntax

```
tf = istriu(A)
```

Description

`tf = istriu(A)` returns logical `1` (`true`) if `A` is an upper triangular matrix; otherwise, it returns logical `0` (`false`).

Examples

Test Upper Triangular Matrix

Create a 5-by-5 matrix.

```
A = triu(magic(5))
```

```
A =

    17    24     1     8    15
     0     5     7    14    16
     0     0    13    20    22
     0     0     0    21     3
     0     0     0     0     9
```

Test `A` to see if it is upper triangular.

```
istriu(A)
```

```
ans =

     1
```

The result is logical `1` (`true`) because all elements below the main diagonal are zero.

Test Matrix of Zeros

Create a 5-by-5 matrix of zeros.

```
Z = zeros(5);
```

Test `Z` to see if it is upper triangular.

```
istriu(Z)
```

```
ans =

     1
```

The result is logical `1` (`true`) because an upper triangular matrix can have any number of zeros on the main diagonal.

Input Arguments

A — Input array

numeric array

Input array, specified as a numeric array. `istriu` returns logical `0` (`false`) if `A` has more than two dimensions.

Data Types: `single | double`
Complex Number Support: Yes

More About

Upper Triangular Matrix

A matrix is upper triangular if all elements below the main diagonal are zero. Any number of the elements on the main diagonal can also be zero.

For example, the matrix

$$A = \begin{pmatrix} 1 & -1 & -1 & -1 \\ 0 & 1 & -2 & -2 \\ 0 & 0 & 1 & -3 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

is upper triangular. A diagonal matrix is both upper and lower triangular.

Tips

- Use the `triu` function to produce upper triangular matrices for which `istriu` returns logical `1` (`true`).
- The functions `isdiag`, `istriu`, and `istril` are special cases of the function `isbanded`, which can perform all of the same tests with suitably defined upper and lower bandwidths. For example, `istriu(A) == isbanded(A,0,size(A,2))`.

See Also

`diag` | `isdiag` | `istril` | `tril` | `triu`

Introduced in R2014a

isundefined

Find undefined elements in categorical array

Syntax

```
TF = isundefined(A)
```

Description

`TF = isundefined(A)` returns a logical array, `TF`, that indicates which elements in the categorical array, `A`, contain undefined values. `isundefined` returns logical `1` (`true`) for undefined elements; otherwise it returns logical `0` (`false`). The size of `TF` is the same as the size of `A`.

Any elements in `A` without a corresponding category are undefined. Undefined values are similar to `NaN` in numeric arrays.

Examples

Categorical Array with Undefined Values

Create a categorical array, `A`, from numeric values where `1`, `2`, and `3` represent red, green, and blue respectively.

```
A = categorical([4 1; 2 3; 2 1; 3 4; 1 1],1:3,{'red','green','blue'})
```

```
A =

     <undefined>      red
     green            blue
     green            red
     blue             <undefined>
     red              red
```

`A` is a 5-by-2 categorical array with three categories: `red`, `green`, and `blue`. Array elements corresponding to the numeric value `4` in the input array to the `categorical`

function do not have a corresponding category. Therefore, they are undefined in the output categorical array, A.

Find undefined elements in A.

```
TF = isundefined(A)
```

```
TF =

     1     0
     0     0
     0     0
     0     1
     0     0
```

A(1,1) and A(4,2) are undefined.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

See Also

ismember

isunix

Determine if version is for Linux or Mac platforms

Syntax

```
tf = isunix
```

Description

`tf = isunix` returns logical `1` (`true`) if the version of MATLAB is for Linux or Apple Mac OS X platforms. Otherwise, it returns logical `0` (`false`).

See Also

`computer` | `is*` | `ismac` | `ispc` | `isstudent`

Introduced before R2006a

isvalid (serial)

Determine whether serial port objects are valid

Syntax

```
out = isvalid(obj)
```

Description

`out = isvalid(obj)` returns the logical array `out`, which contains a `0` where the elements of the serial port object, `obj` are invalid serial port objects and a `1` where the elements of `obj` are valid serial port objects.

Examples

Suppose you create the following two serial port objects.

```
s1 = serial('COM1');
s2 = serial('COM1');
```

`s2` becomes invalid after it is deleted.

```
delete(s2)
```

`isvalid` verifies that `s1` is valid and `s2` is invalid.

```
sarray = [s1 s2];
isvalid(sarray)

ans =
     1     0
```

More About

Tips

`obj` becomes invalid after it is removed from memory with the `delete` function. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command.

See Also

`clear` | `delete`

Introduced before R2006a

isvarname

Determine whether input is valid variable name

Syntax

```
tf = isvarname('str')
isvarname str
```

Description

`tf = isvarname('str')` returns logical `1` (`true`) if the string `str` is a valid MATLAB variable name and logical `0` (`false`) otherwise. A valid variable name is a character string of letters, digits, and underscores, totaling not more than `namelengthmax` characters and beginning with a letter.

MATLAB keywords are not valid variable names. Type the command `iskeyword` with no input arguments to see a list of MATLAB keywords.

`isvarname str` uses the MATLAB command format.

Examples

This variable name is valid:

```
isvarname foo
ans =
   1
```

This one is not because it starts with a number:

```
isvarname 8th_column
ans =
   0
```

If you are building strings from various pieces, place the construction in parentheses.

```
d = date;
```

```
isvarname(['Monday_', d(1:2)])
ans =
   1
```

See Also

`matlab.lang.makeValidName` | `matlab.lang.makeUniqueStrings` | `iskeyword` | `namelengthmax` | `is*`

Introduced before R2006a

isvector

Determine whether input is vector

Syntax

```
isvector(A)
```

Description

`isvector(A)` returns logical `1` (`true`) if size(A) returns `[1 n]` or `[n 1]` with a nonnegative integer value `n`, and logical `0` (`false`) otherwise.

Examples

Test matrix `A` and its row and column vectors:

```
A = rand(5);

isvector(A)
ans =
     0

isvector(A(3, :))
ans =
     1

isvector(A(:, 2))
ans =
     1
```

See Also

`iscolumn` | `isrow` | `ismatrix` | `isscalar` | `isempty` | `isnumeric` | `islogical` | `ischar` | `isa` | `is*`

Introduced before R2006a

isweekend

Determine weekend elements

Syntax

```
tf = isweekend(t)
```

Description

`tf = isweekend(t)` returns an array the same size as `t` containing logical 1 (`true`) where the corresponding element of `t` is a datetime that occurs on a weekend day, and logical 0 (`false`) otherwise. Weekend days are Saturday and Sunday.

Examples

Determine If Date Occurs During Weekend

```
t = datetime(2014,5,2:5,'Format','eee dd-MMM-yyyy')
```

```
t =

   Fri 02-May-2014   Sat 03-May-2014   Sun 04-May-2014   Mon 05-May-2014
```

```
tf = isweekend(t)
```

```
tf =

     0     1     1     0
```

May 3 and May 4, 2014 are days that fall on a weekend.

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

See Also

`day` | `isdst`

Introduced in R2014b

i

Imaginary unit

Syntax

```
1j
z = a + bj
z = x + 1j*y
```

Description

`1j` returns the basic imaginary unit. `j` is equivalent to `sqrt(-1)`.

You can use `j` to enter complex numbers. You also can use the character `i` as the imaginary unit. To create a complex number without using `i` and `j`, use the `complex` function.

`z = a + bj` returns a complex numerical constant, `z`.

`z = x + 1j*y` returns a complex array, `z`.

Examples

Complex Scalar

Create a complex scalar and use the character, `j`, without a multiplication sign as a suffix in forming a complex numerical constant.

```
z = 1+2j
```

```
z =

   1.0000 + 2.0000i
```

Complex Vector

Create a complex vector from two 4-by-1 vectors of real numbers.

```
x = [1:4]';
y = [8:-2:2]';

z = x+1j*y
```

```
z =

   1.0000 + 8.0000i
   2.0000 + 6.0000i
   3.0000 + 4.0000i
   4.0000 + 2.0000i
```

`z` is a 4-by-1 complex vector.

Complex Exponential

Create a complex scalar representing a complex vector with radius, `r`, and angle from the origin, `theta`.

```
r = 4;
theta = pi/4;

z = r*exp(1j*theta)
```

```
z =

   2.8284 + 2.8284i
```

Input Arguments

a — Real component of complex scalar

scalar

Real component of a complex scalar, specified as a scalar.

Data Types: `single` | `double`

b — Imaginary component of complex scalar

scalar

Imaginary component of a complex scalar, specified as a scalar.

If `b` is `double`, you can use the character, `j`, without a multiplication sign as a suffix in forming the complex numerical constant.

Example: `7j`

If `b` is `single`, you must use a multiplication sign when forming the complex numerical constant.

Example: `single(7)*j`

Data Types: `single` | `double`

x — Real component of complex array

scalar | vector | matrix | multidimensional array

Real component of a complex array, specified as a scalar, vector, matrix, or mulitdimensional array.

The size of `x` must match the size of `y`, unless one is a scalar. If either `x` or `y` is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

y — Imaginary component of complex array

scalar | vector | matrix | multidimensional array

Imaginary component of a complex array, specified as a scalar, vector, matrix, or mulitdimensional array.

The size of `x` must match the size of `y`, unless one is a scalar. If either `x` or `y` is a scalar, MATLAB expands the scalar to match the size of the other input.

`single` can combine with `double`.

Data Types: `single` | `double`

Output Arguments

z — Complex array

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of `z` is the same as the input arguments.

`z` is `single` if at least one input argument is `single`. Otherwise, `z` is `double`.

More About

Tips

- For speed and improved robustness in complex arithmetic, use `1i` and `1j` instead of `i` and `j`.
- Since `j` is a function, it can be overridden and used as a variable. However, it is best to avoid using `i` and `j` for variable names if you intend to use them in complex arithmetic.
- Use the `complex` function to create a complex output in the following cases:
  - When the names `i` and `j` might be used for other variables (and do not equal `sqrt(-1)`)
  - When the inputs are not `double` or `single`
  - When the imaginary component is all zeros
- "Complex Numbers"

`complex` | `conj` | `i` | `imag` | `real`

Introduced before R2006a

javaaddpath

Add entries to dynamic Java class path

Syntax

```
javaaddpath(dpath)
javaaddpath(dpath,'-end')
```

Description

`javaaddpath(dpath)` adds one or more folders or Java Archive (JAR) files to the beginning of the current dynamic class path. Use the dynamic path when developing and debugging your own Java classes.

`javaaddpath(dpath,'-end')` adds files or folders to the end of the path.

Examples

Add Folder to Dynamic Class Path

Display the current dynamic path.

```
javaclasspath('-dynamic')
```

```
  DYNAMIC JAVA PATH

    <empty>
```

The output reflects your configuration.

Add the current folder.

```
javaaddpath(pwd)
```

Display the dynamic path.

```
p = javaclasspath
```

```
p =
    'c:\work\Java'
```

The output reflects your current folder.

Append URL to Dynamic Class Path

```
javaaddpath('http://www.example.com','-end')
p = javaclasspath
```

```
p =
    'c:\work\Java'
    'http://www.example.com'
```

Input Arguments

`dpath` — Folder or JAR file

string | cell array of strings

Folder or JAR file, specified as a string or cell array of strings, to add to the dynamic path. When you add a folder to the path, MATLAB includes all files in that folder as part of the path.

Data Types: `char` | `cell`

Limitations

- MATLAB does not support JAR files generated by the MATLAB Compiler SDK product.

More About

Tips

- MATLAB provides the dynamic path as a convenience for when you develop your own Java classes. Although the dynamic path offers flexibility in changing the path, Java classes on the dynamic path might load more slowly than classes on the static path. Also, classes on the dynamic path might not behave the same as classes on the static path. If your class does not behave as expected, use the static path.

After you develop and debug a Java class, add the class to the static path.

- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.
- To add folders to the static path, which MATLAB loads at startup, create a `javaclasspath.txt` file, as described in "Static Path".
- "Bringing Java Classes into MATLAB Workspace"

`clear` | `javaclasspath` | `javarmpath`

Introduced before R2006a

javaArray

Construct Java array object

Syntax

```
ObjArr = javaArray(PackageName.ClassName,x1,...,xN)
```

Description

`ObjArr = javaArray(PackageName.ClassName,x1,...,xN)` constructs an empty Java array object for objects of the specified PackageName.ClassName class.

Examples

Create 4-By-5 Array

Create 4-by-5 array of `java.lang.Double` type.

```
x1 = 4; x2 = 5;
dblArray = javaArray ('java.lang.Double',x1,x2);
```

Fill in values.

```
for m = 1:x1
    for n = 1:x2
        dblArray(m,n) = java.lang.Double((m*10) + n);
    end
end
```

Display results.

```
dblArray
```

```
dblArray =
java.lang.Double[][]:
    [11]    [12]    [13]    [14]    [15]
    [21]    [22]    [23]    [24]    [25]
```

```
    [31]    [32]    [33]    [34]    [35]
    [41]    [42]    [43]    [44]    [45]
```

Input Arguments

`PackageName.ClassName` — Name of Java class

string

Name of Java class, including package name, specified as a string.

Data Types: `char`

`x1,...,xN` — Dimensions of the array

integer

Dimensions of the array, specified as integer.

Data Types: `double`

Output Arguments

`ObjArr` — Java array

Java array

Java array with dimensions x1,...,xN.

More About

Java Array Object

A Java array object is an object with Java dimensionality.

Tips

- The array created by `javaArray` is equivalent to the array created by the following Java code:

  ```
  A = new PackageName.ClassName[x1]...[xN];
  ```

- To create an array of primitive Java types, create an array of the equivalent MATLAB type, shown in the Conversion of MATLAB Types to Java Types table. See "Conversion of MATLAB Argument Data".
- "Working with Java Arrays"

`class` | `isjava` | `javaMethodEDT` | `javaObjectEDT` | `methodsview`

Introduced before R2006a

javachk

Error message based on Java feature support

Syntax

```
MSG = javachk(feature)
javachk(feature,component)
```

Description

`MSG = javachk(feature)` returns a generic error message if the specified Java feature is not available in the current MATLAB session.

`javachk(feature,component)` also names the specified component in the error message.

Examples

Generate Error

```
if isempty(javachk('jvm'))
   scalar = java.lang.Double(5);
end
% Check that JVM is available & JavaFigures are supported
error(javachk('jvm'))
error(javachk('awt'))
```

Generate Error in User-Defined Script

If you write a script, `myFile`, that displays a Java Frame and want it to error gracefully if a frame cannot be displayed, do the following:

```
error(javachk('awt','myFile'));
myFrame = java.awt.Frame;
myFrame.setVisible(1);
```

If the script cannot display a frame, it displays this error:

```
myFile is not supported on this platform.
```

Input Arguments

`feature` — Java feature

`'awt' | 'desktop' | 'jvm' | 'swing'`

Java feature, specified as one of these values:

`'awt'`	UI components in the Java Abstract Window Toolkit (AWT) are available.
`'desktop'`	MATLAB interactive desktop is running.
`'jvm'`	Java Virtual Machine software (JVM™) is running.
`'swing'`	Swing components (Java lightweight UI components in the Java Foundation Classes) are available.

`component` — Identifier

string

Identifier, specified as a string, to display in the error message.

Data Types: `char`

Output Arguments

`MSG` — Error message

structure

Error message, returned as a structure with these fields:

If it is available, `javachk` returns an error structure with empty `message` and `identifier` fields.

`message` — Message

string | empty

Message, specified as a string.

`identifier` — Identifier
string | empty

Identifier, specified as a string.

See Also

`error` | `usejava`

Introduced before R2006a

javaclasspath

Return Java class path or specify dynamic path

Syntax

```
javaclasspath
javaclasspath('-dynamic')
javaclasspath('-static')

dpath = javaclasspath
spath = javaclasspath('-static')
jpath = javaclasspath('-all')

javaclasspath(dpath)
javaclasspath(dpath1,dpath2)

javaclasspath(statusmsg)
```

Description

`javaclasspath` displays the static and dynamic segments of the Java class path.

`javaclasspath('-dynamic')` displays the dynamic path.

`javaclasspath('-static')` displays the static path.

`dpath = javaclasspath` returns the dynamic path, dpath.

`spath = javaclasspath('-static')` returns the static path, spath.

`jpath = javaclasspath('-all')` returns the entire path, `jpath`. The returned cell array contains first the static segment of the path, and then the dynamic segment.

`javaclasspath(dpath)` changes the dynamic path to dpath. Use this syntax to reload Java classes you are actively developing and debugging.

`javaclasspath(dpath1,dpath2)` changes the dynamic path to the concatenation of paths dpath1,dpath2.

`javaclasspath(statusmsg)` enables or disables the display of status messages.

