Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Compare a value to itself.

```
verifyNotEqual(testCase, 5, 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEqual failed.
--> NumericComparator passed.

Actual Value:
         5
Prohibited Value:
         5
```

Test failed.

Compare different number values.

```
verifyNotEqual(testCase, 4.95, 5, '4.95 should be different from 5');
```

```
Interactive verification passed.
```

Values `4.95` and `5` are not equal.

Compare values of different sizes.

```
verifyNotEqual(testCase, [5 5], 5, '[5 5] is not equal to 5');

Interactive verification passed.
```

Values are not equal.

Compare Classes

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEqual(testCase, int8(5), int16(5), 'Classes dont match');

Interactive verification passed.
```

Compare Cell Arrays

Test a cell array by comparing each element.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotEqual failed.
--> CellComparator passed.

Actual Value:
        'cell'    [1x1 struct]    [5]
Prohibited Value:
        'cell'    [1x1 struct]    [5]
```

Test failed.

More About

- “Types of Qualifications”

Introduced in R2013a

verifyNotSameHandle

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is not handle to specified instance

Syntax

```
verifyNotSameHandle(verifiable,actual,notExpectedHandle)
verifyNotSameHandle( ___ ,diagnostic)
```

Description

`verifyNotSameHandle(verifiable,actual,notExpectedHandle)` verifies that actual is a different size and/or does not contain the same instances as the notExpectedHandle handle array.

`verifyNotSameHandle( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  verifiable.verifyThat(actual, ~IsSameHandleAs(notExpectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`notExpectedHandle`

The handle array to compare.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Handles point to different objects.

```
verifyNotSameHandle(testCase, h1, h2);
```

```
Interactive verification passed.
```

Show matching handle combinations.

```
verifyNotSameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotSameHandle failed.
--> The two handles must not refer to the same handle, or should have
different sizes.
```

```
Actual Value:
      1x3 ExampleHandle array with no properties.
Handle Object:
      1x3 ExampleHandle array with no properties.
```

Test failed.

The order of the handle arguments matters.

```
verifyNotSameHandle(testCase, [h1 h2], [h2 h1]);
```

```
Interactive verification passed.
```

Test a handle with itself.

```
verifyNotSameHandle(testCase, h1, h1);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNotSameHandle failed.
--> The two handles must not refer to the same handle, or should have
different sizes.

Actual Value:
      ExampleHandle with no properties.
Handle Object:
      ExampleHandle with no properties.
```

Test failed.

Variables are not same size.

```
verifyNotSameHandle(testCase, h2, [h2 h2]);
```

```
Interactive verification passed.
```

Variables are the same size.

```
verifyNotSameHandle(testCase, [h1 h1], [h1 h1]);
```

```
Interactive verification failed.

---------------------
```

```
Framework Diagnostic:
---------------------
verifyNotSameHandle failed.
--> The two handles must not refer to the same handle, or should have
different sizes.

Actual Value:
      1x2 ExampleHandle array with no properties.
Handle Object:
      1x2 ExampleHandle array with no properties.
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyNumElements

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value has specified element count

Syntax

```
verifyNumElements(verifiable,actual,expectedElementCount)
verifyNumElements( ___ ,diagnostic)
```

Description

`verifyNumElements(verifiable,actual,expectedElementCount)` verifies that actual is a MATLAB array with expectedElementCount number of elements.

`verifyNumElements( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasElementCount;
  verifiable.verifyThat(actual, HasElementCount(expectedElementCount));
  ```

  There exists more functionality when using the `HasElementCount` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedElementCount`

The expected number of elements in the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test Matrices

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
n = 7;
verifyNumElements(testCase, eye(n), n^2);
```

```
Interactive verification passed.
```

```
verifyNumElements(testCase, 3, 1);
```

```
Interactive verification passed.
```

```
verifyNumElements(testCase, [1 2 3; 4 5 6], 5);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNumElements failed.
--> The value did not have the correct number of elements.

    Actual Number of Elements:
             6
    Expected Number of Elements:
             5

Actual Value:
         1     2     3
         4     5     6
```

Test failed.

Test Cell Array

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNumElements(testCase, {'SomeString', 'SomeOtherString'}, 2);
```

```
Interactive verification passed.
```

Test Structure

```
s.Field1 = 1;
s.Field2 = 2;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNumElements(testCase, s, 2);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyNumElements failed.
--> The value did not have the correct number of elements.

    Actual Number of Elements:
             1
    Expected Number of Elements:
             2

Actual Value:
        Field1: 1
        Field2: 2
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyReturnsTrue

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify function returns true when evaluated

Syntax

```
verifyReturnsTrue(verifiable,actual)
verifyReturnsTrue( ___ ,diagnostic)
```

Description

`verifyReturnsTrue(verifiable,actual)` verifies that actual is a function handle that returns a scalar logical whose value is true.

`verifyReturnsTrue( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `verifyTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `verifyTrue`.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ReturnsTrue;
  verifiable.verifyThat(actual, ReturnsTrue());
  ```

  There exists more functionality when using the `ReturnsTrue` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the

primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test if Condition is True

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyReturnsTrue(testCase, @true);
```

```
Interactive verification passed.
```

Verify that it is true that two numbers are equal.

```
verifyReturnsTrue(testCase, @() isequal(1,1));
```

```
Interactive verification passed.
```

Verify that it is true that two letters are not the same.

```
verifyReturnsTrue(testCase, @() ~strcmp('a','b'));
```

```
Interactive verification passed.
```

Cause verification to fail by trying to verify that “false” evaluates to “true”.

```
verifyReturnsTrue(testCase, @false);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyReturnsTrue failed.
--> The function handle should have evaluated to "true".
--> Returned value:
             0

Actual Function Handle:
        @false
```

Test failed.

Cause verification to fail by having the test specified in the function handle return a vector of logical values not a scalar logical value.

```
verifyReturnsTrue(testCase, @() strcmp('a',{'a','a'}));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyReturnsTrue failed.
--> The function handle should have returned a scalar. The return value had a size of
--> Returned value:
             1     1

Actual Function Handle:
        @()strcmp('a',{'a','a'})
```

Test failed.

Cause verification to fail by having the test specified in the function handle return a double not a logical.

```
verifyReturnsTrue(testCase, @() exist('exist'));
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyReturnsTrue failed.
--> The function handle should have returned a logical value. It was of type "double".
--> Returned value:
             5

Actual Function Handle:
        @()exist('exist')
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifySameHandle

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify two values are handles to same instance

Syntax

```
verifySameHandle(verifiable,actual,expectedHandle)
verifySameHandle( ___ ,diagnostic)
```

Description

`verifySameHandle(verifiable,actual,expectedHandle)` verifies that actual is the same size and contains the same instances as the expectedHandle handle array.

`verifySameHandle( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsSameHandleAs;
  verifiable.verifyThat(actual, IsSameHandleAs(expectedHandle));
  ```

  There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedHandle`

The expected handle array.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Show matching handle combinations.

```
verifySameHandle(testCase, h1, h1);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h1], [h1 h1]);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification passed.
```

Handles must point to same object.

```
verifySameHandle(testCase, h1, h2);
```

```
Interactive verification failed.

--------------------
```

```
Framework Diagnostic:
---------------------
verifySameHandle failed.
--> Values do not refer to the same handle.

Actual Value:
      ExampleHandle with no properties.
Expected Handle Object:
      ExampleHandle with no properties.
```

Test failed.

Size of handle objects must match.

```
verifySameHandle(testCase, [h1 h1], h1);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySameHandle failed.
--> Sizes do not match.
     Actual Value Size           : [1  2]
     Expected Handle Object Size : [1  1]

Actual Value:
      1x2 ExampleHandle array with no properties.
Expected Handle Object:
      ExampleHandle with no properties.
```

Test failed.

Order of arguments is important.

```
verifySameHandle(testCase, [h1 h2], [h2 h1]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySameHandle failed.
--> Some elements in the handle array refer to the wrong handle.
```

```
Actual Value:
      1x2 ExampleHandle array with no properties.
Expected Handle Object:
      1x2 ExampleHandle array with no properties.
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifySize

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value has specified size

Syntax

```
verifySize(verifiable,actual,expectedSize)
verifySize( ___ ,diagnostic)
```

Description

`verifySize(verifiable,actual,expectedSize)` verifies that actual is a MATLAB array whose size is expectedSize.

`verifySize( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.HasSize;
  verifiable.verifyThat(actual, HasSize(expectedSize));
  ```

  There exists more functionality when using the `HasSize` constraint directly via `verifyThat`.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`expectedSize`

The expected sizes of each dimension the array.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test Arrays

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifySize(testCase, ones(2, 5, 3), [2 5 3]);
```

```
Interactive verification passed.
```

```
verifySize(testCase, [1 2 3; 4 5 6], [2 3]);
```

```
Interactive verification passed.
```

```
verifySize(testCase, [2 3], [3 2]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySize failed.
--> The value had an incorrect size.

    Actual Size:
             1     2
    Expected Size:
             3     2

Actual Value:
         2     3
```

Test failed.

Number of elements is not the same as size.

```
verifySize(testCase, [1 2 3; 4 5 6], [6 1]);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySize failed.
--> The value had an incorrect size.

    Actual Size:
             2     3
    Expected Size:
             6     1

Actual Value:
         1     2     3
         4     5     6
```

Test failed.

```
verifySize(testCase, eye(2), [4 1]);

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySize failed.
--> The value had an incorrect size.

    Actual Size:
             2     2
    Expected Size:
             4     1

Actual Value:
         1     0
         0     1
```

Test failed.

Test Cell Array

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifySize(testCase, {'SomeString', 'SomeOtherString'}, [1 2]);

Interactive verification passed.
```

More About

- "Types of Qualifications"

Introduced in R2013a

verifySubstring

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify string contains specified string

Syntax

```
verifySubstring(verifiable,actual,substring)
verifySubstring( ___ ,diagnostic)
```

Description

`verifySubstring(verifiable,actual,substring)` verifies that actual is a string that contains substring.

`verifySubstring( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.ContainsSubstring;
  verifiable.verifyThat(actual, ContainsSubstring(substring));
  ```

  There exists more functionality when using the `ContainsSubstring` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The string to test.

Default:

`substring`

The value to match, specified as a string.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test for Substrings

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test that a substring is contained in a string.

```
verifySubstring(testCase, 'SomeLongString', 'Long');
```

```
Interactive verification passed.
```

Show that case matters.

```
verifySubstring(testCase, 'SomeLongString', 'lonG');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySubstring failed.
--> The string must contain the substring.

Actual String:
    SomeLongString
Expected Substring:
    lonG
```

Test failed.

Cause the verification to fail by testing a substring that isn't contained in the actual string.

```
verifySubstring(testCase, 'SomeLongString', 'OtherString');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySubstring failed.
--> The string must contain the substring.

Actual String:
    SomeLongString
Expected Substring:
    OtherString
```

Test failed.

Show that the verification will fail if the substring is longer than the actual string.

```
verifySubstring(testCase, 'SomeLongString', 'SomeLongStringThatIsLonger');
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifySubstring failed.
--> The string must contain the substring.

Actual String:
    SomeLongString
Expected Substring:
    SomeLongStringThatIsLonger
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyThat

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value meets given constraint

Syntax

```
verifyThat(verifiable,actual,constraint)
verifyThat( ___ ,diagnostic)
```

Description

`verifyThat(verifiable,actual,constraint)` verifies that actual is a value that satisfies the constraint provided.

If the constraint is not satisfied, a verification failure is produced utilizing only the framework diagnostic generated by the constraint.

`verifyThat( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

When using this signature, both the diagnostic information contained within diagnostic is used in addition to the diagnostic information provided by the constraint.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`constraint`

Constraint that the actual value must satisfy to pass the verification, specified as a `matlab.unittest.constraints` instance.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Tips

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,
  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is

preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Examples

Test Conditions Using Constraints

```
testCase = matlab.unittest.TestCase.forInteractiveUse;

% Passing scenarios
%%%%%%%%%%%%%%%%%%%%%%
import matlab.unittest.constraints.IsTrue
verifyThat(testCase, true, IsTrue)

import matlab.unittest.constraints.IsEqualTo
verifyThat(testCase, 5, IsEqualTo(5), '5 should be equal to 5')

import matlab.unittest.constraints.IsGreaterThan
import matlab.unittest.constraints.HasNaN
verifyThat(testCase, [5 NaN], IsGreaterThan(10) | HasNaN, ...
    'The value was not greater than 10 or NaN')

% Failing scenarios
%%%%%%%%%%%%%%%%%%%%%%
import matlab.unittest.constraints.AnyCellOf
import matlab.unittest.constraints.ContainsSubstring
verifyThat(testCase, AnyCellOf({'cell','of','strings'}), ...
    ContainsSubstring('char'),'Test description')

import matlab.unittest.constraints.HasSize
verifyThat(testCase, zeros(10,4,2), HasSize([10,5,2]), ...
    @() disp('A function handle diagnostic.'))

import matlab.unittest.constraints.IsEmpty
verifyThat(testCase, 5, IsEmpty)
```

More About

- "Types of Qualifications"

Introduced in R2013a

verifyTrue

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify value is true

Syntax

```
verifyTrue(verifiable,actual)
verifyTrue( ___ ,diagnostic)
```

Description

`verifyTrue(verifiable,actual)` verifies that actual is a scalar logical with the value of true.

`verifyTrue( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IsTrue;
  verifiable.verifyThat(actual, IsTrue());
  ```

  There exists more functionality when using the `IsTrue` constraint directly via `verifyThat`.

  Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered

to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `verifyReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

  - Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
  - Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
  - Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The value to test.

Default:

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Examples

Test MATLAB Logical Functions

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test `true`.

```
verifyTrue(testCase, true);
```

```
Interactive verification passed.
```

Test `false`.

```
verifyTrue(testCase, false);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyTrue failed.
--> The value must evaluate to "true".

Actual Value:
         0
```

Test failed.

Test the Value 1

The number `1` is a `double` value, not a logical value.

A double value of `1` is not `true`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyTrue(testCase, 1);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyTrue failed.
--> The value must be logical. It is of type "double".

Actual Value:
         1
```

Test failed.

Test Array of Logical Values

To be true, the value must be scalar.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyTrue(testCase, [true true true]);
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
verifyTrue failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         1     1     1
```

Test failed.

More About

- "Types of Qualifications"

Introduced in R2013a

verifyWarning

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify function issues specified warning

Syntax

```
verifyWarning(verifiable,actual,warningID)
verifyWarning( ___ ,diagnostic)
[output1,...,outputN] = verifyWarning( ___ )
```

Description

`verifyWarning(verifiable,actual,warningID)` verifies that actual issues a warning with the identifier warningID.

`verifyWarning( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`[output1,...,outputN] = verifyWarning( ___ )` also returns the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesWarnings;
  verifiable.verifyThat(actual, IssuesWarnings({warningID}));
  ```

  There exists more functionality when using the `IssuesWarnings` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the

primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. Assumption failures result in filtered tests, and the testing framework marks the tests as `Incomplete`. For more information, see `matlab.unittest.qualifications.Assumable`.
- Use assertion qualifications when the failure condition invalidates the remainder of the current test content, but does not prevent proper execution of subsequent test methods. A failure at the assertion point renders the current test method as failed and incomplete. For more information, see `matlab.unittest.qualifications.Assertable`.
- Use fatal assertion qualifications to abort the test session upon failure. These qualifications are useful when the failure mode is so fundamental that there is no point in continuing testing. These qualifications are also useful when fixture teardown does not restore the MATLAB state correctly and it is preferable to abort testing and start a fresh session. For more information, see `matlab.unittest.qualifications.FatalAssertable`.

Input Arguments

`verifiable`

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

`actual`

The function handle to test.

Default:

`warningID`

Warning ID, specified as a string.

`diagnostic`

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

Output Arguments

`output1,...,outputN`

Output arguments, 1 through n (if any), from actual, returned as any type. The argument type is specified by the actual argument list.

Examples

Test warning Function

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify actual warning ID is the same as input warning ID.

```
verifyWarning(testCase, @() warning('SOME:warning:id','Warning!'), ...
    'SOME:warning:id');
```

```
Interactive verification passed.
```

```
verifyWarning(testCase, @() warning('SOME:other:id', 'Warning message'),...
    'SOME:warning:id', 'Did not issue specified warning');
```

```
Warning: Warning message
> In @()warning('SOME:other:id','Warning message')

  In IssuesWarnings>IssuesWarnings.invoke at 364
  In IssuesWarnings>IssuesWarnings.issuesExpectedWarnings at 411
  In IssuesWarnings>IssuesWarnings.satisfiedBy at 240
```

```
  In QualificationDelegate>QualificationDelegate.qualifyThat at 90
  In QualificationDelegate>QualificationDelegate.qualifyWarning at 196
  In Verifiable>Verifiable.verifyWarning at 701
Interactive verification failed.

----------------
Test Diagnostic:
----------------
Did not issue specified warning

---------------------
Framework Diagnostic:
---------------------
verifyWarning failed.
--> The function handle did not issue a correct warning profile.
    The expected warning profile ignores:
      Set
      Count
      Order
    --> The function handle did not issue the correct warnings.

        Missing Warnings:
             SOME:warning:id

    Actual Warning Profile:
         SOME:other:id
    Expected Warning Profile:
         SOME:warning:id

Evaluated Function:
        @()warning('SOME:other:id','Warning message')
```

Test a Function Without Warnings

Test the `true` function, which does not issue warnings.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyWarning(testCase, @true, 'SOME:warning:id', ...
'@true did not issue any warning');

Interactive verification failed.

----------------
Test Diagnostic:
----------------
```

```
@true did not issue any warning

---------------------
Framework Diagnostic:
---------------------
verifyWarning failed.
--> The function handle did not issue a correct warning profile.
    The expected warning profile ignores:
      Set
      Count
      Order
    --> The function handle did not issue any warnings.

    Expected Warning Profile:
         SOME:warning:id

Evaluated Function:
        @true
```

Test failed.

Test Function With Output Arguments

Create a `helper` function that generates a warning and returns output.

```
function varargout = helper()
    warning('SOME:warning:id','Warning!');
    varargout = {123, 'abc'};
end
```

Call `helper`.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
[actualOut1, actualOut2] = verifyWarning(testCase, @helper, ...
    'SOME:warning:id');

Interactive verification passed.
```

More About

- "Types of Qualifications"

Introduced in R2013a

verifyWarningFree

Class: matlab.unittest.qualifications.Verifiable
Package: matlab.unittest.qualifications

Verify function issues no warnings

Syntax

```
verifyWarningFree(verifiable,actual)
verifyWarningFree( ___ ,diagnostic)
output1,...,outputN = verifyWarningFree( ___ )
```

Description

`verifyWarningFree(verifiable,actual)` verifies that actual is a function handle that issues no warnings.

`verifyWarningFree( ___ ,diagnostic)` also displays the diagnostic information in diagnostic upon a failure.

`output1,...,outputN = verifyWarningFree( ___ )` also returns the output arguments output1,...,outputN that are produced when invoking actual.

Tips

- This method is functionally equivalent to:

  ```
  import matlab.unittest.constraints.IssuesNoWarnings;
  verifiable.verifyThat(actual, IssuesNoWarnings());
  ```

  There exists more functionality when using the `IssuesNoWarnings` constraint directly via `verifyThat`.
- Use verification qualifications to produce and record failures without throwing an exception. Since verifications do not throw exceptions, all test content runs to completion even when verification failures occur. Typically verifications are the

primary qualification for a unit test since they typically do not require an early exit from the test. Use other qualification types to test for violation of preconditions or incorrect test setup. Alternatively,

- Use assumption qualifications to ensure that the test environment meets preconditions that otherwise do not result in a test failure. More About

- "Types of Qualifications"

Introduced in R2013a

quarter

Quarter number

Syntax

```
q = quarter(t)
```

Description

`q = quarter(t)` returns the quarter numbers for the datetime values in `t`. The `q` output is a `double` array containing integer values from 1 to 4, and is the same size as `t`.

Examples

Find Quarter Number of Dates

```
t = datetime(2013,05,31):calmonths(3):datetime(2014,05,31)
```

```
t =

   31-May-2013   31-Aug-2013   30-Nov-2013   28-Feb-2014   31-May-2014
```

```
q = quarter(t)
```

```
q =

     2     3     4     1     2
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

See Also

`day` | `month` | `week` | `year`

Introduced in R2014b

questdlg

Create question dialog box

Syntax

```
button = questdlg('qstring')
button = questdlg('qstring','title')
button = questdlg('qstring','title',default)
button = questdlg('qstring','title','str1','str2',default)
button = questdlg('qstring','title','str1','str2','str3',default)
button = questdlg('qstring','title', ..., options)
```

Description

`button = questdlg('qstring')` displays a modal dialog box presenting the question `'qstring'`. The dialog has three default buttons, **Yes**, **No**, and **Cancel**. If the user presses one of these three buttons, `button` is set to the name of the button pressed. If the user presses the close button on the dialog without making a choice, `button` is set to the empty string. If the user presses the **Return** key, button is set to `'Yes'`. `'qstring'` is a cell array or a string that automatically wraps to fit within the dialog box.

Note A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

`button = questdlg('qstring','title')` displays a question dialog with `'title'` displayed in the dialog's title bar.

`button = questdlg('qstring','title',default)` specifies which push button is the default in the event that the **Return** key is pressed. `'default'` must be `'Yes'`, `'No'`, or `'Cancel'`.

`button = questdlg('qstring','title','str1','str2',default)` creates a question dialog box with two push buttons labeled `'str1'` and `'str2'`. *`default`* specifies the default button selection and must be `'str1'` or `'str2'`.

`button = questdlg('qstring','title','str1','str2','str3',default)` creates a question dialog box with three push buttons labeled `'str1'`, `'str2'`, and `'str3'`. *`default`* specifies the default button selection and must be `'str1'`, `'str2'`, or `'str3'`.

When *`default`* is specified, but is not set to one of the button names, pressing the **Enter** key displays a warning and the dialog remains open.

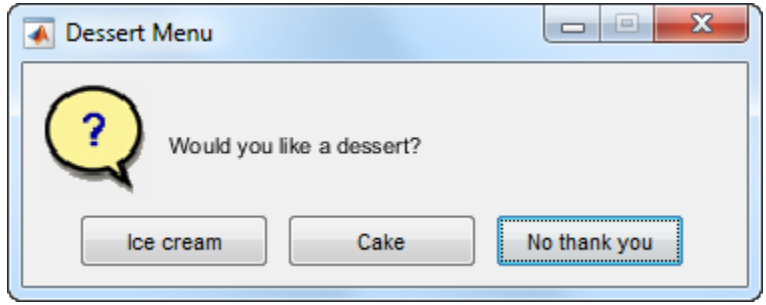
`button = questdlg('qstring','title', ..., options)` replaces the string *`default`* with a structure, `options`. The structure specifies which button string is the default answer, and whether to use TeX to interpret the question string, `qstring`. Button strings and dialog titles cannot use TeX interpretation. The `options` structure must include the fields `Default` and `Interpreter`, both strings. It can include other fields, but `questdlg` does not use them. You can set `Interpreter` to `'none'` or `'tex'`. If the `Default` field does not contain a valid button name, a command window warning is issued and the dialog box does not respond to pressing the **Enter** key.

Examples

Example 1

Create a dialog that requests a dessert preference and encode the resulting choice as an integer.

```
% Construct a questdlg with three options
choice = questdlg('Would you like a dessert?', ...
 'Dessert Menu', ...
 'Ice cream','Cake','No thank you','No thank you');
% Handle response
switch choice
    case 'Ice cream'
        disp([choice ' coming right up.'])
        dessert = 1;
    case 'Cake'
        disp([choice ' coming right up.'])
        dessert = 2;
    case 'No thank you'
        disp('I''ll bring you your check.')
        dessert = 0;
end
```



To access the return value assigned to `dessert`, save the example as a function, for example `choosedessert`, by inserting this line on top:

```
function dessert = choosedessert
```

You can generalize the function by providing the cases as string or cell array calling arguments.

As the example shows, `case` statements can contain white space (but are case-sensitive).

Example 2

Specify an options structure to use the TeX interpreter to format a question.

```
options.Interpreter = 'tex';
% Include the desired Default answer
options.Default = 'Don''t know';
% Create a TeX string for the question
qstring = 'Is \Sigma(\alpha - \beta) < 0?';
choice = questdlg(qstring,'Boundary Condition',...
    'Yes','No','Don''t know',options)
```

Introduced before R2006a

quit

Terminate MATLAB program

Alternatives

As an alternative to the quit function, use the Close box in the MATLAB desktop.

Syntax

```
quit
quit cancel
quit force
```

Description

`quit` displays a confirmation dialog box if the confirm upon quitting preference is selected, and if confirmed or if the confirmation preference is not selected, terminates MATLAB after running `finish.m`, if `finish.m` exists. Call `quit` from the MATLAB command prompt. To interrupt a MATLAB command, see "Stop Execution".

The workspace is not automatically saved by `quit`. To save the workspace or perform other actions when quitting, create a `finish.m` file to perform those actions. For example, you can display a custom dialog box to confirm quitting using a `finish.m` file—see the following examples for details. If an error occurs while `finish.m` is running, `quit` is canceled so that you can correct your `finish.m` file without losing your workspace.

`quit cancel` is for use in `finish.m` and cancels quitting. It has no effect anywhere else.

`quit force` bypasses `finish.m` and terminates MATLAB. Use this to override `finish.m`, for example, if an errant `finish.m` will not let you quit.

Examples

Two sample `finish.m` files are included with MATLAB. Use them to help you create your own `finish.m`, or rename one of the files to `finish.m` to use it.

- `finishsav.m`—Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m`—Displays a dialog allowing you to cancel quitting; it uses `quit cancel` and contains the following code:

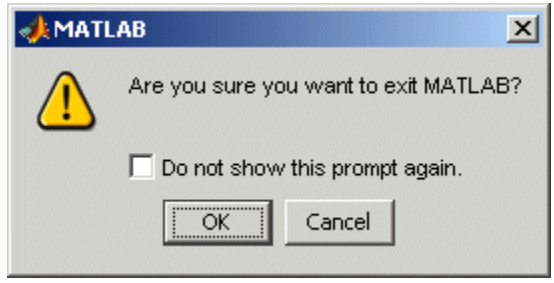
```
button = questdlg('Ready to quit?', ...
        'Exit Dialog','Yes','No','No');
switch button
            case 'Yes',
              disp('Exiting MATLAB');
              %Save variables to matlab.mat
              save
            case 'No',
              quit cancel;
end
```

More About

Tips

When using Handle Graphics objects in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible. See the reference pages for these functions for more information.

If you want MATLAB to display the following confirmation dialog box after running quit, select **Preferences** in the **Environment** section on the **Home** tab. Then select the check box for Confirm before exiting MATLAB, and click **OK**.



- “Stop Execution”

Introduced before R2006a

Quit (COM)

Terminate MATLAB Automation server

Syntax

IDL Method Signature

```
void Quit(void)
```

Microsoft Visual Basic Client

```
Quit
```

MATLAB Client

```
Quit(h)
```

Description

`Quit(h)` terminates the MATLAB server session attached to handle `h`. The MATLAB object is active until all references have been released, such as when the variable in a function call goes out of scope, or by calling the MATLAB `clear h` command.

The function name is case-sensitive.

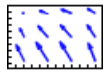
To release the MATLAB object, type:

```
clear h
```

Introduced before R2006a

quiver

Quiver or velocity plot



Syntax

```
quiver(x,y,u,v)
quiver(u,v)
quiver(...,scale)
quiver(...,LineSpec)
quiver(...,LineSpec,'filled')
quiver(...,'PropertyName',PropertyValue,...)
quiver(axes_handle,...)
h = quiver(...)
```

Description

A quiver plot displays velocity vectors as arrows with components `(u,v)` at the points `(x,y)`.

For example, the first vector is defined by components `u(1)`,`v(1)` and is displayed at the point `x(1)`,`y(1)`.

`quiver(x,y,u,v)` plots vectors as arrows at the coordinates specified in each corresponding pair of elements in `x` and `y`. The matrices `x`, `y`, `u`, and `v` must all be the same size and contain corresponding position and velocity components. However, `x` and `y` can also be vectors, as explained in the next section. By default, the arrows are scaled to just not overlap, but you can scale them to be longer or shorter if you want.

`quiver(u,v)` draws vectors specified by `u` and `v` at equally spaced points in the *x*-*y* plane.

`quiver(...,scale)` automatically scales the arrows to fit within the grid and then stretches them by the factor `scale`. `scale = 2` doubles their relative length, and `scale`

= 0.5 halves the length. Use scale = 0 to plot the velocity vectors without automatic scaling. You can also tune the length of arrows after they have been drawn by choosing the Plot Edit  tool, selecting the quiver object, opening the Property Editor, and adjusting the **Length** slider.

quiver(...,LineSpec) specifies line style, marker symbol, and color using any valid LineSpec. quiver draws the markers at the origin of the vectors.

quiver(...,LineSpec,'filled') fills markers specified by LineSpec.

quiver(...,'*PropertyName*',PropertyValue,...) specifies property name and property value pairs for the quiver objects the function creates.

quiver(axes_handle,...) plots into the axes with the handle axes_handle instead of into the current axes (gca).

h = quiver(...) returns the handle to the quiver object.

Expanding x- and y-Coordinates

MATLAB expands x and y if they are not matrices. This expansion is equivalent to calling meshgrid to generate matrices from vectors:

```
[x,y] = meshgrid(x,y);
quiver(x,y,u,v)
```

In this case, the following must be true:

length(x) = n and length(y) = m, where [m,n] = size(u) = size(v).

The vector x corresponds to the columns of u and v, and vector y corresponds to the rows of u and v.

Examples

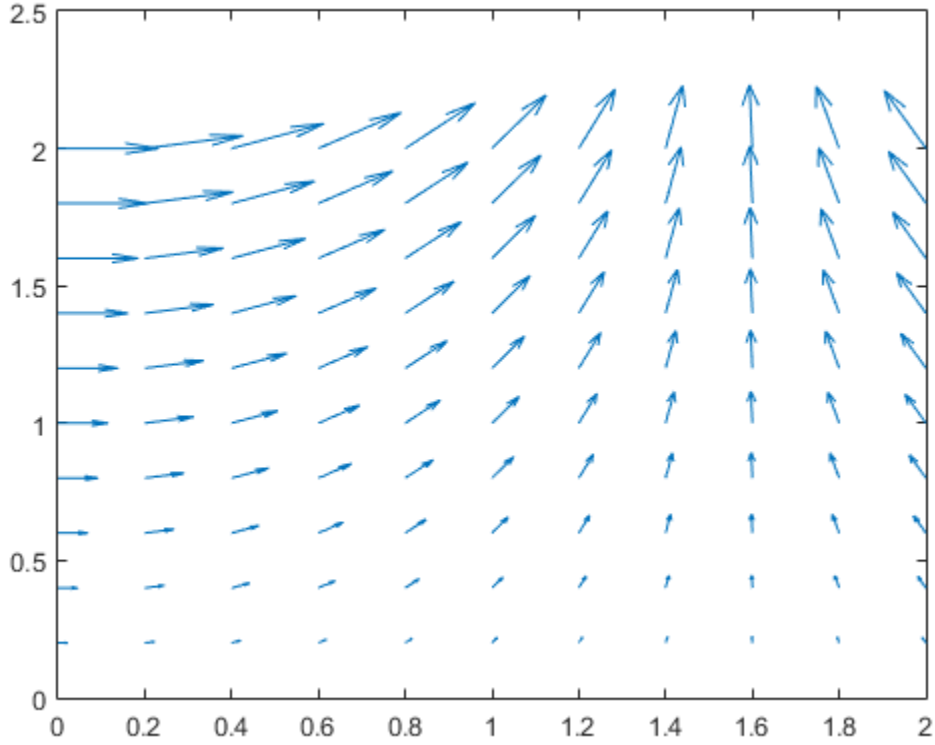
Plot Vector Velocities

Use quiver to display an arrow at each data point in x and y such that the arrow direction and length represent the corresponding values in u and v.

```
[x,y] = meshgrid(0:0.2:2,0:0.2:2);
u = cos(x).*y;
```

```
v = sin(x).*y;

figure
quiver(x,y,u,v)
```



Show Gradient with Quiver Plot

Plot the gradient of the function $z = xe^{-x^2-y^2}$.

```
[X,Y] = meshgrid(-2:.2:2);
Z = X.*exp(-X.^2 - Y.^2);
[DX,DY] = gradient(Z,.2,.2);

figure
```

```
contour(X,Y,Z)
hold on
quiver(X,Y,DX,DY)
hold off
```

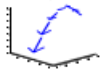
Properties
Quiver Series Properties

Introduced before R2006a

quiver3

3-D quiver or velocity plot



Syntax

```
quiver3(x,y,z,u,v,w)
quiver3(z,u,v,w)
quiver3(...,scale)
quiver3(...,LineSpec)
quiver3(...,LineSpec,'filled')
quiver3(...,'PropertyName',PropertyValue,...)
quiver3(axes_handle,...)
h = quiver3(...)
```

Description

A three-dimensional quiver plot displays vectors with components `(u,v,w)` at the points `(x,y,z)`, where `u`, `v`, `w`, `x`, `y`, and `z` all have real (non-complex) values.

`quiver3(x,y,z,u,v,w)` plots vectors with directions determined by components `(u,v,w)` at points determined by `(x,y,z)`. The matrices `x`,`y`,`z`,`u`,`v`, and `w` must all be the same size and contain the corresponding position and vector components.

`quiver3(z,u,v,w)` plots vectors with directions determined by components `(u,v,w)` at equally spaced points along the surface `z`. For each vector `(u(i,j),v(i,j),w(i,j))`, the column index `j` determines the *x*-value of the point on the surface, the row index `i` determines the *y*-value, and `z(i,j)` determines the *z*-value. That is, `quiver3` locates the vector at the point on the surface `(j,i,z(i,j))`. The `quiver3` function automatically scales the vectors to prevent overlapping based on the distance between them.

`quiver3(...,scale)` automatically scales the vectors to prevent them from overlapping, and then multiplies them by `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves them. Use `scale = 0` to plot the vectors without the automatic scaling.

`quiver3(...,LineSpec)` specifies line style, marker symbol, and color using any valid `LineSpec`. `quiver3` draws the markers at the origin of the vectors.

`quiver3(...,LineSpec,'filled')` fills markers specified by `LineSpec`.

`quiver3(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the quiver series that the function creates.

`quiver3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver3(...)` returns the quiver series handle.

Examples

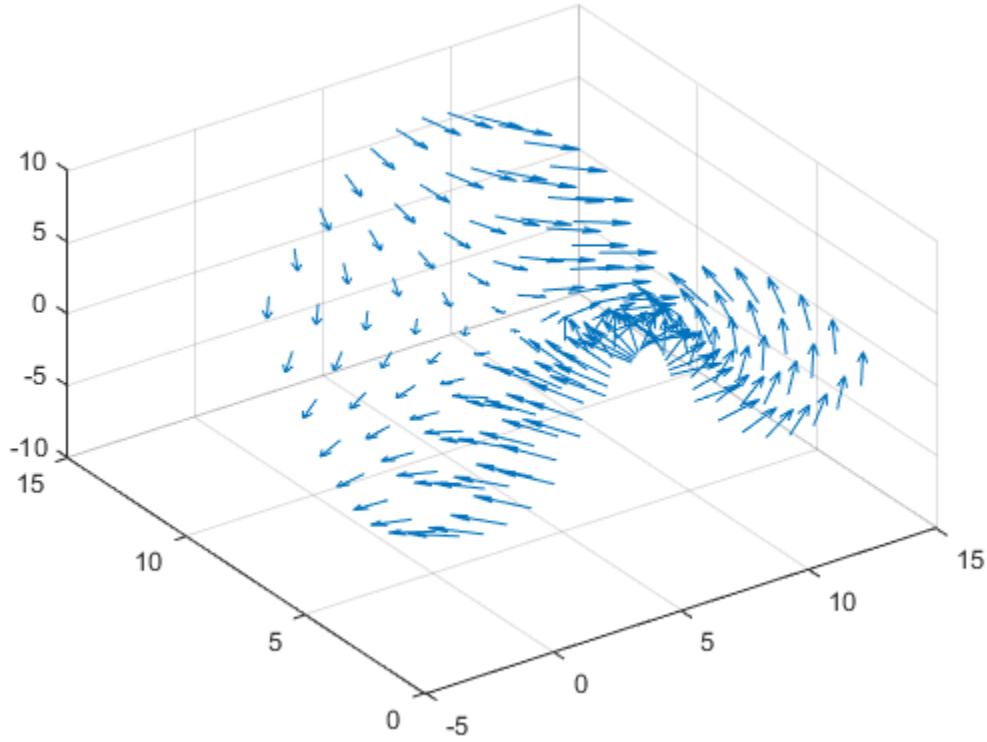
Create 3-D Quiver Plot

Define the data.

```
x = -3:0.5:3;
y = -3:0.5:3;
[X,Y] = meshgrid(x, y);
Z = Y.^2 - X.^2;
[U,V,W] = surfnorm(Z);
```

Plot vectors with components `(U,V,W)` at points that are equally spaced in the *x*-direction and *y*-direction with heights determined by `Z`.

```
figure
quiver3(Z,U,V,W)
view(-35,45)
```



Plot Surface Normals

Plot the surface normals of the function $z = xe^{-x^2-y^2}$.

```
[X,Y] = meshgrid(-2:0.25:2,-1:0.2:1);
Z = X.* exp(-X.^2 - Y.^2);
[U,V,W] = surfnorm(X,Y,Z);

figure
quiver3(X,Y,Z,U,V,W,0.5)

hold on
surf(X,Y,Z)
view(-35,45)
```

```
axis([-2 2 -1 1 -.6 .6])
hold off
```

Properties
Quiver Series Properties

Introduced before R2006a

Quiver Series Properties

Control quiver series appearance and behavior

Quiver series properties control the appearance and behavior of a quiver series object. By changing property values, you can modify certain aspects of the quiver series.

Starting in R2014b, you can use dot notation to query and set properties.

```
q = quiver(1:10,1:10);
c = q.Color;
q.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Arrows

`Color` — Arrow color

`[0 0 1]` (default) | RGB triplet | color string | `'none'`

Arrow color, specified as a three-element RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the arrow is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`

Long Name	Short Name	RGB Triplet
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

LineStyle — Style of arrow stem

'-' (default) | '--' | ':' | '-.' | 'none'

Style of arrow stem, specified as one of the strings listed in this table.

String	Line Style	Result
'-'	Solid line	————
'--'	Dashed line	- - - - -
':'	Dotted line	.....
'-.'	Dash-dotted line	—·—·—·—
'none'	No stem	No stem

LineWidth — Width of arrow stem

0.5 (default) | scalar numeric value

Width of arrow stem, specified as a scalar numeric value greater than zero in point units. One point equals 1/72 inch. The default value is 0.5 point.

Example: 0.75

ShowArrowHead — Arrowhead display

'on' (default) | 'off'

Arrowhead display, specified as one of these values:

- 'on' — Display the vectors with arrowheads.
- 'off' — Display the vectors without arrowheads.

`MaxHeadSize` — Maximum size of arrowhead

`0.2` (default) | scalar

Maximum size of arrowhead, specified as a scalar value in units relative to the length of the arrow.

Example: `0.1`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`AutoScale` — Automatic scaling of arrow length

`'on'` (default) | `'off'`

Automatic scaling of arrow length, specified as one of these values:

- `'on'` — Scale the arrow length to fit within the grid-defined coordinate data and scale arrows so that they do not overlap. The `quiver` function then applies the `AutoScaleFactor` to the arrow length.
- `'off'` — Do not scale the arrow lengths.

`AutoScaleFactor` — Scale factor

`0.9` (default) | scalar

Scale factor, specified as a scalar. A value of `2` doubles the length of the arrows. A value of `0.5` halves the arrow lengths.

This property has an effect only if the `AutoScale` property is set to `'on'`.

Example: `2`

`AlignVertexCenters` — Sharp vertical and horizontal lines

`'off'` (default) | `'on'`

Sharp vertical and horizontal lines, specified as `'off'` or `'on'`.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.

- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the quiver series object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerSize` — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Data

`UData` — Vector lengths in x-direction

vector | matrix

Vector lengths in *x*-direction, specified as a vector or a matrix. The `UData`, `VData`, and `WData` properties together specify the components of the vectors displayed as arrows in the quiver chart.

Example: `1:10`

`VData` — Vector lengths in y-direction

vector | matrix

Vector lengths in *y*-direction, specified as a vector or a matrix. The `UData`, `VData`, and `WData` properties together specify the components of the vectors displayed as arrows in the quiver chart.

Example: `1:10`

`WData` — Vector lengths in z-direction

vector | matrix

Vector lengths in *z*-direction, specified as a vector or a matrix. The `UData`, `VData`, and `WData` properties together specify the components of the vectors displayed as arrows in the quiver chart. For 2-D quiver charts, `WData` is an empty array.

Example: `1:10`

`XData` — x-coordinates

vector | matrix

x-coordinates, specified as a vector or matrix. The input argument `X` to the `quiver` function determines the *x*-coordinates. If you do not specify `X`, then `quiver` uses the indices of `UData` as the *x*-coordinates. `XData` must be equal in size to `YData`.

Setting this property sets the associated mode property to manual mode.

Example: `1:10`

`YData` — y-coordinates

vector | matrix

y-coordinates, specified as a vector or matrix. The input argument `Y` to the `quiver` function determines the *y*-coordinates. If you do not specify `Y`, then `quiver` uses the indices of `VData` as the *y*-coordinates. `YData` must be equal in size to `XData`.

Setting this property sets the associated mode property to manual mode.

Example: `1:10`

`ZData` — z-coordinates

vector | matrix

z-coordinates, specified as a vector or matrix. The input argument `Z` to the `quiver3` function determines the *z*-coordinates. For 2-D quiver charts, `ZData` is an empty array. For 3-D quiver charts, `ZData` must be equal in size to `XData` and `YData`.

Example: `1:10`

`UDataSource` — Variable linked to `UData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `UData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `UData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, MATLAB does not update the `UData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`VDataSource` — Variable linked to `VData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `VData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `VData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, MATLAB does not update the `VData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`WDataSource` — Variable linked to `WData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `WData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `WData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, MATLAB does not update the `WData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`XDataSource` — Variable linked to `XData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`ZDataSource` — Variable linked to `ZData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `ZData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `ZData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `ZData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'z'`

`XDataMode` — Selection mode for `XData`

`'auto' | 'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Automatically select the values.
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or use the input argument `X` to the function.

`YDataMode` — Selection mode for `YData`

`'auto' | 'manual'`

Selection mode for `YData`, specified as one of these values:

- `'auto'` — Automatically select the values.
- `'manual'` — Use manually specified values. To specify the values, set the `YData` property or use the input argument `Y` to the function.

Visibility

`Visible` — Visibility of quiver series

`'on'` (default) | `'off'`

Visibility of quiver series, specified as one of these values:

- `'on'` — Display the quiver series.
- `'off'` — Hide the quiver series without deleting it. You still can access the properties of an invisible quiver series object.

`Clipping` — Clipping of quiver series to axes limits

`'on'` (default) | `'off'`

Clipping of quiver series to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the quiver series that are outside the axes limits.
- `'off'` — Display the entire quiver series, even if parts of it appear outside the axes limits. Parts of the quiver series might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the quiver series that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.

- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'quiver'`

Type of graphics object, returned as `'quiver'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

`Tag` — User-specified tag

`''` (default) | string

Tag to associate with the quiver series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with quiver series

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the quiver series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the quiver series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the quiver series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the quiver series from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the quiver series object in the legend as one entry (default).
   - `'off'` — Do not include the quiver series object in the legend.
   - `'children'` — Include only children of the quiver series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of quiver series

axes object | group object | transform object

Parent of quiver series, specified as an axes, group, or transform object.

`Children` — Children of quiver series

empty `GraphicsPlaceholder` array

The quiver series has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of quiver series object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The quiver series object handle is always visible.
- `'off'` — The quiver series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The quiver series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the quiver series at the command-line, but allows callback functions to access it.

If the quiver series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the quiver series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The quiver series object — You can access properties of the quiver series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the quiver series. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the quiver series when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the quiver series.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the quiver series that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the quiver series responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the quiver series passes the click to the object below it in the current view of the figure window. The HitTest property of the quiver series has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the quiver series. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the quiver series that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the quiver series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for quiver series

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for quiver series, specified as one of these values:

- `'off'` — Click the quiver series plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the quiver series plot to select it, that is, anywhere within the rectangle that encloses the quiver series plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the quiver series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the quiver series tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the quiver series. Setting the `CreateFcn` property on an existing quiver series has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during quiver series creation. MATLAB executes the callback after creating the quiver series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The quiver series object — You can access properties of the quiver series object from within the callback function. You also can access the quiver series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the quiver series. MATLAB executes the callback before destroying the quiver series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The quiver series object — You can access properties of the quiver series object from within the callback function. You also can access the quiver series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of quiver series

`'off'` (default) | `'on'`

Deletion status of quiver series, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the quiver series begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the quiver series no longer exists.

Check the value of the BeingDeleted property to verify that the quiver series is not about to be deleted before querying or modifying it.

qz

QZ factorization for generalized eigenvalues

Syntax

```
[AA,BB,Q,Z] = qz(A,B)
[AA,BB,Q,Z,V,W] = qz(A,B)
qz(A,B,flag)
```

Description

The `qz` function gives access to intermediate results in the computation of generalized eigenvalues.

`[AA,BB,Q,Z] = qz(A,B)` for square matrices `A` and `B`, produces upper quasitriangular matrices `AA` and `BB`, and unitary matrices `Q` and `Z` such that `Q*A*Z = AA`, and `Q*B*Z = BB`. For complex matrices, `AA` and `BB` are triangular.

`[AA,BB,Q,Z,V,W] = qz(A,B)` also produces matrices `V` and `W` whose columns are generalized eigenvectors.

`qz(A,B,flag)` for real matrices `A` and `B`, produces one of two decompositions depending on the value of `flag`:

`'complex'`	Produces a possibly complex decomposition with a triangular `AA`. For compatibility with earlier versions, `'complex'` is the default.
`'real'`	Produces a real decomposition with a quasitriangular `AA`, containing 1-by-1 and 2-by-2 blocks on its diagonal.

If `AA` is triangular, then the diagonal elements `a = diag(AA)` and `b = diag(BB)` are the generalized eigenvalues that satisfy

```
A*V*b = B*V*a
b'*W'*A = a'*W'*B
```

The eigenvalues produced by `lambda = eig(A,B)` are the ratios of the diagonal elements `a` and `b`, such that `lambda = a./b`.

If `AA` is not triangular, it is necessary to further reduce the 2-by-2 blocks to obtain the eigenvalues of the full system.

`eig`

Introduced before R2006a

rand

Uniformly distributed random numbers

Syntax

```
X = rand
X = rand(n)
X = rand(sz1,...,szN)
X = rand(sz)

X = rand(___,typename)
X = rand(___,'like',p)
```

Description

`X = rand` returns a single uniformly distributed random number between 0 and 1.

`X = rand(n)` returns an `n`-by-`n` matrix of random numbers.

`X = rand(sz1,...,szN)` returns an `sz1`-by-...-by-`szN` array of random numbers where `sz1,...,szN` indicate the size of each dimension. For example, `rand(3,4)` returns a 3-by-4 matrix.

`X = rand(sz)` returns an array of random numbers where size vector `sz` specifies `size(X)`. For example, `rand([3 4])` returns a 3-by-4 matrix.

`X = rand(___,typename)` returns an array of random numbers of data type `typename`. The `typename` input can be either `'single'` or `'double'`. You can use any of the input arguments in the previous syntaxes.

`X = rand(___,'like',p)` returns an array of random numbers like `p`; that is, of the same object type as `p`. You can specify either `typename` or `'like'`, but not both.

The sequence of numbers produced by `rand` is determined by the internal settings of the uniform pseudorandom number generator that underlies `rand`, `randi`, and `randn`. You can control that shared random number generator using `rng`.

Note: Use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs. For more information, see " Replace Discouraged Syntaxes of rand and randn"

Examples

Matrix of Random Numbers

Generate a 5-by-5 matrix of uniformly distributed random numbers between 0 and 1.

```
r = rand(5)
```

```
r =

    0.5468    0.6791    0.8852    0.3354    0.6538
    0.5211    0.3955    0.9133    0.6797    0.4942
    0.2316    0.3674    0.7962    0.1366    0.7791
    0.4889    0.9880    0.0987    0.7212    0.7150
    0.6241    0.0377    0.2619    0.1068    0.9037
```

Random Numbers Within Specified Interval

Generate a 10-by-1 column vector of uniformly distributed numbers in the interval `[-5,5]`.

```
r = -5 + (5+5)*rand(10,1)
```

```
r =

    3.1472
    4.0579
   -3.7301
    4.1338
    1.3236
   -4.0246
   -2.2150
    0.4688
    4.5751
    4.6489
```

In general, you can generate `N` random numbers in the interval `[a,b]` with the formula `r = a + (b-a).*rand(N,1)`.

Random Integers

Use the `randi` function (instead of `rand`) to generate 5 random integers from the uniform distribution between 10 and 50.

```
r = randi([10 50],1,5)
```

```
r =

    43    47    15    47    35
```

Random Complex Numbers

Generate a single random complex number with real and imaginary parts in the interval `[0,1]`.

```
a = rand + 1i*rand
```

```
a =

   0.8147 + 0.9058i
```

Reset Random Number Generator

Save the current state of the random number generator and create a 1-by-5 vector of random numbers.

```
s = rng;
r = rand(1,5)
```

```
r =

    0.0975    0.2785    0.5469    0.9575    0.9649
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);
r1 = rand(1,5)
```

```
r1 =
```

```
    0.0975    0.2785    0.5469    0.9575    0.9649
```

Always use the `rng` function (rather than the `rand` or `randn` functions) to specify the settings of the random number generator. For more information, see " Replace Discouraged Syntaxes of rand and randn".

3-D Array of Random Numbers

Create a 3-by-2-by-3 array of random numbers.

```
X = rand([3,2,3])
```

```
X(:,:,1) =

    0.8909    0.1978
    0.3342    0.0305
    0.6987    0.7441

X(:,:,2) =

    0.5000    0.6099
    0.4799    0.6177
    0.9047    0.8594

X(:,:,3) =

    0.8055    0.2399
    0.5767    0.8865
    0.1829    0.0287
```

Specify Data Type of Random Numbers

Create a 1-by-4 vector of random numbers whose elements are single precision.

```
r = rand(1,4,'single')
```

```
r =

    0.1270    0.9134    0.6324    0.0975
```

```
class(r)
```

```
ans =
```

```
single
```

Clone Size from Existing Array

Create a matrix of random numbers with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
X = rand(sz)
```

```
X =

    0.4899    0.9787
    0.1679    0.7127
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = rand(size(A));
```

Clone Size and Data Type from Existing Array

Create a 2-by-2 matrix of single precision random numbers.

```
p = single([3 2; -2 1]);
```

Create an array of random numbers that is the same size and data type as `p`.

```
X = rand(size(p),'like',p)
```

```
X =

    0.5005    0.0596
    0.4711    0.6820
```

```
class(X)
```

```
ans =

single
```

Clone Distributed Array

If you have Parallel Computing Toolbox, create a 1000-by-1000 distributed array of random numbers with underlying data type `single`. For the `distributed` data type, the `'like'` syntax clones the underlying data type in addition to the primary data type.

```
p = rand(1000,'single','distributed');
```

Create an array of random numbers that is the same size, primary data type, and underlying data type as `p`.

```
X = rand(size(p),'like',p);

class(X)

ans =

distributed

classUnderlying(X)

ans =

single
```

- "Create Arrays of Random Numbers"
- "Random Numbers Within a Specific Range"
- "Random Numbers Within a Sphere"

Input Arguments

`n` — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If `n` is `0`, then `X` is an empty matrix.
- If `n` is negative, then it is treated as `0`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz1,...,szN` — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.

- Beyond the second dimension, `rand` ignores trailing dimensions with a size of 1. For example, `rand(3,1,1,1)` produces a 3-by-1 vector of random numbers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `rand` ignores trailing dimensions with a size of 1. For example, `rand([3,1,1,1])` produces a 3-by-1 vector of random numbers.

Example: `sz = [2,3,4]` creates a 2-by-3-by-4 array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`typename` — Data type (class) to create

`'double'` (default) | `'single'`

Data type (class) to create, specified as the string `'double'`, `'single'`, or the name of another class that provides `rand` support.

Example: `rand(5,'single')`

`p` — Prototype of array to create

numeric array

Prototype of array to create, specified as a numeric array.

Example: `rand(5,'like',p)`

Data Types: `single` | `double`
Complex Number Support: Yes

See Also

`randi` | `randn` | `randperm` | `RandStream` | `rng` | `sprand` | `sprandn`

Introduced before R2006a

rand (RandStream)

Uniformly distributed random numbers

Class

`RandStream`

Syntax

```
r = rand(s,n)
r = rand(s,m,n)
r = rand(s,[m,n])
r = rand(s,m,n,p,...)
r = rand(s,[m,n,p,...])
r = rand(s)
r = rand(s,size(A))
r = rand(..., 'double')
r = rand(..., 'single')
```

Description

`r = rand(s,n)` returns an `n`-by-`n` matrix containing pseudorandom values drawn from the standard uniform distribution on the open interval (0,1). The values are drawn from the random stream `s`.

`r = rand(s,m,n)` or `r = rand(s,[m,n])` returns an `m`-by-`n` matrix.

`r = rand(s,m,n,p,...)` or `r = rand(s,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-... array.

`r = rand(s)` returns a scalar.

`r = rand(s,size(A))` returns an array the same size as `A`.

`r = rand(..., 'double')` or `r = rand(..., 'single')` returns an array of uniform values of the specified class.

Note: The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

The sequence of numbers produced by `rand` is determined by the internal state of the random number stream `s`. Resetting that stream to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

See Also

`rand` | `randi (RandStream)` | `randn (RandStream)` | `@RandStream` | `randperm (RandStream)`

randi

Uniformly distributed pseudorandom integers

Syntax

```
X = randi(imax)
X = randi(imax,n)
X = randi(imax,sz1,...,szN)
X = randi(imax,sz)

X = randi(imax,classname)
X = randi(imax,n,classname)
X = randi(imax,sz1,...,szN,classname)
X = randi(imax,sz,classname)

X = randi(imax,'like',p)
X = randi(imax,n,'like',p)
X = randi(imax,sz1,...,szN,'like',p)
X = randi(imax,sz,'like',p)

X = randi([imin,imax], ___ )
```

Description

`X = randi(imax)` returns a pseudorandom scalar integer between `1` and `imax`.

`X = randi(imax,n)` returns an `n`-by-`n` matrix of pseudorandom integers drawn from the discrete uniform distribution on the interval [`1`,`imax`].

`X = randi(imax,sz1,...,szN)` returns an `sz1`-by-...-by-`szN` array where `sz1,...,szN` indicates the size of each dimension. For example, `randi(10,3,4)` returns a 3-by-4 array of pseudorandom integers between 1 and 10.

`X = randi(imax,sz)` returns an array where size vector `sz` defines `size(X)`. For example, `randi(10,[3,4])` returns a 3-by-4 array of pseudorandom integers between 1 and 10.

`X = randi(imax,classname)` returns a pseudorandom integer where `classname` specifies the data type. `classname` can be `'single'`, `'double'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, or `'uint32'`.

`X = randi(imax,n,classname)` returns an `n`-by-`n` array of data type `classname`.

`X = randi(imax,sz1,...,szN,classname)` returns an `sz1`-by-...-by-`szN` array of data type `classname`..

`X = randi(imax,sz,classname)` returns an array where size vector `sz` defines `size(X)` and `classname` defines `class(X)`.

`X = randi(imax,'like',p)` returns a pseudorandom integer like `p`; that is, with the same data type (class).

`X = randi(imax,n,'like',p)` returns an `n`-by-`n` array like `p`.

`X = randi(imax,sz1,...,szN,'like',p)` returns an `sz1`-by-...-by-`szN` array like `p`.

`X = randi(imax,sz,'like',p)` returns an array like `p` where size vector `sz` defines `size(X)`.

`X = randi([imin,imax], ___ )` returns an array containing integers drawn from the discrete uniform distribution on the interval [`imin`,`imax`], using any of the above syntaxes.

The sequence of numbers produced by `randi` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. The `randi` function uses one uniform random value to create each integer random value. You can control that shared random number generator using `rng`.

Examples

Square Matrix of Random Integers

Generate a 5-by-5 matrix of random integers between 1 and 10. The first input to `randi` indicates the largest integer in the sampling interval (the smallest integer in the interval is 1).

```
r = randi(10,5)
```

```
r =

     4     3     2    10     5
     6     5     4    10     6
     5     1     2     1    10
     7    10     5     8     5
     7     2     4     3    10
```

Random Integers Within Specified Interval

Generate a 10-by-1 column vector of uniformly distributed random integers from the sample interval `[-5,5]`.

```
r = randi([-5,5],10,1)
```

```
r =

     3
     4
    -4
     5
     1
    -4
    -2
     1
     5
     5
```

Control Random Number Generation

Save the current state of the random number generator and create a 1-by-5 vector of random integers.

```
s = rng;
r = randi(10,1,5)
```

```
r =

     1     6     9     7     2
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random integers. The values are the same as before.

```
rng(s);
r1 = randi(10,1,5)
```

```
r1 =

     1     6     9     7     2
```

Always use the `rng` function (rather than the `rand` or `randn` functions) to specify the settings of the random number generator. For more information, see " Replace Discouraged Syntaxes of rand and randn".

3-D Array of Random Integers

Create a 3-by-2-by-3 array of uniformly distributed random integers between 1 and 500.

```
X = randi(500,[3,2,3])
```

```
X(:,:,1) =

   185    79
   231   428
   491   323

X(:,:,2) =

   189   242
    96    61
   215   295

X(:,:,3) =

   114   126
   193   146
   292   309
```

Random Integers of Other Data Types

Create a 1-by-4 vector of random numbers whose elements are of type `int16`.

```
r = randi(100,1,4,'int16')
```

```
r =

     28     55     96     97
```

```
class(r)
```

```
ans =

int16
```

Size Defined by Existing Array

Create a matrix of uniformly distributed random integers between 1 and 10 with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
X = randi(10,sz)
```

```
X =

     3    10
     9     8
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = randi(10,size(A));
```

Size and Numeric Data Type Defined by Existing Array

Create a 2-by-2 matrix of 8-bit signed integers.

```
p = int8([3 2; -2 1]);
```

Create an array of random integers that is the same size and data type as `p`.

```
X = randi(10,size(p),'like',p)
```

```
X =

    4    2
    6   10
```

```
class(X)
```

```
ans =

int8
```

- “Random Integers”
- “Create Arrays of Random Numbers”

- “Generate Random Numbers That Are Repeatable”
- “Generate Random Numbers That Are Different”

Input Arguments

`imax` — Largest integer in sample interval

positive integer

Largest integer in sample interval, specified as a positive integer. `randi` draws values from the uniform distribution in the sample interval `[1,imax]`.

Example: `randi(10,5)`

`imin` — Smallest integer in sample interval

1 (default) | scalar integer

Smallest integer in sample interval, specified as a scalar integer.

Both `imin` and `imax` must be integers that satisfy `imin` ≤ `imax`.

For example, `randi([50,100],5)` returns a 5-by-5 matrix of random integers between (and including) 50 and 100.

`n` — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If `n` is `0`, then `X` is an empty matrix.
- If `n` is negative, then it is treated as `0`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz1,...,szN` — Size of each dimension (as separate arguments)

two or more integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is `0`, then `X` is an empty array.

- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `randi` ignores trailing dimensions with a size of 1. For example, `randi([5,10],3,1,1,1)` produces a 3-by-1 vector of random integers between 5 and 10.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `randi` ignores trailing dimensions with a size of 1. For example, `randi([5,10],[3,1,1,1])` produces a 3-by-1 vector of random integers between 5 and 10.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`classname` — Data type (class) to create

`'double'` (default) | `'single'` | `'int8'` | `'uint8'` | ...

Output class, specified as the string `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, or the name of another class that provides `randi` support.

Example: `randi(5,5,'int8')`

Data Types: `char`

`p` — Prototype of array to create

numeric array

Prototype of array to create, specified as a numeric array.

Example: `randi(5,5,'like',p)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`
Complex Number Support: Yes

More About

Tips

- The arrays returned by `randi` might contain repeated integer values. This behavior is sometimes referred to as sampling with replacement. Use `randperm` if you require all unique values.

- "Creating and Controlling a Random Number Stream"
- "Class Support for Array-Creation Functions"
- "Why Do Random Numbers Repeat After Startup?"

`rand` | `randn` | `randperm` | `RandStream` | `rng`

randi (RandStream)

Uniformly distributed pseudorandom integers

Class

`RandStream`

Syntax

```
r = randi(s,imax,n)
r = randi(s,imax,m,n)
r = randi(s,imax,[m,n])
r = randi(s,imax,m,n,p,...)
r = randi(s,imax,[m,n,p,...])
r = randi(s,imax)
r = randi(s,imax,size(A))
r = randi(s,[imin,imax],...)
r = randi(...,classname)
```

Description

`r = randi(s,imax,n)` returns an `n`-by-`n` matrix containing pseudorandom integer values drawn from the discrete uniform distribution on `1:imax`. `randi` draws those values from the random stream `s`.

`r = randi(s,imax,m,n)` or `r = randi(s,imax,[m,n])` returns an `m`-by-`n` matrix.

`r = randi(s,imax,m,n,p,...)` or `r = randi(s,imax,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-... array.

`r = randi(s,imax)` returns a scalar.

`r = randi(s,imax,size(A))` returns an array the same size as `A`.

`r = randi(s,[imin,imax],...)` returns an array containing integer values drawn from the discrete uniform distribution on `imin:imax`.

`r = randi(...,classname)` returns an array of integer values of class `classname`. `classname` does not support 64-bit integers.

Note: The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

The arrays returned by `randi` might contain repeated integer values. This is sometimes referred to as sampling with replacement. To get unique integer values, sometimes referred to as sampling without replacement, use `randperm (RandStream)`.

The sequence of numbers produced by `randi` is determined by the internal state of the random stream `s`. `randi` uses one uniform value from `s` to generate each integer value. Resetting `s` to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

`randi` | `RandStream` | `rand (RandStream)` | `randperm (RandStream)` | `randn (RandStream)`

randn

Normally distributed random numbers

Syntax

```
X = randn
X = randn(n)
X = randn(sz1,...,szN)
X = randn(sz)

X = randn(___,typename)
X = randn(___,'like',p)
```

Description

`X = randn` returns a random scalar drawn from the standard normal distribution.

`X = randn(n)` returns an `n`-by-`n` matrix of normally distributed random numbers.

`X = randn(sz1,...,szN)` returns an `sz1`-by-...-by-`szN` array of random numbers where `sz1,...,szN` indicate the size of each dimension. For example, `randn(3,4)` returns a 3-by-4 matrix.

`X = randn(sz)` returns an array of random numbers where size vector `sz` defines `size(X)`. For example, `randn([3 4])` returns a 3-by-4 matrix.

`X = randn(___,typename)` returns an array of random numbers of data type `typename`. The `typename` input can be either `'single'` or `'double'`. You can use any of the input arguments in the previous syntaxes.

`X = randn(___,'like',p)` returns an array of random numbers like `p`; that is, of the same object type as `p`. You can specify either `typename` or `'like'`, but not both.

The sequence of numbers produced by `randn` is determined by the internal settings of the uniform pseudorandom number generator that underlies `rand`, `randi`, and `randn`. You can control that shared random number generator using `rng`.

Note: Use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs. For more information, see " Replace Discouraged Syntaxes of rand and randn"

Examples

Matrix of Random Numbers

Generate a 5-by-5 matrix of normally distributed random numbers.

```
r = randn(5)
```

```
r =

    1.0347    0.8884    1.4384   -0.1022   -0.0301
    0.7269   -1.1471    0.3252   -0.2414   -0.1649
   -0.3034   -1.0689   -0.7549    0.3192    0.6277
    0.2939   -0.8095    1.3703    0.3129    1.0933
   -0.7873   -2.9443   -1.7115   -0.8649    1.1093
```

Bivariate Normal Random Numbers

Generate values from a bivariate normal distribution with specified mean vector and covariance matrix.

```
mu = [1 2];
sigma = [1 0.5; 0.5 2];
R = chol(sigma);
z = repmat(mu,10,1) + randn(10,2)*R
```

```
z =

    1.3271    3.3688
    2.0826    3.3279
    2.0061    2.9663
    0.3491    3.3285
    1.2571    3.3585
    0.0556    1.8450
   -0.3218    0.4258
    1.9248    1.6005
    1.0000    3.5770
```

```
    0.9451   -0.1597
```

Random Complex Numbers

Generate a single random complex number with normally distributed real and imaginary parts.

```
a = randn + 1i*randn
```

```
a =

   0.5377 + 1.8339i
```

Reset Random Number Generator

Save the current state of the random number generator and create a 1-by-5 vector of random numbers.

```
s = rng;
r = randn(1,5)
```

```
r =

   -0.0245   -1.9488    1.0205    0.8617    0.0012
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);
r1 = randn(1,5)
```

```
r1 =

   -0.0245   -1.9488    1.0205    0.8617    0.0012
```

Always use the `rng` function (rather than the `rand` or `randn` functions) to specify the settings of the random number generator. For more information, see " Replace Discouraged Syntaxes of rand and randn".

3-D Array of Random Numbers

Create a 3-by-2-by-3 array of random numbers.

```
X = randn([3,2,3])
```

```
X(:,:,1) =
```

```
   -0.0708   -2.1924
   -2.4863   -2.3193
    0.5812    0.0799

X(:,:,2) =

   -0.9485    0.8577
    0.4115   -0.6912
    0.6770    0.4494

X(:,:,3) =

    0.1006    0.8979
    0.8261   -0.1319
    0.5362   -0.1472
```

Specify Data Type of Random Numbers

Create a 1-by-4 vector of random numbers whose elements are single precision.

```
r = randn(1,4,'single')
```

```
r =

    0.5377    1.8339   -2.2588    0.8622
```

```
class(r)
```

```
ans =

single
```

Clone Size from Existing Array

Create a matrix of normally distributed random numbers with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
X = randn(sz)
```

```
X =
```

```
    1.0078   -0.5046
   -2.1237   -1.2706
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = randn(size(A));
```

Clone Size and Data Type from Existing Array

Create a 2-by-2 matrix of single precision random numbers.

```
p = single([3 2; -2 1]);
```

Create an array of random numbers that is the same size and data type as `p`.

```
X = randn(size(p),'like',p)
```

```
X =

   -0.3826    0.8257
    0.6487   -1.0149
```

```
class(X)
```

```
ans =

single
```

Clone Distributed Array

If you have Parallel Computing Toolbox, create a 1000-by-1000 distributed array of random numbers with underlying data type `single`. For the `distributed` data type, the `'like'` syntax clones the underlying data type in addition to the primary data type.

```
p = randn(1000,'single','distributed');
```

Create an array of random numbers that is the same size, primary data type, and underlying data type as `p`.

```
X = randn(size(p),'like',p);
```

```
class(X)
```

```
ans =

distributed
```

```
classUnderlying(X)

ans =

single
```

- "Create Arrays of Random Numbers"
- "Random Numbers Within a Specific Range"
- "Random Numbers Within a Sphere"
- "Random Numbers from Normal Distribution with Specific Mean and Variance"

Input Arguments

n — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If `n` is `0`, then `X` is an empty matrix.
- If `n` is negative, then it is treated as `0`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

sz1,...,szN — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `randn` ignores trailing dimensions with a size of 1. For example, `randn(3,1,1,1)` produces a 3-by-1 vector of random numbers.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

sz — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `randn` ignores trailing dimensions with a size of 1. For example, `randn([3,1,1,1])` produces a 3-by-1 vector of random numbers.

Example: `sz = [2,3,4]` creates a 2-by-3-by-4 array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`typename` — Data type (class) to create

`'double'` (default) | `'single'`

Data type (class) to create, specified as the string `'double'`, `'single'`, or the name of another class that provides `randn` support.

Example: `randn(5,'single')`

`p` — Prototype of array to create

numeric array

Prototype of array to create, specified as a numeric array.

Example: `randn(5,'like',p)`

Data Types: `single` | `double`
Complex Number Support: Yes

More About

See Also

`rand` | `randi` | `randperm` | `RandStream` | `rng` | `sprand` | `sprandn`

Introduced before R2006a

randn (RandStream)

Normally distributed pseudorandom numbers

Class

`RandStream`

Syntax

```
r = randn(s,m,n)
r = randn(s,[m,n])
r = randn(s,m,n,p,...)
r = randn(s,[m,n,p,...])
r = randn(s)
r = randn(s,size(A))
r = randn(...,'double')
r = randn(...,'single')
```

Description

`r = randn(s,n)` returns an `n`-by-`n` matrix containing pseudorandom values drawn from the standard normal distribution. `randn` draws those values from the random stream `s`.

`r = randn(s,m,n)` or `r = randn(s,[m,n])` returns an `m`-by-`n` matrix.

`r = randn(s,m,n,p,...)` or `r = randn(s,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-... array.

`r = randn(s)` returns a scalar.

`r = randn(s,size(A))` returns an array the same size as `A`.

`r = randn(...,'double')` or `r = randn(...,'single')` returns an array of uniform values of the specified class.

Note: The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

The sequence of numbers produced by `randn` is determined by the internal state of the random stream `s`. `randn` uses one or more uniform values from `s` to generate each normal value. Resetting that stream to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

See Also

`randn` | `RandStream` | `rand (RandStream)` | `randi (RandStream)`

randperm

Random permutation

Syntax

```
p = randperm(n)
p = randperm(n,k)
```

Description

`p = randperm(n)` returns a row vector containing a random permutation of the integers from 1 to `n` inclusive.

`p = randperm(n,k)` returns a row vector containing `k` unique integers selected randomly from 1 to `n` inclusive.

Examples

`randperm(6)`
might be the vector

```
[3  2  6  4  1  5]
```

or it might be some other permutation of the integers from 1 to 6, depending on the state of the random number generator. Two successive calls to `randperm` would in most cases return two different vectors:

```
randperm(6)
ans =
     5     2     6     4     1     3

randperm(6)
ans =
     4     1     6     2     3     5
```

`randperm(6,3)`
might be the vector

```
[4 2 5]
```
or it might be some other permutation of any three integers from 1 to 6 inclusive, depending on the state of the random number generator.

More About

Tips

For `p = randperm(n,k)`, `p` contains `k` *unique* values. `randperm` performs k-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(n,1,k)`.

`randperm` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

See Also

`permute` | `randi` | `nchoosek` | `randperm(RandStream)` | `perms` | `rng`

Introduced before R2006a

randperm (RandStream)

Random permutation

Class

`RandStream`

Syntax

```
p = randperm(s,n)
p = randperm(s,n,k)
```

Description

`p = randperm(s,n)` returns a row vector containing a random permutation of integers from 1 to `n` inclusive. `randperm(s,n)` uses random values drawn from the random stream `s`.

`p = randperm(s,n,k)` returns a row vector containing `k` unique integers selected randomly from 1 to `n` inclusive.

Examples

Create a random stream `s` and generate a random permutation of the integers from 1 to 6 based on `s`:

```
s = RandStream('mt19937ar','Seed',0);
randperm(s,6)
```

MATLAB returns the vector

```
[6     3     5     1     2     4]
```

Use the random stream `s` to generate three integers between 1 and 10:

```
randperm(s,10,3)
```

```
ans =
     1     8     9
```

More About

Tips

For `p = randperm(s,n,k)`, `p` contains `k` *unique* values. `randperm` performs k-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(s,n,1,k)`.

See Also

`permute` | `randi (RandStream)` | `randperm` | `nchoosek` | `perms` | `rand`

RandStream

Random number stream

Constructor

`RandStream`

Description

Pseudorandom numbers in MATLAB come from one or more random number streams. The simplest way to generate arrays of random numbers is to use `rand`, `randn`, or `randi`. These functions all rely on the same stream of uniform random numbers, known as the *global stream*. You can create other streams that act separately from the global stream, and you can use their `rand`, `randi`, or `randn` methods to generate arrays of random numbers. You can also create a random number stream and make it the global stream.

To create a single random number stream, use the `RandStream` constructor. To create multiple independent random number streams, use `RandStream.create`. The `rng` function provides a simple interface to create a new global stream.

`stream = RandStream.getGlobalStream` returns the global random number stream, that is, the one currently used by the `rand`, `randi`, and `randn` functions.

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream `stream` as the new global stream to be used by the `rand`, `randi`, and `randn` functions, and returns the previous global stream.

A random number stream `s` has properties that control its behavior. Access or assign to a property using `p = s.Property` or `s.Property = p`. The following table lists defined properties:

Properties

Property	Description
`Type`	(Read-only) Generator algorithm used by the stream. The list of possible generators is given by `RandStream.list`.
`Seed`	(Read-only) Seed value used to create the stream.
`NumStreams`	(Read-only) Number of streams in the group in which the current stream was created.
`StreamIndex`	(Read-only) Index of the current stream from among the group of streams with which it was created.
`State`	Internal state of the generator. You should not depend on the format of this property. The value you assign to `S.State` must be a value read from `S.State` previously. Use `reset` to return a stream to a predictable state without having previously read from the `State` property. The sequence of random numbers produced by a random number stream `s` is determined by the internal state of its random number generator. Saving and restoring the generator's internal state with the `State` property allows you to reproduce a sequence of random numbers.
`Substream`	Index of the substream to which the stream is currently set. The default is 1. Multiple substreams are not supported by all generator types; the multiplicative lagged Fibonacci generator (`mlfg6331_64`) and combined multiple recursive generator (`mrg32k3a`) support substreams.
`NormalTransform`	Transformation algorithm used by `randn(s, ...)` to generate normal pseudorandom values. Possible values are `'Ziggurat'`, `'Polar'`, or `'Inversion'`.

Property	Description
`Antithetic`	Logical value indicating whether `S` generates antithetic pseudorandom values, that is, the usual values subtracted from 1. The default is false.
`FullPrecision`	Logical value indicating whether `S` generates values using its full precision. Some generators can create pseudorandom values faster, but with fewer random bits, if `FullPrecision` is false. The default is true.

Methods

Method	Description
`RandStream`	Create a random number stream.
`RandStream.create`	Create multiple independent random number streams.
`get`	Get the properties of a random stream object.
`list`	List available random number generator algorithms.
`set`	Set random stream property.
`RandStream.getGlobalStream`	Get the global random number stream.
`RandStream.setGlobalStream`	Set global random number stream.
`reset`	Reset a stream to its initial internal state
`rand`	Pseudorandom numbers from a uniform distribution
`randn`	Pseudorandom numbers from a standard normal distribution
`randi`	Pseudorandom integers from a uniform discrete distribution
`randperm`	Random permutation of a set of values

Examples

Example 1

Create a single stream and designate it as the current global stream:

```
s = RandStream('mt19937ar','Seed',1);
RandStream.setGlobalStream(s);
```

Example 2

Create three independent streams:

```
[s1,s2,s3] = RandStream.create('mrg32k3a','NumStreams',3);
r1 = rand(s1,100000,1);
r2 = rand(s2,100000,1);
r3 = rand(s3,100000,1);
corrcoef([r1,r2,r3])
```

Example 3

Create only one stream from a set of three independent streams, and designate it as the current global stream:

```
s2 = RandStream.create('mrg32k3a','NumStreams',3,...
     'StreamIndices',2);
RandStream.setGlobalStream(s2);
```

Example 4

Reset the global random number stream that underlies `rand`, `randi`, and `randn` back to its beginning, to reproduce previous results:

```
stream = RandStream.getGlobalStream;
reset(stream);
```

Example 5

Save and restore the current global stream's state to reproduce the output of `rand`:

```
stream = RandStream.getGlobalStream;
savedState = stream.State;
u1 = rand(1,5)
u1 =
    0.8147    0.9058    0.1270    0.9134    0.6324

stream.State = savedState;
u2 = rand(1,5)
u2 =
    0.8147    0.9058    0.1270    0.9134    0.6324
```

`u2` contains exactly the same values as `u1`.

Example 6

Reset the global random number stream to its initial settings. This causes `rand`, `randi`, and `randn` to start over, as if in a new MATLAB session:

```
s = RandStream('mt19937ar','Seed',0);
RandStream.setGlobalStream(s);
```

Example 7

Reinitialize the global random number stream using a seed based on the current time. This causes `rand`, `randi`, and `randn` to return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

Example 8

Change the transformation algorithm that `randn` uses to create normal pseudorandom values from uniform values. This does not replace or reset the global stream.

```
stream = RandStream.getGlobalStream;
stream.NormalTransform = 'inversion'
```

See Also

`rand` | `rng` | `randn` | `randi`

RandStream constructor

Random number stream

Class

`RandStream`

Syntax

```
s = RandStream('gentype')
s = RandStream('gentype',Name,Value)
```

Description

`s = RandStream('gentype')` creates a random number stream that uses the uniform pseudorandom number generator algorithm specified by `gentype`. `RandStream.list` returns all possible values for `gentype`, or see " Choosing a Random Number Generator" for details on generator algorithms.

`s = RandStream('gentype',Name,Value)` allows you to specify one or more optional `Name,Value` pairs to control creation of the stream.

Once you have created a random, you can use `RandStream.setGlobalStream` to make it the global stream, so that the functions `rand`, `randi`, and `randn` draw values from it.

Parameters for `RandStream` are:

Parameter	Description
`Seed`	Nonnegative scalar integer with which to initialize all streams. Seeds must be an integer between 0 and $2^{32} - 1$ or `'shuffle'` to create a seed based on the current time. Default is 0.

Parameter	Description
`NormalTransform`	Transformation algorithm used by `randn(s, ...)` to generate normal pseudorandom values. Possible values are `'Ziggurat'`, `'Polar'`, or `'Inversion'`.

Examples

Example 1

Create a random number stream, make it the global stream, and save and restore its state to reproduce the output of `randn`:

```
s = RandStream('mrg32k3a');
RandStream.setGlobalStream(s);
savedState = s.State;
z1 = randn(1,5)
z1 =
   -0.1894   -1.4426   -0.3592    0.8883   -0.4337
s.State = savedState;
z2 = randn(1,5)
z2 =
   -0.1894   -1.4426   -0.3592    0.8883   -0.4337
```

`z2` contains exactly the same values as `z1`.

Example 2

Return `rand`, `randi`, and `randn` to their default startup settings:

```
s = RandStream('mt19937ar','Seed',0)
RandStream.setGlobalStream(s);
```

Example 3

Replace the current global random number stream with a stream whose seed is based on the current time, so `rand`, `randi`, and `randn` will return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB

session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

More About

Tips

- Streams created using `RandStream` might not be independent from each other. Use `RandStream.create` to create multiple streams that are independent.

See Also

`RandStream` | `RandStream.rand` | `RandStream.randn` | `RandStream.randi` | `RandStream.getGlobalStream` | `RandStream.setGlobalStream` | `RandStream.list` | `rng` | `RandStream.create`

RandStream.getGlobalStream

Current global random number stream

Class

`@RandStream`

Syntax

```
stream = RandStream.getGlobalStream
```

Description

`stream = RandStream.getGlobalStream` returns the current global random number stream.

`rand`, `randi`, and `randn` all rely on the same stream of uniform pseudorandom numbers, known as the *global stream*. `rand` draws one value from that stream to generate each uniform value it returns. `randi` draws one uniform value from that stream to generate each integer value it returns. And `randn` draws one or more uniform values to generate each normal value it returns. Note that there are also `rand`, `randi`, and `randn` methods for which you specify a specific random stream from which to draw values.

Note: The `rng` function is a shorter alternative for many common uses of `RandStream.getGlobalStream`.

More About

- "Creating and Controlling a Random Number Stream"
- "Managing the Global Stream"

`rand` | `randi` | `randn` | `RandStream` | `RandStream.setGlobalStream` | `rng`

RandStream.setGlobalStream

Set global random number stream

Syntax

```
prevstream = RandStream.setGlobalStream(stream)
```

Description

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream, specified as `stream`, to be the global stream that the `rand`, `randi`, and `randn` functions draw values from. It returns the previous global random number stream as `prevstream`.

`rand`, `randi`, and `randn` all rely on the same stream of uniform pseudorandom numbers, known as the *global stream*. `rand` draws one value from that stream to generate each uniform value it returns. `randi` draws one uniform value from that stream to generate each integer value it returns. And `randn` draws one or more uniform values to generate each normal value it returns. Note that there are also `rand`, `randi`, and `randn` methods for which you specify a specific random stream from which to draw values.

Note: The `rng` function is a shorter alternative for many common uses of `RandStream.setGlobalStream`.

rank

Rank of matrix

Syntax

```
k = rank(A)
k = rank(A,tol)
```

Description

The `rank` function provides an estimate of the number of linearly independent rows or columns of a full matrix.

`k = rank(A)` returns the number of singular values of `A` that are larger than the default tolerance, `max(size(A))*eps(norm(A))`.

`k = rank(A,tol)` returns the number of singular values of `A` that are larger than `tol`.

More About

Tips

Use `sprank` to determine the structural rank of a sparse matrix.

Algorithms

There are a number of ways to compute the rank of a matrix. MATLAB software uses the method based on the singular value decomposition, or SVD. The SVD algorithm is the most time consuming, but also the most reliable.

The `rank` algorithm is

```
s = svd(A);
tol = max(size(A))*eps(max(s));
r = sum(s > tol);
```

See Also

sprank

Introduced before R2006a

rat

Rational fraction approximation

Syntax

```
R = rat(X)
R = rat(X,tol)

[N,D] = rat( ___ )
```

Description

`R = rat(X)` returns the rational fraction approximation of `X` to within the default tolerance, `1e-6*norm(X(:),1)`. The approximation is a string containing the truncated continued fractional expansion.

`R = rat(X,tol)` approximates `X` to within the tolerance, `tol`.

`[N,D] = rat( ___ )` returns two arrays, `N` and `D`, such that `N./D` approximates `X`, using any of the above syntaxes.

Examples

Approximate Value of π

Approximate the value of π using a rational representation of the quantity `pi`.

The mathematical quantity π is not a rational number, but the quantity `pi` that approximates it *is* a rational number since all floating-point numbers are rational.

Find the rational representation of `pi`.

```
format rat
pi
```

```
ans =
```

```
355/113
```

The resulting expression is a string. You also can use `rats(pi)` to get the same answer.

Use `rat` to see the continued fractional expansion of `pi`.

```
R = rat(pi)
```

```
R =

3 + 1/(7 + 1/(16))
```

The resulting string is an approximation by continued fractional expansion. If you consider the first two terms of the expansion, you get the approximation $3+\frac{1}{7}=\frac{22}{7}$, which only agrees with `pi` to 2 decimals.

However, if you consider all three terms printed by `rat`, you can recover the value `355/113`, which agrees with `pi` to 6 decimals.

$$3+\frac{1}{7+\frac{1}{16}}=\frac{355}{113}.$$

Specify a tolerance for additional accuracy in the approximation.

```
R = rat(pi,1e-7)
```

```
R =

3 + 1/(7 + 1/(16 + 1/(-294)))
```

The resulting approximation, `104348/33215`, agrees with `pi` to 9 decimals.

Express Array Elements as Ratios

Create a 4-by-4 matrix.

```
format short;
X = hilb(4)
```

```
X =

    1.0000    0.5000    0.3333    0.2500
```

```
    0.5000    0.3333    0.2500    0.2000
    0.3333    0.2500    0.2000    0.1667
    0.2500    0.2000    0.1667    0.1429
```

Express the elements of `X` as ratios of small integers using `rat`.

```
[N,D] = rat(X)
```

```
N =

     1     1     1     1
     1     1     1     1
     1     1     1     1
     1     1     1     1

D =

     1     2     3     4
     2     3     4     5
     3     4     5     6
     4     5     6     7
```

The two matrices, `N` and `D`, approximate `X` with `N./D`.

View the elements of `X` as ratios using `format rat`.

```
format rat
X
```

```
X =

       1            1/2          1/3          1/4
       1/2          1/3          1/4          1/5
       1/3          1/4          1/5          1/6
       1/4          1/5          1/6          1/7
```

In this form, it is clear that `N` contains the numerators of each fraction and `D` contains the denominators.

Input Arguments

`X` — Input array

numeric array

Input array, specified as a numeric array of class `single` or `double`.

Data Types: `single | double`
Complex Number Support: Yes

`tol` — Tolerance
scalar

Tolerance, specified as a scalar. `N` and `D` approximate `X`, such that `N./D - X < tol`. The default tolerance is `1e-6*norm(X(:),1)`.

Output Arguments

`R` — Continued fraction
string

Continued fraction, returned as a string. The accuracy of the rational approximation via continued fractions increases with the number of terms.

`N` — Numerator
numeric array

Numerator, returned as a numeric array. `N./D` approximates `X`.

`D` — Denominator
numeric array

Denominator, returned as a numeric array. `N./D` approximates `X`.

More About

Algorithms

Even though all floating-point numbers are rational numbers, it is sometimes desirable to approximate them by simple rational numbers, which are fractions whose numerator and denominator are small integers. Rational approximations are generated by truncating continued fraction expansions.

The `rat` function approximates each element of `X` by a continued fraction of the form

$$\frac{N}{D} = D_1 + \frac{1}{D_2 + \frac{1}{\left(D_3 + \ldots + \frac{1}{D_k} \right)}}.$$

The *D*s are obtained by repeatedly picking off the integer part and then taking the reciprocal of the fractional part. The accuracy of the approximation increases exponentially with the number of terms and is worst when `X = sqrt(2)`. For `X = sqrt(2)` , the error with `k` terms is about `2.68*(.173)^k`, so each additional term increases the accuracy by less than one decimal digit. It takes 21 terms to get full floating-point accuracy.

See Also

`format | rats`

Introduced before R2006a

rats

Rational output

Syntax

```
S = rats(X)
S = rats(X,strlen)
```

Description

`S = rats(X)` returns a string containing the rational approximations to the elements of `X` using the default string length of `13`.

`rats` returns asterisks for elements that cannot be printed in the allotted space, but which are not negligible compared to the other elements in `X`.

`S = rats(X,strlen)` returns a string of length `strlen`. The rational approximation uses a tolerance that is inversely proportional to string length.

Examples

Rational Representation of Matrix

Create a 4-by-4 matrix.

```
format short
X = hilb(4)
```

```
X =

    1.0000    0.5000    0.3333    0.2500
    0.5000    0.3333    0.2500    0.2000
    0.3333    0.2500    0.2000    0.1667
    0.2500    0.2000    0.1667    0.1429
```

View the rational representation of the matrix using `rats`. The result is the same as using `format rat`.

```
R = rats(X)

R =

       1          1/2        1/3        1/4
      1/2         1/3        1/4        1/5
      1/3         1/4        1/5        1/6
      1/4         1/5        1/6        1/7
```

Adjust Output String Length

Find the rational representation of `pi` with the default string length and approximation tolerance. The result is the same as using `format rat`.

```
rats(pi)

ans =

    355/113
```

Adjust the string length of the output, which also adjusts the approximation tolerance.

```
rats(pi,20)

ans =

    104348/33215
```

The resulting rational approximation has greater accuracy. As the string length increases, the tolerance decreases.

Adjust the string length again to achieve greater accuracy.

```
rats(pi,25)

ans =

      1146408/364913
```

The resulting approximation agrees with `pi` to 10 decimal places.

Input Arguments

`X` — Input array

numeric array

Input array, specified as a numeric array of class `single` or `double`.

Data Types: `single | double`
Complex Number Support: Yes

`strlen` — String length
positive integer

String length, specified as a positive integer. The default string length is 13, which allows for 6 elements in 78 spaces.

Output Arguments

`S` — Rational output
string

Rational output, returned as a string.

More About

Algorithms

`rats` obtains rational approximations with `[N,D] = rat(X,tol)`, where `tol` is `min(10^(-(strlen-1)/2)*norm(X(isfinite(X)),1),.1)`. Thus, the tolerance is inversely proportional to the string length, `strlen`.

`format | rat`

Introduced before R2006a

rbbox

Create rubberband box for area selection

Syntax

```
rbbox
rbbox(initialRect)
rbbox(initialRect,fixedPoint)
rbbox(initialRect,fixedPoint,stepSize)
finalRect = rbbox(...)
```

Description

`rbbox` initializes and tracks a rubberband box in the current figure. It sets the initial rectangular size of the box to 0, anchors the box at the figure's `CurrentPoint`, and begins tracking from this point.

`rbbox(initialRect)` specifies the initial location and size of the rubberband box as `[x y width height]`, where `x` and `y` define the lower left corner, and `width` and `height` define the size. `initialRect` is in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. The corner of the box closest to the pointer position follows the pointer until `rbbox` receives a button-up event.

`rbbox(initialRect,fixedPoint)` specifies the corner of the box that remains fixed. All arguments are in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. `fixedPoint` is a two-element vector, `[x y]`. The tracking point is the corner diametrically opposite the anchored corner defined by `fixedPoint`.

`rbbox(initialRect,fixedPoint,stepSize)` specifies how frequently the rubberband box is updated. When the tracking point exceeds `stepSize` figure units, `rbbox` redraws the rubberband box. The default stepsize is `1`.

`finalRect = rbbox(...)` returns a four-element vector, `[x y width height]`, where `x` and `y` are the *x* and *y* components of the lower left corner of the box, and `width` and `height` are the dimensions of the box.

Examples

Create an annotation rectangle by rubber banding the rectangle size in the figure.

```
set(gcf,'Units','normalized')
k = waitforbuttonpress;
rect_pos = rbbox;
annotation('rectangle',rect_pos,'Color','red')
```

Execute the code, click down and drag a rectangle within the figure. Releasing the mouse button draws a rectangle in the figure.

More About

Tips

`rbbox` is useful for defining and resizing a rectangular region:

- For box definition, `initialRect` is `[x y 0 0]`, where `(x,y)` is the figure's `CurrentPoint`.
- For box resizing, `initialRect` defines the rectangular region that you resize (e.g., a legend). `fixedPoint` is the corner diametrically opposite the tracking point.

`rbbox` returns immediately if a button is not currently pressed. Therefore, you use `rbbox` with `waitforbuttonpress` so that the mouse button is down when `rbbox` is called. `rbbox` returns when you release the mouse button.

See Also

`axis` | `dragrect` | `waitforbuttonpress`

Introduced before R2006a

rcond

Reciprocal condition number

Syntax

```
C = rcond(A)
```

Description

`C = rcond(A)` returns an estimate for the reciprocal condition of `A` in 1-norm. If `A` is well conditioned, `rcond(A)` is near 1.0. If `A` is badly conditioned, `rcond(A)` is near 0.

Examples

Sensitivity of Badly Conditioned Matrix

Examine the sensitivity of a badly conditioned matrix.

A notable matrix that is symmetric and positive definite, but badly conditioned, is the Hilbert matrix. The elements of the Hilbert matrix are $H(i,j) = 1/(i + j - 1)$.

Create a 10-by-10 Hilbert matrix.

```
A = hilb(10);
```

Find the reciprocal condition number of the matrix.

```
C = rcond(A)
```

```
C =

   2.8286e-14
```

The reciprocal condition number is small, so `A` is badly conditioned.

The condition of `A` has an effect on the solutions of similar linear systems of equations. To see this, compare the solution of $Ax = b$ to that of the perturbed system, $Ax = b + 0.01$.

Create a column vector of ones and solve $Ax = b$.

```
b = ones(10,1);
x = A\b;
```

Now change b by `0.01` and solve the perturbed system.

```
b1 = b + 0.01;
x1 = A\b1;
```

Compare the solutions, `x` and `x1`.

```
norm(x-x1)
```

```
ans =

   1.1250e+05
```

Since `A` is badly conditioned, a small change in `b` produces a very large change (on the order of 1e5) in the solution to $x = A\backslash b$. The system is sensitive to perturbations.

Find Condition of Identity Matrix

Examine why the reciprocal condition number is a more accurate measure of singularity than the determinant.

Create a 5-by-5 multiple of the identity matrix.

```
A = eye(5)*0.01;
```

This matrix is full rank and has five equal singular values, which you can confirm by calculating `svd(A)`.

Calculate the determinant of `A`.

```
det(A)
```

```
ans =

   1.0000e-10
```

Although the determinant of the matrix is close to zero, `A` is actually very well conditioned and *not* close to being singular.

Calculate the reciprocal condition number of `A`.

```
rcond(A)

ans =

     1
```

The matrix has a reciprocal condition number of `1` and is, therefore, very well conditioned. Use `rcond(A)` or `cond(A)` rather than `det(A)` to confirm singularity of a matrix.

Input Arguments

`A` — Input matrix

square numeric matrix

Input matrix, specified as a square numeric matrix.

Data Types: `single` | `double`

Output Arguments

`C` — Reciprocal condition number

scalar

Reciprocal condition number, returned as a scalar. The data type of `C` is the same as `A`.

The reciprocal condition number is a scale-invariant measure of how close a given matrix is to the set of singular matrices.

- If `C` is near 0, the matrix is nearly singular and badly conditioned.
- If `C` is near 1.0, the matrix is well conditioned.

More About

Tips

- `rcond` is a more efficient but less reliable method of estimating the condition of a matrix compared to the condition number, `cond`.

See Also

`cond` | `condest` | `norm` | `normest` | `rank` | `svd`

Introduced before R2006a

rdivide, ./

Right array division

Syntax

```
x = A./B
x = rdivide(A,B)
```

Description

`x = A./B` divides each element of A by the corresponding element of B. Inputs `A` and `B` must have the same size unless one is a scalar value. A scalar value is expanded into an array of the same size as the other input.

`x = rdivide(A,B)` is an alternative way to divide A by B, but is rarely used. It enables operator overloading for classes.

Examples

Divide Two Numeric Arrays

Create two numeric arrays, `A` and `B`, and divide the second array, `B`, into the first, `A`.

```
A = [2 4 6 8; 3 5 7 9];
B = 10*ones(2,4);
x = A./B
```

```
x =

    0.2000    0.4000    0.6000    0.8000
    0.3000    0.5000    0.7000    0.9000
```

Integer Division

Divide an `int16` scalar value by each element of an `int16` vector.

```
a = int16(10);
```

```
b = int16([3 4 6]);
x = a./b

x =

      3      3      2
```

MATLAB rounds the results when dividing integer data types.

Divide Scalar by Array

Create an array and divide it into a scalar.

```
C = 5;
D = magic(3);
x = C./D

x =

    0.6250    5.0000    0.8333
    1.6667    1.0000    0.7143
    1.2500    0.5556    2.5000
```

When you specify a scalar value to be divided by an array, the scalar value expands into an array of the same size, then element-by-element division is performed.

Input Arguments

A — Numerator

scalar | vector | matrix | multidimensional array

Numerator, specified as a scalar, vector, matrix, or multidimensional array. If `B` is an integer data type, `A` must be the same integer type or a scalar double.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `duration`
Complex Number Support: Yes

B — Denominator

scalar | vector | matrix | multidimensional array

Denominator, specified as a scalar, vector, matrix, or multidimensional array. If `A` is an integer data type, `B` must be the same integer type or a scalar double.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `duration`
Complex Number Support: Yes

Output Arguments

x — Solution

scalar | vector | matrix | multidimensional array

Solution, returned as a scalar, vector, matrix or multidimensional array. If either `A` or `B` is an integer data type, then `x` is that same integer data type.

More About

Tips

- When dividing integers, use `idivide` for more rounding options.
- MATLAB does not support complex integer division.

- "Array vs. Matrix Operations"
- "Operator Precedence"

See Also

`idivide` | `ldivide` | `mldivide` | `mrdivide`

Introduced before R2006a

read

Class: VideoReader

Read video frame data from file

Note: `VideoReader.read` will be removed in a future release. Use `VideoReader.readFrame` instead.

Syntax

```
video = read(obj)
video = read(obj,index)
video = read( ___ ,'native')
```

Description

`video = read(obj)` reads in all video frames from the file associated with obj. The `read` method returns a `H`-by-`W`-by-`B`-by-`F` matrix, `video`, where `H` is the image frame height, `W` is the image frame width, `B` is the number of bands in the image (for example, 3 for RGB), and `F` is the number of frames read.

`video = read(obj,index)` reads only the specified frames. index can be a single number or a two-element array representing an index range of the video stream.

`video = read( ___ ,'native')` returns data in the format specified by the `VideoFormat` property, and can include any of the input arguments in the previous syntaxes.

Input Arguments

`obj`

Name of multimedia object created with `VideoReader`.

`index`

Frames to read, where the first frame number is 1. Use `Inf` to represent the last frame of the file.

For example:

```
video = read(obj, 1);         % first frame only
video = read(obj, [1 10]);    % first 10 frames
video = read(obj, Inf);       % last frame only
video = read(obj, [50 Inf]);  % frame 50 thru end
```

MATLAB cannot determine the number of frames in a variable frame rate file until you read the last frame. If the requested *`index`* extends beyond the end of the file, `read` returns either a warning or an error.

Default: `[1 Inf]`

Output Arguments

`video`

Array of data representing video frames, returned in a format dependent on the `VideoFormat` property of `obj`. For most files, the data type and dimensions of `video` are as follows. Note that when the `VideoFormat` property of `obj` is `'Indexed'`, the data type and dimensions of `video` depend on whether you call `read` with the `'native'` argument.

Value of `obj.VideoFormat`	Data Type of `video`	Dimensions of `video`	Description
`'RGB24'`	`uint8`	H-by-W-by-3-by-F	RGB24 image
`'Grayscale'`, without specifying `'native'`	`uint8`	H-by-W-by-1-by-F	Grayscale image
`'Indexed'`, without specifying `'native'`	`uint8`	H-by-W-by-3-by-F	RGB24 image
`'Grayscale'` or `'Indexed'`, specifying `'native'`	`struct`	1-by-F	MATLAB movie, which is an array of frame structure

Value of `obj.VideoFormat`	Data Type of `video`	Dimensions of `video`	Description
			arrays, each containing the fields `cdata` and `colormap`.

`H` is the image frame height, `W` is the image frame width, and `F` is the number of frames read.

For Motion JPEG 2000 files, the data type and dimensions of `video` are as follows.

Value of `obj.VideoFormat`	Data Type of `video`	Dimensions of `video`	Description
`'Mono8'`	`uint8`	H-by-W-by-1-by-F	Mono image
`'Mono8 Signed'`	`int8`	H-by-W-by-1-by-F	Mono signed image
`'Mono16'`	`uint16`	H-by-W-by-1-by-F	Mono image
`'Mono16 Signed'`	`int16`	H-by-W-by-1-by-F	Mono signed image
`'RGB24'`	`uint8`	H-by-W-by-3-by-F	RGB24 image
`'RGB24 Signed'`	`int8`	H-by-W-by-3-by-F	RGB24 signed image
`'RGB48'`	`uint16`	H-by-W-by-3-by-F	RGB48 image
`'RGB48 Signed'`	`int16`	H-by-W-by-3-by-F	RGB48 signed image

Examples

Read and Play Back Movie File

Read and play back the movie file `xylophone.mp4`.

```
xyloObj = VideoReader('xylophone.mp4');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;
```

Preallocate the movie structure.

```
mov(1:nFrames) = ...
    struct('cdata',zeros(vidHeight,vidWidth, 3,'uint8'),...
           'colormap',[]);
```

Read one frame at a time.

```
for k = 1 : nFrames
    mov(k).cdata = read(xyloObj,k);
end
```

Size a figure based on the video's width and height.

```
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])
```

Play back the movie once at the video's frame rate.

```
movie(hf, mov, 1, xyloObj.FrameRate);
```

See Also

`movie` | `VideoReader`

How To

- “Read Video Files”

readFrame

Class: VideoReader

Read video frame from video file

Syntax

```
video = readFrame(obj)
video = readFrame(obj,'native')
```

Description

`video = readFrame(obj)` reads the next available video frame from the file associated with `obj`.

`video = readFrame(obj,'native')` returns data in the format specified by the `VideoFormat` property.

Input Arguments

`obj` — Object associated with video file to read

`VideoReader` object

Object associated with the video file to read, specified as a `VideoReader` object.

Output Arguments

`video` — Video frame data

array

Video frame data, returned as an array. The dimensions and data type of `video` depend on the `VideoFormat` property of `obj`.

For most files, the data type and dimensions of `video` are as follows. When the `VideoFormat` property of `obj` is `'Indexed'`, the data type and dimensions of `video` depend on whether you call `read` with the `'native'` argument.

Value of `obj.VideoFormat`	Data Type of `video`	Dimensions of `video`	Description
`'RGB24'`	`uint8`	H-by-W-by-3	RGB24 image
`'Grayscale'`, without specifying `'native'`	`uint8`	H-by-W-by-1	Grayscale image
`'Indexed'`, without specifying `'native'`	`uint8`	H-by-W-by-3	RGB24 image
`'Grayscale'` or `'Indexed'`, specifying `'native'`	`struct`	1-by-1	MATLAB movie, which is an array of frame structure arrays, each containing the fields `cdata` and `colormap`.

`H` is the image frame height and `W` is the image frame width.

For Motion JPEG 2000 files, the data type and dimensions of `video` are as follows.

Value of `obj.VideoFormat`	Data Type of `video`	Dimensions of `video`	Description
`'Mono8'`	`uint8`	H-by-W-by-1	Mono image
`'Mono8 Signed'`	`int8`	H-by-W-by-1	Mono signed image
`'Mono16'`	`uint16`	H-by-W-by-1	Mono image
`'Mono16 Signed'`	`int16`	H-by-W-by-1	Mono signed image
`'RGB24'`	`uint8`	H-by-W-by-3	RGB24 image
`'RGB24 Signed'`	`int8`	H-by-W-by-3	RGB24 signed image
`'RGB48'`	`uint16`	H-by-W-by-3	RGB48 image
`'RGB48 Signed'`	`int16`	H-by-W-by-3	RGB48 signed image

Examples

Read and Play Back Movie File

Read and play back the sample movie file, `xylophone.mp4`.

Construct a `VideoReader` object to read data from the sample file. Then, determine the width and height of the video.

```
xyloObj = VideoReader('xylophone.mp4');

vidWidth = xyloObj.Width;
vidHeight = xyloObj.Height;
```

Create a movie structure array, `mov`.

```
mov = struct('cdata',zeros(vidHeight,vidWidth,3,'uint8'),...
    'colormap',[]);
```

Read one frame at a time until the end of the video is reached.

```
k = 1;
while hasFrame(xyloObj)
    mov(k).cdata = readFrame(xyloObj);
    k = k+1;
end
```

Size a figure based on the video's width and height. Then, play back the movie once at the video's frame rate.

```
hf = figure;
set(hf,'position',[150 150 vidWidth vidHeight]);

movie(hf,mov,1,xyloObj.FrameRate);
```

- "Read Video Files"

See Also

`movie` | `VideoReader`

read

Class: Tiff

Read entire image

Syntax

```
imageData = read(tiffobj)
[Y,Cb,Cr] = read(tiffobj)
```

Description

`imageData = read(tiffobj)` reads the image data from the current image file directory (IFD) in the TIFF file associated with the `Tiff` object, `tiffobj`.

`[Y,Cb,Cr] = read(tiffobj)` reads the YCbCr component data from the current directory in the TIFF file. Depending upon the values of the `YCbCrSubSampling` tag, the size of the `Cb` and `Cr` channels might differ from the `Y` channel.

Examples

Open a `Tiff` object and read data from the TIFF file:

```
t = Tiff('example.tif','r');
imageData = read(t);
close(t)
```

See Also

`Tiff.write` | `imread`

read

Read data from remote host over TCP/IP interface

Syntax

```
read(t)
read(t,size)
read(t,size,datatype)
```

Description

`read(t)` reads all available bytes of data from `tcpclient` object `t` connected to the remote host and returns the data. The number of values read is determined by the `BytesAvailable` property.

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type.

`read(t,size)` reads the specified number of values, `size`, from `tcpclient` object `t` connected to the remote host and returns the data. If `size` is greater than the object's `BytesAvailable` property, then the function waits until the specified amount of data is read or the `timeout` is reached.

`read(t,size,datatype)` reads the specified number of values, `size`, with the specified precision, `datatype`, from `tcpclient` object `t` connected to the remote host and returns the data. The `datatype` argument is a character string of a standard MATLAB data type.

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type.

Examples

Read All Available Data from Host

Create a TCP/IP object called `t`, using the IP address shown, and Port of `4012`.

```
t = tcpclient('172.28.154.231', 4012)
```

```
t =

   tcpclient with properties:

          Address: '172.28.154.231'
             Port: 4012
          Timeout: 10
   BytesAvailable: 0
```

Read all the bytes of data available.

```
read(t)
```

The `read` function used with no arguments reads all available bytes of data from `tcpclient` object `t` connected to the remote host and returns the data. The number of values read is determined by the `BytesAvailable` property, which is equal to the numbers of bytes available in the input buffer.

Close the connection between the TCP/IP client object and the remote host by clearing the object.

```
clear t
```

Specify the Size and Data Type to Read

Create a TCP/IP object called `t`, connecting to a TCP/IP echo server, with Port of `7`.

```
t = tcpclient('localhost', 7)
```

```
t =

   tcpclient with properties:

          Address: 'local host'
             Port: 7
          Timeout: 10
   BytesAvailable: 0
```

Assign 10 bytes of data to the variable `data`.

```
data = (1:10)
```

Check the data.

```
whos data
```

```
Name      Size      Bytes      Class      Attributes

data      1x10         10      double
```

Write data to the echo server.

```
write(t, data)
```

Check that the data was written using the `BytesAvailable` property.

```
t.BytesAvailable
```

```
ans =

    80
```

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type. Since 1 `double` equals 8 `uint8` bytes, there are 80 bytes available.

Read 10 doubles from the server. The object name is always the first argument. The `size` argument must be the second argument, and `datatype` must be the third argument.

```
read(t, 10, 'double')
```

```
ans =

  1    2    3    4    5    6    7    8    9    10
```

Close the connection between the TCP/IP client object and the remote host by clearing the object.

```
clear t
```

Input Arguments

`size` — Number of bytes to read

numeric scalar

Number of bytes to read, specified as a numeric scalar. Size cannot be set to `inf`. If `size` is greater than the object's `BytesAvailable` property, the function waits until the specified amount of data is read. The first argument must be the object name, and the second argument is the size. The `size` argument is optional.

Example: `read(t, 5)`

Data Types: `double`

`datatype` — MATLAB data type

`'uint8'` (default) | `'int8'` | `'uint16'` | `'int16'` | `'uint32'` | `'int32'` | `'uint64'` | `'int64'` | `'single'` | `'double'`

MATLAB data type, specified as a character string. Size cannot be set to `inf`. The `datatype` must be set to one of the 10 values shown above. The first argument must be the object name, the second argument is the size, and the third argument is the data type. The `size` and `datatype` arguments are optional.

For any read or write operation, the data type is converted to `uint8` for the data transfer. It is then converted back to whatever data type you set if you specified another data type.

Example: `read(t, 10, 'double')`

Data Types: `char`

readasync

Read data asynchronously from device

Syntax

```
readasync(obj)
readasync(obj,size)
```

Description

`readasync(obj)` initiates an asynchronous read operation on the serial port object, `obj`.

`readasync(obj,size)` asynchronously reads, at most, the number of bytes given by `size`. If `size` is greater than the difference between the `InputBufferSize` property value and the `BytesAvailable` property value, an error is returned.

Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to a Tektronix TDS 210 oscilloscope, configures `s` to read data asynchronously only if `readasync` is issued, and configures the instrument to return the peak-to-peak value of the signal on channel 1.

```
s = serial('COM1');
fopen(s)
s.ReadAsyncMode = 'manual';
fprintf(s,'Measurement:Meas1:Source CH1')
fprintf(s,'Measurement:Meas1:Type Pk2Pk')
fprintf(s,'Measurement:Meas1:Value?')
```

Begin reading data asynchronously from the instrument using `readasync`. When the read operation is complete, return the data to the MATLAB workspace using `fscanf`.

```
readasync(s)
s.BytesAvailable
```

```
ans =
     15

out = fscanf(s)

out =
2.0399999619E0

fclose(s)
```

More About

Tips

Before you can read data, you must connect `obj` to the device with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

Only use `readasync` to configure the `ReadAsyncMode` property to `manual`. `readasync` is ignored if used when `ReadAsyncMode` is `continuous`.

The `TransferStatus` property indicates if an asynchronous read or write operation is in progress. You can write data while an asynchronous read is in progress because serial ports have separate read and write pins. You can stop asynchronous read and write operations with the `stopasync` function.

You can monitor the amount of data stored in the input buffer with the `BytesAvailable` property. Additionally, you can use the `BytesAvailableFcn` property to execute a callback function when the terminator or the specified amount of data is read.

Rules for Completing an Asynchronous Read Operation

An asynchronous read operation with `readasync` completes when one of these conditions is met:

- The terminator specified by the `Terminator` property is read.
- The time specified by the `Timeout` property passes.
- The specified number of bytes is read.
- The input buffer is filled (if `size` is not specified).

Because `readasync` checks for the terminator, this function can be slow. To increase speed, you might want to configure `ReadAsyncMode` to `continuous` and continuously return data to the input buffer as soon as it is available from the device.

Introduced before R2006a

readEncodedStrip

Class: Tiff

Read data from specified strip

Syntax

```
stripData = readEncodedStrip(tiffobj,stripNumber)
[Y,Cb,Cr] = readEncodedStrip(tiffobj,stripNumber)
```

Description

`stripData = readEncodedStrip(tiffobj,stripNumber)` reads data from the strip specified by `stripNumber`. Strip numbers are one-based numbers.

`[Y,Cb,Cr] = readEncodedStrip(tiffobj,stripNumber)` reads YCbCr component data from the specified strip. The size of the chrominance components `Cb` and `Cr` might differ from the size of the luminance component `Y` depending on the value of the `YCbCrSubSampling` tag.

`readEncodeStrip` clips the last strip, if the strip extends past the `ImageLength` boundary.

Examples

Read a Strip

Read the first strip in the second image of a TIFF file.

Create a `Tiff` object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');
setDirectory(t,2)
```

Read the data in the first strip. Then, close the `Tiff` object.

```
data = readEncodedStrip(t,1);
close(t)
```

`Tiff.readEncodedTile` | `Tiff.isTiled`

readEncodedTile

Class: Tiff

Read data from specified tile

Syntax

```
tileData = readEncodedTile(tiffobj,tileNumber)
[Y,Cb,Cr] = readEncodedTile(tiffobj,tileNumber)
```

Description

`tileData = readEncodedTile(tiffobj,tileNumber)` reads data from the tile specified by `tileNumber`. Tile numbers are one-based numbers.

`[Y,Cb,Cr] = readEncodedTile(tiffobj,tileNumber)` reads YCbCr component data from the specified tile. The size of the chrominance components `Cb` and `Cr` might differ from the size of the luminance component `Y`, depending on the value of the `YCbCrSubSampling` tag.

`readEncodedTile` clips tiles on the last row or right-most column of an image if the tile extends past the `ImageLength` and `ImageLength` boundaries.

Examples

Read a Tile

Create a `Tiff` object associated with the example file, `example.tif`. Then, read the first tile of data.

```
t = Tiff('example.tif','r');
data = readEncodedTile(t,1);
```

```
close(t)
```

References

This method corresponds to the `TIFFReadEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

See Also

`Tiff.readEncodedStrip` | `Tiff.isTiled`

readRGBAImage

Class: Tiff

Read image using RGBA interface

Syntax

```
[RGB,alpha] = readRGBAImage()
```

Description

`[RGB,alpha] = readRGBAImage()` reads an entire image using the RGBA interface. `RGB` consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the tile, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The pixel values may be transformed depending upon the values of the following tags:

`PhotometricInterpretation`

`BitsPerSample`

`SamplesPerPixel`

`Orientation`

`ExtraSamples`

`ColorMap`

Examples

Return all image data as RGB, with associated alpha matting.

```
t = Tiff('example.tif','r');
t.setDirectory(2);
[RGB,A] = t.readRGBAImage();
t.close();
```

References

This method corresponds to the `TIFFReadRGBAImage` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at LibTiff - TIFF Library and Utilities.

See Also

`Tiff.readRGBAStrip` | `Tiff.read` | `Tiff.readRGBATile`

readRGBAStrip

Class: Tiff

Read strip data using RGBA interface

Syntax

```
[RGB,alpha] = readRGBAStrip(row)
```

Description

`[RGB,alpha] = readRGBAStrip(row)` reads a strip using the RGBA interface. `row` is a one-based number of any row contained by the strip. `RGB` consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the strip, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The strip is clipped if the strip boundary extends past the end of the image.

The pixel values may be transformed depending upon the values of the following tags:

`PhotometricInterpretation`
`BitsPerSample`
`SamplesPerPixel`
`Orientation`
`ExtraSamples`
`ColorMap`

Examples

Open a `Tiff` object and read the strip of data that contains the first row, using the RGBA interface, from the example file, `example.tif`

```
t = Tiff('example.tif','r');
```

```
t.setDirectory(2);
[RGB,A] = t.readRGBAStrip(1);
t.close();
```

References

This method corresponds to the `TIFFReadRGBAStrip` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at LibTiff - TIFF Library and Utilities.

`Tiff.readRGBATile` | `Tiff.readRGBAImage`

readRGBATile

Class: Tiff

Read tile data using RGBA interface

Syntax

```
[RGB,alpha] = readRGBATile(row,col)
```

Description

`[RGB,alpha] = readRGBATile(row,col)` reads a tile using the RGBA interface. `row` and `col` are the one-based row and column numbers of any pixel in the requested tile. `RGB` consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the tile, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The tile is clipped if the tile boundaries extend past the edges of the image.

The pixel values may be transformed depending upon the values of the following tags:

```
PhotometricInterpretation
BitsPerSample
SamplesPerPixel
Orientation
ExtraSamples
ColorMap
```

Examples

Open a `Tiff` object and read the first tile using the RGBA interface.

```
t = Tiff('example.tif','r');
```

```
t.setDirectory(1);
[RGB,A] = t.readRGBATile(1,1);
t.close();
```

References

This method corresponds to the `TIFFReadRGBATile` function in the LibTIFF C API.

To use this method, you must be familiar with LibTIFF version 4.0.0, as well as the TIFF specification and technical notes. View this documentation at LibTiff - TIFF Library and Utilities.

`Tiff.readRGBAStrip` | `Tiff.readRGBAImage`

Remove

Convenience function for static .NET System.Delegate Remove method

Syntax

```
result = Remove(combinedDelegate,removedDelegate)
```

Description

`result = Remove(combinedDelegate,removedDelegate)` removes last instance of the `removedDelegate` delegate from the `combinedDelegate` delegate.

Input Arguments

`combinedDelegate`

.NET `System.Delegate` object. The combined delegate from which to remove the `removedDelegate` delegate.

Default:

`removedDelegate`

.NET `System.Delegate` object. The delegate to remove from the `combinedDelegate` delegate.

Default:

Output Arguments

`result`

.NET `System.Delegate` object. A new delegate which is the same as the `combinedDelegate` delegate except without the last instance of the `removedDelegate` delegate.

Alternatives

Use the static `Remove` method of the `System.Delegate` class.

More About

- "Combine and Remove .NET Delegates"
- MSDN System.Delegate.Remove Method reference page

`RemoveAll` | `Combine`

Introduced in R2011a

RemoveAll

Convenience function for static .NET System.Delegate RemoveAll method

Syntax

```
result = RemoveAll(combinedDelegate,removedDelegate)
```

Description

`result = RemoveAll(combinedDelegate,removedDelegate)` removes all instances of `removedDelegate` from `combinedDelegate`.

Input Arguments

`combinedDelegate`

.NET `System.Delegate` object. The combined delegate from which to remove all instances of the `removedDelegate` delegate.

Default:

`removedDelegate`

.NET `System.Delegate` object. The delegate to remove from the `combinedDelegate` delegate.

Default:

Output Arguments

`result`

.NET `System.Delegate` object. A new delegate which is the same as the `combinedDelegate` delegate except without all instances of the `removedDelegate` delegate.

Alternatives

Use the static `RemoveAll` method of the `System.Delegate` class.

`Remove` | `Combine`

Introduced in R2011a

timeseries class

Create `timeseries` object

Description

Time series are data vectors sampled over time, in order, often at regular intervals. They are distinguished from randomly sampled data that form the basis of many other data analyses. Time series represent the time-evolution of a dynamic population or process. The linear ordering of time series gives them a distinctive place in data analysis, with a specialized set of techniques. Time series analysis is concerned with:

- Identifying patterns
- Modeling patterns
- Forecasting values

Construction

`ts = timeseries` creates an empty time-series object.

`ts = timeseries(tsname)` creates an empty time-series object using the name, tsname, for the time-series object. This name can differ from the time-series variable name.

`ts = timeseries(data)` creates the time-series object using the specified data.

`ts = timeseries(data,time)` creates the time-series object using the specified data and time.

`ts = timeseries(data,time,quality)` specifies quality in terms of codes defined by `QualityInfo.Code`.

`ts = timeseries(data,'Name',tsname)` creates the time-series object using the specified data and the name, tsname.

`ts = timeseries(data,time,'Name',tsname)` creates the time-series object using the specified data, time, and the name, tsname.

`ts = timeseries(data,time,quality,'Name',tsname)` uses the specified quality and the name, tsname.

Input Arguments

`data`

The time-series data, which can be an array of samples

`tsname`

Time-series name specified as a string

Default: `''`

`time`

The time vector.

When time values are date strings, you must specify `Time` as a cell array of date strings. When the time vector contains duplicate values:

- Duplicated values must occupy contiguous elements.
- Time values must not be decreasing.

Interpolating time-series data using methods like `resample` and `synchronize` can produce different results depending on whether the input `timeseries` contains duplicate times.

Default: A time vector that ranges from `0` to `N-1` with a 1-second interval, where `N` is the number of samples.

`quality`

An integer vector with values `-128` to `127` that specifies the quality in terms of codes defined by `QualityInfo.Code`

When `Quality` is a vector:

- `Quality` must have the same length as the time vector.

- Each `Quality` value applies to the corresponding data sample.

When `Quality` is an array:

- `Quality` must have the same size as the data array.
- Each `Quality` value applies to the corresponding data value of the `ts.data` array.

Properties

`Data`

Time-series data, where each data sample corresponds to a specific time

The data can be a scalar, a vector, or a multidimensional array. Either the first or last dimension of the data must align with `Time`.

By default, `NaN`s represent missing or unspecified data. Set the `TreatNaNasMissing` property to determine how missing data is treated in calculations.

Attributes:

`Dependent`	`true`

`DataInfo`

Contains fields for storing contextual information about `Data`:

- `Unit` — String that specifies data units
- `Interpolation` — A `tsdata.interpolation` object that specifies the interpolation method for this `timeseries` object.

  Fields of the `tsdata.interpolation` object include:

  - `Fhandle` — Function handle to a user-defined interpolation function
  - `Name` — String that specifies the name of the interpolation method. Predefined methods include `'linear'` and `'zoh'` (zero-order hold). `'linear'` is the default.
- `UserData` — Any user-defined information entered as a string

Events

An array of `tsdata.event` objects that stores event information for this `timeseries` object.

You add events by using the `addevent` method. Fields of the `tsdata.event` object include the following:

- `EventData` — Any user-defined information about the event
- `Name` — String that specifies the name of the event
- `Time` — Time value when this event occurs, specified as a real number or a date string
- `Units` — Time units
- `StartDate` — A reference date specified in MATLAB date-string format. `StartDate` is empty when you have a numerical (non-date-string) time vector.

IsTimeFirst

Logical value (`true` or `false`) specifies whether the time vector is aligned with the first or last dimension of the `Data` array. The value is `false` for 3-D and higher dimensional data and `true` otherwise.

- `true` — The first dimension of the data array is aligned with the time vector. For example, `ts = timeseries(rand(3,3),1:3);`
- `false` — The last dimension of the data array is aligned with the time vector. For example: `ts = timeseries(rand(3,4,5),1:5);`

Attributes:

`Dependent`	`true`
`SetAccess`	`'protected'`

Length

Length of the time vector in the `timeseries` object

Attributes:

`Dependent`	`true`

```
SetAccess                       'protected'
```

Name

The `timeseries` object name entered as a string, tsname.

This name can differ from the name of the `timeseries` variable in the MATLAB workspace.

Quality

An integer vector or array containing values `-128` to `127` that specify the quality in terms of codes defined by `QualityInfo.Code`.

When `Quality` is a vector, it must have the same length as the time vector. In this case, each `Quality` value applies to a corresponding data sample.

When `Quality` is an array, it must have the same size as the data array. In this case, each `Quality` value applies to the corresponding value of the data array.

Attributes:

```
Dependent                       true
```

QualityInfo

Provides a lookup table that converts numerical `Quality` codes to readable descriptions.

`QualityInfo` fields include the following:

- `Code` — Integer vector containing values `-128` to `127` that define the "dictionary" of quality codes. You can assign one of these integer values to each `Data` value by using the `Quality` property.
- `Description` — Cell vector of strings, where each element provides a readable description of the associated quality `Code`.
- `UserData` — Stores any additional user-defined information.

Lengths of `Code` and `Description` must match.

Time

Array of time values.

When `TimeInfo.StartDate` is empty, the numerical `Time` values are measured relative to `0` in specified units. When `TimeInfo.StartDate` is defined, the time values are date strings measured relative to the `StartDate` in specified units.

The length of `Time` must be the same as either the first or the last dimension of `Data`. When the data contains three or more dimensions, the length of `Time` matches the size of the last data dimension. Otherwise, the length of `Time` matches the size of the first data dimension.

Attributes:

`Dependent`	`true`

`TimeInfo`

Uses the following fields for storing contextual information about `Time`:

- `Units` — Time units having any of following values: `'weeks'`, `'days'`, `'hours'`, `'minutes'`, `'seconds'`, `'milliseconds'`, `'microseconds'`, or `'nanoseconds'`
- `Start` — Start time
- `End` — End time (read only)
- `Increment` — Interval between two subsequent time values
- `Length` — Length of the time vector (read only)
- `Format` — String defining the date string display format. See the MATLAB `datestr` function reference page for more information.
- `StartDate` — Date string defining the reference date. See the MATLAB `setabstime` function reference page for more information.
- `UserData` — Stores any additional user-defined information

`TreatNaNasMissing`

Logical value that specifies how to treat `NaN` values in `Data`:

- `true` — (Default) Treats all `NaN` values as missing data except during statistical calculations.
- `false` — Includes `NaN` values in statistical calculations, in which case `NaN` values are propagated to the result.

`UserData`

Generic field for data of any class that you want to add to the object.

Default: [ ]

Methods

Time-Series Methods

.
.
.
.
.

Methods to Query and Set Object Properties and Plot the Data

`get`	Query `timeseries` object property values.
`getdatasamplesize`	Return the size of each data sample in a `timeseries` object.
`getqualitydesc`	Return data quality descriptions based on the `Quality` property values assigned to a `timeseries` object.
`plot`	Plot the `timeseries` object.
`set`	Set `timeseries` property values.

Methods to Manipulate Data and Time

`addsample`	Add a data sample to a `timeseries` object.
`append`	Concatenate `timeseries` objects in the time dimension.
`delsample`	Delete a sample from a `timeseries` object.
`detrend`	Subtract the mean or best-fit line and remove all `NaN`s from time-series data.
`filter`	Shape frequency content of time-series data using a 1-D digital filter.

`getabstime`	Extract a date-string time vector from a `timeseries` object into a cell array.
`getdatasamples`	Extract a subset of data samples from an existing `timeseries` object into an array using a subscripted indexed array.
`getsamples`	Extract a subset of data samples from an existing `timeseries` object into a new `timeseries` object using a subscript indexed array.
`getinterpmethod`	Get the interpolation method for a `timeseries` object.
`getsampleusingtime`	Extract data samples from an existing `timeseries` object into a new `timeseries` object based on specified start and end time values.
`idealfilter`	Apply an ideal pass or notch (noncausal) filter to a `timeseries` object.
`resample`	Select or interpolate data in a `timeseries` object using a new time vector.
`setabstime`	Set the time values in the time vector as date strings.
`setinterpmethod`	Set interpolation method for a `timeseries` object.
`setuniformtime`	Assign uniform time vector to `timeseries` object.
`synchronize`	Synchronize and resample two `timeseries` objects using a common time vector.

Event Methods

To construct an event object, use the constructor `tsdata.event`. For an example of defining events for a time-series object, see "Defining Events".

`addevent`	Add one or more events to a `timeseries` object.
`delevent`	Delete one or more events from a `timeseries` object.
`gettsafterateevent`	Create a new `timeseries` object by extracting the samples from an existing time series that occur after or at a specified event.
`gettsafterevent`	Create a new `timeseries` object by extracting the samples that occur after a specified event from an existing time series.

`gettsatevent`	Create a new `timeseries` object by extracting the samples that occur at the same time as a specified event from an existing time series.
`gettsbeforeatevent`	Create a new `timeseries` object by extracting the samples that occur before or at a specified event from an existing time series.
`gettsbeforeevent`	Create a new `timeseries` object by extracting the samples that occur before a specified event from an existing time series.
`gettsbetweenevents`	Create a new `timeseries` object by extracting the samples that occur between two specified events from an existing time series.

Methods to Arithmetically Combine `timeseries` Objects

`+`	Addition of the corresponding data values of `timeseries` objects.
`-`	Subtraction of the corresponding data values of `timeseries` objects.
`.*`	Element-by-element multiplication of `timeseries` data.
`*`	Matrix-multiply `timeseries` data.
`./`	Right element-by-element division of `timeseries` data.
`/`	Right matrix division of `timeseries` data.
`.\`	Element-by-element left-array divide of `timeseries` data.
`\`	Left matrix division of `timeseries` data.

Methods to Calculate Descriptive Statistics for a `timeseries` Object

`iqr`	Return the interquartile range of `timeseries` data.
`max`	Return the maximum value of `timeseries` data.
`mean`	Return the mean of `timeseries` data.
`median`	Return the median of `timeseries` data.
`min`	Return the minimum of `timeseries` data.
`std`	Return the standard deviation of `timeseries` data.

`sum`	Return the sum of `timeseries` data.
`var`	Return the variance of `timeseries` data.

Definitions

timeseries

The time-series object, called `timeseries`, is a MATLAB variable that contains time-indexed data and properties in a single, coherent structure. For example, in addition to data and time values, you can also use the time-series object to store events, descriptive information about data and time, data quality, and the interpolation method.

Data Sample

A time-series *data sample* consists of one or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

For example, suppose that `ts.data` has the size 3-by-4-by-5 and the time vector has the length 5. Then, the number of samples is `5` and the total number of data values is `3 x 4 x 5 = 60`.

Time Vector

A time vector of a `timeseries` object can be either numerical (`double`) values or valid MATLAB date strings.

When the `timeseries` `TimeInfo.StartDate` property is empty, the numerical `time` values are measured relative to 0 (or another numerical value) in specified units. In this case, the time vector is described as *relative* (that is, it contains time values that are not associated with a specific start date).

When `TimeInfo.StartDate` is nonempty, the time values are date strings measured relative to `StartDate` in specified units. In this case, the time vector is described as *absolute* (that is, it contains time values that are associated with a specific calendar date).

MATLAB supports the following date-string formats for time-series applications.

Date-String Format	Usage Example
dd-mmm-yyyy HH:MM:SS	01-Mar-2000 15:45:17
dd-mmm-yyyy	01-Mar-2000
mm/dd/yy	03/01/00
mm/dd	03/01
HH:MM:SS	15:45:17
HH:MM:SS PM	3:45:17 PM
HH:MM	15:45
HH:MM PM	3:45 PM
mmm.dd,yyyy HH:MM:SS	Mar.01,2000 15:45:17
mmm.dd,yyyy	Mar.01,2000
mm/dd/yyyy	03/01/2000

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create a `timeseries` object called `'LaunchData'` that contains four data sets, each stored as a column of length `5` and using the default time vector:

```
b = timeseries(rand(5, 4),'Name','LaunchData')
```

Create a `timeseries` object containing a single data set of length `5` and a time vector starting at `1` and ending at `5`:

```
b = timeseries(rand(5,1),[1 2 3 4 5])
```

Create a `timeseries` object called `'FinancialData'` containing five data points at a single time point:

```
b = timeseries(rand(1,5),1,'Name','FinancialData')
```

`tscollection` | `tsdata.event`

Introduced before R2006a

addsample

Class: timeseries

Add data sample to `timeseries` object

Syntax

```
ts1 = addsample(ts, s)
ts1 = addsample(ts, 'Data', data-value, 'Time',time-value,...,
Name,Value)
```

Description

`ts1 = addsample(ts, s)` adds one or more new data samples stored in a structure s to the `timeseries` object ts.

`ts1 = addsample(ts, 'Data', data-value, 'Time',time-value,...,Name,Value)` adds one or more data samples to the `timeseries` object ts along with additional options specified by one or more Name,Value pair arguments.

Tips

- If `N` is the number of data samples, you can get the sample size of each time with `SampleSize = getsamplesize(ts)`.

  When `ts.IsTimeFirst` is `true`, the size of the data is `N`-by-`SampleSize`. When `ts.IsTimeFirst` is `false`, the size of the data is `SampleSize`-by-`N`.

Input Arguments

s

A structure that you must define before passing as an argument to `addsample`. It consists of the following optional fields:

- `s.data`
- `s.time`
- `s.quality`
- `s.overwriteflag`

`data-value`

A numeric data value.

`time-value`

A valid time vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Quality'`

Array of data quality codes.

Default: `[ ]`

`'OverwriteFlag'`

Logical value that controls whether to overwrite a data sample at the same time with the new sample you are adding to your `timeseries` object. When set to `true`, the new sample overwrites the old sample at the same time.

Default: `false`

Output Arguments

`ts1`

The `timeseries` object that results when you add the specified samples to the original `timeseries` object.

Definitions

data sample

One or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

Examples

Add a data value of `420` at time `3`:

```
ts = ts.addsample('Time',3,'Data',420);
```

Add a data value of `420` at time `3` and specify quality code `1` for this data value. Set the `OverwriteFlag` to overwrite an existing value at time `3`.

```
ts = ts.addsample('Data',3.2,'Quality',1,'OverwriteFlag',...
        true,'Time',3);
```

See Also

`timeseries` | `delsample` | `getdatasamples`

Introduced before R2006a

append

Class: timeseries

Concatenate time series objects in time dimension

Syntax

```
ts = append(ts1,ts2, ... tsn)
```

Description

`ts = append(ts1,ts2, ... tsn)` creates a new `timeseries` object by concatenating `timeseries` `ts1`, `ts2`, and so on, along the time dimension.

Tips

- A single overlapping time between each input time series is valid, as long as the overlapping samples are identical.
- The time vectors must not overlap by a nonzero amount. That is, the last time in `ts1` must be earlier than or equal to the first time in `ts2`.
- The sample size of the time series must be the same.

Input Arguments

`ts1`

The first `timeseries` object that you want to append.

`ts2`

The second `timeseries` object that you want to append.

`tsn`

The nth `timeseries` object that you want to append.

Output Arguments

`ts`

The `timeseries` object that results from appending the input `timeseries` objects.

Examples

After creating `timeseries` objects, `ts1` and `ts2`, append them:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5]);
ts2 = timeseries(rand(5,1),[6 7 8 9 10]);
ts3 = append(ts1, ts2)
```

See Also

`timeseries`

ctranspose

Class: timeseries

Transpose `timeseries` object

Syntax

```
ts1 = ctranspose(ts)
```

Description

`ts1 = ctranspose(ts)` returns a new `timeseries` object ts1 with the `IsTimeFirst` value set to opposite of what it is for ts. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector as a result of this operation.

Tips

- The overloaded `ctranspose` method for `timeseries` objects does not transpose the data. Instead, this method changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, you must transpose the `Data` property of the `timeseries` object. For example, you can use the syntax `ctranspose(ts.Data)` or `(ts.Data)'`. The `Data` property value must be a 2-D array.
- Consider a `timeseries` object with 10 samples with the property `IsTimeFirst = True`. When you transpose this object, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

  The following table summarizes the size for Data property of the `timeseries` object (up to three dimensions) before and after transposing.

  Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N

Size of Original Data	Size of Transposed Data
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

Input Arguments

`ts`

The `timeseries` object you want to transpose.

Output Arguments

`ts1`

The transposed `timeseries` object.

Examples

Suppose that a `timeseries` object `ts` has `ts.data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is set to `true`, which means that the first dimension of the data is aligned with the time vector. `ctranspose(ts)` modifies `ts`, such that the last dimension of the data is now aligned with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

See Also

`timeseries` | `transpose`

delsample

Class: timeseries

Remove sample from `timeseries` object

Syntax

```
ts1 = delsample(ts,Name,Value)
```

Description

`ts1 = delsample(ts,Name,Value)` deletes samples from the `timeseries` object ts based on the specified Name,Value pair arguments.

Input Arguments

`ts`

A `timeseries` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Index'`

The indices of the time vector that correspond to the samples you want to delete.

`'Value'`

The time values that correspond to the samples you want to delete.

Output Arguments

`ts1`

The `timeseries` object that results from removing the specified samples.

Examples

Create a `timeseries` object, and then remove samples:

```
ts = timeseries(rand(5,1),[10 20 30 40 50]);

% Remove data sample at time index 1

ts1 = delsample(ts,'Index', 1)

% Remove data sample at time value 20:

ts2 = delsample(ts,'Value', [20])
```

See Also

`set` | `timeseries`

Introduced before R2006a

detrend

Class: timeseries

Subtract mean or best-fit line and all NaNs from `timeseries` object

Syntax

```
ts1 = detrend(ts, method)
ts1 = detrend(ts, method, index)
```

Description

`ts1 = detrend(ts, method)` subtracts either a mean or a best-fit line from time-series data, using the specified method. Usually for FFT processing.

`ts1 = detrend(ts, method, index)` uses the optional index to specify the columns or rows to detrend.

Tips

- You cannot apply `detrend` to`timeseries` data with more than two dimensions.

Input Arguments

`ts`

The `timeseries` object from which you want to subtract the mean or best-fit line and all NaNs.

Default:

`method`

A string that specifies one of the following detrend methods:

- `'constant'` — Subtracts the mean.
- `'linear'` — Subtracts the best-fit line.

`index`

An integer array that specifies the columns or rows to detrend when `ts.IsTimeFirst` is true.

Output Arguments

`ts1`

The `timeseries` object resulting from detrending the input `timeseries` object.

See Also

`timeseries`

Introduced before R2006a

filter

Class: timeseries

Shape frequency content of time-series

Syntax

```
ts1 = filter(ts, numerator, denominator)
ts1=filter(ts, numerator, denominator, index)
```

Description

`ts1 = filter(ts, numerator, denominator)` applies the transfer function filter $b(z^{-1})/a(z^{-1})$ to the data in the `timeseries` object ts. b and a are the coefficient arrays of the transfer function numerator and denominator, respectively.

`ts1=filter(ts, numerator, denominator, index)` uses the optional index integer array to specify either the columns or rows to filter, depending on the value of `ts.IsTimeFirst`.

Tips

- The time-series data must be uniformly sampled to use this filter.
- The following function

  ```
  y = filter(b,a,x)
  ```

  creates filtered data `y` by processing the data in vector `x` with the filter described by vectors `a` and `b`.
- The `filter` function is a general tapped delay-line filter, described by the difference equation:
  $a(1)y(n) = b(1)x(n) + b(2)x(n-1) + ... + b(nb)x(n-nb+1) - a\,(2)y(n-1) - ... - a(N_a)y(n-N_b+1)$.

  Here, n is the index of the current sample, N_a is the order of the polynomial described by vector `a`, and N_b is the order of the polynomial described by vector `b`. The output

$y(n)$ is a linear combination of current and previous inputs, $x(n)$ $x(n-1)$..., and previous outputs, $y(n-1)$ $y(n-2)$... .

- You use the discrete filter to shape the data by applying a transfer function to the input signal.

  Depending on your objectives, the transfer function you choose might alter both the amplitude and the phase of the variations in the data at different frequencies to produce either a smoother or a rougher output.

- In digital signal processing (DSP), it is customary to write transfer functions as rational expressions in z^{-1} and to order the numerator and denominator terms in ascending powers of z^{-1}.

  Taking the z-transform of the difference equation
  $a(1)y(n) = b(1)x(n) + b(2)x(n-1) + ... + b(nb)x(n - nb + 1) - a(2)y(n-1) - ... - a(na)y(na + 1)$,

  results in the transfer function

$$Y(z) = H(z^{-1})X(z) = \frac{b(1) + b(2)z^{-1} + ... + b(nb)z^{-nb+1}}{a(1) + a(2)z^{-1} + ... + a(na)z^{-na+1}} X(z),$$

  where $Y(z)$ is the z-transform of the filtered output $y(n)$. The coefficients b and a are unchanged by the z-transform.

Input Arguments

`ts`

The first `timeseries` object for which you want to shape the frequency content.

`numerator`

The coefficient array of the transfer function numerator.

`denominator`

The coefficient array of the transfer function denominator.

index

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

Output Arguments

ts1

The `timeseries` object that results from filtering the input `timeseries` object.

Examples

Apply Transfer Function to Time Series Data

This example applies the following transfer function to the data in `count.dat`:

$$H(z^{-1}) = \frac{b(z^{-1})}{a(z^{-1})} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}$$

Load the matrix `count` into the workspace:

```
load count.dat
```

Create a time-series object based on this matrix:

```
count1 = timeseries(count(:,1),[1:24]);
```

Enter the coefficients of the denominator ordered in ascending powers of z^{-1} to represent $1 + 0.2x$:

```
a = [1 0.2];
```

Enter the coefficients of the numerator to represent $2 - 3z^{-1}$:

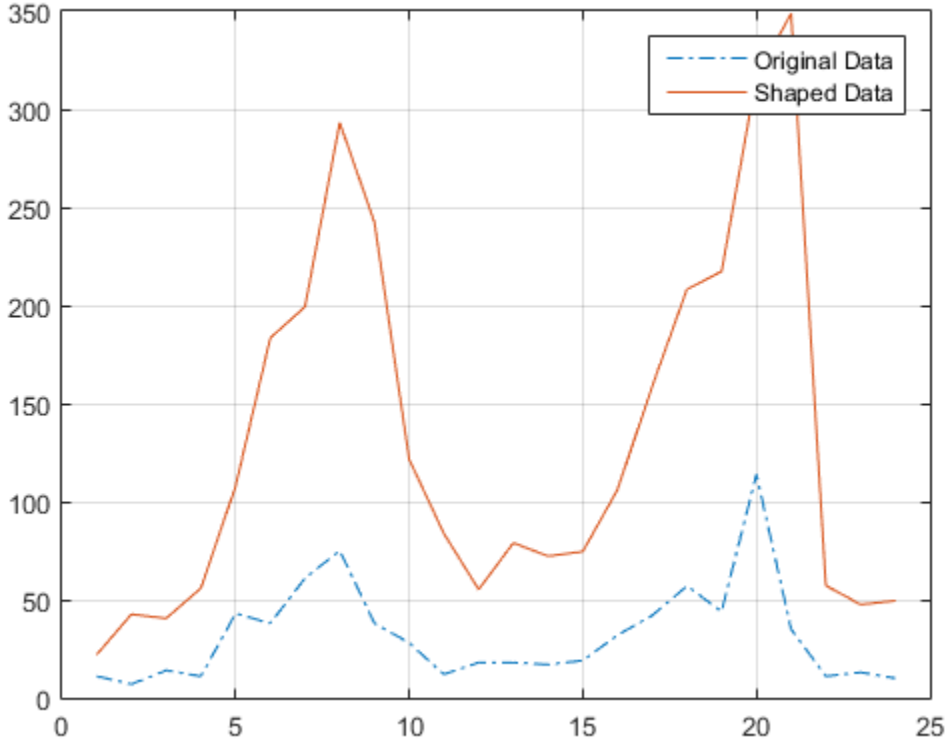
```
b = [2 3];
```

Call the filter method:

```
filter_count = filter(count1, b, a);
```

Compare the original data and the shaped data with an overlaid plot of the two curves:

```
figure
plot(count1,'-.')
grid on
hold on
plot(filter_count,'-')
legend('Original Data','Shaped Data',2)
```



See Also

`timeseries` | `idealfilter`

Introduced before R2006a

get

Class: timeseries

Query `timeseries` object property values

Syntax

```
get(ts)
value = get(ts, PropertyName)
```

Description

`get(ts)` displays all properties and values of the `timeseries` object, ts.

`value = get(ts, PropertyName)` returns the property value for the specified `timeseries` object. The following syntax is equivalent:

```
value = ts.PropertyName
```

Input Arguments

`ts`

A `timeseries` object.

`PropertyName`

String specifying the name of a `timeseries` property. For a list of `timeseries` properties, see `timeseries`.

Output Arguments

`value`

String containing the value associated with the specified property.

Examples

Create a `timeseries` object, and then get the name. This example gets the name three different ways:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5], 'Name', 'MyTimeseries');
get(ts1)
get(ts1, 'Name')
value = ts1.Name
```

See Also

`timeseries` | `set`

Introduced before R2006a

getabstime

Class: timeseries

Extract date-string time vector into cell array

Syntax

```
getabstime(ts)
```

Description

`getabstime(ts)` extracts the time vector from the `timeseries` object ts as a cell array of date strings.

Tips

- To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the `timeseries` object. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

Input Arguments

`ts`

The `timeseries` object from which you want to extract the time vector.

Default:

Examples

The following example extracts a time vector as a cell array of date strings from a `timeseries` object.

First, create a `timeseries` object.

```
ts = timeseries([3 6 8 0 10]);
```

The default time vector for `ts` is `[0 1 2 3 4]`, which starts at 0 and increases in 1-second increments. The length of the time vector is equal to the length of the data.

Next, set the `StartDate` property.

```
ts.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

Extract the time vector.

```
getabstime(ts)
```

MATLAB returns:

```
'27-Oct-2005 07:05:36'
'27-Oct-2005 07:05:37'
'27-Oct-2005 07:05:38'
'27-Oct-2005 07:05:39'
'27-Oct-2005 07:05:40'
```

Change the date-string format of the time vector, and then extract the time vector with the new date-string format:

```
ts.TimeInfo.Format = 'mm/dd/yy';
getabstime(ts)
```

MATLAB returns:

```
'10/27/05'
'10/27/05'
'10/27/05'
'10/27/05'
'10/27/05'
```

See Also

`timeseries` | `setabstime` | `datestr`

Introduced before R2006a

getdatasamples

Class: timeseries

Returns subset of time series samples using subscripted index array

Syntax

```
datasamples = getdatasamples(ts, i)
```

Description

`datasamples = getdatasamples(ts, i)` returns an array corresponding to the samples indicated by the array, i.

Input Arguments

`ts`

The `timeseries` object from which you want to exact samples.

`i`

An array of linear indices or logical values that specifies the time value or values for which you want to extract the corresponding samples.

Output Arguments

`datasamples`

The array that results from extracting the samples corresponding to the time value or values, `ts.time(i)`.

Examples

After creating a `timeseries` object, `ts`, extract the second and third data samples into an array:

```
ts = timeseries(rand(5,1),[1 2 3 4 5]);
samples = getdatasamples(ts, [2 3])
```

See Also

timeseries | getsamples | resample

getdatasamplesize

Class: timeseries

Size of data sample in `timeseries` object

Syntax

```
getdatasamplesize(ts)
```

Description

`getdatasamplesize(ts)` returns the size of each data sample in a `timeseries` object.

Input Arguments

`ts`

String specifying the name of a `timeseries` object.

Definitions

data sample

One or more scalar values recorded at a specific time. The number of data samples is the same as the length of the time vector.

Examples

After loading data and creating a `timeseries` object, get the size of a data sample:

```
% Load a 24-by-3 data array:
load count.dat
```

```
% Create a timeseries object with 24 time values:
count_ts = timeseries(count,[1:24],'Name','VehicleCount')

% Get the size of the data sample for this timeseries object:
getdatasamplesize(count_ts)
```

MATLAB returns the following, which indicates that the size of each data sample in `count_ts` is 1-by-3. In other words, MATLAB stores each data sample as a row with three values.

```
ans =

     1     3
```

See Also

`timeseries` | `set`

Introduced before R2006a

getinterpmethod

Class: timeseries

Interpolation method for `timeseries` object

Syntax

```
getinterpmethod(ts)
```

Description

`getinterpmethod(ts)` returns the interpolation method that the `timeseries` object ts, uses as a string.

Input Arguments

`ts`

The `timeseries` object from which you want to extract the interpolation method.

Definitions

interpolation method

Predefined interpolation methods are zero-order hold, `zoh`, and linear interpolation, `linear`. Linear interpolation is the default.

Examples

Create a `timeseries` object, and then get its interpolation method:

```
ts = timeseries(rand(5));
```

```
getinterpmethod(ts)
```

MATLAB returns:

```
linear
```

See Also

`timeseries` | `setinterpmethod`

Introduced before R2006a

getqualitydesc

Class: timeseries

Data quality descriptions

Syntax

```
getqualitydesc(ts)
```

Description

`getqualitydesc(ts)` returns a cell array of data quality descriptions based on the `Quality` values you assigned to a `timeseries` object, ts.

Input Arguments

`ts`

A `timeseries` object.

Examples

Create a `timeseries` object, and then get the data quality description strings for `ts`:

```
% Create a timeseries object, ts, with Data, Time, and Quality
% values, respectively:

ts = timeseries([3; 4.2; 5; 6.1; 8], 1:5, [1; 0; 1; 0; 1]);

% Set the QualityInfo property, including Code and Description:

ts.QualityInfo.Code = [0 1];
ts.QualityInfo.Description = {'good' 'bad'};

% Get the data quality description strings for ts:
```

```
getqualitydesc(ts)
```

MATLAB returns:

```
ans =

    'bad'
    'good'
    'bad'
    'good'
    'bad'
```

See Also

`timeseries`

Introduced before R2006a

getsamples

Class: timeseries

Subset of time series samples using subscripted index array

Syntax

```
ts1 = getsamples(ts, i)
```

Description

`ts1 = getsamples(ts, i)` returns a new `timeseries` object by extracting samples from `timeseries` `ts` corresponding to the time or times indicated by the subscripted index array, i.

Input Arguments

`ts`

The `timeseries` object from which you want to exact samples.

`i`

A subscripted index array that specifies the time value or values for which you want to extract the corresponding samples.

Output Arguments

`ts1`

The `timeseries` object that results from extracting the samples corresponding to the time value or values `ts.time(i)` .

Examples

After creating a `timeseries` object, `ts`, extract the data samples at times 2 and 3 into a new `timeseries` object, `ts1`:

```
ts = timeseries(rand(5,1),[1 2 3 4 5]);
ts1 = getdatasamples(ts, ts.time([2 3]))
```

See Also

`timeseries` | `getdatasamples` | `resample`

getsampleusingtime

Class: timeseries

Extract data samples into new `timeseries` object

Syntax

```
ts1 = getsampleusingtime(ts,time)
ts1 = getsampleusingtime(ts,time,'AllowDuplicateTimes',true)
ts1 = getsampleusingtime(ts,starttime,endtime)
```

Description

`ts1 = getsampleusingtime(ts,time)` returns a new `timeseries` object, ts1, with a single sample corresponding to specified time in ts.

`ts1 = getsampleusingtime(ts,time,'AllowDuplicateTimes',true)` returns a new `timeseries` object, ts1, with multiple samples when the specified time occurs more than once in ts.

`ts1 = getsampleusingtime(ts,starttime,endtime)` returns a new `timeseries` object, ts1, with samples between the times starttime and endtime in ts.

Tips

- If the time vector in `ts` is not relative to a calendar date, then `starttime` and `endtime` must be numeric.
- If the time vector in `ts` is relative to a calendar date, then `starttime` and `endtime` values must be dates—either strings or `datenum` values.

Input Arguments

`ts`

The `timeseries` object from which you want to extract data samples.

`time`

The time corresponding to data sample you want to extract.

`starttime`

The time corresponding to the first data sample you want to extract.

`endtime`

The time corresponding to the last data sample you want to extract.

Output Arguments

`ts1`

A `timeseries` object that contains the subset of data samples from the original `timeseries` object.

See Also

`timeseries`

Introduced before R2006a

idealfilter

Class: timeseries

Apply ideal (noncausal) filter to `timeseries` object

Syntax

```
ts1 = idealfilter(ts, interval, filtertype)
ts1 = idealfilter(ts, interval, filtertype, index)
```

Description

`ts1 = idealfilter(ts, interval, filtertype)` applies an ideal filter of filtertype to one or more frequency intervals that interval specifies for the `timeseries` object, ts.

`ts1 = idealfilter(ts, interval, filtertype, index)` applies an ideal filter and uses the optional index integer array to specify the columns or rows to filter.

Tips

- Ideal filters require data to have a mean of zero and prepare the data by subtracting its mean. You can restore the filtered signal amplitude by adding the mean of the input data to the filter output values.
- Use the ideal *notch* filter when you want to remove variations in a specific frequency range. Alternatively, use the ideal *pass* filter to allow only the variations in a specific frequency range.
- If the time-series data is sampled nonuniformly, filtering resamples this data on a uniform time vector.
- All `NaN`s in the time series are interpolated before filtering, using the interpolation method you assigned to the `timeseries` object.

Input Arguments

`ts`

The `timeseries` object to which you want to apply an ideal filter.

`interval`

The frequency interval (specified in cycles per time unit) at which you want the ideal filter applied. To specify several frequency intervals, use an n-by-2 array of start and end frequencies, where `n` represents the number of intervals.

`filtertype`

A string specifying the type of filter you want to apply, either `pass` or `notch`.

`index`

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

Output Arguments

`ts1`

The `timeseries` object that results when you apply an ideal filter to the original `timeseries` object.

Definitions

ideal filter

Filters are *ideal* in the sense that they are *not realizable*. An ideal filter is noncausal and the ends of the filter amplitude are perfectly flat in the frequency domain.

Examples

Apply Ideal Notch and Pass Filters

This example first applies an ideal notch filter to the data in `count.dat`. Then, it applies a pass filter to the data.

Load the count matrix into the workspace:

```
load count.dat
```

Create a timeseries object from column one of this matrix. Specify a time vector that ranges from 1 to 24 s in 1-s intervals.

```
count1 = timeseries(count(:,1),1:24);
```

Obtain the mean of the data:

```
countmean = mean(count1);
```

Enter the frequency interval, in hertz, for filtering the data:

```
interval = [0.08 0.2];
```

Invoke an ideal notch filter:

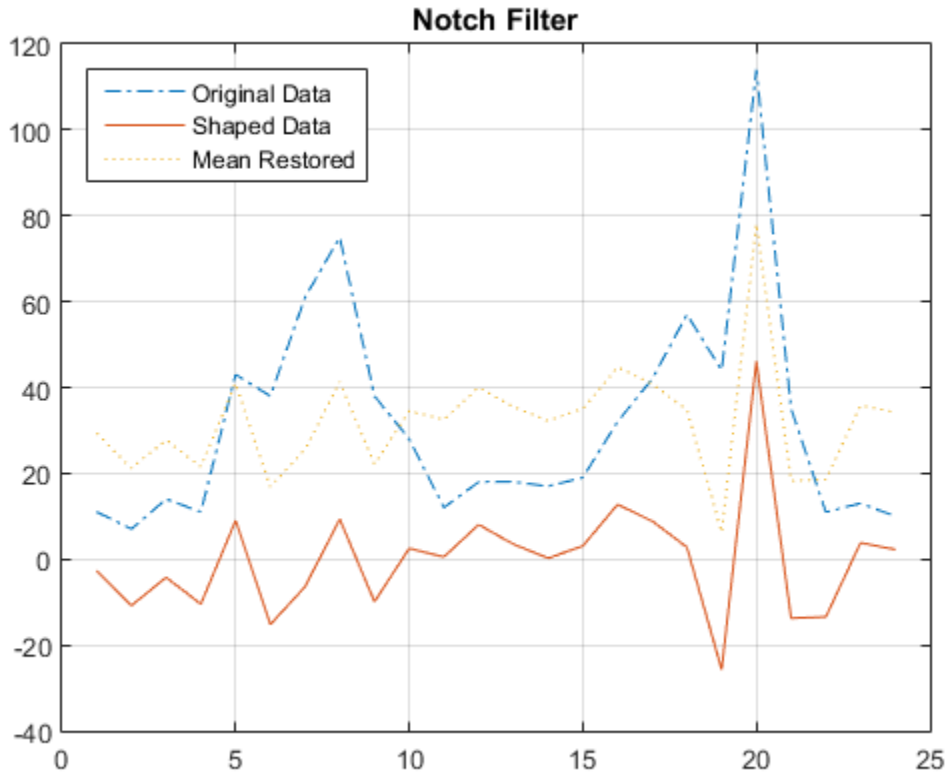
```
idealfilter_countn = idealfilter(count1,interval,'notch');
```

Compare the original data and the shaped data on a line plot:

```
plot(count1,'-.')
grid on
hold on
plot(idealfilter_countn,'-')
```

Restore the mean to the filtered data and show it on the line plot, adding a legend and a title:

```
countn_restored = idealfilter_countn + countmean;
plot(countn_restored,':')
title('Notch Filter')
legend('Original Data','Shaped Data','Mean Restored',...
       'Location','NorthWest')
```



Close the Figure window:

```
close
```

Then, repeat the process using a `pass` rather than a `notch` filter:

```
figure

plot(count1,'-.')
grid on
hold on

idealfilter_countp = idealfilter(count1,interval,'pass');
plot(idealfilter_countp,'-')
```

```
countp_restored = idealfilter_countp + countmean;
plot(countp_restored,':')

title('Pass Filter')
legend('Original Data','Shaped Data','Mean Restored',...
       'Location','NorthWest')
```

`timeseries` | `filter`

Introduced before R2006a

iqr

Class: timeseries

Interquartile range of `timeseries` data

Syntax

```
ts_iqr = iqr(ts)
iqr(ts, Name, Value)
```

Description

`ts_iqr = iqr(ts)` returns the interquartile range of `ts.Data`.

`iqr(ts, Name, Value)` reruns the interquatrile range of `ts.Data` with the specified Name, Value pairs.

Input Arguments

`ts`

The `timeseries` object for which you want the interquartile range of `timeseries` data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

Output Arguments

ts_iqr

The interquartile range of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_iqr` is the difference between the 75th and the 25th percentiles of the `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_iqr` is a row vector containing the interquartile range of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `iqr` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

Create a time series with a missing value, represented by `NaN`, and then calculate the interquartile range of `ts.Data` after removing the missing value from the calculation:

```
ts = timeseries([3.0 NaN 5 6.1 8], 1:5);
iqr(ts,'MissingData','remove')
```

MATLAB returns:

```
    3.0500
```

`mean` | `min` | `sum` | `timeseries` | `max` | `median` | `std` | `var`

Introduced before R2006a

max

Class: timeseries

Maximum value of `timeseries` data

Syntax

```
ts_max = max(ts)
ts_max = max(ts,Name,Value)
```

Description

`ts_max = max(ts)` returns the maximum value in the `timeseries` data.

`ts_max = max(ts,Name,Value)` returns the maximum value in the `timeseries` data with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ts`

The `timeseries` object for which you want to determine the maximum data value.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

`'Quality'`

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

Output Arguments

`ts_max`

The maximum data value in the specified `timeseries` object, as follows:

- When `ts.Data` is a vector, `ts_max` is the maximum value of `ts.Data` values.
- When `ts.Data` is a matrix, `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_max` is a row vector containing the maximum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `max` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

The following example illustrates how to find the maximum values in multivariate time-series data:

```
% Load a 24-by-3 data array:
load count.dat

% Create a timeseries object with 24 time values:
count_ts = timeseries(count,[1:24],'Name','CountPerSecond')

% Find the maximum in each data column for this timeseries object:

max(count_ts)
```

MATLAB returns:

```
114   145   257
```

See Also

`mean` | `min` | `sum` | `timeseries` | `iqr` | `median` | `std` | `var`

Introduced before R2006a

mean

Class: timeseries

Mean value of `timeseries` data

Syntax

```
ts_mn = mean(ts)
ts_mn = mean(ts,Name,Value)
```

Description

`ts_mn = mean(ts)` returns the mean value of `ts.Data`.

`ts_mn = mean(ts,Name,Value)` returns the mean value of `ts.Data` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ts`

The `timeseries` object for which you want the mean value of data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

`'Quality'`

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

`'Weighting'`

A string specifying one of two possible values, `none` or `time`.
When you specify `time`, larger time values correspond to larger weights.

Output Arguments

`ts_mn`

The mean value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_mn` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true` and the first dimension of `ts` is aligned with time, then `ts_mn` is a row vector containing the mean value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `mean` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

Find the mean values in multivariate time-series data:

```
% Load a 24-by-3 data array:

load count.dat

%  Create a timeseries object with 24 time values:

count_ts = timeseries(count,[1:24],'Name','CountPerSecond')

% Find the mean of each data column for this timeseries object:
```

```
mean(count_ts)
```

MATLAB returns:

```
32.0000   46.5417   65.5833
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `(t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note: If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.
3. Multiplying the data for each time by its normalized weighting.

Introduced before R2006a

median

Class: timeseries

Median value of `timeseries` data

Syntax

```
ts_med = median(ts)
ts_med = method(ts,Name,Value)
```

Description

`ts_med = median(ts)` returns the median value of `ts.Data`.

`ts_med = method(ts,Name,Value)` returns the median value of `ts.Data` with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ts`

The `timeseries` object for which you want the median data value.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

'Weighting'

A string specifying one of two possible values, `none` or `time`.
When you specify `time`, larger time values correspond to larger weights.

Output Arguments

ts_med

The median value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_med` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_med` is a row vector containing the median value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `median` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

The following example finds the median values in multivariate time-series data. MATLAB finds the median independently for each data column in the `timeseries` object:

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,[1:24],'Name','CountPerSecond');

% Find the median of each data column for this timeseries object:
```

```
median(count_ts)
```

MATLAB returns:

```
23.5000   36.0000   39.0000
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `(t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note: If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.
3. Multiplying the data for each time by its normalized weighting.

Introduced before R2006a

min

Class: timeseries

Minimum value of `timeseries` data

Syntax

```
ts_min = min(ts)
ts_min = method(ts,Name,Value)
```

Description

`ts_min = min(ts)` returns the minimum value in the `timeseries` data.

`ts_min = method(ts,Name,Value)` uses additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ts`

The `timeseries` object for which you want the minimum data value.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

Output Arguments

ts_min

The minimum value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_min` is the minimum value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_min` is a row vector containing the minimum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `min` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

The following example finds the minimum values in multivariate time-series data. MATLAB finds the minimum independently for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,[1:24],'Name','CountPerSecond');

% Find the minimum in each data column for this timeseries object:

min(count_ts)
```

MATLAB returns:

```
7     9     7
```

See Also

`max` | `median` | `sum` | `timeseries` | `iqr` | `mean` | `std` | `var`

Introduced before R2006a

plot

Class: timeseries

Plot time series

Syntax

```
plot(ts)
plot(tsc.tsname)
plot(ts,linespec)
plot(tsc.tsname,linespec)
plot(ts,Name, Value)
plot(tsc.tsname,Name, Value)
```

Description

`plot(ts)` plots the `timeseries` data ts against time and interpolates values between samples by using either zero-order-hold (`'zoh'`) or linear interpolation (the default). The plot displays in the current axes. MATLAB creates a title and axes, if none exists.

`plot(tsc.tsname)` plots the `timeseries` object, tsname that is part of the `tscollection`, tsc.

`plot(ts,linespec)` plots the `timeseries` data using a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(tsc.tsname,linespec)` plots the `timeseries` object that is part of a `timeseries` collection as a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(ts,Name, Value)` plots a line graph of the time series data using the values specified for Chart Line Properties.

`plot(tsc.tsname,Name, Value)` plots a line graph of the `timeseries` object that is part of the specified `timeseries` collection using the values specified for Chart Line Properties.

Tips

- The `timeseries/plot` method generates titles and axis labels automatically. These labels are:
  - Plot Title — `'Time Series Plot: <name>'`

    where `<name>` is the string assigned to `ts.Name`, or by default, `'unnamed'`
  - X-Axis Label — `'Time (<units>)'`

    where `<units>` is the value of the `ts.TimeInfo.Units` field, which defaults to `'seconds'`
  - Y-Axis Label — `'<name>'`

    where `<name>` is the string assigned to `ts.Name`, or by default, `'unnamed'`
- You can place new time series data on a time series plot (by setting `hold on`, for example, and issuing another `timeseries/plot` command). When you add data to a plot, the title and axis labels become blank strings to avoid labeling confusion. You can add your own labels after plotting using the `title`, `xlabel`, and `ylabel` commands.
- Time series events, when defined, are marked in the plot with a circular marker with red fill. You can also specify markers for all data points using a `linespec` or name/value syntax in addition to any event markers your data defines. The event markers plot on top of the markers you define.
- The value assigned to `ts.DataInfo.Interpolation.Name` controls the type of interpolation the `plot` method uses when plotting and resampling time series data. Invoke the `timeseries` method `setinterpmethod` to change default linear interpolation to zero-order hold interpolation (staircase). This method creates a new `timeseries` object, with which you can overwrite the original one if you want. For example, to cause time series `ts` to use zero-order hold interpolation, type the following:

  ```
  ts = ts.setinterpmethod('zoh');
  ```

Input Arguments

ts

A `timeseries` object.

tsc

A `tscollection`.

tsname

The name of a `timeseries` object within the `tscollection` .

Examples

Plot Time Series Object with Specified Start Date

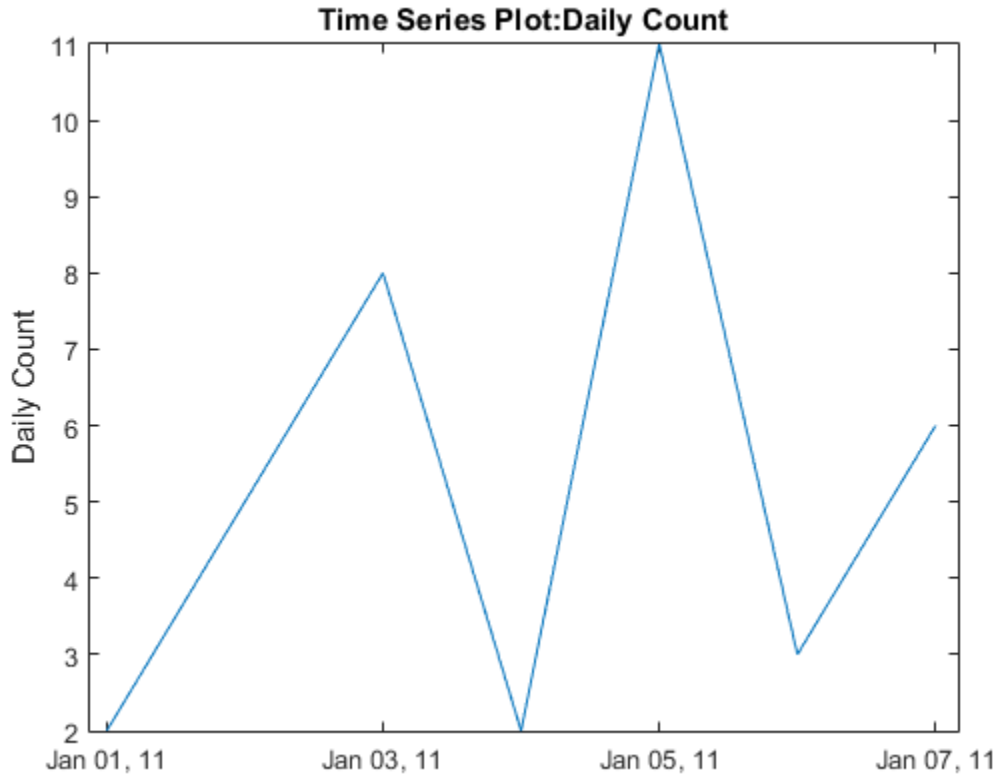
Create a time series object, set the start date, and then plot the time vector relative to the start date.

```
x = [2 5 8 2 11 3 6];
ts1 = timeseries(x,1:7);

ts1.Name = 'Daily Count';
ts1.TimeInfo.Units = 'days';
ts1.TimeInfo.StartDate = '01-Jan-2011';     % Set start date.
ts1.TimeInfo.Format = 'mmm dd, yy';       % Set format for display on x-axis.

ts1.Time = ts1.Time - ts1.Time(1);        % Express time relative to the start date.

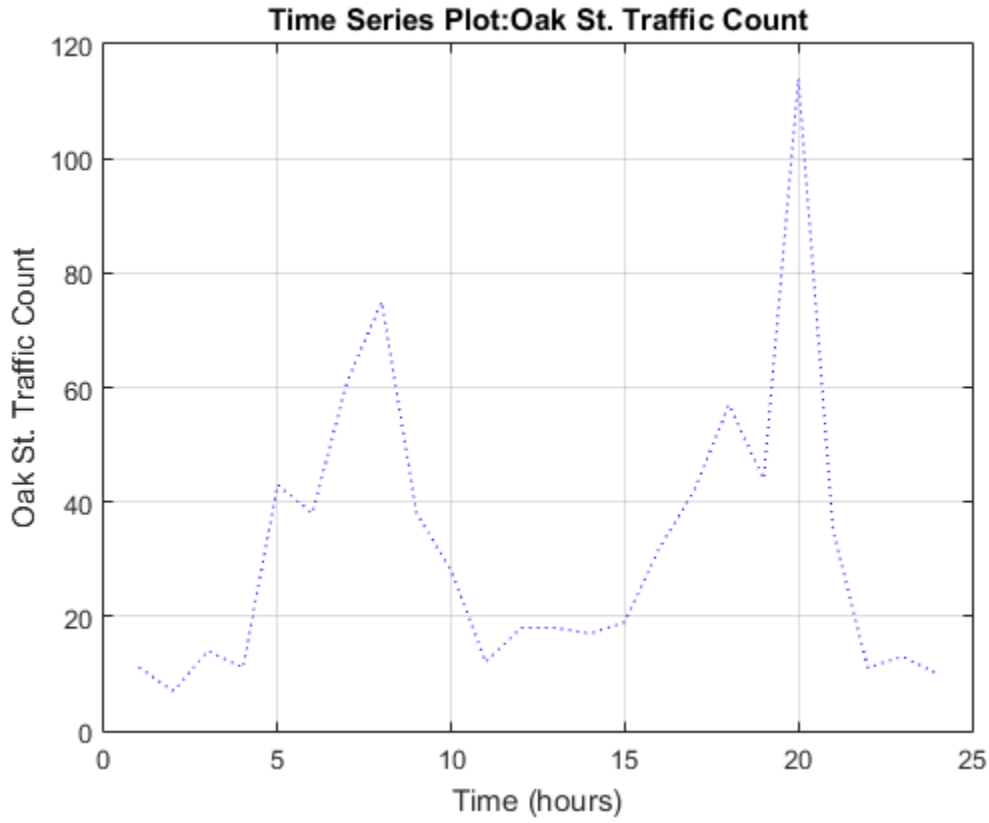
plot(ts1)
```



Plot Two Time Series Objects on the Same Axes

Create two time series objects from traffic count data, and then plot them in sequence on the same axes. Add an event to one series, which is automatically displayed with a red marker.

```
load count.dat;
count1 = timeseries(count(:,1),1:24);
count1.Name = 'Oak St. Traffic Count';
count1.TimeInfo.Units = 'hours';
plot(count1,':b')
grid on
```



Obtain time of maximum value and add it as an event:

```
[~,index] = max(count1.Data);
max_event = tsdata.event('peak',count1.Time(index));
max_event.Units = 'hours';
```

Add the event to the time series:

```
count1 = addevent(count1,max_event);
```

Replace plot with new one showing the event:

```
plot(count1,'.-b')
grid on
```

Make a new time series object from column 2 of the same data source:

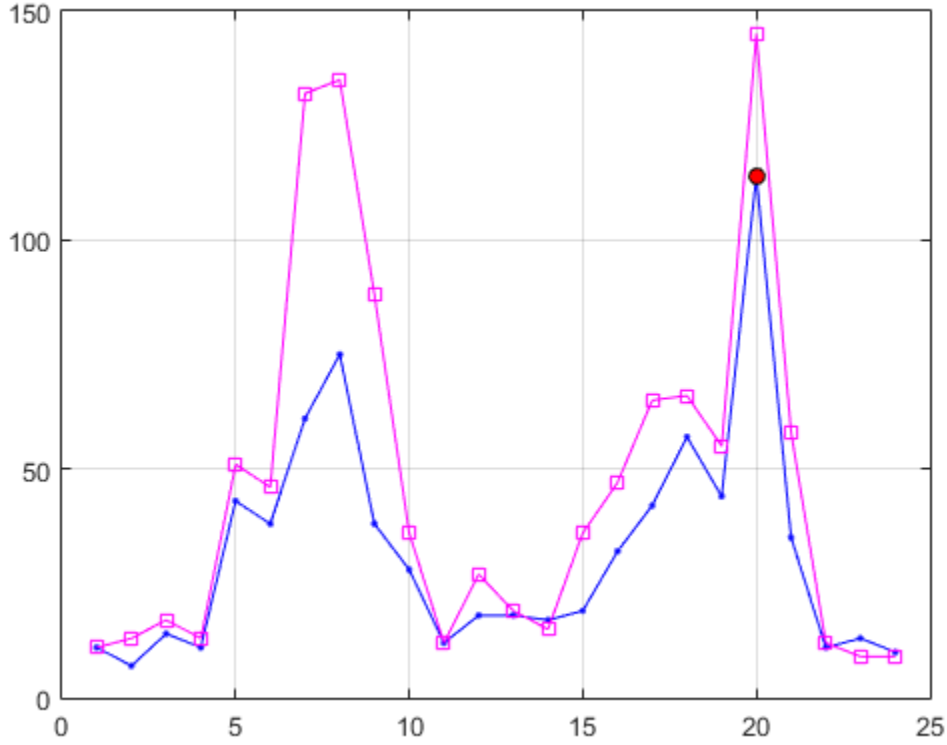
```
count2 = timeseries(count(:,2),1:24);
count2.Name = 'Maple St. Traffic Count';
count2.TimeInfo.Units = 'Hours';
```

Turn hold on to add the new data to the plot:

```
hold on
```

The plot method does not add labels to a held plot. Use property/value pairs to customize markers:

```
plot(count2,'s-m','MarkerSize',6),
```



Labels are erased, so generate them manually:

```
title('Time Series: Oak Street and Maple Street')
xlabel('Hour of day')
ylabel('Vehicle count')
```

Add a legend in the upper left:

```
legend('Oak St.','Maple St.','Location','northwest')
```

`timeseries` | `setinterpmethod` | `tscollection` | `tsdata.event` | `plot`

Introduced before R2006a

resample

Class: timeseries

Select or interpolate `timeseries` data using new time vector

Syntax

```
ts1 = resample(ts, time)
ts1 = resample(ts, time, interp_method)
ts1 = resample(ts, time, interp_method, code)
```

Description

`ts1 = resample(ts, time)` resamples the `timeseries` object, ts, using the new time vector. The `resample` method uses the default interpolation method, which you can view by using the `getinterpmethod(ts)` syntax.

`ts1 = resample(ts, time, interp_method)` resamples the `timeseries` object ts using the specified interpolation method, interp_method.

`ts1 = resample(ts, time, interp_method, code)` resamples the `timeseries` object ts using the interpolation method given by the string interp_method. MATLAB applies the code to all samples.

Input Arguments

`ts`

The `timeseries` object that you want to resample.

`time`

The time vector you want to use to resample the `timeseries` object.

When `ts` uses date strings and `time` is numeric, then `time` is treated as specified relative to the `ts.TimeInfo.StartDate` property and in the same units that `ts` uses.

`interp_method`

A string specifying the interpolation method. Valid interpolation methods are `linear` and zero-order hold, `zoh` .

Default: `linear`

`code`

An integer value that specifies the user-defined `Quality` code for resampling. MATLAB applies this `Quality` code to all samples.

Output Arguments

`ts1`

The `timeseries` object that results when you interpolate the original `timeseries` object with a new time vector.

Examples

This example shows how to resample a `timeseries` object.

Create a `timeseries` object.

```
ts1 = timeseries([1.1; 2.9; 3.7; 4.0; 3.0],1:5,'Name','speed');
```

View the time, data, and interpolation method.

```
ts1.time
ts1.data
ts1.getinterpmethod
```

Resample `ts1` using its default interpolation method.

```
res_ts=resample(ts1,[1 1.5 3.5 4.5 4.9]);
```

View the time, data, and interpolation method for the resampled object.

```
res_ts.time
res_ts.data
```

```
res_ts.getinterpmethod
```

timeseries | getinterpmethod | setinterpmethod | synchronize

Introduced before R2006a

set

Class: timeseries

Set properties of `timeseries` object

Syntax

```
set(ts, PropertyName, Value)
set(ts, PropertyName)
set(ts)
```

Description

`set(ts, PropertyName, Value)` sets the named property, `Name`, of the `timeseries` object, `ts`, to the value, `Value`. The following syntax is equivalent:

```
ts.Property = Value
```

`set(ts, PropertyName)` displays the value of the named property for the `timeseries` object, `ts`.

`set(ts)` displays all properties and values of the `timeseries` object `ts`.

Input Arguments

`ts`

A `timeseries` object.

`PropertyName`

A string specifying the name of a `timeseries` property. For a list of `timeseries` properties, see `timeseries`.

`Value`

The value to which you want to set the named property.

Examples

Create a `timeseries`, set its name to `mytimeseries`, and then view the `timeseries` properties:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5]);
set(ts1, 'Name', 'mytimeseries')
set(ts1)
```

See Also

`timeseries` | `get`

Introduced before R2006a

setabstime

Class: timeseries

Set times of `timeseries` object as date strings

Syntax

```
ts1=setabstime(ts, times)
ts1=setabstime(ts, times, format)
```

Description

`ts1=setabstime(ts, times)` sets the times in ts to the date strings specified in times.

`ts1=setabstime(ts, times, format)` explicitly specifies the date-string format, format, used in times.

Input Arguments

`ts`

The `timeseries` object for which you want to set times as date strings.

`times`

A cell array of strings or a `char` array containing valid date or time values in the same date format.

`format`

The date-string format used for the time values.

Output Arguments

`ts1`

The `timeseries` object that results from setting times as date strings on the original `timeseries` object.

Examples

Create a `timeseries` object, and then set the absolute time vector:

```
ts = timeseries(rand(3,1))
ts1 = setabstime(ts,{'12-DEC-2005 12:34:56',...
     '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})

% View each timeseries object in the Variable Edtior to see the
% differences in the time vectors for each.
```

See Also

`datestr` | `getabstime` | `timeseries`

Introduced before R2006a

setinterpmethod

Class: timeseries

Set default interpolation method for `timeseries` object

Syntax

```
ts = setinterpmethod(ts, method)
ts = setinterpmethod(ts, fhandle)
ts = setinterpmethod(ts, interpobj)
```

Description

`ts = setinterpmethod(ts, method)` sets the default interpolation method, method, for `timeseries` object, ts, and outputs it to ts1.

`ts = setinterpmethod(ts, fhandle)` sets the default interpolation method for `timeseries` object ts, where fhandle is a function handle to the interpolation method.

`ts = setinterpmethod(ts, interpobj)` sets the default interpolation method for `timeseries` object ts, where interpobj is a `tsdata.interpolation` object that directly replaces the interpolation object stored in ts.

Tips

- This method is case sensitive.

Input Arguments

`ts`

The `timeseries` object for which you want to set the default interpolation method.

`method`

A string specifying the interpolation method. Valid values are `linear` and zero-order hold, `zoh`.

Default: `linear`

`fhandle`

A function handle to the interpolation method. The order of input arguments defining the function handle must be `new_time`, `time`, and `data`. The single output argument must be the interpolated data only.

`interpobj`

A `tsdata.interpolation` object that directly replaces the interpolation object stored in ts.

Output Arguments

`ts1`

The `timeseries` object that results when you set the interpolation method for the original `timeseries` object.

Examples

Set the default interpolation method for `timeseries` object `ts` to zero order hold:

```
ts = timeseries(rand(100,1),1:100);
ts = setinterpmethod(ts,'zoh');
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts`, where fhandle is a function handle to the interpolation method defined by function handle `myFuncHandle`:

```
ts = timeseries(rand(100,1),1:100);
myFuncHandle = @(new_time, time, data)...
               interp1(time, data, new_time,...
                       'linear','extrap');
```

```
ts = setinterpmethod(ts, myFuncHandle);
ts = resample(ts, [-5:0.1:10]);
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts` to a `tsdata.interpolation` object:

```
ts = timeseries(rand(100,1),1:100);
myFuncHandle = @(new_time, time, data)...
               interp1(time, data, new_time,...
                       'linear','extrap');
myInterpObj = tsdata.interpolation(myFuncHandle);
ts = setinterpmethod(ts,myInterpObj);
plot(ts);
```

See Also

`timeseries` | `getinterpmethod`

Introduced before R2006a

setuniformtime

Class: timeseries

Modify uniform time vector of `timeseries` object

Syntax

```
ts2 = setuniformtime(ts1,'StartTime',StartTime)
ts2 = setuniformtime(ts1,'Interval',Interval)
ts2 = setuniformtime(ts1,'EndTime',EndTime)
ts2 = setuniformtime(ts1,'StartTime',StartTime,'Interval',Interval)
ts2 = setuniformtime(ts1,'StartTime',StartTime,'EndTime',EndTime)
ts2 = setuniformtime(ts1,'Interval',Interval,'EndTime',EndTime)
```

Description

`ts2 = setuniformtime(ts1,'StartTime',StartTime)` returns the time series with a modified uniform time vector, determined from the StartTime and Interval `1`. `EndTime = StartTime + (length(ts1) - 1)`. The unit of time is unchanged.