Examples

Modify Path Using Cell Array

Create a cell array with two path values.

```
dpath = {'http://domain.com','http://some.domain.com/jarfile.jar'};
```

Set message flag to display class-loading messages.

```
javaclasspath('-v1')
```

Modify path.

```
javaclasspath(dpath)
```

```
Loading following class path(s) from local file system:
* http://domain.com
* http://some.domain.com/jarfile.jar
```

Display updated dynamic path.

```
javaclasspath('-dynamic')
```

```
  DYNAMIC JAVA PATH

 http://domain.com
 http://some.domain.com/jarfile.jar
```

MATLAB adds folders from `dpath` to the existing path.

Capture Contents of Dynamic Path

Create a cell array, `p`, with the entries of the dynamic path.

```
javaclasspath('-v0') %Suppress display of class-loading messages
p = javaclasspath
```

```
p =

     {}
```

If there are no entries on the dynamic path, MATLAB creates an empty cell array.

Input Arguments

`dpath` — Path entries

string | cell array of strings

Path entries, specified as a string or cell array of strings, to specify for the dynamic path. Converts relative paths to absolute paths.

Example: javaclasspath('http://domain.com')

Data Types: `char` | `cell`

`dpath1,dpath2` — Path entries

string | cell array of strings

Path entries, specified as a string or cell array of strings, concatenated, to specify for the dynamic path.

Data Types: `char` | `cell`

`statusmsg` — Message flag

'-v0' (default) | '-v1'

Message flag, specified as one of these values:

`'-v0'`	Does not display status messages while loading the Java path from the file system.
`'-v1'`	Displays status messages.

Controls status message display from the `javaclasspath`, `javaaddpath`, and `javarmpath` functions.

Output Arguments

`dpath` — Dynamic path entries

cell array of strings

Dynamic path entries for the current path, returned as a cell array of strings. If no path entries are defined, `dpath` is an empty cell array.

`spath` — Static path entries

cell array of strings

Static path entries for the current path, returned as a cell array of strings. If no path entries are defined, `spath` is an empty cell array.

`jpath` — All path entries

cell array of strings

All path entries, returned as a cell array of strings. If no path entries are defined, `jpath` is an empty cell array.

More About

Static Path

The static path is a segment of the Java path which is loaded at the start of each MATLAB session from the MATLAB built-in Java path and the file `javaclasspath.txt`.

The static Java path offers better Java class-loading performance than the dynamic Java path. However, to modify the static Java path you need to edit the file `javaclasspath.txt` and restart MATLAB. For more information, see "Static Path".

Dynamic Path

The dynamic path is a segment of the Java class path.

MATLAB provides the dynamic path as a convenience for when you develop your own Java classes. You can load the dynamic path any time during a MATLAB session using the `javaclasspath` function. Although the dynamic path offers flexibility in changing the path, Java classes on the dynamic path might load more slowly than classes on the static path. Also, classes on the dynamic path might not behave the same as classes on the static path. If your class does not behave as expected, use the static path.

After you develop and debug a Java class, add the class to the static path.

You can define the dynamic path (using `javaclasspath`), modify the path (using `javaaddpath` and `javarmpath`), and refresh the Java class definitions for all classes on the dynamic path (using `clear java`) without restarting MATLAB. For more information, see "Dynamic Path".

Tips

- MATLAB searches the static path before the dynamic path.
- Java classes on the static path should not have dependencies on classes on the dynamic path. Such dependencies produce run-time errors.
- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.
- MATLAB displays a warning if you add an entry to the dynamic path that is already specified on the static path.
- "Java Class Path"

Introduced before R2006a

matlab.exception.JavaException class

Package: matlab.exception

Capture error information for Java exception

Description

Process information from a `matlab.exception.JavaException` object to handle Java errors thrown from Java methods called from MATLAB. This class is derived from `MException`.

Construction

`e = matlab.exception.JavaException(msgID,errMsg,excObj)` constructs instance e of `matlab.exception.JavaException` class.

Input Arguments

`msgID`

message identifier

`errMsg`

error message string

`excObj`

`java.lang.Throwable` object that caused the exception

Output Arguments

`e`

Instance of `matlab.exception.JavaException` class

Properties

`ExceptionObject`

Java exception object that caused the error.

Tips

- You do not typically construct a `matlab.exception.JavaException` object explicitly. MATLAB automatically constructs a `JavaException` object whenever Java throws an exception. The `JavaException` object wraps the original Java exception.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

```
try
    java.lang.Class.forName('foo');
catch e
    e.message
    if(isa(e, 'matlab.exception.JavaException'))
        ex = e.ExceptionObject;
        assert(isJava(ex));
        ex.printStackTrace;
    end
end
```

More About

- " Capture Information About Exceptions"
- "Throw an Exception"

Introduced in R2012b

javaMethod

Call Java method

Syntax

```
javaMethod(MethodName,JavaObj,x1,...,xN)
javaMethod(StaticMethodName,ClassName,x1,...,xN)
```

Description

`javaMethod(MethodName,JavaObj,x1,...,xN)` calls the method in the class of the Java object array with the signature matching the arguments x1,...,xN.

`javaMethod(StaticMethodName,ClassName,x1,...,xN)` calls the static method in class ClassName.

Examples

Call Method on Java Object

Create a `java.util.Date` object, `myDate`, and change the month to `3`.

```
myDate = java.util.Date;
javaMethod('setMonth',myDate,3);
```

Call Static Method

Call `java.lang.Double` static method, `isNaN`, to test variable `num`.

```
num = 2.2;
if javaMethod('isNaN','java.lang.Double',num)
    disp('This is not a number')
end
```

Since `num` contains a number, no message is displayed.

Call Method Specified at Runtime

This example, searching for a text pattern in a string, uses variables for the pattern and for the search method. These variables could be set at runtime from user input.

Choose method, `startsWith`, and identify pattern, `str`.

```
fnc = 'startsWith';
str = java.lang.String('Four score');
```

Identify text to search.

```
gAddress = java.lang.String('Four score and seven years ago');
```

Search `gAddress`.

```
javaMethod(fnc,gAddress,str)
```

```
ans =
     1
```

`gAddress` starts with the words `Four score`.

Input Arguments

`MethodName` — Name of nonstatic Java method

string

Name of nonstatic Java method, specified as a string.

Data Types: `char`

`JavaObj` — Array

Java object

Array, specified as a Java object of the class containing the method.

`x1,...,xN` — Java method input arguments

any type

Java method input arguments, 1 through N (if any), required by MethodName or StaticMethodName, specified by any type. The argument type is specified by the method argument list.

`StaticMethodName` — Name of static Java method
string

Name of static Java method, specified as a string.

Data Types: `char`

`ClassName` — Name of Java class
string

Name of Java class, specified as a string, containing StaticMethodName.

Data Types: `char`

More About

Tips

- In most cases, use either MATLAB or Java syntax to call methods on Java objects:

  ```
  % MATLAB syntax
  method(object,arg1,...,argn)

  /* Java syntax */
  object.method(arg1,...,argn)
  ```

- Use `javaMethod` to call methods having names that exceed the maximum length of a MATLAB identifier. (Call the `namelengthmax` function to obtain the maximum identifier length.)

  This is the only way you can call such a method in MATLAB. For example, if you have the following function:

  ```
  javaMethod('DataDefinitionAndDataManipulationTransactions',T);
  ```

- Use `javaMethod` when you want to specify the method name as a variable, to be invoked at runtime. When calling a static method, you also can use a variable in place of the class name argument. For example, see “Call Method Specified at Runtime” on page 1-4325.

- “Calling Syntax”

`import` | `isjava` | `javaArray` | `javaMethodEDT` | `javaObject` | `methods`

Introduced before R2006a

javaMethodEDT

Call Java method from Event Dispatch Thread (EDT)

Syntax

```
javaMethodEDT(MethodName,JavaObj,x1,...,xN)
javaMethodEDT(StaticMethodName,ClassName,x1,...,xN)
```

Description

`javaMethodEDT(MethodName,JavaObj,x1,...,xN)` calls the method in the class of the Java object array with the signature matching the arguments x1,...,xN from the Event Dispatch Thread (EDT)

`javaMethodEDT(StaticMethodName,ClassName,x1,...,xN)` calls the static method in class ClassName.

Examples

Call Method from EDT

Create a `java.util.Vector` object, `v`, and add a `string` element.

```
v = java.util.Vector;
javaMethodEDT('add',v,'string');
```

Input Arguments

`MethodName` — Name of nonstatic Java method

string

Name of nonstatic Java method, specified as a string.

Data Types: `char`

`JavaObj` — Array

Java object

Array, specified as a Java object of the class containing the method.

`x1,...,xN` — Java method input arguments

any type

Java method input arguments, 1 through N (if any), required by MethodName or StaticMethodName, specified by any type. The argument type is specified by the method argument list.

`StaticMethodName` — Name of static Java method

string

Name of static Java method, specified as a string.

Data Types: `char`

`ClassName` — Name of Java class

string

Name of Java class, specified as a string, containing StaticMethodName.

Data Types: `char`

More About

EDT

The EDT is the Event Dispatch Thread, used in Java.

Introduced in R2009a

javaObject

Call Java constructor

Syntax

```
JavaObj = javaObject(ClassName,x1,...,xN)
```

Description

`JavaObj = javaObject(ClassName,x1,...,xN)` returns Java object array, `JavaObj`, created by the Java constructor for the class with the argument list matching x1,...,xN.

Examples

Create Java Object

Create a Java object, `strObj`, of class `java.lang.String`.

```
strObj = javaObject('java.lang.String','hello');
```

Input Arguments

`ClassName` — Name of Java class

string

Name of Java class, specified as a string.

Data Types: `char`

`x1,...,xN` — Java constructor input arguments

any type

Java constructor input arguments, 1 through N (if any), required by ClassName, specified by any type. The argument type is specified by the class constructor argument list.

More About

- "Using the javaObjectEDT Function"

See Also

`import` | `javaArray` | `javaMethod` | `javaObjectEDT` | `methods`

Introduced before R2006a

javaObjectEDT

Call Java constructor on Event Dispatch Thread (EDT)

Syntax

```
JavaObj = javaObjectEDT(ClassName,x1,...,xN)
```

Description

`JavaObj = javaObjectEDT(ClassName,x1,...,xN)` returns Java object array, `JavaObj`, created from the EDT by the Java constructor for the class with the signature matching the arguments x1,...,xN.

Examples

Construct Java Object Array from the EDT

```
f = javaObjectEDT('javax.swing.JFrame','New Title');
```

Call Method on Java Object

Create a `JOptionPane` on the EDT.

```
optPane = javaObjectEDT('javax.swing.JOptionPane');
```

Call the `createDialog` method on the EDT.

```
dlg = optPane.createDialog([],'Sample Dialog');
```

Input Arguments

`ClassName` — Name of Java class

string

Name of Java class, specified as a string.

Data Types: `char`

`x1, . . . , xN` — Java constructor input arguments

any type

Java constructor input arguments, 1 through N (if any), required by ClassName, specified by any type. The argument type is specified by the class constructor argument list.

More About

EDT

The EDT is the Event Dispatch Thread, used in Java.

Tips

- MATLAB calls methods on JavaObj from the EDT.
- Static methods on the specified class or Java object run on the MATLAB thread unless called using the `javaMethodEDT` function.

`import` | `javaMethodEDT` | `javaObject` | `methods`

Introduced in R2009a

javarmpath

Remove entries from dynamic Java class path

Syntax

```
javarmpath(dpath1,...,dpathN)
```

Description

`javarmpath(dpath1,...,dpathN)` removes one or more files or folders from the current dynamic class path.

Examples

Remove Folder from Dynamic Path

In order to preserve the state of the dynamic path on your system, this example first adds folders to the path, then removes one of these folders.

Create a variable that points to the MATLAB examples folder.

```
expath = fullfile(matlabroot,'extern','examples')
```

```
expath =

C:\Program Files\MATLAB\R2012b\extern\examples
```

The path reflects the folder to your MATLAB installation.

Add two folders to the path.

```
javaclasspath({...
   expath,...
   'http://www.example.com'})
javaclasspath('-dynamic')
```

```
  DYNAMIC JAVA PATH
```

```
C:\Program Files\MATLAB\R2012b\extern\examples
http://www.example.com
```

The output displays these new folders on your existing path.

Remove one folder.

```
javarmpath(expath)
javaclasspath('-dynamic')

  DYNAMIC JAVA PATH

 http://www.example.com
```

The path no longer contains the examples folder.

Input Arguments

`dpath1,...,dpathN` — Folders or JAR files

string

Folders or JAR files, specified as strings, to remove from path.

Data Types: `char`

More About

Tips

- MATLAB calls the `clear java` command whenever you change the dynamic path. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory.
- “Bringing Java Classes into MATLAB Workspace”

Functions

`clear` | `javaaddpath` | `javaclasspath`

Introduced before R2006a

join

Merge two tables by matching up rows using key variables

Syntax

```
C = join(A,B)
C = join(A,B,Name,Value)
[C,ib] = join(___)
```

Description

`C = join(A,B)` merges tables `A` and `B` by matching up rows using all the variables with the same name as key variables. The key values must be common to both `A` and `B`, except for order.

`join` retains all the variables from `A` and appends the corresponding contents from the nonkey variables of `B`.

`C = join(A,B,Name,Value)` joins the tables with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the variables to use as key variables.

`[C,ib] = join(___)` also returns an index vector, ib, such that each element of `ib` identifies the row in `B` that corresponds to that row in the output table, `C`. You can use this syntax with any of the input arguments of the previous syntaxes.

Examples

Append Values from One Table to Another

Create a table, `A`.

```
A = table({'John','Jane','Jim','Jerry','Jill'}',[1;2;1;2;1],...
    'VariableNames',{'Employee' 'Department'})
```

```
A =
```

```
    Employee    Department
    ________    __________

    'John'      1
    'Jane'      2
    'Jim'       1
    'Jerry'     2
    'Jill'      1
```

Create a table, `B`, with a variable in common with `A`.

```
B = table([1 2]',{'Mary' 'Mike'}',...
    'VariableNames',{'Department' 'Manager'})
```

```
B =

    Department    Manager
    __________    _______

    1             'Mary'
    2             'Mike'
```

Create a new table, `C`, containing data from tables `A` and `B`. Use the `join` function to repeat and append `Manager` data from table `B` to the data from table `A` based on the key variable, `Department`.

```
C = join(A,B)
```

```
C =

    Employee    Department    Manager
    ________    __________    _______

    'John'      1             'Mary'
    'Jane'      2             'Mike'
    'Jim'       1             'Mary'
    'Jerry'     2             'Mike'
    'Jill'      1             'Mary'
```

Merge Tables with One Variable in Common

Create a table, `A`.

```
A = table([5;12;23;2;6],...
```

```
    {'cereal';'pizza';'salmon';'cookies';'pizza'},...
    'VariableNames',{'Age','FavoriteFood'},...
    'RowNames',{'Amy','Bobby','Holly','Harry','Sally'})
```

```
A =

              Age    FavoriteFood
              ___    ____________

    Amy        5     'cereal'
    Bobby     12     'pizza'
    Holly     23     'salmon'
    Harry      2     'cookies'
    Sally      6     'pizza'
```

Create a table, `B`, with one variable in common with `A`.

```
B = table({'cereal';'cookies';'pizza';'salmon';'cake'},...
    [110;160;140;367;243],...
    {'B';'D';'B-';'A';'C-'},...
    'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

```
B =

    FavoriteFood    Calories    NutritionGrade
    ____________    ________    ______________

    'cereal'        110         'B'
    'cookies'       160         'D'
    'pizza'         140         'B-'
    'salmon'        367         'A'
    'cake'          243         'C-'
```

Create a new table, `C`, with data from tables `A` and `B`. Use `FavoriteFood` as a key variable to the `join` function.

```
C = join(A,B)
```

```
C =

              Age    FavoriteFood    Calories    NutritionGrade
              ___    ____________    ________    ______________

    Amy        5     'cereal'        110         'B'
    Bobby     12     'pizza'         140         'B-'
```

```
    Holly    23     'salmon'        367         'A'
    Harry     2     'cookies'       160         'D'
    Sally     6     'pizza'         140         'B-'
```

Table `C` does not include information from the last row of table `B` about `'cake'` since there is no corresponding entry in table `A`.

Merge Tables by Specifying One Key Variable

Create a table, `A`.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

```
A =

    Var1    Var2    Var3
    ____    ____    ____

    10      5       10
     4      4        3
     2      9        8
     3      6        8
     7      1        4
```

Create a table, `B`, giving `Var2` the same contents as `Var2` from table `A`.

```
B = table([6;1;1;6;8],[5;4;9;6;1])
```

```
B =

    Var1    Var2
    ____    ____

    6       5
    1       4
    1       9
    6       6
    8       1
```

Create a new table, `C`, containing data from tables `A` and `B`. Use `Var1` in table `A` and `Var2` in table `B` as key variables to the `join` function.

```
C = join(A,B,'Keys','Var2')
```

```
C =
```

```
    Var1_A    Var2    Var3    Var1_B
    ______    ____    ____    ______

    10         5       10       6
     4         4        3       1
     2         9        8       1
     3         6        8       6
     7         1        4       8
```

`join` adds a unique suffix to the nonkey variable `Var1` to distinguish the data from tables `A` and `B`.

Keep One Copy of Nonkey Variables

Create a new table with data from tables `A` and `B`. If any nonkey variables have the same name in both tables, keep only the copy from table `A`.

Create a table, `A`.

```
A = table([10;4;2;3;7],[5;4;9;6;1])
```

```
A =

    Var1    Var2
    ____    ____

    10       5
     4       4
     2       9
     3       6
     7       1
```

Create a table, `B`, giving `Var2` the same contents as `Var2` from table `A`.

```
B = table([6;1;1;6;8],[5;4;9;6;1],[10;3;8;8;4])
```

```
B =

    Var1    Var2    Var3
    ____    ____    ____

    6       5       10
    1       4        3
```

```
    1        9        8
    6        6        8
    8        1        4
```

Create a new table, `C`, with data from tables `A` and `B`. Use `Var2` as a key variable to the `join` function and keep only the copy of `Var1` from table `A`.

```
C = join(A,B,'Keys','Var2','KeepOneCopy','Var1')
```

```
C =

    Var1    Var2    Var3
    ____    ____    ____

    10      5       10
     4      4        3
     2      9        8
     3      6        8
     7      1        4
```

`C` does not contain the `Var1` data from table `B`.

Merge Tables Using Row Names as Keys

Create a table, `A`.

```
A = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
    'VariableNames',{'Gender' 'Age'},...
    'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

```
A =

                Gender    Age
                ______    ___

    Smith       M         38
    Johnson     M         43
    Williams    F         38
    Jones       F         40
    Brown       F         49
```

Create a table, `B`, such that there is a one-to-one correspondence between the rows of `A` and the rows of `B`.

```
B = table([64;69;67;71;64],...
```

```
    [119;163;133;176;131],...
    [122 80; 109 77; 117 75; 124 93; 125 83],...
    'VariableNames',{'Height' 'Weight' 'BloodPressure'},...
    'RowNames',{'Brown' 'Johnson' 'Jones' 'Smith' 'Williams'})
```

```
B =

                Height    Weight     BloodPressure
                ______    ______    _______________

    Brown       64        119       122          80
    Johnson     69        163       109          77
    Jones       67        133       117          75
    Smith       71        176       124          93
    Williams    64        131       125          83
```

Create a new table, `C`, with data from tables `A` and `B`. Use the row names as keys to the `join` function.

```
C = join(A,B,'Keys','RowNames')
```

```
C =

                Gender    Age    Height    Weight     BloodPressure
                ______    ___    ______    ______    _______________

    Smith       M         38     71        176       124          93
    Johnson     M         43     69        163       109          77
    Williams    F         38     64        131       125          83
    Jones       F         40     67        133       117          75
    Brown       F         49     64        119       122          80
```

The rows of `C` are in the same order as `A`.

Merge Tables Using Left and Right Keys

Create a table, `A`.

```
A = table([10;4;2;3;7],[5;4;9;6;1],[10;3;8;8;4])
```

```
A =

    Var1    Var2    Var3
    ____    ____    ____
```

```
    10       5        10
     4       4         3
     2       9         8
     3       6         8
     7       1         4
```

Create a table, `B`, giving `Var2` the same contents as `Var1` from table `A`, except for order.

```
B = table([6;1;1;6;8],[2;3;4;7;10])
```

```
B =

    Var1    Var2
    ____    ____

    6        2
    1        3
    1        4
    6        7
    8       10
```

Create a new table, `C`, containing data from tables `A` and `B`. Use `Var1` from table `A` with `Var2` from table `B` as key variables to the `join` function.

```
[C,ib] = join(A,B,'LeftKeys',1,'RightKeys',2)
```

```
C =

    Var1_A    Var2    Var3    Var1_B
    ______    ____    ____    ______

    10         5      10       8
     4         4       3       1
     2         9       8       6
     3         6       8       1
     7         1       4       6

ib =

     5
     3
     1
     2
     4
```

`C` is the horizontal concatenation of `A` and `B(ib,2)`.

Input Arguments

`A,B` — Input tables

tables

Input tables, specified as tables. For all key variables, each row of `A` must match exactly one row in `B`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Keys',2` uses the second variable in `A` and the second variable in `B` as key variables.

`'Keys'` — Variables to use as keys

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | `'RowNames'`

Variables to use as keys, specified as the comma-separated pair consisting of `'Keys'` and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or `'RowNames'`.

If you specify the string `'RowNames'`, then `join` uses the row names of `A` and row names of `B` as keys. In this case, there must be a row in `B` for every row in `A`.

You cannot use the `'Keys'` name-value pair argument with the `'LeftKeys'` and `'RightKeys'` name-value pair arguments.

Example: `'Keys',[1 3]` uses the first and third variables from `A` and `B` as a key variables.

`'LeftKeys'` — Variables to use as keys in `A`

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. join pairs key values based on their order.

Example: 'LeftKeys',1 uses only the first variable in A as a key variable.

'RightKeys' — Variables to use as keys in B

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of 'RightKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'RightKeys' name-value pair argument in conjunction with the 'LeftKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. join pairs values in A and B based on their order.

Example: 'RightKeys',3 uses only the third variable in B as a key variable.

'LeftVariables' — Variables from A to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of 'LeftVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'LeftVariables'to include or exclude key variables, as well as nonkey variables from the output, C.

By default, join includes all variables from A.

'RightVariables' — Variables from B to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from B to include in C, specified as the comma-separated pair consisting of 'RightVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'RightVariables' to include or exclude key variables, as well as nonkey variables from the output, C.

By default, join includes all the variables from B except the key variables.

'KeepOneCopy' — Variables for which join retains only the copy from A
variable name | cell array containing one or more variable names

Variables for which join retains only the copy from A, specified as the comma-separated pair consisting of 'KeepOneCopy' and a variable name or a cell array containing one or more variable names.

Key variables appear once in C, but if nonkey variables with identical names occur in A and B, then join retains both copies in C by default. You must use the 'KeepOneCopy' name-value pair to retain only the copy from A.

Example: 'KeepOneCopy',Var2 keeps only the copy from A of the nonkey variable Var2.

Output Arguments

C — Merged data from A and B
table

Merged data from A and B, returned as a table. The table, C, contains one row for each row in A, appearing in the same order. If A and B contain nonkey variables with the same name, join adds a unique suffix to the corresponding variable names in C, unless you specify the 'KeepOneCopy' name-value pair argument.

join creates C by horizontally concatenating A(:,LeftVars) and B(ib,RightVars). By default, LeftVars is all the variables of A, and RightVars is all the nonkey variables from B. Otherwise, LefttVars consists of the variables specified by the 'LeftVariables' name-value pair argument, and RightVars consists of the variables specified by the 'RightVariables' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the output table, C. For more information, see Table Properties.

`ib` — Index to `B`

column vector

Index to `B`, returned as a column vector. Each element of `ib` identifies the row in `B` that corresponds to that row in the output table, `C`.

More About

Key Variable

Variable used to match and combine data between the input tables, `A` and `B`.

Key Value

Entry in a key variable of `A`.

Algorithms

The `join` function first finds one or more key variables. Then, `join` uses the key variables to find the row in input table `B` that matches each row in input table `A`, and combines those rows to create a row in output table `C`.

- If there is a one-to-one mapping between key values in `A` and `B`, then `join` sorts the data in `B` and appends it to table `A`.
- If there is a many-to-one mapping between key values in `A` and `B`, then `join` sorts and repeats the data in `B` before appending it to table `A`.
- If there is data in a key variable of `B` that does not map to a key value in `A`, then `join` does not include that data in the output table, `C`.

`innerjoin` | `outerjoin`

juliandate

Convert MATLAB datetime to Julian date

Syntax

```
d = juliandate(t)
d = juliandate(t,dateType)
```

Description

`d = juliandate(t)` returns a `double` array containing "Julian date" on page 1-4350 equivalent to the datetime values in `t`. If `t` has a time zone, then `juliandate` computes `d` with respect to UTC. `juliandate` ignores leap seconds unless the time zone of `t` is `UTCLeapSeconds`.

`d = juliandate(t,dateType)` returns the type of Julian dates specified by `dateType`. For example, you can convert datetime values to modified Julian dates.

Examples

Convert Datetime Array to Julian Dates

Create a `datetime` array. Then, convert the dates to Julian dates.

```
t = datetime('today') + calmonths(1:3)
```

```
t =

   23-Mar-2015   23-Apr-2015   23-May-2015
```

```
d = juliandate(t)
```

```
d =
```

```
1.0e+06 *

 2.4571    2.4571    2.4572
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`dateType` — Type of Julian date values

`'juliandate'` (default) | `'modifiedjuliandate'`

Type of Julian date values, specified as either `'juliandate'` or `'modifiedjuliandate'`.

- If `dateType` is `'juliandate'`, then `juliandate` converts the datetime values in `t` to the equivalent Julian dates. A Julian date is the number of days and fractional days since noon on November 24, 4712 BCE in the proleptic Gregorian calendar, or January 1, 4713 BCE in the proleptic Julian calendar.
- If `dateType` is `'modifiedjuliandate'`, then `juliandate` converts the datetime values in `t` to the equivalent modified Julian dates. A modified Julian date is the number of days and fractional days since November 17, 1858 00:00:00.

More About

Julian date

A Julian date is the number of days and fractional days since noon on November 24, 4712 BCE in the proleptic Gregorian calendar, or January 1, 4713 BCE in the proleptic Julian calendar.

Introduced in R2014b

keyboard

Input from keyboard

Syntax

```
keyboard
```

Description

`keyboard` , when placed in a program `.m` file, stops execution of the file and gives control to the keyboard. The special status is indicated by a `K` appearing before the prompt. You can examine or change variables; all MATLAB commands are valid. This keyboard mode is useful for debugging your functions.

To terminate the keyboard mode, type `dbcont`, and then press **Enter**. To terminate keyboard mode and exit the function, type `dbquit`, and press **Enter**.

`dbstop` | `input` | `quit` | `pause` | `dbcont`

Introduced before R2006a

keys

Class: containers.Map
Package: containers

Identify keys of `containers.Map` object

Syntax

```
keySet = keys(mapObj)
```

Description

`keySet = keys(mapObj)` returns cell array `keySet`, which contains all of the keys in `mapObj`.

Input Arguments

`mapObj`

Object of class `containers.Map`.

Output Arguments

`keySet`

1-by-`n` cell array, where `n` is the number of keys in `mapObj`.

Examples

Get the Keys in a Map

Create a map, and view the keys in the map:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);

keySet = keys(mapObj)
```

This code returns 1-by-3 cell array `keySet`:

```
keySet =
    'a'    'b'    'c'
```

See Also

`isKey` | `values` | `containers.Map` | `remove`

kron

Kronecker tensor product

Syntax

```
K = kron(A,B)
```

Description

`K = kron(A,B)` returns the Kronecker tensor product of matrices `A` and `B`. If `A` is an `m`-by-`n` matrix and `B` is a `p`-by-`q` matrix, then `kron(A,B)` is an `m*p`-by-`n*q` matrix formed by taking all possible products between the elements of `A` and the matrix `B`.

Examples

Block Diagonal Matrix

Create a block diagonal matrix.

Create a 4-by-4 identity matrix and a 2-by-2 matrix that you want to be repeated along the diagonal.

```
A = eye(4);
B = [1 -1;-1 1];
```

Use `kron` to find the Kronecker tensor product.

```
K = kron(A,B)
```

```
K =

     1    -1     0     0     0     0     0     0
    -1     1     0     0     0     0     0     0
     0     0     1    -1     0     0     0     0
     0     0    -1     1     0     0     0     0
     0     0     0     0     1    -1     0     0
```

```
     0     0     0     0    -1     1     0     0
     0     0     0     0     0     0     1    -1
     0     0     0     0     0     0    -1     1
```

The result is an 8-by-8 block diagonal matrix.

Repeat Matrix Elements

Expand the size of a matrix by repeating elements.

Create a 2-by-2 matrix of ones and a 2-by-3 matrix whose elements you want to repeat.

```
A = [1 2 3; 4 5 6];
B = ones(2);
```

Calculate the Kronecker tensor product using `kron`.

```
K = kron(A,B)
```

```
K =

     1     1     2     2     3     3
     1     1     2     2     3     3
     4     4     5     5     6     6
     4     4     5     5     6     6
```

The result is a 4-by-6 block matrix.

Sparse Laplacian Operator Matrix

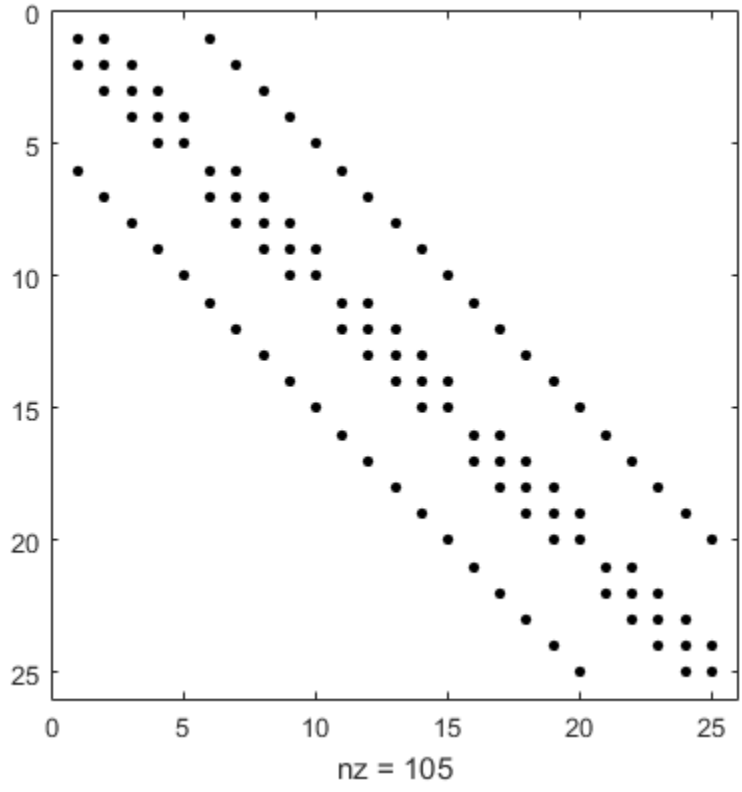
This example visualizes a sparse Laplacian operator matrix.

The matrix representation of the discrete Laplacian operator on a two-dimensional, `n`-by-`n` grid is a `n*n`-by- `n*n` sparse matrix. There are at most five nonzero elements in each row or column. You can generate the matrix as the Kronecker product of one-dimensional difference operators. In this example `n = 5`.

```
n = 5;
I = speye(n,n);
E = sparse(2:n,1:n-1,1,n,n);
D = E+E'-2*I;
A = kron(D,I)+kron(I,D);
```

Visualize the sparsity pattern with `spy`.

```
spy(A,'k')
```



Input Arguments

A,B — Input matrices

scalars | vectors | matrices

Input matrices, specified as scalars, vectors, or matrices. If either `A` or `B` is sparse, then `kron` multiplies only nonzero elements and the result is also sparse.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Complex Number Support: Yes

More About

Kronecker Tensor Product

If A is an m-by-n matrix and B is a p-by-q matrix, then the Kronecker tensor product of A and B is a large matrix formed by multiplying B by each element of A

$$A \otimes B = \begin{bmatrix} a_{11}B & a_{12}B & \cdots & a_{1n}B \\ a_{21}B & a_{22}B & \cdots & a_{2n}B \\ \vdots & \vdots & \ddots & \vdots \\ a_{m1}B & a_{m2}B & \cdots & a_{mn}B \end{bmatrix}.$$

For example, two simple 2-by-2 matrices produce

$$A = \begin{bmatrix} 1 & -2 \\ -1 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 4 & -3 \\ 2 & 3 \end{bmatrix}$$

$$A \otimes B = \begin{bmatrix} 1\cdot 4 & 1\cdot -3 & -2\cdot 4 & -2\cdot -3 \\ 1\cdot 2 & 1\cdot 3 & -2\cdot 2 & -2\cdot 3 \\ -1\cdot 4 & -1\cdot -3 & 0\cdot 4 & 0\cdot -3 \\ -1\cdot 2 & -1\cdot 3 & 0\cdot 2 & 0\cdot 3 \end{bmatrix} = \begin{bmatrix} 4 & -3 & -8 & 6 \\ 2 & 3 & -4 & -6 \\ -4 & 3 & 0 & 0 \\ -2 & -3 & 0 & 0 \end{bmatrix}.$$

Using KeyValueStore Objects

Store key-value pairs for use with mapreduce

The `mapreduce` function automatically creates a `KeyValueStore` object during execution and uses it to store key-value pairs added by the map and reduce functions. Although you never need to explicitly create a `KeyValueStore` object to use `mapreduce`, you do need to use the `add` and `addmulti` object functions to interact with this object in the map and reduce functions.