`ts2 = setuniformtime(ts1,'Interval',Interval)` sets the `StartTime` to `0`, and uses `EndTime = (length(ts1) - 1)*Interval`.

`ts2 = setuniformtime(ts1,'EndTime',EndTime)` sets the StartTime to `0`, and uses `Interval = EndTime/(length(ts1) -1)`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'Interval',Interval)` uses `EndTime = StartTime + (length(ts1) - 1) * Interval`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'EndTime',EndTime)` uses `Interval = (EndTime - StartTime)/(length(ts1) - 1)`.

`ts2 = setuniformtime(ts1,'Interval',Interval,'EndTime',EndTime)` uses `StartTime = EndTime - (length(ts1) - 1) * Interval`.

Input Arguments

`ts1`

`timeseries` object to which you want to assign a uniform time vector.

`StartTime`

Start time of uniform time vector, specified as a numeric value.

`Interval`

Time interval of uniform time vector, specified as a numeric scalar value.

`EndTime`

End time of uniform time vector specified as a numeric scalar value.

Output Arguments

`ts2`

Time series with uniform time vector, returned as a `timeseries` object.

Examples

Specify New Start Time

Modify the uniform time vector of time series data by specifying a new start time.

1. Load the sample data.

   ```
   load count.dat;
   ```

2. Create a `timeseries` object.

   ```
   count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
   ```

3. Modify uniform time vector of `count_ts`.

   ```
   count_ts = setuniformtime(count_ts,'StartTime',10);
   ```

The start time of the time vector is `10` seconds. `setuniformtime` uses a default time interval of `1` and computes the end time using: `EndTime = StartTime + (length(count_ts) - 1)* Interval`.

Specify New Start and End Times

Modify the uniform time vector of time series data by specifying a new start time and end time.

1. Load sample data.

   ```
   load count.dat;
   ```

2. Create `timeseries` object.

   ```
   count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
   ```

3. Assign a uniform time vector to `count_ts`.

   ```
   count_ts2 = setuniformtime(count_ts,'StartTime',10,'EndTime',20);
   ```

   The start time of the time vector is now 10 seconds, and the end time is now 20 seconds. MATLAB computes the time interval using: `Interval = (EndTime - StartTime)/(length(count_ts) - 1)`

See Also

`timeseries`

synchronize

Class: timeseries

Synchronize and resample two `timeseries` objects using common time vector

Syntax

```
[ts1 ts2] = synchronize(ts1,ts2,synchronizemethod)
[ts1 ts2] = synchronize(___,Name,Value)
```

Description

`[ts1 ts2] = synchronize(ts1,ts2,synchronizemethod)` creates two new `timeseries` objects by synchronizing ts1 and ts2 using a common time vector and the specified method.

`[ts1 ts2] = synchronize(___,Name,Value)` creates the two new `timeseries` objects with additional options specified by one or more Name,Value pair arguments for the previous syntax.

Input Arguments

`ts1`

One of the `timeseries` objects that you want to synchronize and resample.

`ts2`

The other `timeseries` object that you want to synchronize and resample.

`synchronizemethod`

A string that defines the method for synchronizing the `timeseries` object. It can be any one of the following:

- `Union` — Resample `timeseries` objects using a time vector that is a union of the time vectors of `ts1` and `ts2` on the time range where the two time vectors overlap.

- `Intersection` — Resample `timeseries` objects on a time vector that is the intersection of the time vectors of `ts1` and `ts2`.
- `Uniform` — Requires an additional argument as follows:

  ```
  [ts1 ts2] = synchronize(ts1,ts2,'Uniform','Interval',value)
  ```

  This method resamples time series on a uniform time vector, where `value` specifies the time interval between two consecutive samples. The uniform time vector is the overlap of the time vectors of `ts1` and `ts2`. The interval units are the smaller units of `ts1` and `ts2`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'InterpMethod'`

Forces the specified interpolation method (over the default method) for this synchronize operation. Can be either a string, `linear` or `zoh`, or a `tsdata.interpolation` object that contains a user-defined interpolation method.

Default: `linear`

`'QualityCode'`

Integer (between -128 and 127) used as the quality code for both time series after the synchronization.

`'KeepOriginalTimes'`

Logical value (`true` or `false`) indicating whether the new time series should keep the original time values.

`'tolerance'`

Real number used as the tolerance for differentiating two time values when comparing the `ts1` and `ts2` time vectors. The default tolerance is `1e-10`. For example, when the sixth time value in `ts1` is `5+(1e-12)` and the sixth time value in `ts2` is `5-(1e-13)`,

both values are treated as 5 by default. To differentiate those two times, you can set `'tolerance'` to a smaller value such as `1e-15`, for example.

Output Arguments

`ts1`

One of the `timeseries` objects that you synchronized and resampled.

`ts2`

The other `timeseries` object that you synchronized and resampled.

Examples

This example illustrates how the `KeepOriginalTime` property affects synchronization.

```
% Create two timeseries, such that ts1.timeinfo.StartDate
% is one day after ts2.timeinfo.StartDate:

ts1 = timeseries([1 2],[datestr(now); datestr(now+1)]);
ts2 = timeseries([1 2],[datestr(now-1); datestr(now)]);

% If you use this code, then ts1.timeinfo.StartDate
% is changed to match ts2.TimeInfo.StartDate
% and ts1.Time changes to 1:

[ts1 ts2] = synchronize(ts1,ts2,'union');

% But if you use this code, then ts1.timeinfo.StartDate
% is unchanged and ts1.Time is still 0:

[ts1 ts2] = synchronize(ts1,ts2,'union','KeepOriginalTimes',true);
```

`set` | `timeseries`

Introduced before R2006a

transpose

Class: timeseries

Transpose `timeseries` object

Syntax

```
ts1 = transpose(ts)
```

Description

`ts1 = transpose(ts)` returns a new `timeseries` object, ts1, with `IsTimeFirst` value set to the opposite of what it is for ts. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector.

Tips

- The `transpose` function that is overloaded for `timeseries` objects does not transpose the data. Instead, this function changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, transpose the `Data` property of the time series. For example, you can use the syntax `transpose(ts.Data)` or `(ts.Data).'`. The value of the `Data` property must be a 2-D array.
- Consider a time series with 10 samples with the property `IsTimeFirst = True`. When you transpose this time series, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

  The following table summarizes how the size for timeseries data (up to three dimensions) display before and after transposing.

  Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N

Size of Original Data	Size of Transposed Data
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

Input Arguments

`ts`

The `timeseries` object that you want to transpose.

Output Arguments

`ts1`

The `timeseries` object that is the result of transposing the original `timeseries` object.

Examples

Suppose that a `timeseries` object, `ts`, has `ts.Data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is `true`, which means that the first dimension of the data aligns with the time vector. `transpose(ts)` modifies the `timeseries` object, such that the last dimension of the data now aligns with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

See Also

`timeseries` | `transpose`

Introduced before R2006a

std

Class: timeseries

Standard deviation of `timeseries` data

Syntax

```
ts_std = std(ts)
ts_std = std(ts,Name,Value)
```

Description

`ts_std = std(ts)` returns the standard deviation of the `timeseries` data.

`ts_std = std(ts,Name,Value)` specifies additional options specified with one or more Name,Value pair arguments.

Input Arguments

`ts`

The `timeseries` object for which you want the standard deviation of the data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

'Weighting'

A string specifying one of two possible values, `none` or `time`.
When you specify `time`, larger time values correspond to larger weights.

Output Arguments

ts_std

The standard deviation of `ts.Data` values as follows:

- When `ts.Data` is a vector, `ts_std` is the standard deviation of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_std` is the standard deviation of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `std` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

The following example finds the standard deviation for a `timeseries` object. MATLAB calculates the standard deviation for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,1:24,'Name','CountPerSecond');

% Calculate the standard deviation of each data column for this
% timeseries object:
```

```
std(count_ts)
```

MATLAB returns:

```
25.3703   41.4057   68.0281
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `(t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note: If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.
3. Multiplying the data for each time by its normalized weighting.

Introduced before R2006a

sum

Class: timeseries

Sum of `timeseries` data

Syntax

```
ts_sm = sum(ts)
ts_sm = sum(ts,Name,Value)
```

Description

`ts_sm = sum(ts)` returns the sum of the `timeseries` data.

`ts_sm = sum(ts,Name,Value)` specifies additional options with one or more Name,Value pair arguments.

Input Arguments

`ts`

The `timeseries` object for which you want the sum of the data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

`'Quality'`

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

`'Weighting'`

A string specifying one of two possible values, `none` or `time`.
When you specify `time`, larger time values correspond to larger weights.

Output Arguments

`ts_sm`

The sum of the `timeseries` data, as follows:

- When `ts.Data` is a vector, ts_sm is the sum of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then ts_sm is a row vector containing the sum of each column of `ts.Data`.

When `ts.Data` is a N-dimensional array, `sum` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

Calculate the sum of each data column for a `timeseries` object:

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,1:24,'Name','CountPerSecond');

% Calculate the sum of each data column for this timeseries object:
```

```
sum(count_ts)
```

MATLAB returns:

```
768         1117         1574
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `(t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note: If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.
3. Multiplying the data for each time by its normalized weighting.

Introduced before R2006a

var

Class: timeseries

Variance of `timeseries` data

Syntax

```
ts_var = var(ts)
ts_var = var(ts,Name,Value)
```

Description

`ts_var = var(ts)` returns the variance of `ts.data`.

`ts_var = var(ts,Name,Value)` uses additional options specified by one or more Name,Value pair arguments.

Input Arguments

`ts`

The `timeseries` object for which you want the variance of the data.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'MissingData'`

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

Default: `remove`

'Quality'

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

'Weighting'

A string specifying one of two possible values, `none` or `time`.
When you specify `time`, larger time values correspond to larger weights.

Output Arguments

ts_var

The variance of `ts.data`, as follows:

- When `ts.Data` is a vector, then `ts_var` is the variance of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_var` is a row vector containing the variance of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `var` always operates along the first nonsingleton dimension of `ts.Data`.

Examples

The following example calculates the variance values of a multivariate `timeseries` object. MATLAB calculates the variance independently for each data column in the `timeseries` object.

Load a 24-by-3 data array. Then create a timeseries object with 24 time values.

```
load count.dat
count_ts = timeseries(count,[1:24],'Name','CountPerSecond');
```

Calculate the variance of each data column.

```
var(count_ts)
```

MATLAB returns:

```
1.0e+03 *
  0.6437    1.7144    4.6278
```

Algorithms

MATLAB determines weighting by:

1. Attaching a weighting to each time value, depending on its order, as follows:
   - First time point — The duration of the first time interval `(t(2) - t(1))`.
   - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval `((t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2)`.
   - Last time point — The duration of the last time interval `(t(end) - t(end - 1))`.
2. Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

   Note: If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.
3. Multiplying the data for each time by its normalized weighting.

Introduced before R2006a

triangulation class

Triangulation in 2-D or 3-D

Description

Use `triangulation` to create an in-memory representation of any 2-D or 3-D triangulation data that is in matrix format, such as the matrix output from the `delaunay` function or other software tools. When your data is represented using `triangulation`, you can perform topological and geometric queries, which you can use to develop geometric algorithms. For example, you can find the triangles or tetrahedra attached to a vertex, those that share an edge, their circumcenters, and other features.

Construction

`TR = triangulation(T,P)` creates a 2-D or 3-D triangulation representation using the triangulation connectivity list, `T`, and the points in matrix `P`.

`TR = triangulation(T,x,y)` creates a 2-D triangulation representation with the point coordinates specified as column vectors, `x` and `y`.

`TR = triangulation(T,x,y,z)` creates a 3-D triangulation representation with the point coordinates specified as column vectors, `x`, `y`, and `z`.

Input Arguments

`T`

Triangulation connectivity list, specified as an `m`-by-`n` matrix, where `m` is the number of triangles or tetrahedra, and `n` is the number of vertices per triangle or tetrahedron. Each element in `T` is a "Vertex ID" on page 1-6833. Each row of `T` contains the vertex IDs that define a triangle or tetrahedron.

`P`

Points, specified as a matrix whose columns are the `x`, `y`, (and possibly `z`) coordinates of the triangulation points. The row numbers of `P` are the vertex IDs in the triangulation.

`x`

x-coordinates vector, specified as a column vector containing the *x*-coordinates of the triangulation points.

`y`

y-coordinates vector, specified as a column vector containing the *y*-coordinates of the triangulation points.

`z`

z-coordinates vector, specified as a column vector containing the *z*-coordinates of the triangulation points.

Properties

`Points`

Points in the triangulation, represented as a matrix containing the following information:

- Each row in `TR.Points` contains the coordinates of a vertex.
- Each row number of `TR.Points` is a vertex ID.

`ConnectivityList`

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each element in `TR.ConnectivityList` is a vertex ID.
- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `TR.ConnectivityList` is a "Triangle or Tetrahedron ID" on page 1-6833.

Methods

barycentricToCartesian	Converts point coordinates from barycentric to Cartesian

cartesianToBarycentric	Converts point coordinates from Cartesian to barycentric
circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
nearestNeighbor	Vertex closest to specified location
neighbors	Neighbors to specified triangle or tetrahedron
pointLocation	Triangle or tetrahedron containing specified point
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex

vertexNormal	Triangulation vertex normal

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

2-D Triangulation

Define the points in the triangulation.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];
```

Define the triangles. This is the triangulation connectivity list.

```
T = [5  3  1;
```

```
     3  2  1;
     3  4  2;
     4  6  2];
```

Create the triangulation representation.

```
TR = triangulation(T,P)
```

```
TR =

  triangulation with properties:

             Points: [6x2 double]
    ConnectivityList: [4x3 double]
```

Examine the coordinates of the vertices of the first triangle.

```
TR.Points(TR.ConnectivityList(1,:),:)
```

```
ans =

See Also

`delaunayTriangulation`

barycentricToCartesian

Class: triangulation

Converts point coordinates from barycentric to Cartesian

Syntax

```
PC = barycentricToCartesian(TR,ti,B)
```

Description

`PC = barycentricToCartesian(TR,ti,B)` returns the Cartesian coordinates of the points in `B`. Each row, `B(j,:)`, contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, `ti(j)`. The point, `PC(j,:)`, is the `j`th point represented in Cartesian coordinates.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`ti`

Triangle or tetrahedron IDs, specified as a column vector.

`B`

Barycentric coordinates, specified as a matrix. Each row, `B(j,:)`, contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, `ti(j)`.

Output Arguments

`PC`

Cartesian coordinates, returned as a matrix. The point, `PC(j,:)`, is the `j`th point represented in Cartesian coordinates.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Barycentric Coordinates Converted to Cartesian Coordinates

Create a triangulation from a set of points, `P`, and triangulation connectivity list, `T`.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];

T = [5  3  1;
     3  2  1;
     3  4  2;
     4  6  2];

TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Specify the barycentric coordinates of the second point in the triangle.

```
B = [0 1 0];
```

Convert the point to Cartesian coordinates.

```
PC = barycentricToCartesian(TR,ti,B)
```

```
PC =

    2.5000    5.0000
```

Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

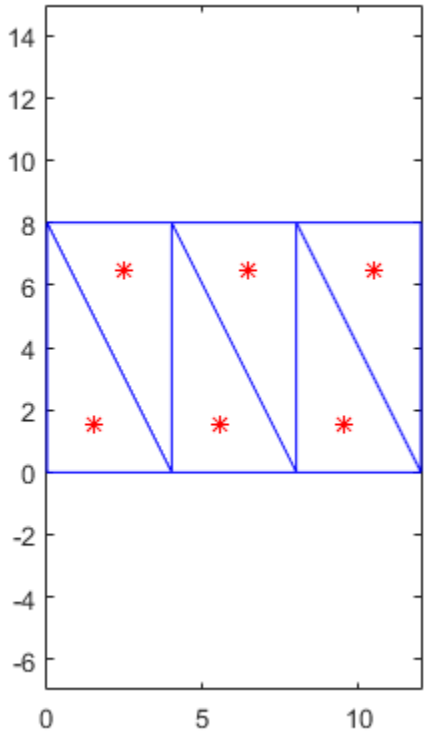
```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
axis equal;
```



Create a new triangulation which is a deformed version of `DT` .

```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

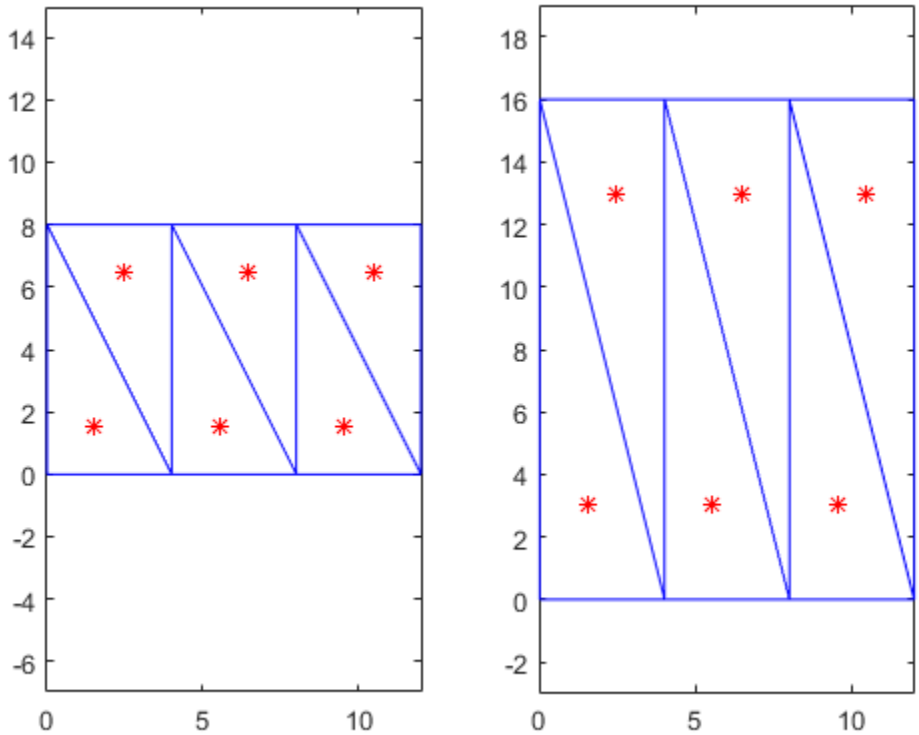
Compute the barycentric coordinates for the incenters of `DT`, and use them to compute the Cartesian coordinates of the analogous points in `TR`.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
```

```
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```



See Also

`cartesianToBarycentric` | `delaunayTriangulation`

cartesianToBarycentric

Class: triangulation

Converts point coordinates from Cartesian to barycentric

Syntax

```
B = cartesianToBarycentric(TR,ti,PC)
```

Description

`B = cartesianToBarycentric(TR,ti,PC)` returns the barycentric coordinates of the points in `PC`. Each row, `PC(j,:)`, contains the Cartesian coordinates of a point you want to convert. `B(j,:)` are the barycentric coordinates of the point, `PC(j,:)`, with respect to triangle or tetrahedron, ti(j).

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`ti`

Triangle or tetrahedron IDs, specified as a column vector.

`PC`

Cartesian coordinates, specified as a matrix. Each row, `PC(j,:)`, contains the Cartesian coordinates of a point with respect to triangle or tetrahedron, `ti(j)`.

Output Arguments

`B`

Barycentric coordinates, returned as a matrix. `B(j,:)` are the barycentric coordinates of `PC(j,:)` with respect to ti(j).

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Cartesian Coordinates Converted to Barycentric Coordinates

Create a triangulation from a set of points, `P`, and triangulation connectivity list, `T`.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];

T = [5  3  1;
     3  2  1;
     3  4  2;
     4  6  2];

TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Get the coordinates of the third vertex in the first triangle.

```
PC = TR.Points(TR.ConnectivityList(1,3),:)
```

```
PC =

    2.5000    8.0000
```

Convert the point to barycentric coordinates.

```
B = cartesianToBarycentric(TR,ti,PC)
```

```
B =

     0     0     1
```

Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

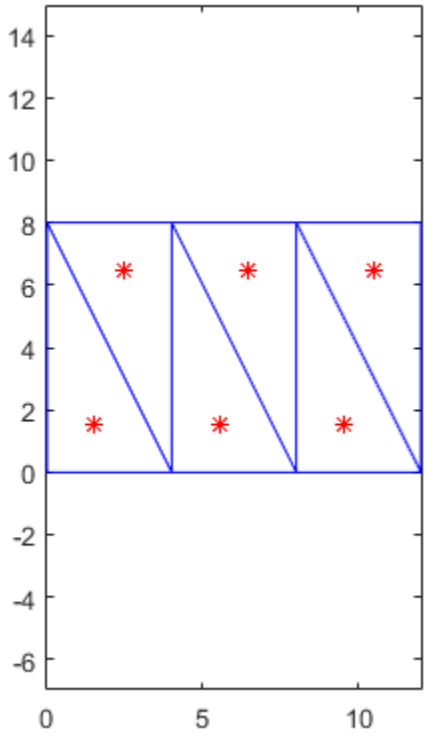
```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
axis equal;
```



Create a new triangulation which is a deformed version of `DT` .

```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of `DT`, and use them to compute the Cartesian coordinates of the analogous points in `TR`.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
```

```
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```

barycentricToCartesian | delaunayTriangulation

circumcenter

Class: triangulation

Circumcenter of triangle or tetrahedron

Syntax

```
CC = circumcenter(TR,ti)
[CC,r] = circumcenter(TR,ti)
CC = circumcenter(TR)
[CC,r] = circumcenter(TR)
```

Description

`CC = circumcenter(TR,ti)` returns the coordinates of the circumcenter of each triangle or tetrahedron specified in `ti`.

`[CC,r] = circumcenter(TR,ti)` also returns the corresponding radii of the circumscribed circles or spheres.

`CC = circumcenter(TR)` returns the circumcenters of all triangles or tetrahedra in the triangulation.

`[CC,r] = circumcenter(TR)` also returns the corresponding radii of the circumscribed circles or spheres for the entire triangulation.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`ti`

Triangle or tetrahedron IDs, specified as a column vector.

Output Arguments

cc

Circumcenters, returned as a matrix. Each row, `CC(j,:)`, contains the coordinates of the circumcenter of `ti(j)`.

r

Radii of the circumscribed circles or spheres, returned as a vector. The radius at `r(j)` corresponds to the circle or sphere circumscribing `ti(j)`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

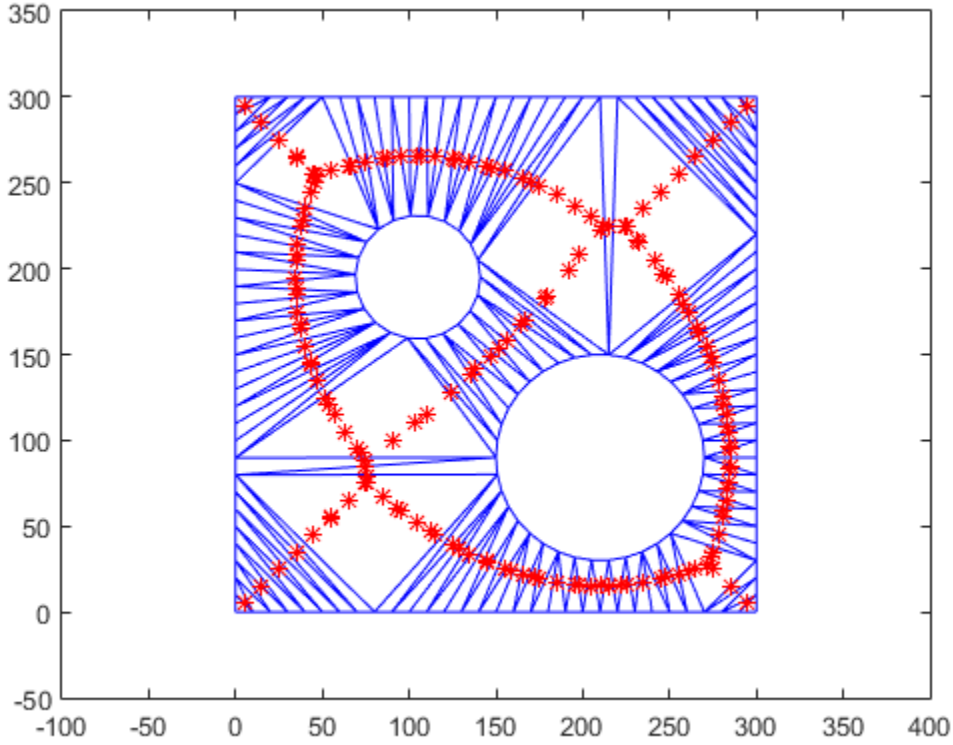
Circumcenters in 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Compute the circumcenters.

```
CC = circumcenter(TR);
triplot(TR)
axis([-100 400 -50 350])
hold on
plot(CC(:,1),CC(:,2),'*r')
hold off
```



The circumcenters represent points on the medial axis of the polygon.

Circumcenters in 3-D Delaunay Triangulation

Create the Delaunay triangulation using a random set of points, `P`.

```
P = gallery('uniformdata',10,3,0);
DT = delaunayTriangulation(P);
```

Calculate the circumcenters of the first five tetrahedra in `DT`.

```
CC = circumcenter(DT,[1:5]')
```

```
CC =

    0.9626    0.3892    0.0928
    6.3458    0.2377    3.1814
    0.4820    0.9064    0.5176
   -1.2993    1.8384   -1.2185
   -0.1595    1.0852   -0.2536
```

delaunayTriangulation | incenter

edgeAttachments

Class: triangulation

Triangles or tetrahedra attached to specified edge

Syntax

```
ti = edgeAttachments(TR,vstart,vend)
ti = edgeAttachments(TR,E)
```

Description

`ti = edgeAttachments(TR,vstart,vend)` returns the triangles or tetrahedra attached to the specified edges. To specify the edges, use the vectors, `vstart` and `vend`. These vectors contain the "Vertex ID" on page 1-6850 at the start and end of each edge.

`ti = edgeAttachments(TR,E)` specifies the starting and ending vertices of each edge in a 2-column matrix, `E`.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`vstart`

IDs of starting vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the start of an edge.

`vend`

IDs of ending vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the end of an edge.

E

IDs of the edge vertices, specified as a 2-column matrix of vertex IDs. Each row of `E` corresponds to an edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of an edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

Output Arguments

ti

IDs of the triangles or tetrahedra attached to the edges, returned as an `m`-by-`1` cell array. Each cell in `ti` contains the IDs of the attached triangles or tetrahedra. The attachments to the edge located between the vertices, `vstart(j)` and `vend(j)`, or `E(j,:)`, are returned in `ti{j}`. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each edge can vary.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Edge Attachments in 3-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load tetmesh
TR = triangulation(tet,X);
```

Define the starting and ending vertices of the edges.

```
vstart = [15; 21];
vend = [936; 716];
```

Find the edge attachments.

```
ti = edgeAttachments(TR,vstart,vend);
```

Examine the attachments to the first edge.

```
ti{1}
```

```
ans =

     927     2060     3438     3423     2583     4690
```

Edge Attachments in 2-D Delaunay Triangulation

Create a Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to edge `(1,5)`.

```
ti = edgeAttachments(DT,1,5);
ti{:}
```

```
ans =

     4     1
```

See Also

`delaunayTriangulation` | `edges` | `vertexAttachments`

edges

Class: triangulation

Triangulation edges

Syntax

```
E = edges(TR)
```

Description

`E = edges(TR)` returns the triangulation edges as a matrix of vertex IDs. The vertices referenced in `E` indicate the beginning and end of each edge.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

Output Arguments

E

Edge vertex IDs, returned as a 2-column matrix. Each row of `E` corresponds to an edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of the edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Edges in a 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Find the edges in the triangulation.

```
E = edges(TR);
```

List the first five edges.

```
E(1:5,:)
```

```
ans =

     1     2
     1   118
     1   119
     1   120
     2     3
```

Edges in a 2-D Delaunay Triangulation

Create 2-D Delaunay triangulation from a set of 10 random points.

```
X = gallery('uniformdata',[10, 2],0);
DT = delaunayTriangulation(X);
```

Find the edges in the triangulation.

```
E = edges(DT)
```

```
E =

     1     3
     1     4
     1     5
     1     6
     1     9
     2     4
     2     5
     2     6
     2     7
     2     8
     2    10
     3     4
     3     7
     3    10
     4     6
     4    10
     5     6
     5     8

     6     9
     7     8
     7    10
```

See Also

`delaunayTriangulation` | `edgeAttachments`

faceNormal

Class: triangulation

Triangulation face normal

Syntax

```
FN = faceNormal(TR,ti)
FN = faceNormal(TR)
```

Description

`FN = faceNormal(TR,ti)` returns the unit normal vector to each triangle specified by `ti`. The `faceNormal` function supports only 2-D triangulations.

`FN = faceNormal(TR)` returns the unit normal vectors to all triangles.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`ti`

Triangle IDs, specified as a column vector.

Output Arguments

`FN`

Face normals, returned as a matrix. Each row, `FN(j,:)`, is the unit normal vector to triangle `ti(j)`.

If you do not specify `ti`, then `faceNormal` returns the unit normal information for the entire triangulation. In this case, the normal associated with `TR.ConnectivityList(j,:)` is `FN(j,:)`.

Definitions

Triangle ID

A row number of the matrix, `TR.ConnectivityList`. You use this ID to refer a specific triangle.

Examples

Plot Unit Normals to Facets on a Spherical Surface

Create a set of random points on a spherical surface.

```
theta = gallery('uniformdata',[100,1],0)*2*pi;
phi = gallery('uniformdata',[100,1],1)*pi;
x = cos(theta).*sin(phi);
y = sin(theta).*sin(phi);
z = cos(phi);
```

Triangulate the points with `delaunayTriangulation`.

```
DT = delaunayTriangulation(x,y,z);
```

Find the free boundary facets and use them to create a triangulation representation for plotting.

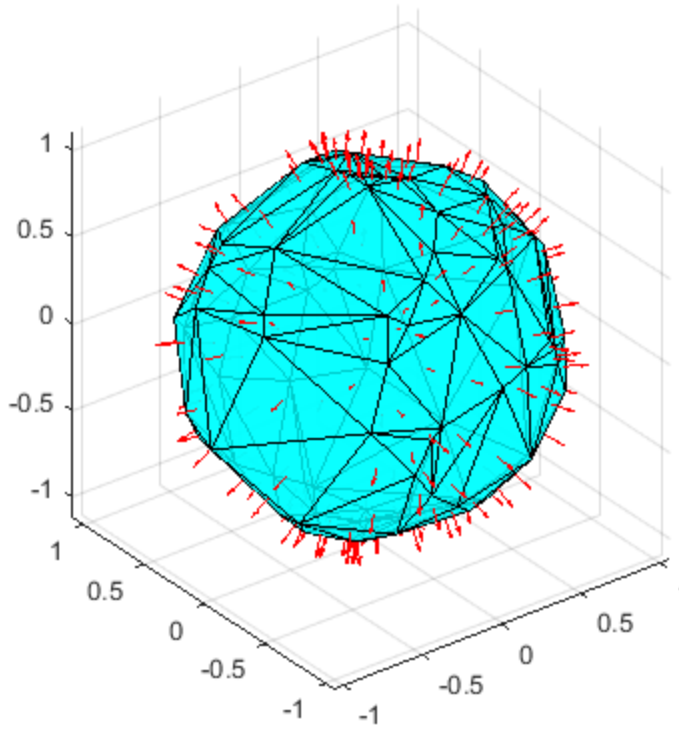
```
[T,Xb] = freeBoundary(DT);
TR = triangulation(T,Xb);
```

Plot the triangulation.

```
figure
trisurf(T,Xb(:,1),Xb(:,2),Xb(:,3), ...
     'FaceColor', 'cyan', 'faceAlpha', 0.8);
axis equal;
hold on;
```

```
% Calulate the incenters and face normals.
P = incenter(TR);
fn = faceNormal(TR);

% Display the normal vectors on the surface.
quiver3(P(:,1),P(:,2),P(:,3), ...
     fn(:,1),fn(:,2),fn(:,3),0.5, 'color','r');
hold off;
```



See Also

delaunayTriangulation | freeBoundary

featureEdges

Class: triangulation

Triangulation sharp edges

Syntax

```
FE = featureEdges(TR,filterangle)
```

Description

`FE = featureEdges(TR,filterangle)` returns the feature edges in a 2-D triangulation.

Use this method to extract the sharp edges in the surface mesh for display purposes. A feature edge is an edge that has any of the following attributes:

- The edge is shared by only one triangle.
- The edge is shared by more than two triangles.
- The edge is shared by a pair of triangles with angular deviation greater than the `filterangle`.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`filterangle`

Filter angle, specified as a scalar value in the range [0,π]. `featureEdges` returns adjacent triangles that have a dihedral angle that deviates from π by an angle greater than `filterangle`.

Output Arguments

FE

Feature edge vertex IDs, returned as a two-column matrix. Each row of `FE` corresponds to a feature edge and contains two IDs:

- `FE(j,1)` is the ID of the vertex at the start of the edge.
- `FE(j,2)` is the ID of the vertex at end of the edge.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Feature Edges Shown on a Surface

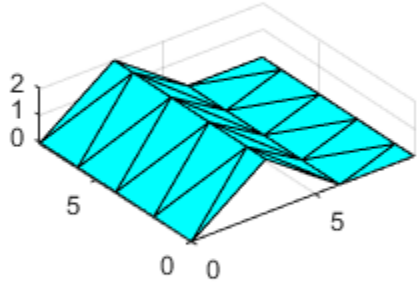
Use `featureEdges` to find the feature edges of a surface and display them on a plot.

Create a surface triangulation.

```
x = [0 0 0 0 0 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
DT = delaunayTriangulation(x,y);
T = DT(:,:);
```

Elevate the 2-D mesh to create a surface.

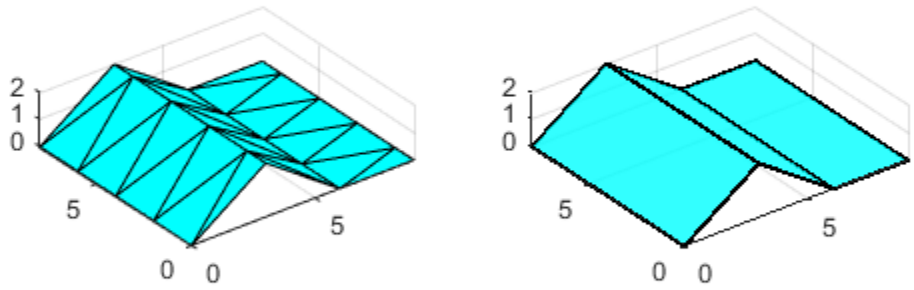
```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(T,x,y,z,'FaceColor','cyan');
axis equal;
```



Compute the feature edges using a filter angle of `pi/6`.

```
TR = triangulation(T,x,y,z);
fe = featureEdges(TR,pi/6)';
subplot(1,2,2);
trisurf(TR,'FaceColor','cyan','EdgeColor',...
'none','FaceAlpha',0.8);
axis equal;

% Add the feature edges to the plot.
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
```



See Also

`delaunayTriangulation` | `edges`

freeBoundary

Class: triangulation

Triangulation facets referenced by only one triangle or tetrahedron

Syntax

```
FBtri = freeBoundary(TR)
[FBtri,FBpoints] = freeBoundary(TR)
```

Description

`FBtri = freeBoundary(TR)` returns the free boundary facets of `TR.ConnectivityList`. A facet in `TR` is on the free boundary if it is referenced by only one triangle or tetrahedron.

`[FBtri,FBpoints] = freeBoundary(TR)` also returns a matrix containing the vertices of the free boundary facets.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

Output Arguments

`FBtri`

Triangulation connectivity list, returned as a matrix that contains the following information:

- Each row in `FBtri` represents a facet on the free boundary.
- Each element is a “Vertex ID” on page 1-6863.

The vertex IDs in `FBtri` reference a specific matrix, depending on the syntax you choose:

- If you call `freeBoundary` with one output argument, then the elements of `FBtri` are row numbers of `TR.Points`.
- If you call `freeBoundary` with two output arguments, then the elements of `FBtri` are row numbers of `FBpoints`.

`FBpoints`

Free boundary points, returned as a matrix containing the coordinates of the vertices of the free boundary facets. Each row of `FBpoints` contains coordinates of a vertex.

Definitions

Vertex ID

A row number of the matrix, `TR.Points` or FBpoints. Use this ID to refer a specific vertex in the triangulation.

Examples

Surface of 3-D Triangulation

Use `freeBoundary` to extract the facets of a 3-D triangulation that cover the surface of an object.

Load a 3-D triangulation.

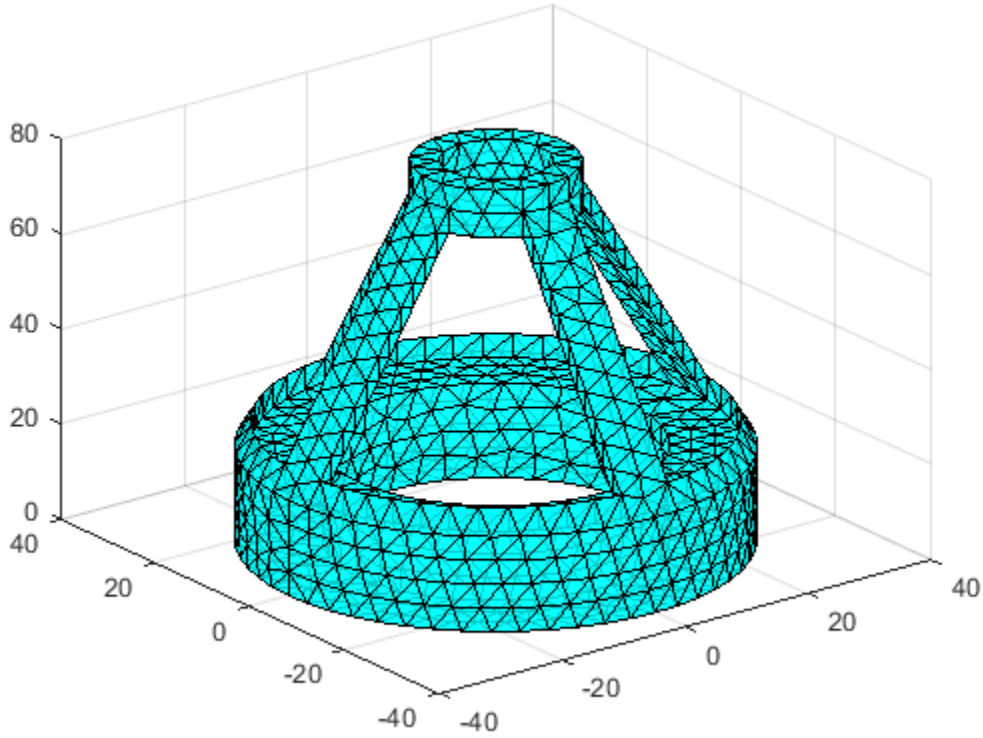
```
load tetmesh;
TR = triangulation(tet,X);
```

Compute the boundary triangulation.

```
[FBtri,FBpoints] = freeBoundary(TR);
```

Plot the boundary triangulation.

```
trisurf(FBtri,FBpoints(:,1),FBpoints(:,2),FBpoints(:,3), ...
       'FaceColor','cyan','FaceAlpha', 0.8);
```



Free Boundary of 2-D Delaunay Triangulation

Use `freeBoundary` when you want to highlight the outer edges of a 2-D Delaunay triangulation.

Create a triangulation from a random set of points.

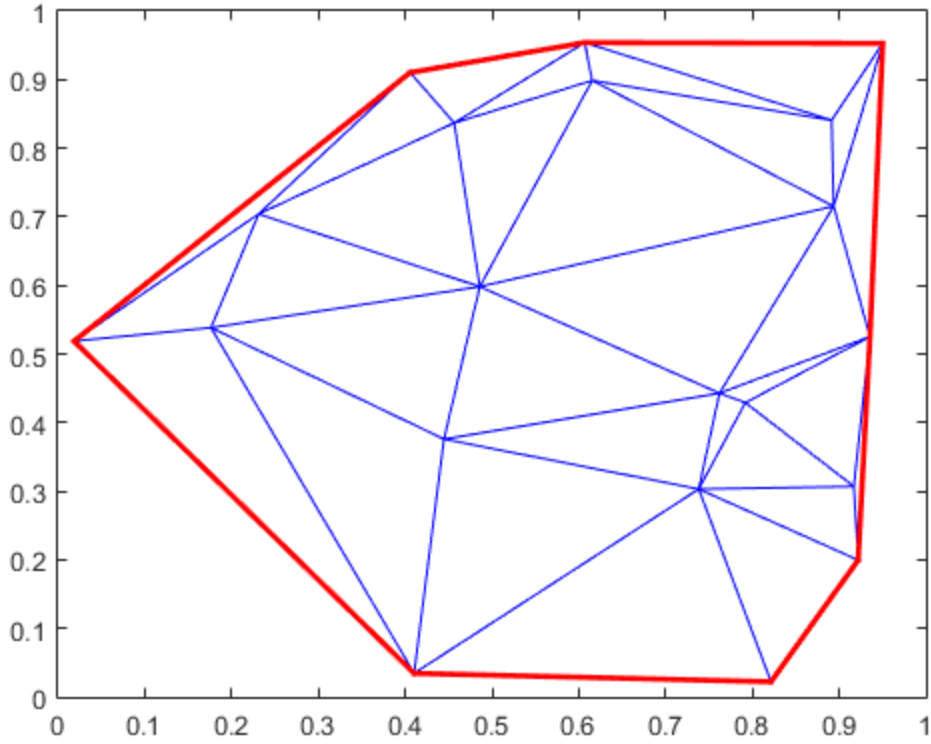
```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

Find the free boundary edges.

```
fe = freeBoundary(DT)';
```

Plot the mesh and highlight the free boundary edges in red.

```
triplot(DT);
hold on;
plot(x(fe),y(fe),'-r','LineWidth',2) ;
hold off;
```



See Also

`delaunayTriangulation` | `faceNormal` | `featureEdges`

incenter

Class: triangulation

Incenter of triangle or tetrahedron

Syntax

```
IC = incenter(TR,ti)
[IC,r] = incenter(TR,ti)
```

Description

`IC = incenter(TR,ti)` returns the coordinates of the incenter of each triangle or tetrahedron specified by `ti`.

`[IC,r] = incenter(TR,ti)` also returns the radii of the inscribed circles or spheres.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`ti`

Triangle or tetrahedron IDs, specified as a column vector.

Output Arguments

`IC`

Incenters, returned as a matrix. Each row of `IC` contains the coordinates of an incenter. For example, `IC(j,:)` is the incenter of `ti(j)`.

`r`

Radii of the inscribed circles or spheres, returned as a vector. `r(j)` is the radius of the inscribed circle or sphere whose center is `IC(j,:)`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Examples

Find Incenters in 3-D Triangulation

Load a 3-D triangulation.

```
load tetmesh
```

Calculate the incenters of the first five tetrahedra.

```
TR = triangulation(tet,X);
IC = incenter(TR,[1:5]')
```

```
IC =

   -6.1083  -31.0234    8.1439
   -2.1439  -31.0283    5.8742
   -1.9555  -31.9463    7.4112
   -4.3019  -30.8460   10.5169
   -3.1596  -29.3642    6.1851
```

Find Incenters in 2-D Delaunay Triangulation

Create the Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Calculate incenters of the triangles

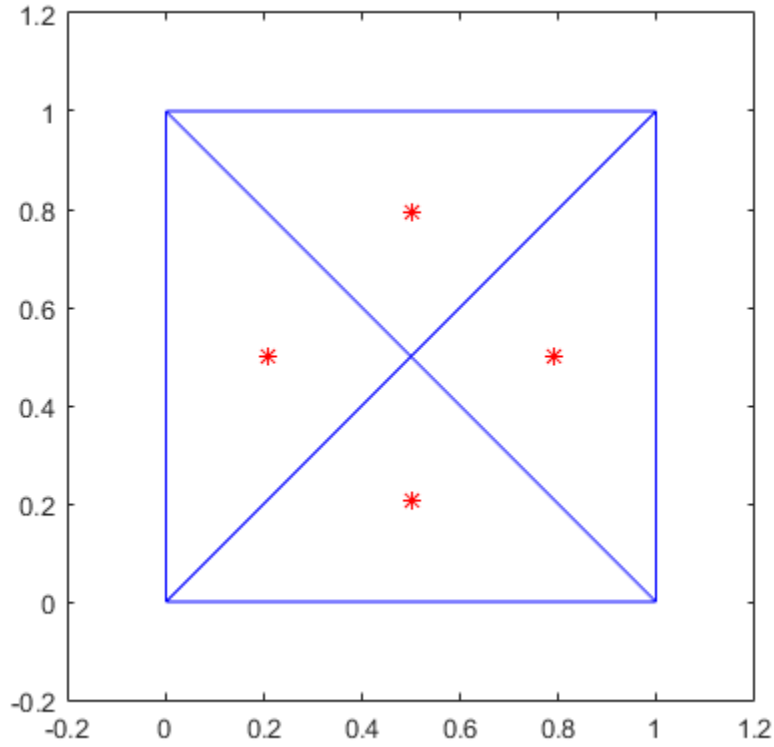
```
IC = incenter(DT)
```

```
IC =

    0.2071    0.5000
    0.5000    0.7929
    0.7929    0.5000
    0.5000    0.2071
```

Plot the triangles and incenters.

```
figure
triplot(DT)
axis equal
axis([-0.2 1.2 -0.2 1.2])
hold on
plot(IC(:,1),IC(:,2),'*r')
hold off
```



See Also

`circumcenter` | `delaunayTriangulation`

isConnected

Class: triangulation

Test if two vertices are connected by edge

Syntax

```
tf = isConnected(TR,vstart,vend)
tf = isConnected(TR,E)
```

Description

`tf = isConnected(TR,vstart,vend)` returns a `logical` array of `true` or `false` values that indicate whether the specified pairs of vertices are connected by an edge. Element `tf(j)` is `true` when the vertices, `vstart(j)` and `vend(j)`, are connected by an edge.

`tf = isConnected(TR,E)` specifies the edge start and end indices in matrix `E`. Element `tf(j)` is `true` when the vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`vstart`

IDs of start vertices, specified as a column vector. Each vertex ID refers to a vertex at the start of an edge.

`vend`

IDs of end vertices, specified as a column vector. Each vertex ID refers to a vertex at the end of an edge.

`E`

IDs of the edge vertices, specified as a two-column matrix. Each row of `E` corresponds to a candidate edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of a candidate edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

Output Arguments

`tf`

Logical values, returned as a column vector. Element `tf(j)` is `true` when either of the following are true:

- The vertices, `vstart(j)` and `vend(j)`, are connected by an edge.
- The vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

Otherwise, `tf(j)` is false.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Determine Whether Vertices are connected by an Edge in 2-D

Load a 2-D triangulation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Determine whether vertices `3` and `117` are connected by an edge.

```
isConnected(TR,3,117)

ans =

     1
```

The vertices are connected by an edge.

Determine whether vertices 3 and 164 are connected by an edge.

```
isConnected(TR,3,164)

ans =

     0
```

The vertices are not connected by an edge.

Determine Whether Vertices are connected by an Edge in 3-D

```
X = gallery('uniformdata',[10,3],0);
DT = delaunayTriangulation(X);
```

Determine whether vertices 2 and 7 are connected by an edge.

```
E = [2 7];
isConnected(DT,E)

ans =

     1
```

The vertices are connected by an edge.

`delaunayTriangulation` | `edgeAttachments` | `edges`

nearestNeighbor

Class: triangulation

Vertex closest to specified location

Syntax

```
vi = nearestNeighbor(T,QP)
vi = nearestNeighbor(T,qx,qy)
vi = nearestNeighbor(T,qx,qy,qz)
[vi,d] = nearestNeighbor( ___ )
```

Description

`vi = nearestNeighbor(T,QP)` returns the IDs of the vertices closest to the query points in `QP`. Each row in matrix `QP` contains the `x`, `y`, (and possibly `z`) coordinates of a query point.

`vi = nearestNeighbor(T,qx,qy)` specifies the `x` and `y` coordinates of the query points in 2-D as separate column vectors.

`vi = nearestNeighbor(T,qx,qy,qz)` specifies the `x`, `y`, and `z` coordinates of the query points in 3-D as separate column vectors.

`[vi,d] = nearestNeighbor( ___ )` also returns the Euclidean distance between each query point and its nearest neighbor. You can specify both output arguments with any of the previous syntaxes.

Note: `nearestNeighbor` does not support Delaunay triangulations with constrained edges.

Input Arguments

`T` — Triangulation representation

`triangulation` object | `delaunayTriangulation` object

Triangulation representation, specified as a `triangulation` object or `delaunayTriangulation` object. For more information, see `triangulation` or `delaunayTriangulation`.

`QP` — Query points

matrix with 2 columns (2-D) | matrix with 3 columns (3-D)

Query points, specified as a matrix with 2 or 3 columns. `QP` contains the `x`, `y`, (and possibly `z`) coordinates of the query points.

`qx` — Query point x-coordinates

column vector

Query point x-coordinates, specified as a column vector.

`qy` — Query point y-coordinates

column vector

Query point y-coordinates, specified as a column vector.

`qz` — Query point z-coordinates

column vector

Query point z-coordinates, specified as a column vector.

Output Arguments

`vi` — Vertex IDs of nearest neighbor

column vector

Vertex IDs of the nearest neighbor, returned as a column vector. `vi(j)` is the vertex ID of the nearest neighbor to the query point `QP(j,:)`.

`d` — Distance to nearest neighbor

column vector

Distance to the nearest neighbor, returned as a column vector of the same length as `vi`. The value at `d(j)` is the Euclidean distance between the `j`th query point `QP(j,:)` and its nearest neighbor.

Examples

Determine Nearest Neighbors of Query Points

Define the points and connectivity of the triangulation.

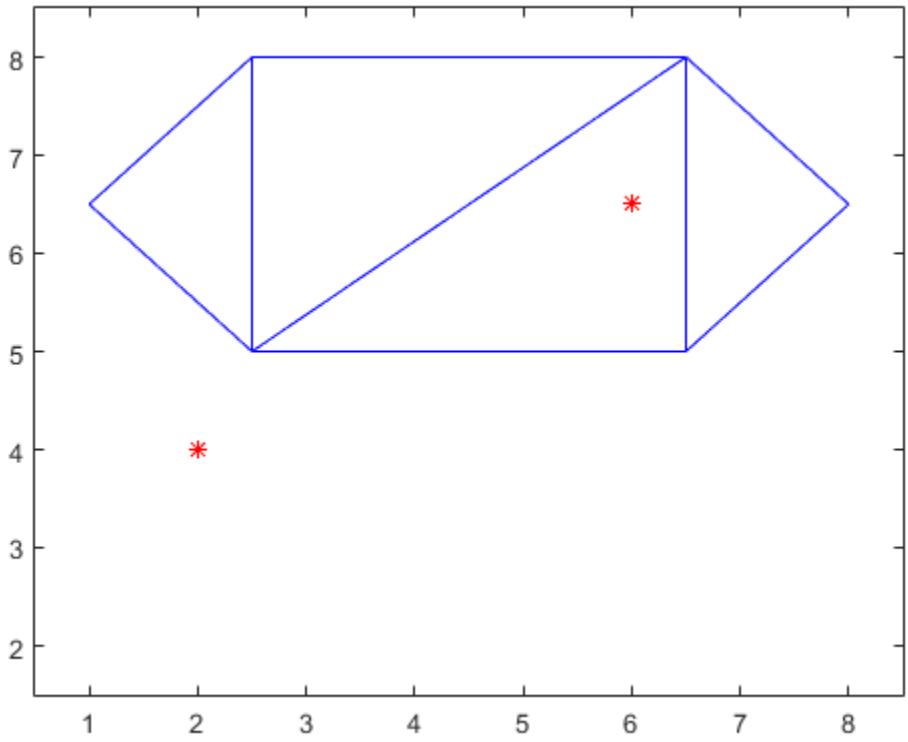
```
P = [2.5 8.0; 6.5 8.0; 2.5 5.0; 6.5 5.0; 1.0 6.5; 8.0 6.5];
T = [5 3 1; 3 2 1; 3 4 2; 4 6 2];
TR = triangulation(T,P);
```

Define two query points.

```
QP = [2 4; 6 6.5];
```

Plot the triangulation and the query points.

```
triplot(TR)
hold on
plot(QP(:,1),QP(:,2),'r*')
ylim([1.5 8.5])
xlim([0.5 8.5])
```

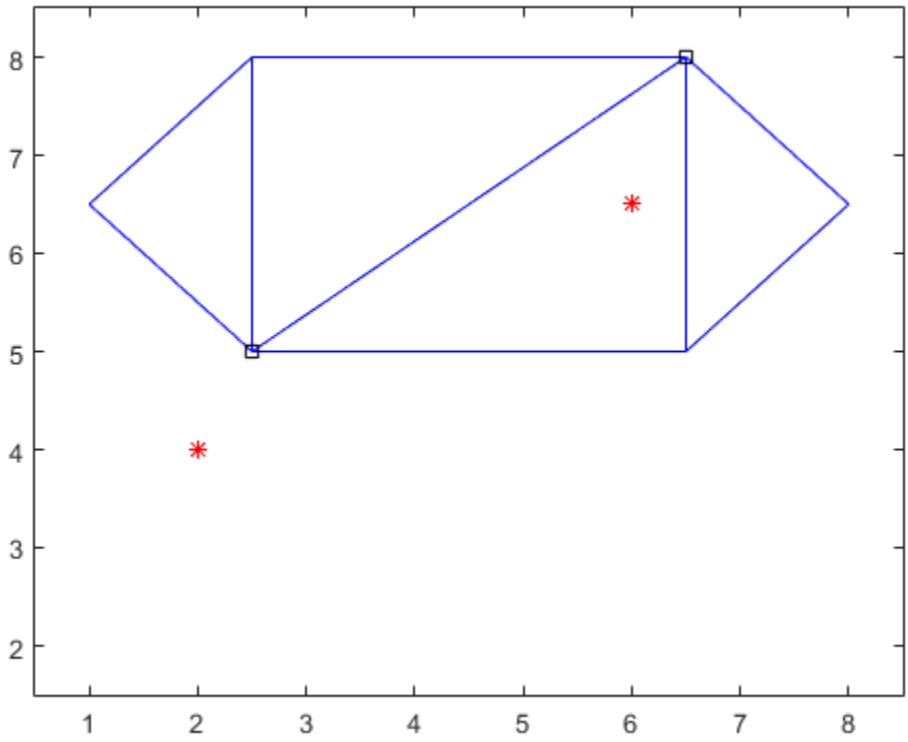


Find the nearest neighbors to the query points, as well as the distances between them.

```
[vi,d] = nearestNeighbor(TR,QP);
```

Highlight the points in the triangulation that are the nearest neighbors to the query points.

```
TP = P(vi,:);
plot(TP(:,1),TP(:,2),'ks')
```



Examine the distance between each query point and its nearest neighbor.

```
d
```

```
d =

    1.1180
    1.5811
```

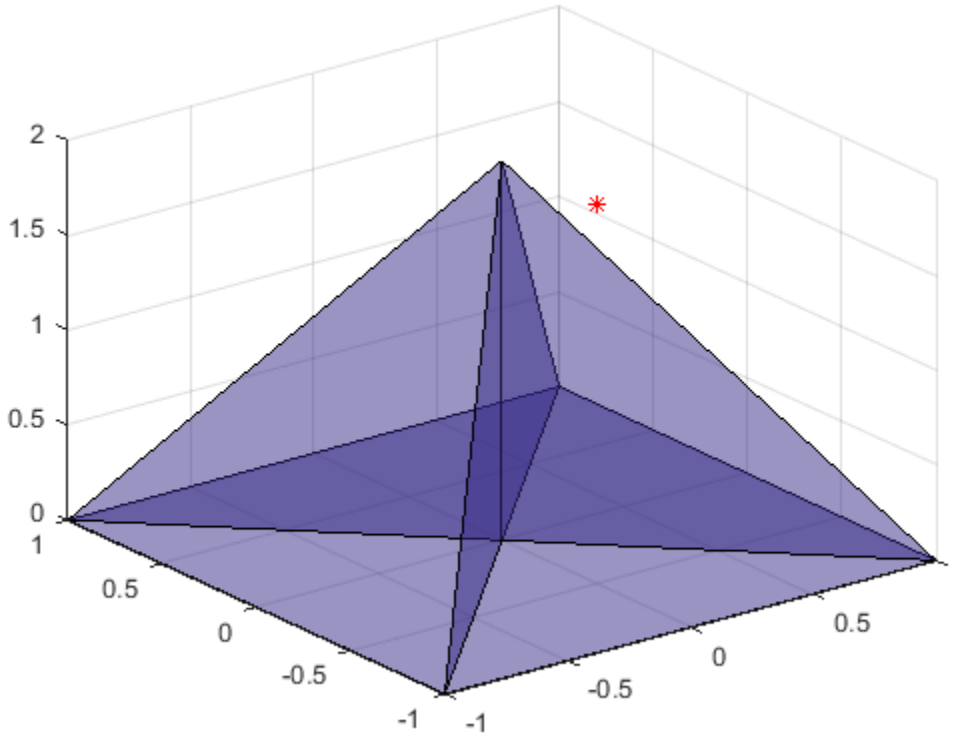
Locate Nearest Neighbors in 3-D Delaunay Triangulation

Create a 3-D Delaunay Triangulation.

```
P = [1 1 0; -1 1 0; -1 -1 0; 1 -1 0; 0 0 2; 0 0 0];
DT = delaunayTriangulation(P);
```

Plot the triangulation and a query point.

```
tri = DT(:,:);
trisurf(tri,P(:,1),P(:,2),P(:,3),'FaceAlpha',0.5)
hold on
QP = [0 -0.5 2];
plot3(QP(1),QP(2),QP(3),'r*')
```



Find the coordinates for the nearest-neighbor of the query point.

```
nnVertexID = nearestNeighbor(DT,QP);
```

```
nnCoordinates = DT.Points(nnVertexID,:)

nnCoordinates =

     0     0     2
```

`delaunayTriangulation` | `triangulation`

More About

- "Spatial Searching"

neighbors

Class: triangulation

Neighbors to specified triangle or tetrahedron

Syntax

```
N = neighbors(TR,ti)
N = neighbors(TR)
```

Description

`N = neighbors(TR,ti)` returns the neighbors of the triangles or tetrahedra specified in `ti`.

`N = neighbors(TR)` returns the neighbors of all the triangles or tetrahedra.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`ti`

Triangle or tetrahedron IDs, specified as a column vector.

Output Arguments

`TN`

IDs of the neighboring triangles or tetrahedra, returned as a matrix. The elements in `TN(i,:)` are the neighbors associated with `ti(i)`.

By convention, `TN(i,j)` is the neighbor opposite the `j`th vertex of `ti(i)`. If a triangle or tetrahedron has one or more boundary facets, the nonexistent neighbors are represented as `NaN` values in `TN`.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Query Neighbors in 2-D Delaunay Triangulation

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);
y = gallery('uniformdata',[10,1],1);
DT = delaunayTriangulation(x,y);
```

Find the neighbors of the first triangle.

```
TN = neighbors(DT,1)
```

```
TN =

   NaN     4     5
```

The first triangle has a boundary edge and two neighbors.

Examine the vertex IDs of the first neighbor, `TN(2)`.

```
DT.ConnectivityList(TN(2),:)
```

```
ans =

     2     4     7
```

Query Neighbors in 3-D Triangulation

Create the Delaunay triangulation.

```
load tetmesh
TR = triangulation(tet,X);
```

Find the neighbors to each triangle in the triangulation.

```
TN = neighbors(TR);
```

Find the neighbors of the fifth tetrahedron.

```
TN(5,:)
```

```
ans =

        2360        1539           2        1851
```

Examine the vertex IDs of the first neighbor, `TN(1)`.

```
TR.ConnectivityList(TN(1),:)
```

```
ans =

        1093         891         893         858
```

See Also

`delaunayTriangulation` | `edgeAttachments`

pointLocation

Class: triangulation

Triangle or tetrahedron containing specified point

Syntax

```
ti = pointLocation(T,QP)
ti = pointLocation(T,qx,qy)
ti = pointLocation(T,qx,qy,qz)
[ti,B] = pointLocation( ___ )
```

Description

`ti = pointLocation(T,QP)` returns the enclosing triangles or tetrahedra for each query point in `QP`. Each row in matrix `QP` contains the `x`, `y`, (and possibly `z`) coordinates of a query point.

`ti = pointLocation(T,qx,qy)` specifies the `x` and `y` coordinates of the query points in 2-D as separate column vectors.

`ti = pointLocation(T,qx,qy,qz)` specifies the `x`, `y`, and `z` coordinates of the query points in 3-D as separate column vectors.

`[ti,B] = pointLocation( ___ )` also returns the barycentric coordinates of each query point with respect to its enclosing triangle or tetrahedron. You can specify both output arguments with any of the previous syntaxes.

Input Arguments

`T` — Triangulation representation

`triangulation` object | `delaunayTriangulation` object

Triangulation representation, specified as a `triangulation` object or `delaunayTriangulation` object. For more information, see `triangulation` or `delaunayTriangulation`.

QP — Query points

matrix with 2 columns (2-D) | matrix with 3 columns (3-D)

Query points, specified as a matrix with 2 or 3 columns. `QP` contains the `x`, `y`, (and possibly `z`) coordinates of the query points.

qx — Query point x-coordinates

column vector

Query point x-coordinates, specified as a column vector.

qy — Query point y-coordinates

column vector

Query point y-coordinates, specified as a column vector.

qz — Query point z-coordinates

column vector

Query point z-coordinates, specified as a column vector.

Output Arguments

ti — IDs of enclosing triangles or tetrahedra

column vector

IDs of the enclosing triangles or tetrahedra, returned as a column vector. The values in `ti` correspond to the row numbers of the triangulation connectivity matrix `T.ConnectivityList`. For a query point `QP(k,:)`, the triangle or tetrahedron enclosing the point is `ti(k)`.

`ti` contains `NaN` values for points that are not located in a triangle or tetrahedron of the triangulation, `T`.

B — Barycentric coordinates

matrix

Barycentric coordinates, returned as a matrix. The values at `B(j,:)` are the barycentric coordinates of the `j`th query point `QP(j,:)` with respect to `ti(j)`.

Examples

Find Enclosing Triangles of Query Points

Define the points and connectivity of the triangulation.

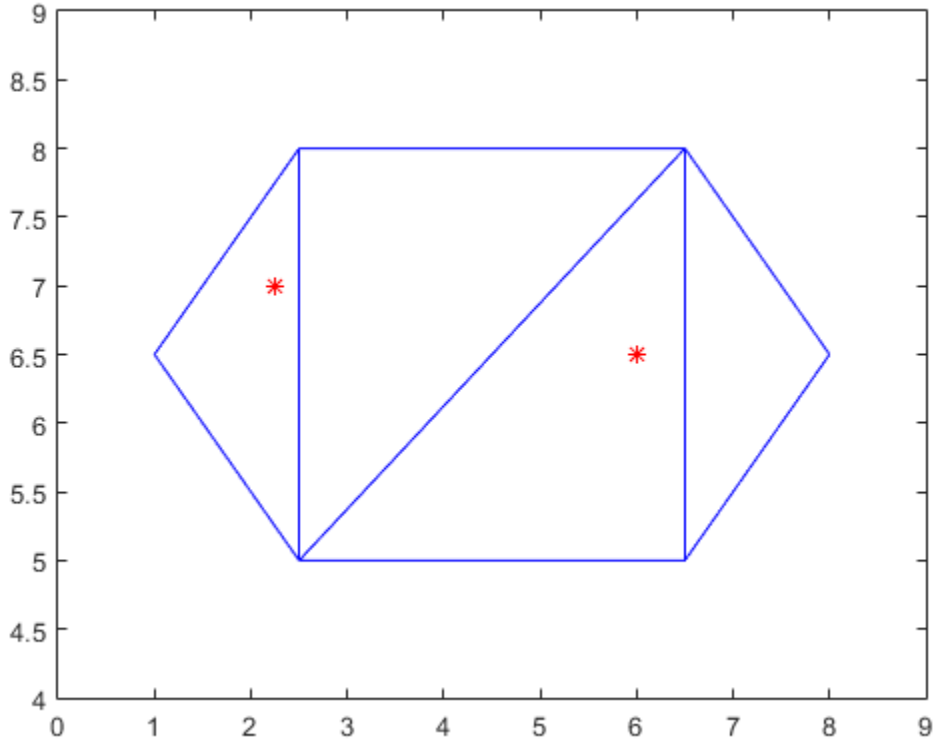
```
P = [2.5 8.0; 6.5 8.0; 2.5 5.0; 6.5 5.0; 1.0 6.5; 8.0 6.5];
T = [5 3 1; 3 2 1; 3 4 2; 4 6 2];
TR = triangulation(T,P);
```

Define two query points.

```
QP = [2.25 7; 6 6.5];
```

Plot the triangulation and the query points.

```
triplot(TR)
hold on
plot(QP(:,1),QP(:,2),'r*')
ylim([4 9])
xlim([0 9])
```



Determine which triangles in the triangulation enclose each query point.

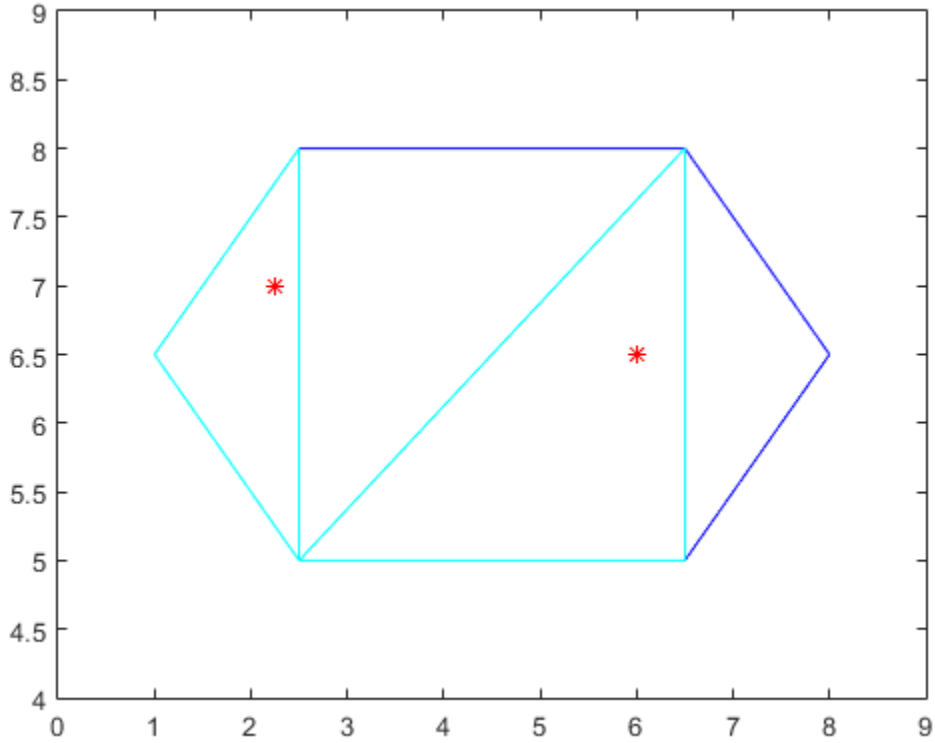
```
ti = pointLocation(TR,QP)
```

```
ti =

     1
     3
```

Highlight the triangles that enclose each of the query points.

```
triplot(TR.ConnectivityList(ti,:),P(:,1),P(:,2),'c')
```



Find Enclosing Tetrahedra and Barycentric Coordinates in 3-D

Create a 3-D Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20 1],0);
y = gallery('uniformdata',[20 1],1);
z = gallery('uniformdata',[20 1],2);
DT = delaunayTriangulation(x,y,z);
```

Find the tetrahedra that enclose the query points and calculate the barycentric coordinates of the query points.

```
QP = [0.7 0.6 0.3; 0.5 0.5 0.5];
[ti,B] = pointLocation(DT,QP)
```

```
ti =

    57
    56

B =

    0.2796    0.0184    0.5286    0.1734
    0.3687    0.0149    0.5343    0.0821
```

See Also

`delaunayTriangulation` | `triangulation`

More About

- "Spatial Searching"

size

Class: triangulation

Size of triangulation connectivity list

Syntax

```
sz = size(TR)
```

Description

`sz = size(TR)` returns the size the triangulation connectivity list.

Input Arguments

TR

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

Output Arguments

sz

Size of connectivity list, returned as a two-element row vector. The first element, `sz(1)` is the number of triangles or tetrahedra in the triangulation, and `sz(2)` is the number of vertices per triangle or tetrahedron.

Examples

Size of 2-D Triangulation

Create a triangulation.

```
P = [ 2.5    8.0
      6.5    8.0
      2.5    5.0
      6.5    5.0
      1.0    6.5
      8.0    6.5];

T = [5  3  1;
     3  2  1;
     3  4  2;
     4  6  2];

TR = triangulation(T,P);
```

Get the size of the connectivity list.

```
size(TR)
```

```
ans =

     4     3
```

The triangulation has 4 triangles, and each triangle has 3 vertices.

See Also

`delaunayTriangulation` | `size`

vertexAttachments

Class: triangulation

Triangles or tetrahedra attached to specified vertex

Syntax

```
ti = vertexAttachments(TR,vi)
ti = vertexAttachments(TR)
```

Description

`ti = vertexAttachments(TR,vi)` returns the triangles or tetrahedra attached to the specified vertices, `vi`.

`ti = vertexAttachments(TR)` returns the triangles or tetrahedra attached to every vertex in the triangulation.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`vi`

Query vertices, specified as a column vector of vertex IDs.

Output Arguments

`ti`

IDs of the triangles or tetrahedra attached to the vertices, returned as an `m`-by-`1` cell array. Each cell in `ti` contains the IDs of the attached triangles or tetrahedra. `ti{j}` contains the attachments to the vertex, `vi(j)`. The attachments are returned in a cell

array because the number of triangles or tetrahedra associated with each vertex can vary.

Definitions

Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Attachments to Specific Vertex in 2-D Delaunay Triangulation

Locate and plot the attachments to a specific vertex.

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to the fifth vertex.

```
ti = vertexAttachments(DT,5);
ti{:}
```

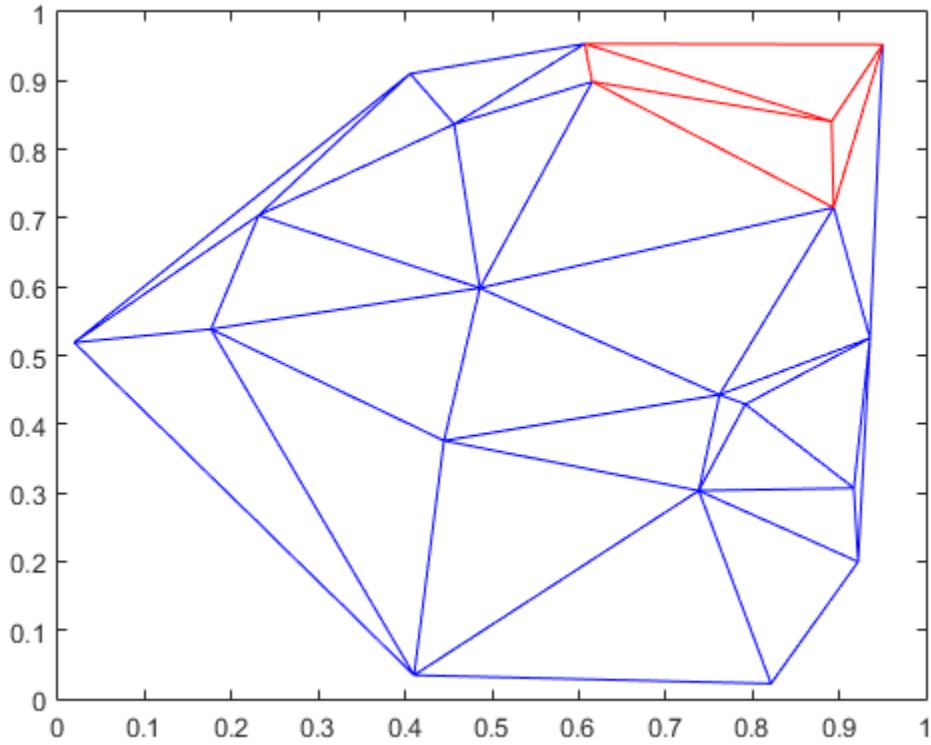
```
ans =

    18     23     21     22
```

Plot the triangulation. Plot the triangles attached to vertex 5 in red.

```
triplot(DT)
hold on

triplot(DT(ti{:},:),x,y,'Color','r')  % vertex 5 (in red)
hold off
```



See Also

delaunayTriangulation | edgeAttachments

vertexNormal

Class: triangulation

Triangulation vertex normal

Syntax

```
VN = vertexNormal(TR,vi)
VN = vertexNormal(TR)
```

Description

`VN = vertexNormal(TR,vi)` returns the unit normal vector to each of the specified vertices in `vi`.

`VN = vertexNormal(TR)` returns the normal information for all vertices in the triangulation.

Input Arguments

`TR`

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

`vi`

IDs of vertices to query, specified as a column vector. Each element in `vi` is a "Vertex ID" on page 1-6895.

Output Arguments

`VN`

Vertex normals, returned a matrix. Each row, `VN(j,:)`, is the unit normal vector at the vertex `vi(j)`. The vector at `VN(j,:)` is the average unit normal of the faces attached to vertex `vi(j)`.

If you do not specify `vi`, then `vertexNormal` returns the unit normal information for all vertices in the triangulation. In this case, the normal associated with `TR.Points(j,:)` is `VN(j,:)`.

Definitions

Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Unit Normal Vectors to the Surface of a Cube

Create a 3-D triangulation representing the volume of a cube.

```
[X,Y,Z] = meshgrid(1:4);
X = X(:);
Y = Y(:);
Z = Z(:);
dt = delaunayTriangulation(X,Y,Z);
```

Find the surfaces of the cube and isolate them in a 2-D triangulation.

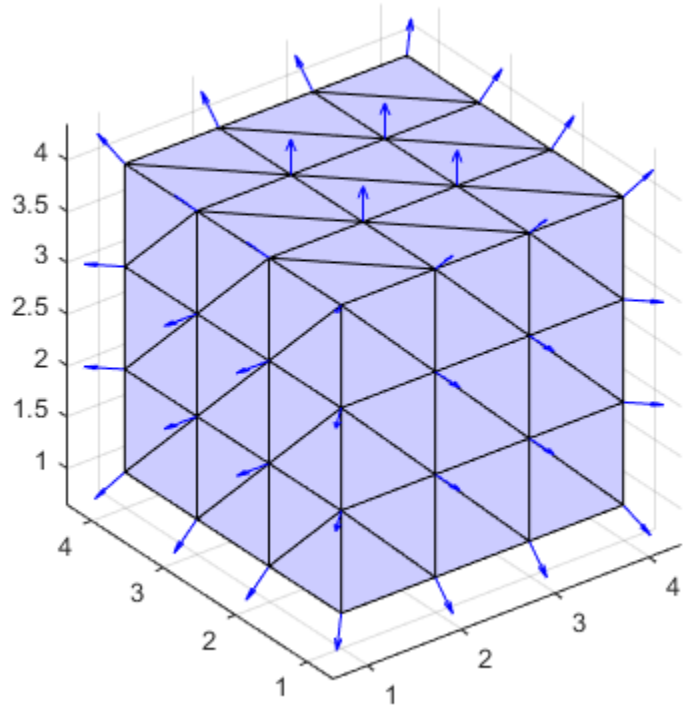
```
[Tfb,Xfb] = freeBoundary(dt);
TR = triangulation(Tfb,Xfb);
```

Find the unit normal vectors to the triangles on the surface of the cube.

```
vn = vertexNormal(TR);
```

Plot the results.

```
trisurf(TR,'FaceColor', [0.8 0.8 1.0]);
axis equal
hold on
quiver3(Xfb(:,1),Xfb(:,2),Xfb(:,3),...
     vn(:,1),vn(:,2),vn(:,3),0.5,'color','b');
hold off
```



See Also

`delaunayTriangulation` | `freeBoundary`

readtable

Create table from file

Syntax

```
T = readtable(filename)
T = readtable(filename,Name,Value)
```

Description

`T = readtable(filename)` creates a table by reading column oriented data from a file.

`readtable` determines the file format from the file name's extension:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, `.xlsx`, `.xltm`, `.xltx`, or `.ods` for spreadsheet files

`readtable` creates one variable in `T` for each column in the file and reads variable names from the first row of the file. By default, the variables created are `double` if the entire column is numeric, or cell arrays of strings if any element in a column is not numeric.

`T = readtable(filename,Name,Value)` creates a table from a file with additional options specified by one or more Name,Value pair arguments.

For example, you can specify not to read the first row of the file as variable names.

Examples

Create Table from Text File

Create a file, `myCsvTable.dat`, that contains the following comma-separated column oriented data.

```
LastName,Gender,Age,Height,Weight,Smoker
```

```
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file.

```
T = readtable('myCsvTable.dat')
```

```
T =

     LastName      Gender    Age    Height    Weight    Smoker
    ___________    ______    ___    ______    ______    ______

    'Smith'        'M'       38     71        176       1
    'Johnson'      'M'       43     69        163       0
    'Williams'     'F'       38     64        131       0
    'Jones'        'F'       40     67        133       0
    'Brown'        'F'       49     64        119       0
```

`T` contains one variable for each column in the file and `readtable` the entries in first line of the file as variable names.

Create Table from Text File without Column Headings

Create a file, `mySpaceDelimTable.txt`, that contains the following space delimited, column oriented data.

```
M 45 45 NY true
F 41 32 CA false
M 40 34 MA false
```

Create a table from the space delimited text file that does not contain variable names as column headings.

```
T = readtable('mySpaceDelimTable.txt',...
    'Delimiter',' ','ReadVariableNames',false)
```

```
T =

    Var1    Var2    Var3    Var4     Var5
    ____    ____    ____    ____    _______

    'M'     45      45      'NY'    'true'
```

```
    'F'      41      32      'CA'    'false'
    'M'      40      34      'MA'    'false'
```

`T` contains default variable names.

Create and Format Table from Text File

Create a file, `myCsvTable.dat`, that contains the following comma-separated column oriented data.

```
LastName,Gender,Age,Height,Weight,Smoker
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file. Format the first two variables as strings, the third variable as `uint32`, and the next two variables as double-precision, floating-point numbers. Format the last variable as a string.

```
T = readtable('myCsvTable.dat','Format','%s%s%u%f%f%s')
```

```
T =

     LastName      Gender    Age    Height    Weight    Smoker
    ___________    ______    ___    ______    ______    ______

    'Smith'        'M'       38     71        176       '1'
    'Johnson'      'M'       43     69        163       '0'
    'Williams'     'F'       38     64        131       '0'
    'Jones'        'F'       40     67        133       '0'
    'Brown'        'F'       49     64        119       '0'
```

The conversion specifiers are `%s` for a cell array of strings, `%f` for `double`, and `%u` for `uint32`.

Read Foreign-Language Dates from Text File

Create a sample file named `myfile.txt` that contains comma-separated values. The first column of values contains dates in German and the second and third columns are numeric values.

```
fileID = fopen('myfile.txt','w','n','ISO-8859-15');
```

```
fprintf(fileID,'1 Januar 2014, 20.2, 100.5 \n');
fprintf(fileID,'1 Februar 2014, 21.6, 102.7 \n');
fprintf(fileID,'1 März 2014, 20.7, 99.8 \n');
fclose(fileID);
```

The sample file looks like this:

```
1 Januar 2014, 20.2, 100.5
1 Februar 2014, 21.6, 102.7
1 März 2014, 20.7, 99.8
```

Read the sample file using `readtable`. The conversion specifiers are `%D` for a date and `%f` for floating-point values. Specify the file encoding using the `FileEncoding` name-value pair argument. Specify the format and locale of the dates using the `DateLocale` name-value pair argument.

```
T = readtable('myfile.txt','ReadVariableNames',false,...
    'Format','%{dd MMMM yyyy}D %f %f',...
    'FileEncoding','ISO-8859-15',...
    'DateLocale','de_DE')
```

```
T =

          Var1           Var2    Var3
    ________________     ____    _____

    01 January 2014      20.2    100.5
    01 February 2014     21.6    102.7
    01 March 2014        20.7     99.8
```

Create Table from Spreadsheet Including Row Names

Create a table from a spreadsheet that contains variable names in the first row and row names in the first column.

```
T = readtable('patients.xls','ReadRowNames',true);
```

Display the first five rows and first four variables of the table.

```
T(1:5,1:4)
```

```
ans =

                    Gender      Age             Location                Height
```

```
                ________    ___    ____________________________    ______

    Smith       'Male'      38     'County General Hospital'       71
    Johnson     'Male'      43     'VA Hospital'                   69
    Williams    'Female'    38     'St. Mary's Medical Center'     64
    Jones       'Female'    40     'VA Hospital'                   67
    Brown       'Female'    49     'County General Hospital'       64
```

View the `DimensionNames` property of the table.

```
T.Properties.DimensionNames
```

```
ans =

    'LastName'    'Variable'
```

`'LastName'` is the name in the first column of the first row of the spreadsheet.

Read Specific Range of Data from Spreadsheet

Create a table from the 5-by-3 rectangular region between the two corners `C2` and `E6` on the spreadsheet `patients.xls`. Do not use the first row of this region as variable names.

```
T = readtable('patients.xls',...
    'Range','C2:E6',...
    'ReadVariableNames',false)
```

```
T =

    Var1              Var2                    Var3
    ____    ____________________________    ____

    38      'County General Hospital'       71
    43      'VA Hospital'                   69
    38      'St. Mary's Medical Center'     64
    40      'VA Hospital'                   67
    49      'County General Hospital'       64
```

`T` contains default variable names.

- “Access Data in a Table”

Input Arguments

`filename` — Name of file to read

string

Name of the file to read, specified as a string. If `filename` includes the file extension, then `readtable` determines the file format from the extension. Otherwise, you must specify the `'FileType'` name-value pair arguments to indicate the type of file.

On Windows systems with Microsoft Excel software, `readtable` reads any Excel spreadsheet file format recognized by your version of Excel. If your system does not have Excel for Windows, `readtable` operates in `basic` import mode, and reads only XLS, XLSX, XLSM, XLTX, and XLTM files.

For a delimited text file, `readtable` converts empty fields in the file to either `NaN` (for a numeric variable) or the empty string (for a string-valued variable). All lines in the text file must have the same number of delimiters. `readtable` ignores insignificant white space in the file.

Example: `'myFile.xlsx'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'ReadVariableNames',false` indicates that the first row of the file does not correspond to variable names.

Delimited Text Files and Spreadsheet Files

`'FileType'` — Type of file

`'text'` | `'spreadsheet'`

Type of file, specified as the comma-separated pair consisting of `'FileType'` and the string `'text'` or `'spreadsheet'`.

You must specify the `'FileType'` name-value pair argument if the `filename` input argument does not include the file extension or if the extension is other than one of the following.

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, `.xlsx`, `.xltm`, `.xltx`, or `.ods` for spreadsheet files

Example: `'FileType','text'`

`'ReadVariableNames'` — Indicator for reading first row as variable names

`true` (default) | `false` | `1` | `0`

Indicator for reading the first row as variable names, specified as the comma-separated pair consisting of `'ReadVariableNames'` and either `true`, `false`, `1`, or `0`.

`true`	The first row of the region to read contains the variable names for the table. This is the default behavior. If both the `'ReadVariableNames'` and `'ReadRowNames'` logical indicators are `true`, then `readtable` saves the name in the first column of the first row of the region to read as the first dimension name in the property, `T.Properties.DimensionNames`.
`false`	The first row of the region to read contains the first row of data in the table. `readtable` creates default variable names of the form `'Var1',...,'VarN'`, where `N` is the number of variables.

`'ReadRowNames'` — Indicator for reading the first column as row names

`false` (default) | `true` | `0` | `1`

Indicator for reading first column as row names, specified as the comma-separated pair consisting of `'ReadRowNames'` and either `false`, `true`, `0`, or `1`.

`false`	The first column of the region to read contains the first variable in the table. It does not contain the row names for the table. This is the default behavior.
`true`	The first column of the region to read contains the row names for the table. If both the `'ReadVariableNames'` and `'ReadRowNames'` logical indicators are `true`, then `readtable` saves the name in the first column of the first row of the region to read as the first dimension name in the property, `T.Properties.DimensionNames`.

'TreatAsEmpty' — Strings to treat as empty value

string | cell array of strings

Strings to treat as empty value, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a string or a cell array of strings. Table elements corresponding to these are set to NaN.

'TreatAsEmpty' only applies to numeric columns in the file, and readtable does not accept numeric literals, such as '-99'.

Example: 'TreatAsEmpty','N/A' sets N/A within numeric columns to NaN.

Example: 'TreatAsEmpty',{'.','NA','N/A'} sets ., NA and N/A within numeric columns to NaN.

Delimited Text Files Only

When reading delimited text files, you can specify any of the name-value pair arguments listed here. Also, if you specify the 'Format' name-value pair argument, you can specify any of the name-value pair arguments accepted by the textscan function.

'Delimiter' — Field delimiter character

string

Field delimiter character, specified as the comma-separated pair consisting of 'Delimiter' and one of the following strings:

','	Comma. This is the default behavior.
'comma'	
' '	Space
'space'	
'\t'	Tab
'tab'	
';'	Semicolon
'semi'	
'|'	Vertical bar
'bar'	

Example: `'Delimiter','space'`

`'HeaderLines'` — Number of lines to skip at beginning of file

`0` (default) | positive integer

Number of lines to skip at beginning of file, specified as the comma-separated pair consisting of `'HeaderLines'` and a positive integer.

Data Types: `single` | `double`

`'Format'` — Format of columns in file

string of one or more conversion specifiers

Format of the columns in the file, specified as the comma-separated pair consisting of `'Format'` and a string of one or more conversion specifiers. The conversion specifiers are the same as those accepted by the `textscan` function.

Specifying the format can significantly improve speed for some large files. If you do not specify a value for `Format`, then `readtable` uses `%q` to interpret nonnumeric columns. The `%q` specifier reads a string and omits double quotation marks (") if appropriate.

By default, the variables created are either `double`, if the entire column is numeric, or cell arrays of strings, if any element in a column is not numeric.

`'FileEncoding'` — Character encoding scheme

`'UTF-8'` | `'ISO-8859-1'` | `'windows-1251'` | `'windows-1252'` | ...

Character encoding scheme associated with the file, specified as the comma-separated pair consisting of `'FileEncoding'` and one of the following strings.

`'Big5'`	`'ISO-8859-1'`	`'windows-932'`
`'GB2312'`	`'ISO-8859-2'`	`'windows-936'`
`'EUC-KR'`	`'ISO-8859-3'`	`'windows-949'`
`'EUC-JP'`	`'ISO-8859-4'`	`'windows-950'`
`'GBK'`	`'ISO-8859-9'`	`'windows-1250'`
`'KSC_5601'`	`'ISO-8859-13'`	`'windows-1251'`
`'Macintosh'`	`'ISO-8859-15'`	`'windows-1252'`
`'Shift_JIS'`		`'windows-1253'`
`'US-ASCII'`		`'windows-1254'`

`'UTF-8'` `'windows-1257'`

The default encoding is system-dependent.

Data Types: `char`

Spreadsheet Files Only

`'Sheet'` — Worksheet to read

1 (default) | positive integer indicating worksheet index | string containing worksheet name

Worksheet to read, specified as the comma-separated pair consisting of `'Sheet'` and a positive integer indicating the worksheet index or a string containing the worksheet name. The worksheet name string cannot contain a colon (`:`). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsfinfo(filename)`.

Example: `'Sheet',2`

`'Range'` — Rectangular portion of worksheet to read

string

Rectangular portion of the worksheet to read, specified as the comma-separated pair consisting of `'Range'` and a string.

Specify the range using the syntax `'Corner1:Corner2'`, where *`Corner1`* and *`Corner2`* are two opposing corners that define the region to read. For example, `'D2:H4'` represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `'Range'` name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help).