Examples

Add Key-Value Pair to KeyValueStore in Map Function

The following map function uses the `add` function to add key-value pairs one at a time to an intermediate `KeyValueStore` object (named `intermKVStore`).

```
function MeanDistMapFun(data, info, intermKVStore)
    distances = data.Distance(~isnan(data.Distance));
    sumLenKey = 'sumAndLength';
    sumLenValue = [sum(distances), length(distances)];
    add(intermKVStore, sumLenKey, sumLenValue);
end
```

Add Multiple Key-Value Pairs to KeyValueStore in Map Function

The following map function uses `addmulti` to add several key-value pairs to an intermediate `KeyValueStore` object (named `intermKVStore`). Note that this map function collects multiple keys in the `intermKeys` variable, and multiple values in the `intermVals` variable. This prepares a single call to `addmulti` to add all of the key-value pairs at once. It is a best practice to use a single call to `addmulti` rather than using `add` in a loop.

```
function meanArrivalDelayByDayMapper(data, ~, intermKVStore)
% Mapper function for the MeanByGroupMapReduceExample.

% Copyright 2014 The MathWorks, Inc.

% Data is an n-by-2 table: first column is the DayOfWeek and the second
% is the ArrDelay. Remove missing values first.
delays = data.ArrDelay;
```

```
day = data.DayOfWeek;
notNaN =~isnan(delays);
day = day(notNaN);
delays = delays(notNaN);

% find the unique days in this chunk
[intermKeys,~,idx] = unique(day, 'stable');

% group delays by idx and apply @grpstatsfun function to each group
intermVals = accumarray(idx,delays,size(intermKeys),@countsum);
addmulti(intermKVStore,intermKeys,intermVals);

function out = countsum(x)
n = length(x); % count
s = sum(x); % mean
out = {[n, s]};
```

Object Functions

`add` `addmulti`

Create Object

The `mapreduce` function automatically creates `KeyValueStore` objects during execution.

`mapreduce`

More About

- “Getting Started with MapReduce”

lastDirectory

Class: Tiff

Determine if current IFD is last in file

Syntax

```
tf = lastDirectory(tiffobj)
```

Description

`tf = lastDirectory(tiffobj)` returns `true` if the current image file directory (IFD) is the last IFD in the TIFF file; otherwise, `false`. If the file contains only one image, the current IFD is the last.

Examples

Determine if Current Directory is the Last Directory

Open a `Tiff` object and determine if the current directory is the last directory in the file.

```
t = Tiff('example.tif','r');
tf = lastDirectory(t)
```

```
tf =

     0
```

The current directory is not the last directory in the file.

Close the `Tiff` object.

```
close(t)
```

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

References

This method corresponds to the `TIFFLastDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

Chart Line Properties

Control chart line appearance and behavior

Chart line properties control the appearance and behavior of a chart line object. By changing property values, you can modify certain aspects of the line.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = plot(1:10);
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Line

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	
`':'`	Dotted line	
`'-.'`	Dash-dotted line	`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`Color` — Line color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the `Color` as `'none'`, then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`AlignVertexCenters` — Sharp vertical and horizontal lines

`'off'` (default) | `'on'`

Sharp vertical and horizontal lines, specified as `'off'` or `'on'`.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the chart line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerSize` — Marker size

`6` (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Data

`XData` — x values

vector

x values, specified as a vector.

- For 2-D line plots, if you do not specify the *x* values, then MATLAB uses the indices of `YData` as the *x* values for the plot. `XData` and `YData` must have equal lengths.

- For 3-D line plots, if you do not specify the *x* values, then MATLAB uses the indices of `ZData` as the *x* values for the plot. `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1:10]`

`YData` — y values

vector

y values, specified as a vector. For 2-D line plots, `XData` and `YData` must have equal lengths. For 3-D line plots, `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1:10]`

`ZData` — z values

vector

z values for the 3-D line plot, specified as a vector. `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1:10]`

`XDataSource` — Variable linked to `XData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`ZDataSource` — Variable linked to `ZData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `ZData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `ZData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `ZData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'z'`

`XDataMode` — Selection mode for `XData`

`'auto'` (default) | `'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the indices of the values in `YData` (or `ZData` for 3-D plots).
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

Visibility

`Visible` — Visibility of chart line

`'on'` (default) | `'off'`

Visibility of chart line, specified as one of these values:

- `'on'` — Display the chart line.
- `'off'` — Hide the chart line without deleting it. You still can access the properties of an invisible chart line object.

`Clipping` — Clipping of chart line to axes limits

`'on'` (default) | `'off'`

Clipping of chart line to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the chart line that are outside the axes limits.
- `'off'` — Display the entire chart line, even if parts of it appear outside the axes limits. Parts of the chart line might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the chart line that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.

- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object
`'line'`

Type of graphics object, returned as `'line'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — User-specified tag
`''` (default) | string

Tag to associate with the chart line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with chart line
`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the chart line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the chart line.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the chart line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the chart line from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:

- `'on'` — Include the chart line object in the legend as one entry (default).
- `'off'` — Do not include the chart line object in the legend.
- `'children'` — Include only children of the chart line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of chart line

axes object | group object | transform object

Parent of chart line, specified as an axes, group, or transform object.

`Children` — Children of chart line

empty `GraphicsPlaceholder` array

The chart line has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of chart line object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The chart line object handle is always visible.
- `'off'` — The chart line object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The chart line object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the chart line at the command-line, but allows callback functions to access it.

If the chart line object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle

properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the chart line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the chart line. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the chart line when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the chart line.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the chart line that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the chart line responds to the click or if an ancestor does.

- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'` and you can click a part of the chart line that has no color. The HitTest property determines if the chart line responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the chart line passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the chart line. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the chart line that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the chart line object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the ButtonDownFcn callback of the chart line is the running callback, then the Interruptible property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a drawnow, figure, getframe, waitfor, or pause command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

BusyAction — Callback queuing
'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The BusyAction property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the ButtonDownFcn callback of the chart line tries to interrupt a running callback that cannot be interrupted, then the BusyAction property determines if it is discarded or put in the queue. Specify the BusyAction property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.

- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the chart line. Setting the `CreateFcn` property on an existing chart line has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during chart line creation. MATLAB executes the callback after creating the chart line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function. You also can access the chart line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the chart line. MATLAB executes the callback before destroying the chart line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart line object — You can access properties of the chart line object from within the callback function. You also can access the chart line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of chart line

`'off'` (default) | `'on'`

Deletion status of chart line, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the chart line begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the chart line no longer exists.

Check the value of the BeingDeleted property to verify that the chart line is not about to be deleted before querying or modifying it.

- “Graphics Object Properties”

lasterr

Last error message

Note: `lasterr` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See " Capture Information About Exceptions" in the Programming Fundamentals documentation.

Syntax

```
msgstr = lasterr
[msgstr, msgid] = lasterr
lasterr('new_msgstr')
lasterr('new_msgstr', 'new_msgid')
[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')
```

Description

`msgstr = lasterr` returns the last error message generated by the MATLAB software.

`[msgstr, msgid] = lasterr` returns the last error in `msgstr` and its message identifier in `msgid`. If the error was not defined with an identifier, `lasterr` returns an empty string for `msgid`. See "Message Identifiers" in the MATLAB Programming Fundamentals documentation for more information on the `msgid` argument and how to use it.

`lasterr('new_msgstr')` sets the last error message to a new string, `new_msgstr`, so that subsequent invocations of `lasterr` return the new error message string. You can also set the last error to an empty string with `lasterr('')`.

`lasterr('new_msgstr', 'new_msgid')` sets the last error message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lasterr` return the new error message and message identifier.

`[msgstr, msgid] = lasterr('new_msgstr', 'new_msgid')` returns the last error message and its identifier, also changing these values so that subsequent

invocations of `lasterr` return the message and identifier strings specified by `new_msgstr` and `new_msgid` respectively.

Examples

Example 1

Here is a function that examines the `lasterr` string and displays its own message based on the error that last occurred. This example deals with two cases, each of which is an error that can result from a matrix multiply:

```
function matrix_multiply(A, B)
try
   A * B
catch
   errmsg = lasterr;
   if(strfind(errmsg, 'Inner matrix dimensions'))
      disp('** Wrong dimensions for matrix multiply')
   else
      if(strfind(errmsg, 'not defined for variables of class'))
         disp('** Both arguments must be double matrices')
      end
   end
end
```

If you call this function with matrices that are incompatible for matrix multiplication (e.g., the column dimension of `A` is not equal to the row dimension of `B`), MATLAB catches the error and uses `lasterr` to determine its source:

```
A = [1  2  3; 6  7  2; 0  -1  5];
B = [9  5  6; 0  4  9];

matrix_multiply(A, B)
** Wrong dimensions for matrix multiply
```

Example 2

Specify a message identifier and error message string with `error`:

```
error('MyToolbox:angleTooLarge', ...
      'The angle specified must be less than 90 degrees.');
```

In your error handling code, use `lasterr` to determine the message identifier and error message string for the failing operation:

```
[errmsg, msgid] = lasterr
errmsg =
   The angle specified must be less than 90 degrees.
msgid =
   MyToolbox:angleTooLarge
```

Introduced before R2006a

lasterror

Last error message and related information

Note: `lasterror` will be removed in a future version. You can obtain information about any error that has been generated by catching an `MException`. See " Capture Information About Exceptions" in the Programming Fundamentals documentation.

Syntax

```
s = lasterror
s = lasterror(err)
s = lasterror('reset')
```

Description

`s = lasterror` returns a structure `s` containing information about the most recent error issued by the MATLAB software. The return structure contains the following fields:

Fieldname	Description
`message`	Character array containing the text of the error message.
`identifier`	Character array containing the message identifier of the error message. If the last error issued by MATLAB had no message identifier, then the `identifier` field is an empty character array.
`stack`	Structure providing information on the location of the error. The structure has fields `file`, `name`, and `line`, and is the same as the structure returned by the `dbstack` function. If `lasterror` returns no stack information, `stack` is a 0-by-1 structure having the same three fields.

Note The `lasterror` return structure might contain additional fields in future versions of MATLAB.

The fields of the structure returned in `stack` are

Fieldname	Description
`file`	Name of the file in which the function generating the error appears. This field is the empty string if there is no file.
`name`	Name of the function in which the error occurred. If this is the primary function in the file, and the function name differs from the file name, `name` is set to the file name.
`line`	Line number of the file at which the error occurred.

See "Message Identifiers" in the MATLAB Programming Fundamentals documentation for more information on the syntax and usage of message identifiers.

`s = lasterror(err)` sets the last error information to the error message and identifier specified in the structure `err`. Subsequent invocations of `lasterror` return this new error information. The optional return structure `s` contains information on the previous error.

`s = lasterror('reset')` sets the last error information to the default state. In this state, the `message` and `identifier` fields of the return structure are empty strings, and the `stack` field is a 0-by-1 structure.

Examples

Example 1

Save the following MATLAB code in a file called `average.m`:

```
function y = average(x)
% AVERAGE Mean of vector elements.
% AVERAGE(X), where X is a vector, is the mean of vector elements.
% Nonvector input results in an error.
check_inputs(x)
y = sum(x)/length(x);      % The actual computation

function check_inputs(x)
[m,n] = size(x);
if (~((m == 1) || (n == 1)) || (m == 1 && n == 1))
    error('AVG:NotAVector', 'Input must be a vector.')
end
```

Now run the function. Because this function requires vector input, passing a scalar value to it forces an error. The error occurs in subroutine `check_inputs`:

```
average(200)
Error using average>check_inputs (line 11)
Input must be a vector.

Error in average (line 5)
check_inputs(x)
```

Get the three fields from `lasterror`:

```
err = lasterror
err =
       message: [1x61 char]
    identifier: 'AVG:NotAVector'
         stack: [2x1 struct]
```

Display the text of the error message:

```
msg = err.message
msg =
    Error using average>check_inputs (line 11)
    Input must be a vector.
```

Display the fields containing the `stack` information. `err.stack` is a 2-by-1 structure because it provides information on the failing subroutine `check_inputs` and also the outer, primary function `average`:

```
st1 = err.stack(1,1)
st1 =
    file: 'd:\matlab_test\average.m'
    name: 'check_inputs'
    line: 11

st2 = err.stack(2,1)
st2 =
    file: 'd:\matlab_test\average.m'
    name: 'average'
    line: 5
```

Note As a rule, the name of your primary function should be the same as the name of the file that contains that function. If these names differ, MATLAB uses the file name in the `name` field of the `stack` structure.

Example 2

`lasterror` is often used in conjunction with the `MException.rethrow` function in `try, catch` statements. For example,

```
try
   do_something
catch
   do_cleanup
   rethrow(lasterror)
end
```

More About

Tips

MathWorks is gradually transitioning MATLAB error handling to an object-oriented scheme that is based on the `MException` class. Although support for `lasterror` is expected to continue, using the static `MException.last` method of `MException` is preferable.

Warning `lasterror` and `MException.last` are not guaranteed to always return identical results. For example, `MException.last` updates its error status only on uncaught errors, where `lasterror` can update its error status on any error, whether it is caught or not.

Introduced before R2006a

lastwarn

Last warning message

Syntax

```
msgstr = lastwarn
[msgstr, msgid] = lastwarn
lastwarn('new_msgstr')
lastwarn('new_msgstr', 'new_msgid')
[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')
```

Description

`msgstr = lastwarn` returns the last warning message generated by MATLAB, regardless of its display state.

`[msgstr, msgid] = lastwarn` returns the last warning in `msgstr` and its message identifier in `msgid`. If the warning was not defined with an identifier, `lastwarn` returns an empty string for `msgid`.

`lastwarn('new_msgstr')` sets the last warning message to a new string, `new_msgstr`, so that subsequent invocations of `lastwarn` return the new warning message string. You can also set the last warning to an empty string with `lastwarn('')`.

`lastwarn('new_msgstr', 'new_msgid')` sets the last warning message and its identifier to new strings `new_msgstr` and `new_msgid`, respectively. Subsequent invocations of `lastwarn` return the new warning message and message identifier.

`[msgstr, msgid] = lastwarn('new_msgstr', 'new_msgid')` returns the last warning message and its identifier, also changing these values so that subsequent invocations of `lastwarn` return the message and identifier strings specified by `new_msgstr` and `new_msgid`, respectively.

Examples

Write a short function that generates a warning message. At the start of the function, enable any warnings that have a message identifier called `TestEnv:InvalidInput`:

```
function myfun(p1)
warning on TestEnv:InvalidInput;

exceedMax = find(p1 > 5000);
if any(exceedMax)
    warning('TestEnv:InvalidInput', ...
        '%d values in the "%s" array exceed the maximum.', ...
        length(exceedMax), inputname(1))
end
```

Pass an invalid value to the function:

```
dataIn = magic(10) - 2;

myfun(dataIn)
Warning: 2 values in the "dataIn" array exceed the maximum.
> In myfun at 4
```

Use `lastwarn` to determine the message identifier and error message string for the operation:

```
[warnmsg, msgid] = lastwarn
warnmsg =
   2 values in the "dataIn" array exceed the maximum.
msgid =
   TestEnv:InvalidInput
```

More About

Tips

`lastwarn` does not return warnings that are reported during the parsing of MATLAB commands. (Warning messages that include the failing file name and line number are parse-time warnings.)

Introduced before R2006a

lcm

Least common multiple

Syntax

```
L = lcm(A,B)
```

Description

`L = lcm(A,B)` returns the least common multiples of the elements of `A` and `B`.

Examples

Least Common Multiples of Double Array and a Scalar

```
A = [5 17; 10 60];
B = 45;
L = lcm(A,B)
```

```
L =

    45   765
    90   180
```

Least Common Multiples of Unsigned Integers

```
A = uint16([255 511 15]);
B = uint16([15 127 1023]);
L = lcm(A,B)
```

```
L =

    255  64897   5115
```

Input Arguments

`A,B` — Input values

scalars, vectors, or arrays of real, positive integer values

Input values, specified as scalars, vectors, or arrays of real, positive integer values. A and B can be any numeric type, and they can be of different types within certain limitations:

- If A or B is of type `single`, then the other can be of type `single` or `double`.
- If A or B belongs to an integer class, then the other must belong to the same class or it must be a `double` scalar value.

A and B must be the same size or one must be a scalar.

Example: `[20 3 13],[10 6 7]`

Example: `int16([100 30 200]),int16([20 15 9])`

Example: `int16([100 30 200]),20`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Output Arguments

L — Least common multiple

real, positive integer values

Least common multiple, returned as an array of real positive integer values. L is the same size as A and B, and it has the same type as A and B. If A and B are of different types, then L is returned as the nondouble type.

`gcd`

Introduced before R2006a

ldl

Block LDL' factorization for Hermitian indefinite matrices

Syntax

```
L = ldl(A)
[L,D] = ldl(A)
[L,D,P] = ldl(A)
[L,D,p] = ldl(A,'vector')
[U,D,P] = ldl(A,'upper')
[U,D,p] = ldl(A,'upper','vector')
[L,D,P,S] = ldl(A)
[L,D,P,S] = LDL(A,THRESH)
[U,D,p,S] = LDL(A,THRESH,'upper','vector')
```

Description

`L = ldl(A)` returns only the permuted lower triangular matrix `L` as in the two-output form. The permutation information is lost, as is the block diagonal factor `D`. By default, `ldl` references only the diagonal and lower triangle of `A`, and assumes that the upper triangle is the complex conjugate transpose of the lower triangle. Therefore `[L,D,P] = ldl(TRIL(A))` and `[L,D,P] = ldl(A)`both return the exact same factors. Note, this syntax is not valid for sparse `A`.

`[L,D] = ldl(A)` stores a block diagonal matrix `D` and a permuted lower triangular matrix in `L` such that `A = L*D*L'`. The block diagonal matrix `D` has 1-by-1 and 2-by-2 blocks on its diagonal. Note, this syntax is not valid for sparse `A`.

`[L,D,P] = ldl(A)` returns unit lower triangular matrix `L`, block diagonal `D`, and permutation matrix `P` such that `P'*A*P = L*D*L'`. This is equivalent to `[L,D,P] = ldl(A,'matrix')`.

`[L,D,p] = ldl(A,'vector')` returns the permutation information as a vector, `p`, instead of a matrix. The `p` output is a row vector such that `A(p,p) = L*D*L'`.

`[U,D,P] = ldl(A,'upper')` references only the diagonal and upper triangle of `A` and assumes that the lower triangle is the complex conjugate transpose of the upper triangle.

This syntax returns a unit upper triangular matrix `U` such that `P'*A*P = U'*D*U` (assuming that `A` is Hermitian, and not just upper triangular). Similarly, `[L,D,P] = ldl(A,'lower')` gives the default behavior.

`[U,D,p] = ldl(A,'upper','vector')` returns the permutation information as a vector, `p`, as does `[L,D,p] = ldl(A,'lower','vector')`. `A` must be a full matrix.

`[L,D,P,S] = ldl(A)` returns unit lower triangular matrix `L`, block diagonal `D`, permutation matrix `P`, and scaling matrix `S` such that `P'*S*A*S*P = L*D*L'`. This syntax is only available for real sparse matrices, and only the lower triangle of `A` is referenced. `ldl` uses MA57 for sparse real symmetric `A`.

`[L,D,P,S] = LDL(A,THRESH)` uses `THRESH` as the pivot tolerance in MA57. `THRESH` must be a double scalar lying in the interval `[0, 0.5]`. The default value for `THRESH` is `0.01`. Using smaller values of `THRESH` may give faster factorization times and fewer entries, but may also result in a less stable factorization. This syntax is available only for real sparse matrices.

`[U,D,p,S] = LDL(A,THRESH,'upper','vector')` sets the pivot tolerance and returns upper triangular `U` and permutation vector `p` as described above.

Examples

These examples illustrate the use of the various forms of the `ldl` function, including the one-, two-, and three-output form, and the use of the `vector` and `upper` options. The topics covered are:

Before running any of these examples, you will need to generate the following positive definite and indefinite Hermitian matrices:

```
A = full(delsq(numgrid('L', 10)));
```

```
B = gallery('uniformdata',10,0);
M = [eye(10) B; B' zeros(10)];
```

The structure of M here is very common in optimization and fluid-flow problems, and M is in fact indefinite. Note that the positive definite matrix A must be full, as `ldl` does not accept sparse arguments.

Example 1 — Two-Output Form of ldl

The two-output form of `ldl` returns L and D such that `A-(L*D*L')` is small, L is permuted unit lower triangular, and D is a block 2-by-2 diagonal. Note also that, because A is positive definite, the diagonal of D is all positive:

```
[LA,DA] = ldl(A);
fprintf(1, ...
'The factorization error ||A - LA*DA*LA''|| is %g\n', ...
norm(A - LA*DA*LA'));
neginds = find(diag(DA) < 0)
```

Given a b, solve Ax=b using LA, DA:

```
bA = sum(A,2);
x = LA'\(DA\(LA\bA));
fprintf(...
'The absolute error norm ||x - ones(size(bA))|| is %g\n', ...
norm(x - ones(size(bA))));
```

Example 2 — Three Output Form of ldl

The three output form returns the permutation matrix as well, so that L is in fact unit lower triangular:

```
[Lm, Dm, Pm] = ldl(M);
fprintf(1, ...
'The error norm ||Pm''*M*Pm - Lm*Dm*Lm''|| is %g\n', ...
norm(Pm'*M*Pm - Lm*Dm*Lm'));
fprintf(1, ...
'The difference between Lm and tril(Lm) is %g\n', ...
norm(Lm - tril(Lm)));
```

Given b, solve Mx=b using Lm, Dm, and Pm:

```
bM = sum(M,2);
```

```
x = Pm*(Lm'\(Dm\(Lm\(Pm'*bM))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

Example 3 — The Structure of D

D is a block diagonal matrix with 1-by-1 blocks and 2-by-2 blocks. That makes it a special case of a tridiagonal matrix. When the input matrix is positive definite, D is almost always diagonal (depending on how definite the matrix is). When the matrix is indefinite however, D may be diagonal or it may express the block structure. For example, with A as above, DA is diagonal. But if you shift A just a bit, you end up with an indefinite matrix, and then you can compute a D that has the block structure.

```
figure; spy(DA); title('Structure of D from ldl(A)');
[Las, Das] = ldl(A - 4*eye(size(A)));
figure; spy(Das);
title('Structure of D from ldl(A - 4*eye(size(A)))');
```

Example 4 — Using the 'vector' Option

Like the `lu` function, `ldl` accepts an argument that determines whether the function returns a permutation vector or permutation matrix. `ldl` returns the latter by default. When you select `'vector'`, the function executes faster and uses less memory. For this reason, specifying the `'vector'` option is recommended. Another thing to note is that indexing is typically faster than multiplying for this kind of operation:

```
[Lm, Dm, pm] = ldl(M, 'vector');
fprintf(1, 'The error norm ||M(pm,pm) - Lm*Dm*Lm''|| is %g\n', ...
  norm(M(pm,pm) - Lm*Dm*Lm'));

% Solve a system with this kind of factorization.
clear x;
x(pm,:) = Lm'\(Dm\(Lm\(bM(pm,:))));
fprintf('The absolute error norm ||x - ones(size(b))|| is %g\n', ...
  norm(x - ones(size(bM))));
```

Example 5 — Using the 'upper' Option

Like the `chol` function, `ldl` accepts an argument that determines which triangle of the input matrix is referenced, and also whether `ldl` returns a lower (`L`) or upper (`L'`) triangular factor. For dense matrices, there are no real savings with using the upper triangular version instead of the lower triangular version:

```
Ml = tril(M);
[Lml, Dml, Pml] = ldl(Ml, 'lower'); % 'lower' is default behavior.
fprintf(1, ...
'The difference between Lml and Lm is %g\n', norm(Lml - Lm));
[Umu, Dmu, pmu] = ldl(triu(M), 'upper', 'vector');
fprintf(1, ...
'The difference between Umu and Lm'' is %g\n', norm(Umu - Lm'));

% Solve a system using this factorization.
clear x;
x(pm,:) = Umu\(Dmu\(Umu'\(bM(pmu,:))));
fprintf(...
'The absolute error norm ||x - ones(size(b))|| is %g\n', ...
norm(x - ones(size(bM))));
```

When specifying both the `'upper'` and `'vector'` options, `'upper'` must precede `'vector'` in the argument list.

Example 6 — linsolve and the Hermitian indefinite solver

When using the `linsolve` function, you may experience better performance by exploiting the knowledge that a system has a symmetric matrix. The matrices used in the examples above are a bit small to see this so, for this example, generate a larger matrix. The matrix here is symmetric positive definite, and below we will see that with each bit of knowledge about the matrix, there is a corresponding speedup. That is, the symmetric solver is faster than the general solver while the symmetric positive definite solver is faster than the symmetric solver:

```
Abig = full(delsq(numgrid('L', 30)));
bbig = sum(Abig, 2);
LSopts.POSDEF = false;
LSopts.SYM = false;
tic; linsolve(Abig, bbig, LSopts); toc;
LSopts.SYM = true;
tic; linsolve(Abig, bbig, LSopts); toc;
LSopts.POSDEF = true;
tic; linsolve(Abig, bbig, LSopts); toc;
```

More About

Algorithms

`ldl` uses the MA57 routines in the Harwell Subroutine Library (HSL) for real sparse matrices.

`chol` | `lu` | `qr`

ldivide, .\

Left array division

Syntax

```
x = B.\A
x = ldivide(B,A)
```

Description

`x = B.\A` divides each element of A by the corresponding element of B.

- If A and B are arrays, then they must be the same size.
- If either A or B is a scalar, then MATLAB expands the scalar value into an appropriately sized array.

`x = ldivide(B,A)` is an alternative way to divide A by B, but is rarely used. It enables operator overloading for classes.

Examples

Divide Two Numeric Arrays

```
A = ones(2, 3);
B = [1 2 3; 4 5 6];
x = B.\A
```

```
x =

    1.0000    0.5000    0.3333
    0.2500    0.2000    0.1667
```

Divide a Scalar by a Numeric Array

```
C = 2;
D = [1 2 3; 4 5 6];
x = D.\C
```

```
x =

    2.0000    1.0000    0.6667
    0.5000    0.4000    0.3333
```

Input Arguments

A — Numerator

scalar | vector | matrix | multidimensional array

Numerator, specified as a scalar, vector, matrix or multidimensional array. If B is an integer data type, then A must be the same integer type or a scalar double.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `duration`
Complex Number Support: Yes

B — Denominator

scalar | vector | matrix | multidimensional array

Denominator, specified as a scalar, vector, matrix or multidimensional array. If A is an integer data type, then B must be the same integer type or a scalar double.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `duration`
Complex Number Support: Yes

Output Arguments

x — Solution

scalar | vector | matrix | multidimensional array

Solution, returned as a scalar, vector, matrix or multidimensional array. If either A or B are integer data types, then x is that same integer data type.

More About

Tips

- MATLAB does not support complex integer division.

`mldivide` | `mrdivide` | `rdivide`

Introduced before R2006a

le, <=

Determine less than or equal to

Syntax

```
A <= B
le(A,B)
```

Description

`A <= B` returns a logical array with elements set to logical 1 (`true`) where `A` is less than or equal to `B`; otherwise, it returns logical `0` (`false`).

The test compares only the real part of numeric arrays. `le` returns logical `0` (`false`) where `A` or `B` have NaN or undefined categorical elements.

`le(A,B)` is an alternate way to execute `A <= B`, but is rarely used. It enables operator overloading for classes.

Examples

Test Vector Elements

Find which vector elements are less than or equal to a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than or equal to `12`.

```
A <= 12
```

```
ans =

     1     1     0     1     1     1     1     0
```

The result is a vector with values of logical 1 (`true`) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than or equal to 12.

```
A(A <= 12)
```

```
ans =

     1    12     7     9    11     2
```

The result is a subset of the elements in A.

Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =

    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Replace all values less than or equal to 9 with the value 10.

```
A(A <= 9) = 10
```

```
A =

    16    10    10    13
    10    11    10    10
    10    10    10    12
    10    14    15    10
```

The result is a new matrix whose smallest element is 10.

Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
```

```
'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)

A =

     large       medium      small
     medium      small       large
```

The array has three categories: `'small'`, `'medium'`, and `'large'`.

Find all values less than or equal to the category `'medium'`.

```
A <= 'medium'

ans =

     0     1     1
     1     1     0
```

A value of logical `1` (`true`) indicates a value less than or equal to the category `'medium'`.

Compare the rows of `A`.

```
A(1,:) <= A(2,:)

ans =

     0     0     1
```

The function returns logical `1` (`true`) where the first row has a category value less than or equal to the second row.

Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than or equal to `3`.

```
A(A <= 3)

ans =

   1.0000 + 1.0000i   2.0000 - 2.0000i   1.0000 + 3.0000i   1.0000 - 2.0000i
```

`le` compares only the real part of the elements in `A`.

Use `abs` to find which elements are within a radius of `3` from the origin.

```
A(abs(A) <= 3)
```

```
ans =

   1.0000 + 1.0000i   2.0000 - 2.0000i   1.0000 - 2.0000i
```

The result has one less element. The element `1.0000 + 3.0000i` is not within a radius of `3` from the origin.

Test Duration Values

Create a `duration` array.

```
d = hours(21:25) + minutes(75)
```

```
d =

   22.25 hrs   23.25 hrs   24.25 hrs   25.25 hrs   26.25 hrs
```

Test the array for elements that are less than or equal to one standard day.

```
d <= 1
```

```
ans =

     1     1     0     0     0
```

Input Arguments

A — Left array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Left array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

B — Right array

numeric array | logical array | character array | ordinal categorical array | datetime array | duration array

Right array, specified as a numeric array, logical array, character array, categorical array, datetime array, or duration array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See "Compare Categorical Array Elements" for more details.

If one input is a datetime array, the other input can be a datetime array, a date string, or a cell array of date strings.

If one input is a duration array, the other input can be a duration array or a numeric array. `eq` treats each numeric value as a number of standard (86400 s) days.

More About

Tips

- Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the `<=` operator reflects. For more information, see "Avoiding Common Problems with Floating-Point Arithmetic".
- "Ordinal Categorical Arrays"

`eq | ge | gt | lt | ne`

Introduced before R2006a

legend

Add legend to graph

Syntax

```
legend('string1',...,'stringN')
legend('string1',...,'stringN','Location',Value)
legend(___,'Orientation',Value)

legend(strings)
legend(strings,Name,Value)

legend(entries,___)

legend('boxon')
legend('boxoff')

legend('hide')
legend('show')
legend('toggle')
legend('off')

legend(ax,___)

h = legend(___)
[h,icons,plots,str] = legend(___)
```

Description

`legend('string1',...,'stringN')` creates a legend in the current axes using the specified strings to label each set of data. The legend shows an icon of the associated object next to each string.

`legend('string1',...,'stringN','Location',Value)` specifies the legend location. Set `Value` to a location string such as `'northoutside'`. For a list of strings, see the Location property.

`legend( ___ ,'Orientation',Value)` specifies the legend orientation. This option can be used with either of the input argument combinations in the previous syntaxes. Set `Value` as either `'vertical'` or `'horizontal'`. For more information, see the Orientation property.

`legend(strings)` creates a legend in the current axes and uses the entries in `strings` to label each set of data. Specify `strings` as either a cell array of strings or a matrix of strings.

`legend(strings,Name,Value)` specifies legend properties. Use this syntax if you want to specify `Name,Value` pairs other than Location and Orientation when creating a legend. For example, `'FontSize',12` sets the font size to 12 points.

`legend(entries, ___ )` displays legend entries for the objects in the graph specified by the vector `entries`. Use this syntax if you want to display legend entries for only some of the objects in the graph. The option, `entries`, can precede any of the input argument combinations in the previous syntaxes.

`legend('boxon')` displays the box around the legend.

`legend('boxoff')` removes the box around the legend.

`legend('hide')` hides the legend associated with the current axes. Hiding the legend does not delete it.

`legend('show')` makes the legend in the current axes visible. If a legend does not exist, then MATLAB creates one using the default strings.

`legend('toggle')` toggles the legend visibility. If a legend does not exist, then MATLAB creates one using the default strings.

`legend('off')` deletes the legend from the current axes.

`legend(ax, ___ )` uses the axes specified by `ax` instead of the current axes (`gca`). The option, `ax`, can precede any of the previous input argument combinations.

`h = legend( ___ )` returns the legend object. Use `h` to query and set properties of the legend after it is created.

Note: Starting in R2014b, the `legend` function returns a legend object. In previous releases it returns an axes object.

`[h,icons,plots,str] = legend( ___ )` additionally returns the objects used to create the legend icons, the objects plotted in the graph, and an array of text strings.