If the spreadsheet contains figures or other nontablular information, use the `'Range'` name-value pair argument to read only the tabular data. By default, `readtable` reads data from a spreadsheet contiguously out to the right-most column that contains data, including any empty columns that precede it.

Example: `'Range','D2:H4'`

`'Basic'` — Indicator for reading in `basic` mode

`true` | `false` | `1` | `0`

Indicator for reading in `basic` mode, specified as the comma-separated pair consisting of `'Basic'` and either `true`, `false`, `1`, or `0`.

`basic` mode is the default for systems without Excel for Windows. In `basic` mode, `readtable`:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support the `'Range'` name-value pair argument when reading XLS files.
- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

Output Arguments

`T` — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

`table` | `textscan` | `writetable`

Introduced in R2013b

real

Real part of complex number

Syntax

```
X = real(Z)
```

Description

`X = real(Z)` returns the real part of the elements of the complex array `Z`.

Examples

`real(2+3*i)` is 2.

See Also

`abs` | `angle` | `conj` | `i` | `j` | `imag`

Introduced before R2006a

reallog

Natural logarithm for nonnegative real arrays

Syntax

```
Y = reallog(X)
```

Description

`Y = reallog(X)` returns the natural logarithm of each element in array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

Examples

```
M = magic(4)

M =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

reallog(M)

ans =
    2.7726    0.6931    1.0986    2.5649
    1.6094    2.3979    2.3026    2.0794
    2.1972    1.9459    1.7918    2.4849
    1.3863    2.6391    2.7081         0
```

See Also

`log` | `realpow` | `realsqrt`

Introduced before R2006a

realmax

Largest positive floating-point number

Syntax

```
n = realmax
```

Description

`n = realmax` returns the largest finite floating-point number in IEEE double precision.

`realmax('double')` is the same as `realmax` with no arguments.

`realmax('single')` returns the largest finite floating-point number in IEEE single precision.

Examples

Find the value of the constant `realmax`:

```
ndouble = realmax
nsingle = realmax('single')
```

```
ndouble =

  1.7977e+308

nsingle =

  3.4028e+38
```

See Also

`eps` | `realmin` | `intmax`

Introduced before R2006a

realmin

Smallest positive normalized floating-point number

Syntax

```
n = realmin
realmin('double')
realmin('single')
```

Description

`n = realmin` returns the smallest positive normalized floating-point number in IEEE double precision.

`realmin('double')` is the same as `realmin` with no arguments.

`realmin('single')` returns the smallest positive normalized floating-point number in IEEE single precision.

Examples

Find the value of the constant `realmin`:

```
ndouble = realmin
nsingle = realmin('single')
```

```
ndouble =

  2.2251e-308

nsingle =

  1.1755e-38
```

`eps` | `realmax` | `intmin`

Introduced before R2006a

realpow

Array power for real-only output

Syntax

```
Z = realpow(X,Y)
```

Description

`Z = realpow(X,Y)` raises each element of array `X` to the power of its corresponding element in array `Y`. Arrays `X` and `Y` must be the same size. The range of `realpow` is the set of all real numbers, i.e., all elements of the output array `Z` must be real.

Examples

```
X = -2*ones(3,3)

X =
     -2     -2     -2
     -2     -2     -2
     -2     -2     -2

Y = pascal(3)

ans =
     1     1     1
     1     2     3
     1     3     6

realpow(X,Y)

ans =
    -2    -2    -2
    -2     4    -8
    -2    -8    64
```

realsqrt

Square root for nonnegative real arrays

Syntax

```
Y = realsqrt(X)
```

Description

`Y = realsqrt(X)` returns the square root of each element of array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

Examples

```
M = magic(4)

M =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

realsqrt(M)

ans =
    4.0000    1.4142    1.7321    3.6056
    2.2361    3.3166    3.1623    2.8284
    3.0000    2.6458    2.4495    3.4641

`reallog` | `sqrt` | `sqrtm` | `realpow`

Introduced before R2006a

record

Record data and event information to file

Syntax

```
record(obj)
record(obj,'switch')
```

Description

`record(obj)` toggles the recording state for the serial port object, `obj`.

`record(obj,'switch')` initiates or terminates recording for `obj`. *`switch`* can be `on` or `off`. If *`switch`* is `on`, recording is initiated. If *`switch`* is `off`, recording is terminated.

Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to the device, configures `s` to record information to a file, writes and reads text data, and then disconnects `s` from the device.

```
s = serial('COM1');
fopen(s)
s.RecordDetail = 'verbose';
s.RecordName = 'MySerialFile.txt';
record(s,'on')
fprintf(s,'*IDN?')
out = fscanf(s);
record(s,'off')
fclose(s)
```

More About

Tips

Before you can record information to disk, `obj` must be connected to the device with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An

error is returned if you attempt to record information while `obj` is not connected to the device. Each serial port object must record information to a separate file. Recording is automatically terminated when `obj` is disconnected from the device with `fclose`.

The `RecordName` and `RecordMode` properties are read-only while `obj` is recording, and must be configured before using `record`.

For a detailed description of the record file format and the properties associated with recording data and event information to a file, refer to Debugging: Recording Information to Disk.

Introduced before R2006a

record

Record audio to `audiorecorder` object

Syntax

```
record(recorderObj)
record(recorderObj, length)
```

Description

`record(recorderObj)` records audio from an input device, such as a microphone connected to your system. *`recorderObj`* is an `audiorecorder` object that defines the sample rate, bit depth, and other properties of the recording.

`record(recorderObj, length)` records for the number of seconds specified by *`length`*.

Examples

Record 5 seconds of your speech with a microphone:

```
myVoice = audiorecorder;

% Define callbacks to show when
% recording starts and completes.
myVoice.StartFcn = 'disp(''Start speaking.'')';
myVoice.StopFcn = 'disp(''End of recording.'')';

record(myVoice, 5);
```

To listen to the recording, call the `play` method:

```
play(myVoice);
```

See Also

`audiorecorder` | `getaudiodata` | `recordblocking`

How To

- “Record Audio”
- “Record or Play Audio within a Function”

recordblocking

Record audio to `audiorecorder` object, holding control until recording completes

Syntax

```
recordblocking(recorderObj, length)
```

Description

`recordblocking(recorderObj, length)` records audio from an input device, such as a microphone connected to your system, for the number of seconds specified by *`length`*. The `recordblocking` method does not return control until recording completes. *`recorderObj`* is an `audiorecorder` object that defines the sample rate, bit depth, and other properties of the recording.

Examples

Record 5 seconds of your speech with a microphone, and play it back:

```
myVoice = audiorecorder;

disp('Start speaking.');
recordblocking(myVoice, 5);
disp('End of recording. Playing back ...');

play(myVoice);
```

How To

- "Record Audio"

rectangle

Create 2-D rectangle object

Syntax

```
rectangle
rectangle('Position',[x,y,w,h])
rectangle('Curvature',[x,y])
rectangle('PropertyName',propertyvalue,...)
h = rectangle(...)
```

Properties

For a list of properties, see Rectangle Properties.

Description

`rectangle` draws a rectangle with `Position` `[0,0,1,1]` and `Curvature` `[0,0]` (i.e., no curvature).

`rectangle('Position',[x,y,w,h])` draws the rectangle from the point `x`,`y` and having a width of `w` and a height of `h`. Specify values in axes data units.

Note that, to display a rectangle in the specified proportions, you need to set the axes data aspect ratio so that one unit is of equal length along both the x and y axes. You can do this with the command `axis equal` or `daspect([1,1,1])`.

`rectangle('Curvature',[x,y])` specifies the curvature of the rectangle sides, enabling it to vary from a rectangle to an ellipse. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from `0` (no curvature) to `1` (maximum curvature). A value of `[0,0]` creates a rectangle with square sides. A value of `[1,1]` creates an ellipse.

If you specify only one value for `Curvature`, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

`rectangle('PropertyName',propertyvalue,...)` draws the rectangle using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Rectangle Properties.

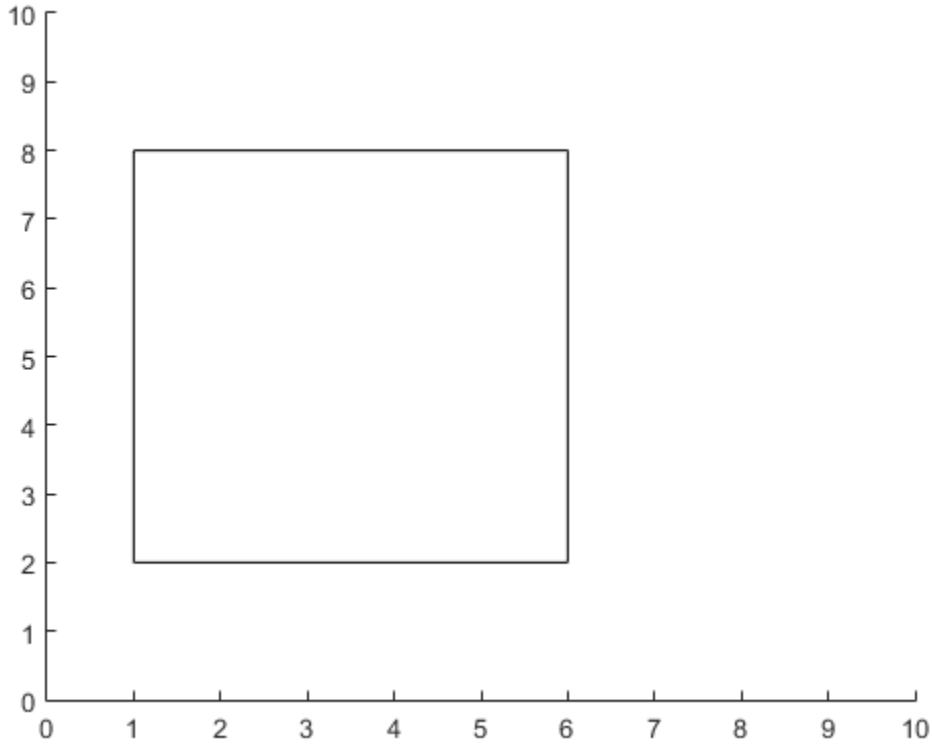
`h = rectangle(...)` returns the handle of the rectangle object created.

Examples

Draw Rectangle

Draw a rectangle that has a lower left corner at the point (1,2) and an upper right corner at (6,8). The width of the rectangle is 5 units and the height is 6 units. Additionally, change the axis limits.

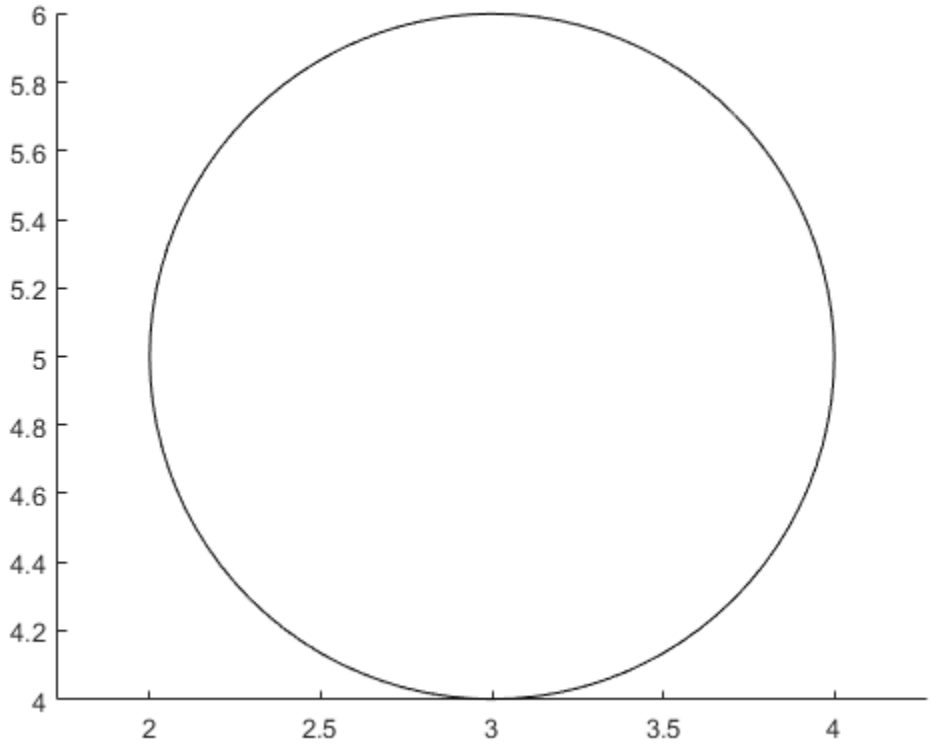
```
rectangle('Position',[1 2 5 6])
axis([0 10 0 10])
```



Draw Circle

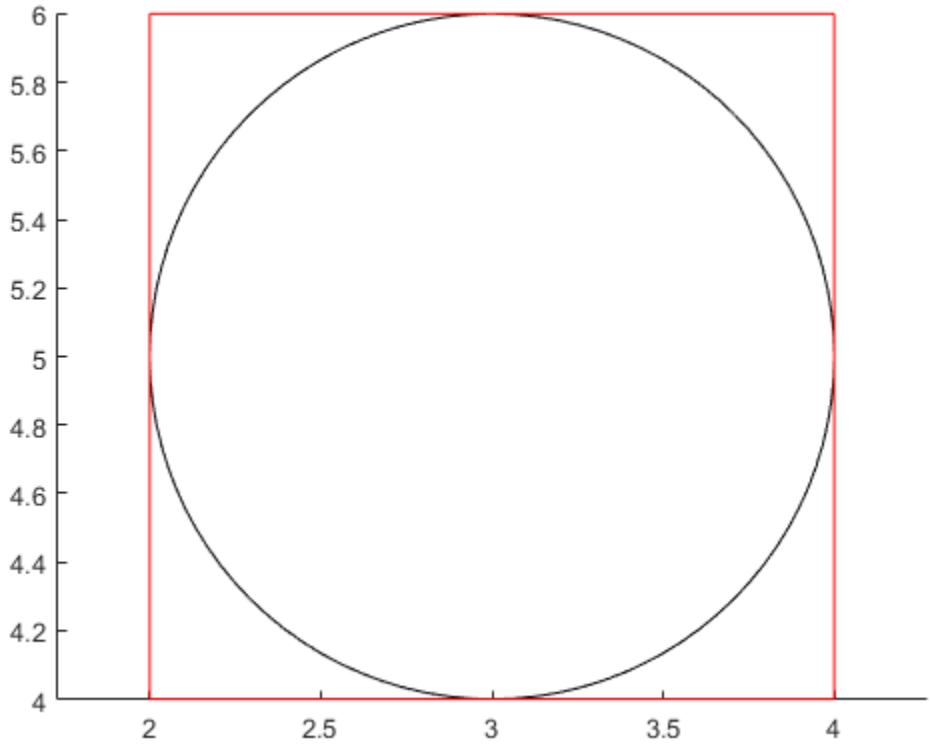
Draw a circle using the `rectangle` function and setting the `Curvature` property to `[1 1]`. Set the `Position` property to define the smallest rectangle that contains the circle. Draw the circle so that it fills the rectangular area between the points (2,4) and (4,6).

```
pos = [2 4 2 2];
rectangle('Position',pos,'Curvature',[1 1])
axis equal
```



Draw a red rectangle using the same position values to show how the circle fills the rectangular area.

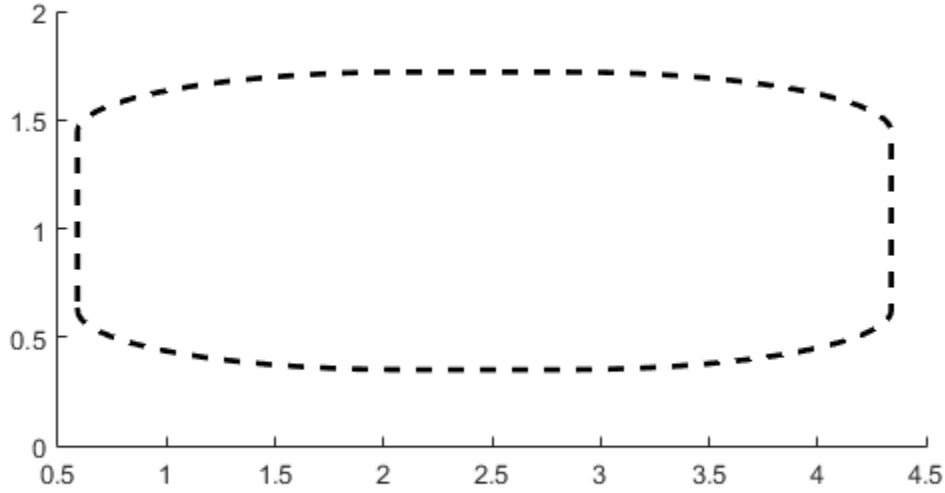
```
rectangle('Position',pos,'EdgeColor','r')
```



Rectangle with Different Curvatures

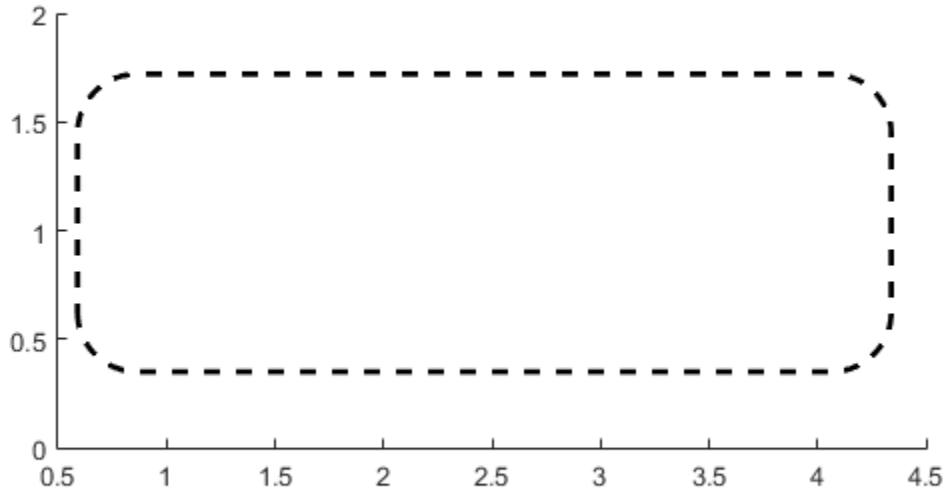
Create a rectangle with a curvature of `[0.8,0.4]`, which produces a rectangle with different horizontal and vertical curvatures. Set the data aspect ratio to `[1,1,1]` so that MATLAB® displays the rectangle in the specified proportions.

```
figure
rectangle('Position',[0.59,0.35,3.75,1.37],...
          'Curvature',[0.8,0.4],...
          'LineWidth',2,...
          'LineStyle','--')
daspect([1,1,1])
```



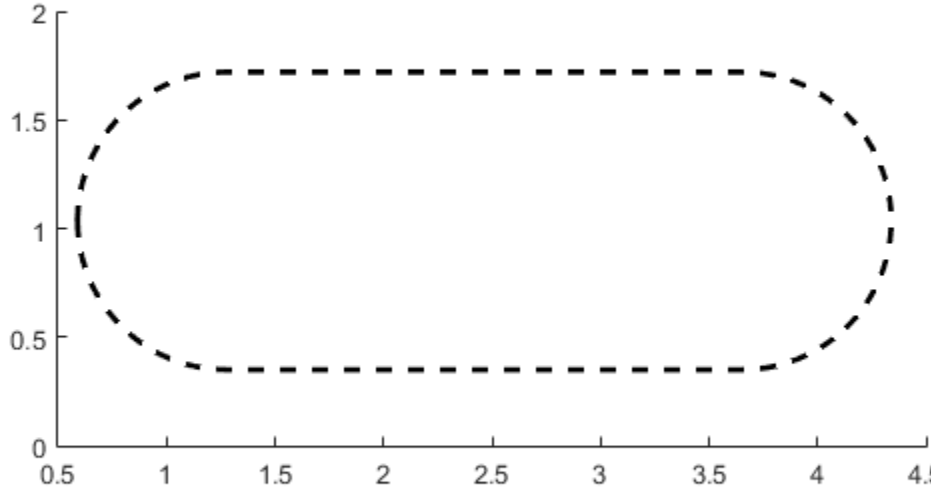
Create a rectangle with a curvature of `0.4`.

```
figure
rectangle('Position',[0.59,0.35,3.75,1.37],...
          'Curvature',0.4,...
          'LineWidth',2,...
          'LineStyle','--')
daspect([1,1,1])
```



Create a rectangle with a curvature of 1, which produces a rectangle with the shortest side completely round.

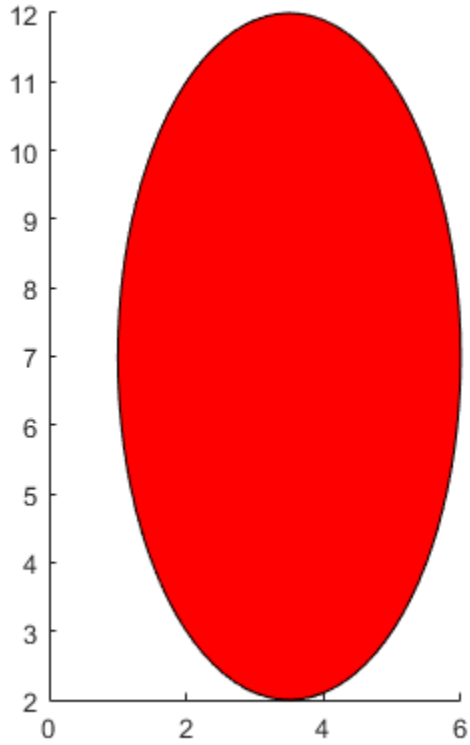
```
figure
rectangle('Position',[0.59,0.35,3.75,1.37],...
          'Curvature',1,...
          'LineWidth',2,...
          'LineStyle','--')
daspect([1,1,1])
```



Create Red Ellipse

Create an ellipse and color the face red.

```
figure
rectangle('Position',[1,2,5,10],...
    'Curvature',[1,1],...
    'FaceColor','r')
daspect([1,1,1])
```



More About

Tips

Rectangles are children of axes and are defined in coordinates of the axes data.

Functions

`annotation` | `line` | `patch`

Properties
Rectangle Properties

Introduced before R2006a

Rectangle Properties

Control rectangle appearance and behavior

Rectangle properties control the appearance and behavior of a rectangle object. By changing property values, you can modify certain aspects of the rectangle.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = rectangle;
w = h.LineWidth;
h.LineWidth = 3;
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Curvature` — Amount of horizontal and vertical curvature

`[0 0]` (default) | two-element vector | scalar

Amount of horizontal and vertical curvature, specified as a two element vector of the form `[x y]` or a scalar value. Use this property to vary the shape of the rectangle from rectangular to ellipsoidal. The horizontal curvature is the fraction of the width that is curved along the top and bottom edges. The vertical curvature is the fraction of the height that is curved along the left and right edges.

- To use different horizontal and vertical curvatures, specify a two-element vector of the form `[x y]`. The `x` element determines the horizontal curvature and the `y` element determines the vertical curvature. Specify `x` and `y` as values between 0 (no curvature) and 1 (maximum curvature). For example, a value of `[0 0]` creates a rectangle with square edges and value of `[1 1]` creates an ellipse.
- To use the same curvature for the horizontal and vertical edges, specify a scalar value in the range `[0,1]`. The shorter dimension determines the length of the curvature.

Example: `[0.5 0.6]`

Example: `0.75`

`EdgeColor` — Outline color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Outline color, specified as an RGB triplet, a color string, or `'none'`. The `'none'` option makes the edge invisible. The default RGB triplet value of `[0 0 0]` corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`FaceColor` — Fill color

`'none'` (default) | RGB triplet | color string

Fill color, specified as `'none'`, an RGB triplet, or a color string. The `'none'` option makes the fill invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	————
'--'	Dashed line	- - - - -
':'	Dotted line	.....
'-.'	Dash-dotted line	—·—·—·—
'none'	No line	No line

LineWidth — Line width

0.5 (default) | positive value

Line width, specified as a positive value in point units.

Example: 0.75

AlignVertexCenters — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to

plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Location and Size

`Position` — Size and location of rectangle

`[0 0 1 1]` (default) | four-element vector

Size and location of the rectangle, specified as a four-element vector of the form `[x y width height]`. Specify the values in data units. The `x` and `y` elements define the coordinate for the lower-left corner of the rectangle. The `width` and `height` elements define the dimensions of the rectangle.

Example: `[0.5 0.5 0.3 0.4]`

Visibility

`Visible` — Visibility of rectangle

`'on'` (default) | `'off'`

Visibility of rectangle, specified as one of these values:

- `'on'` — Display the rectangle.
- `'off'` — Hide the rectangle without deleting it. You still can access the properties of an invisible rectangle object.

`Clipping` — Clipping of rectangle to axes limits

`'on'` (default) | `'off'`

Clipping of rectangle to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the rectangle that are outside the axes limits.
- `'off'` — Display the entire rectangle, even if parts of it appear outside the axes limits. Parts of the rectangle might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the rectangle that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the

printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'rectangle'`

Type of graphics object, returned as `'rectangle'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — Tag to associate with rectangle

`''` (default) | string

Tag to associate with the rectangle, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with rectangle

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the rectangle object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent of rectangle

axes object | group object | transform object

Parent of rectangle, specified as an axes, group, or transform object.

`Children` — Children of rectangle

empty `GraphicsPlaceholder` array

The rectangle has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of rectangle object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The rectangle object handle is always visible.
- `'off'` — The rectangle object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The rectangle object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the rectangle at the command-line, but allows callback functions to access it.

If the rectangle object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the rectangle. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The rectangle object — You can access properties of the rectangle object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the rectangle. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the rectangle when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the rectangle.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the rectangle that has a defined color. You cannot click a part that has an associated color property set to `'none'`. The HitTest property determines if the rectangle responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'` and you can click a part of the rectangle that has no color. The HitTest property determines if the rectangle responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the rectangle passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the rectangle. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the rectangle that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the rectangle object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the rectangle is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the rectangle tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the rectangle. Setting the `CreateFcn` property on an existing rectangle has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during rectangle creation.

MATLAB executes the callback after creating the rectangle and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The rectangle object — You can access properties of the rectangle object from within the callback function. You also can access the rectangle object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the rectangle. MATLAB executes the callback before destroying the rectangle so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The rectangle object — You can access properties of the rectangle object from within the callback function. You also can access the rectangle object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of rectangle

`'off'` (default) | `'on'`

Deletion status of rectangle, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the rectangle begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the rectangle no longer exists.

Check the value of the BeingDeleted property to verify that the rectangle is not about to be deleted before querying or modifying it.

rectint

Rectangle intersection area

Syntax

```
area = rectint(A,B)
```

Description

`area = rectint(A,B)` returns the area of intersection of the rectangles specified by position vectors `A` and `B`.

If `A` and `B` each specify one rectangle, the output `area` is a scalar.

`A` and `B` can also be matrices, where each row is a position vector. `area` is then a matrix giving the intersection of all rectangles specified by `A` with all the rectangles specified by `B`. That is, if `A` is `n`-by-`4` and `B` is `m`-by-`4`, then `area` is an `n`-by-`m` matrix where `area(i,j)` is the intersection area of the rectangles specified by the `i`th row of `A` and the `j`th row of `B`.

Note A position vector is a four-element vector `[x,y,width,height]`, where the point defined by `x` and `y` specifies one corner of the rectangle, and `width` and `height` define the size in units along the x and y axes respectively.

`polyarea`

Introduced before R2006a

recycle

Set option to move deleted files to recycle folder

Syntax

```
status = recycle
oldState = recycle(state)
```

Description

`status = recycle` returns the current state for recycling files you remove using the `delete` function. When `status` is `off`, the `delete` function permanently removes the files. When `status` is `on`, deleted files move to a different location. For details, see the Tips section.

`oldState = recycle(state)` sets the recycle option for MATLAB to the specified state, either `on` or `off`. The `previousStat` value is the recycle state before running the statement.

Examples

View Current Recycling State

Start from a state where file recycling is off. Verify the current recycle state.

```
state = recycle
```

```
state =

off
```

Turn File Recycling On

Turn file recycling on. Then, delete an existing file and move it to the recycle bin or temporary folder.

```
recycle('on');
```

```
delete('myfile.txt')
```

Input Arguments

`state` — State of recycle option

`'on' | 'off'`

State of the recycle option, specified as `'on'` or `'off'`.

More About

Tips

- The location for storing recycled files varies by platform, as follows:
  - Microsoft Windows systems — Recycle bin.
  - Apple Macintosh systems — Trash.
  - Linux systems — Subfolder with the prefix `MATLAB_Files_` in the system temporary folder, as returned by the `tempdir` function.
- The general preference for **Deleting files** sets the state of the `recycle` function at startup. When you change the preference, it changes the state of `recycle`. However, when you change the state of `recycle`, it does not change the preference.
- "General Preferences"

`delete` | `dir` | `ls` | `rmdir`

Introduced before R2006a

reducepatch

Reduce number of patch faces

Syntax

```
reducepatch(p,r)
nfv = reducepatch(p,r)
nfv = reducepatch(fv,r)
nfv = reducepatch(p)
nfv = reducepatch(fv)
reducepatch(...,'fast')
reducepatch(...,'verbose')
nfv = reducepatch(f,v,r)
[nf,nv] = reducepatch(...)
```

Description

`reducepatch(p,r)` reduces the number of faces of the patch identified by handle `p`, while attempting to preserve the overall shape of the original object. The MATLAB software interprets the reduction factor `r` in one of two ways depending on its value:

- If `r` is less than 1, `r` is interpreted as a fraction of the original number of faces. For example, if you specify `r` as 0.2, then the number of faces is reduced to 20% of the number in the original patch.
- If `r` is greater than or equal to 1, then `r` is the target number of faces. For example, if you specify `r` as 400, then the number of faces is reduced until there are 400 faces remaining.

`nfv = reducepatch(p,r)` returns the reduced set of faces and vertices but does not set the `Faces` and `Vertices` properties of patch `p`. The struct `nfv` contains the faces and vertices after reduction.

`nfv = reducepatch(fv,r)` performs the reduction on the faces and vertices in the struct `fv`.

`nfv = reducepatch(p)` and `nfv = reducepatch(fv)` uses a reduction value of `0.5`.

`reducepatch(...,'fast')` assumes the vertices are unique and does not compute shared vertices.

`reducepatch(...,'verbose')` prints progress messages to the command window as the computation progresses.

`nfv = reducepatch(f,v,r)` performs the reduction on the faces in `f` and the vertices in `v`.

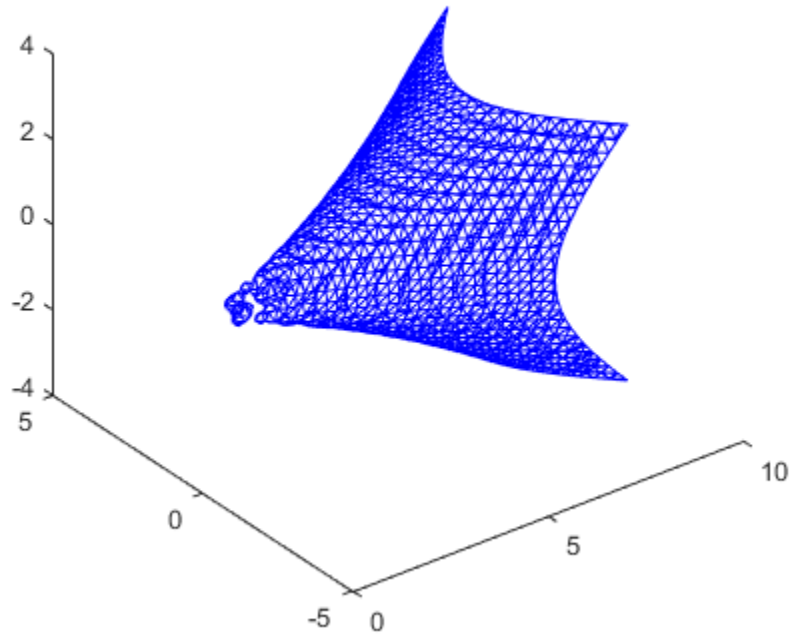
`[nf,nv] = reducepatch(...)` returns the faces and vertices in the arrays `nf` and `nv`.

Examples

Reduce Number of Patch Faces

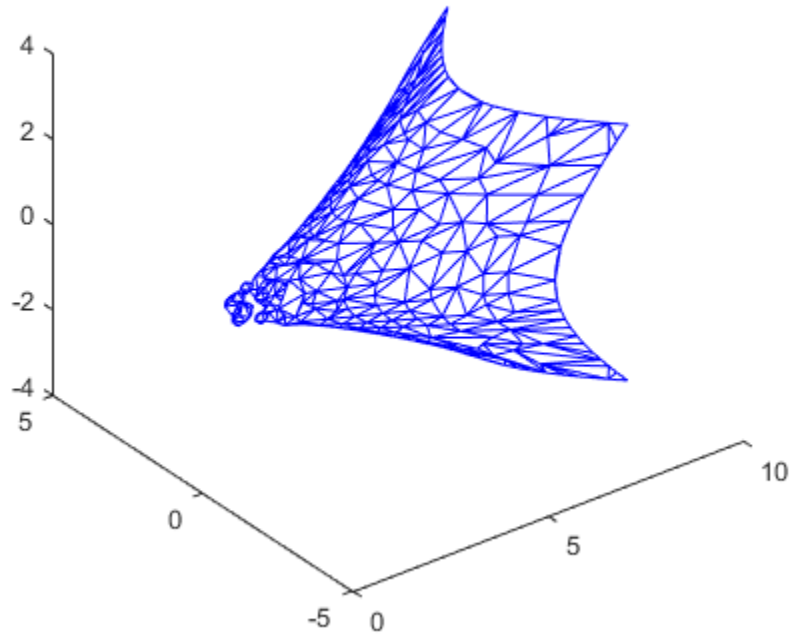
This example illustrates the effect of reducing the number of faces to only 15% of the original value.

```
figure
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
p.FaceColor = 'w';
p.EdgeColor = 'b';
daspect([1,1,1])
view(3)
```



Reduce the number of faces.

```
reducepatch(p,0.15)
```



More About

Tips

If the patch contains nonshared vertices, MATLAB computes shared vertices before reducing the number of faces. If the faces of the patch are not triangles, MATLAB triangulates the faces before reduction. The faces returned are always defined as triangles.

The number of output triangles may not be exactly the number specified with the reduction factor argument (`r`), particularly if the faces of the original patch are not triangles.

`isosurface` | `isocaps` | `isonormals` | `smooth3` | `subvolume` | `reducevolume`

Introduced before R2006a

reducevolume

Reduce number of elements in volume data set

Syntax

```
[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])
[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])
nv = reducevolume(...)
```

Description

`[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])` reduces the number of elements in the volume by retaining every Rx^{th} element in the *x* direction, every Ry^{th} element in the *y* direction, and every Rz^{th} element in the *z* direction. If a scalar `R` is used to indicate the amount or reduction instead of a three-element vector, the MATLAB software assumes the reduction to be `[R R R]`.

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The reduced volume is returned in `nv`, and the coordinates of the reduced volume are returned in `nx`, `ny`, and `nz`.

`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(V)`.

`nv = reducevolume(...)` returns only the reduced volume.

Examples

Reduce Volume Data Set

This example uses a data set that is a collection of MRI slices of a human skull. This data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then reduced (`reducevolume`) so that what remains is every fourth element in the x and y directions and every element in the z direction.

- The reduced data is smoothed (`smooth3`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with an interpolated face color draws the end caps (`FaceColor`) isocaps).
- The view of the object is set (`view`, `axis`, `daspect`).
- A 100-element grayscale colormap provides coloring for the end caps (`colormap`).
- Adding a light to the right of the camera illuminates the object (`camlight`, `lighting`).

```
load mri
D = squeeze(D);
[x,y,z,D] = reducevolume(D,[4,4,1]);
D = smooth3(D);
p1 = patch(isosurface(x,y,z,D,5),...
    'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1)
p2 = patch(isocaps(x,y,z,D,5),...
    'FaceColor','interp','EdgeColor','none');
view(3)
axis tight
daspect([1,1,.4])
colormap(gray(100))
camlight
lighting gouraud
```

Introduced before R2006a

refresh

Redraw current figure

Syntax

```
refresh
refresh(h)
```

Description

`refresh` erases and redraws the current figure.

`refresh(h)` redraws the figure identified by `h`.

Introduced before R2006a

refreshdata

Refresh data in graph when data source is specified

Syntax

```
refreshdata
refreshdata(figure_handle)
refreshdata(object_handles)
refreshdata(object_handles,'workspace')
```

Description

`refreshdata` evaluates any data source properties (`XDataSource`, `YDataSource`, or `ZDataSource`) on all objects in graphs in the current figure. If the specified data source has changed, the MATLAB software updates the graph to reflect this change.

Note: The variable assigned to the data source property must be in the base workspace or you must specify the *`workspace`* option as `'caller'`.

`refreshdata(figure_handle)` refreshes the data of the objects in the specified figure.

`refreshdata(object_handles)` refreshes the data of the objects specified in `object_handles` or the children of those objects. Therefore, `object_handles` can contain figure, axes, or plot object handles.

`refreshdata(object_handles,'workspace')` enables you to specify whether the data source properties are evaluated in the base workspace or the workspace of the function in which `refreshdata` was called. *`workspace`* is a string that can be

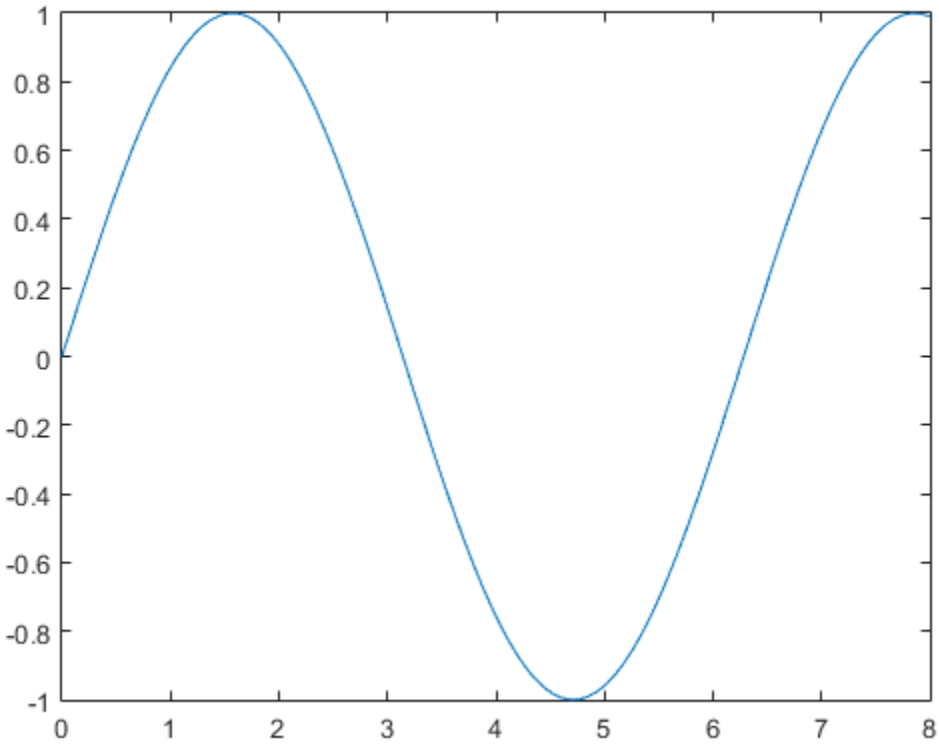
- `base` — Evaluate the data source properties in the base workspace.
- `caller` — Evaluate the data source properties in the workspace of the function that called refreshdata.

Examples

Refresh Graph with Updated Data

Plot a sine wave and return the chart line handle, `h`.

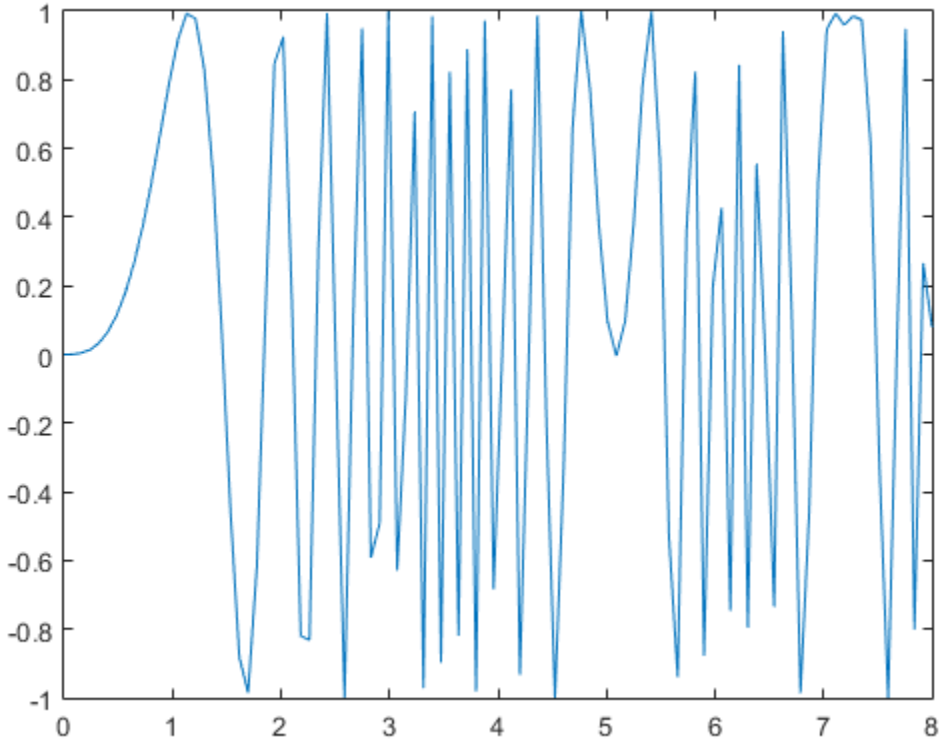
```
x = linspace(0,8);
y = sin(x);
figure
h = plot(x,y);
```



Identify the data sources for the plot by setting the `XDataSource` and `YDataSource` properties of the line to `x` and `y`, respectively. Then, modify `y`. Call `refreshdata` so that the graph updates with the changes to `y`.

```
h.XDataSource = 'x';
h.YDataSource = 'y';

y = sin(x.^3);
refreshdata
```



More About

Tips

The Linked Plots feature (see documentation for `linkdata`) sets up data sources for graphs and synchronizes them with the workspace variables they display. When you use

this feature, you do not also need to call `refreshdata`, as it is essentially automatically triggered every time a data source changes.

If you are not using the Linked Plots feature, you need to set the `XDataSource`, `YDataSource`, and/or `ZDataSource` properties of a graph in order to use `refreshdata`. You can do that programmatically, as shown in the examples below, or use the Property Editor, one of the plotting tools. In the Property Editor, select the graph (e.g., a lineseries object) and type in (or select from the drop-down choices) the name(s) of the workspace variable(s) from which you want the plot to refresh, in the fields labelled **X Data Source**, **Y Data Source**, and/or **Z Data Source**. The call to `refreshdata` causes the graph to update.

`linkprop` | `linkaxes`

Introduced before R2006a

regexp

Match regular expression (case sensitive)

Syntax

```
startIndex = regexp(str,expression)
[startIndex,endIndex] = regexp(str,expression)

out = regexp(str,expression,outkey)
[out1,...,outN] = regexp(str,expression,outkey1,...,outkeyN)

___ = regexp( ___ ,option1,...,optionM)
```

Description

`startIndex = regexp(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexp(str,expression)` returns the starting and ending indices of all matches.

`out = regexp(str,expression,outkey)` returns the output specified by outkey. For example, if `outkey` is `'match'`, then `regexp` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] = regexp(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match'`,`'tokens'`, then `regexp` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexp( ___ ,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'ignorecase'` to perform a case-insensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

Examples

Find Patterns in Single Strings

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car coat court CUT ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexp(str,expression)
```

```
startIndex =

     5    17
```

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.
- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression. The matching word `cat` starts at index 5, and `coat` starts at index 17. The words `CUT` and `CAT` do not match because they are uppercase.

Find Patterns in Multiple Strings

Find the location of capital letters and spaces within strings in a cell array.

```
str = {'Madrid, Spain','Romeo and Juliet','MATLAB is great'};
capExpr = '[A-Z]';
spaceExpr = '\s';

capStartIndex = regexp(str,capExpr);
spaceStartIndex = regexp(str,spaceExpr);
```

`capStartIndex` and `spaceStartIndex` are cell arrays because the input `str` is a cell array.

View the indices for the capital letters.

```
celldisp(capStartIndex)
```

```
capStartIndex{1} =

     1     9

capStartIndex{2} =

     1    11

capStartIndex{3} =

     1     2     3     4     5     6
```

View the indices for the spaces.

```
celldisp(spaceStartIndex)
```

```
spaceStartIndex{1} =

     8

spaceStartIndex{2} =

     6    10

spaceStartIndex{3} =

     7    10
```

Return Substrings Using match Keyword

Capture words within a string that contain the letter `x`.

```
str = 'EXTRA! The regexp function helps you relax.';
expression = '\w*x\w*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =

    'regexp'    'relax'
```

The regular expression `'\w*x\w*'` specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Contains the lowercase letter `x`.
- Ends with any number of alphanumeric or underscore characters after the `x`, including none, as indicated by `\w*`.

Split String at Delimiter Using split Keyword

Split a string into several substrings, where each substring is delimited by a `^` character.

```
str = ['Split ^this string into ^several pieces'];
expression = '\^';
splitStr = regexp(str,expression,'split')
```

```
splitStr =

    'Split '    'this string into '    'several pieces'
```

Because the caret symbol has special meaning in regular expressions, precede it with the escape character, a backslash (\). To split a string at other delimiters, such as a semicolon, you do not need to include the backslash.

Return Both Matching and Nonmatching Substrings

Capture parts of a string that match a regular expression using the `'match'` keyword, and the remaining parts that do not match using the `'split'` keyword.

```
str = 'She sells sea shells by the seashore.';
expression = '[Ss]h.';
[match,noMatch] = regexp(str,expression,'match','split')
```

```
match =

    'She'    'she'    'sho'

noMatch =

    ''    ' sells sea '    'lls by the sea'    're.'
```

The regular expression `'[Ss]h.'` specifies that:

- `S` or `s` is the first character.
- `h` is the second character.
- The third character can be anything, including a space, as indicated by the dot (`.`).

When the first (or last) character in a string matches a regular expression, the first (or last) return value from the `'split'` keyword is an empty string.

Optionally, reassemble the original string from the substrings.

```
combinedStr = strjoin(noMatch,match)
```

```
combinedStr =

She sells sea shells by the seashore.
```

Capture Substrings of Matches Using Ordinal Tokens

Find the names of HTML tags by defining a token within a regular expression. Tokens are indicated with parentheses, `()`.

```
str = '<title>My Title</title><p>Here is some text.</p>';
expression = '<(\w+).*>.*</\1>';
[tokens,matches] = regexp(str,expression,'tokens','match');
```

The regular expression `<(\w+).*>.*</\1>` specifies this pattern:

- `<(\w+)` finds an opening angle bracket followed by one or more alphanumeric or underscore characters. Enclosing `\w+` in parentheses captures the name of the HTML tag in a token.
- `.*>` finds any number of additional characters, such as HTML attributes, and a closing angle bracket.
- `</\1>` finds the end tag corresponding to the first token (indicated by `\1`). The end tag has the form `<\tagname>`.

View the tokens and matching substrings.

```
celldisp(tokens)
```

```
tokens{1}{1} =
   title

tokens{2}{1} =
   p
```

```
celldisp(matches)
```

```
matches{1} =
   <title>My Title</title>

matches{2} =
   <p>Here is some text.</p>
```

Capture Substrings of Matches Using Named Tokens

Parse dates that can appear with either the day or the month first, in these forms: `mm/dd/yyyy` or `dd-mm-yyyy`. Use named tokens to identify each part of the date.

```
str = '01/11/2000  20-02-2020  03/30/2000  16-04-2020';
```

```
expression = ['(?<month>\d+)/(?<day>\d+)/(?<year>\d+)|'...
              '(?<day>\d+)-(?<month>\d+)-(?<year>\d+)'];
tokenNames = regexp(str,expression,'names');
```

The regular expression specifies this pattern:

- `(?<name>\d+)` finds one or more numeric digits and assigns the result to the token indicated by name.
- `|` is the logical `or` operator, which indicates that there are two possible patterns for dates. In the first pattern, slashes (`/`) separate the tokens. In the second pattern, hyphens (`-`) separate the tokens.

View the named tokens.

```
for k = 1:length(tokenNames)
   disp(tokenNames(k))
end
```

```
    month: '01'
      day: '11'
     year: '2000'

    month: '02'
      day: '20'
     year: '2020'

    month: '03'
      day: '30'
     year: '2000'

    month: '04'
      day: '16'
     year: '2020'
```

Perform Case-Insensitive Matches

Find both uppercase and lowercase instances of a word.

By default, `regexp` performs case-sensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexp(str,expression,'match')
```

```
matchStr =

    'lowercase'
```

The regular expression specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Ends with the literal text `case`.

The `regexpi` function uses the same syntax as `regexp`, but performs case-insensitive matching.

```
matchWithRegexpi = regexpi(str,expression,'match')
```

```
matchWithRegexpi =

    'UPPERCASE'    'lowercase'
```

Alternatively, disable case-sensitive matching for `regexp` using the `'ignorecase'` option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
```

```
matchWithIgnorecase =

    'UPPERCASE'    'lowercase'
```

For multiple expressions, disable case-sensitive matching for selected expressions using the `(?i)` search flag.

```
expression = {'(?-i)\w*case';...
              '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =

lowercase
```

```
matchStr{2}{1} =

UPPERCASE

matchStr{2}{2} =

lowercase
```

Parse Strings with Newline Characters

Create a string that contains a newline, `\n`, and parse the string using a regular expression.

```
str = sprintf('abc\n de');
expression = '.*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =

    [1x7 char]
```

By default, the dot (`.`) matches every character, including the newline, and returns a single match that is equivalent to the original string.

Exclude newline characters from the match using the `'dotexceptnewline'` option. This returns separate matches for each line of text.

```
matchStrNoNewline = regexp(str,expression,'match','dotexceptnewline')
```

```
matchStrNoNewline =

    'abc'    ' de'
```

Find the first or last character of each line using the `^` or `$` metacharacters and the `'lineanchors'` option.

```
expression = '.$';
lastInLine = regexp(str,expression,'match','lineanchors')
```

```
lastInLine =

    'c'    'e'
```

Input Arguments

`str` — Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If str and expression are both cell arrays, they must have the same dimensions.

Data Types: `char` | `cell`

`expression` — Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in str.

The following tables describe the elements of regular expressions.

Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
`.`	Any single character, including white space	`'..ain'` matches sequences of five consecutive characters that end with `'ain'`.
`[`$c_1c_2c_3$`]`	Any character contained within the brackets. The following characters are treated literally: `$ | . * + ?` and `-` when not used to indicate a range.	`'[rp.]ain'` matches `'rain'` or `'pain'` or ‘`.ain`’.

Metacharacter	Description	Example
`[^c1c2c3]`	Any character not contained within the brackets. The following characters are treated literally: `$ | . * + ?` and `-` when not used to indicate a range.	`'[^*rp]ain'` matches all four-letter sequences that end in `'ain'`, except `'rain'` and `'pain'` and `'*ain'`. For example, it matches `'gain'`, `'lain'`, or `'vain'`.
`[c1-c2]`	Any character in the range of `c1` through `c2`	`'[A-G]'` matches a single character in the range of `A` through `G`.
`\w`	Any alphabetic, numeric, or underscore character. For English character sets, `\w` is equivalent to `[a-zA-Z_0-9]`	`'\w*'` identifies a word.
`\W`	Any character that is not alphabetic, numeric, or underscore. For English character sets, `\W` is equivalent to `[^a-zA-Z_0-9]`	`'\W*'` identifies a substring that is not a word.
`\s`	Any white-space character; equivalent to `[ \f\n\r\t\v]`	`'\w*n\s'` matches words that end with the letter `n`, followed by a white-space character.
`\S`	Any non-white-space character; equivalent to `[^ \f\n\r\t\v]`	`'\d\S'` matches a numeric digit followed by any non-white-space character.
`\d`	Any numeric digit; equivalent to `[0-9]`	`'\d*'` matches any number of consecutive digits.
`\D`	Any nondigit character; equivalent to `[^0-9]`	`'\w*\D\>'` matches words that do not end with a numeric digit.
`\oN` or `\o{N}`	Character of octal value `N`	`'\o{40}'` matches the space character, defined by octal `40`.
`\xN` or `\x{N}`	Character of hexadecimal value `N`	`'\x2C'` matches the comma character, defined by hex `2C`.

Character Representation

Operator	Description
`\a`	Alarm (beep)
`\b`	Backspace

Operator	Description
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab
`\char`	Any character with special meaning in regular expressions that you want to match literally (for example, use `\\` to match a single backslash)

Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
`expr*`	0 or more times consecutively.	`'\w*'` matches a word of any length.
`expr?`	0 times or 1 time.	`'\w*(\.m)?'` matches words that optionally end with the extension `.m`.
`expr+`	1 or more times consecutively.	`'<img src="\w+\.gif">'` matches an `<img>` HTML tag when the file name contains one or more characters.
`expr{m,n}`	At least `m` times, but no more than `n` times consecutively. `{0,1}` is equivalent to `?`.	`'\S{4,8}'` matches between four and eight non-white-space characters.
`expr{m,}`	At least `m` times consecutively. `{0,}` and `{1,}` are equivalent to `*` and `+`, respectively.	`'<a href="\w{1,}\.html">'` matches an `<a>` HTML tag when the file name contains one or more characters.
`expr{n}`	Exactly `n` times consecutively. Equivalent to `{n,n}`.	`'\d{4}'` matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
expr*q*	Greedy expression: match as many characters as possible.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*>'` matches all characters between `<tr` and `/td>`: `'<tr><td><p>text</p></td>'`
expr*q*?	Lazy expression: match as few characters as necessary.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*?>'` ends each match at the first occurrence of the closing bracket (`>`): `'<tr>'  '<td>'  '</td>'`
expr*q*+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*+>'` does not return any matches, because the closing bracket is captured using `.*`, and is not rescanned.

Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
`(expr)`	Group elements of the expression and capture tokens.	`'Joh?n\s(\w*)'` captures a token that contains the last name of any person with the first name `John` or `Jon`.
`(?:expr)`	Group, but do not capture tokens.	`'(?:[aeiou][^aeiou]){2}'` matches two consecutive patterns of a vowel followed by a nonvowel, such as `'anon'`. Without grouping, `'[aeiou][^aeiou]{2}'` matches a vowel followed by two nonvowels.
`(?>expr)`	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	`'A(?>.*)Z'` does not match `'AtoZ'`, although `'A(?:.*)Z'` does. Using the

Grouping Operator	Description	Example
		atomic group, `Z` is captured using `.*` and is not rescanned.
`(expr1|expr2)`	Match expression `expr1` or expression `expr2`. If there is a match with `expr1`, then `expr2` is ignored. You can include `?:` or `?>` after the opening parenthesis to suppress tokens or group atomically.	`'(let|tel)\w+'` matches words in a string that start with `let` or `tel`.

Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
`^expr`	Beginning of the input string.	`'^M\w*'` matches a word starting with `M` at the beginning of the string.
`expr$`	End of the input string.	`'\w*m$'` matches words ending with `m` at the end of the string.
`\<expr`	Beginning of a word.	`'\<n\w*'` matches any words starting with `n`.
`expr\>`	End of a word.	`'\w*e\>'` matches any words ending with `e`.

Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
`expr(?=test)`	Look ahead for characters that match `test`.	`'\w*(?=ing)'` matches strings that are followed by `ing`, such as `'Fly'` and `'fall'` in the input string `'Flying, not falling.'`
`expr(?!test)`	Look ahead for characters that do not match `test`.	`'i(?!ng)'` matches instances of the letter `i` that are not followed by `ng`.
`(?<=test)expr`	Look behind for characters that match `test`.	`'(?<=re)\w*'` matches strings that follow `'re'`, such as `'new'`, `'use'`, and `'cycle'` in the input string `'renew, reuse, recycle'`
`(?<!test)expr`	Look behind for characters that do not match `test`.	`'(?<!\d)(\d)(?!\d)'` matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical `AND`.

Operation	Description	Example
`(?=test)expr`	Match both `test` and `expr`.	`'(?=[a-z])[^aeiou]'` matches consonants.
`(?!test)expr`	Match `expr` and do not match `test`.	`'(?![aeiou])[a-z]'` matches consonants.

Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical `OR`, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
`expr1|expr2`	Match expression `expr1` or expression `expr2`.	`'(let|tel)\w+'` matches words in a string that start with `let` or `tel`.

Conditional Operator	Description	Example
	If there is a match with `expr1`, then `expr2` is ignored.	
`(?(cond)expr)`	If condition `cond` is `true`, then match `expr`.	`'(?(?@ispc)[A-Z]:\\)'` matches a drive name, such as `C:\`, when run on a Windows system.
`(?(cond)expr1|expr2)`	If condition `cond` is `true`, then match `expr1`. Otherwise, match `expr2`.	`'Mr(s?)\..*?(?(1)her|his)\w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
`(expr)`	Capture in a token the characters that match the enclosed expression.	`'Joh?n\s(\w*)'` captures a token that contains the last name of any person with the first name `John` or `Jon`.
`\N`	Match the `N`th token.	`'<(\w+).*>.*</\1>'` captures tokens for HTML tags, such as `'title'` from the string `'<title>Some text</title>'`.
`(?(N)expr1|expr2)`	If the `N`th token is found, then match `expr1`. Otherwise, match `expr2`.	`'Mr(s?)\..*?(?(1)her|his)\w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Named Token Operator	Description	Example
`(?<name>expr)`	Capture in a named token the characters that match the enclosed expression.	`'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)'` creates named tokens for the month, day, and year in an

Named Token Operator	Description	Example
		input date string of the form `mm-dd-yy`.
`\k<name>`	Match the token referred to by `name`.	`'<(?<tag>\w+).*>.*</\k<tag>>'` captures tokens for HTML tags, such as `'title'` from the string `'<title>Some text</title>'`.
`(?(name)expr1|expr2)`	If the named token is found, then match `expr1`. Otherwise, match `expr2`.	`'Mr(?<sex>s?)\..*?(?(sex)her|his) \w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Note: If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern `'(and(y|rew))'`, MATLAB creates a token for `'andrew'` but not for `'y'` or `'rew'`.

Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
`(??expr)`	Parse `expr` and include the resulting string in the match expression. When parsed, `expr` must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of `expr`, and one for the complete match.	`'^(\d+)((??\\w{$1}))'` determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching `'5XXXXX'` captures tokens for `'5'` and `'XXXXX'`.

Operator	Description	Example
`(??@cmd)`	Execute the MATLAB command represented by `cmd`, and include the string returned by the command in the match expression.	`'(.{2,}).?(??@fliplr($1))'` finds palindromes that are at least four characters long, such as `'abba'`.
`(?@cmd)`	Execute the MATLAB command represented by `cmd`, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	`'\w*?(\w)(?@disp($1))\1\w*'` matches words that include double letters (such as `pp`), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
`$&` or `$0`	Portion of the input string that is currently a match
`$``	Portion of the input string that precedes the current match
`$'`	Portion of the input string that follows the current match (use `$''` to represent the string `$'`)
`$N`	`N`th token
`$<name>`	Named token
`${cmd}`	String returned when MATLAB executes the command, `cmd`

Comments

Characters	Description	Example
`(?#comment)`	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	`'(?# Initial digit)\<\d\w+'` includes a comment, and matches words that begin with a number.

Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
`(?-i)`	Match letter case (default for `regexp` and `regexprep`).

Flag	Description
`(?i)`	Do not match letter case (default for `regexpi`).
`(?s)`	Match dot (`.`) in the pattern string with any character (default).
`(?-s)`	Match dot in the pattern with any character that is not a newline character.
`(?-m)`	Match the `^` and `$` metacharacters at the beginning and end of a string (default).
`(?m)`	Match the `^` and `$` metacharacters at the beginning and end of a line.
`(?-x)`	Include space characters and comments when matching (default).
`(?x)`	Ignore space characters and comments when matching. Use `'\ '` and `'\#'` to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (`:`), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types: `char | cell`

`outkey` — Keyword that indicates which outputs to return

`'start' | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'`

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
`'start'`	Starting indices of all matches, startIndex
`'end'`	Ending indices of all matches, endIndex
`'tokenExtents'`	Starting and ending indices of all tokens
`'match'`	Text of each substring that matches the pattern in expression
`'tokens'`	Text of each captured token in str
`'names'`	Name and text of each named token

Output Keyword	Returns
`'split'`	Text of nonmatching substrings of str

Data Types: `char`

`option` — Search option

`'once'` | `'warnings'` | `'ignorecase'` | `'emptymatch'` | `'dotexceptnewline'` | `'lineanchors'` | ...

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
`'all'`	`'once'`	Match the expression as many times as possible (default), or only once.
`'nowarnings'`	`'warnings'`	Suppress warnings (default), or display them.
`'matchcase'`	`'ignorecase'`	Match letter case (default), or ignore case.
`'noemptymatch'`	`'emptymatch'`	Ignore zero length matches (default), or include them.
`'dotall'`	`'dotexceptnewline'`	Match dot with any character (default), or all except newline (`\n`).
`'stringanchors'`	`'lineanchors'`	Apply `^` and `$` metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
`'literalspacing'`	`'freespacing'`	Include space characters and comments when matching (default), or ignore them. With `freespacing`, use `'\ '` and `'\#'` to match space and # characters.

Data Types: `char`

Output Arguments

`startIndex` — Starting index of each match

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

`endIndex` — Ending index of each match

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

`out` — Information about matches

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for outkey, as follows.

Output Keyword	Output Description	Output Type and Dimensions
`'start'`	Starting indices of matches	For both `'start'` and `'end'`: • If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array). • If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.
`'end'`	Ending indices of matches	

Output Keyword	Output Description	Output Type and Dimensions
`'tokenExtents'`	Starting and ending indices of all tokens	By default, when returning all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array, where `n` is the number of matches. Each cell contains an `m`-by-2 numeric array of indices, where `m` is the number of tokens in the match. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array, where each inner cell contains an `m`-by-2 numeric array. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is either an `m`-by-2 numeric array or a cell array with the same dimensions as `str` and/or `expression`. If a token is expected at a particular index `N`, but is not found, then MATLAB returns extents for that token of `[N,N-1]`.

Output Keyword	Output Description	Output Type and Dimensions
`'match'`	Text of each substring that matches the pattern in expression	By default, when returning all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array of strings, where `n` is the number of matches. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array of strings. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is either a string or a cell array of strings with the same dimensions as `str` and `expression`.

Output Keyword	Output Description	Output Type and Dimensions
`'tokens'`	Text of each captured token in str	By default, when returning all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array, where `n` is the number of matches. Each cell contains a 1-by-`m` cell array of strings, where `m` is the number of tokens in the match. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array, where each inner cell contains a 1-by-`m` cell array of strings. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is a 1-by-`m` cell array of strings or a cell array that has the same dimensions as `str` and/or `expression`. If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, `''`.
`'names'`	Name and text of each named token	For all matches: • If str and expression are both strings, the output is a 1-by-`n` structure array, where `n` is the number of matches. The structure field names correspond to the token names. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` structure array. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

Output Keyword	Output Description	Output Type and Dimensions
`'split'`	Text of nonmatching substrings of str	For all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array of strings, where `n` is the number of nonmatching strings. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array of strings. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

More About

Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form `dd-mmm-yyyy`, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}
```

```
ans =
    '01'    'April'    '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')
```

```
mydate =
```

```
      day: '01'
    month: 'Apr'
     year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

Tips

- Use `strfind` to find an exact character match within a string. Use `regexp` to look for a pattern of characters.

Algorithms

MATLAB parses each input string from left to right, attempting to match the text in the string with the first element of the regular expression. During this process, MATLAB skips over any text that does not match.

When MATLAB finds the first match, it continues parsing the string to match the second piece of the expression, and so on.

- “Dynamic Regular Expressions”

See Also

`regexpi` | `regexprep` | `regexptranslate` | `strfind` | `strjoin` | `strrep` | `strsplit`

Introduced before R2006a

regexpi

Match regular expression (case insensitive)

Syntax

```
startIndex = regexpi(str,expression)
[startIndex,endIndex] = regexpi(str,expression)

out = regexpi(str,expression,outkey)
[out1,...,outN] = regexpi(str,expression,outkey1,...,outkeyN)

___ = regexpi( ___ ,option1,...,optionM)
```

Description

`startIndex = regexpi(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression, without regard to letter case. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexpi(str,expression)` returns the starting and ending indices of all matches.

`out = regexpi(str,expression,outkey)` returns the output specified by outkey. For example, if `outkey` is `'match'`, then `regexpi` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] = regexpi(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify `'match'`,`'tokens'`, then `regexpi` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexpi( ___ ,option1,...,optionM)` modifies the search using the specified option flags. For example, specify `'matchcase'` to perform a case-sensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

Examples

Pattern Matching

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car COAT court cut ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexpi(str,expression)
```

```
startIndex =
     5    17    28    35
```

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression.

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.
- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

Case-Sensitive Match

Match letter case in all or part of an expression.

By default, `regexpi` performs case-insensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexpi(str,expression,'match')
```

```
matchStr =
    'UPPERCASE'    'lowercase'
```

Use the `regexp` function with the same syntax as `regexpi` to perform case-sensitive matching.

```
matchWithRegexp = regexp(str,expression,'match')
```

```
matchWithRegexp =
    'lowercase'
```

To disable case-sensitive matching for `regexp`, use the `'ignorecase'` option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
```

```
matchWithIgnorecase =
    'UPPERCASE'    'lowercase'
```

For multiple expressions, enable and disable case-insensitive matching for selected expressions using the `(?i)` and `(?-i)` search flags.

```
expression = {'(?-i)\w*case';...
              '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =
   lowercase

matchStr{2}{1} =
   UPPERCASE

matchStr{2}{2} =
   lowercase
```

Input Arguments

`str` — Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If str and expression are both cell arrays, they must have the same dimensions.

Data Types: `char` | `cell`

`expression` — Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in str.

The following tables describe the elements of regular expressions.

Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
`.`	Any single character, including white space	`'..ain'` matches sequences of five consecutive characters that end with `'ain'`.
`[`$c_1c_2c_3$`]`	Any character contained within the brackets. The following characters are treated literally: `$ | . * + ?` and `-` when not used to indicate a range.	`'[rp.]ain'` matches `'rain'` or `'pain'` or ‘`.ain`’.
`[^`$c_1c_2c_3$`]`	Any character not contained within the brackets. The following characters are treated literally: `$ | . * + ?` and `-` when not used to indicate a range.	`'[^*rp]ain'` matches all four-letter sequences that end in `'ain'`, except `'rain'` and `'pain'` and ‘`*ain`’. For example, it matches `'gain'`, `'lain'`, or `'vain'`.
`[`c_1`-`c_2`]`	Any character in the range of c_1 through c_2	`'[A-G]'` matches a single character in the range of `A` through `G`.
`\w`	Any alphabetic, numeric, or underscore character. For English character sets, `\w` is equivalent to `[a-zA-Z_0-9]`	`'\w*'` identifies a word.
`\W`	Any character that is not alphabetic, numeric, or underscore. For English character sets, `\W` is equivalent to `[^a-zA-Z_0-9]`	`'\W*'` identifies a substring that is not a word.
`\s`	Any white-space character; equivalent to `[ \f\n\r\t\v]`	`'\w*n\s'` matches words that end with the letter `n`, followed by a white-space character.
`\S`	Any non-white-space character; equivalent to `[^ \f\n\r\t\v]`	`'\d\S'` matches a numeric digit followed by any non-white-space character.
`\d`	Any numeric digit; equivalent to `[0-9]`	`'\d*'` matches any number of consecutive digits.

Metacharacter	Description	Example
`\D`	Any nondigit character; equivalent to `[^0-9]`	`'\w*\D\>'` matches words that do not end with a numeric digit.
`\oN` or `\o{N}`	Character of octal value `N`	`'\o{40}'` matches the space character, defined by octal `40`.
`\xN` or `\x{N}`	Character of hexadecimal value `N`	`'\x2C'` matches the comma character, defined by hex `2C`.

Character Representation

Operator	Description
`\a`	Alarm (beep)
`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab
`\char`	Any character with special meaning in regular expressions that you want to match literally (for example, use `\\` to match a single backslash)

Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
`expr*`	0 or more times consecutively.	`'\w*'` matches a word of any length.
`expr?`	0 times or 1 time.	`'\w*(\.m)?'` matches words that optionally end with the extension `.m`.
`expr+`	1 or more times consecutively.	`'<img src="\w+\.gif">'` matches an `<img>` HTML tag when the file name contains one or more characters.

Quantifier	Matches the expression when it occurs...	Example
`expr{m,n}`	At least `m` times, but no more than `n` times consecutively. `{0,1}` is equivalent to `?`.	`'\S{4,8}'` matches between four and eight non-white-space characters.
`expr{m,}`	At least `m` times consecutively. `{0,}` and `{1,}` are equivalent to `*` and `+`, respectively.	`'<a href="\w{1,}\.html">'` matches an `<a>` HTML tag when the file name contains one or more characters.
`expr{n}`	Exactly `n` times consecutively. Equivalent to `{n,n}`.	`'\d{4}'` matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
`expr`*q*	Greedy expression: match as many characters as possible.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*>'` matches all characters between `<tr` and `/td>`: `'<tr><td><p>text</p></td>'`
`expr`*q*`?`	Lazy expression: match as few characters as necessary.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*?>'` ends each match at the first occurrence of the closing bracket (`>`): `'<tr>'  '<td>'  '</td>'`
`expr`*q*`+`	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*+>'` does not return any matches, because the closing bracket is captured using `.*`, and is not rescanned.

Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
`(expr)`	Group elements of the expression and capture tokens.	`'Joh?n\s(\w*)'` captures a token that contains the last name of any person with the first name `John` or `Jon`.
`(?:expr)`	Group, but do not capture tokens.	`'(?:[aeiou][^aeiou]){2}'` matches two consecutive patterns of a vowel followed by a nonvowel, such as `'anon'`. Without grouping, `'[aeiou][^aeiou]{2}'`matches a vowel followed by two nonvowels.
`(?>expr)`	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	`'A(?>.*)Z'` does not match `'AtoZ'`, although `'A(?:.*)Z'` does. Using the atomic group, `Z` is captured using `.*` and is not rescanned.
`(expr1|expr2)`	Match expression `expr1` or expression `expr2`. If there is a match with `expr1`, then `expr2` is ignored. You can include `?:` or `?>` after the opening parenthesis to suppress tokens or group atomically.	`'(let|tel)\w+'` matches words in a string that start with `let` or `tel`.

Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
`^expr`	Beginning of the input string.	`'^M\w*'` matches a word starting with `M` at the beginning of the string.
`expr$`	End of the input string.	`'\w*m$'` matches words ending with `m` at the end of the string.
`\<expr`	Beginning of a word.	`'\<n\w*'` matches any words starting with `n`.

Anchor	Matches the...	Example
`expr\>`	End of a word.	`'\w*e\>'` matches any words ending with `e`.

Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
`expr(?=test)`	Look ahead for characters that match `test`.	`'\w*(?=ing)'` matches strings that are followed by `ing`, such as `'Fly'` and `'fall'` in the input string `'Flying, not falling.'`
`expr(?!test)`	Look ahead for characters that do not match `test`.	`'i(?!ng)'` matches instances of the letter `i` that are not followed by `ng`.
`(?<=test)expr`	Look behind for characters that match `test`.	`'(?<=re)\w*'` matches strings that follow `'re'`, such as `'new'`, `'use'`, and `'cycle'` in the input string `'renew, reuse, recycle'`
`(?<!test)expr`	Look behind for characters that do not match `test`.	`'(?<!\d)(\d)(?!\d)'` matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical `AND`.

Operation	Description	Example
`(?=test)expr`	Match both `test` and `expr`.	`'(?=[a-z])[^aeiou]'` matches consonants.
`(?!test)expr`	Match `expr` and do not match `test`.	`'(?![aeiou])[a-z]'` matches consonants.

Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical `OR`, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
`expr1|expr2`	Match expression `expr1` or expression `expr2`. If there is a match with `expr1`, then `expr2` is ignored.	`'(let|tel)\w+'` matches words in a string that start with `let` or `tel`.
`(?(cond)expr)`	If condition `cond` is `true`, then match `expr`.	`'(?(?@ispc)[A-Z]:\\)'` matches a drive name, such as `C:\`, when run on a Windows system.
`(?(cond)expr1|expr2)`	If condition `cond` is `true`, then match `expr1`. Otherwise, match `expr2`.	`'Mr(s?)\..*?(?(1)her|his)\w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
`(expr)`	Capture in a token the characters that match the enclosed expression.	`'Joh?n\s(\w*)'` captures a token that contains the last name of any person with the first name `John` or `Jon`.
`\N`	Match the `N`th token.	`'<(\w+).*>.*</\1>'` captures tokens for HTML tags, such as `'title'` from the string `'<title>Some text</title>'`.

Ordinal Token Operator	Description	Example
`(?(N)expr1|expr2)`	If the Nth token is found, then match `expr1`. Otherwise, match `expr2`.	`'Mr(s?)\..*?(?(1)her|his) \w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Named Token Operator	Description	Example
`(?<name>expr)`	Capture in a named token the characters that match the enclosed expression.	`'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)'` creates named tokens for the month, day, and year in an input date string of the form `mm-dd-yy`.
`\k<name>`	Match the token referred to by `name`.	`'<(?<tag>\w+).*>.*</\k<tag>>'` captures tokens for HTML tags, such as `'title'` from the string `'<title>Some text</title>'`.
`(?(name)expr1|expr2)`	If the named token is found, then match `expr1`. Otherwise, match `expr2`.	`'Mr(?<sex>s?)\..*?(?(sex)her|his) \w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Note: If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern `'(and(y|rew))'`, MATLAB creates a token for `'andrew'` but not for `'y'` or `'rew'`.

Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
`(??expr)`	Parse `expr` and include the resulting string in the match expression. When parsed, `expr` must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of `expr`, and one for the complete match.	`'^(\d+)((??\\w{$1}))'` determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching `'5XXXXX'` captures tokens for `'5'` and `'XXXXX'`.
`(??@cmd)`	Execute the MATLAB command represented by `cmd`, and include the string returned by the command in the match expression.	`'(.{2,}).?(??@fliplr($1))'` finds palindromes that are at least four characters long, such as `'abba'`.
`(?@cmd)`	Execute the MATLAB command represented by `cmd`, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	`'\w*?(\w)(?@disp($1))\1\w*'` matches words that include double letters (such as `pp`), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
`$&` or `$0`	Portion of the input string that is currently a match
`$``	Portion of the input string that precedes the current match
`$'`	Portion of the input string that follows the current match (use `$''` to represent the string `$'`)
`$N`	Nth token
`$<name>`	Named token
`${cmd}`	String returned when MATLAB executes the command, `cmd`

Comments

Characters	Description	Example
`(?#comment)`	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	`'(?# Initial digit)\<\d\w+'` includes a comment, and matches words that begin with a number.

Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
`(?-i)`	Match letter case (default for `regexp` and `regexprep`).
`(?i)`	Do not match letter case (default for `regexpi`).
`(?s)`	Match dot (`.`) in the pattern string with any character (default).
`(?-s)`	Match dot in the pattern with any character that is not a newline character.
`(?-m)`	Match the `^` and `$` metacharacters at the beginning and end of a string (default).
`(?m)`	Match the `^` and `$` metacharacters at the beginning and end of a line.
`(?-x)`	Include space characters and comments when matching (default).
`(?x)`	Ignore space characters and comments when matching. Use `'\ '` and `'\#'` to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (`:`), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types: `char` | `cell`

`outkey` — Keyword that indicates which outputs to return

`'start'` | `'end'` | `'tokenExtents'` | `'match'` | `'tokens'` | `'names'` | `'split'`

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
`'start'`	Starting indices of all matches, startIndex
`'end'`	Ending indices of all matches, endIndex
`'tokenExtents'`	Starting and ending indices of all tokens
`'match'`	Text of each substring that matches the pattern in expression
`'tokens'`	Text of each captured token in str
`'names'`	Name and text of each named token
`'split'`	Text of nonmatching substrings of str

Data Types: `char`

`option` — Search option

`'once' | 'warnings' | 'matchcase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors' | ...`

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
`'all'`	`'once'`	Match the expression as many times as possible (default), or only once.
`'nowarnings'`	`'warnings'`	Suppress warnings (default), or display them.
`'ignorecase'`	`'matchcase'`	Ignore letter case (default), or match case.
`'noemptymatch'`	`'emptymatch'`	Ignore zero length matches (default), or include them.
`'dotall'`	`'dotexceptnewline'`	Match dot with any character (default), or all except newline (`\n`).
`'stringanchors'`	`'lineanchors'`	Apply `^` and `$` metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.

Default	Override	Description
`'literalspacing'`	`'freespacing'`	Include space characters and comments when matching (default), or ignore them. With `freespacing`, use `'\ '` and `'\#'` to match space and # characters.

Data Types: `char`

Output Arguments

`startIndex` — Starting index of each match

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

`endIndex` — Ending index of each match

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

`out` — Information about matches

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for outkey, as follows.

Output Keyword	Output Description	Output Type and Dimensions
`'start'`	Starting indices of matches	For both `'start'` and `'end'`: • If str and expression are both strings, the output is a row vector (or, if there are no matches, an empty array). • If str or expression is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.
`'end'`	Ending indices of matches	
`'tokenExtents'`	Starting and ending indices of all tokens	By default, when returning all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array, where `n` is the number of matches. Each cell contains an `m`-by-2 numeric array of indices, where `m` is the number of tokens in the match. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array, where each inner cell contains an `m`-by-2 numeric array. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is either an `m`-by-2 numeric array or a cell array with the same dimensions as `str` and/or `expression`.

Output Keyword	Output Description	Output Type and Dimensions
		If a token is expected at a particular index `N`, but is not found, then MATLAB returns extents for that token of `[N,N-1]`.
`'match'`	Text of each substring that matches the pattern in expression	By default, when returning all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array of strings, where `n` is the number of matches. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array of strings. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is either a string or a cell array of strings with the same dimensions as `str` and `expression`.

Output Keyword	Output Description	Output Type and Dimensions
`'tokens'`	Text of each captured token in str	By default, when returning all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array, where `n` is the number of matches. Each cell contains a 1-by-`m` cell array of strings, where `m` is the number of tokens in the match. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array, where each inner cell contains a 1-by-`m` cell array of strings. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions. When you specify the `'once'` option to return only one match, the output is a 1-by-`m` cell array of strings or a cell array that has the same dimensions as `str` and/or `expression`. If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, `''`.
`'names'`	Name and text of each named token	For all matches: • If str and expression are both strings, the output is a 1-by-`n` structure array, where `n` is the number of matches. The structure field names correspond to the token names. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` structure array. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

Output Keyword	Output Description	Output Type and Dimensions
`'split'`	Text of nonmatching substrings of str	For all matches: • If str and expression are both strings, the output is a 1-by-`n`-cell array of strings, where `n` is the number of nonmatching strings. • If str or expression is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-`n` cell array of strings. • If str and expression are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

More About

Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form `dd-mmm-yyyy`, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}
```

```
ans =
    '01'    'April'    '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')
```

```
mydate =
```

```
      day: '01'
    month: 'Apr'
     year: '2020'
```

Introduced before R2006a

regexprep

Replace string using regular expression

Syntax

```
newStr = regexprep(str,expression,replace)
newStr = regexprep(str,expression,replace,option1,...optionM)
```

Description

`newStr = regexprep(str,expression,replace)` replaces the text in str that matches expression with the text described by replace. The `regexprep` function returns the updated text in newStr.

- If str is a string, then newStr is also a string, even when expression or replace is a cell array of strings. When `expression` is a cell array, `regexprep` applies the first expression to the string, and then applies each subsequent expression to the preceding result.
- If str is a cell array, then newStr is a cell array with the same dimensions as str. For each element of str, the `regexprep` function applies each expression in sequence.
- If there are no matches to expression, then newStr is equivalent to str.

`newStr = regexprep(str,expression,replace,option1,...optionM)` modifies the search using the specified options. For example, specify `'ignorecase'` to perform a case-insensitive match.

Examples

Update a Single String

Replace words that begin with `M`, end with `y`, and have at least one character between them.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
```

```
replace = 'April';

newStr = regexprep(str,expression,replace)

newStr =

My flowers may bloom in April
```

Include Tokens in Replacement Text

Replace variations of the phrase `'walk up'` by capturing the letters that follow `'walk'` in a token.

```
str = 'I walk up, they walked up, we are walking up.';
expression = 'walk(\w*) up';
replace = 'ascend$1';

newStr = regexprep(str,expression,replace)

newStr =

I ascend, they ascended, we are ascending.
```

Include Dynamic Expression in Replacement Text

Replace lowercase letters at the beginning of sentences with their uppercase equivalents using the `upper` function.

```
str = 'here are two sentences. neither is capitalized.';
expression = '(^|\.)\s*.';
replace = '${upper($0)}';

newStr = regexprep(str,expression,replace)

newStr =

Here are two sentences. Neither is capitalized.
```

The regular expression matches single characters (`.`) that follow the beginning of the string (`^`) or a period (`\.`) and any whitespace (`\s*`). The `replace` expression calls the `upper` function for the currently matching character (`$0`).

Update Multiple Strings

Replace each occurrence of a double letter in a set of strings with the symbols `'--'`.

```
str = {                                    ...
'Whose woods these are I think I know.' ; ...
'His house is in the village though;'   ; ...
'He will not see me stopping here'      ; ...
'To watch his woods fill up with snow.'};

expression = '(.)\1';
replace = '--';
newStr = regexprep(str,expression,replace)

newStr =

    'Whose w--ds these are I think I know.'
    'His house is in the vi--age though;'
    'He wi-- not s-- me sto--ing here'
    'To watch his w--ds fi-- up with snow.'
```

Preserve Case in Original String

Ignore letter case in the regular expression when finding matches, but mimic the letter case of the original string when updating.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
replace = 'April';

newStr = regexprep(str,expression,replace,'preservecase')

newStr =

My flowers april bloom in April
```

Replace Zero-Length Matches

Insert text at the beginning of a string using the `'^'` operator, which returns a zero-length match, and the `'emptymatch'` keyword.

```
str = 'abc';
expression = '^';
replace = '__';

newStr = regexprep(str,expression,replace,'emptymatch')

newStr =
```

```
__abc
```

Input Arguments

`str` — Text to update

string | cell array of strings

Text to update, specified as a string or a cell array of strings.

Data Types: `char` | `cell`

`expression` — Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in str.

The following tables describe the elements of regular expressions.

Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
`.`	Any single character, including white space	`'..ain'` matches sequences of five consecutive characters that end with `'ain'`.
`[`$c_1c_2c_3$`]`	Any character contained within the brackets. The following characters are treated literally: `$ | . * + ?` and `-` when not used to indicate a range.	`'[rp.]ain'` matches `'rain'` or `'pain'` or ‘`.ain`’.
`[^`$c_1c_2c_3$`]`	Any character not contained within the brackets. The following characters are treated literally: `$ | . * + ?` and `-` when not used to indicate a range.	`'[^*rp]ain'` matches all four-letter sequences that end in `'ain'`, except `'rain'` and `'pain'` and ‘`*ain`’. For example, it matches `'gain'`, `'lain'`, or `'vain'`.

Metacharacter	Description	Example
`[c1-c2]`	Any character in the range of `c1` through `c2`	`'[A-G]'` matches a single character in the range of `A` through `G`.
`\w`	Any alphabetic, numeric, or underscore character. For English character sets, `\w` is equivalent to `[a-zA-Z_0-9]`	`'\w*'` identifies a word.
`\W`	Any character that is not alphabetic, numeric, or underscore. For English character sets, `\W` is equivalent to `[^a-zA-Z_0-9]`	`'\W*'` identifies a substring that is not a word.
`\s`	Any white-space character; equivalent to `[ \f\n\r\t\v]`	`'\w*n\s'` matches words that end with the letter `n`, followed by a white-space character.
`\S`	Any non-white-space character; equivalent to `[^ \f\n\r\t\v]`	`'\d\S'` matches a numeric digit followed by any non-white-space character.
`\d`	Any numeric digit; equivalent to `[0-9]`	`'\d*'` matches any number of consecutive digits.
`\D`	Any nondigit character; equivalent to `[^0-9]`	`'\w*\D\>'` matches words that do not end with a numeric digit.
`\oN` or `\o{N}`	Character of octal value `N`	`'\o{40}'` matches the space character, defined by octal `40`.
`\xN` or `\x{N}`	Character of hexadecimal value `N`	`'\x2C'` matches the comma character, defined by hex `2C`.

Character Representation

Operator	Description
`\a`	Alarm (beep)
`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab

Operator	Description
`\v`	Vertical tab
`\char`	Any character with special meaning in regular expressions that you want to match literally (for example, use `\\` to match a single backslash)

Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
`expr*`	0 or more times consecutively.	`'\w*'` matches a word of any length.
`expr?`	0 times or 1 time.	`'\w*(\.m)?'` matches words that optionally end with the extension `.m`.
`expr+`	1 or more times consecutively.	`'<img src="\w+\.gif">'` matches an `<img>` HTML tag when the file name contains one or more characters.
`expr{m,n}`	At least `m` times, but no more than `n` times consecutively. `{0,1}` is equivalent to `?`.	`'\S{4,8}'` matches between four and eight non-white-space characters.
`expr{m,}`	At least `m` times consecutively. `{0,}` and `{1,}` are equivalent to `*` and `+`, respectively.	`'<a href="\w{1,}\.html">'` matches an `<a>` HTML tag when the file name contains one or more characters.
`expr{n}`	Exactly `n` times consecutively. Equivalent to `{n,n}`.	`'\d{4}'` matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
`expr`*q*	Greedy expression: match as many characters as possible.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*>'` matches all characters between `<tr` and `/td>`:

Mode	Description	Example
		`'<tr><td><p>text</p></td>'`
`expr`*q*`?`	Lazy expression: match as few characters as necessary.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*?>'` ends each match at the first occurrence of the closing bracket (`>`): `'<tr>'  '<td>'  '</td>'`
`expr`*q*`+`	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string `'<tr><td><p>text</p></td>'`, the expression `'</?t.*+>'` does not return any matches, because the closing bracket is captured using `.*`, and is not rescanned.

Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
`(expr)`	Group elements of the expression and capture tokens.	`'Joh?n\s(\w*)'` captures a token that contains the last name of any person with the first name `John` or `Jon`.
`(?:expr)`	Group, but do not capture tokens.	`'(?:[aeiou][^aeiou]){2}'` matches two consecutive patterns of a vowel followed by a nonvowel, such as `'anon'`. Without grouping, `'[aeiou][^aeiou]{2}'` matches a vowel followed by two nonvowels.
`(?>expr)`	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	`'A(?>.*)Z'` does not match `'AtoZ'`, although `'A(?:.*)Z'` does. Using the atomic group, `Z` is captured using `.*` and is not rescanned.
`(expr1|expr2)`	Match expression `expr1` or expression `expr2`.	`'(let|tel)\w+'` matches words in a string that start with `let` or `tel`.

Grouping Operator	Description	Example
	If there is a match with `expr1`, then `expr2` is ignored. You can include `?:` or `?>` after the opening parenthesis to suppress tokens or group atomically.	

Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
`^expr`	Beginning of the input string.	`'^M\w*'` matches a word starting with `M` at the beginning of the string.
`expr$`	End of the input string.	`'\w*m$'` matches words ending with `m` at the end of the string.
`\<expr`	Beginning of a word.	`'\<n\w*'` matches any words starting with `n`.
`expr\>`	End of a word.	`'\w*e\>'` matches any words ending with `e`.

Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
`expr(?=test)`	Look ahead for characters that match `test`.	`'\w*(?=ing)'` matches strings that are followed by `ing`, such as `'Fly'` and `'fall'` in the input string `'Flying, not falling.'`

Lookaround Assertion	Description	Example
`expr(?!test)`	Look ahead for characters that do not match `test`.	`'i(?!ng)'` matches instances of the letter `i` that are not followed by `ng`.
`(?<=test)expr`	Look behind for characters that match `test`.	`'(?<=re)\w*'` matches strings that follow `'re'`, such as `'new'`, `'use'`, and `'cycle'` in the input string `'renew, reuse, recycle'`
`(?<!test)expr`	Look behind for characters that do not match `test`.	`'(?<!\d)(\d)(?!\d)'` matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical `AND`.