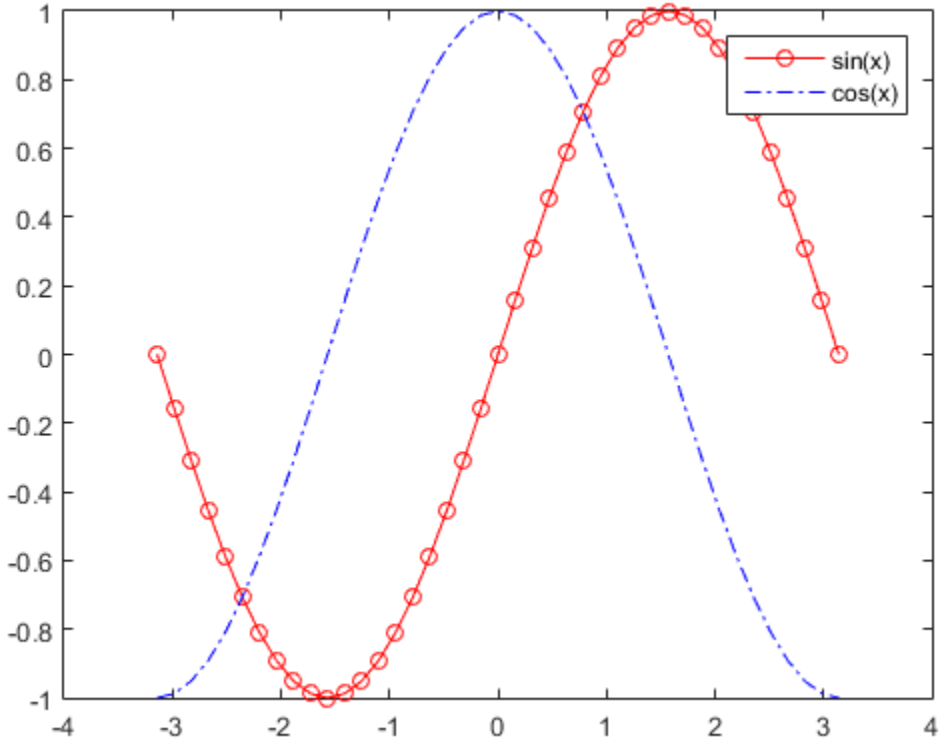
Examples

Add Legend to Graph

Create a graph of sine and cosine. Add a legend to the graph indicating the two functions.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)','cos(x)')
```

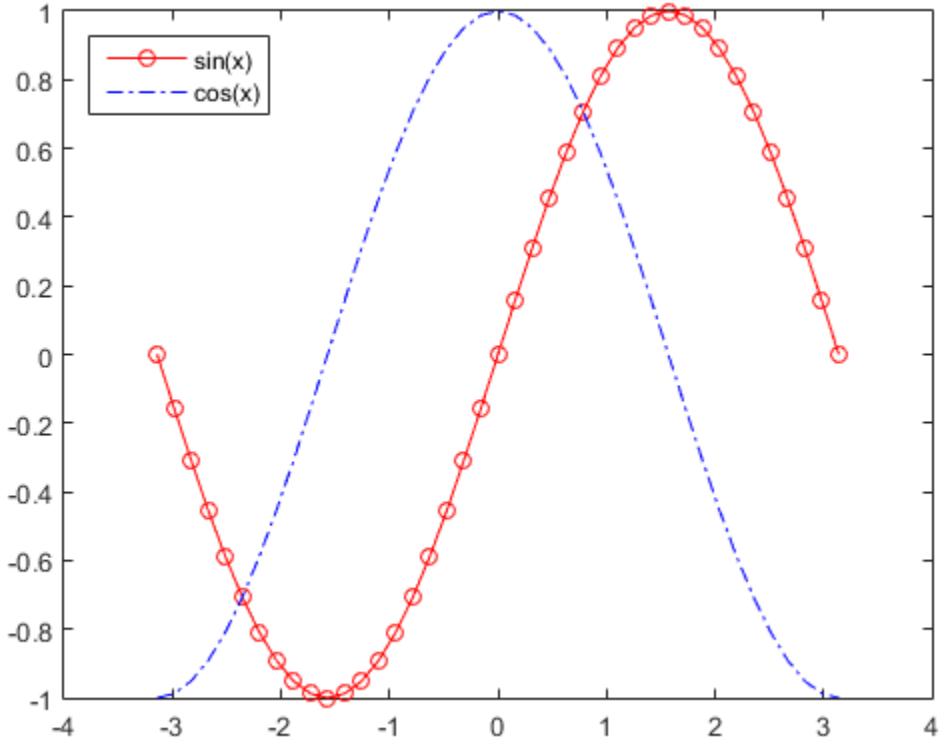


Specify Legend Location

Create a graph of sine and cosine. Add a legend to the top left corner of the graph by specifying the `'Location'` property as `'northwest'`.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)','cos(x)','Location','northwest')
```

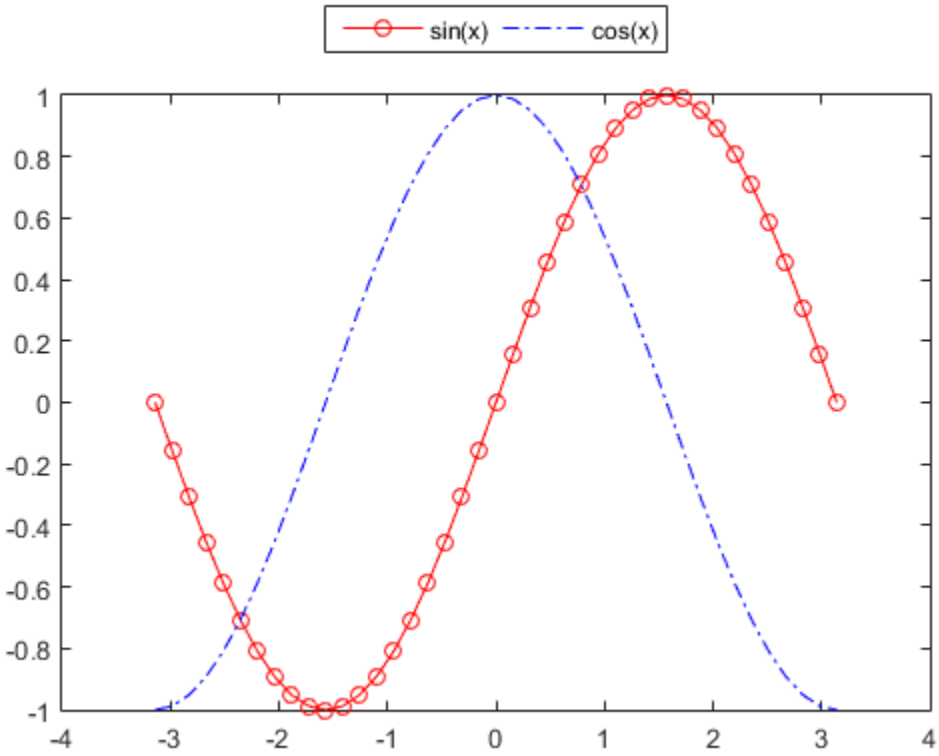


Add Horizontal Legend Above Graph

Create a graph of sine and cosine. Add a horizontal legend above the axes.

```
x = -pi:pi/20:pi;
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,'-ro',x,y2,'-.b')
legend('sin(x)','cos(x)','Location','northoutside','Orientation','horizontal')
```



Change Legend Font Size

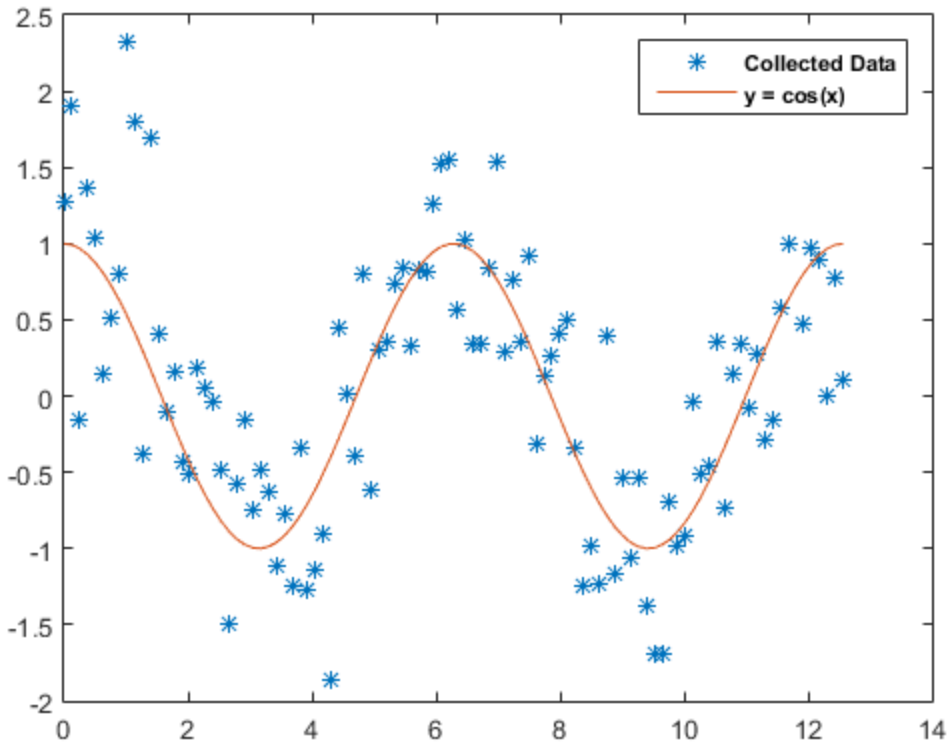
Define the data, `x`, `ydata`, and `ycos`.

```
rng default % initialize random number generator
x = linspace(0,4*pi,100);
ydata = cos(x) + 0.5*randn(1,100);
ycos = cos(x);
```

Plot `ydata` and `ycos`. Add a legend to the graph using a small, bold font. To specify `Name,Value` pairs when creating a legend, you must specify the legend description strings as a cell array by using curly braces, `{}`.

```
figure
```

```
plot(x,ydata,'*',x,ycos)
legend({'Collected Data','y = cos(x)'},'FontSize',8,'FontWeight','bold')
```



Display Subset of Lines in Legend

Define the data.

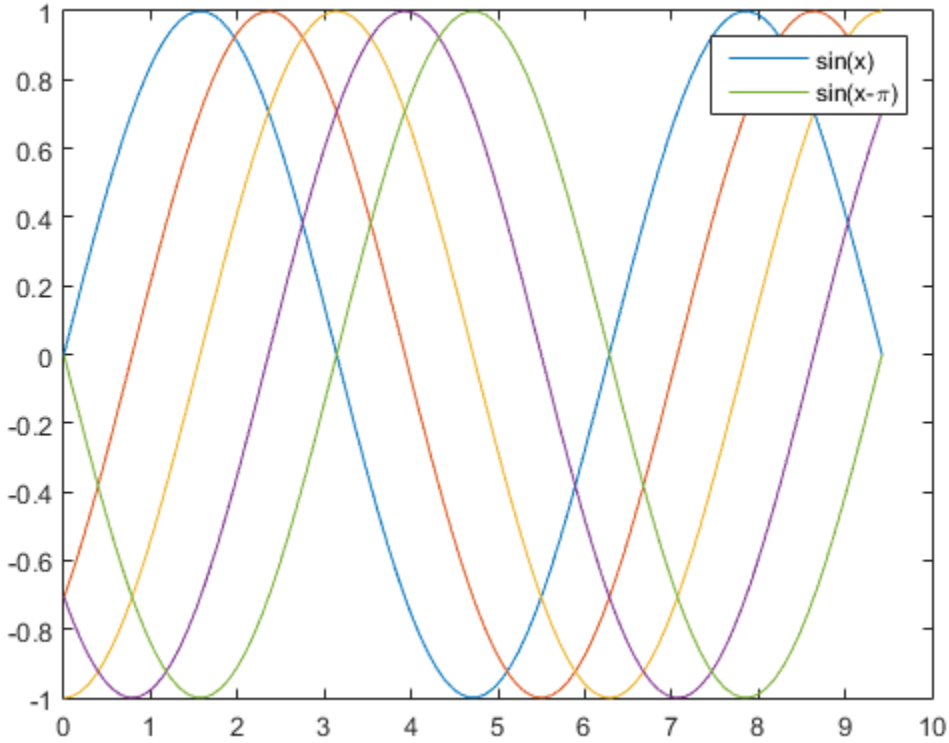
```
x = linspace(0,3*pi);
y1 = sin(x);
y2 = sin(x - pi/4);
y3 = sin(x - pi/2);
y4 = sin(x - 3*pi/4);
y5 = sin(x - pi);
```

Plot the data and return the charting line handles.

```
figure
hLine1 = plot(x,y1);
hold all
hLine2 = plot(x,y2);
hLine3 = plot(x,y3);
hLine4 = plot(x,y4);
hLine5 = plot(x,y5);
hold off
```

Add a legend for the first and last lines by specifying their handles, `hLine1` and `hLine5`.

```
legend([hLine1,hLine5],'sin(x)','sin(x-\pi)')
```



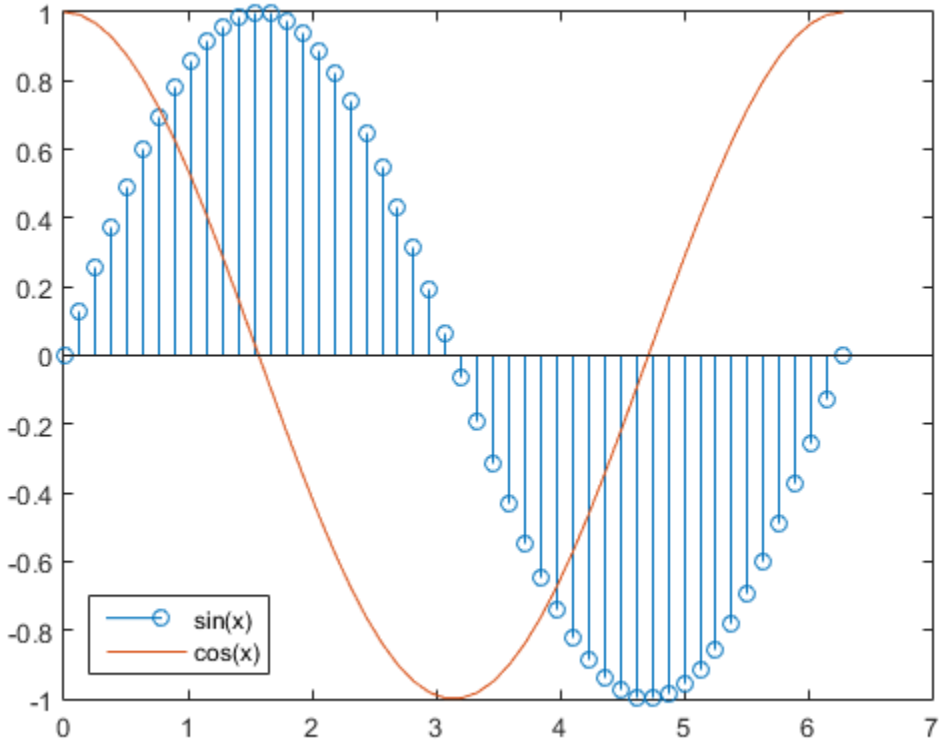
Specify Legend Location and Remove Border

Create a plot of sine and cosine. Add a legend to the bottom left of the axes.

```
x = linspace(0,2*pi,50);
ysin = sin(x);
ycos = cos(x);

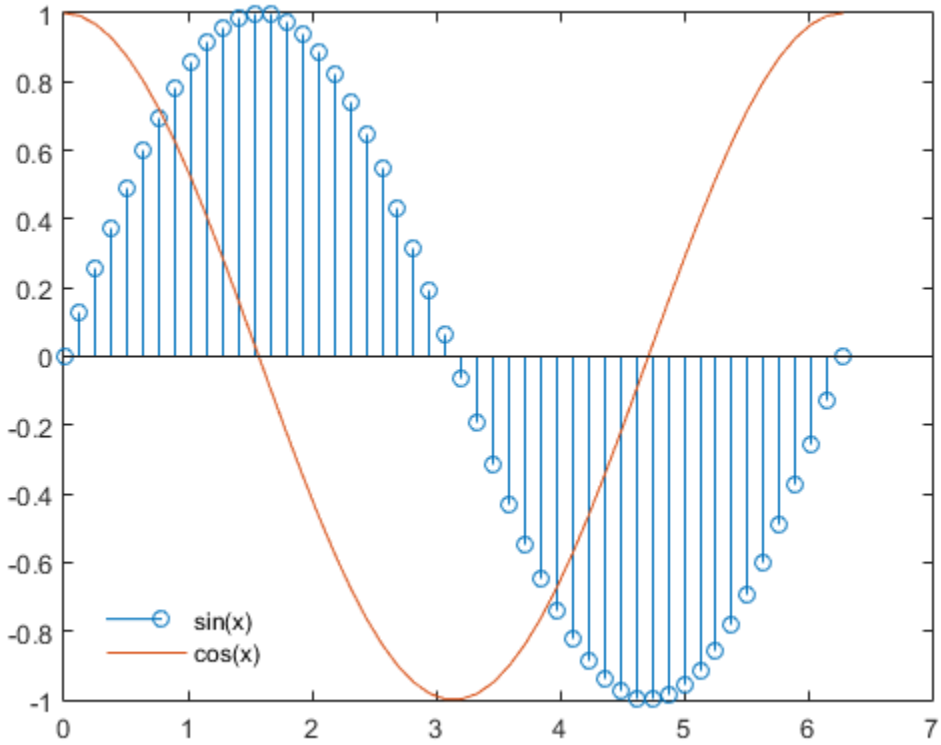
figure
stem(x,ysin)
hold all
plot(x,ycos)
hold off
```

```
legend('sin(x)','cos(x)','Location','southwest')
```