Operation	Description	Example
`(?=test)expr`	Match both `test` and `expr`.	`'(?=[a-z])[^aeiou]'` matches consonants.
`(?!test)expr`	Match `expr` and do not match `test`.	`'(?![aeiou])[a-z]'` matches consonants.

Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical `OR`, and `if` or `if/else` conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
`expr1|expr2`	Match expression `expr1` or expression `expr2`. If there is a match with `expr1`, then `expr2` is ignored.	`'(let|tel)\w+'` matches words in a string that start with `let` or `tel`.

Conditional Operator	Description	Example
`(?(cond)expr)`	If condition `cond` is `true`, then match `expr`.	`'(?(?@ispc)[A-Z]:\\)'` matches a drive name, such as `C:\`, when run on a Windows system.
`(?(cond)expr1|expr2)`	If condition `cond` is `true`, then match `expr1`. Otherwise, match `expr2`.	`'Mr(s?)\..*?(?(1)her|his)\w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
`(expr)`	Capture in a token the characters that match the enclosed expression.	`'Joh?n\s(\w*)'` captures a token that contains the last name of any person with the first name `John` or `Jon`.
`\N`	Match the `N`th token.	`'<(\w+).*>.*</\1>'` captures tokens for HTML tags, such as `'title'` from the string `'<title>Some text</title>'`.
`(?(N)expr1|expr2)`	If the `N`th token is found, then match `expr1`. Otherwise, match `expr2`.	`'Mr(s?)\..*?(?(1)her|his)\w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Named Token Operator	Description	Example
`(?<name>expr)`	Capture in a named token the characters that match the enclosed expression.	`'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)'` creates named tokens for the month, day, and year in an

Named Token Operator	Description	Example
		input date string of the form `mm-dd-yy`.
`\k<name>`	Match the token referred to by `name`.	`'<(?<tag>\w+).*>.*</\k<tag>>'` captures tokens for HTML tags, such as `'title'` from the string `'<title>Some text</title>'`.
`(?(name)expr1|expr2)`	If the named token is found, then match `expr1`. Otherwise, match `expr2`.	`'Mr(?<sex>s?)\..*?(?(sex)her|his) \w*'` matches strings that include `her` when the string begins with `Mrs`, or that include `his` when the string begins with `Mr`.

Note: If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern `'(and(y|rew))'`, MATLAB creates a token for `'andrew'` but not for `'y'` or `'rew'`.

Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
`(??expr)`	Parse `expr` and include the resulting string in the match expression. When parsed, `expr` must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of `expr`, and one for the complete match.	`'^(\d+)((??\\w{$1}))'` determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching

Operator	Description	Example
		`'5XXXXX'` captures tokens for `'5'` and `'XXXXX'`.
`(??@cmd)`	Execute the MATLAB command represented by `cmd`, and include the string returned by the command in the match expression.	`'(.{2,}).?(??@fliplr($1))'` finds palindromes that are at least four characters long, such as `'abba'`.
`(?@cmd)`	Execute the MATLAB command represented by `cmd`, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	`'\w*?(\w)(?@disp($1))\1\w*'` matches words that include double letters (such as `pp`), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
`$&` or `$0`	Portion of the input string that is currently a match
`$``	Portion of the input string that precedes the current match
`$'`	Portion of the input string that follows the current match (use `$''` to represent the string `$'`)
`$N`	`N`th token
`$<name>`	Named token
`${cmd}`	String returned when MATLAB executes the command, `cmd`

Comments

Characters	Description	Example
`(?#comment)`	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	`'(?# Initial digit)\<\d\w+'` includes a comment, and matches words that begin with a number.

Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
`(?-i)`	Match letter case (default for `regexp` and `regexprep`).
`(?i)`	Do not match letter case (default for `regexpi`).
`(?s)`	Match dot (`.`) in the pattern string with any character (default).
`(?-s)`	Match dot in the pattern with any character that is not a newline character.
`(?-m)`	Match the `^` and `$` metacharacters at the beginning and end of a string (default).
`(?m)`	Match the `^` and `$` metacharacters at the beginning and end of a line.
`(?-x)`	Include space characters and comments when matching (default).
`(?x)`	Ignore space characters and comments when matching. Use `'\ '` and `'\#'` to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (`:`), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

Data Types: `char` | `cell`

`replace` — Replacement text

string | cell array of strings

Replacement text, specified as a string or a cell array of strings, as follows:

- If `replace` is a single string and `expression` is a cell array of strings, then `regexprep` uses the same replacement text for each expression.
- If `replace` is a cell array of `N` strings and `expression` is a single string, then `regexprep` attempts `N` matches and replacements.
- If both `replace` and `expression` are cell arrays of strings, then they must contain the same number of elements. `regexprep` pairs each `replace` element with its matching element in `expression`.

The replacement text can include regular characters, special characters (such as tabs or new lines), or string operators, as shown in the following tables.

Replacement String Operator	Description
`$&` or `$0`	Portion of the input string that is currently a match
`$``	Portion of the input string that precedes the current match
`$'`	Portion of the input string that follows the current match (use `$''` to represent the string `$'`)
`$N`	Nth token
`$<name>`	Named token
`${cmd}`	String returned when MATLAB executes the command, `cmd`

Operator	Description
`\a`	Alarm (beep)
`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab
`\`*`char`*	Any character with special meaning in regular expressions that you want to match literally (for example, use `\\` to match a single backslash)

Data Types: `char` | `cell`

`option` — Search or replacement option

`'once'` | `N` | `'warnings'` | `'ignorecase'` | `'preservecase'` | `'emptymatch'` | `'dotexceptnewline'` | `'lineanchors'` | ...

Search or replacement option, specified as a string or an integer value, as shown in the following table.

Options come in sets: one option that corresponds to the default behavior, and one or two options that allow you to override the default. Specify only one option from a set. Options can appear in any order.

Default	Override	Description
`'all'`	`'once'`	Match and replace the expression as many times as possible (default), or only once.
	`N`	Replace only the `N`th occurrence of the match, where `N` is an integer value.
`'nowarnings'`	`'warnings'`	Suppress warnings (default), or display them.
`'matchcase'`	`'ignorecase'`	Match letter case (default), or ignore case while matching and replacing.
	`'preservecase'`	Ignore case while matching, but preserve the case of corresponding characters in the original string while replacing.
`'noemptymatch'`	`'emptymatch'`	Ignore zero length matches (default), or include them.
`'dotall'`	`'dotexceptnewline'`	Match dot with any character (default), or all except newline (`\n`).
`'stringanchors'`	`'lineanchors'`	Apply `^` and `$` metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
`'literalspacing'`	`'freespacing'`	Include space characters and comments when matching (default), or ignore them. With `freespacing`, use `'\ '` and `'\#'` to match space and # characters.

Data Types: `char`

Output Arguments

`newStr` — Updated text

string | cell array of strings

Updated text, returned as a string or a cell array of strings. The data type of newStr is the same as the data type of str.

`regexp` | `strcmp` | `strfind` | `strrep`

Introduced before R2006a

regexptranslate

Translate string into regular expression

Syntax

```
s2 = regexptranslate(type, s1)
```

Description

`s2 = regexptranslate(type, s1)` translates string `s1` into a regular expression string `s2` that you can then use as input into one of the MATLAB regular expression functions such as `regexp`. The `type` input can be either one of the following strings that define the type of translation to be performed. See “Regular Expressions” in the MATLAB Programming Fundamentals documentation for more information.

Type	Description
`'escape'`	Translate all special characters (e.g., '$', '.', '?', '[') in string `s1` so that they are treated as literal characters when used in the `regexp` and `regexprep` functions. The translation inserts an escape character ('\') before each special character in `s1`. Return the new string in `s2`.
`'wildcard'`	Translate all wildcard and '.' characters in string `s1` so that they are treated as literal wildcards and periods when used in the `regexp` and `regexprep` functions. The translation replaces all instances of '*' with '.*', all instances of '?' with '.', and all instances of '.' with '\.'. Return the new string in `s2`.

Examples

Example 1 — Using the 'escape' Option

Because `regexp` interprets the sequence '\n' as a newline character, it cannot locate the two consecutive characters '\' and 'n' in this string:

```
str = 'The sequence \n generates a new line';
```

```
pat = '\n';

regexp(str, pat)

ans =

     []
```

To have `regexp` interpret the expression `expr` as the characters '\' and 'n', first translate the expression using `regexptranslate`:

```
pat2 = regexptranslate('escape', pat)

pat2 =

\\n

regexp(str, pat2)

ans =

    14
```

Example 2 — Using 'escape' In a Replacement String

Replace the word '`walk`' with '`ascend`' in this string, treating the characters '`$1`' as a token designator:

```
str = 'I walk up, they walked up, we are walking up.';
pat = 'walk(\w*) up';

regexprep(str, pat, 'ascend$1')

ans =

I ascend, they ascended, we are ascending.
```

Make another replacement on the same string, this time treating the '`$1`' as literal characters:

```
regexprep(str, pat, regexptranslate('escape', 'ascend$1'))

ans =
```

```
I ascend$1, they ascend$1, we are ascend$1.
```

Example 3 — Using the 'wildcard' Option

Given the following string of filenames, pick out just the MAT-files. Use `regexptranslate` to interpret the `'*'` wildcard as `'\w+'` instead of as a regular expression quantifier:

```
files = ['test1.mat, myfile.mat, newfile.txt, ' ...
         'jan30.mat, table3.xls'];
regexp(files, regexptranslate('wildcard', '*.mat'), 'match')

ans =

    'test1.mat, myfile.mat, newfile.txt, jan30.mat'
```

To see the translation, you can type

```
regexptranslate('wildcard','*.mat')

ans =

.*\.mat
```

Introduced in R2006a

registerevent

Associate event handler for COM object event at run time

Syntax

```
registerevent(h,eventhandler)
```

Description

`registerevent(h,eventhandler)` registers event handler routines with their corresponding events. The `eventhandler` argument can be either a string that specifies the name of the event handler function, or a function handle that maps to that function. Strings used in the `eventhandler` argument are not case-sensitive.

COM functions are available on Microsoft Windows systems only.

Examples

Show events in the MATLAB sample control:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
events(h)
```

```
   Click = void Click()
   DblClick = void DblClick()
   MouseDown = void MouseDown(int16 Button, int16 Shift,
     Variant x, Variant y)
   Event_Args = void Event_Args(int16 typeshort,
     int32 typelong, double typedouble, string typestring,
     bool typebool)
```

MATLAB displays all events associated with the instance of the control.

Register all events with the same event handler routine, `sampev`:

```
registerevent(h,'sampev');
```

```
eventlisteners(h)

ans =
    'Click'         'sampev'
    'DblClick'      'sampev'
    'MouseDown'     'sampev'
    'Event_Args'    'sampev'
```

Register individual events:

```
% Unregister existing events
unregisterallevents(h);
% Register specific events
registerevent(h,{'click' 'myclick'; ...
    'dblclick' 'my2click'});
eventlisteners(h)

ans =
    'click'       'myclick'
    'dblclick'    'my2click'
```

Register events using a function handle (`@sampev`) instead of the function name:

```
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200]);
registerevent(h,@sampev);
```

rehash

Refresh function and file system path caches

Syntax

```
rehash
rehash path
rehash toolbox
rehash pathreset
rehash toolboxreset
rehash toolboxcache
```

Description

`rehash` with no arguments updates the MATLAB list of known files and classes for directories on the search path that are not in *`matlabroot`*`/toolbox`. It compares the timestamps for loaded functions against their timestamps on disk. It clears loaded functions if the files on disk are newer. All of this normally happens each time MATLAB displays the Command Window prompt. Use `rehash` with no arguments only when you run a program file that updates another program file, and the calling file needs to reuse the updated version of the second file before the calling file has finished running.

`rehash path` performs the same updates as `rehash`, but uses a different technique for detecting the files and directories that require updates. Run `rehash path` only if you receive a warning during MATLAB startup notifying you that MATLAB could not tell if a directory has changed, and you encounter problems with MATLAB not using the most current versions of your program files.

`rehash toolbox` performs the same updates as rehash path, except it updates the list of known files and classes for *all* directories on the search path, including those in *`matlabroot`*`/toolbox`. Run `rehash toolbox` when you change, add, or remove files in *`matlabroot`*`/toolbox` during a session. Typically, you should not make changes to files and directories in *`matlabroot`*`/toolbox`.

`rehash pathreset` performs the same updates as `rehash path`, and also ensures the known files and classes list follows precedence rules for shadowed functions.

`rehash toolboxreset` performs the same updates as `rehash toolbox`, and also ensures the known files and classes list follows precedence rules for shadowed functions.

`rehash toolboxcache` performs the same updates as `rehash toolbox`, and also updates the cache file. This is the equivalent of clicking the **Update Toolbox Path Cache** button in the General Preferences dialog box.

`addpath` | `path` | `rmpath` | `clear` | `matlabroot`

Introduced before R2006a

release

Release COM interface

Syntax

```
release(h)
```

Description

`release(h)` releases the interface and all resources used by the interface. Other interfaces on that object might still be active.

You must release the handle when you are done with the interface. A released interface is no longer valid. MATLAB generates an error if you try to use an object that represents that interface.

To release the interface and delete the control itself, use the `delete` function.

COM functions are available on Microsoft Windows systems only.

More About

- Releasing Interfaces

`delete (COM)` | `actxcontrol` | `actxserver`

Introduced before R2006a

rem

Remainder after division

Syntax

```
R = rem(X,Y)
```

Description

`R = rem(X,Y)` returns the remainder after division of `X` by `Y`. In general, if `Y` does not equal `0`, `R = rem(X,Y)` returns `X - n.*Y`, where `n = fix(X./Y)`. If `Y` is not an integer and the quotient `X./Y` is within roundoff error of an integer, then `n` is that integer. Inputs `X` and `Y` must have the same dimensions unless one of them is a scalar double. If one of the inputs has an integer data type, then the other input must be of the same integer data type or be a scalar double.

The following are true by convention:

- `rem(X,0)` is `NaN`.
- `rem(X,X)` for `X~=0` is `0`.
- `rem(X,Y)` for `X~=Y` and `Y~=0` has the same sign as `X`.

Examples

Remainder of Two Scalars

Compute the remainder after dividing 5 into 23.

```
X = 23;
Y = 5;
R = rem(X,Y)
```

```
R =
```

```
     3
```

Remainder of a Vector

Create a vector, then use `rem` to find the remainder after dividing a scalar into each element of the vector.

```
X = 1:5;
Y = 3;
R = rem(X,Y)

R =

     1     2     0     1     2
```

When you specify one or more of the inputs as an array, the `rem` function acts on each array element independently.

Remainder of Two Arrays

Create two 3-by-3 matrices, then use `rem` to find the remainder after dividing `Y` into `X`.

```
X = [1 2 3;4 5 6;7 8 9];
Y = [9 8 7;6 5 4;3 2 1];
R = rem(X,Y)

R =

     1     2     3
     4     0     2
     1     0     0
```

Inputs `X` and `Y` must have the same dimensions unless one is a scalar double.

Forced Rounding in rem

If `Y` is not an integer and `X./Y` is within roundoff error of an integer, then `rem` rounds to that integer for its calculation. The size of the roundoff error is very small.

```
X = 2;
Y = 2 - eps(2)

Y =

    2.0000
```

It looks like `Y` is trivially equal to 2, but in fact there is an infinitesimal difference.

```
2 - Y
```

```
ans =

  4.4409e-16
```

This difference is forced to zero by `rem` if it is small enough.

```
R = rem(X,Y)
```

```
R =

     0
```

Make the difference a little larger and the forced rounding disappears.

```
Y = 2 - eps(4);
R = rem(X,Y)
```

```
R =

   8.8818e-16
```

Difference Between rem and mod

Define `X` and `Y` with different signs.

```
X = 5;
Y = -2;
```

Compute the remainder after division with `rem`, then compute the modulus after division with `mod`.

```
R = rem(X,Y)
```

```
R =

     1
```

```
M = mod(X,Y)
```

```
M =

    -1
```

`rem(X,Y)` and `mod(X,Y)` are equal if `X` and `Y` have the same sign, but differ by `Y` if `X` and `Y` have different signs. Notice that `rem` retains the sign of `X`, while `mod` retains the sign of `Y`.

Input Arguments

`X` — Dividend

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

`Y` — Divisor

scalar | vector | matrix | multidimensional array

Divisor, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

See Also

`mod`

Introduced before R2006a

remove

Class: containers.Map
Package: containers

Remove key-value pairs from `containers.Map` object

Syntax

```
remove(mapObj,keySet)
```

Description

`remove(mapObj,keySet)` erases all specified keys, and the values associated with them, from `mapObj`. Input `keySet` can be a scalar key or a cell array of keys.

Input Arguments

`mapObj`

Object of class `containers.Map`.

`keySet`

Scalar value, string, or cell array that specifies keys in `mapObj` to delete.

Examples

Remove Key-Value Pairs from a Map

Create a map and view the keys and the `Count` property:

```
myKeys = {'a','b','c','d'};
myValues = [1,2,3,4];
mapObj = containers.Map(myKeys,myValues);
```

```
mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The initial map contains four key-value pairs:

```
mapKeys =
    'a'    'b'    'c'    'd'

mapCount =
                    4
```

Remove the pairs corresponding to keys `b` and `d`:

```
keySet = {'b','d'};
remove(mapObj,keySet)

mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The modified map contains two key-value pairs:

```
mapKeys =
    'a'    'c'

mapCount =
                    2
```

See Also

`keys` | `values` | `containers.Map` | `isKey`

removecats

Remove categories from categorical array

Syntax

```
B = removecats(A)
B = removecats(A,oldcats)
```

Description

`B = removecats(A)` removes unused categories from the categorical array, `A`. The output categorical array, `B`, has the same size and values as `A`. However, `B` possibly has fewer categories.

`B = removecats(A,oldcats)` removes the categories specified by oldcats. The function `removecats` removes categories, but does not remove any elements of the array. Therefore, elements of `B`, whose values correspond to `oldcats`, are undefined.

Examples

Remove All Unused Categories

Create a categorical array representing political parties of four people.

```
A = categorical({'republican' 'democrat' 'democrat' 'republican'},...
    {'democrat' 'republican' 'independent'})
```

```
A =

     republican      democrat      democrat      republican
```

`A` is a 1-by-4 categorical array.

Summarize the categorical array, `A`.

```
summary(A)
```

```
     democrat      republican      independent
            2               2                0
```

A has three categories. `democrat` appears twice in the array, `republican` appears twice in the array, and `independent` is unused.

Remove the unused category, `independent`.

```
B = removecats(A)
```

```
B =

     republican      democrat      democrat      republican
```

B has the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =

    'democrat'
    'republican'
```

B has fewer categories than A.

Remove Categories with Corresponding Values Used in A

Create a categorical array, A, containing modes of transportation.

```
A = categorical({'plane' 'car'; 'train' 'car'; 'plane' 'car'})
```

```
A =

     plane      car
     train      car
     plane      car
```

A is a 3-by-2 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
    'car'
    'plane'
    'train'
```

A has three categories, `car`, `plane`, and `train`.

Remove the category, `train`.

```
B = removecats(A,'train')
```

```
B =

     plane            car
     <undefined>      car
     plane            car
```

The element that was from the category `train` is now undefined.

Display the categories of B.

```
categories(B)
```

```
ans =

    'car'
    'plane'
```

B has one fewer category than A.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

oldcats — Categories to remove

string | cell array of strings

Categories to remove, specified as a string or cell array of strings. The default is all the unused categories from A.

More About

Tips

- `~ismember(categories(A),unique(A))` returns logical `true` (1) for any unused category of A.

See Also

`addcats` | `categories` | `iscategory` | `mergecats` | `renamecats` | `reordercats` | `setcats` | `summary`

removets

Remove `timeseries` objects from `tscollection` object

Syntax

```
tsc = removets(tsc,Name)
```

Description

`tsc = removets(tsc,Name)` removes one or more `timeseries` objects with the name specified in `Name` from the `tscollection` object tsc. `Name` can either be a string or a cell array of strings.

Examples

The following example shows how to remove a time series from a `tscollection`.

1. Create two `timeseries` objects, `ts1` and `ts2`.

   ```
   ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
   ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
   ```

2. Create a `tscollection` object `tsc`, which includes `ts1` and `ts2`.

   ```
   tsc=tscollection({ts1 ts2});
   ```

3. To view the members of `tsc`, type the following at the MATLAB prompt:

   ```
   tsc
   ```

   The response is

   ```
   Time Series Collection Object: unnamed

   Time vector characteristics

         Start time            1 seconds
         End time              5 seconds
   ```

```
Member Time Series Objects:

      acceleration
      speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of `ts1` and `ts2`, respectively.

4 Remove `ts2` from `tsc`.

```
tsc=removets(tsc,'speed');
```

5 To view the current members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed

Time vector characteristics

      Start time            1 seconds
      End time              5 seconds

Member Time Series Objects:
      acceleration
```

The remaining member of `tsc` is `acceleration`. The `timeseries` `speed` has been removed.

See Also

`addts` | `tscollection`

Introduced before R2006a

renamecats

Rename categories in categorical array

Syntax

```
B = renamecats(A,newnames)
B = renamecats(A,oldnames,newnames)
```

Description

`B = renamecats(A,newnames)` renames all the categories in the categorical array, `A`. Elements of `B` use the new category names.

`B = renamecats(A,oldnames,newnames)` renames only the categories specified by `oldnames`.

Examples

Rename All Categories

Create a categorical array containing states from New England.

```
A = categorical({'MA';'ME';'CT';'VT';'ME';'NH';'VT';'MA';'NH';'CT';'RI'})
```

```
A =

     MA
     ME
     CT
     VT
     ME
     NH
     VT
     MA
     NH
     CT
     RI
```

A is an 11-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =

    'CT'
    'MA'
    'ME'
    'NH'
    'RI'
    'VT'
```

A has six categories.

Rename the categories to use the full state name instead of the abbreviation.

```
B = renamecats(A,{'Connecticut','Massachusetts',...
    'Maine','New Hampshire','Rhode Island' 'Vermont'})
```

```
B =

     Massachusetts
     Maine
     Connecticut
     Vermont
     Maine
     New Hampshire
     Vermont
     Massachusetts
     New Hampshire
     Connecticut
     Rhode Island
```

Elements of B use the new category names.

Display the categories of B.

```
categories(B)
```

```
ans =

    'Connecticut'
```

```
    'Massachusetts'
    'Maine'
    'New Hampshire'
    'Rhode Island'
    'Vermont'
```

Rename One Category

Create a categorical array containing colors.

```
A = categorical({'red' 'blue'; 'purple' 'white'; 'green' 'red'})
```

```
A =

     red          blue
     purple       white
     green        red
```

`A` is a 3-by-2 categorical array.

Display the categories of `A`.

```
categories(A)
```

```
ans =

    'blue'
    'green'
    'purple'
    'red'
    'white'
```

`A` has five categories that are listed in alphabetical order.

Change the category name from `purple` to `violet`.

```
B = renamecats(A,'purple','violet')
```

```
B =

     red          blue
     violet       white
     green        red
```

The element `B(2,1)` is `violet` instead of `purple`.

Display the categories of B.

```
categories(B)
```

```
ans =

    'blue'
    'green'
    'violet'
    'red'
    'white'
```

violet replaces purple and the categories are no longer in alphabetical order. Note that the category has not changed its position.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

newnames — New category names for B

string | cell array of strings

New category names for B, specified as a string or a cell array of strings. The new category names must be unique, and must not duplicate any existing names.

oldnames — Old category names from A

string | cell array of strings

Old category names from A, specified as a string or a cell array of strings.

More About

Tips

- Renaming categories does not change their position in `categories(B)`. Use `reordercats` to change the category ordering. For example, you can use `B = reordercats(B,sort(categories(B)))` to put the categories in alphabetical order.

See Also

addcats | categories | iscategory | mergecats | removecats | reordercats | setcats

reordercats

Reorder categories in categorical array

Syntax

```
B = reordercats(A)
B = reordercats(A,neworder)
```

Description

`B = reordercats(A)` reorders the categories in the categorical array, `A`, to be in alphanumeric order.

The order of the categories is used by functions such as `summary` and `hist`. If the categorical array is ordinal, the order of the categories defines their mathematical ordering. The first category specified is the smallest and the last category is the largest.

`B = reordercats(A,neworder)` puts the categories in the order specified by neworder.

Examples

Alphabetize Categories of Nonordinal Categorical Array

Create two categorical arrays, `X` and `Y`.

```
X = categorical({'frog';'cat';'cat';'ant';'frog'})

Y = categorical({'deer';'bear';'eagle';'deer'})
```

```
X =

     frog
     cat
     cat
     ant
     frog
```

```
Y =

     deer
     bear
     eagle
     deer
```

X is a 5-by-1 categorical array. The categories of X are the sorted unique values from the array: `{'ant';'cat';'frog'}`.

Y is a 4-by-1 categorical array. The categories of Y are the sorted unique values from the array: `{'bear';'deer';'eagle'}`.

Concatenate X and Y into a single categorical array, A.

```
A = [X;Y]
```

```
A =

     frog
     cat
     cat
     ant
     frog
     deer
     bear
     eagle
     deer
```

`vertcat` appends the values from Y to the values from X.

List the categories of the categorical array, A.

```
acats = categories(A)
```

```
acats =

    'ant'
    'cat'
    'frog'
    'bear'
    'deer'
    'eagle'
```

`vertcat` appends the categories of `Y` to the categories from `X`. The categories of `A` are *not* in alphabetical order.

Reorder the categories of `A` into alphabetical order.

```
B = reordercats(A)
```

```
B =

     frog
     cat
     cat
     ant
     frog
     deer
     bear
     eagle
     deer
```

The output categorical array, `B`, has the same elements in the same order as the input categorical array, `A`.

List the categories of the categorical array, `B`.

```
bcats = categories(B)
```

```
bcats =

    'ant'
    'bear'
    'cat'
    'deer'
    'eagle'
    'frog'
```

The categories of `B` are in alphabetical order.

Reorder Categories in Nonordinal Categorical Array

Create a categorical array containing the color of various items.

```
A = categorical({'red';'green';'blue';'red';'green';'red';'blue';'blue'})
```

```
A =

     red
```

```
     green
     blue
     red
     green
     red
     blue
     blue
```

A is an 8-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =

    'blue'
    'green'
    'red'
```

The categories of A are in alphabetical order and have no mathematical meaning.

Reorder the categories to match the order commonly used for colors.

```
B = reordercats(A,{'red','green','blue'})
```

```
B =

     red
     green
     blue
     red
     green
     red
     blue
     blue
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
    'red'
    'green'
    'blue'
```

B is not ordinal and the order of the categories has no mathematical meaning. Although the categories appear in the order of the color spectrum, relational operations, such as greater than and less than, have no meaning.

Reorder Categories in Ordinal Categorical Array

Create an ordinal categorical array, A, containing modes of transportation. Order the categories based on the average price of travel.

```
A = categorical({'plane';'car'; 'train';'car';'plane';'car'},...
    {'car','train','plane'},'Ordinal',true)
```

```
A =

     plane
     car
     train
     car
     plane
     car
```

A is a 6-by-1 ordinal categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =

    'car'
    'train'
    'plane'
```

Since A is ordinal, `car < train < plane`.

Reorder the categories to reflect a decrease in the cost of train travel.

```
B = reordercats(A,{'train','car','plane'})
```

```
B =
```

```
     plane
     car
     train
     car
     plane
     car
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =

    'train'
    'car'
    'plane'
```

The mathematical ordering of the categories is now `train < car < plane`. The results from relational operations, `min`, and `max` reflect the new category ordering.

Reorder Categories with Numeric Vector

Create a categorical array, A, containing modes of transportation.

```
A = categorical({'plane';'car';'train';'car';'car';'plane';'car'})
```

```
A =

     plane
     car
     train
     car
     car
     plane
     car
```

Display the categories of A.

```
categories(A)
```

```
ans =

    'car'
```

```
    'plane'
    'train'
```

Reorder categories from least to most frequent occurrence in A.

```
B = countcats(A);
[C,neworder] = sort(B);
neworder

neworder =

     3
     2
     1

D = reordercats(A,neworder);
categories(D)

ans =

    'train'
    'plane'
    'car'
```

Because `countcats` counts the occurrences of each category, `neworder` describes how to reorder the categories—not the elements—of A.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array. If A is an ordinal categorical array, a reordering of the categories changes the mathematical meaning. Consequently, the relational operators, such as greater than and less than, might return different results.

neworder — New category order for B

cell array of strings | numeric vector

New category order for B, specified as a cell array of strings or a numeric vector. `neworder` must be a permutation of `categories(A)`.

More About

Tips

- To convert the categorical array, `B`, to an ordinal categorical array, use `B = categorical(B,'Ordinal',true)`. You can specify the order of the categories with `B = categorical(B,`*`valueset`*`,'Ordinal',true)`, where the order of the values in *`valueset`* defines the category order.

See Also

`addcats` | `categories` | `iscategory` | `mergecats` | `removecats` | `renamecats` | `setcats`

rename

Class: FTP

Rename file on FTP server

Syntax

```
rename(ftpobj,oldname,newname)
```

Description

`rename(ftpobj,oldname,newname)` changes the name of the file `oldname` to `newname` in the current folder on an FTP server.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`oldname`

String enclosed in single quotation marks that specifies the original name of the file.

`newname`

String enclosed in single quotation marks that specifies a new name for the file.

Examples

Suppose that hypothetical FTP server `ftp.testsite.com` contains a file named `testfile.m`. Rename the file to `final.m`:

```
test = ftp('ftp.testsite.com');
rename(test, 'testfile.m', 'final.m');
```

```
close(test);
```

See Also

`dir` | `ftp` | `mput` | `delete` | `mget`

Introduced before R2006a

repelem

Repeat copies of array elements

Syntax

```
u = repelem(v,n)
B = repelem(A,r1,...,rN)
```

Description

`u = repelem(v,n)`, where `v` is a scalar or vector, returns a vector of repeated elements of `v`.

- If `n` is a scalar, then each element of `v` is repeated `n` times. The length of `u` is `length(v)*n`.
- If `n` is a vector, then it must be the same length as `v`. Each element of `n` specifies the number of times to repeat the corresponding element of `v`.

This syntax is not supported for `table` input.

`B = repelem(A,r1,...,rN)` returns an array with each element of `A` repeated according to `r1,...,rN`. Each `r1,...,rN` must either be a scalar or a vector with the same length as `A` in the corresponding dimension. For example, if `A` is a matrix, `repelem(A,2,3)` returns a matrix containing a `2`-by-`3` block of each element of `A`.

Examples

Repeat Vector Elements

Create a vector and repeat each of its elements three times into a new vector.

```
v = [1 2 3 4];
u = repelem(v,3)
```

```
u =
```

```
     1     1     1     2     2     2     3     3     3     4     4     4
```

Repeat the first two elements of `v` twice and the last two elements three times.

```
u = repelem(v,[2 2 3 3])
```

```
u =

     1     1     2     2     3     3     3     4     4     4
```

Repeat Matrix Elements

Create a matrix and repeat each element into a 3-by-2 block of a new matrix.

```
A = [1 2; 3 4]
```

```
A =

     1     2
     3     4
```

```
B = repelem(A,3,2)
```

```
B =

     1     1     2     2
     1     1     2     2
     1     1     2     2
     3     3     4     4
     3     3     4     4
     3     3     4     4
```

Repeat Matrix Columns

Create a matrix and copy its columns into a new array, repeating the first column twice and second column three times.

```
A = [1 2; 3 4]
```

```
B = repelem(A,1,[2 3])

A =

     1     2
     3     4

B =

     1     1     2     2     2
     3     3     4     4     4
```

Input Arguments

v — Input element

scalar | vector

Input element, specified as a scalar or a vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`
Complex Number Support: Yes

n — Number of times to repeat each element

scalar | vector

Number of times to repeat each element, specified as a scalar or a vector. If `n` is a scalar, then all elements of `v` are repeated `n` times. If `n` is a vector, then each element of `n` specifies the number of times to repeat the corresponding element of `v`. In either case, `n` must be integer-valued.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

A — Input array

matrix | multidimensional array

Input array, specified as a matrix or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`
Complex Number Support: Yes

`r1,...,rN` — Repetition factors for each dimension (as separate arguments)

scalars | vectors

Repetition factors for each dimension, specified as separate arguments of integer-valued scalars or vectors. If `A` is a table, each repetition factor must be a scalar.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`u` — Output vector

vector

Output vector. If `v` is a row vector or scalar, `u` is a row vector. If `v` is a column vector, `u` is also a column vector.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`

`B` — Output array

matrix | multidimensional array

Output array, returned as a matrix or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `datetime` | `duration`

See Also

`kron` | `repmat`

Introduced in R2015a

repmat

Repeat copies of array

Syntax

```
B = repmat(A,n)
B = repmat(A,r1,...,rN)
B = repmat(A,r)
```

Description

`B = repmat(A,n)` returns an array containing `n` copies of `A` in the row and column dimensions. The size of `B` is `size(A)*n` when `A` is a matrix.

`B = repmat(A,r1,...,rN)` specifies a list of scalars, `r1,..,rN`, that describes how copies of `A` are arranged in each dimension. When `A` has `N` dimensions, the size of `B` is `size(A).*[r1...rN]`. For example, `repmat([1 2; 3 4],2,3)` returns a 4-by-6 matrix.

`B = repmat(A,r)` specifies the repetition scheme with row vector `r`. For example, `repmat(A,[2 3])` returns the same result as `repmat(A,2,3)`.

Examples

Square Block Format

Repeat copies of a matrix into a 2-by-2 block arrangement.

```
A = diag([100 200 300])
```

```
A =

   100     0     0
     0   200     0
     0     0   300
```

```
B = repmat(A,2)

B =

   100     0     0   100     0     0
     0   200     0     0   200     0
     0     0   300     0     0   300
   100     0     0   100     0     0
     0   200     0     0   200     0
     0     0   300     0     0   300
```

Rectangular Block Format

Repeat copies of a matrix into a 2-by-3 block arrangement.

```
A = diag([100 200 300])

A =

   100     0     0
     0   200     0
     0     0   300

B = repmat(A,2,3)

B =

   100     0     0   100     0     0   100     0     0
     0   200     0     0   200     0     0   200     0
     0     0   300     0     0   300     0     0   300
   100     0     0   100     0     0   100     0     0
     0   200     0     0   200     0     0   200     0
     0     0   300     0     0   300     0     0   300
```

3-D Block Array

Repeat copies of a matrix into a 2-by-3-by-2 block arrangement.

```
A = [1 2; 3 4]
```

```
A =

     1     2
     3     4

B = repmat(A,[2 3 2])

B(:,:,1) =

     1     2     1     2     1     2
     3     4     3     4     3     4
     1     2     1     2     1     2
     3     4     3     4     3     4

B(:,:,2) =

     1     2     1     2     1     2
     3     4     3     4     3     4
     1     2     1     2     1     2
     3     4     3     4     3     4
```

Vertical Stack of Row Vectors

Vertically stack a row vector four times.

```
A = 1:4;
B = repmat(A,4,1)

B =

     1     2     3     4
     1     2     3     4
     1     2     3     4
     1     2     3     4
```

Horizontal Stack of Column Vectors

Horizontally stack a column vector four times.

```
A = (1:3)';
B = repmat(A,1,4)
```

```
B =

     1     1     1     1
     2     2     2     2
     3     3     3     3
```

Tabular Block Format

Create a table with variables `Age` and `Height`.

```
A = table([39; 26],[70; 63],'VariableNames',{'Age' 'Height'})
```

```
A =

    Age    Height
    ___    ______

    39     70
    26     63
```

Repeat copies of the table into a 2-by-3 block format.

```
B = repmat(A,2,3)
```

```
B =

    Age    Height    Age_1    Height_1    Age_2    Height_2
    ___    ______    _____    ________    _____    ________

    39     70        39       70          39       70
    26     63        26       63          26       63
    39     70        39       70          39       70
    26     63        26       63          26       63
```

`repmat` repeats the entries of the table and appends a number to the new variable names.

Input Arguments

`A` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`
Complex Number Support: Yes

`n` — Number of times to repeat input array in row and column dimensions

integer value

Number of times to repeat the input array in the row and column dimensions, specified as an integer value. If `n` is `0` or negative, the result is an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`r1,...,rN` — Repetition factors for each dimension (as separate arguments)

integer values

Repetition factors for each dimension, specified as separate arguments of integer values. If any repetition factor is `0` or negative, the result is an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`r` — Vector of repetition factors for each dimension (as a row vector)

integer values

Vector of repetition factors for each dimension, specified as a row vector of integer values. If any value in `r` is `0` or negative, the result is an empty array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

More About

Tips

- To build block arrays by forming the tensor product of the input with an array of ones, use `kron`. For example, to stack the row vector `A = 1:3` four times vertically, you can use `B = kron(A,ones(4,1))`.
- To create block arrays and perform a binary operation in a single pass, use `bsxfun`. In some cases, `bsxfun` provides a simpler and more memory efficient solution. For example, to add the vectors `A = 1:5` and `B = (1:10)'` to produce a 10-by-5 array, use `bsxfun(@plus,A,B)` instead of `repmat(A,10,1) + repmat(B,1,5)`.
- When `A` is a scalar of a certain type, you can use other functions to get the same result as `repmat`.

repmat Syntax	Equivalent Alternative
`repmat(NaN,m,n)`	`NaN(m,n)`
`repmat(single(inf),m,n)`	`inf(m,n,'single')`
`repmat(int8(0),m,n)`	`zeros(m,n,'int8')`
`repmat(uint32(1),m,n)`	`ones(m,n,'uint32')`
`repmat(eps,m,n)`	`eps(ones(m,n))`

Introduced before R2006a

resample (tscollection)

Select or interpolate data in `tscollection` using new time vector

Syntax

```
tsc = resample(tsc,Time)
tsc = resample(tsc,Time,interp_method)
tsc = resample(tsc,Time,interp_method,code)
```

Description

`tsc = resample(tsc,Time)` resamples the `tscollection` object tsc on the new Time vector. When `tsc` uses date strings and Time is numeric, Time is treated as numerical specified relative to the `tsc.TimeInfo.StartDate` property and in the same units that tsc uses. The `resample` method uses the default interpolation method for each time series member.

`tsc = resample(tsc,Time,interp_method)` resamples the `tscollection` object tsc using the interpolation method given by the string interp_method. Valid interpolation methods include `'linear'` and `'zoh'` (zero-order hold).

`tsc = resample(tsc,Time,interp_method,code)` resamples the `tscollection` object tsc using the interpolation method given by the string interp_method. The integer code is a user-defined quality code for resampling, applied to all samples.

Examples

The following example shows how to resample a `tscollection` that consists of two `timeseries` members.

1. Create two `timeseries` objects.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

2. Create a `tscollection` `tsc`.

```
tsc=tscollection({ts1 ts2});
```

The time vector of the collection `tsc` is [1:5], which is the same as for `ts1` and `ts2` (individually).

3 Get the interpolation method for `acceleration` by typing

```
tsc.acceleration
```

MATLAB responds with

```
Time Series Object: acceleration

Time vector characteristics

      Length               5
      Start time           1 seconds
      End time             5 seconds

Data characteristics

      Interpolation method  linear
      Size                  [1  1  5]
      Data type             double
```

4 Set the interpolation method for `speed` to zero-order hold by typing

```
setinterpmethod(tsc.speed,'zoh')
```

MATLAB responds with

```
Time Series Object: acceleration

Time vector characteristics

      Length               5
      Start time           1 seconds
      End time             5 seconds

Data characteristics

      Interpolation method  zoh
      Size                  [1  1  5]
```

```
        Data type              double
```

5 Resample the time-series collection `tsc` by individually resampling each time-series member of the collection and using its interpolation method.

```
res_tsc=resample(tsc,[1 1.5 3.5 4.5 4.9])
```

`getinterpmethod` | `setinterpmethod` | `tscollection`

Introduced before R2006a

reset

Reset graphics object properties to their defaults

Syntax

```
reset(h)
```

Description

`reset(h)` resets all properties on the object identified by `h` to their default values. Properties that do not have default values are not affected.

If `h` is a figure, the MATLAB software does not reset `Position`, `Units`, `WindowStyle`, or `PaperUnits`. If `h` is an `axes`, MATLAB does not reset `Position` and `Units`.

Examples

`reset(gca)` resets the properties of the current axes.

`reset(gcf)` resets the properties of the current figure.

`cla` | `clf` | `gca` | `gcf` | `hold`

Introduced before R2006a

reset (RandStream)

Reset random number stream

Class

`RandStream`

Syntax

```
reset(s)
reset(s,seed)
```

Description

`reset(s)` resets the generator for the random stream, `s`, to the internal state corresponding to its seed. This is similar to clearing `s` and recreating it using `RandStream(Type,...)`, except that `reset` does not set the stream's `NormalTransform`, `Antithetic`, and `FullPrecision` properties to their original values.

`reset(s,seed)` resets the generator for the random stream, `s`, to the internal state corresponding to `seed` (the seed value), and it updates the `seed` property of `s`. The value of `seed` must be an integer between 0 and $2^{32} - 1$. Resetting a stream's seed can invalidate independence with other streams.

Note: Resetting a stream should be used primarily for reproducing results.

Examples

Example 1

Reset a random number stream to its initial state. This does not create a random number stream, it simply resets the stream:

```
stream = RandStream('twister','Seed',0)

stream =

mt19937ar random stream
             Seed: 0
  NormalTransform: Ziggurat

reset(stream);
stream.Seed

ans =

           0
```

Example 2

Reset a random number stream using a specific seed:

```
stream = RandStream('twister','Seed',0)

stream =

mt19937ar random stream
             Seed: 0
  NormalTransform: Ziggurat

reset(stream,1);
stream.Seed

ans =

           1
```

See Also

RandStream | RandStream.getGlobalStream

reshape

Reshape array

Syntax

```
B = reshape(A,sz)
B = reshape(A,sz1,...,szN)
```

Description

`B = reshape(A,sz)` reshapes `A` using the size vector, `sz`, to define `size(B)`. For example, `reshape(A,[2,3])` reshapes `A` into a 2-by-3 matrix. `sz` must contain at least 2 elements, and `prod(sz)` must be the same as `numel(A)`.

`B = reshape(A,sz1,...,szN)` reshapes `A` into a `sz1`-by-`...`-by-`szN` array where `sz1,...,szN` indicates the size of each dimension. You can specify a single dimension size of `[]` to have the dimension size automatically calculated, such that the number of elements in `B` matches the number of elements in `A`. For example, if `A` is a 10-by-10 matrix, then `reshape(A,2,2,[])` reshapes the 100 elements of `A` into a 2-by-2-by-25 array.

Examples

Reshape Vector into Matrix

Reshape a 1-by-10 vector into a 5-by-2 matrix.

```
A = 1:10;
B = reshape(A,[5,2])
```

```
B =

     1     6
     2     7
     3     8
```

```
     4     9
     5    10
```

Reshape Matrix to Have Specified Number of Columns

Reshape a 6-by-6 magic square matrix into a matrix that has only 3 columns. Specify `[]` for the first dimension size to let `reshape` automatically calculate the appropriate number of rows.

```
A = magic(6);
B = reshape(A,[],3)

B =

    35     6    19
     3     7    23
    31     2    27
     8    33    10
    30    34    14
     4    29    18
     1    26    24
    32    21    25
     9    22    20
    28    17    15
     5    12    16
    36    13    11
```

The result is a 12-by-3 matrix, which maintains the same number of elements (36) as the original 6-by-6 matrix. The elements in `B` also maintain their columnwise order from `A`.

Reshape Multidimensional Array into Matrix

Reshape a 3-by-2-by-3 array of zeros into a 9-by-2 matrix.

```
A = zeros(3,2,3);
B = reshape(A,9,2)

B =

     0     0
     0     0
     0     0
     0     0
     0     0
```

```
     0     0
     0     0
     0     0
     0     0
```

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell` | `datetime` | `duration` | `calendarDuration`
Complex Number Support: Yes

sz — Output size

row vector of integers

Output size, specified as a row vector of integers. Each element of `sz` indicates the size of the corresponding dimension in `B`. You must specify `sz` so that the number of elements in `A` and `B` are the same. That is, `prod(sz)` must be the same as `numel(A)`.

Beyond the second dimension, the output, `B`, does not reflect trailing dimensions with a size of `1`. For example, `reshape(A,[3,2,1,1])` produces a 3-by-2 matrix.

Example: `reshape(A,[3,2])`

Example: `reshape(A,[6,4,10])`

Example: `reshape(A,[5,5,5,5])`

sz1,...,szN — Size of each dimension

two or more integers | `[]` (optional)

Size of each dimension, specified as two or more integers with at most one `[]` (optional). You must specify at least 2 dimension sizes, and at most one dimension size can be specified as `[]`, which automatically calculates the size of that dimension to ensure that `numel(B)` matches `numel(A)`. When you use `[]` to automatically calculate a dimension size, the dimensions that you *do* explicitly specify must divide evenly into the number of elements in the input matrix, `numel(A)`.

Beyond the second dimension, the output, `B`, does not reflect trailing dimensions with a size of `1`. For example, `reshape(A,3,2,1,1)` produces a 3-by-2 matrix.

Example: `reshape(A,3,2)`

Example: `reshape(A,6,[],10)`

Example: `reshape(A,2,5,3,[])`

Example: `reshape(A,5,5,5,5)`

Output Arguments

`B` — Reshaped array

vector | matrix | multidimensional array | cell array

Reshaped array, returned as a vector, matrix, multidimensional array, or cell array. The data type and number of elements in `B` are the same as the data type and number of elements in `A`. The elements in `B` preserve their columnwise ordering from `A`.

See Also

`colon (:)` | `permute` | `repmat` | `shiftdim` | `squeeze`

Introduced before R2006a

residue

Convert between partial fraction expansion and ratio of two polynomials

Syntax

```
[r,p,k] = residue(b,a)
[b,a] = residue(r,p,k)
```

Description

`[r,p,k] = residue(b,a)` finds the residues, poles, and direct term of a "Partial Fraction Expansion" on page 1-7080 of the ratio of two polynomials, where the expansion is of the form

$$\frac{b(s)}{a(s)} = \frac{b_1 s^m + b_2 s^{m-1} + b_3 s^{m-2} + \ldots + b_{m+1}}{a_1 s^n + a_2 s^{n-1} + a_3 s^{n-2} + \ldots + a_{n+1}}$$

The inputs to `residue` are vectors of coefficients of the polynomials `b = [bn ... b1 b0]` and `a = [am ... a1 a0]`. The outputs are the residues `r = [rm ... r2 r1]`, the poles `p = [pm ... p2 p1]`, and the polynomial k. For most textbook problems, k is `0` or a constant.

`[b,a] = residue(r,p,k)` converts the partial fraction expansion back to the ratio of two polynomials and returns the coefficients in `b` and `a`.

Examples

Find Partial Fraction Expansion

Find the partial fraction expansion of the following ratio of polynomials *F*(*s*) using `residue`

$$F(s) = \frac{b(s)}{a(s)} = \frac{5s^3 + 3s^2 - 2s + 7}{-4s^3 + 8s + 3}.$$

```
b = [ 5 3 -2 7];
a = [-4 0 8 3];
[r,p,k] = residue(b,a)
```

```
r =

   -1.4167
   -0.6653
    1.3320

p =

    1.5737
   -1.1644
   -0.4093

k =

   -1.2500
```

This represents the partial fraction expansion

$$F(s) = \frac{b(s)}{a(s)} = \frac{-1.4167}{s - 1.5737} - \frac{0.6653}{s + 1.1644} + \frac{1.3320}{s + 0.4093} - 1.2500.$$

Convert the partial fraction expansion back to polynomial coefficients using `residue`.

```
[b,a] = residue(r,p,k)
```

```
b =

   -1.2500   -0.7500    0.5000   -1.7500

a =

    1.0000   -0.0000   -2.0000   -0.7500
```

The result is normalized for the leading coefficient in the denominator and represents

$$F(s) = \frac{b(s)}{a(s)} = \frac{-1.25s^3 - 0.75s^2 + 0.50s - 1.75}{s^3 - 2s - 0.75}.$$

Expansion with Numerator Degree Greater Than Denominator Degree

The ratio of polynomials *F*(*s*) and its partial fraction expansion is

$$F(s) = \frac{b(s)}{a(s)} = \frac{2s^4 + s}{s^2 + 1} = \frac{0.5 - 1i}{s - 1i} + \frac{0.5 + 1i}{s + 1i} + 2s^2 - 2.$$

Find the partial fraction expansion of *F*(*s*) using `residue`. When the degree of the numerator is greater than the degree of the denominator, output `k` is a vector that represents the coefficients of a polynomial in *s*.

```
b = [2 0 0 1 0];
a = [1 0 1];
[r,p,k] = residue(b,a)
```

```
r =

   0.5000 - 1.0000i
   0.5000 + 1.0000i

p =

   0.0000 + 1.0000i
   0.0000 - 1.0000i

k =

     2     0    -2
```

`k` represents the polynomial $2s^2 - 2$.

- "Partial Fraction Expansion"

Input Arguments

b — Coefficients of numerator polynomial

vector of numbers

Coefficients of the polynomial in the numerator, specified as a vector of numbers representing the coefficients of the polynomial in descending powers of *s*.

Data Types: `single | double`
Complex Number Support: Yes

a — Coefficients of denominator polynomial

vector of numbers

Coefficients of the polynomial in the denominator, specified as a vector of numbers representing the coefficients of the polynomial in descending powers of *s*.

Data Types: `single | double`
Complex Number Support: Yes

Output Arguments

r — Residues of partial fraction expansion

column vector of numbers

Residues of partial fraction expansion, returned as a column vector of numbers.

p — Poles of partial fraction expansion

column vector of numbers

Poles of partial fraction expansion, returned as a column vector of numbers.

k — Direct term

row vector of numbers

Direct term, returned as a row vector of numbers that specify the coefficients of the polynomial in descending powers of *s*.

More About

Partial Fraction Expansion

Consider the fraction $F(s)$ of two polynomials b and a of degree n and m, respectively

$$F(s) = \frac{b(s)}{a(s)} = \frac{b_n s^n + \ldots + b_2 s^2 + b_1 s + b_0}{a_m s^m + \ldots + a_2 s^2 + a_1 s + a_0}.$$

The fraction $F(s)$ can be represented as a sum of simple fractions

$$\frac{b(s)}{a(s)} = \frac{r_1}{s - p_1} + \frac{r_2}{s - p_2} + \ldots + \frac{r_n}{s - p_n} + k(s)$$

This sum is called the partial fraction expansion of F. The values $r_m,\ldots,r_1$ are the residues, the values $p_m,\ldots,p_1$ are the poles, and $k(s)$ is a polynomial in s. For most textbook problems, $k(s)$ is 0 or a constant.

The number of poles `n` is

```
n = length(a)-1 = length(r) = length(p)
```

The direct term vector is empty if `length(b) < length(a)`; otherwise

```
length(k) = length(b)-length(a)+1
```

If `p(i) = ... = p(i+j-1)` is a pole of multiplicity `j`, then the expansion includes terms of the form

$$\frac{r_j}{s - p_j} + \frac{r_{j+1}}{(s - p_j)^2} + \ldots + \frac{r_{j+m-1}}{(s - p_j)^m}.$$

Algorithms

`residue` first obtains the poles using `roots`. Next, if the fraction is nonproper, the direct term `k` is found using `deconv`, which performs polynomial long division. Finally, `residue` determines the residues by evaluating the polynomial with individual roots removed. For repeated roots, `resi2` computes the residues at the repeated root locations.

Numerically, the partial fraction expansion of a ratio of polynomials represents an ill-posed problem. If the denominator polynomial, $a(s)$, is near a polynomial with multiple roots, then small changes in the data, including roundoff errors, can result in arbitrarily large changes in the resulting poles and residues. Problem formulations making use of state-space or zero-pole representations are preferable.

Introduced before R2006a

restoredefaultpath

Restore search path to its factory-installed state

Alternatives

As an alternative to the `restoredefaultpath` function, use the `rmpath` function or use the `pathtool` function to open the Set Path dialog box.

Syntax

```
restoredefaultpath
```

Description

`restoredefaultpath` restores the MATLAB search path to its factory-installed state.

Note: `restoredefaultpath` is intended only for situations where MATLAB is experiencing startup problems due to a corrupt search path. For general search-path cleanup, use the `rmpath` function or the Set Path dialog box.

If MATLAB fails to initialize properly on startup, then call both `restoredefaultpath` and `matlabrc`. For more details, see "Path Unsuccessfully Set at Startup".

MATLAB does not support issuing `restoredefaultpath` from a UNC path name. Doing so might result in MATLAB being unable to find files on the search path. If you do use `restoredefaultpath` from a UNC path name, restore the expected behavior by changing the current folder to an absolute path, and then reissuing the `restoredefaultpath` command.

More About

- "Path Unsuccessfully Set at Startup"

- “What Is the MATLAB Search Path?”

`rmpath` | `pathtool` | `addpath` | `genpath` | `matlabrc` | `savepath`

Introduced before R2006a

rethrow

Reissue error

Note: As of version 7.5, MATLAB supports error handling that is based on the `MException` class. Calling `rethrow` with a structure argument, as described on this page, is now replaced by calling rethrow with an `MException` object, as described on the reference page for `MException.rethrow`. `rethrow` called with a structure input will be removed in a future version.

Syntax

```
rethrow(errorStruct)
```

Description

`rethrow(errorStruct)` reissues the error specified by `errorStruct`. The currently running function terminates and control returns to the keyboard (or to any enclosing `catch` block). The `errorStruct` argument must be a MATLAB structure containing at least the `message` and `identifier` fields:

Fieldname	Description
`message`	Text of the error message
`identifier`	Message identifier of the error message
`stack`	Information about the error from the program stack

See "Message Identifiers" in the MATLAB documentation for more information on the syntax and usage of message identifiers.

Examples

`rethrow` is usually used in conjunction with `try, catch` statements to reissue an error from a `catch` block after performing `catch`-related operations. For example,

```
try
   do_something
catch
   do_cleanup
   rethrow(previous_error)
end
```

More About

Tips

The `errorStruct` input can contain the field `stack`, identical in format to the output of the `dbstack` command. If the `stack` field is present, the stack of the rethrown error will be set to that value. Otherwise, the stack will be set to the line at which the rethrow occurs.

`MException.rethrow` | `MException.throwAsCaller` | `MException.throw` | `MException` | `assert` | `error` | `try, catch`

Introduced before R2006a

return

Return control to invoking function

Syntax

```
return
```

Description

`return` forces MATLAB to return control to the invoking function before it reaches the end of the function. The invoking function is the function that calls the script or function containing the call to `return`. If you call the function or script that contains `return` directly, there is no invoking function and MATLAB returns control to the command prompt.

Note: Be careful when you use `return` within conditional blocks, such as `if` or `switch`, or within loop control statements, such as `for` or `while`. When MATLAB reaches a `return` statement, it does not just exit the loop; it exits the script or function and returns control to the invoking function or command prompt.

Examples

Return Control to Keyboard

In your current working folder, create a function, `findSqrRootIndex`, to find the index of the first occurrence of the square root of a value within an array. If the square root isn't found, the function returns `NaN`.

```
function idx = findSqrRootIndex(target,arrayToSearch)

idx = NaN;
if target < 0
   return
```

```
end

for idx = 1:length(arrayToSearch)
    if arrayToSearch(idx) == sqrt(target)
        return
    end
end
```

At the command prompt, call the function.

```
A = [3 7 28 14 42 9 0];
b = 81;
findSqrRootIndex(b,A)

ans =

     6
```

When MATLAB encounters the `return` statement, it returns control to the keyboard because there is no invoking function.

Return Control to Invoking Function

In a file, `myFunction.m`, in your current working folder, create the following function to find the index of the first occurrence of the square root of a value within an array. This function calls the `findSqrRootIndex` function you created in the previous example.

```
function myFunction(target)

arrayToSearch = [3 7 28 14 42 9 0];
idx = findSqrRootIndex(target,arrayToSearch);

if isnan(idx)
    disp('Square root not found.')
else
    disp(['Square root found at index ' num2str(idx)])
end
```

At the command prompt, call the function.

```
myFunction(49)

Square root found at index 2
```

When MATLAB encounters the `return` statement within `findSqrRootIndex`, it returns control to the invoking function, `myFunction`, and displays the relevant message.

Introduced before R2006a

rewriteDirectory

Class: Tiff

Write modified metadata to existing IFD

Syntax

```
rewriteDirectory(tiffobj)
```

Description

`rewriteDirectory(tiffobj)` writes modified metadata (tag) data to an existing directory. Use this tag when you want to change the value of a tag in an existing image file directory.

Examples

Modify Value of Tag

Write a sample TIFF file, `mytif.tif`. Create a TIFF object associated with this file.

```
imdata = peaks(256);
imwrite(imdata,'mytif.tif');
t = Tiff('mytif.tif','r+');
```

Modify the value of a tag.

```
setTag(t,'Software','MATLAB')
rewriteDirectory(t)
close(t);
```

References

This method corresponds to the `TIFFRewriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

`Tiff.writeDirectory`

rgb2gray

Convert RGB image or colormap to grayscale

Syntax

```
I = rgb2gray(RGB)
newmap = rgb2gray(map)
```

Description

`I = rgb2gray(RGB)` converts the truecolor image RGB to the grayscale intensity image I. The `rgb2gray` function converts RGB images to grayscale by eliminating the hue and saturation information while retaining the luminance. If you have Parallel Computing Toolbox installed, `rgb2gray` can perform this conversion on a GPU.

`newmap = rgb2gray(map)` returns a grayscale colormap equivalent to map.

Examples

Convert RGB Image to Grayscale Image

Read and display an RGB image, and then convert it to grayscale.

Read the sample file, `peppers.png`, and display the RGB image.

```
RGB = imread('peppers.png');
imshow(RGB)
```

Convert the RGB image to a grayscale image and display it.

```
I = rgb2gray(RGB);
figure
imshow(I)
```

Convert RGB Colormap to Grayscale Colormap

Read an indexed image with an RGB colormap. Then, convert the colormap to grayscale.

Read the sample file, `corn.tif`, which is an indexed image with an RGB colormap.

```
[X,map] = imread('corn.tif');
```

Display the image.

```
imshow(X,map)
```

Convert the RGB colormap to a grayscale colormap and redisplay the image.

```
newmap = rgb2gray(map);
imshow(X,newmap)
```

Input Arguments

RGB — Truecolor image

3-D numeric array

Truecolor image, specified as 3-D numeric array.

If you have Parallel Computing Toolbox installed, RGB can also be a gpuArray.

Data Types: `single` | `double` | `uint8` | `uint16`

`map` — Colormap
m-by-3 numeric array

Colormap, specified as an *m*-by-3 numeric array.

If you have Parallel Computing Toolbox installed, map can also be a gpuArray.

Data Types: `double`

Output Arguments

`I` — grayscale image
numeric array

Grayscale image, returned as a numeric array.

If you have Parallel Computing Toolbox installed, then I can also be a gpuArray.

`newmap` — grayscale color map
m-by-3 numeric array

Grayscale colormap, returned as an *m*-by-3 numeric array.

If you have Parallel Computing Toolbox installed, then newmap can also be a gpuArray.

More About

Tips

- `rgb2gray` supports the generation of C code using MATLAB Coder.

Algorithms

`rgb2gray` converts RGB values to grayscale values by forming a weighted sum of the *R*, *G*, and *B* components:

```
0.2989 * R + 0.5870 * G + 0.1140 * B
```

These are the same weights used by the `rgb2ntsc` function to compute the *Y* component.

See Also

`ind2gray` | `mat2gray` | `ntsc2rgb` | `rgb2ind` | `rgb2ntsc`

rgb2hsv

Convert RGB colormap to HSV colormap

Syntax

```
cmap = rgb2hsv(M)
hsv_image = rgb2hsv(rgb_image)
```

Description

`cmap = rgb2hsv(M)` converts an RGB colormap `M` to an HSV colormap `cmap`. Both colormaps are *m*-by-3 matrices. The elements of both colormaps are in the range 0 to 1.

The columns of the input matrix `M` represent intensities of red, green, and blue, respectively. The columns of the output matrix `cmap` represent hue, saturation, and value, respectively.

`hsv_image = rgb2hsv(rgb_image)` converts the RGB image to the equivalent HSV image. RGB is an m-by-n-by-3 image array whose three planes contain the red, green, and blue components for the image. HSV is returned as an m-by-n-by-3 image array whose three planes contain the hue, saturation, and value components for the image.

See Also

`brighten` | `colormap` | `hsv2rgb` | `rgbplot`

Introduced before R2006a

rgb2ind

Convert RGB image to indexed image

Syntax

```
[X,map] = rgb2ind(RGB,n)
X = rgb2ind(RGB, map)
[X,map] = rgb2ind(RGB, tol)
[ ___ ] = rgb2ind( ___ ,dither_option)
```

Description

`[X,map] = rgb2ind(RGB,n)` converts the RGB image to an indexed image `X` using minimum variance quantization and dithering. `map` contains at most `n` colors. `n` must be less than or equal to 65,536.

`X = rgb2ind(RGB, map)` converts the RGB image to an indexed image `X` with colormap `map` using the inverse colormap algorithm and dithering. `size(map,1)` must be less than or equal to 65,536.

`[X,map] = rgb2ind(RGB, tol)` converts the RGB image to an indexed image `X` using uniform quantization and dithering. `map` contains at most `(floor(1/tol)+1)^3` colors. `tol` must be between 0.0 and 1.0.

`[ ___ ] = rgb2ind( ___ ,dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

`'dither'` (default)	Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution
`'nodither'`	Maps each color in the original image to the closest color in the new map. No dithering is performed.

Note The values in the resultant image `X` are indexes into the colormap `map` and should not be used in mathematical processing, such as filtering operations.

Class Support

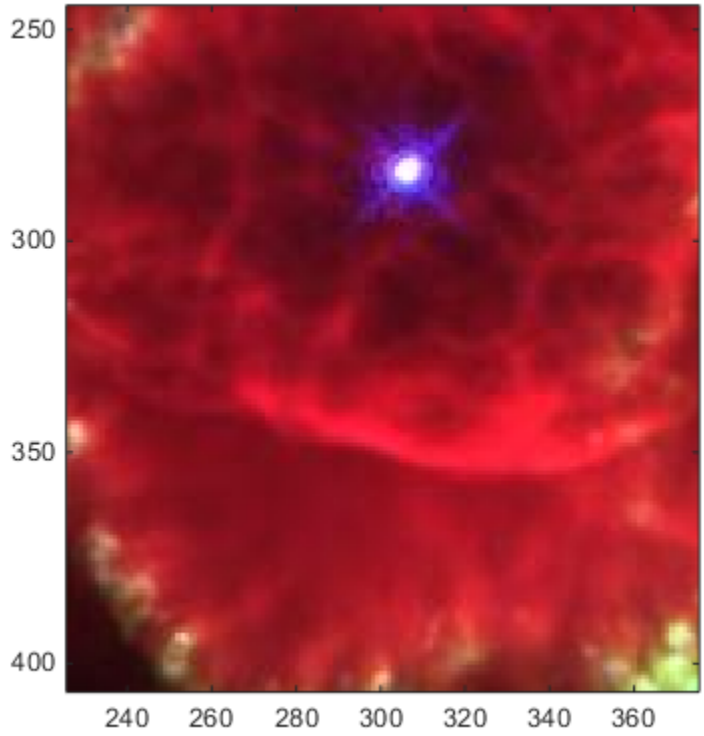
The input image can be of class `uint8`, `uint16`, `single`, or `double`. If the length of `map` is less than or equal to 256, the output image is of class `uint8`. Otherwise, the output image is of class `uint16`.

The value `0` in the output array `X` corresponds to the first color in the colormap.

Examples

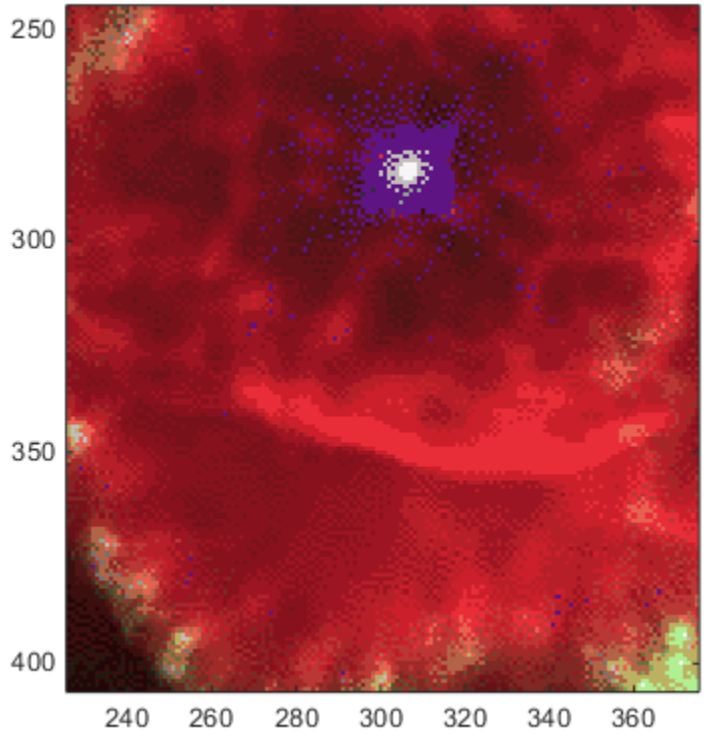
Read and display a truecolor `uint8` JPEG image of a nebula.

```
RGB = imread('ngc6543a.jpg');
figure('Name','RGB Image')
imagesc(RGB)
axis image
zoom(4)
```



Convert RGB to an indexed image with 32 colors

```
[IND,map] = rgb2ind(RGB,32);
figure('Name','Indexed image with 32 Colors')
imagesc(IND)
colormap(map)
axis image
zoom(4)
```



More About

Tips

- If you specify `tol`, `rgb2ind` uses uniform quantization to convert the image. This method involves cutting the RGB color cube into smaller cubes of length `tol`.
- If you specify `n`, `rgb2ind` uses minimum variance quantization. This method involves cutting the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number you specify, the output colormap is also smaller.

- If you specify `map`, `rgb2ind` uses colormap mapping, which involves finding the colors in `map` that best match the colors in the RGB image.

Algorithms

- **Uniform Quantization** — Uniform quantization cuts the RGB color cube into smaller cubes of length `tol`. For example, if you specify a `tol` of 0.1, the edges of the cubes are one-tenth the length of the RGB cube. The total number of small cubes is:

  ```
  n = (floor(1/tol)+1)^3
  ```

  Each cube represents a single color in the output image. Therefore, the maximum length of the colormap is `n`. `rgb2ind` removes any colors that don't appear in the input image, so the actual colormap can be much smaller than `n`.
- **Minimum Variance Quantization** — Minimum variance quantization cuts the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number specified, the output colormap is also smaller.
- **Inverse Colormap** — The inverse colormap algorithm quantizes the specified colormap into 32 distinct levels per color component. Then, for each pixel in the input image, the closest color in the quantized colormap is found.

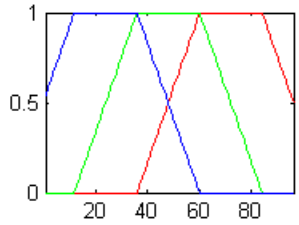
rgbplot

Plot colormap



Syntax

```
rgbplot(cmap)
```

Description

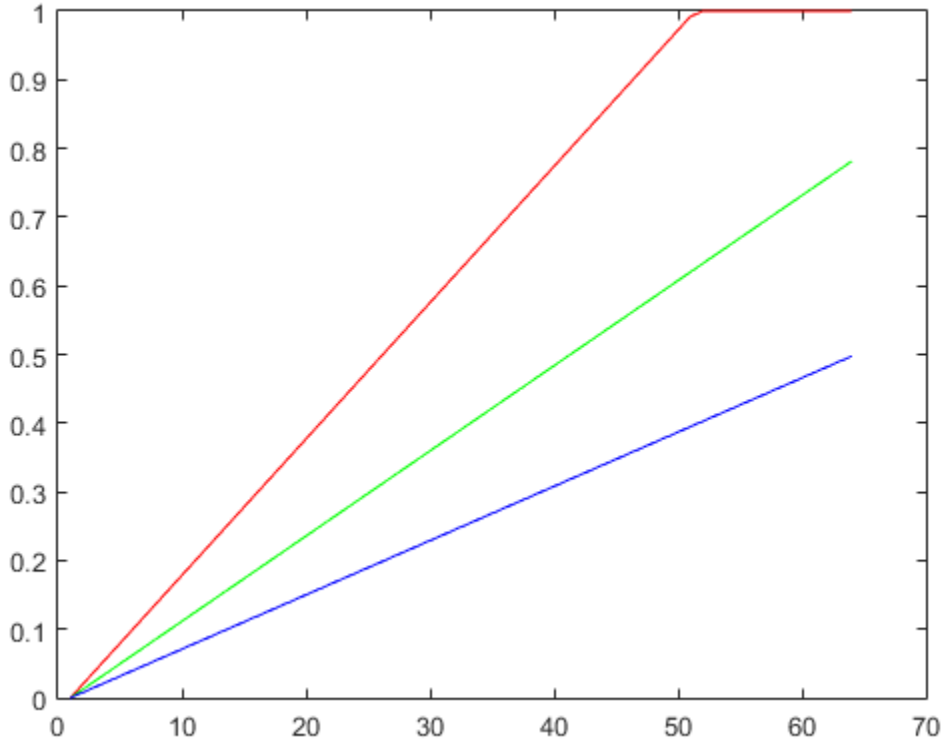
`rgbplot(cmap)` plots the three columns of `cmap`, where `cmap` is an *m*-by-3 colormap matrix. `rgbplot` draws the first column in red, the second in green, and the third in blue.

Examples

Copper Colormap

Plot the RGB values of the `copper` colormap.

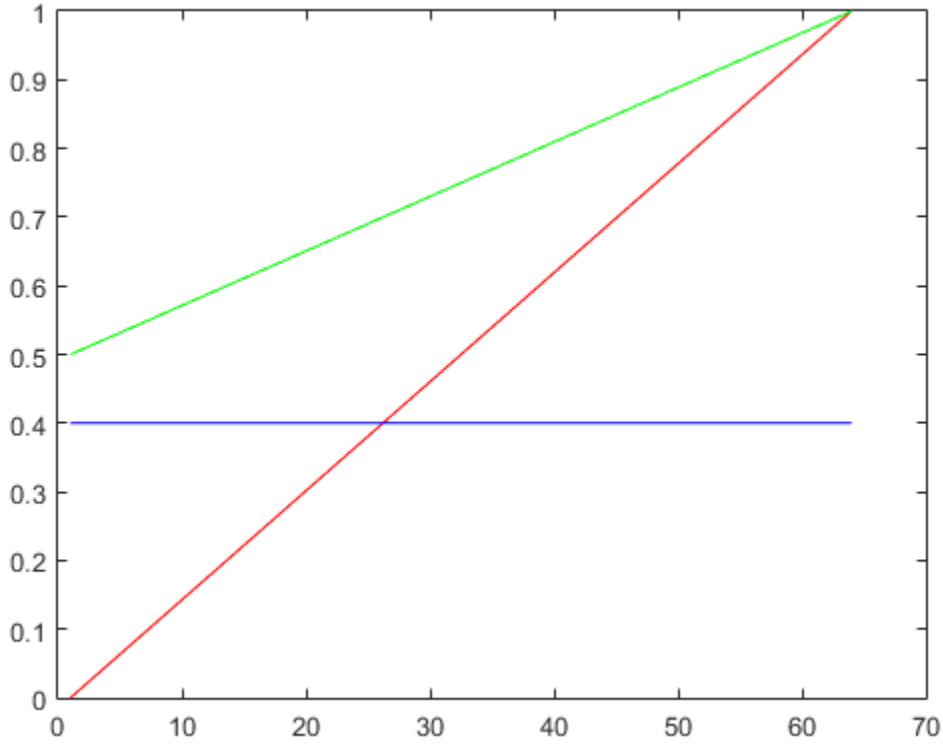
```
rgbplot(copper)
```



Summer Colormap

Plot the RGB values of the `summer` colormap.

```
rgbplot(summer)
```



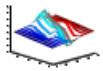
See Also

`colormap`

Introduced before R2006a

ribbon

Ribbon plot



Syntax

```
ribbon(Y)
ribbon(X,Y)
ribbon(X,Y,width)
ribbon(axes_handle,...)
h = ribbon(...)
```

Description

`ribbon(Y)` plots the columns of `Y` as three-dimensional ribbons of uniform width using `X = 1:size(Y,1)`. Ribbons advance along the *x*-axis centered on tick marks at unit intervals, three-quarters of a unit in width. Ribbon maps values in `X` to colors in colormap linearly. To change ribbon colors in the graph, change the `colormap`.

`ribbon(X,Y)` plots three dimensional ribbons for data in `Y`, centered at locations specified in `X`. `X` and `Y` are vectors or matrices of the same size. Additionally, `X` can be a row or a column vector, and `Y` a matrix with `length(X)` rows. When `Y` is a matrix, `ribbon` plots each column in `Y` as a ribbon at the corresponding `X` location.

`ribbon(X,Y,width)` specifies the width of the ribbons. The default is `0.75`. If `width = 1`, the ribbons touch, leaving no space between them when viewed down the *z*-axis. If `width > 1`, ribbons overlap and can intersect.

`ribbon(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ribbon(...)` returns a vector of handles to surface graphics objects. `ribbon` returns one handle per strip.

Examples

Ribbon Plot

Create a ribbon plot of the `peaks` function.

```
[x,y] = meshgrid(-3:.5:3,-3:.1:3);
z = peaks(x,y);

figure
ribbon(y,z)
```

`plot` | `plot3` | `surface` | `waterfall`

Introduced before R2006a

rmappdata

Remove application-defined data

Syntax

```
rmappdata(h,name)
```

Description

`rmappdata(h,name)` removes the application-defined data, `name`, from its association with the UI component, `h`.

See Also

`getappdata` | `isappdata` | `setappdata`

Introduced before R2006a

rmdir

Remove folder

Syntax

```
rmdir(folderName)
rmdir(folderName,'s')
[status, message, messageid] = rmdir(folderName,'s')
```

Description

`rmdir(folderName)` removes the folder folderName from the current folder if folderName is empty. If folderName is not in the current folder, then specify the relative path or the full path for folderName.

`rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder. With the `'s'` option, `rmdir` attempts to remove all subfolders and files in folderName regardless of their write permissions.

`[status, message, messageid] = rmdir(folderName,'s')` removes the folder folderName and its contents from the current folder, returning the status, a message, and the MATLAB message ID.

Input Arguments

`folderName`

String specifying the absolute or relative path name of the folder you want to remove.

Default: None

`'s'`

Literal string that directs `rmdir` to remove all subfolders and files in the specified folder, regardless of their write permissions. The result for read-only files follows the practices of the operating system.

Default: `rmdir` does not remove subfolders and files in the specified folder.

Output Arguments

`status`

Logical scalar indicating the outcome of the `rmdir` operation. The status value is `1` if the operation was successful and `0` if it returned an error.

`message`

String containing the warning or error message text if the operation is unsuccessful. An empty string, if the operation is successful.

`messageid`

String containing the warning or error message ID, if the operation is unsuccessful. MATLAB returns an empty string if the operation is successful.

Examples

These examples remove an empty folder, `myfiles`, assuming it is in the current folder:

```
% Remove myfiles from the current folder:

rmdir('myfiles')

% Use the relative path to remove myfiles. Assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project, type this:

rmdir('project/myfiles')

% Use the full path to remove myfiles, assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project:

rmdir('d:/matlab/work/project/myfiles')
```

This example removes the `myfiles` folder and its contents, assuming `myfiles` is in the current folder:

```
rmdir('myfiles','s')
```

This example unsuccessfully attempts to remove the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess, id]=rmdir('myfiles')
```

MATLAB returns:

```
stat =
     0

mess =

No directories were removed.

id =

MATLAB:RMDIR:NoDirectoriesRemoved
```

This example successfully removes the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess]=rmdir('myfiles','s')
```

MATLAB returns:

```
stat =
     1

mess =

     ''
```

Alternatives

Open the Current Folder browser by running `filebrowser`. Then, in the Current Folder browser, right-click the folder name and select **Delete** from the context menu.

More About

Tips

- If you specify the `'s'` flag or include a wildcard in the folder name, MATLAB produces an error if it is unable to remove all folders. The error message lists the folder and files that MATLAB could not remove.

See Also

`| cd | copyfile | delete | dir | fileattrib | filebrowser | mkdir | movefile`

Introduced before R2006a

rmdir

Class: FTP

Remove folder on FTP server

Syntax

```
rmdir(ftpobj,folder)
```

Description

`rmdir(ftpobj,folder)` removes the specified folder from the current folder on an FTP server.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`folder`

String enclosed in single quotation marks that specifies the name of the folder to delete.

Examples

Remove the folder `temp` from the hypothetical FTP server `ftp.testsite.com`:

```
test = ftp('ftp.testsite.com');
rmdir(test, 'temp');
```

See Also

`delete` | `dir` | `mkdir` | `cd` | `ftp`

Introduced before R2006a

rmfield

Remove fields from structure

Syntax

```
s = rmfield(s,field)
```

Description

`s = rmfield(s,field)` removes the specified field or fields from structure array `s`. Specify multiple fields using a cell array of strings. The dimensions of `s` remain the same.

Examples

Remove Single Field

Define a scalar structure with fields named `a`, `b`, and `c`.

```
s.a = 1;
s.b = 2;
s.c = 3;
```

Remove field `b`.

```
field = 'b';
s = rmfield(s,field)
```

```
s =
    a: 1
    c: 3
```

Remove Multiple Fields

Define a scalar structure with fields `first`, `second`, `third`, and `fourth`.

```
S.first = 1;
S.second = 2;
```

```
S.third = 3;
S.fourth = 4;
```

Remove fields `first` and `fourth`.

```
fields = {'first','fourth'};
S = rmfield(S,fields)
```

```
S =
    second: 2
     third: 3
```

Input Arguments

s — Input structure

structure array

Input structure, specified as a structure array.

Data Types: `struct`

field — Field name or names

character array | cell array of strings

Field name or names, specified as a character array or a cell array of strings.

Example: `'f1'`

Example: `{'f1';'f2'}`

Data Types: `char` | `cell`

- "Generate Field Names from Variables"

See Also

`fieldnames` | `isfield` | `orderfields`

Introduced before R2006a

rmpath

Remove folders from search path

Syntax

```
rmpath(folderName)
```

Description

`rmpath(folderName)` removes the specified folder from the search path.

Examples

Remove Folder from Search Path

Remove `/usr/local/matlab/mytools` from the search path.

```
rmpath('/usr/local/matlab/mytools')
```

Input Arguments

`folderName` — Name of folder

string

Name of folder to remove from the search path, specified as a string. Use the full path name for `folderName`.

Example: `'c:\matlab\work'`

Example: `'/home/user/matlab'`

More About

- "What Is the MATLAB Search Path?"

See Also

`addpath` | `path` | `savepath`

Introduced before R2006a

rmpref

Remove preference

Syntax

```
rmpref('group','pref')
rmpref('group',{'pref1','pref2',...'prefn'})
rmpref('group')
```

Description

`rmpref('group','pref')` removes the preference specified by `group` and `pref`. It is an error to remove a preference that does not exist.

`rmpref('group',{'pref1','pref2',...'prefn'})` removes each preference specified in the cell array of preference names. It is an error if any of the preferences do not exist.

`rmpref('group')` removes all the preferences for the specified `group`. It is an error to remove a group that does not exist.

Examples

```
addpref('mytoolbox','version','1.0')
rmpref('mytoolbox')
```

`addpref` | `ispref` | `getpref` | `setpref` | `uigetpref` | `uisetpref`

Introduced before R2006a

rng

Control random number generation

Syntax

```
rng(seed)
rng('shuffle')
rng(seed, generator)
rng('shuffle', generator)
rng('default')
scurr = rng
rng(s)
sprev = rng(...)
```

Description

Note: To use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs, see the documentation on " Replace Discouraged Syntaxes of rand and randn".

`rng(seed)` seeds the random number generator using the nonnegative integer `seed` so that `rand`, `randi`, and `randn` produce a predictable sequence of numbers.

`rng('shuffle')` seeds the random number generator based on the current time. Thus, `rand`, `randi`, and `randn` produce a different sequence of numbers after each time you call `rng`.

`rng(seed, generator)` and `rng('shuffle', generator)` additionally specify the type of the random number generator used by `rand`, `randi`, and `randn`. The `generator` input is one of:

- `'twister'`: Mersenne Twister
- `'simdTwister'`: SIMD-oriented Fast Mersenne Twister
- `'combRecursive'`: Combined Multiple Recursive

- `'multFibonacci'`: Multiplicative Lagged Fibonacci
- `'v5uniform'`: Legacy MATLAB 5.0 uniform generator
- `'v5normal'`: Legacy MATLAB 5.0 normal generator
- `'v4'`: Legacy MATLAB 4.0 generator

`rng('default')` puts the settings of the random number generator used by `rand`, `randi`, and `randn` to their default values. This way, the same random numbers are produced as if you restarted MATLAB. The default settings are the Mersenne Twister with seed 0.

`scurr = rng` returns the current settings of the random number generator used by `rand`, `randi`, and `randn`. The settings are returned in a structure `scurr` with fields `'Type'`, `'Seed'`, and `'State'`.

`rng(s)` restores the settings of the random number generator used by `rand`, `randi`, and `randn` back to the values captured previously with a command such as `s = rng`.

`sprev = rng(...)` returns the previous settings of the random number generator used by `rand`, `randi`, and `randn` before changing the settings.

Examples

Example 1 — Retrieve and Restore Generator Settings

Save the current generator settings in `s`:

```
s = rng;
```

Call `rand` to generate a vector of random values:

```
x = rand(1,5)
```

```
x =

    0.8147    0.9058    0.1270    0.9134    0.6324
```

Restore the original generator settings by calling `rng`. Generate a new set of random values and verify that `x` and `y` are equal:

```
rng(s);
```

```
y = rand(1,5)

y =

    0.8147    0.9058    0.1270    0.9134    0.6324
```

Example 2 — Restore Settings for Legacy Generator

Use the legacy generator.

```
sprev = rng(0,'v5uniform')

sprev =
     Type: 'twister'
     Seed: 0
    State: [625x1 uint32]

x = rand

x =

    0.9501
```

Restore the previous settings by calling `rng`:

```
rng(sprev)
```

Root Properties

Graphics environment and state information

The root object is the root of the graphics object tree. Root properties contain information about the graphics environment and the current state of the graphics system. Starting in R2014b, you can use dot notation to refer to a particular object and property:

```
r = groot;
fig = r.Children;
```

If you are using an earlier release, use the `get` function to query property values.

Display Information

`MonitorPositions` — Width and height of displays

n-by-4 matrix

Width and height of displays, returned as an n-by-4 matrix, where n is the number of displays. Each row corresponds to one display and is a four-element vector of the form `[x y width height]`. For example, if there are two displays, then the matrix has this form:

```
[x1 y1 width1 height1
 x2 y2 width2 height2]
```

The first two elements in each row indicate the display location with respect to the origin point. The last two elements in each row indicate the display size. The origin point is the lower-left corner of the primary display. If the units are pixels, then the origin point is `(1,1)`. For all other units, the origin point is `(0,0)`. The `Units` property determines the units of this measurement.

Note: MATLAB sets the display information values for this property at startup. The values are static. If your system display settings change, the values do not update. To refresh the values, restart MATLAB.

`PointerLocation` — Current location of pointer

two-element vector

Current location of pointer, specified as a two-element vector of the form `[x y]`. The `x` and `y` values are the coordinates of the pointer position measured from the origin point. The origin point is the lower-left corner of the primary display. If the units are pixels, then the origin point is `(1,1)`. For all other units, the origin point is `(0,0)`. The `Units` property determines the units of this measurement.

This property contains the current pointer location, even if the pointer is outside a MATLAB window. Move the pointer by changing the values of this property. On Macintosh systems, you cannot change the pointer location by setting this property.

Querying the `PointerLocation` property in a callback routine might return a value that is different from the location of the pointer when the callback was triggered. This difference results from delays in callback execution caused by competition for system resources.

Example: `[500 400]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ScreenDepth` — Number of bits that define each pixel color

scalar

Number of bits that define each pixel color, specified as a scalar. The default value depends on the computer. The maximum number of simultaneously displayed colors on the current graphics device equals 2 raised to the value of this property.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ScreenPixelsPerInch` — Display resolution

scalar

Display resolution, specified as a scalar in pixels per inch. The default value depends on the computer. The value is the setting of the display resolution specified in your system preferences.

Example: `72`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ScreenSize` — Size of primary display

four-element vector

Size of primary display, returned as a four-element vector of the form `[left bottom width height]` that defines the display size. If the units are pixels, then the first two elements are both `1`. For all other units, the first two elements are both `0`. The last two elements are the display dimensions in units specified by the `Units` property.

The values might not represent the usable display size due to the presence of UIs, such as the Microsoft Windows task bar.

Note: MATLAB sets the display size values for this property at startup. The values are static. If your system display settings change, the display size values do not update. To refresh the values, restart MATLAB.

`FixedWidthFontName` — Font name for fixed-width font

string

Font name for fixed-width font, specified as a string giving the name of a system supported font. This property determines the font for axes, text, and uicontrols that have a `FontName` property set to `'FixedWidth'`. The default value depends on the system. `'Courier'` is the default in systems that use Latin-based characters.

Specifying the `FixedWidthFontName` property eliminates the need to hardcode font names in MATLAB applications. These applications can run without modification in systems that require non-ASCII character sets. In these cases, MATLAB attempts to set `FixedWidthFontName` property to the correct value for the system.

If you are a MATLAB application developer and want to use a fixed-width font, set the `FontName` property for axes, text, and uicontrol objects to `'FixedWidth'` instead of setting this root property. Users of the application can set the root property if they do not want to use the preselected value.

Example: `'Courier New'`

`Units` — Units for `MonitorPositions`, `ScreenSize`, and `PointerLocation`

`'pixels'` (default) | `'inches'` | `'centimeters'` | `'points'` | `'characters'` | `'normalized'`

Units for the `MonitorPositions`, `ScreenSize`, and `PointerLocation` properties, specified as one of the values shown in this table.

Units	Description
`'pixels'` (default)	Pixels. Pixel size depends on the display resolution.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'points'`	Points. One point equals 1/72 inch.
`'normalized'`	Normalized with respect to the display. The lower-left corner of the display maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.

All units are measured from the lower-left corner of the primary display. If the units are pixels, then the lower-left corner maps to `(1,1)`. For all other units, the lower-left corner maps to `(0,0)`.

If you change the units, it is good practice to return it to its default value after completing your operation to prevent affecting other functions that assume the `Units` property is set to the default value.

Identifiers

`CallbackObject` — Object whose callback is executing

`[ ]` (default) | graphics object

Object whose callback is executing, returned as a graphics object. For more information, see the `gcbo` command.

`CurrentFigure` — Current figure

empty `GraphicsPlaceholder` (default) | figure object

Current figure, specified as a figure object. The current figure is typically the one most recently created, clicked on, or made current by calling the `figure` function. Setting

this property makes a figure the current figure without sorting it to the front of other figures on the display. However, using the `figure` function to make a figure the current figure sorts that figure to the front of the display. To become the current figure, the `HandleVisibility` property of the figure must be set to `'on'`.

This property returns an empty `GraphicsPlaceholder` array if there are no figures. However, the `gcf` command always returns a figure object. If there are no figure objects, then `gcf` creates one.

`Type` — Type of graphics object

`'root'`

Type of graphics object, returned as the string `'root'`. The root object handle is always visible using the `groot` function.

`Tag` — Tag to associate with root

`''` (default)

Tag to associate with root, specified as a string. There is only one root object, which you can always access using the `groot` function.

`UserData` — Data to associate with root

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the root object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent

empty `GraphicsPlaceholder`

The root object has no parent. This property is always an empty `GraphicsPlaceholder`.

`Children` — Children

empty `GraphicsPlaceholder` | array of figure objects

Children, specified as an array of figure objects that have visible handles. The `HandleVisibility` property of the figure determines if the handle is visible or hidden. This property does not contain figures with hidden handles.

Change the order of the children to change the sorting order of the figures on the display.

`HandleVisibility` — Visibility of root object handle

`'on'` (default) | `'callback'` | `'off'`

This property has no effect. The root object handle is always visible using the `groot` function.