Remove the legend border.

```
legend('boxoff')
```



Specify Custom Legend Size and Location

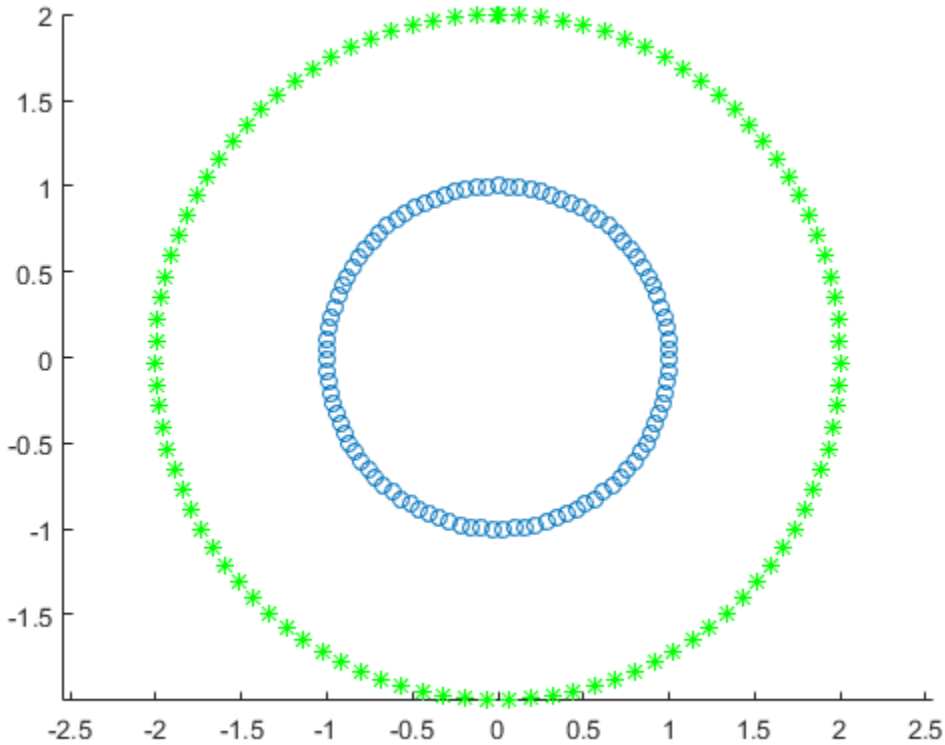
Define the data.

```
theta = linspace(0,2*pi,100);
x1 = sin(theta);
y1 = cos(theta);

x2 = 2*sin(theta);
y2 = 2*cos(theta);
```

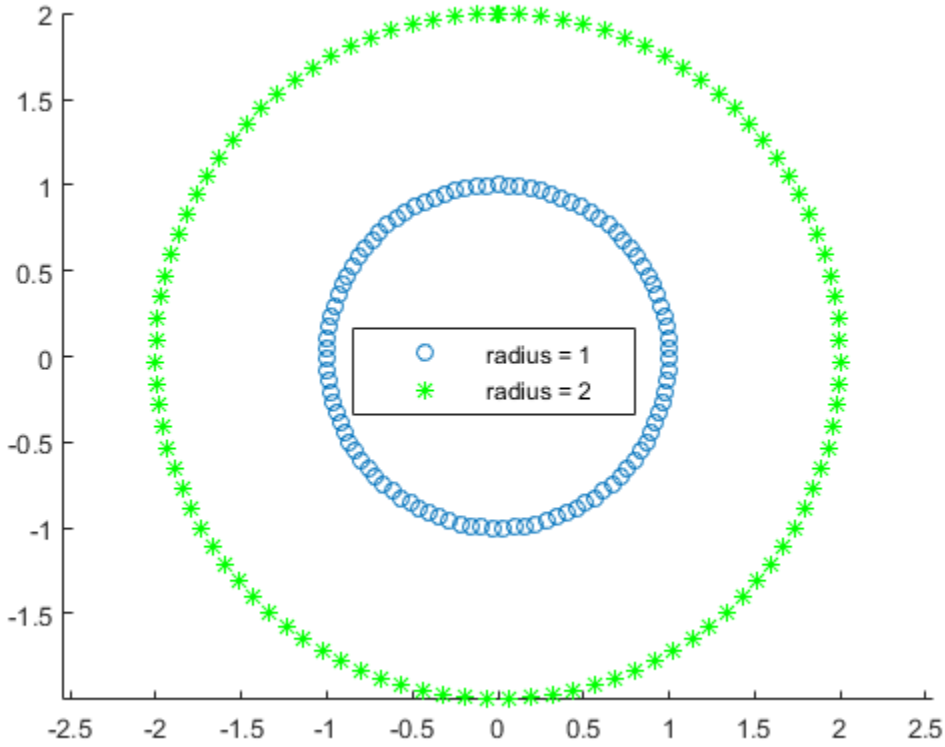
Create a scatter plot of two circles. Use `axis equal` to set equal scaling along both the *x*-axis and *y*-axis.

```
figure
scatter(x1,y1)
hold on
scatter(x2,y2,'*g')
hold off
axis equal
```



Add a legend to the center of the graph using the `Position` property. To set the `Position` property when creating a legend, you must define the legend strings as a cell array by using curly braces, `{}`.

```
legend({'radius = 1','radius = 2'},'Position',[0.39,0.45,0.25,0.1])
```

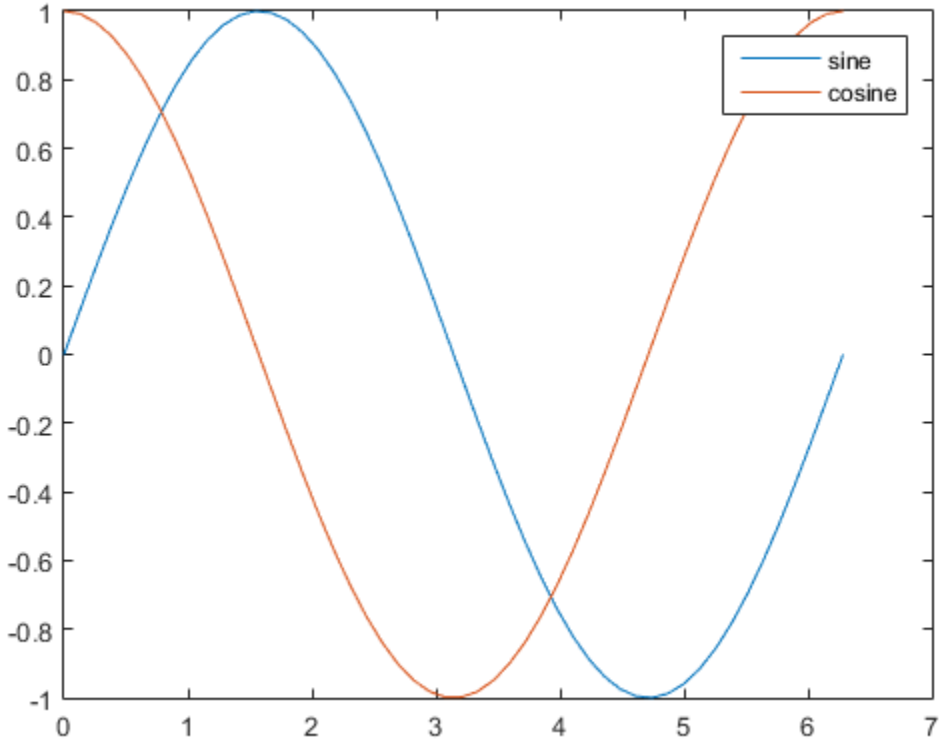


Delete Legend

Create a plot of sine and cosine and add a legend.

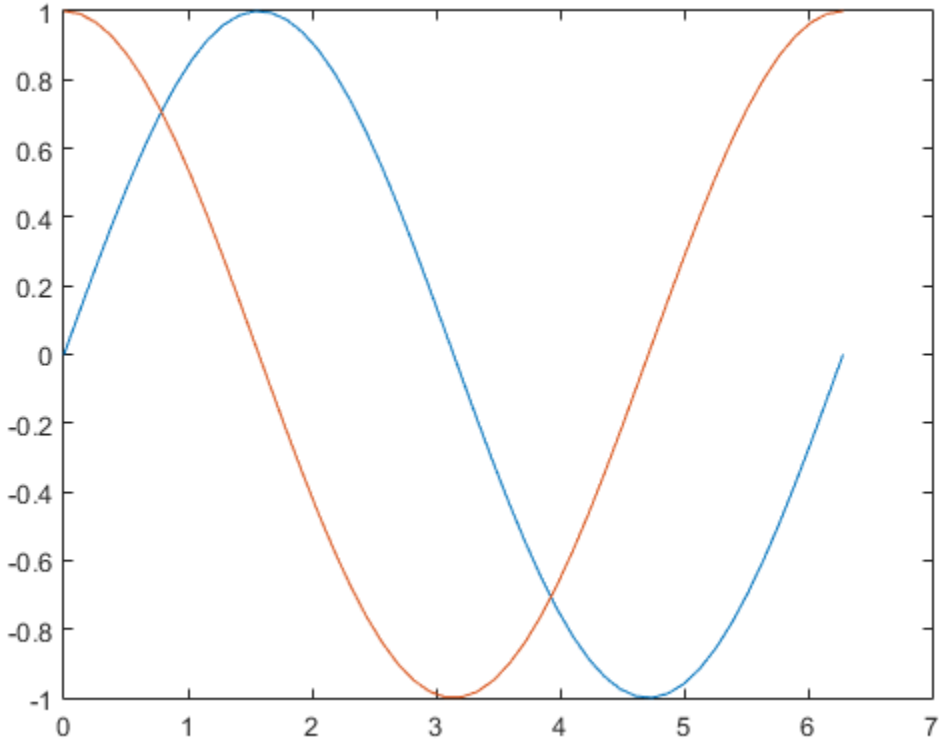
```
x = linspace(0,2*pi,50);
ysin = sin(x);
ycos = cos(x);

figure
plot(x,ysin,x,ycos)
legend('sine','cosine')
```



Delete the legend.

```
legend('off')
```



Specify Axes for Legend

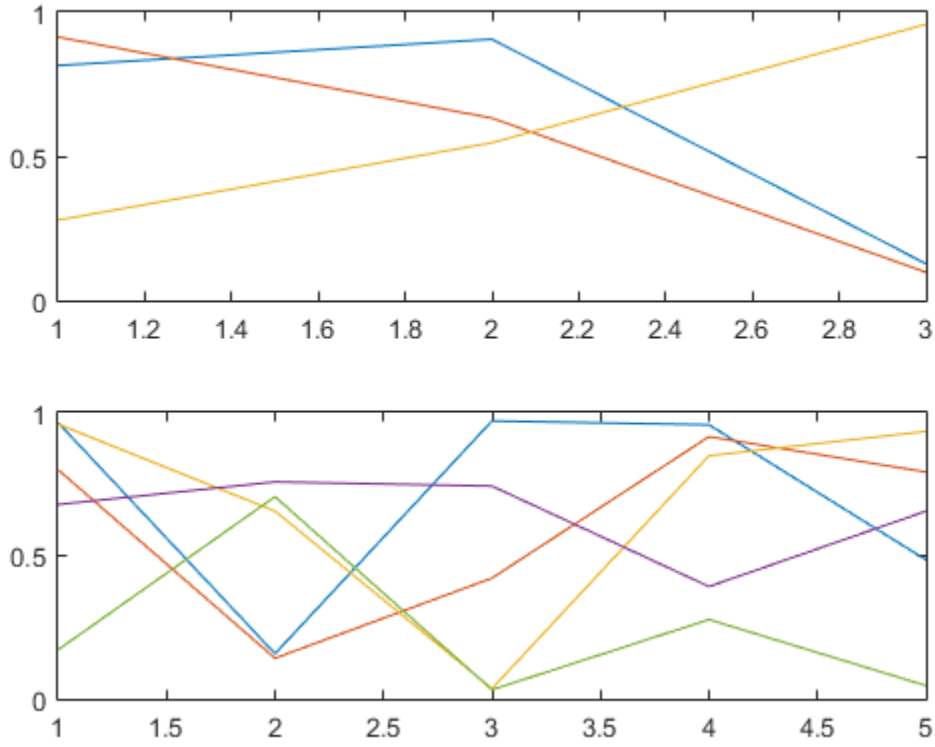
Create a figure with two subplots and return the two axes handles, `ax1` and `ax2`. Plot random data in each subplot.

```
rng default % initialize random number generator
y1 = rand(3);
y2 = rand(5);

figure
ax1 = subplot(2,1,1); % upper subplot
plot(y1)

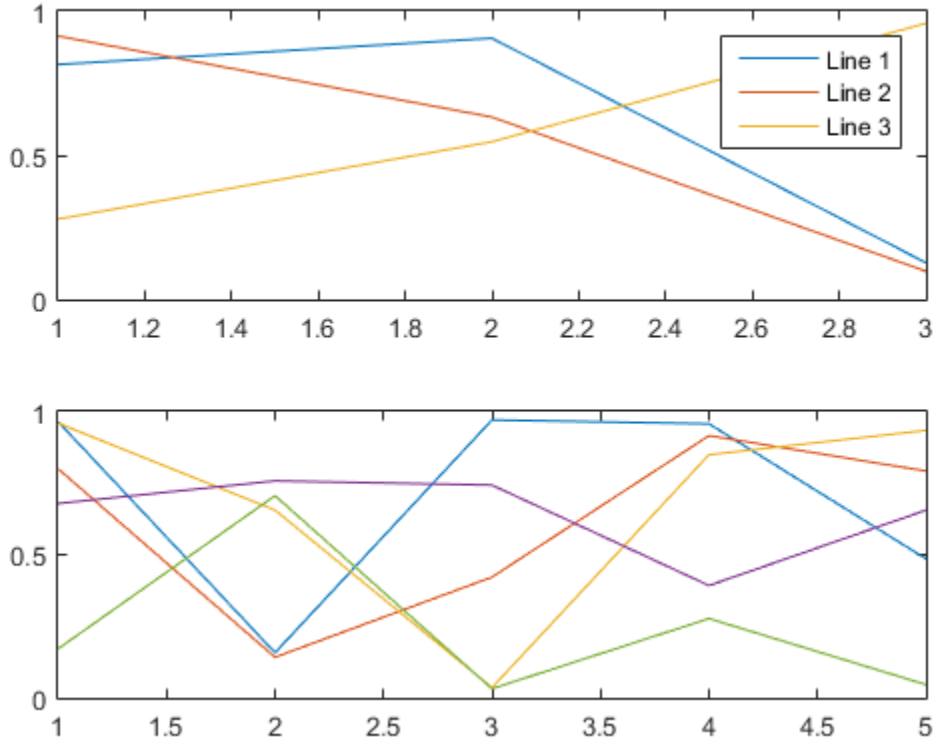
ax2 = subplot(2,1,2); % lower subplot
```

```
plot(y2)
```



Add a legend to the upper subplot by passing its axes handle to `legend`.

```
legend(ax1,'Line 1','Line 2','Line 3')
```



- “Include Subset of Objects in Graph Legend”
- “Specify Legend Descriptions During Line Creation”

Input Arguments

`'string1',...,'stringN'` — Description for each object

comma-separated list of strings

Description for each object, specified as a comma-separated list of strings.

MATLAB sets the `String` property of the legend to the specified strings. MATLAB also sets the `DisplayName` properties of the objects to the specified strings.

If you do not specify legend strings, then `legend` uses the `DisplayName` properties of the objects instead. If an object does not have a `DisplayName` property, or if you have not defined a value for this property, then `legend` uses a string of the form `'data1'`, `'data2'`, and so on.

Example: `'Sine Function','Cosine Function'`

`strings` — Description for each object

cell array of strings | matrix of strings

Description for each object, specified as a cell array of strings or a matrix of strings. If `strings` is a matrix, then the `legend` function uses each row of the matrix to label a set of data.

MATLAB sets the `String` property of the legend to the specified strings. MATLAB also sets the `DisplayName` properties of the objects to the specified strings.

If you do not specify legend strings, then `legend` uses the `DisplayName` properties of the objects instead. If an object does not have a `DisplayName` property, or if you have not defined a value for this property, then `legend` uses a string of the form `'data1'`, `'data2'`, and so on.

Example: `{'Sine Function','Cosine Function'}`

`entries` — List of graphics objects to include in legend

vector

List of graphics objects to include in the legend, specified as a vector. Specifying objects is useful if you do not want to add a description for every object in the graph.

These are the graphics objects that can be included in the legend:

- `Animated line` objects
- `Area` objects
- `Bar series` objects
- `Chart line` objects
- `Chart surface` objects
- `Contour` objects
- `Errorbar series` objects
- `Group` objects

- `Histogram` objects
- `Patch` objects
- `Primitive line` objects
- `Primitive surface` objects
- `Quiver series` objects
- `Scatter series` objects
- `Stair` objects
- `Stem series` objects
- `Transform` objects

ax — Axes object

axes object

Axes object. If you do not specify an axes, then the `legend` function adds a legend to the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

The properties listed here are only a subset. For a complete list see Legend Properties.

Example: `'FontSize',12,'TextColor','blue'`

'Location' — Location with respect to axes

supported location string

Location with respect to the axes, specified as one of the location strings listed in this table.

Supported String	Resulting Location
`'north'`	Inside top of axes
`'south'`	Inside bottom of axes
`'east'`	Inside right of axes
`'west'`	Inside left of axes

Supported String	Resulting Location
'northeast'	Inside top-right of axes (default for 2-D axes)
'northwest'	Inside top-left of axes
'southeast'	Inside bottom-right of axes
'southwest'	Inside bottom-left of axes
'northoutside'	Above the axes
'southoutside'	Below the axes
'eastoutside'	To the right of the axes
'westoutside'	To the left of the axes
'northeastoutside'	Outside top-right corner of the axes (default for 3-D axes)
'northwestoutside'	Outside top-left corner of the axes
'southeastoutside'	Outside bottom-right corner of the axes
'southwestoutside'	Outside bottom-left corner of the axes
'best'	Inside axes where least conflict with data in plot
'bestoutside'	To the right of the axes
'none'	Determined by Position property

To display the legend in a location that is not listed in the table, use the `Position` property to specify a custom location. If you set the `Position` property, then MATLAB automatically sets the `Location` property to `'none'`.

Example: `'northoutside'`

`'Orientation'` — Orientation

`'vertical'` (default) | `'horizontal'`

Orientation, specified as one of these values:

- `'vertical'` — Stacks the legend entries vertically. This is the default.
- `'horizontal'` — Lists the legend entries side-by-side.

Example: `'horizontal'`

`'Box'` — Box outline

`'on'` (default) | `'off'`

Box outline, specified as one of these values:

- `'on'` — Displays the box around the legend. This is the default.
- `'off'` — Removes the box around the legend.

Example: `'off'`

`'String'` — Legend entry descriptions

cell array of strings

Legend entry descriptions, specified as a cell array of strings. If you specify strings as input to `legend`, then MATLAB sets the `String` property to the specified strings and uses these strings in the legend display. If you do not specify strings, then MATLAB uses the `DisplayName` properties of the objects, or a string of the form `'data1'`, `'data2'`, and so on. The `String` property reflects the entries in the legend.

Example: `{'Sine','Cosine','Tangent'}`

`'Interpreter'` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
`\alpha`	α	`\upsilon`	υ	`\sim`	~
`\angle`	∠	`\phi`	Φ	`\leq`	≤
`\ast`	*	`\chi`	χ	`\infty`	∞

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

`'TextColor'` — Text color
`[0,0,0]` or `'black'` (default) | RGB triplet | supported color string

Text color, specified as an RGB triplet or a supported color string. The default color is black with an RGB triplet value of `[0,0,0]`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0,0,1]

Example: 'blue'

'FontSize' — Font size

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the legend font size to 90% of the axes font size. If you manually set the legend font size, then changing the axes font size does not affect the legend.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Output Arguments

h — Legend object

legend object

Legend object. Use h to modify the legend after it has been created.

icons — Objects used to create legend icons and descriptions

text, patch, and line objects

Objects used to create the legend icons and descriptions, returned as text, patch, and line object.

plots — Objects plotted in graph

vector of objects

Objects plotted in the graph, returned as a vector of objects.

`str` — Text strings used in legend

cell array

Text strings used in the legend, returned as a cell array.

More About

Tips

- An axes can have only one legend.
- To use legend keywords, such as `'Location'` or `'off'` as legend descriptions, you must pass the string in a cell array to `legend`. For example, `l = legend({'Location'})` displays a legend with the entry `Location`.
- To label more than 20 objects in the legend, you must specify a string for each object. Otherwise, `legend` depicts only the first 20 objects in the graph.
- `legend` associates strings with objects in the same order that the objects are listed in the axes `Children` property.
- “Control Legend Content”

Properties

Legend Properties

Introduced before R2006a

Legend Properties

Control legend appearance and behavior

Legend properties control the appearance and behavior of a legend object. By changing property values, you can modify certain aspects of the legend. Use dot notation to refer to a particular object and property:

```
h = legend('show');
c = h.TextColor;
h.TextColor = 'red';
```

Appearance

`TextColor` — Text color

`[0,0,0]` or `'black'` (default) | RGB triplet | supported color string

Text color, specified as an RGB triplet or a supported color string. The default color is black with an RGB triplet value of `[0,0,0]`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0,0,1]`

Example: `'blue'`

`Color` — Background color

`[1,1,1]` or `'white'` (default) | RGB triplet | supported color string

Background color, specified as an RGB triplet or a supported color string. The default color is white with an RGB triplet value of `[1,1,1]`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0,0,1]`

Example: `'b'`

`Box` — Box outline

`'on'` (default) | `'off'`

Box outline, specified as one of these values:

- `'on'` — Displays the box around the legend. This is the default.
- `'off'` — Removes the box around the legend.

Example: `'off'`

`EdgeColor` — Box outline color

`[0.15 0.15 0.15]` (default) | RGB triplet | supported color string

Box outline color, specified as an RGB triplet or a supported color string. The default color is dark gray with an RGB triplet value of `[0.15,0.15,0.15]`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0,1,0]`

Example: `'g'`

`LineWidth` — Width of box outline

`0.5` (default) | positive value

Width of box outline, specified as a positive value in point units. One point equals 1/72 inches.

Example: `1.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Location and Size

`Location` — Location with respect to axes

supported location string

Location with respect to the axes, specified as one of the location strings listed in this table.

Supported String	Resulting Location
'north'	Inside top of axes
'south'	Inside bottom of axes
'east'	Inside right of axes
'west'	Inside left of axes
'northeast'	Inside top-right of axes (default for 2-D axes)
'northwest'	Inside top-left of axes
'southeast'	Inside bottom-right of axes
'southwest'	Inside bottom-left of axes
'northoutside'	Above the axes
'southoutside'	Below the axes
'eastoutside'	To the right of the axes
'westoutside'	To the left of the axes
'northeastoutside'	Outside top-right corner of the axes (default for 3-D axes)
'northwestoutside'	Outside top-left corner of the axes
'southeastoutside'	Outside bottom-right corner of the axes
'southwestoutside'	Outside bottom-left corner of the axes
'best'	Inside axes where least conflict with data in plot
'bestoutside'	To the right of the axes
'none'	Determined by Position property

To display the legend in a location that is not listed in the table, use the `Position` property to specify a custom location. If you set the `Position` property, then MATLAB automatically sets the `Location` property to `'none'`.

Example: `'northoutside'`

`Orientation` — Orientation

`'vertical'` (default) | `'horizontal'`

Orientation, specified as one of these values:

- `'vertical'` — Stacks the legend entries vertically. This is the default.
- `'horizontal'` — Lists the legend entries side-by-side.

Example: `'horizontal'`

`Position` — Custom location and size

four-element vector

Custom location and size, specified as a four-element vector of the form `[left, bottom, width, height]`. The first two values, `left` and `bottom`, specify the distance from the lower-left corner of the figure to the lower-left corner of the legend. The last two values, `width` and `height`, specify the dimensions of the legend. The `Units` property determines the position units.

If you specify the `Position` property, then MATLAB automatically changes the legend's `Location` property to `'none'`.

Example: `[0.1,0.1,0.3,0.7]`

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

`Units`	Description
`'normalized'` (default)	Normalized with respect to the container, which is usually the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.

Units	Description
'points'	Points. One point equals 1/72 inch.
'pixels'	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the container window.

This property affects the Position property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume Units is the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the legend, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

Text

`String` — Legend entry descriptions

cell array of strings

Legend entry descriptions, specified as a cell array of strings. If you specify strings as input to `legend`, then MATLAB sets the `String` property to the specified strings and uses these strings in the legend display. If you do not specify strings, then MATLAB uses the `DisplayName` properties of the objects, or a string of the form `'data1'`, `'data2'`, and so on. The `String` property reflects the entries in the legend.

Example: `{'Sine','Cosine','Tangent'}`

`Interpreter` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\alpha	α	\upsilon	υ	\sim	~
\angle	∠	\phi	Φ	\leq	≤

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

Font Style

`FontAngle` — Character slant

`'normal'` (default) | `'italic'`

Character slant, specified as `'normal'` or `'italic'`. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

Note: The `'oblique'` value has been removed. Use `'italic'` instead.

`FontName` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`FontSize` — Font size

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the legend font size to 90% of the axes font size. If you manually set the legend font size, then changing the axes font size does not affect the legend.

Example: `12`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`FontWeight` — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

Visibility

`Visible` — Visibility of legend

`'on'` (default) | `'off'`

Visibility of legend, specified as one of these values:

- `'on'` — Display the legend.
- `'off'` — Hide the legend without deleting it. You still can access the properties of an invisible legend object.

Identifiers

`Type` — Type of graphics object

`'legend'` (default)

Type of graphics object, returned as `'legend'`. Use this property to find all objects of a given type within a plotting hierarchy.

`Tag` — Tag to associate with legend

`'legend'` (default) | string

Tag to associate with the legend, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: `char`

`UserData` — Data to associate with legend

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the legend object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent of legend

figure object | uipanel object | uitab object

Parent of the legend, specified as a figure object, uipanel object, or a uitab object.

The legend must have the same parent as the associated axes. If you change the parent of the associated axes, then the legend automatically updates to use the same parent.

`Children` — Children of legend

empty `GraphicsPlaceholder` array

The legend has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of legend object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The legend object handle is always visible.
- `'off'` — The legend object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The legend object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the legend at the command-line, but allows callback functions to access it.

If the legend object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Callback that executes when you click the legend

`@bdowncb` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the legend. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu handle (default)

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the legend. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the legend when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the legend.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the legend that has a defined color. You cannot click a part that has an associated color property set to `'none'`. The HitTest property determines if the legend responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the legend passes the click to the object below it in the current view of the figure window. The HitTest property of the legend has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the legend. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the legend that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the legend object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'off'` (default) | `'on'`

Callback interruption, specified as `'off'` or `'on'`. The `Interruptible` property determines if a running callback can be interrupted.

If the `ButtonDownFcn` callback of the legend is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- `'off'` — The running callback cannot be interrupted. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.
- `'on'` — The running callback can be interrupted. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

Example: `'off'`

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the legend tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the legend. Setting the `CreateFcn` property on an existing legend has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during legend creation. MATLAB executes the callback after creating the legend and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function. You also can access the legend object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the legend. MATLAB executes the callback before destroying the legend so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The legend object — You can access properties of the legend object from within the callback function. You also can access the legend object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of legend

`'off'` (default) | `'on'`

Deletion status of legend, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the legend begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the legend no longer exists.

Check the value of the BeingDeleted property to verify that the legend is not about to be deleted before querying or modifying it.

legendre

Associated Legendre functions

Syntax

```
P = legendre(n,X)
S = legendre(n,X,'sch')
N = legendre(n,X,'norm')
```

Description

`P = legendre(n,X)` computes the associated Legendre functions of degree `n` and order `m = 0,1,...,n`, evaluated for each element of `X`. Argument `n` must be a scalar integer, and `X` must contain real values in the domain $-1 \le x \le 1$.

If `X` is a vector, then `P` is an `(n+1)`-by-`q` matrix, where `q = length(X)`. Each element `P(m+1,i)` corresponds to the associated Legendre function of degree `n` and order `m` evaluated at `X(i)`.

In general, the returned array `P` has one more dimension than `X`, and each element `P(m+1,i,j,k,...)` contains the associated Legendre function of degree `n` and order `m` evaluated at `X(i,j,k,...)`. Note that the first row of `P` is the Legendre polynomial evaluated at `X`, i.e., the case where `m` = 0.

`S = legendre(n,X,'sch')` computes the "Schmidt Seminormalized Associated Legendre Functions" on page 1-4453.

`N = legendre(n,X,'norm')` computes the "Fully Normalized Associated Legendre Functions" on page 1-4453.

Examples

Example 1

The statement `legendre(2,0:0.1:0.2)` returns the matrix

	x = 0	x = 0.1	x = 0.2
m = 0	-0.5000	-0.4850	-0.4400
m = 1	0	-0.2985	-0.5879
m = 2	3.0000	2.9700	2.8800

Example 2

Given,

```
X = rand(2,4,5);
n = 2;
P = legendre(n,X)
```

then

```
size(P)
ans =
     3     2     4     5
```

and

```
P(:,1,2,3)
ans =
   -0.2475
   -1.1225
    2.4950
```

is the same as

```
legendre(n,X(1,2,3))
ans =
   -0.2475
   -1.1225
    2.49501
```

More About

Associated Legendre Functions

The Legendre functions are defined by

$$P_n^m(x) = (-1)^m (1-x^2)^{m/2} \frac{d^m}{dx^m} P_n(x),$$

where

$$P_n(x)$$

is the Legendre polynomial of degree n:

$$P_n(x) = \frac{1}{2^n n!}\left[\frac{d^n}{dx^n}(x^2-1)^n\right]$$

Schmidt Seminormalized Associated Legendre Functions

The Schmidt seminormalized associated Legendre functions are related to the nonnormalized associated Legendre functions $P_n^m(x)$ by

$$P_n(x) \text{ for } m = 0,$$
$$S_n^m(x) = (-1)^m \sqrt{\frac{2(n-m)!}{(n+m)!}} P_n^m(x) \text{ for } m > 0.$$

Fully Normalized Associated Legendre Functions

The fully normalized associated Legendre functions are normalized such that

$$\int_{-1}^{1} \left(N_n^m(x)\right)^2 dx = 1$$

and are related to the unnormalized associated Legendre functions $P_n^m(x)$ by

$$N_n^m = (-1)^m \sqrt{\frac{(n+\frac{1}{2})(n-m)!}{(n+m)!}} P_n^m(x)$$

Algorithms

`legendre` uses a three-term backward recursion relationship in `m`. This recursion is on a version of the Schmidt seminormalized associated Legendre functions $Q_n^m(x)$, which are complex spherical harmonics. These functions are related to the standard Abramowitz and Stegun [1] functions $P_n^m(x)$ by

$$P_n^m(x) = \sqrt{\frac{(n+m)!}{(n-m)!}}\, Q_n^m(x)$$

They are related to the Schmidt form given previously by

$$m = 0: \quad S_n^m(x) = Q_n^0(x)$$
$$m > 0: \quad S_n^m(x) = (-1)^m \sqrt{2}\, Q_n^m(x)$$

Introduced before R2006a

length

Length of largest array dimension

Syntax

```
L = length(X)
```

Description

`L = length(X)` returns the length of the largest array dimension in `X`. For vectors, the length is simply the number of elements. For arrays with more dimensions, the length is `max(size(X))`. The length of an empty array is zero.

Examples

Number of Vector Elements

Find the length of a uniformly spaced vector in the interval `[5,10]`.

```
v = 5:10
```

```
v =

     5     6     7     8     9    10
```

```
L = length(v)
```

```
L =

     6
```

Length of Rectangular Matrix

Find the length of a 3-by-7 matrix of zeros.

```
X = zeros(3,7);
L = length(X)
```

```
L =

     7
```

Length of Structure Fields

Create a structure with fields for `Day` and `Month`. Use the `structfun` function to apply `length` to each field.

```
S = struct('Day',[1 13 14 26],'Month',{{'Jan','Feb', 'Mar'}})
```

```
S =

      Day: [1 13 14 26]
    Month: {'Jan'  'Feb'  'Mar'}
```

```
L = structfun(@(field) length(field),S)
```

```
L =

     4
     3
```

Input Arguments

X — Input array

numeric array | character array | logical array | structure | cell array | categorical array | datetime array | duration array | calendarDuration array

Input array, specified as a numeric array, character array, logical array, structure, cell array, categorical array, datetime array, duration array, or calendarDuration array.

`length` does not operate on tables. To examine the dimensions of a table, use the `height`, `width`, or `size` functions.

Complex Number Support: Yes