`ShowHiddenHandles` — Hidden handle display

`'off'` (default) | `'on'`

Hidden handle display, specified as one of these values:

- `'off'` — Do not display hidden object handles. The `HandleVisibility` property of the object determines if the handle is visible or hidden.
- `'on'` — Expose all object handles regardless of the `HandleVisibility` property.

roots

Polynomial roots

The `roots` function solves polynomial equations of the form $p_1x^n + ... + p_nx + p_{n+1} = 0$. Polynomial equations contain a single variable with nonnegative exponents. To find the roots of other types of equations, use `fzero`.

Syntax

```
r = roots(p)
```

Description

`r = roots(p)` returns the roots of the polynomial represented by `p` as a column vector.

`p` is a vector containing `n+1` polynomial coefficients, starting with the coefficient of x^n. A coefficient of `0` indicates an intermediate power that is not present in the equation. For example, `p = [3 2 -2]` represents the polynomial $3x^2 + 2x - 2$.

Examples

Roots of Quadratic Polynomial

Solve the equation $3x^2 - 2x - 4 = 0$.

Create a vector to represent the polynomial, then find the roots.

```
p = [3 -2 -4];
r = roots(p)
```

```
r =

    1.5352
   -0.8685
```

Roots of Quartic Polynomial

Solve the equation $x^4 - 1 = 0$.

Create a vector to represent the polynomial, then find the roots.

```
p = [1 0 0 0 -1];
r = roots(p)
```

```
r =

  -1.0000 + 0.0000i
   0.0000 + 1.0000i
   0.0000 - 1.0000i
   1.0000 + 0.0000i
```

Input Arguments

p — Polynomial coefficients

vector

Polynomial coefficients, specified as a vector. For example, the vector `[1 0 1]` represents the polynomial $x^2 + 1$, and the vector `[3.13 -2.21 5.99]` represents the polynomial $3.13x^2 - 2.21x + 5.99$.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

More About

Tips

- Use the `poly` function to obtain a polynomial from its roots: `p = poly(r)`. The `poly` function is the inverse of the `roots` function.

Algorithms

The `roots` function considers `p` to be a vector with `n+1` elements representing the `n`th degree characteristic polynomial of an `n`-by-`n` matrix, `A`. The roots of the polynomial are calculated by computing the eigenvalues of the companion matrix, `A`.

```
A = diag(ones(n-1,1),-1);
A(1,:) = -p(2:n+1)./p(1);
r = eig(A)
```

The results produced are the exact eigenvalues of a matrix within roundoff error of the companion matrix, `A`. However, this does not mean that they are the exact roots of a polynomial whose coefficients are within roundoff error of those in `p`.

`fzero` | `poly` | `residue`

Introduced before R2006a

rose

Angle histogram plot

Syntax

```
rose(theta)
rose(theta,x)
rose(theta,nbins)
rose(axes_handle,...)
h = rose(...)
[tout,rout] = rose(...)
```

Description

`rose(theta)` creates an angle histogram, which is a polar plot showing the distribution of values grouped according to their numeric range, showing the distribution of `theta` in 20 angle bins or less. The vector `theta`, expressed in radians, determines the angle of each bin from the origin. The length of each bin reflects the number of elements in `theta` that fall within a group, which ranges from 0 to the greatest number of elements deposited in any one bin.

`rose(theta,x)` uses the vector `x` to specify the number and the locations of bins. `length(x)` is the number of bins and the values of `x` specify the center angle of each bin. For example, if `x` is a five-element vector, `rose` distributes the elements of `theta` in five bins centered at the specified `x` values.

`rose(theta,nbins)` plots `nbins` equally spaced bins in the range `[0,2*pi]`. The default is `20`.

`rose(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = rose(...)` returns the handle of the line object used to create the graph.

`[tout,rout] = rose(...)` returns the vectors `tout` and `rout` so `polar(tout,rout)` generates the histogram for the data. This syntax does not generate a plot.

Examples

Create Rose Histogram

Load the `sunspot.dat` data set which contains the 2-column matrix `sunspot`. Store the second column of the data set as `theta`.

```
load sunspot.dat
theta = sunspot(:,2);
```

Create a rose histogram of `theta` using 12 bins.

```
figure
rose(theta,12)
```

`compass` | `feather` | `histogram` | `line` | `polar`

Introduced before R2006a

rosser

Classic symmetric eigenvalue test problem

Syntax

```
A = rosser
A = rosser(classname)
```

Description

`A = rosser` returns the Rosser matrix in double precision.

`A = rosser(classname)` returns the Rosser matrix with a class specified by classname. Specify classname as `'single'` to return the Rosser matrix in single precision.

Examples

Generate the Rosser matrix

`rosser` returns the Rosser matrix.

```
rosser
```

```
ans =
   611   196  -192   407    -8   -52   -49    29
   196   899   113  -192   -71   -43    -8   -44
  -192   113   899   196    61    49     8    52
   407  -192   196   611     8    44    59   -23
    -8   -71    61     8   411  -599   208   208
   -52   -43    49    44  -599   411   208   208
   -49    -8     8    59   208   208    99  -911
    29   -44    52   -23   208   208  -911    99
```

Generate matrix of class 'single'

Specify classname as `single` to return a Rosser matrix of that class.

```
Y = rosser('single')
whos('Y')
```

```
Y =

   611   196  -192   407    -8   -52   -49    29
   196   899   113  -192   -71   -43    -8   -44
  -192   113   899   196    61    49     8    52
   407  -192   196   611     8    44    59   -23
    -8   -71    61     8   411  -599   208   208
   -52   -43    49    44  -599   411   208   208
   -49    -8     8    59   208   208    99  -911
    29   -44    52   -23   208   208  -911    99

  Name      Size            Bytes  Class     Attributes

  Y         8x8               256  single
```

Input Arguments

`classname` — Input class

`'double'` (default) | `'single'`

Input class, specified as `'double'` (default) or `'single'`. `rosser(C)` produces a matrix of the specified class.

More About

Rosser Matrix

The Rosser matrix is a well known matrix used, for example, to evaluate eigenvalue algorithms. The matrix is 8-by-8 with integer elements. It has:

- A double eigenvalue
- Three nearly equal eigenvalues
- Dominant eigenvalues of the opposite sign
- A zero eigenvalue
- A small, nonzero eigenvalue

See Also

`eig`

Introduced before R2006a

rot90

Rotate array 90 degrees

Syntax

```
B = rot90(A)
B = rot90(A,k)
```

Description

`B = rot90(A)` rotates array `A` counterclockwise by 90 degrees. For multidimensional arrays, `rot90` rotates in the plane formed by the first and second dimensions.

`B = rot90(A,k)` rotates array `A` counterclockwise by `k*90` degrees, where `k` is an integer.

Examples

Rotate Column Vector

Create a column vector of sequential elements.

```
A = (1:5)'
```

```
A =

     1
     2
     3
     4
     5
```

Rotate `A` counterclockwise by 90 degrees using `rot90`.

```
B = rot90(A)
```

```
B =

     1     2     3     4     5
```

The result, B, has the same elements as A but a different orientation.

Rotate Multidimensional Array

Create a 3-by-3-by-2 cell array of strings.

```
A = cat(3,{'a' 'b' 'c';'d' 'e' 'f';'g' 'h' 'i'},{'j' 'k' 'l';'m' 'n' 'o';'p' 'q' 'r'})
```

```
A(:,:,1) =

    'a'    'b'    'c'
    'd'    'e'    'f'
    'g'    'h'    'i'

A(:,:,2) =

    'j'    'k'    'l'
    'm'    'n'    'o'
    'p'    'q'    'r'
```

Rotate the cell array by 270 degrees.

```
B = rot90(A,3)
```

```
B(:,:,1) =

    'g'    'd'    'a'
    'h'    'e'    'b'
    'i'    'f'    'c'

B(:,:,2) =

    'p'    'm'    'j'
    'q'    'n'    'k'
    'r'    'o'    'l'
```

The function rotates each page of the array independently. Since a full 360 degree rotation (`k = 4`) leaves the array unchanged, `rot90(A,3)` is equivalent to `rot90(A,-1)`.

Input Arguments

A — Input array

vector | matrix | array | cell array | categorical array

Input array, specified as a vector, matrix, array, cell array, or categorical array of any data type.
Complex Number Support: Yes

k — Rotation constant

integer

Rotation constant, specified as an integer. Specify `k` to rotate by `k*90` degrees rather than nesting calls to `rot90`.

Example: `rot90(A,-2)` rotates `A` by -180 degrees and is equivalent to `rot90(A,2)`, which rotates by 180 degrees.

More About

Tips

- Use the `flip` function to flip arrays in any dimension.

See Also

`flip` | `fliplr` | `flipud`

Introduced before R2006a

rotate

Rotate object about specified origin and direction

Syntax

```
rotate(h,direction,alpha)
rotate(...,origin)
```

Description

The `rotate` function rotates a graphics object in three-dimensional space.

`rotate(h,direction,alpha)` rotates the graphics object `h` by `alpha` degrees. `direction` is a two- or three-element vector that describes the axis of rotation in conjunction with the origin of the axis of rotation. The default origin of the axis of rotation is the center of the plot box. This point is not necessarily the origin of the axes.

Positive `alpha` is defined as the righthand-rule angle about the direction vector as it extends from the origin of rotation.

If `h` is an array of handles, all objects must be children of the same axes.

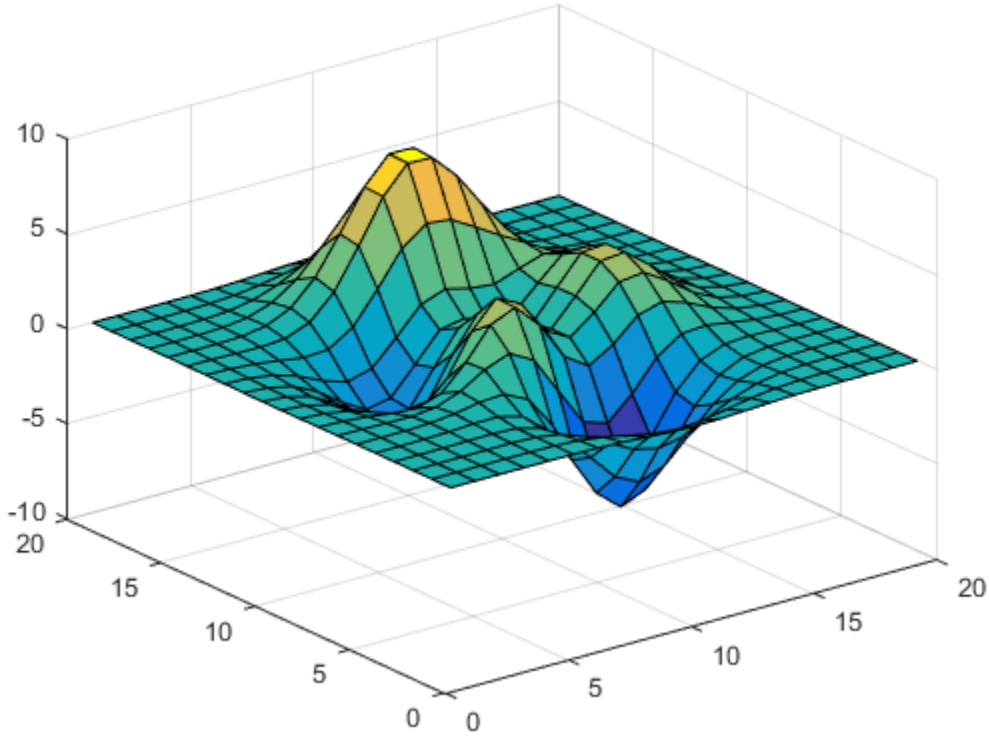
`rotate(...,origin)` specifies the origin of the axis of rotation as a three-element vector `[x0,y0,z0]`.

Examples

Rotate Plot Around *x*-Axis

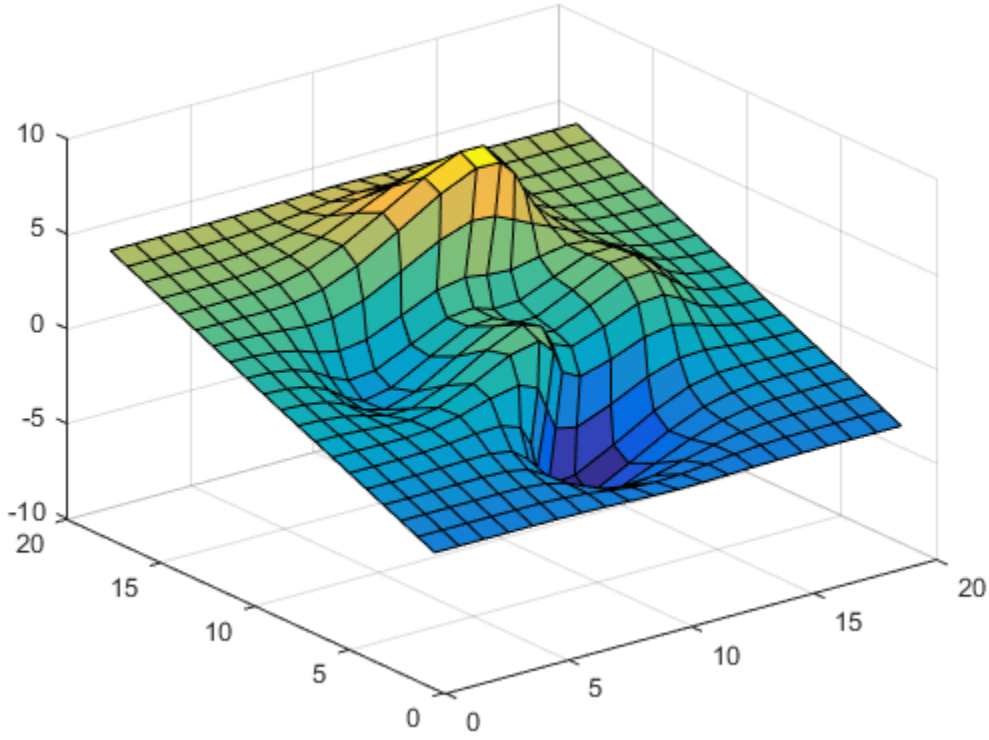
Create a surface plot of the `peaks` function and return the surface handle.

```
hSurface = surf(peaks(20));
```



Rotate the surface plot 25 degrees around its *x*-axis.

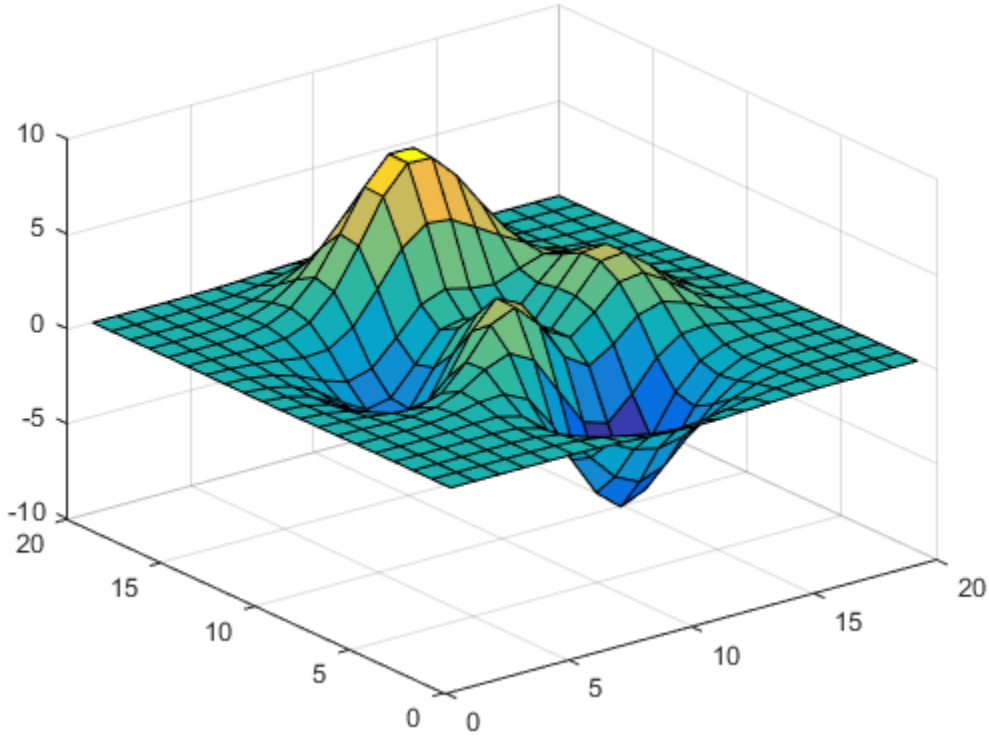
```
direction = [1 0 0];
rotate(hSurface,direction,25)
```



Rotate Plot Around *y*-Axis

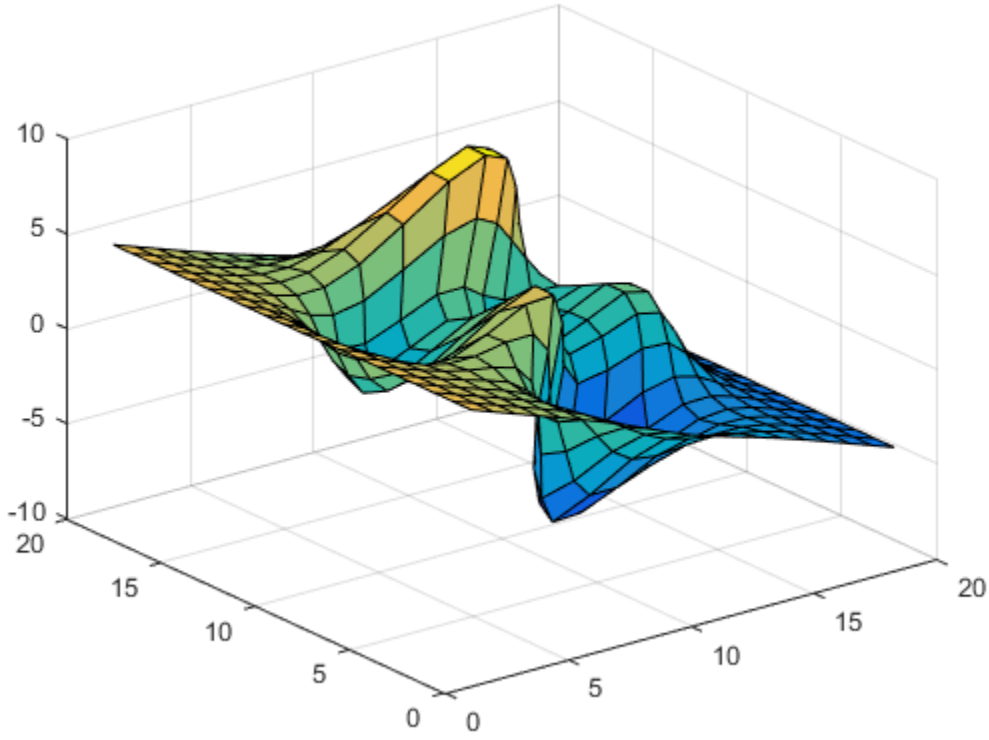
Create a surface plot of the `peaks` function and return the surface handle.

```
hSurface = surf(peaks(20));
```



Rotate the surface plot 25 degrees around its *y*-axis.

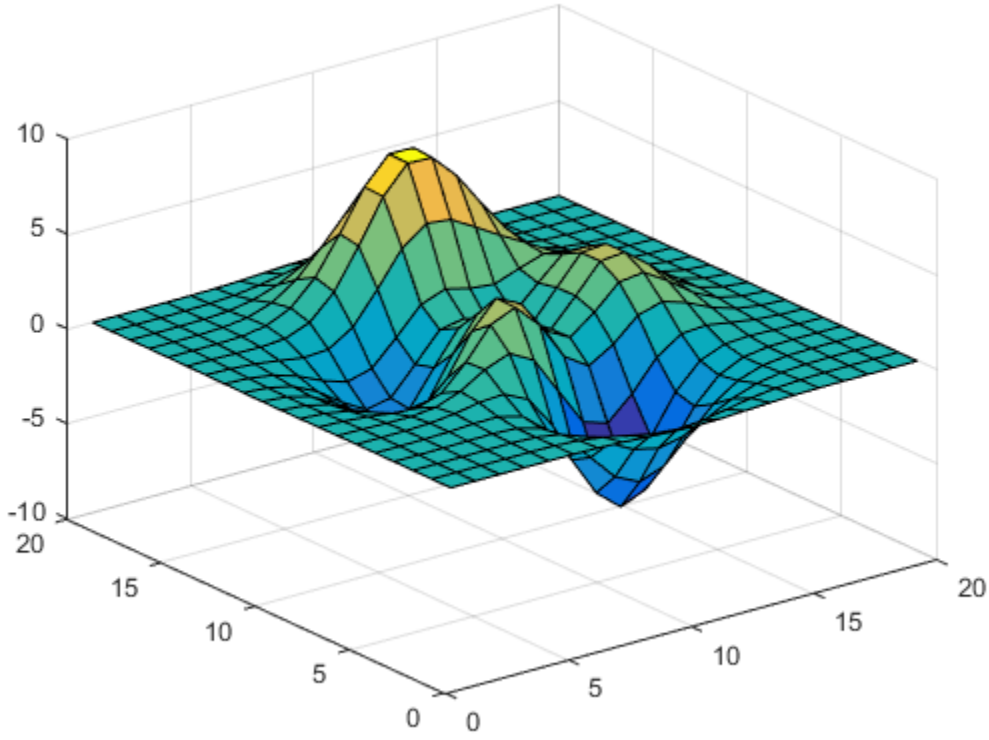
```
direction = [0 1 0];
rotate(hSurface,direction,25)
```



Rotate Plot Around *x*-Axis and *y*-Axis

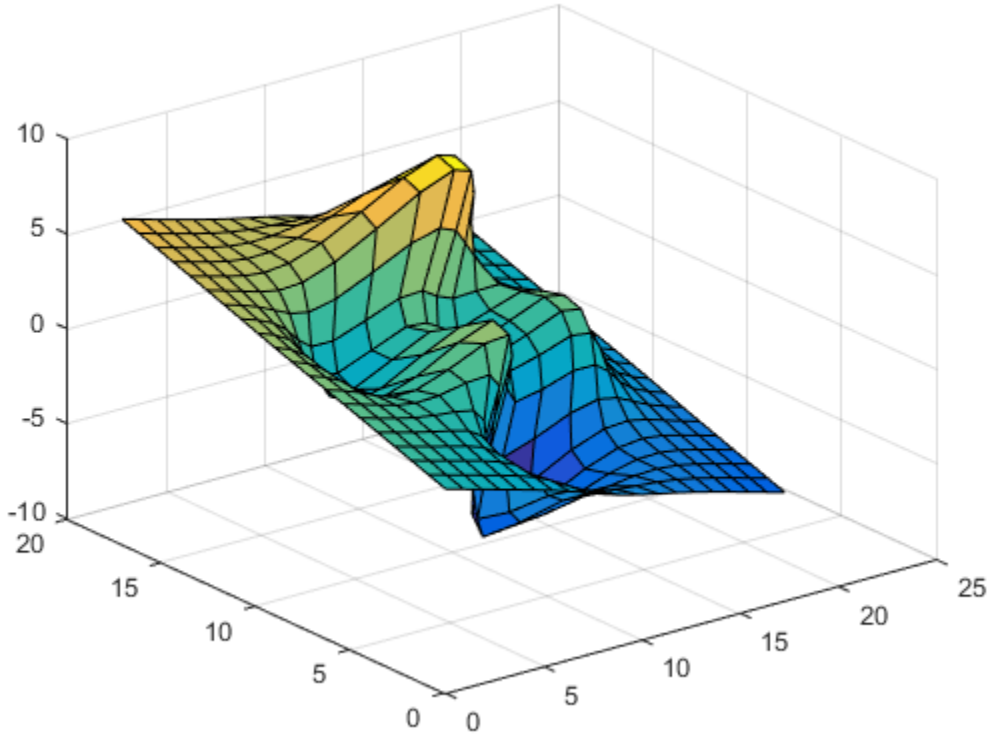
Create a surface plot of the `peaks` function and return the surface handle.

```
hSurface = surf(peaks(20));
```



Rotate the surface plot 25 degrees around its *x*-axis and *y*-axis.

```
direction = [1 1 0];
rotate(hSurface,direction,25)
```

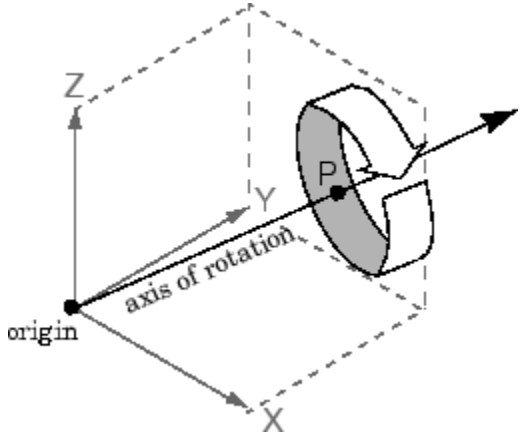


More About

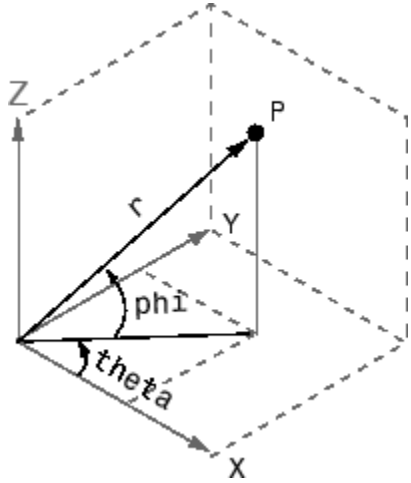
Tips

The rotation transformation modifies the object's data. This technique is different from that used by `view` and `rotate3d`, which modify only the viewpoint.

The axis of rotation is defined by an origin of rotation and a point `P`. Specify `P` as the spherical coordinates `[theta phi]` or as the Cartesian coordinates `[`x_p`,`y_p`,`z_p`]`.



In the two-element form for `direction`, `theta` is the angle in the *x*-*y* plane counterclockwise from the positive *x*-axis. `phi` is the elevation of the direction vector from the *x*-*y* plane.



The three-element form for `direction` specifies the axis direction using Cartesian coordinates. The direction vector is the vector from the origin of rotation to `P`.

Tips

`rotate` changes the values of the `Xdata`, `Ydata`, and `Zdata` properties to rotate graphics objects.

`rotate3d` | `sph2cart` | `view`

Introduced before R2006a

rotate3d

Rotate 3-D view using mouse

Syntax

```
rotate3d on
rotate3d off
rotate3d
rotate3d(figure_handle,...)
rotate3d(axes_handle,...)
h = rotate3d(figure_handle)
```

Description

`rotate3d on` enables mouse-base rotation on all axes within the current figure.

`rotate3d off` disables interactive axes rotation in the current figure.

`rotate3d` toggles interactive axes rotation in the current figure.

`rotate3d(figure_handle,...)` enables rotation within the specified figure instead of the current figure.

`rotate3d(axes_handle,...)` enables rotation only in the specified axes.

`h = rotate3d(figure_handle)` returns a rotate3d *mode object* for figure figure_handle for you to customize the mode's behavior.

Using Rotate Mode Objects

You access the following properties of rotate mode objects.

- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set
- *`Enable`* `'on'|'off'` — Specifies whether this figure mode is currently enabled on the figure

- *RotateStyle* `'orbit'|'box'` — Sets the method of rotation

  `'orbit'` rotates the entire axes; `'box'` rotates a plot-box outline of the axes.

Rotate3D Mode Callbacks

You can program the following callbacks for rotate3d mode operations.

- `ButtonDownFilter <function_handle>` — Function to intercept `ButtonDown` events

  The application can inhibit the rotate operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to handle callbacks):

  ```
  function [res] = myfunction(obj,event_obj)
  % obj          handle to the object that has been clicked on
  % event_obj    handle to event data object (empty in this release)
  % res [output] logical flag to determine whether the rotate
  %              operation should take place or the 'ButtonDownFcn'
  %              property of the object should take precedence
  ```

- `ActionPreCallback <function_handle>` — Function to execute before rotating

  Set this callback to listen to when a rotate operation will start. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

  ```
  function myfunction(obj,event_obj)
  % obj         handle to the figure that has been clicked on
  % event_obj   object containing struct of event data
  ```

  The event data has the following field:

`Axes`	The handle of the axes that is being panned

- `ActionPostCallback <function_handle>` — Function to execute after rotating

  Set this callback to listen to when a rotate operation has finished. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

  ```
  function myfunction(obj,event_obj)
  % obj         handle to the figure that has been clicked on
  ```

```
% event_obj   object containing struct of event data (same as the
%             event data of the 'ActionPreCallback' callback)
```

Rotate3D Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesRotate(h,axes)` — Function querying permission to rotate axes

  Calling the function `isAllowAxesRotate` on the rotate3d object, `h`, with a vector of axes handles, `axes`, as input will return a logical array of the same dimension as the axes handle vector which indicate whether a rotate operation is permitted on the axes objects.
- `setAllowAxesRotate(h,axes,flag)` — Function to set permission to pan axes

  Calling the function `setAllowAxesRotate` on the rotate3d object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, will either allow or disallow a rotate operation on the axes objects.

Examples

Example 1

Rotate the plot using the mouse:

```
surf(peaks);
rotate3d on;
```

Example 2

Rotate the plot using the "Plot Box" rotate style:

```
surf(peaks);
h = rotate3d;
h.RotateStyle = 'box';
h.Enable = 'on';
```

Example 3

Create two axes as subplots and then prevent one from rotating:

```
ax1 = subplot(1,2,1);
surf(peaks);
h = rotate3d;
h.Enable = 'on';
ax2 = subplot(1,2,2);
surf(membrane);
setAllowAxesRotate(h,ax2,false); % disable rotating for second plot
```

Example 4

Create a buttonDown callback for rotate mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd
% Allow a line to have its own 'ButtonDownFcn' callback
hLine = plot(rand(1,10),'ButtonDownFcn','disp(''This executes'')');
hLine.Tag = 'DoNotIgnore';
h = rotate3d;
h.ButtonDownFilter = @mycallback;
h.Enable = 'on';
% mouse-click on the line
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true
objTag = obj.Tag;
if strcmpi(objTag,'DoNotIgnore')
   flag = true;
else
   flag = false;
end
```

Example 5

Create callbacks for pre- and post-buttonDown events for rotate3D mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd2
% Listen to rotate events
surf(peaks);
h = rotate3d;
```

```
h.ActionPreCallback = @myprecallback;
h.ActionPostCallback = @mypostcallback;
h.Enable = 'on';

function myprecallback(obj,evd)
disp('A rotation is about to occur.');

function mypostcallback(obj,evd)
newView = round(evd.Axes.View);
msgbox(sprintf('The new view is [%d %d].',newView));
```

Alternatives

Use the Rotate3D tool  on the figure toolbar to enable and disable rotate3D mode on a plot, or select **Rotate 3D** from the figure's **Tools** menu. For details, see “Rotate in 3-D”.

More About

Tips

When enabled, `rotate3d` provides continuous rotation of axes and the objects it contains through mouse movement. A numeric readout appears in the lower left corner of the figure during rotation, showing the current azimuth and elevation of the axes. Releasing the mouse button removes the animated box and the readout. This differs from the `camorbit` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the aspect ratio and modifies the `CameraTarget`, `CameraPosition` and `CameraUpVector` properties of the axes. See Axes Properties for more information.

You can also enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

You can create a `rotate3d` mode object once and use it to customize the behavior of different axes, as example 3 illustrates. You can also change its callback functions on the fly.

Note: Do not change figure callbacks within an interactive mode. While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change

any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a UI that updates a figure's callbacks, the UI should some keep track of which interactive mode is active, if any, before attempting to do this.

When you assign different 3-D rotation behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse will carry over to the linked axes, regardless of the behavior you previously set for the other axes.

Introduced before R2006a

round

Round to nearest decimal or integer

Syntax

```
Y = round(X)
Y = round(X,N)
Y = round(X,N,type)

Y = round(t)
Y = round(t,unit)
```

Description

`Y = round(X)` rounds each element of `X` to the nearest integer. In the case of a tie, where an element has a fractional part of exactly `0.5`, the `round` function rounds away from zero to the integer with larger magnitude.

`Y = round(X,N)` rounds to `N` digits:

- `N > 0`: round to `N` digits to the *right* of the decimal point.
- `N = 0`: round to the nearest integer.
- `N < 0`: round to `N` digits to the *left* of the decimal point.

`Y = round(X,N,type)` specifies the type of rounding. Specify `'significant'` to round to `N` significant digits (counted from the leftmost digit). In this case, `N` must be a positive integer.

`Y = round(t)` rounds each element of the `duration` array `t` to the nearest number of seconds.

`Y = round(t,unit)` rounds each element of `t` to the nearest number of the specified unit of time.

Examples

Round Matrix Elements

Round the elements of a 2-by-2 matrix to the nearest integer.

```
X = [2.11 3.5; -3.5 0.78];
Y = round(X)
```

```
Y =

     2     4
    -4     1
```

Round to Specified Number of Decimal Digits

Round `pi` to the nearest 3 decimal digits.

```
Y = round(pi,3)
```

```
Y =

    3.1420
```

Round to Nearest Multiple of 100

Round the number `863178137` to the nearest multiple of 100.

```
round(863178137,-2)
```

```
ans =

   863178100
```

Round Elements to Specified Number of Significant Digits

Round the elements of a vector to retain 2 significant digits.

```
format shortg
x = [1253 1.345 120.44]
y = round(x,2,'significant')
```

```
x =

         1253        1.345       120.44
```

```
y =

        1300         1.3         120
```

Controlling Number Display While Rounding

The `format` command controls how MATLAB displays numbers at the command line. If a number has extra digits that cannot be displayed in the current format, then MATLAB automatically rounds the number for display purposes. This can lead to unexpected results when combined with the `round` function.

Consider the result of the following subtraction operation, which displays 5 digits.

```
format short
x = 112.05 - 110
```

```
x =

    2.0500
```

Based on the displayed value of `x`, rounding `x` to 1 decimal should return `2.1`.

```
round(x,1)
```

```
ans =

     2
```

In fact, the problem here is that MATLAB is rounding `x` to 5 digits for display purposes. The `round` function returns the correct answer. Confirm the answer by viewing `x` with `format long`, which displays `x` rounded to 15 digits.

```
format long
x
```

```
x =

   2.049999999999997
```

Round Duration Values

Round each value in a duration array to the nearest number of seconds.

```
t = hours(8) + minutes(29:31) + seconds(1.3:0.5:2.3);
```

```
t.Format = 'hh:mm:ss.SS'

t =

   08:29:01.30   08:30:01.80   08:31:02.30

Y1 = round(t)

Y1 =

   08:29:01.00   08:30:02.00   08:31:02.00
```

Round each value in t to the nearest number of hours.

```
Y2 = round(t,'hours')

Y2 =

   08:00:00.00   09:00:00.00   09:00:00.00
```

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex `X`, `round` treats the real and imaginary parts independently.

`X` must be `single` or `double` when you use `round` with more than one input.

`round` converts logical and `char` elements of `X` into `double` values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`
Complex Number Support: Yes

N — Number of digits

scalar integer

Number of digits, specified as a scalar integer. When you specify `N`, the `round` function rounds `X` to the nearest multiple of 10^{-N}.

If you specify the `'significant'` rounding type, then `N` must be a positive integer.

`type` — Rounding type

`'decimals'` (default) | `'significant'`

Rounding type, specified as `'decimals'` or `'significant'`. The rounding type determines whether `round` considers digits in relation to the decimal point or the overall number of significant digits. `N` must be a positive integer when you specify `'significant'`. In that case, the `round` function rounds to the nearest number with `N` significant digits.

The default value is `'decimals'`, so that `round(X,N,'decimals')` is equivalent to `round(X,N)`.

Example: `round(3132,2,'significant')` returns `3100`, which is the closest number to `3132` that has `2` significant digits.

Data Types: `char`

`t` — Input duration

`duration` array

Input duration, specified as a `duration` array.

`unit` — Unit of time

`'seconds'` (default) | `'minutes'` | `'hours'` | `'days'`

Unit of time, specified as `'seconds'`, `'minutes'`, `'hours'`, or `'days'`.

More About

Tips

- `format short` and `format long` both display rounded numbers. This can cause unexpected results when combined with the `round` function.
- For display purposes, use `sprintf` to control the exact display of a number as a string. For example, to display exactly 2 decimal digits of `pi` (and no trailing zeros), use `sprintf(%.2f,pi)`.

- “Integers”
- “Floating-Point Numbers”

`ceil` | `fix` | `floor`

Introduced before R2006a

rowfun

Apply function to table rows

Syntax

```
B = rowfun(func,A)
B = rowfun(func,A,Name,Value)
```

Description

`B = rowfun(func,A)` applies the function func to each row of the table `A` and returns the results in the table `B`.

`func` accepts `size(A,2)` inputs.

`B = rowfun(func,A,Name,Value)` applies the function `func` to each row of the table `A` with additional options specified by one or more Name,Value pair arguments.

For example, you can specify which variables to pass to the function `func` and how to call `func`.

Examples

Apply Function with Single Output to Rows

Apply the function `hypot` to each row of the 5-by-2 table `A` to find the shortest distance between the variables `x` and `y`.

Create a table, `A`, with two variables of numeric data.

```
x = gallery('integerdata',10,[5,1],2);
y = gallery('integerdata',10,[5,1],8);

A = table(x,y)
```

```
A =

    x    y
```

```
    _    __

    9     1
    4     5
    3     2
    7     3
    1    10
```

Apply the function, `hypot` to each row of `A`. The function `hypot` takes two inputs and returns one output.

```
B = rowfun(@hypot,A,'OutputVariableNames','z')
```

```
B =

      z
    ______

    9.0554
    6.4031
    3.6056
    7.6158
     10.05
```

`B` is a table.

Append the function output, `B`, to the input table, `A`.

```
[A B]
```

```
ans =

    x    y       z
    _    __    ______

    9     1    9.0554
    4     5    6.4031
    3     2    3.6056
    7     3    7.6158
    1    10     10.05
```

Apply Function with Multiple Outputs to Rows

Define and apply a geometric Brownian motion model to a range of parameters.

Create a function in a file named `gbmSim.m` that contains the following code.

```
function [m,mtrue,s,strue] = gbmSim(mu,sigma)
% Discrete approximation to geometric Brownian motion
%
% [m,mtrue,s,strue] = gbmSim(mu,sigma) computes the
% simulated mean, true mean, simulated standard deviation,
% and true standard deviation based on the parameters mu and sigma.

numReplicates = 1000; numSteps = 100;
y0 = 1;
t1 = 1;
dt = t1 / numSteps;
y1 = y0*prod(1 + mu*dt + sigma*sqrt(dt)*randn(numSteps,numReplicates));
m = mean(y1); s = std(y1);
% Theoretical values
mtrue = y0 * exp(mu*t1); strue = mtrue * sqrt(exp(sigma^2*t1) - 1);
```

`gbmSim` accepts two inputs, `mu` and `sigma`, and returns four outputs, `m`, `mtrue`, `s`, and `strue`.

Define the table, `params`, containing the parameters to input to the Brownian Motion Model.

```
mu = [-.5; -.25; 0; .25; .5];
sigma = [.1; .2; .3; .2; .1];

params = table(mu,sigma)
```

```
params =

     mu      sigma
    -----    -----
     -0.5    0.1
    -0.25    0.2
       0     0.3
     0.25    0.2
      0.5    0.1
```

Apply the function, `gbmSim` to the rows of the table, `params`.

```
stats = rowfun(@gbmSim,params,...
    'OutputVariableNames',...
    {'simulatedMean' 'trueMean' 'simulatedStd' 'trueStd'})
```

```
stats =
```

```
    simulatedMean    trueMean    simulatedStd    trueStd
    _____________    ________    ____________    ________

    0.60501          0.60653     0.05808         0.060805
    0.77916           0.7788       0.161          0.15733
     1.0024                1      0.3048          0.30688
     1.2795            1.284     0.25851          0.25939
     1.6498           1.6487     0.16285          0.16529
```

The 4 strings specified by the `'OutputVariableNames'` name-value pair argument indicate that `rowfun` should obtain 4 outputs from `gbmSim`. You can specify fewer output variable names to return fewer outputs from `gbmSim`.

Append the function output, `stats`, to the input, `params`.

```
[params stats]
```

```
ans =

     mu      sigma    simulatedMean    trueMean    simulatedStd    trueStd
    _____    _____    _____________    ________    ____________    ________

     -0.5    0.1      0.60501          0.60653     0.05808         0.060805
    -0.25    0.2      0.77916           0.7788       0.161          0.15733
        0    0.3       1.0024                1      0.3048          0.30688
     0.25    0.2       1.2795            1.284     0.25851          0.25939
      0.5    0.1       1.6498           1.6487     0.16285          0.16529
```

Apply Function to Groups of Rows

Create a table, `A`, where `g` is a grouping variable.

```
g = gallery('integerdata',3,[15,1],1);
x = gallery('uniformdata',[15,1],9);
y = gallery('uniformdata',[15,1],2);

A = table(g,x,y)
```

```
A =

    g       x          y
    _    _______    ________

    3    0.24756     0.87516
    3     0.4358      0.3179
    3    0.97755     0.27323
```

```
    2    0.85995      0.6765
    3    0.30063    0.071171
    2    0.26589     0.19659
    3    0.13338     0.52908
    2     0.7425     0.17176
    1    0.85692     0.86996
    2    0.24286     0.24369
    3    0.19492     0.84291
    2    0.39076     0.55766
    1    0.29683     0.35681
    1    0.39031      0.2324
    2    0.18726      0.6476
```

Define the anonymous function, `func`, to compute the average difference between `x` and `y`.

```
func = @(x,y) mean(x-y);
```

Find the average difference between variables in groups `1`, `2`, and `3` defined by the grouping variable, `g`.

```
B = rowfun(func,A,...
    'GroupingVariable','g',...
    'OutputVariableName','MeanDiff')
```

```
B =

    g    GroupCount    MeanDiff
    _    __________    ________

1   1    3             0.028298
2   2    6             0.032569
3   3    6             -0.10327
```

The variable `GroupCount` indicates the number of rows in `A` for each group.

Input Arguments

`func` — Function

function handle

Function, specified as a function handle. You can define the function in a file or as an anonymous function. If `func` corresponds to more than one function file (that is, if `func`

represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

`func` can accept no more than `size(A,2)` inputs. By default, `rowfun` returns the first output of `func`. To return more than one output from `func`, use the `'NumOutputs'` or `'OutputVariableNames'` name-value pair arguments.

Example: `func = @(x,y) x.^2+y.^2;` takes two inputs and finds the sum of the squares.

A — Input table

table

Input table, specified as a table.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'InputVariables',2` uses only the second variable in `A` as an input to `func`.

'InputVariables' — Variables of A to pass to func

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `rowfun` only passes the variables in `A` where the specified function returns `1` (`true`).

'GroupingVariables' — One or more variables in A that define groups of rows

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in A that have the same grouping variable values belong to the same group. rowfun applies func to each group of rows, rather than separately to each row of A. The output, B, contains one row for each group.

'SeparateInputs' — Indicator for calling func with separate inputs
true (default) | false | 1 | 0

Indicator for calling func with separate inputs, specified as the comma-separated pair consisting of 'SeparateInputs' and either true, false, 1, or 0.

true	func expects separate inputs. rowfun calls func with size(A,2) inputs, one argument for each data variable. This is the default behavior.
false	func expects one vector containing all inputs. rowfun creates the input vector to func by concatenating the values in each row of A.

'ExtractCellContents' — Indicator to pass values from cell variables to func
false (default) | true | 0 | 1

Indicator to pass values from cell variables to func, specified as the comma-separated pair consisting of 'ExtractCellContents' and either false, true, 0, or 1.

true	rowfun extracts the contents of a variable in A whose data type is cell and passes the values, rather than the cells, to func For grouped computation, the values within each group in a cell variable must allow vertical concatenation.
false	rowfun passes the cells of a variable in A whose data type is cell to func. This is the default behavior.

'OutputVariableNames' — Variable names for outputs of func
string | cell array of nonempty, distinct strings

Variable names for outputs of func, specified as the comma-separated pair consisting of 'OutputVariableNames' and a string or a cell array of nonempty, distinct strings. The number of strings must equal the number of outputs desired from func.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of *N* strings of the form `{'Var1' ... 'VarN'}` where *N* is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

`'NumOutputs'` — Number of outputs from `func`

`0` | positive integer

Number of outputs from `func`, specified as the comma-separated pair consisting of `'NumOutputs'` and `0` or a positive integer. The integer must be less than or equal to the possible number of outputs from `func`.

Example: `'NumOutputs',2` causes `rowfun` to call `func` with two outputs.

`'OutputFormat'` — Format of `B`

`'table'` (default) | `'uniform'` | `'cell'`

Format of `B`, specified as the comma-separated pair consisting of `'OutputFormat'` and either the string `'table'`, `'uniform'`, or `'cell'`.

`'table'`	`rowfun` returns a table with one variable for each output of `func`. For grouped computation, `B`, also contains the grouping variables. `'table'` allows you to use a function that returns values of different sizes or data types. However, for ungrouped computation, all of the outputs from `func` must have one row each time it is called. For grouped computation, all of the outputs from `func` must have the same number of rows. This is the default output format.
`'uniform'`	`rowfun` concatenates the values returned by `func` into a vector. All of the outputs from `func` must be scalars with the same data type.
`'cell'`	`rowfun` returns `B` as a cell array. `'cell'` allows you to use a function that returns values of different sizes or data types.

`'ErrorHandler'` — Function to call if `func` fails

function handle

Function to call if `func` fails, specified as the comma-separated pair consisting of `'ErrorHandler'` and a function handle. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

`identifier`	Error identifier.
`message`	Error message text.
`index`	Row or group index at which the error occurred.

- The set of input arguments to function `func` at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
warning(S.identifier, S.message);
A = NaN; B = NaN;
```

Output Arguments

`B` — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

rref

Reduced row echelon form (Gauss-Jordan elimination)

Syntax

```
R = rref(A)
[R,jb] = rref(A)
[R,jb] = rref(A,tol)
```

Description

`R = rref(A)` produces the reduced row echelon form of `A` using Gauss Jordan elimination with partial pivoting. A default tolerance of (`max(size(A))*eps *norm(A,inf)`) tests for negligible column elements.

`[R,jb] = rref(A)` also returns a vector `jb` such that:

- `r = length(jb)` is this algorithm's idea of the rank of `A`.
- `x(jb)` are the pivot variables in a linear system `Ax = b`.
- `A(:,jb)` is a basis for the range of `A`.
- `R(1:r,jb)` is the `r`-by-`r` identity matrix.

`[R,jb] = rref(A,tol)` uses the given tolerance in the rank tests.

Roundoff errors may cause this algorithm to compute a different value for the rank than `rank`, `orth` and `null`. Additionally, use `mldivide` to solve linear systems when high precision is required.

Examples

Use `rref` on a rank-deficient magic square:

```
A = magic(4), R = rref(A)
```

```
A =
```

```
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1

R =
     1     0     0     1
     0     1     0     3
     0     0     1    -3
     0     0     0     0
```

rsf2csf

Convert real Schur form to complex Schur form

Syntax

```
[U,T] = rsf2csf(U,T)
```

Description

The *complex Schur form* of a matrix is upper triangular with the eigenvalues of the matrix on the diagonal. The *real Schur form* has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal.

`[U,T] = rsf2csf(U,T)` converts the real Schur form to the complex form.

Arguments `U` and `T` represent the unitary and Schur forms of a matrix `A`, respectively, that satisfy the relationships: `A = U*T*U'` and `U'*U = eye(size(A))`. See `schur` for details.

Examples

Given matrix `A`,

```
 1     1     1     3
 1     2     1     1
 1     1     3     1
-2     1     1     4
```

with the eigenvalues

```
4.8121    1.9202 + 1.4742i    1.9202 + 1.4742i    1.3474
```

Generating the Schur form of `A` and converting to the complex Schur form

```
[u,t] = schur(A);
[U,T] = rsf2csf(u,t)
```

yields a triangular matrix T whose diagonal (underlined here for readability) consists of the eigenvalues of A.

```
U =

-0.4916       -0.2756 - 0.4411i    0.2133 + 0.5699i   -0.3428
-0.4980       -0.1012 + 0.2163i   -0.1046 + 0.2093i    0.8001
-0.6751        0.1842 + 0.3860i   -0.1867 - 0.3808i   -0.4260
-0.2337        0.2635 - 0.6481i    0.3134 - 0.5448i    0.2466

T =

4.8121        -0.9697 + 1.0778i   -0.5212 + 2.0051i   -1.0067
     0         1.9202 + 1.4742i    2.3355              0.1117 + 1.6547i
     0              0              1.9202 - 1.4742i    0.8002 + 0.2310i
     0              0                   0              1.3474
```

run

Run MATLAB script

Syntax

```
run(scriptname)
```

Description

`run(scriptname)` runs the MATLAB script specified by `scriptname`.

Examples

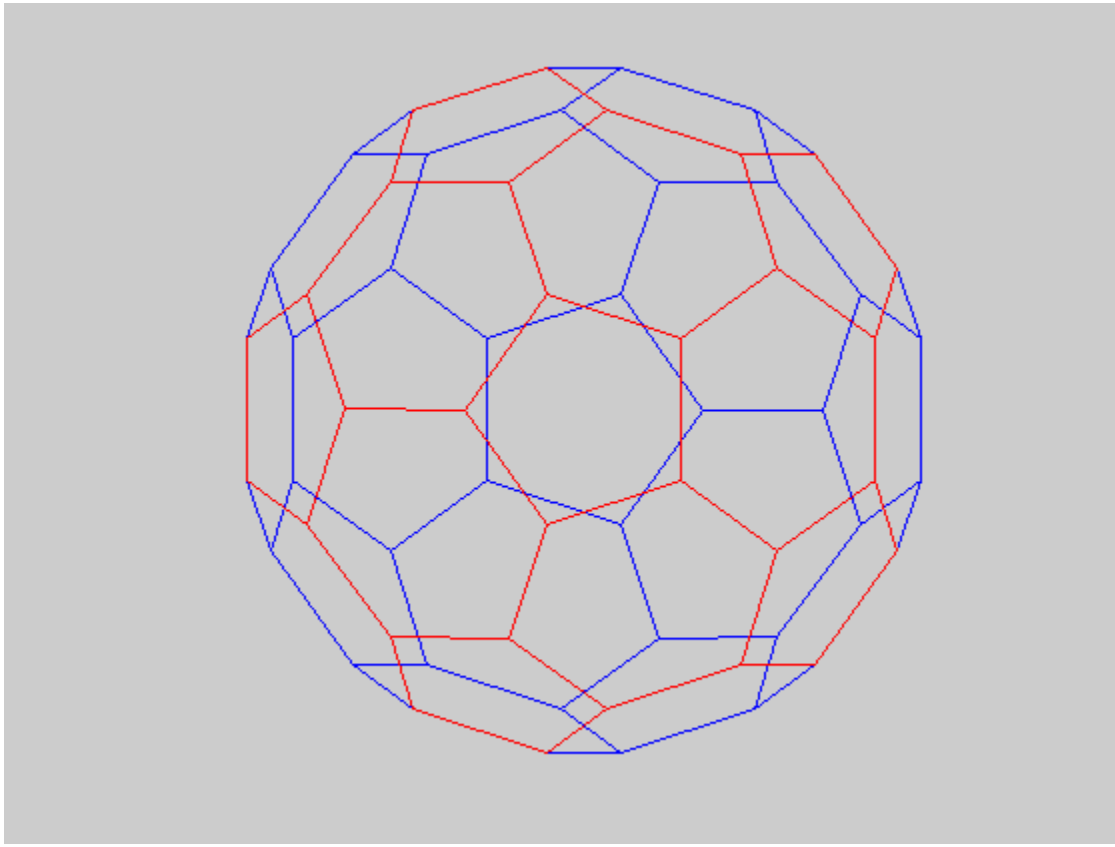
Run Script Not on Current Path

Create a temporary folder and copy an example MATLAB script to it.

```
tmp = tempname;
mkdir(tmp);
runtmp = fullfile(tmp,'buckyball.m');
demodir = fullfile(matlabroot,'toolbox','matlab',...
    'demos','buckydem.m');
copyfile(demodir,runtmp);
```

Run the new script.

```
run(runtmp)
```



Input Arguments

`scriptname` — Full or relative script path

string

Full or relative script path to a MATLAB script, specified as a string. scriptname can specify any file type that MATLAB can execute, such as MATLAB script files, Simulink models, or MEX-files.

More About

Tips

- `run` executes scripts not currently on the MATLAB path. However, you should use `cd` or `addpath` to navigate to or to add the appropriate folder, making a script executable by entering its name alone.
- `scriptname` can access any variables in the current workspace.
- `run` changes to the folder that contains the script, executes it, and resets back to the original folder. If the script itself changes folders, then `run` does not revert to the original folder, unless `scriptname` changes to the folder in which this script resides.
- If `scriptname` corresponds to both a `.m` file and a P-file residing in the same folder, then `run` executes the P-file. This occurs even if you specify `scriptname` with a `.m` extension.
- If a script is not on the MATLAB path, executing the `run` command caches the script. In the same session and after calling `run`, you can edit the script using an external editor. Call `clear scriptname` before calling `run` again to use the changed version of the script rather than the cached version. If you edit the script with the MATLAB editor, `run` executes the changed version and there is no need to call `clear scriptname`.

runtests

Run set of tests

Syntax

```
results = runtests
results = runtests(tests)
results = runtests(tests,Name,Value)
```

Description

`results = runtests` runs all the tests in your current folder, and returns the results as a `TestResult` object.

`results = runtests(tests)` runs a specified set of tests.

`results = runtests(tests,Name,Value)` runs a set of tests with additional options specified by one or more Name,Value pair arguments.

Examples

Run Tests in Working Folder

Create a folder `myExample` in your current working folder, and change into that folder.

In the `myExample` folder, create a test script, `typeTest.m`.

```
%% Test double class
exp = 'double';
act = ones;
assert(isa(act,exp))

%% Test single class
exp = 'single';
act = ones('single');
assert(isa(act,exp))
```

```
%% Test uint16 class
exp = 'uint16';
act = ones('uint16');
assert(isa(act,exp))
```

In the `myExample` folder, create a test script, `sizeValueTest.m`.

```
%% Test size
exp = [7 13];
act = ones([7 13]);
assert(isequal(size(act),exp))

%% Test values
act = ones(42);
assert(unique(act) == 1)
```

Run all tests in the current folder.

```
runtests
```

```
Running sizeValueTest
..
Done sizeValueTest
__________

Running typeTest
...
Done typeTest
__________

ans =

  1x5 TestResult array with properties:

    Name
    Passed
    Failed
    Incomplete
    Duration

Totals:
   5 Passed, 0 Failed, 0 Incomplete.
   0.013069 seconds testing time.
```

MATLAB ran 5 tests. There are 2 passing tests from `sizeValueTest` and 3 passing tests from `typeTest`.

Run Tests Using File Name

Create the test file shown below, and save it as `runtestsExampleTest.m` on your MATLAB path.

```
function tests = runtestsExampleTest
tests = functiontests(localfunctions);

function testFunctionOne(testCase)
```

Run the tests.

```
results = runtests('runtestsExampleTest.m');
```

```
Running runtestsExampleTest
.
Done runtestsExampleTest
__________
```

Run Tests in Subdirectory

If it doesn't already exist, create the test file, `runtestsExampleTest.m`, in the example above.

Create a subdirectory, `tmpTest`, and, in that directory, create the following `runtestsExampleSubFolderTest.m` file.

```
function tests = runtestsExampleSubFolderTest
tests = functiontests(localfunctions);

function testFunctionTwo(testCase)
```

Run the tests from the directory above `tmpTest` by setting `'Recursively'` to true.

```
results = runtests(pwd,'Recursively',true);
```

```
Running runtestsExampleTest
.
Done runtestsExampleTest
__________

Running runtestsExampleSubFolderTest
.
```

```
Done runtestsExampleSubFolderTest
__________
```

`runtests` ran the tests in both the current directory and the subdirectory.

If you do not specify the `'Recursively'` property for the `runtests` function, it does not run the test in the subdirectory.

```
results = runtests(pwd);
```

```
Running runtestsExampleTest
.
Done runtestsExampleTest
__________
```

Run Select Parameterized Tests

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
        type = {'single','double','uint16'};
        outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
```

```
end
```

The full test suite has 11 test elements: 6 from the `testClass` method, 2 from the `testSize` method, and 1 each from the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

At the command prompt, run the test elements that use the `outSize` parameter property.

```
runtests('testZeros','ParameterProperty','outSize')
```

```
Running testZeros
........
Done testZeros
__________

ans =

  1x8 TestResult array with properties:

    Name
    Passed
    Failed
    Incomplete
    Duration

Totals:
   8 Passed, 0 Failed, 0 Incomplete.
   0.013499 seconds testing time.
```

`runtests` executed eight tests that use the `outSize` parameter property: six from the `testClass` method and two from the `testSize` method.

At the command prompt, run the test elements that use the `singe` parameter name.

```
runtests('testZeros','ParameterName','single')
```

```
Running testZeros
..
Done testZeros
__________

c =
```

```
  1x2 TestResult array with properties:

    Name
    Passed
    Failed
    Incomplete
    Duration

Totals:
   2 Passed, 0 Failed, 0 Incomplete.
   0.0034442 seconds testing time.
```

`runtests` executed the two tests from the `testClass` method that use the `outSize` parameter name.

- "Write Function-Based Unit Tests"
- "Write Simple Test Case Using Functions"
- "Write Test Using Setup and Teardown Functions"

Input Arguments

`tests` — Array of tests

string | cell array of strings

Suite of tests specified as a string or cell array of strings. Each string in the cell array can contain the name of a test class, a test file, a package that containing your test classes, or a folder containing your test files.

Example: `'mypackage.MyTestClass'`

Example: `'ATestFile.m'`

Example: `pwd`

Example:
`{'mypackage.MyTestClass','ATestFile.m',pwd,'mypackage.subpackage'}`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

`'Recursively'` — Indicator to run tests in subfolders and subpackages
`false` (default) | `true` | `0` | `1`

Indicator to run tests in subfolders and subpackages, specified as `false` or `true` (`0` or `1`). By default `runtests` runs tests in the specified folder or package and not in their subfolders or subpackages.

Data Types: `logical`

`'Name'` — Name of suite element
string

String indicating the name of the suite element. For the testing framework to run a test, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterProperty'` — Name of parameterization property
string

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterName'` — Name of parameter
string

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'BaseFolder'` — Name of base folder
string

String indicating the name of the folder that contains the file defining the test class, function, or script. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one

character. For test files defined in packages, the base folder is the parent of the top-level package folder.

`'Tag'` — Name of test element tag

string

Name of test element tag, specified as a string. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`matlab.unittest.TestResult` | `matlab.unittest.TestRunner` | `matlab.unittest.TestSuite` | `functiontests`

Introduced in R2013b

Chart Surface Properties

Control chart surface appearance and behavior

Chart surface properties control the appearance and behavior of chart surface objects. By changing property values, you can modify certain aspects of the surface.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = surf(...);
c = h.CData;
h.CDataMapping = 'direct';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Faces

`FaceColor` — Face color

`'flat'` (default) | `'interp'` | `'none'` | `'texturemap'` | RGB triplet or color string

Face color, specified as one of these values:

- `'flat'` — Use uniform face colors. Use the CData values. The color data at the first vertex determines the color for the entire face. You cannot use this value when the `FaceAlpha` property is set to `'interp'`.
- `'interp'` — Interpolate the face colors. Bilinear interpolation of the CData values at each vertex determines the colors. You cannot use this value when the `FaceAlpha` property is set to `'flat'`.
- `'none'` — Do not draw the faces.
- `'texturemap'` — Transform the color data in CData so that it conforms to the surface.
- RGB triplet or color string — Use the same color for all of the faces.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

FaceAlpha — Face transparency

1 (default) | scalar in range [0,1] | 'flat' | 'interp'

Face transparency, specified as one of these values:

- Scalar in range [0,1] — Use the same transparency value for all of the faces. A value of 1 is fully opaque and 0 is completely transparent.
- 'flat' — Use uniform transparency across each face. Use the AlphaData values to determine the transparency values. The alpha data at the first vertex determines the transparency for the entire face. You must first specify the AlphaData property as a matrix equal in size to ZData. You cannot use this value when the FaceColor property is set to 'interp'.
- 'interp' — Interpolate the transparency across each face. Bilinear interpolation of the AlphaData values at each vertex determines the transparency values. You must first specify the AlphaData property as a matrix equal in size to ZData. You cannot use this value when the FaceColor property is set to 'flat'.

FaceLighting — Effect of light objects on faces

'flat' (default) | 'gouraud' | 'none'

Effect of light objects on faces, specified as one of these values:

- 'flat' — Apply light uniformly across the faces. Use this value to view faceted objects.
- 'gouraud' — Vary the light across the faces. Calculate the light at the vertices and then linearly interpolate the light across the faces. Use this value to view curved surfaces.
- 'none' — Do not apply light from light objects to the faces.

Note: The `'phong'` value has been removed. Use `'gouraud'` instead.

`BackFaceLighting` — Face lighting when normals point away from camera

`'reverslit'` (default) | `'unlit'` | `'lit'`

Face lighting when the vertex normals point away from camera, specified as one of these values:

- `'reverslit'` — Light the face as if the vertex normal pointed towards the camera.
- `'unlit'` — Do not light the face.
- `'lit'` — Light the face according to the vertex normal.

Use this property to discriminate between the internal and external surfaces of an object. For an example, see "Back Face Lighting".

Edges

`MeshStyle` — Edges to display

`'both'` (default) | `'row'` | `'column'`

Edges to display, specified as `'both'`, `'row'`, or `'column'`.

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	————
`'--'`	Dashed line	- - - - -
`':'`	Dotted line	.....
`'-.'`	Dash-dotted line	_._._._.-
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

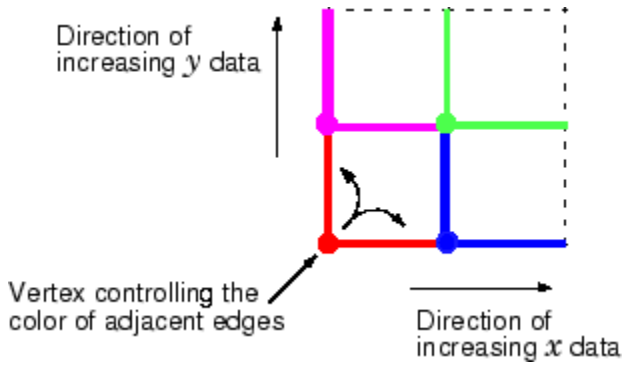
Example: `0.75`

`EdgeColor` — Edge line color

`[0 0 0]` (default) | `'none'` | `'flat'` | `'interp'` | RGB triplet or color string

Surface edge line color, specified as one of these values:

- `'none'` — Do not draw edges.
- `'flat'` — Draw uniform edge colors. Use the `CData` value of the first vertex of the face to determine the color for each edge. You cannot use this value when the `EdgeAlpha` property is set to `'interp'`.



- `'interp'` — Interpolate the edge colors. Use a linear interpolation of the `CData` values at the face vertices to determine the edge color. You cannot use this value when the `EdgeAlpha` property is set to `'flat'`.
- RGB triplet or color string — Use the same color for all edges.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

EdgeAlpha — Surface edge transparency

1 (default) | scalar value in range[0,1] | 'flat' | 'interp'

Surface edge transparency, specified as one of these values:

- Scalar in range[0,1] — Use the same transparency value for all of the edges. A value of 1 is fully opaque and 0 is completely transparent.
- 'flat' — Use uniform transparency across each edge. Use the values in AlphaData to determine the transparency for each edge. The value at the first vertex of the face determines the transparency for the edge. You must specify AlphaData as a matrix equal in size to ZData. You cannot use this value when the EdgeColor property is set to 'interp'.
- 'interp' — Interpolate the transparency across each edge. Use a bilinear interpolation of the AlphaData values for each vertex. You must specify AlphaData as a matrix equal in size to ZData. You cannot use this value when the EdgeColor property is set to 'flat'.

EdgeLighting — Effect of light objects on edges

'none' (default) | 'flat' | 'gouraud'

Effect of light objects on edges, specified as one of these values:

- 'flat' — Apply light uniformly across the each edges.
- 'none' — Do not apply lights from light objects to the edges.
- 'gouraud' — Calculate the light at the vertices, and then linearly interpolate across the edges.

Note: The 'phong' value has been removed. Use 'gouraud' instead.

`AlignVertexCenters` — Sharp vertical and horizontal lines

`'off'` (default) | `'on'`

Sharp vertical and horizontal lines, specified as `'off'` or `'on'`.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the chart surface object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond

String	Marker Symbol
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | 'flat' | RGB triplet or color string

Marker outline color, specified as specified as one of these values:

- 'auto' — Use the same color as the EdgeColor property.
- 'none' — Use no color, which makes unfilled markers invisible.
- 'flat' — Use the CData value at the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]

Long Name	Short Name	RGB Triplet
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | `'flat'` | RGB triplet or color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which allows the background to show through.
- `'auto'` — Use the same color as the `Color` property for the axes.
- `'flat'` — Use the CData value of the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]

Long Name	Short Name	RGB Triplet
'black	'k'	[0 0 0]

This property affects only the circle, square, diamond, pentagram, hexagram, and the four triangle marker types.

Example: [0.3 0.2 0.1]

Example: 'green'

Example:

Face and Vertex Normals

FaceNormals — Normal vectors for each surface face

[ ] (default) | (m-1)-by-(n-1)-by-3 array

Normal vectors for each surface face, specified as a (m-1)-by-(n-1)-by-3 array, where [m,n] = size(ZData). Specify one normal vector per face.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: single | double

FaceNormalsMode — Selection mode for FaceNormals

'auto' (default) | 'manual'

Selection mode for FaceNormals, specified as one of these values:

- 'auto' — Calculate the normal vectors based on the coordinate data.
- 'manual' — Use manually specified values. To specify the values, set the FaceNormals property.

VertexNormals — Normal vectors for each surface vertex

[ ] (default) | m-by-n-by-3 array

Normal vectors for each surface vertex, specified as a m-by-n-by-3 array, where [m,n] = size(ZData). Specify one normal vector per vertex.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: `single` | `double`

`VertexNormalsMode` — Selection mode for `VertexNormals`

`'auto'` (default) | `'manual'`

Selection mode for `VertexNormals`, specified as one of these values:

- `'auto'` — Calculate the normal vectors based on the coordinate data.
- `'manual'` — Use manually specified values. To specify the values, set the VertexNormals property.

`NormalMode` — (removed) Selection mode for `VertexNormals`

`'auto'` (default) | `'manual'`

The `NormalMode` property will be removed in a future release. Use VertexNormalsMode instead.

Color and Transparency Mapping

`CData` — Vertex colors

2-D or 3-D array

Vertex colors, specified in one of these forms:

- 2-D array — Use colormap colors. Specify a color for each vertex by setting CData to an array the same size as `ZData`. The CDataMapping property determines how these values map into the current colormap. If the FaceColor property is set to `'texturemap'`, then CData does not need to be the same size as ZData. However, it must be of type `double` or `uint8`. The CData values map to conform to the surface defined by ZData.
- 3-D array — Use true colors. Specify an RGB triplet color for each vertex by setting `CData` to an m-by-n-by-3 array where `[m,n] = size(ZData)`. An RGB triplet is a three-element vector that specifies the intensities of the red, green, and blue components of a color. The first page of the array contains the red components, the second the green components, and the third the blue components of the colors. Since the surface uses true colors instead of colormap colors, the `CDataMapping` property has no effect.
  - If `CData` is of type `double` or `single`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.

- If `CData` is an integer type, then the surface uses the full range of data to determine the color. For example, if `CData` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CDataMode` — Selection mode for `CData`

`'auto'` (default) | `'manual'`

Selection mode for `CData`, specified as one of these values:

- `'auto'` — Use the `ZData` values to set the colors.
- `'manual'` — Use manually specified values. To specify the values, set the `CData` property.

`CDataSource` — Variable linked to `CData`

`''` | string containing MATLAB workspace variable name

Variable linked to `CData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `CData`.

By default, there is no linked variable, so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `CData` values immediately. To force an update of the values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, then you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`CDataMapping` — Color mapping method

`'scaled'` (default) | `'direct'`

Color mapping method, specified as `'scaled'` or `'direct'`. Use this property to control the mapping of color data values in CData into the colormap.

The methods have these effects:

- `'direct'` — Interpret the values as indices into the current colormap. Values with a decimal portion are fixed to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of `1` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap.
  - If the values are of type `uint8`, `uint16`, `uint32`, `uint64` , `int8`, `int16`, `int32`, or `int64`, then values of `0` or less map to the first color in the colormap. Values equal to or greater than the length of the colormap map to the last color in the colormap (or up to the range limits of the type).
  - If the values are of type `logical`, then values of `0` map to the first color in the colormap and values of `1` map to the second color in the colormap.
- `'scaled'` — Scale the values to range between the minimum and maximum color limits. The `CLim` property of the axes contains the color limits.

`AlphaData` — Transparency data

1 (default) | scalar | m-by-n array

Transparency data for each face or each vertex, specified in one of these forms:

- Scalar — Use the same transparency value.
- m-by-n array — Use different transparency values for each face or vertex. Specify an m-by-n array of numeric values where `[m,n] = size(ZData)`.

The AlphaDataMapping property determines the mapping of transparency data values into the alphamap. The `Alphamap` property for the figure contains the alphamap.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`AlphaDataMapping` — Transparency data mapping method

`'scaled'` (default) | `'direct'` | `'none'`

Transparency data mapping method, specified as `'scaled'`, `'none'`, or `'direct'`. Use this property to control the mapping of transparency values contained in AlphaData into the figure alphamap.

The methods have these effects:

- `'scaled'` — Transform the values to range between the alpha limits and then linearly map the data values to the alpha values. The `ALim` property for the axes contains the alpha limits.

- `'none'` — Clamp the values between `0` and `1`. A value of 1 or greater is completely opaque and 0 or less is transparent.
- `'direct'` — Interpret the values as indices into the figure alphamap. Fix values with a decimal portion to the nearest lower integer.
  - If the values are of type `double` or `single`, then values of 1 or less map to the first value in the alphamap. Values equal to or greater than the length of the alphamap map to the last value in the alphamap.
  - If the values are of type `uint8`, `uint16`. `uint32`, `uint64`. `int8`, `int16`, `int32`, or `int64`, then values of 0 or less map to the first value in the alphamap. Values equal to or greater than the length of the alphamap map to the last value in the alphamap (or up to the range limits of the type).
  - If the values are of type `logical`, then 0 maps the first value in the alphamap and 1 maps to the second value in the alphamap.

Ambient Lighting

`AmbientStrength` — Strength of ambient light

`0.3` (default) | scalar in range `[0,1]`

Strength of ambient light, specified as a scalar value in the range `[0,1]`. Ambient light is a nondirectional light that illuminates the entire scene. There must be at least one visible light object in the axes for the ambient light to be visible.

The `AmbientLightColor` property for the axes sets the color of the ambient light. The color is the same for all objects in the axes.

Example: `0.5`

Data Types: `double`

`DiffuseStrength` — Strength of diffuse light

`0.6` (default) | scalar in range `[0,1]`

Strength of diffuse light, specified as a scalar value in the range `[0,1]`. Diffuse light is the nonspecular reflectance from light objects in the axes.

Example: `0.3`

Data Types: `double`

`SpecularColorReflectance` — Color of specular reflections

1 (default) | scalar in range `[0,1]`

Color of specular reflections, specified as a scalar value in the range `[0,1]`. A value of `1` sets the color using only the color of the light source. A value of `0` sets the color using both the color of the object from which it reflects and the color of the light source. The `Color` property of the light contains the color of the light source. The proportions vary linearly for values in between.

Example: `0.5`

Data Types: `double`

`SpecularExponent` — Size of specular spot

10 (default) | scalar greater than or equal to 1

Size of specular spot, specified as a scalar value greater than or equal to 1. Most materials have exponents in the range `[5 20]`.

Example: `7`

Data Types: `double`

`SpecularStrength` — Strength of specular reflection

`0.9` (default) | scalar in range `[0,1]`

Strength of specular reflection, specified as a scalar value in the range `[0,1]`. Specular reflections are the bright spots on the surface from light objects in the axes.

Example: `0.3`

Data Types: `double`

Data

`XData` — x-coordinate data

matrix | vector

x-coordinate data specified as a matrix that is the same size as ZData or as a vector of length `n`, where `[m,n] = size(ZData)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

YData — y-coordinate data

matrix | vector

y-coordinate data, specified as a matrix that is the same size as ZData or a vector of length `m`, where `[m,n] = size(ZData)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

ZData — z-coordinate data

matrix

z-coordinate data, specified as a matrix of numeric values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

XDataSource — Variable linked to XData

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

YDataSource — Variable linked to YData

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`ZDataSource` — Variable linked to `ZData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `ZData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `ZData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `ZData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'z'`

`XDataMode` — Selection mode for `XData`

`'auto' | 'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the column indices of `ZData`..
- `'manual'` — Use manually specified values. To specify the values, use an input argument to the plotting function or directly set the `XData` property.

`YDataMode` — Selection mode for `YData`

`'auto' | 'manual'`

Selection mode for `YData`, specified as one of these values:

- `'auto'` — Use the row indices of `ZData`.
- `'manual'` — Use manually specified values. To specify the values, use an input argument to the plotting function or directly set the `YData` property.

Visibility

`Visible` — Visibility of chart surface

`'on'` (default) | `'off'`

Visibility of chart surface, specified as one of these values:

- `'on'` — Display the chart surface.
- `'off'` — Hide the chart surface without deleting it. You still can access the properties of an invisible chart surface object.

`Clipping` — Clipping of chart surface to axes limits

`'on'` (default) | `'off'`

Clipping of chart surface to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the chart surface that are outside the axes limits.
- `'off'` — Display the entire chart surface, even if parts of it appear outside the axes limits. Parts of the chart surface might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the chart surface that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.

- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'surface'`

Type of graphics object, returned as the string `'surface'`.

`Tag` — User-specified tag

`''` (default) | any string

Tag to associate with the chart surface, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with chart surface

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the chart surface object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the chart surface.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the chart surface object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the chart surface from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:

- `'on'` — Include the chart surface object in the legend as one entry (default).
- `'off'` — Do not include the chart surface object in the legend.
- `'children'` — Include only children of the chart surface object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of chart surface

axes object | group object | transform object

Parent of chart surface, specified as an axes, group, or transform object.

`Children` — Children of chart surface

empty `GraphicsPlaceholder` array

The chart surface has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of chart surface object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The chart surface object handle is always visible.
- `'off'` — The chart surface object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The chart surface object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the chart surface at the command-line, but allows callback functions to access it.

If the chart surface object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle

properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the chart surface. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart surface object — You can access properties of the chart surface object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the chart surface. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the chart surface when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the chart surface.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the chart surface that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the chart surface responds to the click or if an ancestor does.

- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'` and you can click a part of the chart surface that has no color. The HitTest property determines if the chart surface responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the chart surface passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the chart surface. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the chart surface that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the chart surface object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the chart surface is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the chart surface tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.

- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the chart surface. Setting the `CreateFcn` property on an existing chart surface has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during chart surface creation. MATLAB executes the callback after creating the chart surface and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart surface object — You can access properties of the chart surface object from within the callback function. You also can access the chart surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the chart surface. MATLAB executes the callback before destroying the chart surface so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The chart surface object — You can access properties of the chart surface object from within the callback function. You also can access the chart surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of chart surface

`'off'` (default) | `'on'`

Deletion status of chart surface, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the chart surface begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the chart surface no longer exists.

Check the value of the BeingDeleted property to verify that the chart surface is not about to be deleted before querying or modifying it.

More About

- "Access Property Values"

- “Graphics Object Properties”

Primitive Surface Properties

Control primitive surface appearance and behavior

Primitive surface properties control the appearance and behavior of primitive surface objects. By changing property values, you can modify certain aspects of the primitive surface.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = surface;
c = h.CData;
h.CDataMapping = 'direct';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Faces

`FaceColor` — Face color

`'flat'` (default) | `'interp'` | `'none'` | `'texturemap'` | RGB triplet or color string

Face color, specified as one of these values:

- `'flat'` — Use uniform face colors. Use the CData values. The color data at the first vertex determines the color for the entire face. You cannot use this value when the `FaceAlpha` property is set to `'interp'`.
- `'interp'` — Interpolate the face colors. Bilinear interpolation of the CData values at each vertex determines the colors. You cannot use this value when the `FaceAlpha` property is set to `'flat'`.
- `'none'` — Do not draw the faces.
- `'texturemap'` — Transform the color data in CData so that it conforms to the surface.
- RGB triplet or color string — Use the same color for all of the faces.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

FaceAlpha — Face transparency

1 (default) | scalar in range [0,1] | 'flat' | 'interp'

Face transparency, specified as one of these values:

- Scalar in range [0,1] — Use the same transparency value for all of the faces. A value of 1 is fully opaque and 0 is completely transparent.
- 'flat' — Use uniform transparency across each face. Use the AlphaData values to determine the transparency values. The alpha data at the first vertex determines the transparency for the entire face. You must first specify the AlphaData property as a matrix equal in size to ZData. You cannot use this value when the FaceColor property is set to 'interp'.
- 'interp' — Interpolate the transparency across each face. Bilinear interpolation of the AlphaData values at each vertex determines the transparency values. You must first specify the AlphaData property as a matrix equal in size to ZData. You cannot use this value when the FaceColor property is set to 'flat'.

FaceLighting — Effect of light objects on faces

'flat' (default) | 'gouraud' | 'none'

Effect of light objects on faces, specified as one of these values:

- 'flat' — Apply light uniformly across the faces. Use this value to view faceted objects.
- 'gouraud' — Vary the light across the faces. Calculate the light at the vertices and then linearly interpolate the light across the faces. Use this value to view curved surfaces.

- `'none'` — Do not apply light from light objects to the faces.

Note: The `'phong'` value has been removed. Use `'gouraud'` instead.

`BackFaceLighting` — Face lighting when normals point away from camera

`'reverslit'` (default) | `'unlit'` | `'lit'`

Face lighting when the vertex normals point away from camera, specified as one of these values:

- `'reverslit'` — Light the face as if the vertex normal pointed towards the camera.
- `'unlit'` — Do not light the face.
- `'lit'` — Light the face according to the vertex normal.

Use this property to discriminate between the internal and external surfaces of an object. For an example, see “Back Face Lighting”.

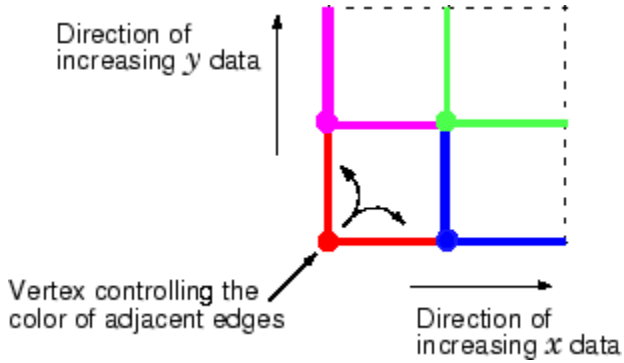
Edges

`EdgeColor` — Edge line color

`[0 0 0]` (default) | `'none'` | `'flat'` | `'interp'` | RGB triplet or color string

Surface edge line color, specified as one of these values:

- `'none'` — Do not draw edges.
- `'flat'` — Draw uniform edge colors. Use the `CData` value of the first vertex of the face to determine the color for each edge. You cannot use this value when the `EdgeAlpha` property is set to `'interp'`.



- `'interp'` — Interpolate the edge colors. Use a linear interpolation of the `CData` values at the face vertices to determine the edge color. You cannot use this value when the `EdgeAlpha` property is set to `'flat'`.
- RGB triplet or color string — Use the same color for all edges.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

`EdgeAlpha` — Surface edge transparency

1 (default) | scalar value in range `[0,1]` | `'flat'` | `'interp'`

Surface edge transparency, specified as one of these values:

- Scalar in range `[0,1]` — Use the same transparency value for all of the edges. A value of `1` is fully opaque and `0` is completely transparent.
- `'flat'` — Use uniform transparency across each edge. Use the values in `AlphaData` to determine the transparency for each edge. The value at the first vertex of the face determines the transparency for the edge. You must specify `AlphaData` as a matrix equal in size to `ZData`. You cannot use this value when the `EdgeColor` property is set to `'interp'`.
- `'interp'` — Interpolate the transparency across each edge. Use a bilinear interpolation of the `AlphaData` values for each vertex. You must specify `AlphaData` as a matrix equal in size to `ZData`. You cannot use this value when the `EdgeColor` property is set to `'flat'`.

`EdgeLighting` — Effect of light objects on edges

`'none'` (default) | `'flat'` | `'gouraud'`

Effect of light objects on edges, specified as one of these values:

- `'flat'` — Apply light uniformly across the each edges.
- `'none'` — Do not apply lights from light objects to the edges.
- `'gouraud'` — Calculate the light at the vertices, and then linearly interpolate across the edges.

Note: The `'phong'` value has been removed. Use `'gouraud'` instead.

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	————
`'--'`	Dashed line	- - - - -
`':'`	Dotted line	.....
`'-.'`	Dash-dotted line	_._._._.-

String	Line Style	Resulting Line
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`AlignVertexCenters` — Sharp vertical and horizontal lines

`'off'` (default) | `'on'`

Sharp vertical and horizontal lines, specified as `'off'` or `'on'`.

If the associated figure has a `GraphicsSmoothing` property set to `'on'` and a `Renderer` property set to `'opengl'`, then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the `AlignVertexCenters` property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

`MeshStyle` — Edges to display

`'both'` (default) | `'row'` | `'column'`

Edges to display, specified as `'both'`, `'row'`, or `'column'`.

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the primitive surface object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerSize` — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | `'flat'` | RGB triplet or color string

Marker outline color, specified as specified as one of these values:

- `'auto'` — Use the same color as the EdgeColor property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- `'flat'` — Use the CData value at the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | `'flat'` | RGB triplet or color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which allows the background to show through.
- `'auto'` — Use the same color as the `Color` property for the axes.
- `'flat'` — Use the CData value of the vertex to set the color.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

`[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

This property affects only the circle, square, diamond, pentagram, hexagram, and the four triangle marker types.

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Example:

Face and Vertex Normals

`FaceNormals` — Normal vectors for each surface face

`[ ]` (default) | (m-1)-by-(n-1)-by-3 array

Normal vectors for each surface face, specified as a (m-1)-by-(n-1)-by-3 array, where `[m,n] = size(ZData)`. Specify one normal vector per face.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: `single` | `double`

`FaceNormalsMode` — Selection mode for `FaceNormals`

`'auto'` (default) | `'manual'`

Selection mode for `FaceNormals`, specified as one of these values:

- `'auto'` — Calculate the normal vectors based on the coordinate data.
- `'manual'` — Use manually specified values. To specify the values, set the FaceNormals property.

`VertexNormals` — Normal vectors for each surface vertex

`[ ]` (default) | m-by-n-by-3 array

Normal vectors for each surface vertex, specified as a m-by-n-by-3 array, where `[m,n] = size(ZData)`. Specify one normal vector per vertex.

Specifying values for this property sets the associated mode to manual. If you do not specify normal vectors, then the surface generates this data for lighting calculations.

Data Types: `single` | `double`

`VertexNormalsMode` — Selection mode for `VertexNormals`

`'auto'` (default) | `'manual'`

Selection mode for `VertexNormals`, specified as one of these values:

- `'auto'` — Calculate the normal vectors based on the coordinate data.
- `'manual'` — Use manually specified values. To specify the values, set the VertexNormals property.

Color and Transparency Mapping

`AlphaData` — Transparency data

1 (default) | scalar | m-by-n array

Transparency data for each face or each vertex, specified in one of these forms:

- Scalar — Use the same transparency value.
- m-by-n array — Use different transparency values for each face or vertex. Specify an m-by-n array of numeric values where `[m,n] = size(ZData)`.

The AlphaDataMapping property determines the mapping of transparency data values into the alphamap. The `Alphamap` property for the figure contains the alphamap.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`AlphaDataMapping` — Transparency data mapping method

`'scaled'` (default) | `'direct'` | `'none'`

Transparency data mapping method, specified as `'scaled'`, `'none'`, or `'direct'`. Use this property to control the mapping of transparency values contained in AlphaData into the figure alphamap.

The methods have these effects:

- `'scaled'` — Transform the values to range between the alpha limits and then linearly map the data values to the alpha values. The `ALim` property for the axes contains the alpha limits.
- `'none'` — Clamp the values between `0` and `1`. A value of 1 or greater is completely opaque and 0 or less is transparent.
- `'direct'` — Interpret the values as indices directly into the figure alphamap. When not scaled, the values are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first value in the alphamap and values greater than `length(alphamap)` to the last value in the alphamap. Values with a decimal portion are fixed to the nearest lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the alphamap).

`CData` — Vertex colors

2-D or 3-D array

Vertex colors, specified in one of these forms:

- 2-D array — Use colormap colors. Specify a color for each vertex by setting CData to an array the same size as `ZData`. The CDataMapping property determines how these values map into the current colormap. If the FaceColor property is set to `'texturemap'`, then CData does not need to be the same size as ZData. However, it must be of type `double` or `uint8`. The CData values map to conform to the surface defined by ZData.
- 3-D array — Use true colors. Specify an RGB triplet color for each vertex by setting `CData` to an m-by-n-by-3 array where `[m,n] = size(ZData)`. An RGB triplet is a three-element vector that specifies the intensities of the red, green, and blue components of a color. The first page of the array contains the red components, the second the green components, and the third the blue components of the colors. Since the surface uses true colors instead of colormap colors, the `CDataMapping` property has no effect.

- If `CData` is of type `double` or `single`, then an RGB triplet value of `[0 0 0]` corresponds to black and `[1 1 1]` corresponds to white.
- If `CData` is an integer type, then the surface uses the full range of data to determine the color. For example, if `CData` is of type `uint8`, then `[0 0 0]` corresponds to black and `[255 255 255]` corresponds to white. If `CData` is of type `int8`, then `[-128 -128 -128]` corresponds to black and `[127 127 127]` corresponds to white.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`CDataMapping` — Direct or scaled colormapping

`'scaled'` (default) | `'direct'`

Direct or scaled colormapping, specified as one of these values:

- `scaled` — Transform the color data to span the portion of the colormap indicated by the axes `CLim` property, linearly mapping data values to colors. See the `caxis` reference page for more information on this mapping.
- `direct` — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to `length(colormap)`. MATLAB maps values less than 1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

`CDataMode` — Selection mode for `CData`

`'auto'` (default) | `'manual'`

Selection mode for `CData`, specified as one of these values:

- `'auto'` — Use the `ZData` values to set the colors.
- `'manual'` — Use manually specified values. To specify the values, set the `CData` property.

Lighting

`AmbientStrength` — Strength of ambient light

`0.3` (default) | scalar in range `[0,1]`

Strength of ambient light, specified as a scalar value in the range `[0,1]`. Ambient light is a nondirectional light that illuminates the entire scene. There must be at least one visible light object in the axes for the ambient light to be visible.

The `AmbientLightColor` property for the axes sets the color of the ambient light. The color is the same for all objects in the axes.

Example: `0.5`

Data Types: `double`

`DiffuseStrength` — Strength of diffuse light

`0.6` (default) | scalar in range `[0,1]`

Strength of diffuse light, specified as a scalar value in the range `[0,1]`. Diffuse light is the nonspecular reflectance from light objects in the axes.

Example: `0.3`

Data Types: `double`

`SpecularColorReflectance` — Color of specular reflections

1 (default) | scalar in range `[0,1]`

Color of specular reflections, specified as a scalar value in the range `[0,1]`. A value of `1` sets the color using only the color of the light source. A value of `0` sets the color using both the color of the object from which it reflects and the color of the light source. The `Color` property of the light contains the color of the light source. The proportions vary linearly for values in between.

Example: `0.5`

Data Types: `double`

`SpecularExponent` — Size of specular spot

10 (default) | scalar greater than or equal to 1

Size of specular spot, specified as a scalar value greater than or equal to 1. Most materials have exponents in the range `[5 20]`.

Example: `7`

Data Types: `double`

`SpecularStrength` — Strength of specular reflection

`0.9` (default) | scalar in range `[0,1]`

Strength of specular reflection, specified as a scalar value in the range `[0,1]`. Specular reflections are the bright spots on the surface from light objects in the axes.

Example: `0.3`

Data Types: `double`

Data

`XData` — x-coordinate data

[3x3 double] (default) | vector or matrix

x-coordinate data specified as a matrix that is the same size as `ZData` or a vector of `length(n)`, where `[m,n] = size(ZData)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`YData` — y-coordinate data

[3x3 double] (default) | vector or matrix

y-coordinate data specified as a matrix that is the same size as `ZData` or a vector of `length(m)`, where `[m,n] = size(ZData)`.

Example:

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ZData` — z-coordinate data

[3x3 double] (default) | 2–D array

z-coordinate data specified as a 2-D array of numeric values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`XDataMode` — Selection mode for `XData`

`'auto'` | `'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the column indices of `ZData`.

- `'manual'` — Use manually specified value. To specify the value, pass an input argument to the plotting function or directly set the `XData` property.

`YDataMode` — Selection mode for `YData`

`'auto' | 'manual'`

Selection mode for `YData`, specified as one of these values:

- `'auto'` — Use the row indices of `ZData`.
- `'manual'` — Use manually specified value. To specify the value, pass an input argument to the plotting function or directly set the `YData` property.

Visibility

`Visible` — Visibility of primitive surface

`'on'` (default) | `'off'`

Visibility of primitive surface, specified as one of these values:

- `'on'` — Display the primitive surface.
- `'off'` — Hide the primitive surface without deleting it. You still can access the properties of an invisible primitive surface object.

`Clipping` — Clipping of primitive surface to axes limits

`'on'` (default) | `'off'`

Clipping of primitive surface to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the primitive surface that are outside the axes limits.
- `'off'` — Display the entire primitive surface, even if parts of it appear outside the axes limits. Parts of the primitive surface might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the primitive surface that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Tag` — User-specified tag

`''` (default) | any string

Tag to associate with the primitive surface, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`Type` — Type of graphics object

`'surface'`

Type of graphics object, returned as the string `'surface'`

`UserData` — Data to associate with primitive surface

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the primitive surface object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the primitive surface.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the primitive surface object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the primitive surface from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the primitive surface object in the legend as one entry (default).
   - `'off'` — Do not include the primitive surface object in the legend.
   - `'children'` — Include only children of the primitive surface object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of primitive surface

axes object | group object | transform object

Parent of primitive surface, specified as an axes, group, or transform object.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of primitive surface object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The primitive surface object handle is always visible.
- `'off'` — The primitive surface object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The primitive surface object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the primitive surface at the command-line, but allows callback functions to access it.

If the primitive surface object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

`Children` — Children of primitive surface

empty `GraphicsPlaceholder` array

The primitive surface has no children. You cannot set this property.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the primitive surface. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive surface object — You can access properties of the primitive surface object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the primitive surface. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the primitive surface when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the primitive surface.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the primitive surface that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the primitive surface responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'` and you can click a part of the primitive surface that has no color. The HitTest property determines if the primitive surface responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the primitive surface passes the click through it to the object below it in the current view of the figure window. The `HitTest` property has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the primitive surface. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the primitive surface that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the primitive surface object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the primitive surface tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the primitive surface is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the primitive surface. Setting the `CreateFcn` property on an existing primitive surface has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during primitive surface creation. MATLAB executes the callback after creating the primitive surface and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive surface object — You can access properties of the primitive surface object from within the callback function. You also can access the primitive surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see “Callback Definition”.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the primitive surface. MATLAB executes the callback before destroying the primitive surface so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The primitive surface object — You can access properties of the primitive surface object from within the callback function. You also can access the primitive surface object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of primitive surface

`'off'` (default) | `'on'`

Deletion status of primitive surface, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the primitive surface begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the primitive surface no longer exists.

Check the value of the BeingDeleted property to verify that the primitive surface is not about to be deleted before querying or modifying it.

save

Save workspace variables to file

Syntax

```
save(filename)
save(filename,variables)
save(filename,variables,fmt)
save(filename,variables,version)
save(filename,variables,'-append')

save filename
```

Description

`save(filename)` saves all variables from the current workspace in a MATLAB formatted binary file (MAT-file) called `filename`. If `filename` exists, `save` overwrites the file.

`save(filename,variables)` saves only the variables or fields of a structure array specified by `variables`.

`save(filename,variables,fmt)` saves in the file format specified by `fmt`. The `variables` argument is optional. If you do not specify `variables`, the `save` function saves all variables in the workspace.

`save(filename,variables,version)` saves to the MAT-file version specified by `version`. The `variables` argument is optional.

`save(filename,variables,'-append')` adds new variables to an existing file, and does not overwrite it. The `variables` argument is optional.

To append to a Version 6 MAT-file, you must also include `'-v6'` as an input argument.

`save filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to save a file named `test.mat`, these statements are equivalent:

```
save test.mat      % command form
save('test.mat')   % function form
```

You can include any of the inputs described in previous syntaxes. For example, to save the variable named `X`:

```
save test.mat X       % command form
save('test.mat','X')  % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

Note: If you save a figure to a MAT-file in MATLAB release R2014b or later, you cannot open the MAT-file in earlier versions of MATLAB. Use `savefig` to save figures that are compatible with earlier versions of MATLAB.

Saving graphics handle variables can cause the creation of very large files because graphics objects contain their defining data. To save graphics figures, use `savefig`.

Examples

Save All Workspace Variables to MAT-File

Save all variables from the workspace in a binary MAT-file, `test.mat`. If `filename` is a variable, use function syntax.

```
filename = 'test.mat';
save(filename)
```

Otherwise, you also can use command syntax.

```
save test.mat
```

Remove the variables from the workspace, and then retrieve the data with the `load` function.

```
clear
load('test.mat')
```

Save Specific Variables to MAT-File

Create and save two variables, `p` and `q`, to a file called `pqfile.mat`.

```
p = rand(1,10);
q = ones(10);
save('pqfile.mat','p','q')
```

MATLAB® saves the variables to the file, `pqfile.mat`, in the current folder.

You also can use command syntax to save the variables, `p` and `q`.

```
save pqfile.mat p q
```

Save Data to ASCII File

Create two variables, save them to an ASCII file, and then view the contents of the file.

```
p = rand(1,10);
q = ones(10);
save('pqfile.txt','p','q','-ascii')
type('pqfile.txt')
```

The `type` function displays the contents of the file.

Alternatively, use command syntax for the `save` operation.

```
save pqfile.txt p q -ascii
```

Save Structure Fields as Individual Variables

Create a structure, `s1`, that contains three fields, `a`, `b`, and `c`.

```
s1.a = 12.7;
s1.b = {'abc',[4 5; 6 7]};
s1.c = 'Hello!';
```

Save the fields of structure `s1` as individual variables in a file called `newstruct.mat`.

```
save('newstruct.mat','-struct','s1');
```

Check the contents of the file using the `whos` function.

```
disp('Contents of newstruct.mat:')
whos('-file','newstruct.mat')
```

```
Contents of newstruct.mat:
  Name      Size            Bytes  Class     Attributes

  a         1x1                 8  double
  b         1x2               262  cell
  c         1x6                12  char
```

Save Variables to Version 7.3 MAT-File

Create two variables and save them to a version 7.3 MAT-file called `example.mat`.

```
A = rand(5);
B = magic(10);
save('example.mat','A','B','-v7.3')
```

You also can use command syntax for the `save` operation.

```
save example.mat A B -v7.3
```

Append Variable to MAT-File

Save two variables to a MAT-file. Then, append a third variable to the same file.

```
p = rand(1,10);
q = ones(10);
save('test.mat','p','q')
```

View the contents of the MAT-file.

```
whos('-file','test.mat')
```

```
  Name        Size             Bytes  Class     Attributes

  p           1x10                80  double
  q          10x10               800  double
```

Create a new variable, `a`, and append it to the MAT-file.

```
a = 50;
save('test.mat','a','-append')
```

View the contents of the MAT-file.

```
whos('-file','test.mat')
```

```
  Name        Size             Bytes  Class     Attributes

  a           1x1                  8  double
  p           1x10                80  double
  q          10x10               800  double
```

The variable, `a`, is appended to `test.mat`, without overwriting the previous variables, `p` and `q`.

Note: To append to a Version 6 MAT-file, specify both `'-v6'` and `'-append'`. For example, to save variable `a` to the file, `test.mat`, call:

```
save('test.mat','a','-v6','-append')
```

Input Arguments

`filename` — Name of file

`'matlab.mat'` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `save` function saves to a file named `matlab.mat`.

If `filename` has no extension (that is, no period followed by text), and the value of `format` is `-mat` (the default), then MATLAB appends `.mat`. If `filename` does not include a full path, MATLAB saves to the current folder. You must have permission to write to the file.

When using the command form of `save`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, `save 'filename withspace.mat'`.

Example: `'myFile.mat'`

Data Types: `char`

`variables` — Names of variables to save

string

Names of variables to save, specified as one or more strings. When using the command form of `save`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of `variables` Input	Variables to Save
`var1,...,varN`	Save the listed variables, specified as individual strings. Use the `'*'` wildcard to match patterns. For example, `save('filename.mat','A*')` saves all variables in the file that start with `A`.

Form of variables Input	Variables to Save
`'-regexp',expr1,...,exprN`	Save only the variables whose names match the regular expressions, specified as strings. For example, `save('filename.mat','-regexp','^Mon','^Tues')` saves only the variables in the file whose names begin with `Mon` or `Tues`.
`'-struct',structName`	Store the fields of the scalar structure specified by *`structName`* as individual variables in the file. For example, `save('filename.mat','-struct','S')` saves the scalar structure, `S`.
`'-struct',structName,field1,...,`	Store the specified fields of the specified scalar structure as individual variables in the file. For example, `save('filename.mat,'-struct','S','a','b')` saves the fields `S.a` and `S.b`.
`'-struct',structName,'-regexp',expr1,...,exprN`	Store only the fields whose names match the regular expressions, specified as strings.

Data Types: `char`

`fmt` — File format

`'-mat'` (default) | `'-ascii'` | `'-ascii','-tabs'` | `'-ascii','-double'` | `'-ascii','-double','-tabs'`

File format, specified as one of the following strings. When using the command form of `save`, you do not need to enclose input strings in single quotes, for example, `save myFile.txt -ascii -tabs`.

Value of `fmt`	File Format
`'-mat'`	Binary MAT-file format.
`'-ascii'`	Text format with 8 digits of precision.
`'-ascii','-tabs'`	Tab-delimited text format with 8 digits of precision.
`'-ascii','-double'`	Text format with 16 digits of precision.

Value of `fmt`	File Format
`'-ascii','-double','-tabs'`	Tab-delimited text format with 16 digits of precision.

For MAT-files, data saved on one machine and loaded on another machine retains as much accuracy and range as the different machine floating-point formats allow.

Use one of the text formats to save MATLAB numeric values to text files. In this case:

- Each variable must be a two-dimensional `double` array.
- The output includes only the real component of complex numbers.
- MATLAB writes data from each variable sequentially to the file. If you plan to use the `load` function to read the file, all variables must have the same number of columns. The `load` function creates a single variable from the file.

If you specify a text format and any variable is a two-dimensional character array, then MATLAB translates characters to their corresponding internal ASCII codes. For example, `'abc'` appears in a text file as:

```
  9.7000000e+001   9.8000000e+001   9.9000000e+001
```

`version` — MAT-file version

`'-v7.3' | '-v7' | '-v6' | '-v4'`

MAT-file version, specified as one of the following strings. When using the command form of `save`, you do not need to enclose input strings in single quotes.

Value of `version`	Loads in MATLAB Versions	Supported Features	Compression	Maximum Size of Each Variable
`'-v7.3'`	7.3 (R2006b) or later	Saving and loading parts of variables, and all Version 7 features	Yes	≥ 2 GB on 64-bit computers
`'-v7'`	7.0 (R14) or later	Unicode character encoding, which enables file sharing between systems that use different default character encoding schemes, and all Version 6 features.	Yes	2^31 bytes per variable

Value of `version`	Loads in MATLAB Versions	Supported Features	Compression	Maximum Size of Each Variable
`'-v6'`	5 (R8) or later	N-dimensional arrays, cell arrays, structure arrays, variable names longer than 19 characters, and all Version 4 features.	No	2^31 bytes per variable
`'-v4'`	All	Two-dimensional `double`, character, and sparse arrays	No	100,000,000 elements per array, and 2^31 bytes per variable

If any data items require features that the specified version does not support, MATLAB does not save those items and issues a warning. You cannot specify a version later than your current version of MATLAB software.

Note: Version 7.3 MAT-files use an HDF5 based format that requires some overhead storage to describe the contents of the file. For cell arrays, structure arrays, or other containers that can store heterogeneous data types, Version 7.3 MAT-files are sometimes larger than Version 7 MAT-files.

To view or set the default version for MAT-files, select a **MAT-file save format** option in the General Preferences.

More About

Tips

- For more flexibility in creating ASCII files, use `dlmwrite` or `fprintf`.

Introduced before R2006a

save (COM)

Serialize control object to file

Syntax

```
save(h,'filename')
```

Description

`save(h,'filename')` saves the COM control object, `h`, to the file specified in the string, `filename`.

Note The COM `save` function is only supported for controls.

Examples

Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
save(h,'mwsample')
```

Now, alter the figure by changing its label and the radius of the circle.

```
h.Label = 'Circle';
h.Radius = 50;
Redraw(h);
```

Using the `load` function, you can restore the control to its original state.

```
load(h,'mwsample');
get(h)
```

```
ans =
     Label: 'Label'
    Radius: 20
```

More About

Tips

COM functions are available on Microsoft Windows systems only.

`load (COM)` | `delete (COM)` | `actxcontrol` | `actxserver` | `release`

Introduced before R2006a

save (serial)

Save serial port objects and variables to file

Syntax

```
save filename
save filename obj1 obj2...
```

Description

`save filename` saves all MATLAB variables to the file `filename`. If an extension is not specified for `filename`, then the `.mat` extension is used.

`save filename obj1 obj2...` saves the serial port objects `obj1` `obj2...` to the file `filename`.

Examples

This example illustrates how to use the command and functional form of `save` on a Windows platform.

```
s = serial('COM1');
set(s,'BaudRate',2400,'StopBits',1)
save MySerial1 s
set(s,'BytesAvailableFcn',@mycallback)
save('MySerial2','s')
```

More About

Tips

You can use `save` in the functional form as well as the command form shown above. When using the functional form, you must specify the filename and serial port objects as strings. For example. to save the serial port object `s` to the file `MySerial.mat` on a Windows platform

```
s = serial('COM1');
save('MySerial','s')
```

Any data that is associated with the serial port object is not automatically stored in the file. For example, suppose there is data in the input buffer for `obj`. To save that data to a file, you must bring it into the MATLAB workspace using one of the synchronous read functions, and then save to the file using a separate variable name. You can also save data to a text file with the `record` function.

You return objects and variables to the MATLAB workspace with the `load` command. Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

See Also

`load` | `record` | `Status`

Introduced before R2006a

saveas

Save figure to specific file format

Syntax

```
saveas(fig,filename)
saveas(fig,filename,formattype)
```

Description

`saveas(fig,filename)` saves the figure or Simulink block diagram specified by `fig` to file `filename`. Specify the file name as a string that includes a file extension, for example, `'myplot.jpg'`. The file extension defines the file format. If you do not specify an extension, then `saveas` saves the figure to a FIG-file.To save the current figure, specify `fig` as `gcf`.

`saveas(fig,filename,formattype)` creates the file using the specified file format, `formattype`. If you do not specify a file extension in the file name, for example, `'myplot'`, then the standard extension corresponding to the specified format automatically appends to the file name. If you specify a file extension, it does not have to match the format. `saveas` uses `formattype` for the format, but saves the file with the specified extension. Thus, the file extension might not match the actual format used.

Examples

Save Figure as PNG File

Create a bar chart and save it as a PNG file.

```
x = [2 4 7 2 4 5 2 5 1 4];
bar(x);
saveas(gcf,'Barchart.png')
```

Save Figure as EPS File

Create a bar chart and save it as an EPS file. Specify the `'epsc'` driver to save it in color.

```
x = [2 4 7 2 4 5 2 5 1 4];
bar(x);
saveas(gcf,'Barchart','epsc')
```

`saveas` saves the bar chart as `Barchart.eps`.

Save Simulink Block Diagram as BMP File

Save a Simulink block diagram named `'sldemo_tank'` as a BMP file. Use `get_param` to get the handle of the diagram. You must have Simulink installed to run this code.

```
sldemo_tank
fig = get_param('sldemo_tank','Handle');
saveas(fig,'MySimulinkDiagram.bmp');
```

- "Save Figure for Document or Presentation"

Input Arguments

`fig` — Figure to save

figure object | Simulink block diagram

Figure to save, specified as a figure object or a Simulink block diagram. If you specify other types of graphics objects, such as an axes, then `saveas` saves the parent figure to the object. This means that `saveas` cannot save a subplot without also saving all subplots in the parent figure.

Example: `saveas(gcf,'MyFigure.png')`

To save a Simulink block diagram, use `get_param` to get the handle of the diagram. For example, save a block diagram named `'sldemo_tank'`.

```
sldemo_tank
saveas(get_param('sldemo_tank','Handle'),'MySimulinkDiagram.bmp');
```

`filename` — File name

string

File name, specified as a string with or without a file extension.

Example: `'Bar Chart'`

Example: `'Bar Chart.png'`

If you specify a file extension, then `saveas` uses the associated format. If you specify a file extension and additionally specify the `formattype` input argument, then `saveas` uses `formattype` for the format and saves the file with the specified file name. Thus, the file extension might not match the actual format used.

You can specify any extension corresponding to a file format. This table lists some common file extensions.

Extension	Resulting Format
`.fig`	MATLAB FIG-file (invalid for Simulink block diagrams)
`.m`	MATLAB FIG-file and MATLAB code that opens figure (invalid for Simulink block diagrams)
`.jpg`	JPEG image
`.png`	Portable Network Graphics
`.eps`	EPS Level 3 Black and White
`.pdf`	Portable Document Format
`.bmp`	Windows bitmap
`.emf`	Enhanced metafile
`.pbm`	Portable bitmap
`.pcx`	Paintbrush 24-bit
`.pgm`	Portable Graymap
`.ppm`	Portable Pixmap
`.tif`	TIFF image, compressed

`formattype` — File format

`'fig'` | `'m'` | `'mfig'` | bitmap image file format | vector graphics file format

File format, specified as one of these options:

- `'fig'` — Save the figure as a MATLAB figure file with the `.fig` extension. To open figures saved with the `.fig` extension, use the `openfig` function. This format is not value for Simulink block diagrams.

- `'m'` or `'mfig'` — Save the figure as a MATLAB figure file and additionally create a MATLAB file that opens the figure. To open the figure, run the MATLAB file. This option is not valid for Simulink block diagrams.
- Bitmap image file format — Specify the format as one of the bitmap image options in the table, Bitmap Image Formats.
- Vector graphics file format — Specify the format as one of the vector graphics options in the table, Vector Graphics Formats.

Bitmap Image File

Bitmap images contain a pixel-based representation of the figure. The size of the generated file depends on the figure and the format used. Bitmap images are widely used by web browsers and other applications that display graphics. However, they do not scale well and you cannot modify individual graphics objects (such as lines and text) in other graphics applications.

Bitmap Image Formats

Option	Format	Default File Extension
`'jpeg'`	JPEG 24-bit	`.jpg`
`'png'`	PNG 24-bit	`.png`
`'tiff'`	TIFF 24-bit (compressed)	`.tif`
`'tiffn'`	TIFF 24-bit (not compressed)	`.tif`
`'meta'`	Enhanced metafile (Windows only)	`.emf`
`'bmpmono'`	BMP Monochrome	`.bmp`
`'bmp'`	BMP 24-bit	`.bmp`
`'bmp16m'`	BMP 24-bit	`.bmp`
`'bmp256'`	BMP 8-bit (256 color, uses a fixed colormap)	`.bmp`
`'hdf'`	HDF 24-bit	`.hdf`
`'pbm'`	PBM (plain format) 1-bit	`.pbm`
`'pbmraw'`	PBM (raw format) 1-bit	`.pbm`

Option	Format	Default File Extension
`'pcxmono'`	PCX 1-bit	`.pcx`
`'pcx24b'`	PCX 24-bit color (three 8-bit planes)	`.pcx`
`'pcx256'`	PCX 8-bit newer color (256 color)	`.pcx`
`'pcx16'`	PCX older color (EGA/VGA 16-color)	`.pcx`
`'pgm'`	PGM (plain format)	`.pgm`
`'pgmraw'`	PGM (raw format)	`.pgm`
`'ppm'`	PPM (plain format)	`.ppm`
`'ppmraw'`	PPM (raw format)	`.ppm`

Vector Graphics File

Vector graphics files store commands that redraw the figure. This type of format scales well, but can result in a large file. In some cases, a vector graphics format might not produce the correct 3-D arrangement of objects. Some applications support extensive editing of vector graphics formats, but others do not support editing beyond resizing the graphic. The best practice is to make all the necessary changes while your figure is still in MATLAB.

Typically, `saveas` uses the Painters renderer when generating vector graphics files. For some complex figures, `saveas` uses the OpenGL renderer instead. If it uses the OpenGL renderer, then the vector graphics file contains an embedded image, which might limit the extent to which you can edit the image in other applications. To ensure that `saveas` uses the Painters renderer, set the `Renderer` property for the figure to `'painters'`.

If you set the `Renderer` property for the figure, then `saveas` uses that renderer. Otherwise, it chooses the appropriate renderer. However, if `saveas` chooses a renderer that differs from the renderer used for the figure on the display, then some details of the saved figure can differ from the displayed figure. If necessary, you can make the displayed figure and the saved figure use the same renderer by setting the `Renderer` property for the figure.

Vector Graphics Formats

Option	Format	Default File Extension
`'pdf'`	Full page Portable Document Format (PDF) color	`.pdf`
`'eps'`	Encapsulated PostScript (EPS) Level 3 black and white	`.eps`
`'epsc'`	Encapsulated PostScript (EPS) Level 3 color	`.eps`
`'eps2'`	Encapsulated PostScript (EPS) Level 2 black and white	`.eps`
`'epsc2'`	Encapsulated PostScript (EPS) Level 2 color	`.eps`
`'meta'`	Enhanced Metafile (Windows only)	`.emf`
`'svg'`	SVG (scalable vector graphics)	`.svg`
`'ps'`	Full-page PostScript (PS) Level 3 black and white	`.ps`
`'psc'`	Full-page PostScript (PS) Level 3 color	`.ps`
`'ps2'`	Full-page PostScript (PS) Level 2 black and white	`.ps`
`'psc2'`	Full-page PostScript (PS) Level 2 color	`.ps`

Note: Only PDF and PS formats use the `PaperOrientation` property of the figure and the `left` and `bottom` elements of the `PaperPosition` property. Other formats ignore these values.

More About

Tips

- To control the size or resolution when you save a figure, use the `print` function instead.
- The `saveas` function and the **Save As** dialog box (accessed from the **File** menu) do not produce identical results. The **Save As** dialog box produces images at screen resolution and at screen size. The `saveas` function uses a resolution of 150 DPI and uses the `PaperPosition` and `PaperPositionMode` properties of the figure to determine the size of the image.
- Details of saved and printed figures can differ from the figure on the display. To get output that is more consistent with the display, see “Save Figure Preserving Background Color” and “Save Figure at Specific Size and Resolution”.

See Also

`open` | `print` | `savefig`

Introduced before R2006a

savefig

Save figure and contents to FIG-file

Syntax

```
savefig(filename)
savefig(H,filename)
savefig(H,filename,'compact')
```

Description

`savefig(filename)` saves the current figure to a FIG-file named *`filename`*`.fig`.

`savefig(H,filename)` saves the figures identified by the graphics array `H` to a FIG-file named *`filename`*`.fig`.

`savefig(H,filename,'compact')` saves the specified figures in a FIG-file that can be opened only in MATLAB R2014b or later releases. The `'compact'` option reduces the size of the `.fig` file and the time required to create the file.

Examples

Save Current Figure to FIG-File

Create a surface plot of the `peaks` function. Save the figure to the file `PeaksFile.fig`.

```
figure
surf(peaks)
savefig('PeaksFile.fig')
```

To open the saved figure, use the command:

```
openfig('PeaksFile.fig');
```

MATLAB creates a new figure using the saved `.fig` file.

Save Multiple Figures to FIG-File

Create two plots and store the figure handles in array `h`. Save the figures to the file `TwoFiguresFile.fig`. Close the figures after saving them.

```
h(1) = figure;
z = peaks;
surf(z)

h(2) = figure;
plot(z)

savefig(h,'TwoFiguresFile.fig')
close(h)
```

To open the two figures, use the command:

```
figs = openfig('TwoFiguresFile.fig');
```

`figs` contains the handles of the two figures created.

Save Figure Using `'compact'` Option

Save a figure using the compact option:

```
h = figure
surf(peaks)
savefig(h,'PeaksFile.fig','compact')
```

To open the figure, use the command:

```
openfig('PeaksFile.fig');
```

- "Save Figure for Document or Presentation"

Input Arguments

`H` — One or more figures

single figure | array of figures

One or more figures, specified as a single figure or an array of figures.

`filename` — File name

`'Untitled.fig'` (default) | string

File name, specified as a string. If you do not specify a file name, then MATLAB saves the file as `Untitled.fig`, which is the default.

If the specified string does not include a `.fig` file extension, then MATLAB appends the extension. `savefig` does not accept other file extensions.

Example: `'ExampleFile.fig'`

`'compact'` — File format for R2014b or later releases

`'compact'`

File format for R2014b or later releases of MATLAB, specified as the string `'compact'`. This option results in smaller `.fig` files. However, do not use the `'compact'` option if you want to open the `.fig` file in versions of MATLAB before R2014b.

More About

Tips

- You must use MATLAB to open files saved using `savefig`. To open the file, pass the file name to the function `openfig` or `open`. For example,

  ```
  openfig('ExampleFile.fig')
  ```
  opens the file, `ExampleFile.fig`, in MATLAB.
- `savefig` saves the full MATLAB figure. To save only part of a figure, such as an axes, or to save handles in addition to the data, use the `save` function to create a MAT-file.

See Also

`findobj` | `load` | `open` | `openfig` | `save`

Introduced in R2013b

saveobj

Modify save process for object

Syntax

```
b = saveobj(a)
```

Description

`b = saveobj(a)` is called by the `save` function if the class of `a` defines a `saveobj` method. `save` writes the returned value, `b`, to the MAT-file.

Define a `loadobj` method to take the appropriate action when loading the object.

If `A` is an array of objects, MATLAB invokes `saveobj` separately for each object saved.

Examples

Call the superclass `saveobj` method from the subclass implementation of `saveobj` with the following syntax:

```
classdef mySub < super
   methods
      function sobj = saveobj(obj)
         % Call superclass saveobj method
         sobj = saveobj@super(obj);
         % Perform subclass save operations
         ...
      end
   ...
   end
...
end
```

Update object when saved:

```
function b = saveobj(a)
```

```
   % If the object does not have an account number,
   % Add account number to AccountNumber property
   if isempty(a.AccountNumber)
      a.AccountNumber = getAccountNumber(a);
   end
   b = a;
end
```

See Also

`save` | `load` | `loadobj`

Introduced before R2006a

savepath

Save current search path

Syntax

```
savepath
savepath folderName/pathdef.m

status = savepath( ___ )
```

Description

`savepath` saves the current MATLAB search path to an existing `pathdef.m` file in the current folder. If there is no `pathdef.m` file in the current folder, then `savepath` saves the search path to the first `pathdef.m` file on the current path. If there is no such file on the current path, then `savepath` saves the search path to the `pathdef.m` file that MATLAB located at startup.

On a Windows system with User Account Control (UAC) enabled, you might be prompted to allow the update operation because it requires administrator-level permission.

`savepath folderName/pathdef.m` saves the current search path to `pathdef.m` located in the folder specified by `folderName`. If you do not specify `folderName`, then `savepath` saves `pathdef.m` in the current folder.

Use this syntax if you do not have write access to the current `pathdef.m` file.

`status = savepath( ___ )` additionally indicates if the operation is successful, using any of the input arguments in the previous syntaxes. The `status` output is `0` when `savepath` is successful, and `1` otherwise.

Examples

Save Search Path to Specific Folder

Save the current search path to `pathdef.m` located in the folder, `I:/my_matlab_files`.

```
savepath I:/my_matlab_files/pathdef.m
```

Input Arguments

`folderName` — Folder name

string

Folder name, specified as a string. `folderName` can be a relative or absolute path.

Example: `C:\myFolder`

More About

Tips

- To display the paths to all `pathdef.m` files in the current folder and on the current search path, use `which`.

  ```
  which pathdef.m -all
  ```

  The `savepath` command updates the first `pathdef.m` file in this list.
- To save the search path programmatically each time you exit MATLAB, use `savepath` in a `finish.m` file.
- To save a search path and automatically use it in a future session, use the `savepath` *`folderName`*`/pathdef.m` syntax and set the folder specified by `folderName` as the MATLAB startup folder.
- “What Is the MATLAB Search Path?”
- “Running a Script When Exiting”

Introduced before R2006a

scatter

Scatter plot

Syntax

```
scatter(x,y)
scatter(x,y,a)
scatter(x,y,a,c)
scatter(___,'filled')
scatter(___,markertype)
scatter(___,Name,Value)

scatter(ax,___)

s = scatter(___)
```

Description

`scatter(x,y)` creates a scatter plot with circles at the locations specified by the vectors `x` and `y`. This type of graph is also known as a bubble plot.

`scatter(x,y,a)` specifies the circle areas. To plot each circle with equal area, specify `a` as a scalar. To plot each circle with a different area, specify `a` as a vector with length equal to the length of x and y.

`scatter(x,y,a,c)` specifies the circle colors. To plot all circles with the same color, specify `c` as a single color string or an RGB triplet. To use varying color, specify `c` as a vector or a three-column matrix of RGB triplets.

`scatter(___,'filled')` fills in the circles. Use the `'filled'` option with any of the input argument combinations in the previous syntaxes.

`scatter(___,markertype)` specifies the marker type.

`scatter(___,Name,Value)` specifies scatter series properties using one or more Name,Value pair arguments. For example, `'LineWidth',2` sets the marker outline width to 2 points.

`scatter(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes. The option `ax` can precede any of the input argument combinations in the previous syntaxes.

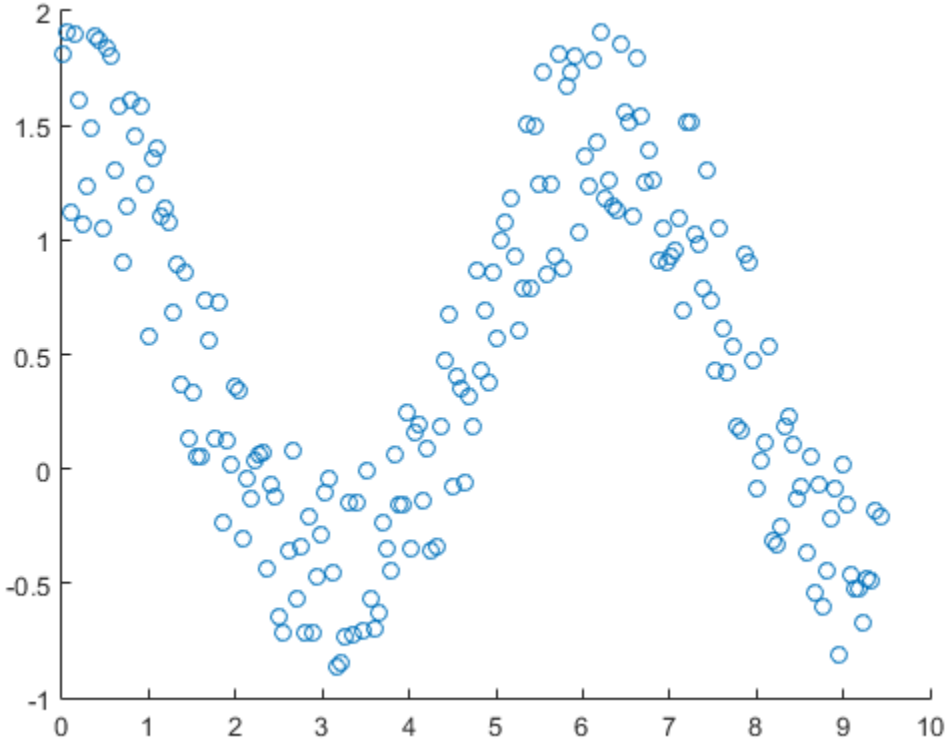
`s = scatter( ___ )` returns the scatter series object. Use `s` to make future modifications to the scatter series after it is created.

Examples

Create Scatter Plot

Create `x` as 200 equally spaced values between 0 and 3π. Create `y` as cosine values with random noise. Then, create a scatter plot.

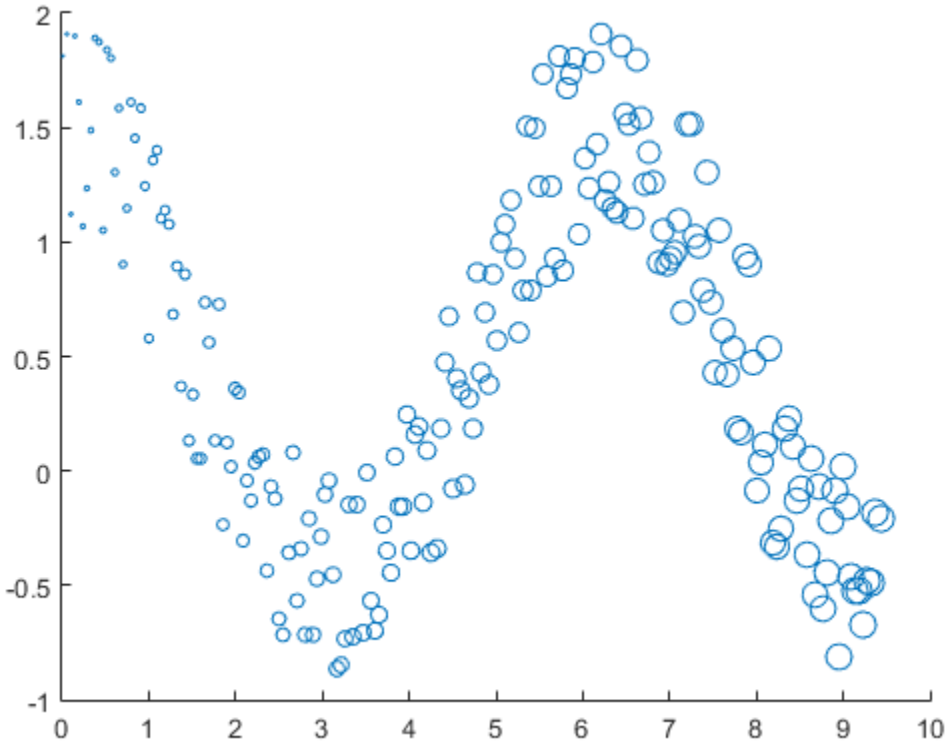
```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
scatter(x,y)
```



Vary Circle Size

Create a scatter plot using circles with different areas.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
a = linspace(1,100,200);
scatter(x,y,a)
```

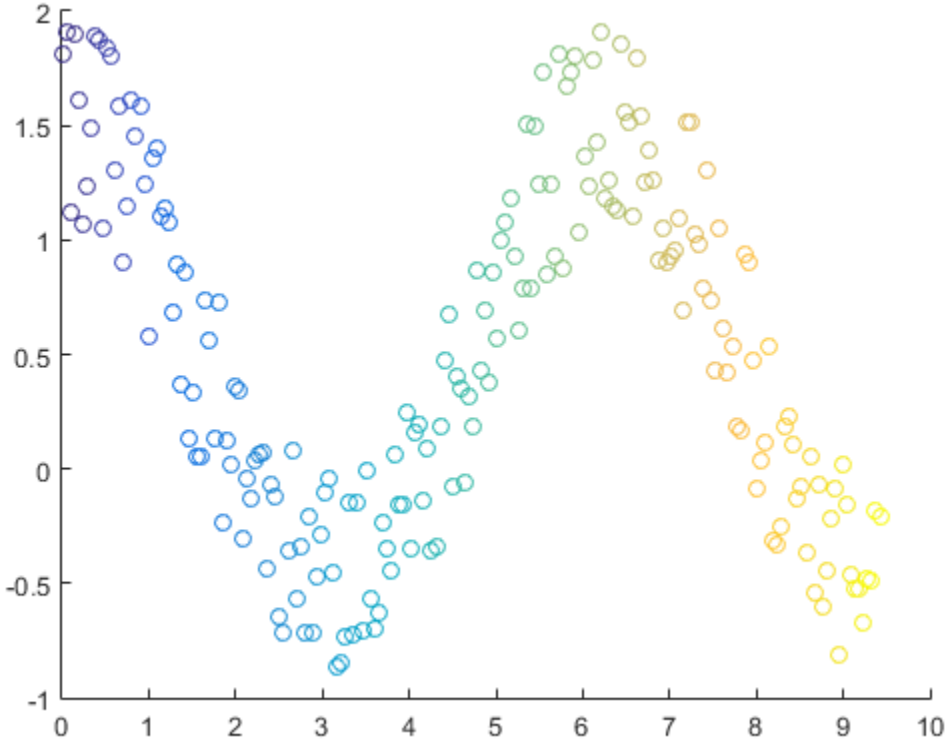


Corresponding elements in `x`, `y`, and `a` determine the location and area of each circle. To plot all circles with the equal area, specify `a` as a numeric scalar.

Vary Circle Color

Create a scatter plot and vary the circle color.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
c = linspace(1,10,length(x));
scatter(x,y,[],c)
```

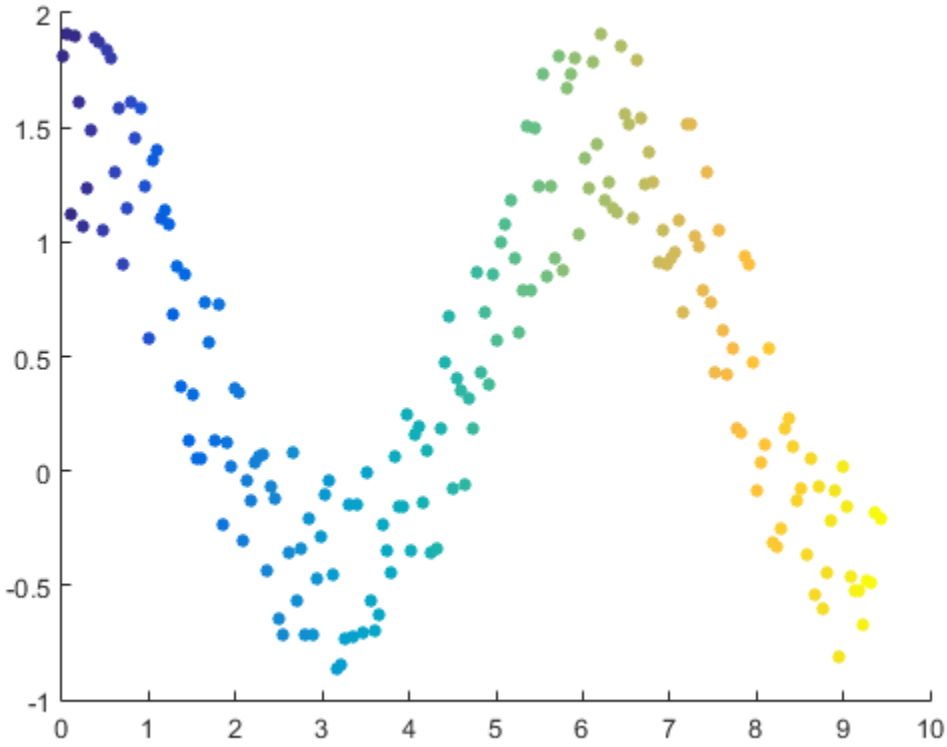


Corresponding elements in `x`, `y`, and `c` determine the location and color of each circle. The `scatter` function maps the elements in `c` to colors in the current colormap.

Fill the Markers

Create a scatter plot and fill in the markers. `scatter` fills each marker using the color of the marker edge.

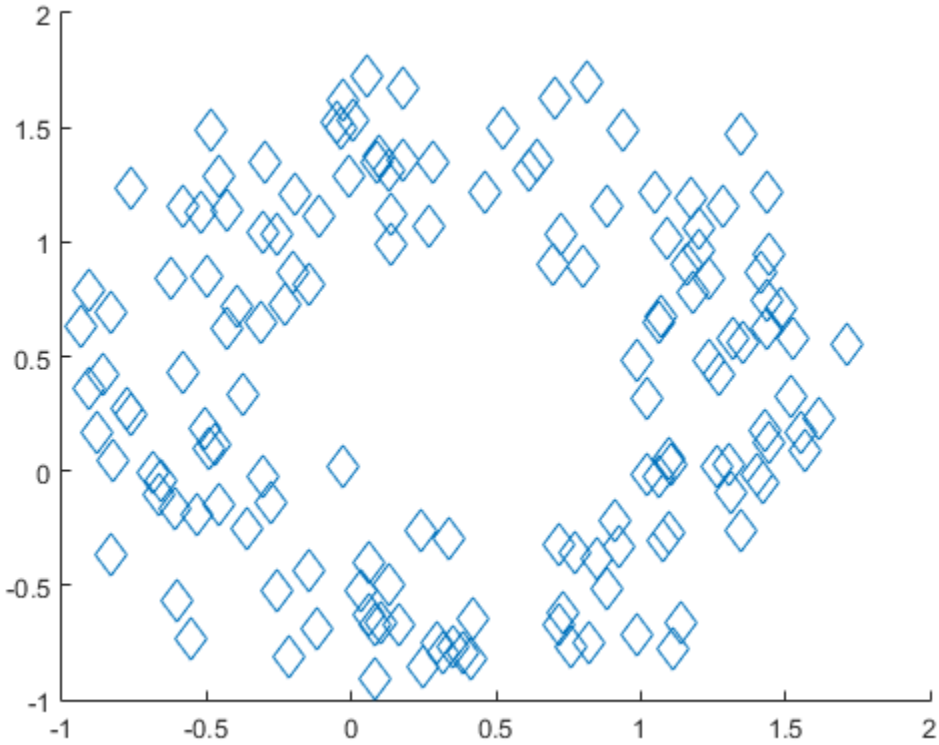
```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
a = 25;
c = linspace(1,10,length(x));
scatter(x,y,a,c,'filled')
```



Specify Marker Symbol

Create vectors `x` and `y` as sine and cosine values with random noise. Then, create a scatter plot and use diamond markers with an area of 140 points squared.

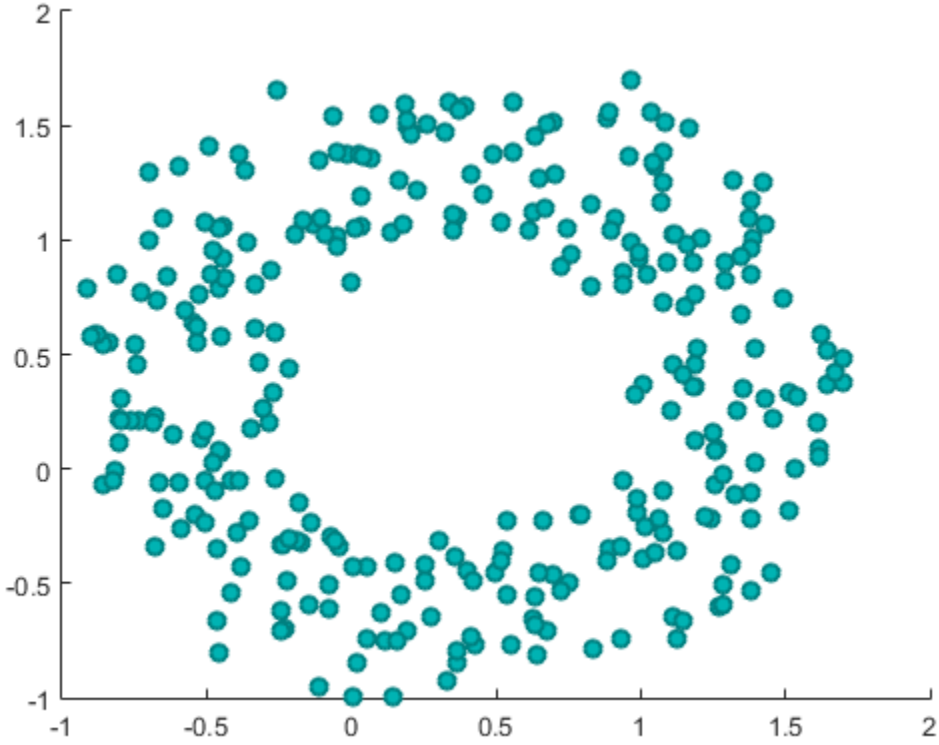
```
theta = linspace(0,2*pi,150);
x = sin(theta) + 0.75*rand(1,150);
y = cos(theta) + 0.75*rand(1,150);
a = 140;
scatter(x,y,a,'d')
```



Change Marker Color and Line Width

Create vectors `x` and `y` as sine and cosine values with random noise. Create a scatter plot and set the marker edge color, marker face color, and line width.

```
theta = linspace(0,2*pi,300);
x = sin(theta) + 0.75*rand(1,300);
y = cos(theta) + 0.75*rand(1,300);
a = 40;
scatter(x,y,a,'MarkerEdgeColor',[0 .5 .5],...
              'MarkerFaceColor',[0 .7 .7],...
              'LineWidth',1.5)
```

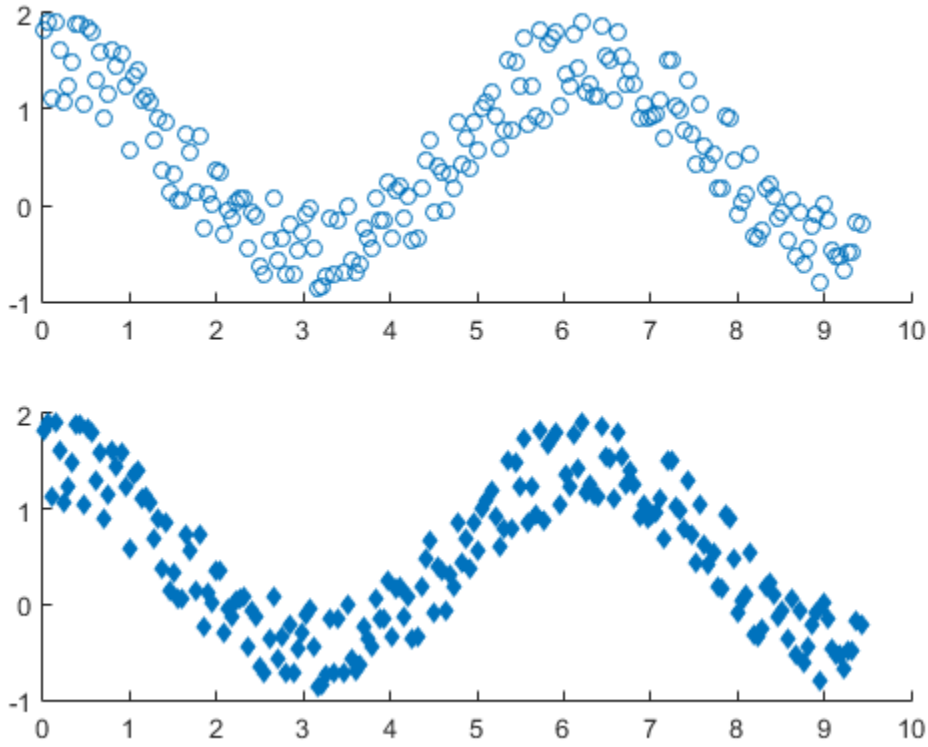


Specify Subplot for Scatter Plot

Create a figure with two subplots and add a scatter plot to each subplot. Use filled diamond markers for the scatter plot in the lower subplot.

```
x = linspace(0,3*pi,200);
y = cos(x) + rand(1,200);
ax1 = subplot(2,1,1);
scatter(ax1,x,y)

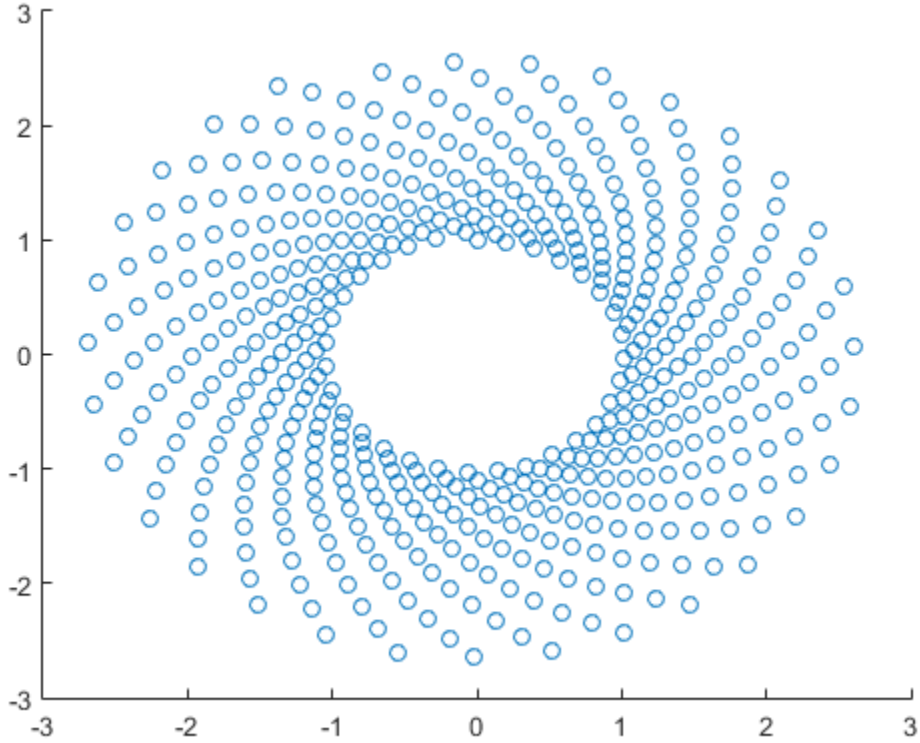
ax2 = subplot(2,1,2);
scatter(ax2,x,y,'filled','d')
```



Modify Scatter Series After Creation

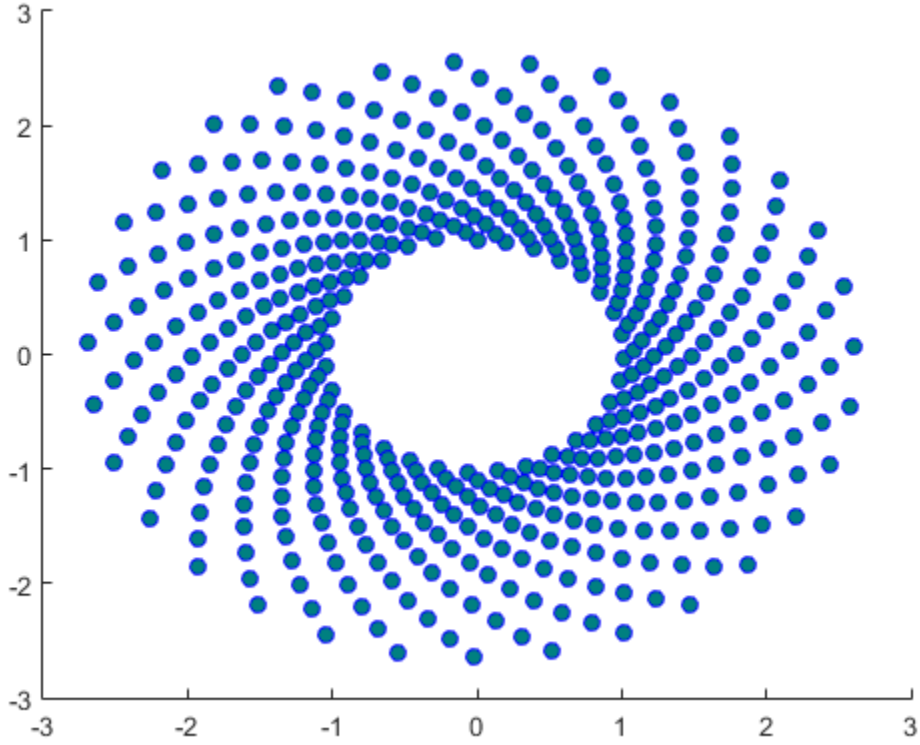
Create a scatter plot and return the scatter series object, `s`.

```
theta = linspace(0,1,500);
x = exp(theta).*sin(100*theta);
y = exp(theta).*cos(100*theta);
s = scatter(x,y);
```



Use `s` to query and set properties of the scatter series after it has been created. Set the line width to `0.6` point. Set the marker edge color to blue. Set the marker face color using an RGB triplet color. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
s.LineWidth = 0.6;
s.MarkerEdgeColor = 'b';
s.MarkerFaceColor = [0 0.5 0.5];
```



Input Arguments

x — x values

vector

x values, specified as a vector. `x` and `y` must be vectors of equal length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

y — y values

vector

y values, specified as a vector. `x` and `y` must be vectors of equal length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

a — Marker area

36 (default) | numeric scalar | row or column vector | `[]`

Marker area, specified in one of these forms:

- Numeric scalar — Plot all markers with equal area.
- Row or column vector — Use different areas for each marker. Corresponding elements in `x`, `y`, and `a` determine the location and area of each marker. The length of `a` must equal the length of `x` and `y`.
- `[]` — Use the default area of 36 points squared.

The units for the marker area is points squared.

Example: `50`

Example: `[36 25 25 17 46]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

c — Marker color

`[0 0 1]` (default) | color string | RGB triplet | three-column matrix of RGB triplets | vector

Marker color, specified in one of these forms:

- Color string or RGB triplet — Plot all markers with the same color.
- Three column matrix of RGB triplets — Use different colors for each marker. Each row of the matrix specifies an RGB triplet color for the corresponding marker. The number of rows must equal the length of `x` and `y`.
- Vector — Use different colors for each marker and linearly map values in `c` to the colors in the current colormap. The length of `c` must equal the length of `x` and `y`. To change the colormap for the axes, use the `colormap` function.

  If you have three points in the scatter plot and want the colors to be indices into the colormap, specify `c` as a three-element column vector.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'k'`

Example: `[1 2 3 4]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

`markertype` — Marker type

`'o'` (default) | `'+'` | `'*'` | `'.'` | ...

Marker type, specified as one of the strings listed in this table.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond

String	Marker Symbol
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

ax — Axes object
axes object

Axes object. If you do not specify an axes, then the `scatter` function uses the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'MarkerFaceColor','red'` sets the marker face color to red.

The scatter series properties listed here are only a subset. For a complete list, see Scatter Series Properties.

'MarkerEdgeColor' — Marker outline color
'flat' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'flat' — Colors defined by the CData property.
- 'none' — No color, which makes unfilled markers invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

`[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`'MarkerFaceColor'` — Marker fill color

`'none'` (default) | `'flat'` | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — No color, which makes the interior invisible.
- `'flat'` — Colors defined by the CData property.
- `'auto'` — Same color as the `Color` property for the axes.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

'LineWidth' — Width of marker edge
0.5 (default) | positive value

Width of marker edge, specified as a positive value in point units.

Example: 0.75

Output Arguments

s — Scatter series object
scatter series object

Scatter series object. Use s to access and modify properties of the scatter series after it has been created.

Functions
hold | plot | scatter3

Properties
Scatter Series Properties

Introduced before R2006a

scatter3

3-D scatter plot

Syntax

```
scatter3(X,Y,Z)
scatter3(X,Y,Z,S)
scatter3(X,Y,Z,S,C)
scatter3(___,'filled')
scatter3(___,markertype)
scatter3(___,Name,Value)

scatter3(ax,___)

h = scatter3(___)
```

Description

`scatter3(X,Y,Z)` displays circles at the locations specified by the vectors `X`, `Y`, and `Z`.

`scatter3(X,Y,Z,S)` draws each circle with the size specified by `S`. To plot each circle with equal size, specify `S` as a scalar. To plot each circle with a specific size, specify `S` as a vector.

`scatter3(X,Y,Z,S,C)` draws each circle with the color specified by `C`.

- If `C` is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If `C` is a three column matrix with the number of rows in `C` equal to the length of `X`, `Y`, and `Z`, then each row of `C` specifies an RGB color value for the corresponding circle.
- If `C` is a vector with length equal to the length of `X`, `Y`, and `Z`, then the values in `C` are linearly mapped to the colors in the current colormap.

`scatter3(___,'filled')` fills in the circles, using any of the input argument combinations in the previous syntaxes.

`scatter3( ___ ,markertype)` specifies the marker type.

`scatter3( ___ ,Name,Value)` specifies scatter series properties using one or more Name,Value pair arguments.

`scatter3(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The `ax` option can precede any of the input argument combinations in the previous syntaxes.

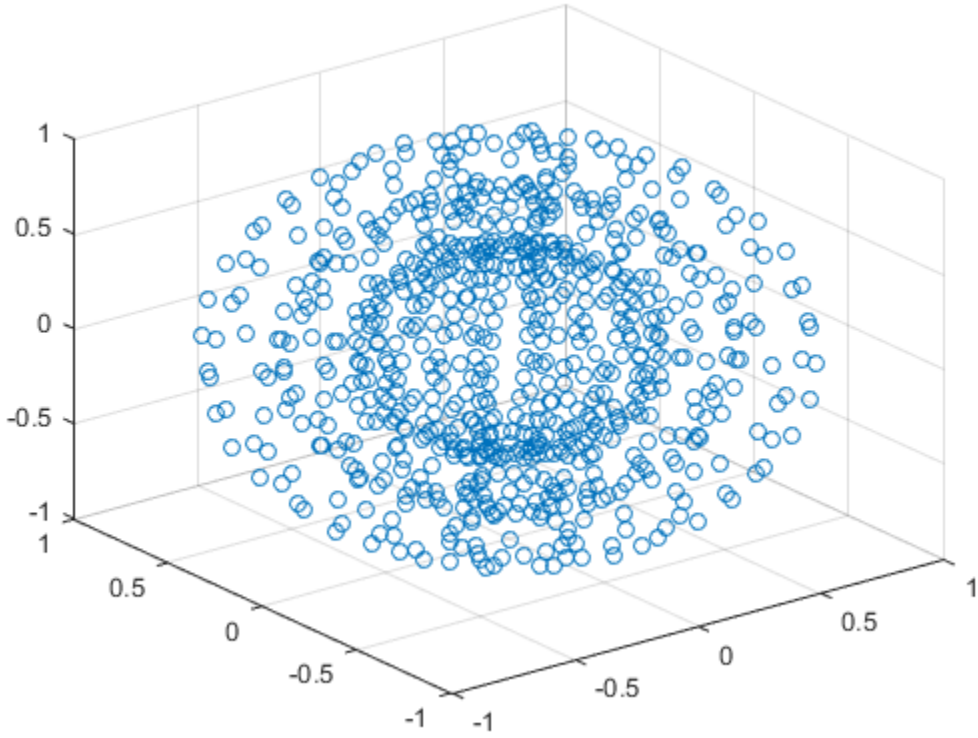
`h = scatter3( ___ )` returns the scatter series object. Use `h` to modify properties of the scatter series after it is created.

Examples

Create 3-D Scatter Plot

Create a 3-D scatter plot. Use `sphere` to define vectors `x`, `y`, and `z`.

```
figure
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
scatter3(x,y,z)
```



Vary Marker Size

Use `sphere` to define vectors `x`, `y`, and `z`.

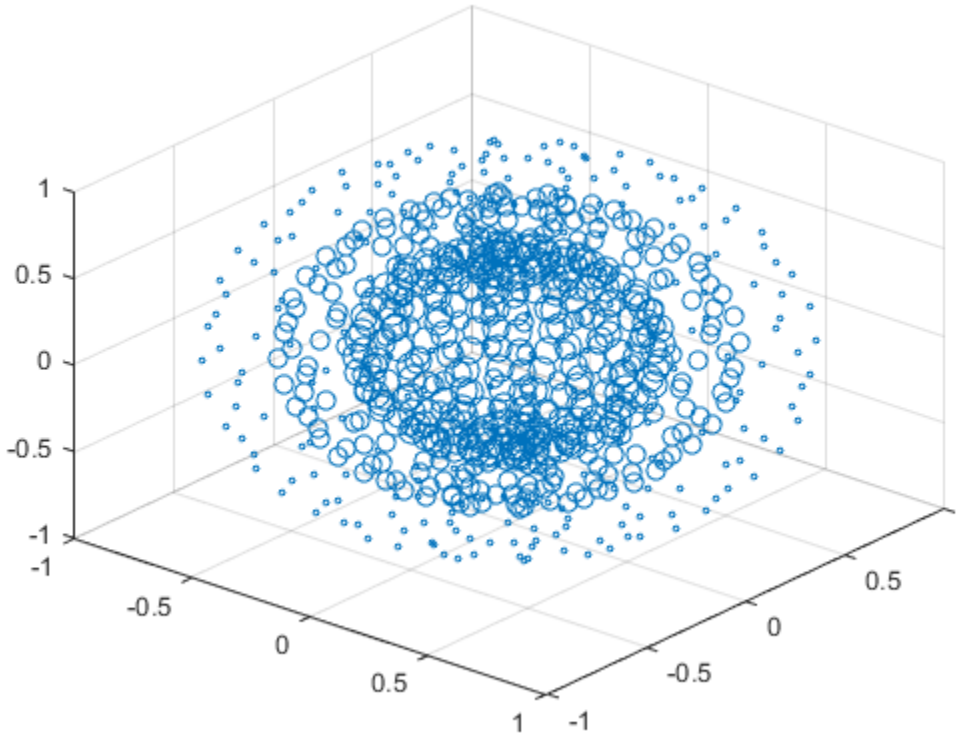
```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vector `s` to specify the marker sizes.

```
S = repmat([100,50,5],numel(X),1);
s = S(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s)
view(40,35)
```



Corresponding entries in `x`, `y`, `z`, and `s` determine the location and size of each marker.

Vary Marker Color

Use `sphere` to define vectors `x`, `y`, and `z`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
```

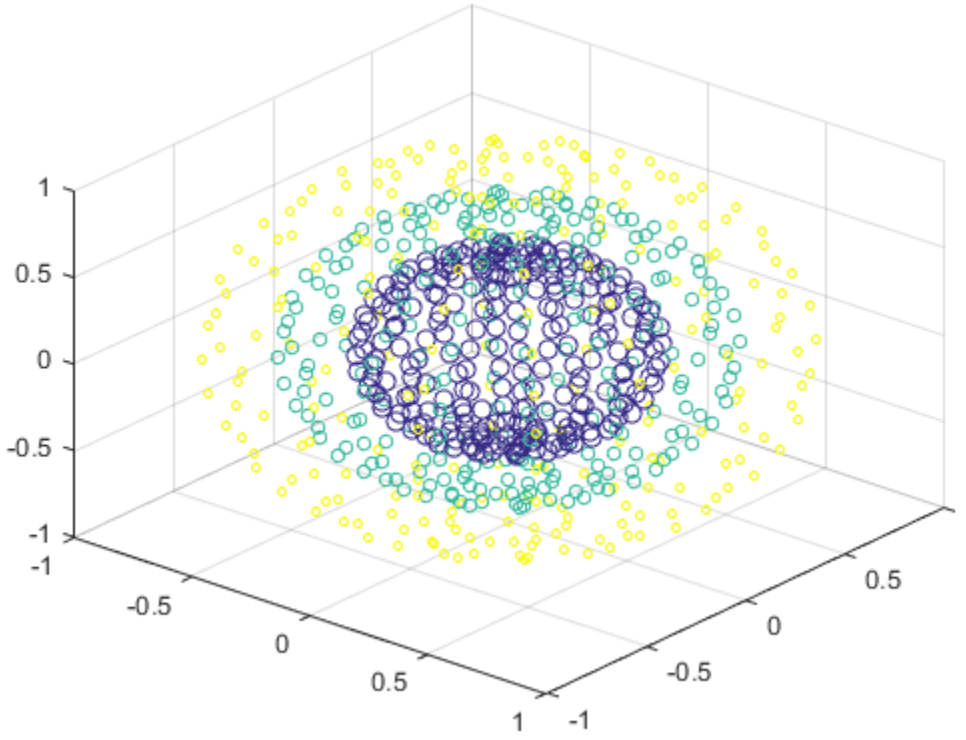
```
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vectors `s` and `c` to specify the size and color of each marker.

```
S = repmat([50,25,10],numel(X),1);
C = repmat([1,2,3],numel(X),1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s,c)
view(40,35)
```



Corresponding entries in `x`, `y`, `z`, and `c` determine the location and color of each marker.

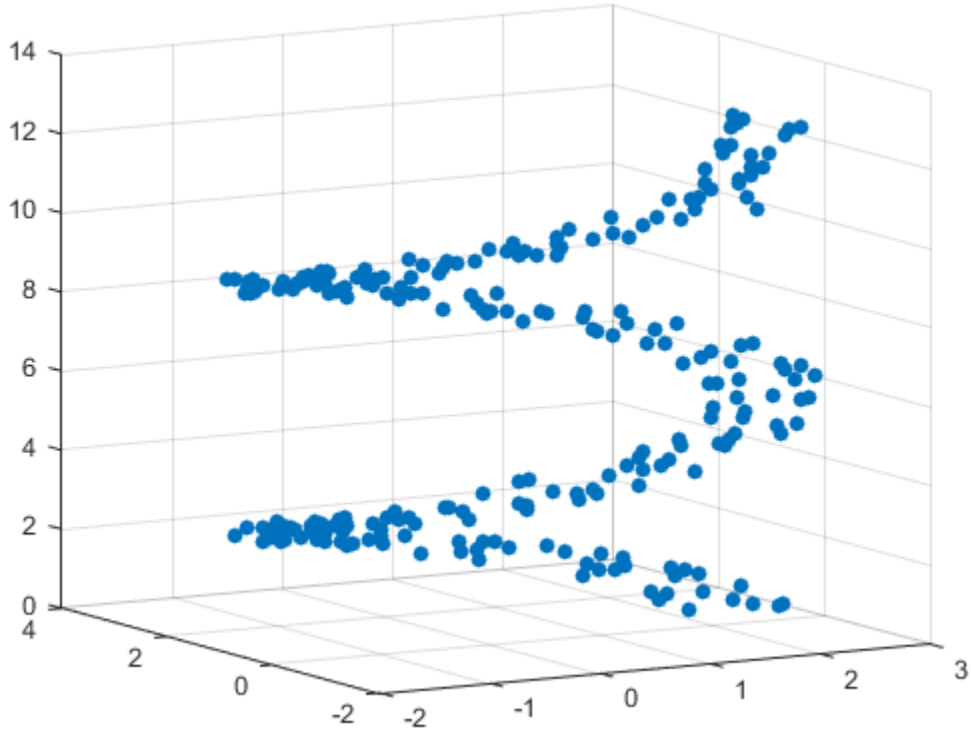
Fill in Markers

Create vectors `x` and `y` as cosine and sine values with random noise.

```
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and fill in the markers. Use `view` to change the angle of the axes in the figure.

```
scatter3(x,y,z,'filled')
view(-30,10)
```



Set Marker Type

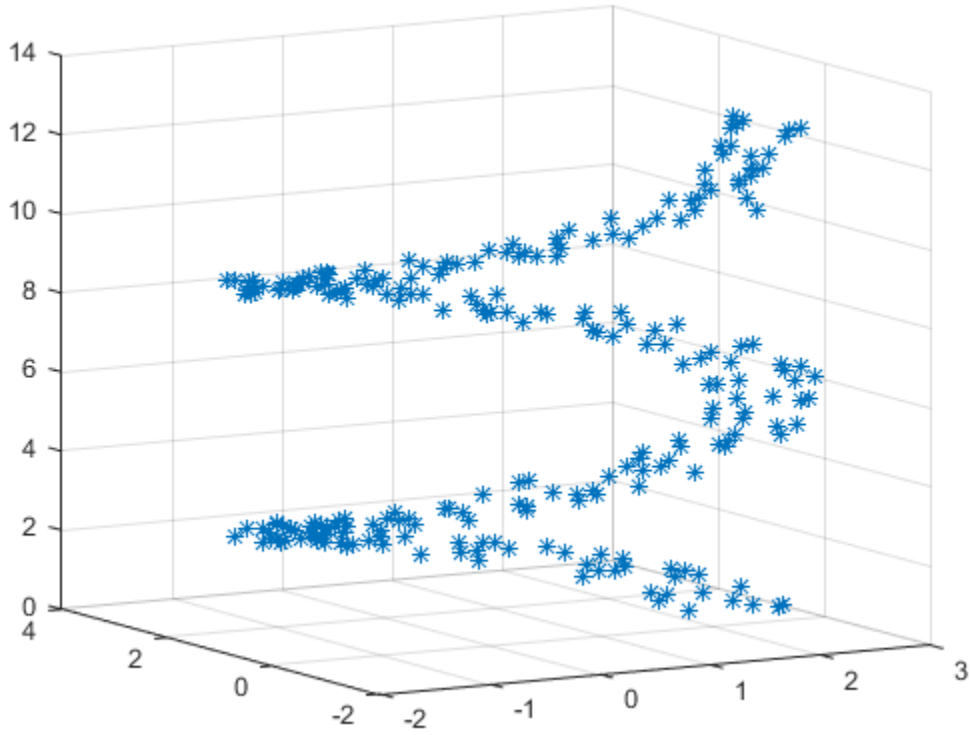
Initialize the random-number generator to make the output of `rand` repeatable. Define vectors `x` and `y` as cosine and sine values with random noise.

```
rng default
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker type. Use `view` to change the angle of the axes in the figure.

```
figure
```

```
scatter3(x,y,z,'*')
view(-30,10)
```



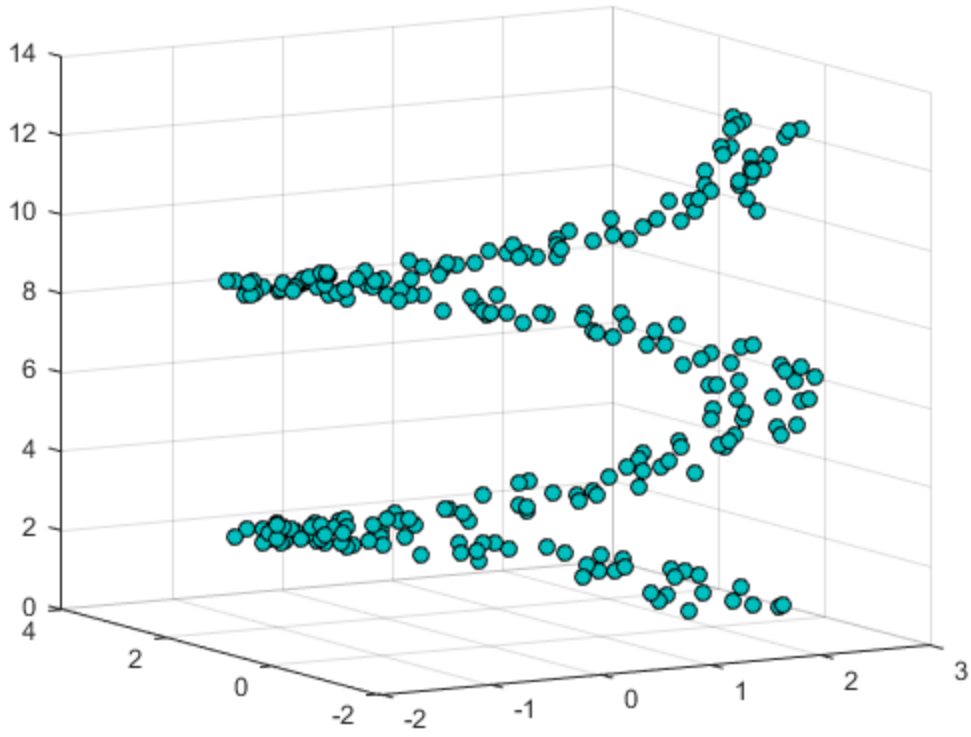
Set Marker Properties

Initialize the random-number generator to make the output of `rand` repeatable. Define vectors `x` and `y` as cosine and sine values with random noise.

```
rng default
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker edge color and the marker face color. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,...
        'MarkerEdgeColor','k',...
        'MarkerFaceColor',[0 .75 .75])
view(-30,10)
```



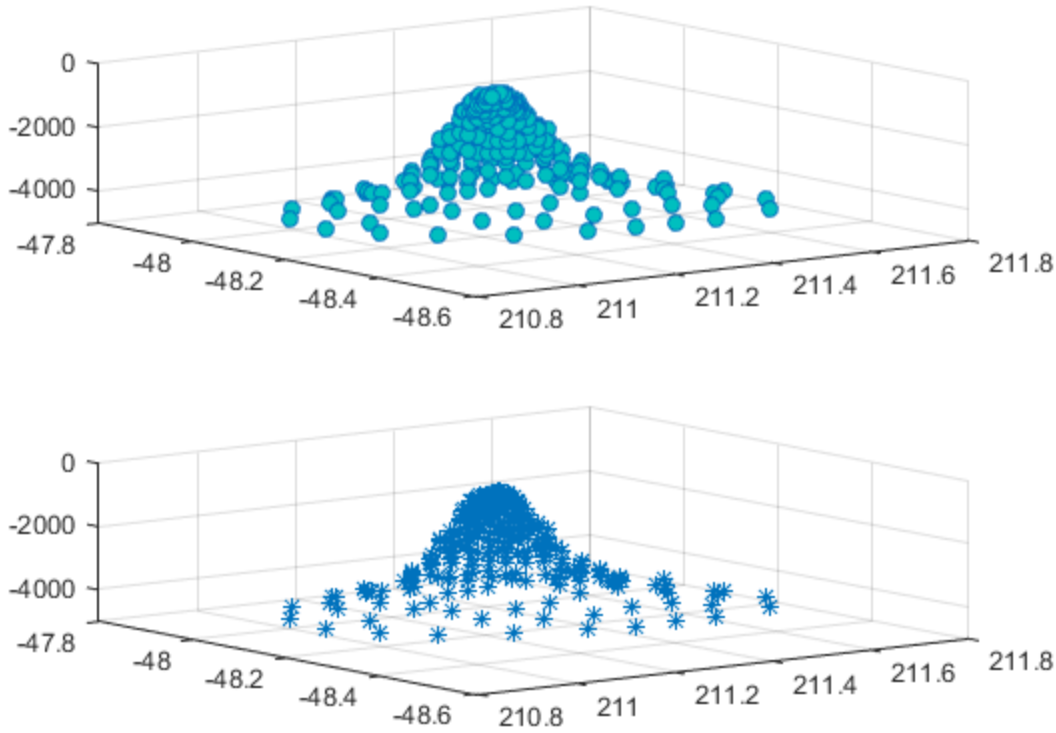
Specify Axes for 3-D Scatter Plot

Load the `seamount` data set to get vectors `x`, `y`, and `z`.

```
load seamount
```

Create a figure with two subplots and return the handles to the two axes in array `hs`. In each subplot, create a 3-D scatter plot. Specify the marker properties for each scatter plot.

```
figure
hs(1) = subplot(2,1,1);
hs(2) = subplot(2,1,2);
scatter3(hs(1),x,y,z,'MarkerFaceColor',[0 .75 .75])
scatter3(hs(2),x,y,z,'*')
```



Set Scatter Series Properties Using Handle

Use the `sphere` function to create vectors `x`, `y`, and `z`.

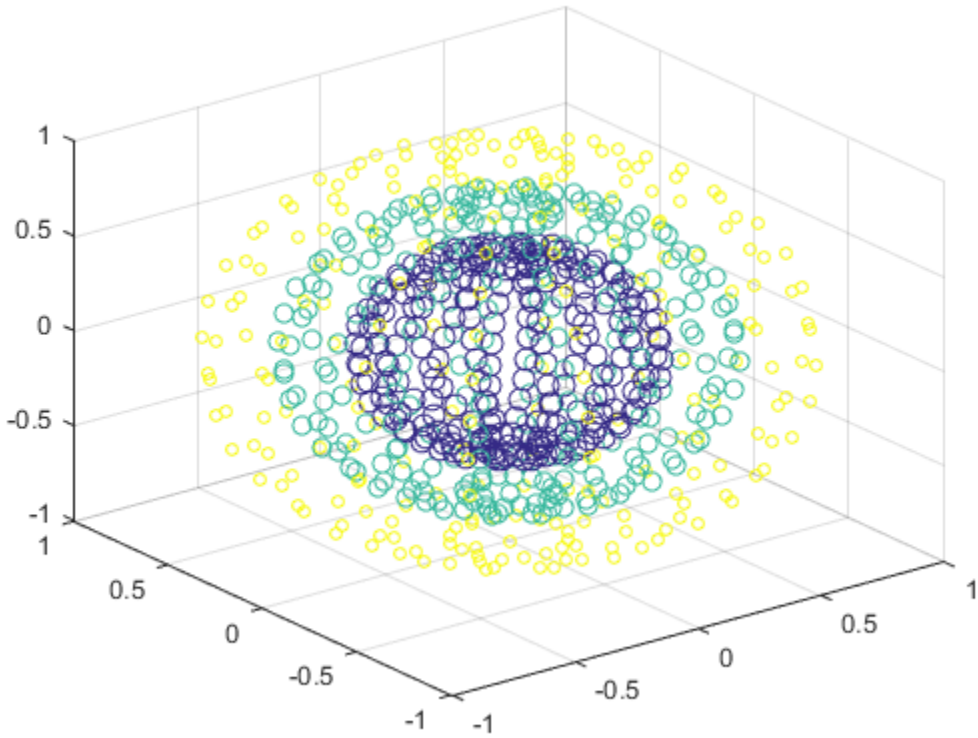
```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Create vectors `s` and `c` to specify the size and color for each marker.

```
S = repmat([70,50,20],numel(X),1);
C = repmat([1,2,3],numel(X),1);
s = S(:);
c = C(:);
```

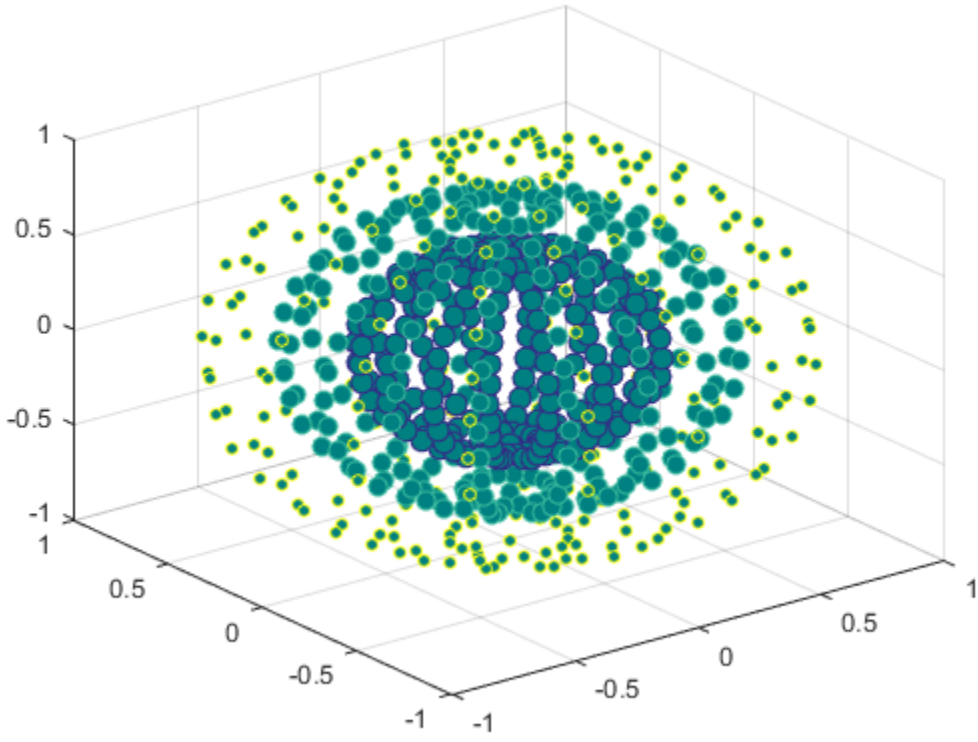
Create a 3-D scatter plot and return the scatter series object.

```
h = scatter3(x,y,z,s,c);
```



Use an RGB triplet color value to set the marker face color. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
h.MarkerFaceColor = [0 0.5 0.5];
```



Input Arguments

X — x values

vector

x values, specified as a vector. `X`, `Y`, and `Z` must be vectors of equal length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Y — y values

(default) | vector

y values, specified as a vector. `X`, `Y`, and `Z` must be vectors of equal length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Z — z values

(default) | vector

z values, specified as a vector. `X`, `Y`, and `Z` must be vectors of equal length.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

S — Marker area

36 (default) | scalar | vector | []

Marker area, specified as a scalar, a vector, or `[]`. The values in `S` must be positive. The units for area are points squared.

- If `S` is a scalar, then `scatter3` plots all markers with the specified area.
- If `S` is a row or column vector, then each entry in `S` specifies the area for the corresponding marker. The length of `S` must equal the length of `X`, `Y` and `Z`. Corresponding entries in `X`, `Y`, `Z` and `S` determine the location and area of each marker.
- If `S` is empty, then the default size of 36 points squared is used.

Example: `50`

Example: `[36,25,25,17,46]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

C — Marker color

[0 0 1] (blue) (default) | color string | RGB row vector | three-column matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The

intensities must be in the range `[0 1]`. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify `C` as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
`[1 1 0]`	`'y'`	`'yellow'`
`[1 0 1]`	`'m'`	`'magenta'`
`[0 1 1]`	`'c'`	`'cyan'`
`[1 0 0]`	`'r'`	`'red'`
`[0 1 0]`	`'g'`	`'green'`
`[0 0 1]`	`'b'`	`'blue'`
`[1 1 1]`	`'w'`	`'white'`
`[0 0 0]`	`'k'`	`'black'`

Example: `'y'`

Example: `[1,2,3,4]`

Example: `reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`markertype` — Marker type

`'o'` (default) | string

Marker type, specified as a string. The table below lists the supported marker types.

Specifier	Marker Type
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square

Specifier	Marker Type
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

ax — Axes object

axes object

Axes object. If you do not specify an axes, then `scatter3` plots into the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'MarkerFaceColor','red'` sets the marker face color to red.

The properties listed here are only a subset. For a complete list, see Scatter Series Properties.

'LineWidth' — Width of marker edge

`0.5` (default) | positive value

Width of marker edge, specified as a positive value in point units.

Example: `0.75`

'MarkerEdgeColor' — Marker outline color

`'flat'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'flat'` — Colors defined by the CData property.
- `'none'` — No color, which makes unfilled markers invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`'MarkerFaceColor'` — Marker fill color

`'none'` (default) | `'flat'` | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — No color, which makes the interior invisible.
- `'flat'` — Colors defined by the CData property.
- `'auto'` — Same color as the `Color` property for the axes.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Output Arguments

h — Scatter series object

scalar

Scatter series object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the scatter object after it is created.

See Also

Functions

`LineSpec` | `plot3` | `scatter`

Properties

Scatter Series Properties

Introduced before R2006a

Scatter Series Properties

Control scatter series appearance and behavior

Scatter series properties control the appearance and behavior of scatter series object. By changing property values, you can modify certain aspects of the scatter series.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = scatter(1:10,1:10);
m = h.Marker;
h.Marker = '*';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Markers

`Marker` — Marker symbol

`'o'` (default) | `'+'` | `'*'` | `'.'` | `'x'` | ...

Marker symbol, specified as one of the strings listed in this table:

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)

String	Marker Symbol
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

`MarkerEdgeColor` — Marker outline color

`'flat'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'flat'` — Colors defined by the CData property.
- `'none'` — No color, which makes unfilled markers invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'flat'` | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — No color, which makes the interior invisible.

- `'flat'` — Colors defined by the CData property.
- `'auto'` — Same color as the `Color` property for the axes.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.3 0.2 0.1]`

Example: `'green'`

`LineWidth` — Width of marker edge

`0.5` (default) | positive value

Width of marker edge, specified as a positive value in point units.

Example: `0.75`

Data

`XData` — x values

`[ ]` (default) | scalar | vector

x values, specified as a scalar or a vector. The scatter plot displays an individual marker for each value in `XData`.

The input argument `X` to the `scatter` and `scatter3` functions set the *x* values. `XData` and `YData` must have equal lengths.

Example: `[1 2 4 2 6]`

`YData` — y values

[ ] (default) | scalar | vector

y values, specified as a scalar or a vector. The scatter plot displays an individual marker for each value in `YData`.

The input argument `Y` to the `scatter` and `scatter3` functions set the *y* values. `XData` and `YData` must have equal lengths.

Example: `[1 3 3 4 6]`

`ZData` — z values

[ ] (default) | scalar | vector

z values, specified as a scalar or a vector.

- For 2-D scatter plots, `ZData` is empty by default.
- For 3-D scatter plots, the input argument `Z` to the `scatter3` function sets the *z* values. `XData`, `YData`, and `ZData` must have equal lengths.

Example: `[1 2 2 1 0]`

`CData` — Marker colors

[ ] (default) | RGB triplet | matrix of RGB triplets | vector

Marker colors, specified as one of these values:

- RGB triplet — Use the same color for all the markers in the plot. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.5 0.6 0.7]`.
- Three-column matrix of RGB triplets — Use a different color for each marker in the plot. Each row of the matrix defines one color. The number of rows must equal the number of markers.
- Vector — Use a different color for each marker in the plot. Specify `CData` as a vector the same length as `XData`. Linearly map the values in the vector to the colors in the current colormap.

Example: `[1 0 0; 0 1 0; 0 0 1]`

`SizeData` — Marker sizes

`[ ]` (default) | scalar | vector

Marker sizes, specified in one of these forms:

- Scalar — Use the same size for all of the markers.
- Vector — Use a different size for each marker. Specify `SizeData` as a vector the same length as `XData`.

Specify the values in point units, where one point equals 1/72 inch. To specify a marker that has an area of one square inch, use a value of 72^2.

Example: `50`

`XDataSource` — Variable linked to `XData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`ZDataSource` — Variable linked to `ZData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `ZData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `ZData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `ZData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'z'`

`CDataSource` — Variable linked to `CData`

`''` | string containing MATLAB workspace variable

Variable linked to `CData`, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable in the base workspace to generate the `CData`.

By default, there is no linked variable so the value is an empty string. If you link a variable, then MATLAB does not update the `CData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`SizeDataSource` — Variable linked to `SizeData`

`''` | string containing MATLAB workspace variable

Variable linked to `SizeData`, specified as a string containing a MATLAB workspace variable. MATLAB evaluates the variable in the base workspace to generate the `SizeData`.

By default, there is no linked variable so the value is an empty string. If you link a variable, then MATLAB does not update the `SizeData` values. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Visibility

`Visible` — Visibility of scatter series

`'on'` (default) | `'off'`

Visibility of scatter series, specified as one of these values:

- `'on'` — Display the scatter series.
- `'off'` — Hide the scatter series without deleting it. You still can access the properties of an invisible scatter series object.

`Clipping` — Clipping of scatter series to axes limits

`'on'` (default) | `'off'`

Clipping of scatter series to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the scatter series that are outside the axes limits.
- `'off'` — Display the entire scatter series, even if parts of it appear outside the axes limits. Parts of the scatter series might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the scatter series that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'scatter'`

Type of graphics object, returned as `'scatter'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — Tag to associate with scatter series

`''` (default) | string

Tag to associate with the scatter series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with scatter series

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the scatter series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the scatter series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the scatter series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the scatter series from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the scatter series object in the legend as one entry (default).
   - `'off'` — Do not include the scatter series object in the legend.
   - `'children'` — Include only children of the scatter series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of scatter series

axes object | group object | transform object

Parent of scatter series, specified as an axes, group, or transform object.

`Children` — Children of scatter series

empty `GraphicsPlaceholder` array

The scatter series has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of scatter series object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The scatter series object handle is always visible.
- `'off'` — The scatter series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The scatter series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the scatter series at the command-line, but allows callback functions to access it.

If the scatter series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the scatter series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The scatter series object — You can access properties of the scatter series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the scatter series. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the scatter series when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the scatter series.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the scatter series that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the scatter series responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the scatter series passes the click to the object below it in the current view of the figure window. The HitTest property of the scatter series has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the scatter series. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the scatter series that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the scatter series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for scatter series

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for scatter series, specified as one of these values:

- `'off'` — Click the scatter series plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the scatter series plot to select it, that is, anywhere within the rectangle that encloses the scatter series plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the scatter series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

BusyAction — Callback queuing

'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The BusyAction property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the ButtonDownFcn callback of the scatter series tries to interrupt a running callback that cannot be interrupted, then the BusyAction property determines if it is discarded or put in the queue. Specify the BusyAction property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- 'cancel' — Discard the interrupting callback.

Creation and Deletion Control

CreateFcn — Creation callback

'' (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the scatter series. Setting the `CreateFcn` property on an existing scatter series has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during scatter series creation. MATLAB executes the callback after creating the scatter series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The scatter series object — You can access properties of the scatter series object from within the callback function. You also can access the scatter series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the scatter series. MATLAB executes the callback before destroying the scatter series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The scatter series object — You can access properties of the scatter series object from within the callback function. You also can access the scatter series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of scatter series

`'off'` (default) | `'on'`

Deletion status of scatter series, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the scatter series begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the scatter series no longer exists.

Check the value of the BeingDeleted property to verify that the scatter series is not about to be deleted before querying or modifying it.

schur

Schur decomposition

Syntax

```
T = schur(A)
T = schur(A,flag)
[U,T] = schur(A,...)
```

Description

The `schur` command computes the Schur form of a matrix.

`T = schur(A)` returns the Schur matrix `T`.

`T = schur(A,flag)` for real matrix A, returns a Schur matrix `T` in one of two forms depending on the value of `flag`:

`'complex'`	`T` is triangular and is complex if `A` is real and has complex eigenvalues.
`'real'`	`T` has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal. `'real'` is the default when `A` is real.

If `A` is complex, `schur` returns the complex Schur form in matrix `T` and `flag` is ignored. The complex Schur form is upper triangular with the eigenvalues of `A` on the diagonal.

The function `rsf2csf` converts the real Schur form to the complex Schur form.

`[U,T] = schur(A,...)` also returns a unitary matrix `U` so that `A = U*T*U'` and `U'*U = eye(size(A))`.

Examples

`H` is a 3-by-3 eigenvalue test matrix:

```
H = [ -149    -50   -154
       537    180    546
       -27     -9    -25 ]
```

Its Schur form is

```
schur(H)

ans =
     1.0000   -7.1119 -815.8706
          0    2.0000  -55.0236
          0         0    3.0000
```

The eigenvalues, which in this case are 1, 2, and 3, are on the diagonal. The fact that the off-diagonal elements are so large indicates that this matrix has poorly conditioned eigenvalues; small changes in the matrix elements produce relatively large changes in its eigenvalues.

Introduced before R2006a

script

Sequence of MATLAB statements in file

Description

A script file is an external file that contains a sequence of MATLAB statements. By typing the filename, you can obtain subsequent MATLAB input from the file. Script files have a filename extension of `.m`.

Scripts are the simplest kind of MATLAB program. They are useful for automating blocks of MATLAB commands, such as computations you have to perform repeatedly from the command line. Scripts can operate on existing data in the workspace, or they can create new data on which to operate. Although scripts do not return output arguments, any variables that they create remain in the workspace, so you can use them in further computations. In addition, scripts can produce graphical output using commands like `plot`.

Scripts can contain any series of MATLAB statements. They require no declarations or begin/end delimiters.

Like any MATLAB program, scripts can contain comments. Any text following a percent sign (`%`) on a given line is comment text. Comments can appear on lines by themselves, or you can append them to the end of any executable line.

scatteredInterpolant class

Scattered data interpolation

Description

Use `scatteredInterpolant` to perform interpolation on a 2-D or 3-D "Scattered Data" on page 1-7323 set. For example, you can pass a set of `(x,y)` points and values, `v`, to `scatteredInterpolant`, and it returns a surface of the form $v = F(x, y)$. This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point, `(xq,yq)`, to produce an interpolated value, `vq`.

Use `scatteredInterpolant` to create the "Interpolant" on page 1-7323, `F`. Then, you can evaluate `F` at specific points using any of the following syntaxes:

- `Vq = F(Pq)` specifies the query points in the matrix `Pq`. Each row in `Pq` contains the coordinates of a query point.
- `Vq = F(Xq,Yq)` and `Vq = F(Xq,Yq,Zq)` specify the query points as two or three matrices of equal size.
- `Vq = F({xq,yq})` and `Vq = F({xq,yq,zq})` specify the query points as "Grid Vectors" on page 1-7323. The interpolated values are returned in `Vq`. Use this syntax to conserve memory when you want to query a large grid of points.

Construction

`F = scatteredInterpolant(x,y,v)` creates an interpolant that fits a surface of the form $v = F(x,y)$. Vectors `x` and `y` specify the `(x,y)` coordinates of the sample points. `v` is a vector that contains the sample values associated with the points, `(x,y)`.

`F = scatteredInterpolant(x,y,z,v)` creates a 3-D interpolant of the form $v = F(x,y,z)$.

`F = scatteredInterpolant(P,v)` specifies the coordinates of the sample points as an array. The rows of `P` contain the (x, y) or (x, y, z) coordinates for the values in `v`.

`F = scatteredInterpolant(___,Method)` specifies a string that describes an interpolation method: `'nearest'`, `'linear'`, or `'natural'`. Specify Method as the last input argument in any of the first three syntaxes.

`F = scatteredInterpolant(___,Method,ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `Method` can be one of three strings: `'nearest'`, `'linear'`, or `'natural'`. Specify `ExtrapolationMethod` as one of the following strings: `'nearest'`, `'linear'`, or `'none'`. Pass Method and ExtrapolationMethod together as the last two input arguments in any of the first three syntaxes.

`F = scatteredInterpolant()` creates an empty scattered data interpolant. Use `F.Points = P` to initialize `F` with the points in matrix `P`. Use `F.Values = v` to initialize `F` with the values in `v`.

Input Arguments

`x`

Sample points *x*-coordinates, specified as a vector of the same size as `v`.

`y`

Sample points *y*-coordinates, specified as a vector of the same size as `v`.

`z`

Sample points *z*-coordinates, specified as a vector of the same size as `v`.

`P`

Sample points array, specified as an `m`-by-`n` matrix, where `m` is the number of points and `n` is the dimension of the space where the points reside. Each row of `P` contains the (*x*, *y*) or (*x*, *y*, *z*) coordinates of a sample point.

`v`

Sample values, specified as a vector that defines the function values, $v = F(x,y)$, at the sample points.

`Method`

Interpolation method, specified as one of the following options.

Method String	Description	Continuity
`'linear'` (default)	Linear interpolation.	C^0

Method String	Description	Continuity
`'nearest'`	Nearest neighbor interpolation.	Discontinuous
`'natural'`	Natural neighbor interpolation.	C^1 except at sample points

`ExtrapolationMethod`

Extrapolation method, specified as one of these strings.

ExtrapolationMethod String	Description
`'linear'`	Linear extrapolation based on boundary gradients. Default when `Method` is `'linear'` or `'natural'`.
`'nearest'`	Nearest neighbor extrapolation. This method evaluates to the value of the nearest neighbor on the boundary. Default when `Method = 'nearest'`.
`'none'`	No extrapolation. Any queries outside the convex hull of `F.Points` return `NaN`.

Properties

`Points`

Array of sample points (locations) for the values in `F.Values`. Each row of `F.Points` contains the (x, y) or (x, y, z) coordinates of a sample point.

`Values`

Vector of values associated with each point in `F.Points`.

`Method`

A string specifying the method used to interpolate the data: `'nearest'`, `'linear'`, or `'natural'`.

`ExtrapolationMethod`

A string specifying the method used to extrapolate the data: `'nearest'`, `'linear'`, or `'none'`. A value of `'none'` indicates that extrapolation is disabled.

Definitions

Interpolant

Interpolating function that you can evaluate at query locations.

Scattered Data

A set of points that have no structure among their relative locations.

Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices `X` and `Y`. You can represent the same grid using the grid vectors, `xg` and `yg`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Indexing

`scatteredInterpolant` supports index-based editing of the properties of F. You can add or remove points in `F.Points` and update the corresponding values in `F.Values`.

For example, `F.Points(5,:) = []` removes the fifth point, and `F.Values(5) = []` removes the corresponding value.

Examples

2-D Interpolation

Define 200 random points.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1);
y = xy(:,2);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

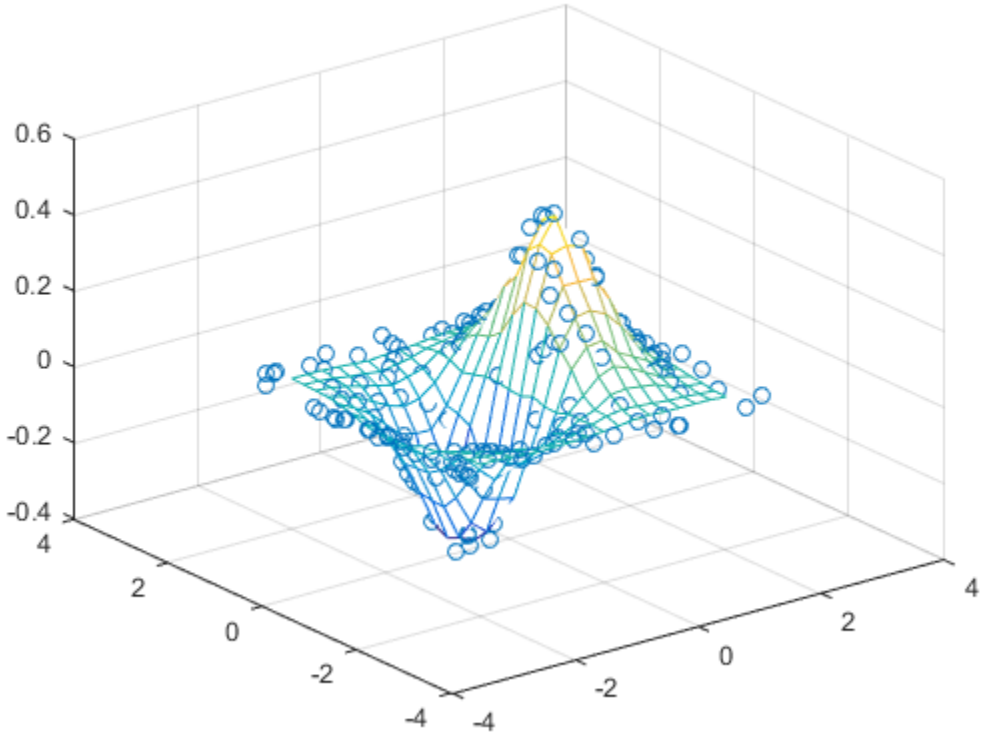
```
F = scatteredInterpolant(x,y,v);
```

Evaluate the interpolant at query locations (xq, yq).

```
ti = -2:.25:2;
[xq,yq] = meshgrid(ti,ti);
vq = F(xq,yq);
```

Plot the result.

```
figure
mesh(xq,yq,vq);
hold on;
plot3(x,y,v,'o');
hold off;
```



2-D Extrapolation

Query the interpolant at a single point outside the convex hull using nearest neighbor extrapolation.

Define a matrix of 200 random points.

```
P = -2.5 + 5*gallery('uniformdata',[200 2],0);
```

Sample an exponential function. These are the sample values for the interpolant.

```
x = P(:,1);
y = P(:,2);
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant, specifying linear interpolation and nearest neighbor extrapolation.

```
F = scatteredInterpolant(P,v,'linear','nearest')
```

```
F =

  scatteredInterpolant with properties:

                Points: [200x2 double]
                Values: [200x1 double]
                Method: 'linear'
    ExtrapolationMethod: 'nearest'
```

Evaluate the interpolant outside the convex hull.

```
vq = F(3.0,-1.5)
```

```
vq =

    0.0031
```

Disable extrapolation and evaluate `F` at the same point.

```
F.ExtrapolationMethod = 'none';
vq = F(3.0,-1.5)
```

```
vq =

   NaN
```

Replacement of Sample Values

Replace the elements in the `Values` property when you want to change the values at the sample points. You get immediate results when you evaluate the new interpolant because the original triangulation has not changed.

Create 50 random points.

```
x = -2.5 + 5*gallery('uniformdata',[50 1],0);
y = -2.5 + 5*gallery('uniformdata',[50 1],1);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v)
```

```
F =

  scatteredInterpolant with properties:

                Points: [50x2 double]
                Values: [50x1 double]
                Method: 'linear'
    ExtrapolationMethod: 'linear'
```

Evaluate the interpolant at `(1.40,1.90)`.

```
F(1.40,1.90)
```

```
ans =

    0.0029
```

Change the interpolant sample values.

```
vnew = x.^2 + y.^2;
F.Values = vnew;
```

Evaluate the interpolant at `(1.40,1.90)`.

```
F(1.40,1.90)
```

```
ans =

    6.1109
```

How To

- Class Attributes
- Property Attributes
- “Interpolating Gridded Data”

sec

Secant of angle in radians

Syntax

```
Y = sec(X)
```

Description

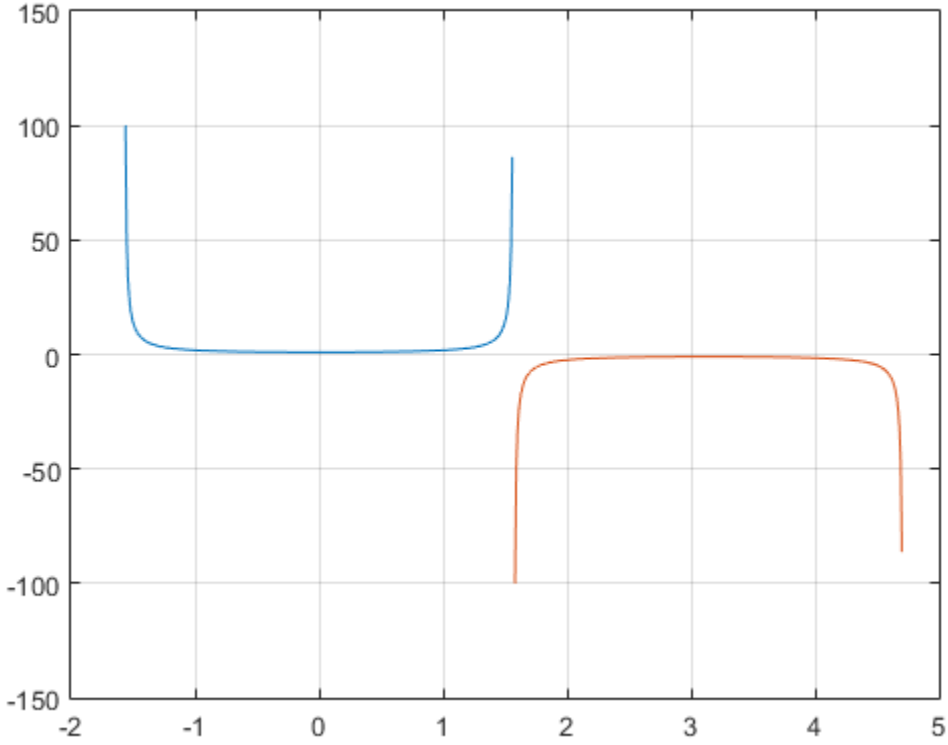
`Y = sec(X)` returns the secant of the elements of `X`. The `sec` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of X in the interval [-Inf, Inf], `sec` returns real values in the interval [-Inf ,-1] and [1,Inf]. For complex values of X, `sec` returns complex values. All angles are in radians.

Examples

Plot Secant Function

Plot the secant over the domain $-\pi/2 < x < \pi/2$ and $\pi/2 < x < 3\pi/2$.

```
x1 = -pi/2+0.01:0.01:pi/2-0.01;
x2 = pi/2+0.01:0.01:(3*pi/2)-0.01;
plot(x1,sec(x1),x2,sec(x2)), grid on
```



Secant of Vector of Complex Angles

Calculate the secant of the complex angles in vector `x`.

```
x = [-i pi+i*pi/2 -1+i*4];
y = sec(x)
```

```
y =

   0.6481 + 0.0000i  -0.3985 + 0.0000i   0.0198 - 0.0308i
```

Input Arguments

X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Secant of input angle

scalar value | vector | matrix | N-D array

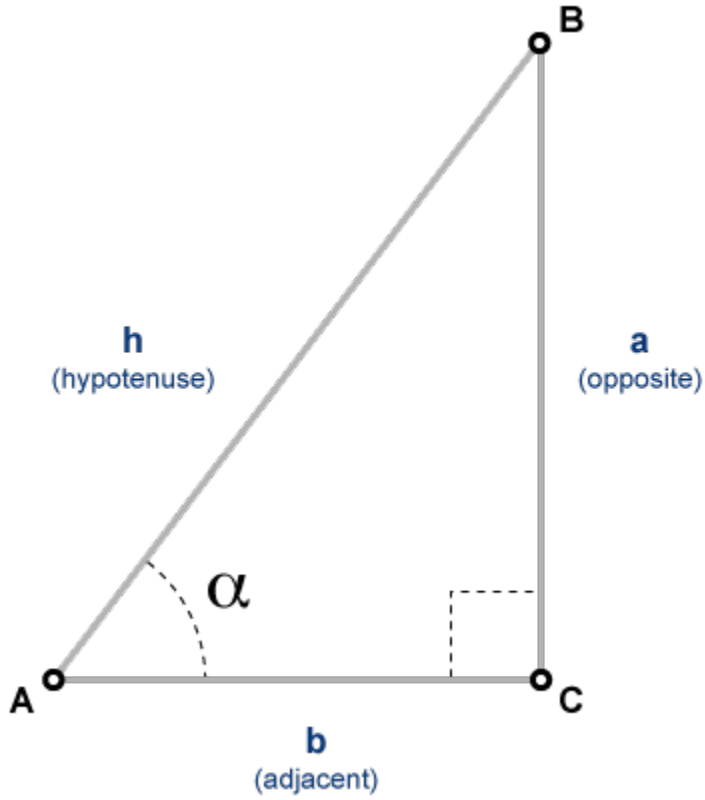
Secant of input angle, returned as real-valued or complex-valued scalar value, vector, matrix or N-D array.

More About

Secant Function

The secant of an angle, α, defined with reference to a right angled triangle is

$$\sec(\alpha) = \frac{1}{\cos(\alpha)} = \frac{\text{hypotenuse}}{\text{adjacent side}} = \frac{h}{b}.$$



The secant of a complex angle, α, is

$$\sec(\alpha) = \frac{2}{e^{i\alpha} + e^{-i\alpha}}.$$

See Also

asec | asecd | asech | secd | sech

Introduced before R2006a

secd

Secant of argument in degrees

Syntax

```
Y = secd(X)
```

Description

`Y = secd(X)` returns the secant of the elements of `X`, which are expressed in degrees.

Examples

Secant of 90 degrees compared to secant of π/2 radians

```
secd(90)
```

```
ans =

   Inf
```

```
sec(pi/2)
```

```
ans =

   1.6331e+16
```

`secd(90)` is infinite, whereas `sec(pi/2)` is large but finite.

Secant of vector of complex angles, specified in degrees

```
z = [35+i 15+2i 10+3i];
y = secd(z)
```

```
y =
```

```
   1.2204 + 0.0149i   1.0346 + 0.0097i   1.0140 + 0.0094i
```

Input Arguments

X — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `secd` operation is element-wise when `X` is nonscalar.

Example:

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Secant of angle

scalar value | vector | matrix | N-D array

Secant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

See Also

`asec` | `asecd` | `sec`

Introduced before R2006a

sech

Hyperbolic secant

Syntax

```
Y = sech(X)
```

Description

The `sech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

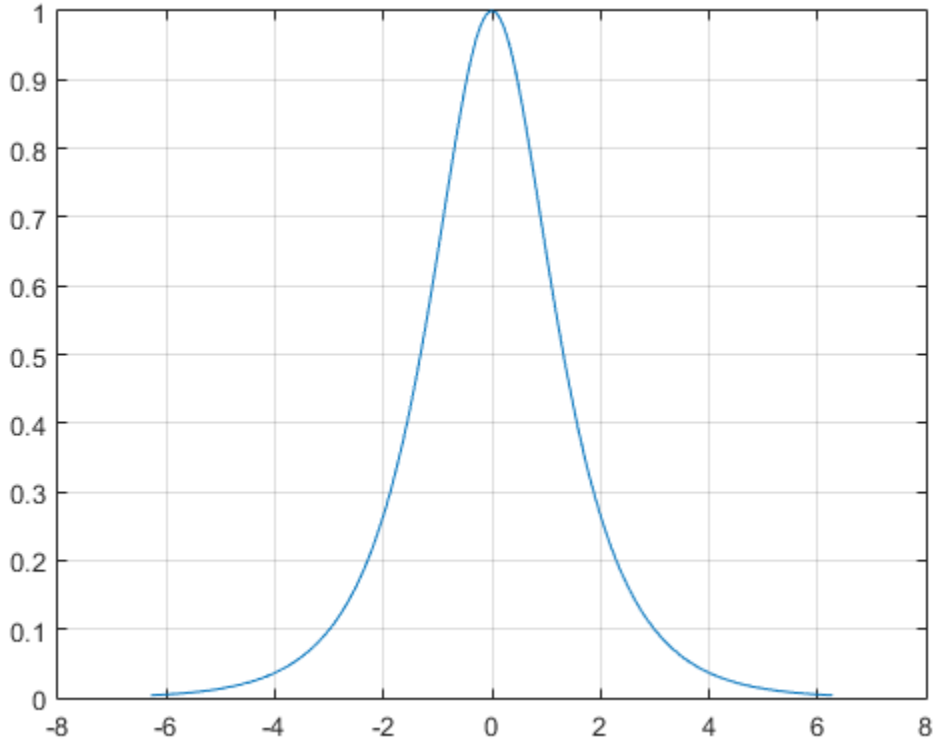
`Y = sech(X)` returns an array the same size as `X` containing the hyperbolic secant of the elements of `X`.

Examples

Graph of Hyperbolic Secant Function

Graph the hyperbolic secant over the domain $-2\pi \le x \le 2\pi$.

```
x = -2*pi:0.01:2*pi;
plot(x,sech(x)), grid on
```



More About

Hyperbolic Secant

The hyperbolic secant of z is

$$\operatorname{sech}(z) = \frac{1}{\cosh(z)}.$$

See Also

`asech` | `sec` | `sinh` | `cosh`

Introduced before R2006a

second

Second number

Syntax

```
s = second(t)
s = second(t,secondType)
```

Description

`s = second(t)` returns the second values, including a fractional part, for the datetime values in `t`. The `s` output is a `double` array the same size as `t` and contains values from 0 to less than 60.

For datetime values whose time zone is `UTCLeapSeconds`, the `s` output can contain a value between 60 and 61 for times that fall during a leap second occurrence.

`s = second(t,secondType)` returns the type of second number specified by `secondType`.

The `second` function returns the second numbers of datetime values. To assign second values to datetime array `t`, use `t.Second` and modify the `Second` property.

Examples

Find Second Number of Datetime Values

```
t1 = datetime('now','Format','dd-MMM-yyyy HH:mm:ss.SSS');
t = t1 + seconds(30:15:60)
```

```
t =

Columns 1 through 2

   23-Feb-2015 09:56:07.528   23-Feb-2015 09:56:22.528
```

```
Columns 3 through 3

   23-Feb-2015 09:56:37.528

s = second(t)

s =

    7.5280   22.5280   37.5280
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`secondType` — Type of second values

`'secondofminute'` (default) | `'secondofday'`

Type of second values, specified as either `'secondofminute'` or `'secondofday'`.

- If `secondType` is `'secondofminute'`, then `second` returns the second of the minute.
- If `secondType` is `'secondofday'`, then `second` returns the second of the day, which (except for leap seconds) is in the range [0, 86400).

See Also

datetime Properties | `hms` | `hour` | `minute` | `timeofday`

Introduced in R2014b

seconds

Duration in seconds

Syntax

```
S = seconds(X)
```

Description

`S = seconds(X)` returns an array of seconds equivalent to the values in `X`.

- If `X` is a numeric array, then `S` is a `duration` array in units of seconds.
- If `X` is a `duration` array, then `S` is a `double` array with each element equal to the number of seconds in the corresponding element of X.

The `seconds` function converts between `duration` and `double` values. To display a duration in units of seconds, set its `Format` property to `'s'`.

Examples

Create Duration Array of Seconds

```
X =  magic(4);
S = seconds(X)
```

```
S =

   16 secs    2 secs    3 secs   13 secs
    5 secs   11 secs   10 secs    8 secs
    9 secs    7 secs    6 secs   12 secs
    4 secs   14 secs   15 secs     1 sec
```

Convert Durations to Numeric Array of Seconds

Create a `duration` array.

```
X = hours(1) + minutes(1:4)

X =

   1.0167 hrs   1.0333 hrs     1.05 hrs   1.0667 hrs
```

Convert each duration in `X` to a number of seconds.

```
S = seconds(X)

S =

        3660         3720         3780         3840
```

`S` is a `double` array.

Find the natural logarithm of `S`. The `log` function accepts inputs of type `double`.

```
Y = log(S)

Y =

    8.2052    8.2215    8.2375    8.2532
```

Input Arguments

X — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

See Also

`duration`

Introduced in R2014b

selectmoveresize

Select, move, resize, or copy axes and uicontrol graphics objects

Note: The `selectmoveresize` was removed in R2014b. Use the `plotedit` function to copy, move, resize, and edit objects instead.

Syntax

```
A = selectmoveresize
set(gca,'ButtonDownFcn','selectmoveresize')
```

Description

In releases before R2014b, `selectmoveresize` was useful as the callback routine for axes and uicontrol button down functions. It allowed users to move, resize, and copy axes and uicontrol objects.

`A = selectmoveresize` returns a structure array containing

- `A.Type`: a string containing the action type, which can be `Select`, `Move`, `Resize`, or `Copy`
- `A.Handles`: a list of the selected handles, or, for a `Copy`, an m-by-2 matrix containing the original handles in the first column and the new handles in the second column

`set(gca,'ButtonDownFcn','selectmoveresize')` sets the ButtonDownFcn property of the current axes to `'selectmoveresize'`.

Introduced before R2006a

matlab.unittest.selectors

Summary of classes in MATLAB Selectors Interface

Description

Use selectors to filter or select elements of a test suite based on their attributes. The `matlab.unittest.selectors` package consists of the following selectors.

matlab.unittest.selectors.HasParameter	Selector for TestSuite elements determined by parameterization
matlab.unittest.selectors.HasSharedTestFixture	Selector for TestSuite elements that use shared test fixture
matlab.unittest.selectors.HasBaseFolder	Selector for TestSuite elements determined by folder
matlab.unittest.selectors.HasName	Selector for TestSuite elements determined by name
matlab.unittest.selectors.HasTag	Selector for TestSuite elements determined by tag

See Also

`matlab.unittest.TestSuite.selectIf`

matlab.unittest.selectors.HasParameter class

Package: matlab.unittest.selectors

Selector for TestSuite elements determined by parameterization

Description

The `HasParameter` selector filters `TestSuite` array elements determined by parameterization.

Construction

`matlab.unittest.selectors.HasParameter` constructs a selector for `TestSuite` elements determined by their parameterization. When you instantiate `HasParameter` without input arguments, the resulting `TestSuite` array only contains elements that have parameterized test methods.

`matlab.unittest.selectors.HasParameter(Name,Value)` constructs a selector with additional options specified by one or more Name,Value pair arguments. The selector filters based on the name of the property that defines a parameter, the name of the parameter, and the value of the parameter. For an element to be selected for the `TestSuite` array, it must have at least one parameter that satisfies all the conditions.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Property'`

Name of the property that defines the parameter specified as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified property

name is a string, the testing framework creates an `IsEqualTo` constraint with the input string, `Property`, as the expected value.

`'Name'`

Name of the parameter specified as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified name is a string, the testing framework creates an `IsEqualTo` constraint with the input string, `Name`, as the expected value.

`'Value'`

Value of the parameter specified as any MATLAB data type or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified property name is not a constraint, the testing framework creates an `IsEqualTo` constraint with the input data, `Value`, as the expected value.

Properties

`PropertyConstraint`

Condition that the test element's parameter property name must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Property` input argument.

`NameConstraint`

Condition that the test element's parameter name must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Name` input argument.

`ValueConstraint`

Condition that the test element's parameter property value must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Value` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Filter Test Suite by Parameterization

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
        type = {'single','double','uint16'};
        outSize = struct('s2d',3, 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the file.

```
s = matlab.unittest.TestSuite.fromFile('testZeros.m');
{s.Name}'

ans =

    'testZeros/testClass(type=single,outSize=s2d)'
```

```
    'testZeros/testClass(type=single,outSize=s3d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s3d)'
    'testZeros/testSize(outSize=s2d)'
    'testZeros/testSize(outSize=s3d)'
    'testZeros/testDefaultClass'
    'testZeros/testDefaultSize'
    'testZeros/testDefaultValue'
```

The suite contains 11 test elements: 6 from the parameterized `testClass` method, 2 from the parameterized `testSize` method, and 1 from each of the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

Select all of the test elements from parameterized test methods.

```
import matlab.unittest.selectors.HasParameter;

s1 = s.selectIf(HasParameter);
{s1.Name}'

ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=single,outSize=s3d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s3d)'
    'testZeros/testSize(outSize=s2d)'
    'testZeros/testSize(outSize=s3d)'
```

The suite contains the eight test elements from the two parameterized test methods.

Select all of the test elements from nonparameterized test methods.

```
s2 = s.selectIf(~HasParameter);
{s2.Name}'

ans =

    'testZeros/testDefaultClass'
    'testZeros/testDefaultSize'
    'testZeros/testDefaultValue'
```

Select all test elements that are parameterized and have a property named `'type'` with a parameter name `'double'`.

```
s3 = s.selectIf(HasParameter('Property','type', 'Name','double'));
{s3.Name}'
```

```
ans =

    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
```

The resulting suite contains two elements. The `testClass` method is the only method in `testZeros` that uses the `'type'` property. Selecting only `'double'` from the parameters results in two test elements — one for each value of `'outSize'`.

Select all test elements that a have a parameter defined by a property starting with `'t'`.

```
import matlab.unittest.constraints.StartsWithSubstring;

s4 = s.selectIf(HasParameter('Property',StartsWithSubstring('t')));
{s4.Name}'
```

```
ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=single,outSize=s3d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s3d)'
```

The resulting suite contains the six parameterized test elements from the `testClass` method. The `testSize` method is parameterized, but the elements from the method are not included in the suite because the method does not use a property that starts with `'t'`.

Select all test elements that are parameterized and test the `zeros` function with a `2-D` array. A parameter value representing a `2-D` array has a length of `1` (for example `zeros(3)`) or `2` (for example `zeros(2,3)`).

```
import matlab.unittest.constraints.HasLength;

s5 = s.selectIf(HasParameter('Property','outSize',...
    'Value', HasLength(1)|HasLength(2)));
```

```
{s5.Name}'

ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testSize(outSize=s2d)'
```

Select only the test element that tests that the output is a `double` data type and that it has the correct size for a `2-D` array.

```
s6 = s.selectIf(HasParameter('Property','type','Name','double')...
    & HasParameter('Property','outSize','Name','s2d'))

s6 =

  Test with properties:

                 Name: 'testZeros/testClass(type=double,outSize=s2d)'
      Parameterization: [1x2 matlab.unittest.parameters.TestParameter]
    SharedTestFixtures: []
                 Tags: {0x1 cell}

Tests Include:
   2 Unique Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

- “Create Basic Parameterized Test”
- “Create Advanced Parameterized Test”

Introduced in R2014a

matlab.unittest.selectors.HasSharedTestFixture class

Package: matlab.unittest.selectors

Selector for TestSuite elements that use shared test fixture

Description

The `HasSharedTestFixture` selector filters `TestSuite` array elements based on shared test fixtures.

Construction

`matlab.unittest.selectors.HasSharedTestFixture(f)` constructs a selector for `TestSuite` elements based on their required shared test fixtures. For an element to be selected for the `TestSuite` array, it must use a fixture that is compatible with the specified fixture, `f`.

Input Arguments

`f` — Shared test fixture

`Fixture`

Shared test fixture specified as a `matlab.unittest.fixtures.Fixture` instance. The `TestSuite` array element must use the shared text fixture, `f`, to be selected for the `TestSuite`.

Properties

`ExpectedFixture`

The shared test fixture that a `TestSuite` array element must use to be selected for the `TestSuite`. The `ExpectedFixture` property is specified as a `matlab.unittest.fixtures.Fixture` in the input argument, `f`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Filter Test Suite by Shared Test Fixtures

Create a package folder, `+mytestpackage`, in your current working folder. This package contains two test classes.

In the `+mytestpackage` folder, create `AExampleTest.m`. This class contains two tests that use a suppressed warnings fixture.

```
classdef (SharedTestFixtures={matlab.unittest.fixtures.SuppressedWarningsFixture( ...
        'MATLAB:rmpath:DirNotFound')})...
        AExampleTest < matlab.unittest.TestCase
    methods (Test)
        function testOne(testCase)
            % test code
        end
        function testTwo(testCase)
            % test code
        end
    end
end
```

In the `+mytestpackage` folder, create `BExampleTest.m`. This class contains one test that uses a shared path fixture and a suppressed warnings fixture.

```
classdef (SharedTestFixtures={...
        matlab.unittest.fixtures.PathFixture( ...
        fullfile(matlabroot,'help', 'techdoc', 'matlab_oop', 'examples')),...
        matlab.unittest.fixtures.SuppressedWarningsFixture( ...
        'MATLAB:rmpath:DirNotFound')}) ...
        BExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testPathAdd(testCase)
            % test code
        end
    end
```

```
end
```

At the command prompt, define the following fixtures.

```
pf = matlab.unittest.fixtures.PathFixture(...
    fullfile(matlabroot,'help','techdoc','matlab_oop','examples'));
swf = matlab.unittest.fixtures.SuppressedWarningsFixture(...
    'MATLAB:rmpath:DirNotFound');
```

Create a test suite from the package.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasSharedTestFixture;

suite = TestSuite.fromPackage('mytestpackage')
```

```
suite =

  1x3 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   0 Parameterizations, 2 Unique Shared Test Fixture Classes, 0 Tags.
```

The test suite has three test elements.

Create a filtered suite that only contains tests that use the path fixture, `pf`.

```
s1 = suite.selectIf(HasSharedTestFixture(pf));
```

The resulting suite, `s1`, contains the test element from `BExampleTest.m`, since the test in that class uses the shared test fixture, `pf`.

Alternatively, pass the selector to the `TestSuite.fromPackage` method instead of generating a full test suite, and then using the `TestSuite.selectIf` method to filter the suite.

```
s1 = TestSuite.fromPackage('mytestpackage', HasSharedTestFixture(pf));
```

Create a filtered test suite that contains tests that use the suppressed warnings fixture, `swf`, but not the path fixture, `pf`.

```
s2 = suite.selectIf(~HasSharedTestFixture(pf) & HasSharedTestFixture(swf));
```

The test suite, `s2`, only contains the two test elements from `AExampleTest.m`. Tests in `BExampleTest.m` are excluded because, in addition to the suppressed warnings fixture, they use the path fixture.

Create a filtered suite that only contains tests that use the path fixture to a different location.

```
pf2 = matlab.unittest.fixtures.PathFixture(fullfile(matlabroot));
s3 =  TestSuite.fromPackage('mytestpackage', HasSharedTestFixture(pf2))
```

```
s3 =

  1x0 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

The test suite does not contain any test elements. The tests in `BExampleTest.m` use a shared path fixture, but the selected path fixture, `pf2`, adds a different folder to the path so its tests are not included in the suite.

See Also

`fromClass` | `fromFile` | `fromFolder` | `fromMethod` | `fromPackage` | `matlab.unittest.selectors` | `selectIf`

Introduced in R2014a

matlab.unittest.selectors.HasBaseFolder class

Package: matlab.unittest.selectors

Selector for TestSuite elements determined by folder

Description

The `HasBaseFolder` selector filters `TestSuite` array elements determined by the name of the folder that contains the file that defines the test class or function.

Construction

`matlab.unittest.selectors.HasBaseFolder(f)` constructs a selector for `TestSuite` elements determined by the folder, `f`, which contains the file that defines the test class or function. You can specify the base folder as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified base folder, `f`, is a string instead of a `Constraint`, the testing framework creates an `IsEqualTo` constraint with the input string, `f`, as the expected value.

For a test element to be included in the suite, the file that defines it must be contained in the specified base folder. For test classes defined in packages, the base folder is the parent of the top-level package folder. The base folder never contains any folders that start with `'+'` or `'@'`.

Input Arguments

`f` — Base folder

string | `Constraint`

Base folder specified as a string or a `matlab.unittest.constraints.Constraint` instance. The following conditions must be satisfied for the test element to be selected for the `TestSuite`:

- If `f` is a string, the test element's base folder must exactly match the specified folder.
- If `f` is a constraint, the test element's base folder must satisfy the specified constraint.

Properties

`Constraint`

Condition the base folder must satisfy to be included in the test suite, specified as an instance of the `matlab.unittest.constraints.Constraints` class.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Filter Test Suite by Base Folder

Create a folder, `MyTests`, in your current working folder. In this folder, create two subfolders, `Feature1` and `Feature2`.

In a new file, `Feature1_Test.m`, in the `Feature1` subfolder, create the following test class.

```
classdef Feature1_Test < matlab.unittest.TestCase
    methods (Test)
        function testA1(testCase)
            % test code
        end
        function testB1(testCase)
            % test code
        end
    end
end
```

In a new file, `Feature2_Test.m`, in the `Feature2` subfolder, create the following test class.

```
classdef Feature2_Test < matlab.unittest.TestCase
    methods (Test)
        function testA2(testCase)
```

```
            % test code
        end
        function testB2(testCase)
            % test code
        end
    end
end
```

If necessary, set your current working folder to the folder above `MyTests`. At the command prompt, create a test suite from the `MyTests` folder and examine the contents.

```
import matlab.unittest.TestSuite
import matlab.unittest.selectors.HasBaseFolder;
import matlab.unittest.constraints.ContainsSubstring;

suite = TestSuite.fromFolder('MyTests', 'IncludingSubfolders', true);
{suite.Name}

ans =

    'Feature1_Test/testA1'    'Feature1_Test/testB1'    'Feature2_Test/testA2'    'Feat
```

The suite contains the four tests from the two test files.

Select all test suite elements for classes that are defined in the `'Feature1'` folder.

```
 s1 = suite.selectIf(HasBaseFolder(fullfile(pwd,'MyTests','Feature1')));
{s1.Name}

ans =

    'Feature1_Test/testA1'    'Feature1_Test/testB1'
```

The filtered test suite contains only test elements from the `Feature1` folder.

Select all the test suite elements for classes that are defined in folders that do not contain the string `'Feature1'`, and then examine the contents.

```
s1 = suite.selectIf(HasBaseFolder(...
    fullfile(pwd,'MyTests','Feature1')));
{s1.Name}

ans =

    'Feature2_Test/testA2'    'Feature2_Test/testB2'
```

The filtered test suite only contains test elements from the `Feature2` folder.

Alternatively, to generate a filtered suite directly, pass the selector to the `TestSuite.fromFolder` method.

```
s1 = TestSuite.fromFolder('MyTests',...
    ~HasBaseFolder(ContainsSubstring('Feature1')),...
    'IncludingSubfolders',true);
```

See Also

`fromClass` | `fromFile` | `fromFolder` | `fromMethod` | `fromPackage` | `matlab.unittest.selectors` | `selectIf`

Introduced in R2014a

matlab.unittest.selectors.HasName class

Package: matlab.unittest.selectors

Selector for TestSuite elements determined by name

Description

The `HasName` selector filters `TestSuite` array elements determined by the test element name.

Construction

`matlab.unittest.selectors.HasName(n)` constructs a selector for `TestSuite` elements determined by the test element name, `n`. You can specify the name as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified name, `n`, is a string, the testing framework creates an `IsEqualTo` constraint with the input string, `n`, as the expected value.

For a test element to be included in the suite, the test element must have the same name as the specified name.

Input Arguments

`n` — Test element name

string | `Constraint`

Test element name specified as a string or `matlab.unittest.constraints.Constraint` instance. The following conditions must be satisfied for the test element to be selected for the `TestSuite`:

- If `n` is a string, the test element's name must exactly match the specified name.
- If `n` is a constraint, the test element's name must satisfy the specified constraint.

Properties

`Constraint`

Condition the test element name must satisfy to be included in the test suite, specified as an instance of the `matlab.unittest.constraints.Constraints` class.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Filter Test Suite by Name

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testPathAdd(testCase)
            % test code
        end
        function testOne(testCase)
            % test code
        end
         function testTwo(testCase)
            % test code
        end
    end
end
```

At the command prompt, create a test suite from the `ExampleTest.m` file and examine the contents.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasName;
import matlab.unittest.constraints.EndsWithSubstring;

suite = TestSuite.fromFile('ExampleTest.m');
```

```
{suite.Name}

ans =

    'ExampleTest/testPathAdd'    'ExampleTest/testOne'    'ExampleTest/testTwo'
```

The suite contains three tests.

Select all the test suite elements that have the name `'ExampleTest/testPathAdd'`, and examine the contents.

```
s1 = suite.selectIf(HasName('ExampleTest/testPathAdd'));
{s1.Name}

ans =

    'ExampleTest/testPathAdd'
```

The filtered test suite only contains one test element.

Select all the test suite elements that end in either `'One'` or `'Two'`, and examine the contents.

```
s1 =  suite.selectIf(HasName(EndsWithSubstring('One')) | ...
    HasName(EndsWithSubstring('Two')));
{s1.Name}

ans =

    'ExampleTest/testOne'    'ExampleTest/testTwo'
```

At the time of the test suite construction, create a test suite that only contains tests with the substring `'One'`.

```
import matlab.unittest.constraints.ContainsSubstring;
s2 = TestSuite.fromFile('ExampleTest.m',...
    HasName(ContainsSubstring('One')))

s2 =

  Test with properties:

                Name: 'ExampleTest/testOne'
      Parameterization: []
    SharedTestFixtures: []
```

```
                Tags: {0x1 cell}

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

See Also

`fromClass` | `fromFile` | `fromFolder` | `fromMethod` | `fromPackage` | `matlab.unittest.selectors` | `selectIf`

Introduced in R2014a

matlab.unittest.selectors.HasTag class

Package: matlab.unittest.selectors

Selector for TestSuite elements determined by tag

Description

The `HasTag` selector filters `TestSuite` array elements determined by the test element tag.

Construction

`matlab.unittest.selectors.HasTag` constructs a selector for `TestSuite` elements determined by the test element tag. When you instantiate `HasTag` without input arguments, the resulting `TestSuite` array contains only elements with one or more tags.

`matlab.unittest.selectors.HasTag(t)` constructs a selector for `TestSuite` elements determined by the test element tag, `t`. You can specify the name as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified name, `t`, is a string, the testing framework creates an `IsEqualTo` constraint with the input string, `t`, as the expected value.

For a test element to be included in the suite, the test element must be tagged with the specified string or with a value that satisfies the specified constraint.

Input Arguments

`t` — Test element tag

string | `Constraint`

Test element tag, specified as a string or `matlab.unittest.constraints.Constraint` instance. If a test element tag meets the following conditions, the `TestSuite` contains the test:

- If `t` is a string, the test element tag is the specified value.

- If `t` is a constraint, the test element tag is a value that satisfies the specified constraint.

Properties

`Constraint` — Condition test element tag must satisfy

instance of `matlab.unittest.constraints.Constraints` class

Condition the test element tag must satisfy to be included in the test suite, specified as an instance of the `matlab.unittest.constraints.Constraints` class.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Filter Test Suite by Tag

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods (Test)
        function testA (testCase)
            % test code
        end
    end
    methods (Test, TestTags = {'Unit'})
        function testB (testCase)
            % test code
        end
        function testC (testCase)
            % test code
        end
    end
    methods (Test, TestTags = {'Unit','FeatureA'})
        function testD (testCase)
```

```
            % test code
        end
    end
    methods (Test, TestTags = {'System','FeatureA'})
        function testE (testCase)
            % test code
        end
    end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and examine the contents.

```
import matlab.unittest.TestSuite
import matlab.unittest.selectors.HasTag

suite = TestSuite.fromClass(?ExampleTest)
```

```
suite =

  1x5 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 3 Unique Tags.
```

Click the hyperlink for `3 Unique Tags` to display all the tags in the suite.

```
       Tag
    __________

    'FeatureA'
    'System'
    'Unit'
```

Select all the test suite elements that have the tag `'Unit'`.

```
s1 = suite.selectIf(HasTag('Unit'))
```

```
s1 =
```

```
  1x3 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 2 Unique Tags.
```

Select all the test suite elements that do not contain the tag `'FeatureA'`.

```
s2 =  suite.selectIf(~HasTag('FeatureA'));
{s2.Name}

ans =

    'ExampleTest/testB'    'ExampleTest/testC'    'ExampleTest/testA'
```

Select all the test suite elements that have no tags.

```
s3 =  suite.selectIf(~HasTag)

s3 =

  Test with properties:

                 Name: 'ExampleTest/testA'
      Parameterization: []
    SharedTestFixtures: []
                 Tags: {0x1 cell}

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

- “Tag Unit Tests”

Alternatives

Use the `HasTag` selector for maximum flexibility to create test suites from tags. Alternatively, at the time of test suite construction, you can filter the test suite Using the `'Tag'` name-value pair. For example,

```
s = TestSuite.fromClass(?ExampleTest,'Tag','Unit');
```

You can also select and run tagged tests using the `'Tag'` name-value pair with the `runtests` function. For example,

```
runtests('ExampleTest.m','Tag','Unit')
```

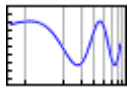
Introduced in R2015a

semilogx

Semilogarithmic plot



Syntax

```
semilogx(Y)
semilogx(X1,Y1,...)
semilogx(X1,Y1,LineSpec,...)
semilogx(...,'PropertyName',PropertyValue,...)
h = semilogx(...)
```

Description

`semilogx` plot data as logarithmic scales for the *x*-axis.

`semilogx(Y)` creates a plot using a base 10 logarithmic scale for the *x*-axis and a linear scale for the *y*-axis. It plots the columns of `Y` versus their index if `Y` contains real numbers. `semilogx(Y)` is equivalent to `semilogx(real(Y),imag(Y))` if `Y` contains complex numbers. `semilogx` ignores the imaginary component in all other uses of this function.

`semilogx(X1,Y1,...)` plots all `Yn` versus `Xn` pairs. If only one of `Xn` or `Yn` is a matrix, `semilogx` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogx(X1,Y1,LineSpec,...)` plots all lines defined by the `Xn,Yn,LineSpec` triples. `LineSpec` determines line style, marker symbol, and color of the plotted lines.

`semilogx(...,'PropertyName',PropertyValue,...)` sets property values for all charting lines created by `semilogx`. For a list of properties, see Chart Line Properties.

`h = semilogx(...)` return a vector of chart line handles, one handle per line.

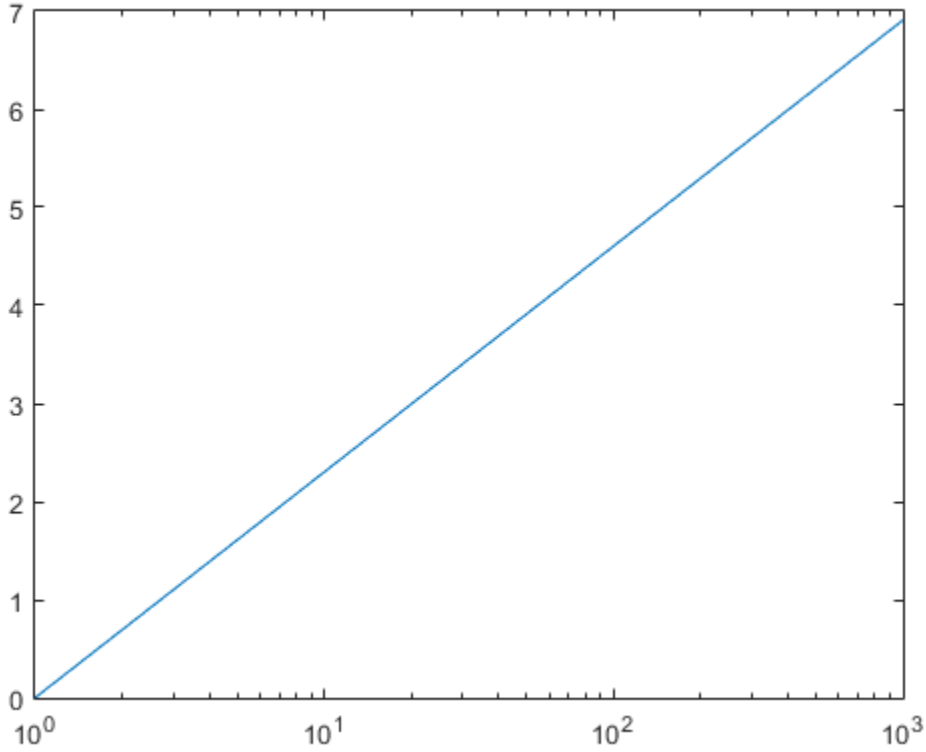
Examples

Logarithmic Scale for x-Axis

Create a plot with a logarithmic scale for the x-axis and a linear scale for the y-axis.

```
x = 0:1000;
y = log(x);

figure
semilogx(x,y)
```



More About

Tips

If you do not specify a color when plotting more than one line, `semilogx` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix `Xn,Yn` pairs with `Xn,Yn,`*`LineSpec`* triples; for example,

```
semilogx(X1,Y1,X2,Y2,LineSpec,X3,Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

See Also

Functions

`LineSpec` | `loglog` | `plot` | `semilogy`

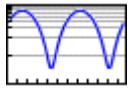
Properties

Chart Line Properties

Introduced before R2006a

semilogy

Semilogarithmic plot



Syntax

```
semilogy(Y)
semilogy(X1,Y1,...)
semilogy(X1,Y1,LineSpec,...)
semilogy(...,'PropertyName',PropertyValue,...)
h = semilogy(...)
```

Description

`semilogy` plots data with logarithmic scale for the *y*-axis.

`semilogy(Y)` creates a plot using a base 10 logarithmic scale for the *y*-axis and a linear scale for the *x*-axis. It plots the columns of `Y` versus their index if `Y` contains real numbers. `semilogy(Y)` is equivalent to `semilogy(real(Y),imag(Y))` if `Y` contains complex numbers. `semilogy` ignores the imaginary component in all other uses of this function.

`semilogy(X1,Y1,...)` plots all `Yn` versus `Xn` pairs. If only one of `Xn` or `Yn` is a matrix, `semilogy` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`semilogy(X1,Y1,LineSpec,...)` plots all lines defined by the `Xn,Yn,LineSpec` triples. `LineSpec` determines line style, marker symbol, and color of the plotted lines.

`semilogy(...,'PropertyName',PropertyValue,...)` sets property values for all the charting lines created by `semilogy`. For a list of properties, see Chart Line Properties.

`h = semilogy(...)` returns a vector of chart line handles, one handle per line.

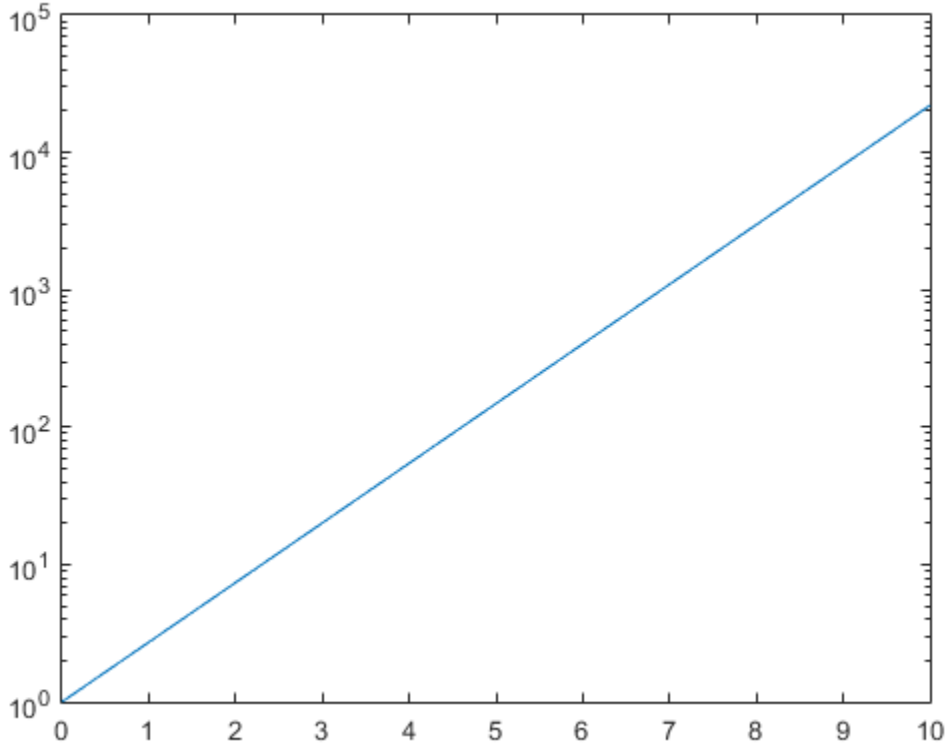
Examples

Logarithmic Scale for y-Axis

Create a plot with a logarithmic scale for the y-axis and a linear scale for the x-axis.

```
x = 0:0.1:10;
y = exp(x);

figure
semilogy(x,y)
```



More About

Tips

If you do not specify a color when plotting more than one line, `semilogy` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix `Xn,Yn` pairs with `Xn,Yn,`*`LineSpec`* triples; for example,

```
semilogy(X1,Y1,X2,Y2,LineSpec,X3,Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

Properties
Chart Line Properties

Introduced before R2006a

sendmail

Send email message to address list

Syntax

```
sendmail(recipients,subject)
sendmail(recipients,subject,message)
sendmail(recipients,subject,message,attachments)
```

Description

`sendmail(recipients,subject)` sends email to `recipients` with the specified `subject`. The `recipients` input is a string for a single address, or a cell array of strings for multiple addresses.

`sendmail(recipients,subject,message)` includes the specified `message`. If `message` is a string, `sendmail` automatically wraps text at 75 characters. To force a line break in the message text, use `10`, as shown in the Examples. If `message` is a cell array of strings, each cell represents a new line of text.

`sendmail(recipients,subject,message,attachments)` attaches the files listed in the string or cell array `attachments`.

Examples

Send a message with two attachments to a hypothetical email address:

```
sendmail('user@otherdomain.com',...
         'Test subject','Test message',...
         {'folder/attach1.html','attach2.doc'});
```

Send a message with forced line breaks (using `10`) to a hypothetical email address:

```
sendmail('user@otherdomain.com','New subject', ...
        ['Line1 of message' 10 'Line2 of message' 10 ...
         'Line3 of message' 10 'Line4 of message']);
```

The resulting message is:

```
Line1 of message
Line2 of message
Line3 of message
Line4 of message
```

Alternatives

On Windows systems with Microsoft Outlook®, you can send email directly through Outlook by accessing the COM server with `actxserver`. For an example, see Solution 1-RTY6J.

More About

Tips

- The `sendmail` function does not support HTML-formatted messages. However, you can send HTML files as attachments.
- If `sendmail` cannot determine your email address or outgoing SMTP mail server from your system registry, specify those settings using the `setpref` function. For example:

  ```
  setpref('Internet','SMTP_Server','my_server.example.com');
  setpref('Internet','E_mail','my_email@example.com');
  ```

  To identify the SMTP server for the call to `setpref`, check the preferences for your electronic mail application, or consult your email system administrator. If you cannot easily determine the server name, try `'mail'`, which is a common default, such as:

  ```
  setpref('Internet','SMTP_Server','mail');
  ```

- By default, the `sendmail` function does not support email servers that require authentication. To support these servers, change your system settings and set preferences for the SMTP user name and password, with commands in the following form:

  ```
  props = java.lang.System.getProperties;
  props.setProperty('mail.smtp.auth','true');
  ```

```
setpref('Internet','SMTP_Username','myaddress@example.com');
setpref('Internet','SMTP_Password','mypassword');
```

- To override the default character encoding, set the preference for email character encoding as follows:

  ```
  setpref('Internet','E_mail_Charset',encoding);
  ```
  where *`encoding`* is a string specifying the character encoding, such as `'SJIS'`.

- "Specify Proxy Server Settings for Connecting to the Internet"

See Also

`getpref` | `setpref`

serial

Create serial port object

Syntax

```
obj = serial('port')
obj = serial('port','PropertyName',PropertyValue,...)
```

Description

`obj = serial('port')` creates a serial port object associated with the serial port specified by *`port`*. If *`port`* does not exist, or if it is in use, you will not be able to connect the serial port object to the device.

`Port` object name will depend upon the platform that the serial port is on. `instrhwinfo` ('serial') provides a list of available serial ports. This list is an example of serial constructors on different platforms:

Platform	Serial Port Constructor
Linux and Linux 64	`serial('/dev/ttyS0');`
Mac OS X 64	`serial('/dev/tty.KeySerial1');`
Windows 32 and Windows 64	`serial('com1');`

`obj = serial('port','PropertyName',PropertyValue,...)` creates a serial port object with the specified property names and property values. If an invalid property name or property value is specified, an error is returned and the serial port object is not created.

Examples

This example creates the serial port object `s1` associated with the serial port COM1 on a Windows platform.

```
s1 = serial('COM1');
```

The `Type`, `Name`, and `Port` properties are automatically configured.

```
get(s1,{'Type','Name','Port'})
ans =
    'serial'    'Serial-COM1'    'COM1'
```

To specify properties during object creation

```
s2 = serial('COM2','BaudRate',1200,'DataBits',7);
```

More About

Tips

When you create a serial port object, these property values are automatically configured:

- The `Type` property is given by `serial`.
- The `Name` property is given by concatenating `Serial` with the port specified in the `serial` function.
- The `Port` property is given by the port specified in the `serial` function.

You can specify the property names and property values using any format supported by the `set` function. For example, you can use property name/property value cell array pairs. Additionally, you can specify property names without regard to case, and you can make use of property name completion. For example, the following commands are all valid on a Windows platform.

```
s = serial('COM1','BaudRate',4800);
s = serial('COM1','baudrate',4800);
s = serial('COM1','BAUD',4800);
```

Refer to Configuring Property Values for a list of serial port object properties that you can use with `serial`.

Before you can communicate with the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt a read or write operation while the object is not connected to the device. You can connect only one serial port object to a given serial port.

See Also

`fclose` | `fopen` | `Name` | `Port` | `Status` | `Type`

Introduced before R2006a

serialbreak

Send break to device connected to serial port

Syntax

```
serialbreak(obj)
serialbreak(obj,time)
```

Description

`serialbreak(obj)` sends a break of 10 milliseconds to the device connected to the serial port object, `obj`.

`serialbreak(obj,time)` sends a break to the device with a duration, in milliseconds, specified by `time`. Note that the duration of the break might be inaccurate under some operating systems.

More About

Tips

For some devices, the break signal provides a way to clear the hardware buffer.

Before you can send a break to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to send a break while `obj` is not connected to the device.

`serialbreak` is a synchronous function, and blocks the command line until execution is complete.

If you issue `serialbreak` while data is being asynchronously written, an error is returned. In this case, you must call the `stopasync` function or wait for the write operation to complete.

See Also

`fopen` | `stopasync` | `Status`

Introduced before R2006a

set

Set graphics object properties

Syntax

```
set(H,Name,Value)
set(H,NameArray,ValueArray)
set(H,S)
s = set(H)
values = set(H,Name)
```

Description

Note: Do not use the `set` function on Java objects as it will cause a memory leak. For more information, see "Accessing Private and Public Data"

`set(H,Name,Value)` specifies a value for the property `Name` on the object identified by `H`. Use single quotes around the property name, for example, `set(H,'Color','red')`. If `H` is a vector of objects, then `set` sets the property for all the objects. If `H` is empty (that is, `[]`), `set` does nothing, but does not return an error or warning.

`set(H,NameArray,ValueArray)` specifies multiple property values using the cell arrays `NameArray` and `ValueArray`. To set `n` property values on each of `m` graphics objects, specify `ValueArray` as an `m`-by-`n` cell array, where `m = length(H)` and `n` is equal to the number of property names contained in `NameArray`.

`set(H,S)` specifies multiple property values using `S`, where `S` is a structure whose field names are the object property names and whose field values are the corresponding property values. MATLAB ignores empty structures.

`s = set(H)` returns the user-settable properties and possible values for the object identified by `H`. `s` is a structure array whose field names are the object's property names and whose field values are the possible values of the corresponding properties. If you do not specify an output argument, the MATLAB software displays the information on the screen. `H` must be a single object.

`values = set(H,Name)` returns the possible values for the specified property. If the possible values are strings, `set` returns each in a cell of the cell array `values`. For other properties, `set` returns a statement indicating that `Name` does not have a fixed set of property values. If you do not specify an output argument, MATLAB displays the information on the screen. `H` must be a single object.

Note: For more information about properties you can set, see the property pages for each object, for example, Figure Properties, Axes Properties, Chart Line Properties, Text Properties, and so on.

Examples

Change Color of Specific Line

Plot a line and return the chart line object as `p`. Set the `Color` property of the line to `'red'`.

```
p = plot(1:10);
set(p,'Color','red')
```

Change Color for Multiple Lines

Create a plot with four lines using random data and return the four chart line objects as `P`. Set the `Color` property for all of the lines to `'red'`.

```
P = plot(rand(4));
set(P,'Color','red')
```

Set Line Style to Different Value for Multiple Lines

Set the value of the `LineStyle` property for four chart line objects each to a different value. Transpose the value of the cell array so that it has the proper shape.

```
P = plot(rand(4));
NameArray = {'LineStyle'};
ValueArray = {'-','--',':','-.'}';
set(P,NameArray,ValueArray)
```

Set Different Values for Multiple Properties on Multiple Objects

Set the values of the `Marker` and `Tag` properties on three different stem series objects to different values. Each row of the value cell array corresponds to an object in `h` and contains two values, one for the `Marker` property and one for the `Tag` property.

```
x = 0:30;
y = [1.5*cos(x); 4*exp(-.1*x).*cos(x); exp(.05*x).*cos(x)]';
S = stem(x,y);
NameArray = {'Marker','Tag'};
ValueArray = {'o','Decaying Exponential';...
   'square','Growing Exponential';...
   '*','Steady State'};
set(S,NameArray,ValueArray)
```

More About

Tips

You can use any combination of property name/property value pairs, structure arrays, and cell arrays in one call to `set`.

Setting Property Units

Note that if you are setting both the `FontSize` and the `FontUnits` properties in one function call, you must set the `FontUnits` property first so that the MATLAB software can correctly interpret the specified `FontSize`. The same applies to figure and axes units — always set the `Units` property before setting properties whose values you want to be interpreted in those units. For example,

```
f = figure('Units','characters','Position',[30 30 120 35]);
```

- “Default Property Values”
- “Graphics Object Properties”

See Also

`findobj` | `gca` | `gcf` | `gco` | `gcbo` | `get`

Introduced before R2006a

set

Set property values for `audioplayer` object

Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

Description

`set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

Examples

View the list of properties that you can set for an `audioplayer` object:

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj)
```

Set the `Tag` and `UserData` properties of an `audioplayer` object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};

load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj, newValues)

% View the values all properties.
get(handelObj)
```

Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for an object called `handelObj` (as created in the Examples):

```
handelObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(handelObj, 'Tag', 'This is my tag.');
```

See Also

`audioplayer` | `get`

set

Set property values for `audiorecorder` object

Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

Description

`set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

Examples

View the list of properties that you can set for an `audiorecorder` object:

```
recorderObj = audiorecorder;
set(recorderObj)
```

Set the `Tag` and `UserData` properties of an `audiorecorder` object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};

recorderObj = audiorecorder;
set(recorderObj, newValues)

% View the values all properties.
get(recorderObj)
```

Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for an object called `recorderObj` (as created in the Examples):

```
recorderObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(recorderObj, 'Tag', 'This is my tag.');
```

See Also

`audiorecorder` | `get`

set (COM)

Set object or interface property to specified value

Syntax

```
set(h,'pname',value)
set(h,'pname1',value1,'pname2',value2,...)
```

Description

`set(h,'pname',value)` sets the property specified in the string `pname` to the given `value`.

`set(h,'pname1',value1,'pname2',value2,...)` sets each property specified in the `pname` strings to the given `value`.

For information on how MATLAB converts workspace matrices to COM data types, see "Handling COM Data in MATLAB Software".

COM functions are available on Microsoft Windows systems only.

Examples

Create an `mwsamp` control and use `set` to change the `Label` and `Radius` properties:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1',[0 0 200 200],f);

set(h,'Label','Click to fire event','Radius',40);
invoke(h,'Redraw');
```

Here is another way to do the same thing, only without `set` and `invoke`:

```
h.Label = 'Click to fire event';
h.Radius = 40;
Redraw(h);
```

Introduced before R2006a

matlab.mixin.SetGet class

Package: matlab.mixin

Abstract class used to derive handle classes with set and get methods

---

Note: `hgsetget` will be removed in a future release. Use `matlab.mixin.SetGet` instead.

Description

`classdef` *`MySubClass`* `<` `matlab.mixin.SetGet` makes *`MySubClass`* a subclass of the `matlab.mixin.SetGet` class, which is itself a subclass of the `handle` class

Use the `matlab.mixin.SetGet` class to derive classes that inherit `set` and `get` methods that behave like MATLAB graphics `set` and `get` functions.

Methods

The `matlab.mixin.SetGet` class defines these method:

Method	Purpose
`set`	Assigns values to the specified properties or returns a cell array of possible values for writable properties.
`get`	Returns value of specified property or a `struct` with all property values.
`setdisp`	Implicitly called when `set` is called with no output arguments and a handle array, but no property name. Override this method to change what set displays.
`getdisp`	Implicitly called when `get` is called with no output arguments and handle array, but no property name. Override this method to change what get displays.

Attributes

`Abstract`	`true`
`ConstructOnLoad`	`true`
`HandleCompatible`	`true`

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see “Handle Objects” in the MATLAB documentation.

More About

- Class Attributes

set

Class: matlab.mixin.SetGet
Package: matlab.mixin

Assign specified property name/property value pairs

Syntax

```
set(H,'Name',Value,...)
set(H,pn,pv)
set(H,S)
S = set(h)
```

Description

`set(H,'Name',Value,...)` sets the named property to the specified value for the objects in the handle array `H`.

`set(H,pn,pv)` sets the named properties specified in the cell array of strings `pn` to the corresponding values in the cell array `pv` for all objects specified in `H`. The cell array `pn` must be `1`-by-`n` (where `n` is the number of property names), but the cell array `pv` can be `m`-by-`n` where `m` is equal to `length(H)`. `set` updates each object with the associated set of values for the list of property names contained in.

`set(H,S)` sets the properties identified by each field name of `struct` `S` with the values contained in `S`. `S` is a `struct` whose field names are object property names.

`S = set(h)` returns the user-settable properties of scalar `h`. `S` is a `struct` whose field names are the object's property names and values that are either empty cell arrays or cell arrays of possible values for properties that have a finite set of predefined possible values.

Tips

- Override the `matlab.mixin.SetGet` class `setdisp` method to change how MATLAB displays information returned by `set`.

Input Arguments

`H` — Input handle array
handle array

Input handle array, specified as a single handle or an array of handles

`'Name'` — Property name
string

Property name, specified as a quoted string

`Value` — Property value to assign to the named property
property value

Property value to assign to the named property, specified as appropriate for that property.

`pn` — Property names
cell array of strings

Property names, specified as a cell array of strings. The cell array `pn` must be `1`-by-`n` (where `n` is the number of property names).

Data Types: `cell`

`pv` — Property values
cell array

Property values, specified as a cell array. The cell array `pv` can be `m`-by-`n` where `m` is equal to `length(H)` and `n` is the number of property names in `pn`.

Data Types: `cell`

`S` — Property name and value structure
`struct`

Property name and value structure. The fields of `S` correspond to property names and the values of the fields are the property values to set.

Data Types: `struct`

`h` — Scalar object handle
handle

Scalar object handle. To obtain user-settable properties, input argument must be a scalar object handle.

Output Arguments

S — Settable properties

`struct`

Settable properties, returned as a structure with fields corresponding to property names and values that are either empty cell arrays or cell arrays of possible values for properties that have a finite set of predefined possible values.

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

More About

- "Implementing a Set/Get Interface for Properties"

setdisp

Class: matlab.mixin.SetGet
Package: matlab.mixin

Customize set method display

Syntax

```
setdisp(h)
```

Description

`setdisp(h)` called by `set` when `set` is called with no output arguments and a single input argument that is a scalar handle. Override this `matlab.mixin.SetGet` class method in a subclass to change how property information is displayed in the command window.

Input Arguments

h — Object handle

handle

Object handle whose settable properties and their possible values are to be displayed.

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

get

Class: matlab.mixin.SetGet
Package: matlab.mixin

Query specified property values

Syntax

```
CV = get(H,'Name')
SV = get(h)
get(h)
```

Description

`CV = get(H,'Name')` returns the value of the named property from the objects in the handle array `H`. If `H` is scalar, `get` returns a single value; if `H` is an array, `get` returns a cell array of property values.

If you specify a cell array of property names as the second argument, then `get` returns a cell array of values, where each row in the cell corresponds to an element in `H` and each column in the cell corresponds to an element in the property name cell array.

If `H` is nonscalar and `'Name'` is the name of a dynamic property, `get` returns a value only if the property exists in all objects referenced in `H`.

`SV = get(h)` returns a structure array in which the field names are the object's property names and the values are the current values of the corresponding properties. If `h` is nonscalar, then `SV` is a `numel(h)`-by-`1` array of structures.

`get(h)` displays all property names and their current values for the MATLAB objects with handle `h`.

Your subclass can override the `matlab.mixin.SetGet` `getdisp` method to control how MATLAB displays this information.

Tips

- Override the `matlab.mixin.SetGet` class `matlab.mixin.SetGet.getdisp` method to change how MATLAB displays information returned by `get`.

Input Arguments

`H` — Input handle array

object array

Input handle array, specified as a single handle or an array of handles

`'Name'` — Property to query

string

Property to query, specified as a case-sensitive string.

Output Arguments

`CV` — Value of queried property

property value

Value of queried property, returned as a single value or a cell array of values.

`SV` — Structure array of property names and values

`struct`

Structure array of property names and values, in which the field names are the object's property names and the values are the current values of the corresponding properties.

Data Types: `struct`

Attributes

`Access`	`public`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

More About

- "Implementing a Set/Get Interface for Properties"

set

Class: VideoReader

Set property values for video reader object

Syntax

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

Description

`set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

Tips

The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

Examples

View Settable Properties

View the list of properties that you can set for a `VideoReader` object.

```
xyloObj = VideoReader('xylophone.mp4');
set(xyloObj)
```

```
            Tag: {}
       UserData: {}
    CurrentTime: {}
```

Set Object Properties

Set the `Tag` and `UserData` properties of a `VideoReader` object using a structure array.

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data',pi,[1 2 3 4]};

xyloObj = VideoReader('xylophone.mp4');
set(xyloObj,newValues)
```

View the values all properties.

```
get(xyloObj)
```

```
obj =

  VideoReader with properties:

   General Properties:
           Name: 'xylophone.mp4'
           Path: 'matlabroot\toolbox\matlab\audiovideo'
       Duration: 4.7000
    CurrentTime: 0
            Tag: 'My Tag'
       UserData: {'My User Data'  [3.1416]  [1 2 3 4]}

   Video Properties:
          Width: 320
         Height: 240
      FrameRate: 30
    BitsPerPixel: 24
```

```
    VideoFormat: 'RGB24'
```

Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for a reader object called `xyloObj` (as created in the Examples):

```
xyloObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(xyloObj,'Tag','This is my tag.');
```

See Also

`VideoReader` | `get`

set (RandStream)

Set random number stream property

Class

`RandStream`

Syntax

```
set(stream,'PropertyName',Value)
set(stream,'Property1',Value1,'Property2',Value2,...)
set(stream,A)
A = set(stream,'Property')
set(stream,'Property')
A = set(stream)
set(stream)
```

Description

`set(stream,'PropertyName',Value)` sets the property `'PropertyName'` of the random stream `stream` to the value `Value`.

`set(stream,'Property1',Value1,'Property2',Value2,...)` sets multiple random stream property values with a single statement.

`set(stream,A)` where `A` is a structure whose field names are property names of the random stream `stream` sets the properties of `stream` named by each field with the values contained in those fields.

`A = set(stream,'Property')` or `set(stream,'Property')` displays possible values for the specified property of `stream`.

`A = set(stream)` or `set(stream)` displays or returns all writable properties of `stream` and their possible values.

See Also

`RandStream` | `get (RandStream)` | `rand` | `randn` | `randi`

set (serial)

Configure or display serial port object properties

Syntax

```
set(obj)
props = set(obj)
set(obj,'PropertyName')
props = set(obj,'PropertyName')
set(obj,'PropertyName',PropertyValue,...)
set(obj,PN,PV)
set(obj,S)
```

Description

`set(obj)` displays all configurable properties values for the serial port object, `obj`. If a property has a finite list of possible string values, then these values are also displayed.

`props = set(obj)` returns all configurable properties and their possible values for `obj` to `props`. `props` is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values. If the property does not have a finite set of possible values, then the cell array is empty.

`set(obj,'PropertyName')` displays the valid values for *`PropertyName`* if it possesses a finite list of string values.

`props = set(obj,'PropertyName')` returns the valid values for *`PropertyName`* to `props`. If *`PropertyName`* does not have a finite list of possible values, `props` is a cell array of possible string values or an empty cell array.

`set(obj,'PropertyName',PropertyValue,...)` configures multiple property values with a single command.

`set(obj,PN,PV)` configures the properties specified in the cell array of strings `PN` to the corresponding values in the cell array `PV`. `PN` must be a vector. `PV` can be m-by-n where m is equal to the number of serial port objects in `obj` and n is equal to the length of `PN`.

`set(obj,S)` configures the named properties to the specified values for `obj`. `S` is a structure whose field names are serial port object properties, and whose field values are the values of the corresponding properties.

Examples

This example illustrates shows how to use the `set` function to configure or return property values, on a Windows platform.

```
s = serial('COM1');
set(s,'BaudRate',9600,'Parity','even')
set(s,{'StopBits','RecordName'},{2,'sydney.txt'})
set(s,'Parity')
[ {none} | odd | even | mark | space ]
```

More About

Tips

Refer to Configuring Property Values for a list of serial port object properties that you can configure with `set`.

You can use any combination of property name/property value pairs, structures, and cell arrays in one call to the `set` function. Additionally, you can specify a property name without regard to case, and you can use property name completion. For example, if `s` is a serial port object, then the following commands are all valid.

```
set(s,'BaudRate')
set(s,'baudrate')
set(s,'BAUD')
```

`get`

Introduced before R2006a

set (tscollection)

Set properties of `tscollection` object

Syntax

```
set(tsc,'Property',Value)
set(tsc,'Property1',Value1,'Property2',Value2,...)
set(tsc,'Property')
```

Description

`set(tsc,'Property',Value)` sets the property `'Property'` of the `tscollection` `tsc` to the value `Value`. The following syntax is equivalent:

```
tsc.Property = Value
```

`set(tsc,'Property1',Value1,'Property2',Value2,...)` sets multiple property values for `tsc` with a single statement.

`set(tsc,'Property')` displays values for the specified property in the time-series collection `tsc`.

`set(tsc)` displays all properties and values of the `tscollection` object `tsc`.

See Also

`get (tscollection)`

Introduced before R2006a

setabstime (tscollection)

Set times of `tscollection` object as date strings

Syntax

```
tsc = setabstime(tsc,Times)
tsc = setabstime(tsc,Times,format)
```

Description

`tsc = setabstime(tsc,Times)` sets the times in tsc using the date strings Times. Times must be either a cell array of strings, or a `char` array containing valid date or time values in the same date format.

`tsc = setabstime(tsc,Times,format)` specifies the date-string format used in Times explicitly.

Examples

1. Create a `tscollection` object.

   ```
   tsc = tscollection(timeseries(rand(3,1)))
   ```

2. Set the absolute time vector.

   ```
   tsc = setabstime(tsc,{'12-DEC-2005 12:34:56',...
         '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
   ```

setappdata

Store application-defined data

Use the `setappdata` function to store data in a UI. You can retrieve the data elsewhere in your code using the `getappdata` function. Both of these functions provide a convenient way to share data between callbacks or between separate UIs.

Syntax

```
setappdata(obj,name,val)
```

Description

`setappdata(obj,name,val)` stores the contents of `val`. The graphics object, obj, and the name identifier, name, uniquely identify the data for later retrieval.

Examples

Store and Retrieve Date Information

Create a figure window. Then, get the current time using the `date` function.

```
f = figure;
val = date
```

```
val =

23-Dec-2014
```

Store the contents of `val` using the `setappdata` function. In this case, `val` is stored in the figure object using the name identifier, `'todaysdate'`.

```
setappdata(f,'todaysdate',val);
```

Retrieve the data and display it.

```
getappdata(f,'todaysdate')
```

```
ans =

23-Dec-2014
```

Input Arguments

`obj` — Graphics object in which to store the value

figure | uipanel | uibuttongroup | uicontrol | ...

Graphics object in which to store the value, specified as any graphics object (except an ActiveX component). The graphics object must be accessible from within the functions you plan to store and retrieve the data.

`name` — Name identifier

`string`

Name identifier, specified as a `string` value. Select a unique name identifier that is easy to remember so that you can easily recall it when you want to retrieve the data.

Data Types: `char`

`val` — Value to store

any MATLAB data type

Value to store, specified as any MATLAB data type.

Introduced before R2006a

setcats

Set categories in categorical array

Syntax

```
B = setcats(A,newcats)
```

Description

`B = setcats(A,newcats)` sets categories in output categorical array `B` using categories defined by `newcats` and elements defined by `A`. If an element of `A` is in a category listed in `newcats`, then the corresponding element of `B` has the same value as in `A`.

- If `A` has a category not listed in `newcats`, then `B` does not have that category. The corresponding elements in `B` are undefined.
- If `newcats` lists a category that is not a category of `A`, then `B` has no elements equal to that category.

Examples

Set New Categories

Create a categorical array containing various colors.

```
A = categorical({'blue','black','red';'red','blue','black';'black','red','blue'})
```

```
A =

     blue       black      red
     red        blue       black
     black      red        blue
```

Set new categories.

```
B = setcats(A,{'red','black'})
```

```
B =

     <undefined>      black            red
     red              <undefined>      black
     black            red              <undefined>
```

Elements that were `blue` in `A` are undefined in `B`.

Set New Categories and Assign Elements

Create a categorical array containing various colors.

```
A = categorical({'blue','black','red';'red','blue','black';'black','red','blue'})
```

```
A =

     blue       black      red
     red        blue       black
     black      red        blue
```

Set new categories. Include a category that is not a category of `A`.

```
B = setcats(A,{'red','pink','blue'})
```

```
B =

     blue             <undefined>      red
     red              blue             <undefined>
     <undefined>      red              blue
```

No element of `B` is `pink`, because `pink` is not a category of `A`. Assign an element of `B` to be `pink`.

```
B(1,2) = 'pink';
B
```

```
B =

     blue              pink      red
     red               blue      <undefined>
     <undefined>       red       blue
```

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

newcats — New categories

string | cell array of strings

New categories, specified as a string or a cell array of strings.

More About

Tips

- To change category names in a categorical array, use `renamecats`.

See Also

`addcats` | `categories` | `iscategory` | `mergecats` | `removecats` | `renamecats` | `reordercats`

setdiff

Set difference of two arrays

Syntax

```
C = setdiff(A,B)
C = setdiff(A,B,'rows')
[C,ia] = setdiff(A,B)
[C,ia] = setdiff(A,B,'rows')

[C,ia] = setdiff( ___ ,setOrder)
[C,ia] = setdiff(A,B,'legacy')
[C,ia] = setdiff(A,B,'rows','legacy')
```

Description

`C = setdiff(A,B)` returns the data in `A` that is not in `B`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `setdiff` returns the values in `A` that are not in `B`. The values of `C` are in sorted order.
- If `A` and `B` are tables, then `setdiff` returns the rows from `A` that are not in `B`, with repetitions removed. The rows of table `C` are in sorted order.

`C = setdiff(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the rows from `A` that are not in `B`. The rows of `C` are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia] = setdiff(A,B)` also returns the index vector `ia`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `C = A(ia)`.
- If `A` and `B` are tables, then `C = A(ia,:)`.

`[C,ia] = setdiff(A,B,'rows')` also returns the index vector `ia`, such that `C = A(ia,:)`.

`[C,ia] = setdiff( ___ ,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`. If no value is specified, the default is `'sorted'`.

`[C,ia] = setdiff(A,B,'legacy')` and `[C,ia] = setdiff( A,B,'rows','legacy')` preserve the behavior of the `setdiff` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays, tables, datetime arrays, or duration arrays.

Examples

Difference of Two Vectors

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in `A` that are not in `B`.

```
C = setdiff(A,B)
```

```
C =

     1     3     5
```

Difference of Two Tables

Define two tables with rows in common.

```
A = table([1:5]',['A';'B';'C';'D';'E'],logical([0;1;0;1;0]))
B = table([1:2:10]',['A';'C';'E';'G';'I'],logical(zeros(5,1)))
```

```
A =

    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
```

```
    2       B       true
    3       C       false
    4       D       true
    5       E       false

B =

    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    3       C       false
    5       E       false
    7       G       false
    9       I       false
```

Find the rows in `A` that are not in `B`.

```
C = setdiff(A,B)
```

```
C =

    Var1    Var2    Var3
    ----    ----    -----
    2       B       true
    4       D       true
```

Difference of Two Vectors and Indices to Different Values

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in `A` that are not in `B` as well as the index vector `ia`, such that `C = A(ia)`.

```
[C,ia] = setdiff(A,B)
```

```
C =

     1     3     5

ia =

     4
     1
```

```
     5
```

Difference of Two Tables and Indices to Different Rows

Define a table, `A`, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =

             Gender    Age    Height
             ------    ---    ------
    Ted      M         27     74
    Fred     M         52     68
    Betty    F         31     64
    Bob      M         46     61
    Judy     F         35     64
```

Define a table, `B`, with the same variables as `A`.

```
B = table(['F';'M';'F';'F'],[64;68;62;58],[31;47;35;23],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe' 'Beth' 'Amy'})
```

```
B =

             Gender    Height    Age
             ------    ------    ---
    Meg      F         64        31
    Joe      M         68        47
    Beth     F         62        35
    Amy      F         58        23
```

Find the rows in `A` that are not in `B`, as well as the index vector `ia`, such that `C = A(ia,:)`.

```
[C,ia] = setdiff(A,B)
```

```
C =

             Gender    Age    Height
             ------    ---    ------
    Judy     F         35     64
    Ted      M         27     74
```

```
    Bob      M          46      61
    Fred     M          52      68

ia =

     5
     1
     4
     2
```

The rows of `C` are in sorted order first by `Gender` and next by `Age`.

Difference of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 9 7; 0 0 0; 7 9 7; 5 5 5; 1 4 5];
B = [0 0 0; 5 5 5];
```

Find the rows from `A` that are not in `B` as well as the index vector `ia`, such that `C = A(ia,:)`.

```
[C,ia] = setdiff(A,B,'rows')

C =

     1     4     5
     7     9     7

ia =

     5
     1
```

Difference of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` or `'sorted'` when the order of the values in `C` are important.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C,ia] = setdiff(A,B,'stable')

C =
```

```
     3     1     5

ia =

     1
     4
     5
```

Alternatively, you can specify `'sorted'` order.

```
 [C,ia] = setdiff(A,B,'sorted')

C =

     1     3     5

ia =

     4
     1
     5
```

Difference of Vectors Containing NaNs

Define two vectors containing `NaN`.

```
A = [5 NaN NaN]; B = [5 NaN];
```

Find the set difference of `A` and `B`.

```
C = setdiff(A,B)

C =

   NaN   NaN
```

`setdiff` treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, `A`.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, `B`, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings in A that are not in B.

```
[C,ia] = setdiff(A,B)
```

```
C =

    'dog'    'fish'

ia =

     1
     3
```

`setdiff` treats trailing white space in cell arrays of strings as distinct characters.

Difference of Char and Cell Array of Strings

Create a character array, A.

```
A = ['cat';'dog';'fox';'pig'];
class(A)
```

```
ans =

char
```

Create a cell array of strings, B.

```
B={'dog','cat','fish','horse'};
class(B)
```

```
ans =

cell
```

Find the strings in A that are not in B.

```
C = setdiff(A,B)
```

```
C =

    'fox'
    'pig'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =

cell
```

Preserve Legacy Behavior of setdiff

Use the `'legacy'` flag to preserve the behavior of `setdiff` from R2012b and prior releases in your code.

Find the difference of A and B with the current behavior.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C1,ia1] = setdiff(A,B)
```

```
C1 =

     1     3     5

ia1 =

     4
     1
     5
```

Find the difference of A and B, and preserve the legacy behavior.

```
[C2,ia2] = setdiff(A,B,'legacy')
```

```
C2 =

     1     3     5

ia2 =

     7     1     5
```

Input Arguments

A,B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays | duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the `'rows'` option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If A and B are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, A and B can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

`setOrder` — Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in C.

Order Flag	Meaning
`'sorted'`	The values (or rows) in C return in sorted order. For example: `C = setdiff([4 1 3 2],[2 1],'sorted')` returns `C = [3 4]`.

Order Flag	Meaning
`'stable'`	The values (or rows) in `C` return in the same order as in `A`. For example: `C = setdiff([4 1 3 2],[2 1],'stable')` returns `C = [4 3]`.

Output Arguments

`C` — Difference of `A` and `B`

vector | matrix | table

Difference of `A` and `B`, returned as a vector, matrix, or table. If the inputs `A` and `B` are tables, the order of the variables in the resulting table, `C`, is the same as the order of the variables in `A`.

The following describes the shape of `C` when the inputs are vectors or matrices and when the `'legacy'` flag is not specified:

- If the `'rows'` flag is not specified and `A` is a row vector, then `C` is a row vector.
- If the `'rows'` flag is not specified and `A` is not a row vector, then `C` is a column vector.
- If the`'rows'` flag is specified, then `C` is a matrix containing the rows of `A` that are not in `B`.
- If all the values (or rows) of `A` are also in `B`, then `C` is an empty matrix.

The class of `C` is the same as the class of `A`, unless:

- `A` is a character array and `B` is a cell array of strings, in which case `C` is a cell array of strings.
- `A` is a cell array of strings or single string and `B` is a categorical array, in which case `C` is a categorical array.
- `A` is a cell array of strings or single string and `B` is a datetime array, in which case `C` is a datetime array.

`ia` — Index to `A`

column vector

Index to `A`, returned as a column vector when the `'legacy'` flag is not specified. `ia` identifies the values (or rows) in `A` that are not in `B`. If there is a repeated value (or row)

appearing exclusively in `A`, then `ia` contains the index to the first occurrence of the value (or row).

More About

Tips

- To find the set difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `setdiff(A(:,vars),B(:,vars))`, where *`vars`* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.
- "Combine Categorical Arrays"

Introduced before R2006a

setDirectory

Class: Tiff

Make specified IFD current IFD

Syntax

```
setDirectory(tiffobj,dirNum)
```

Description

`setDirectory(tiffobj,dirNum)` sets the image file directory (IFD) specified by `dirNum` as the current IFD. `Tiff` object methods operate on the current IFD. The directory index number is one-based.

Examples

Open a TIFF file and move to an IFD in the file by specifying its index number. The TIFF file should contain multiple images.

```
t = Tiff('example.tif','r');
setDirectory(t,2)
close(t)
```

References

This method corresponds to the `TIFFSetDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

See Also

`Tiff.currentDirectory` | `Tiff.nextDirectory`

setenv

Set environment variable

Syntax

```
setenv(name,value)
setenv(name)
```

Description

`setenv(name,value)` sets the value of an environment variable belonging to the underlying operating system. Inputs `name` and `value` are both strings. If `name` already exists as an environment variable, then `setenv` replaces its current value with the string given in `value`. If `name` does not exist, `setenv` creates a new environment variable called `name` and assigns `value` to it.

`setenv(name)` is equivalent to `setenv(name, '')` and assigns a null value to the variable `name`. On the Microsoft Windows platform, this is equivalent to undefining the variable. On most UNIX platforms, it is possible to have an environment variable defined as empty.

The maximum number of characters in `name` is 2^{15} - 2 (or 32766). If `name` contains the character `=`, `setenv` throws an error. The behavior of environment variables with `=` in the name is not well-defined.

On all platforms, `setenv` passes the `name` and `value` strings to the operating system unchanged. Special characters such as `;`, `/`, `:`, `$`, `%`, etc. are left unexpanded and intact in the variable value.

Values assigned to variables using `setenv` are picked up by any process that is spawned using the MATLAB `system`, `unix`, `dos` or `!` functions. You can retrieve any value set with `setenv` by using `getenv(name)`.

Examples

% Set and retrieve a new value for the environment variable `TEMP`:

```
setenv('TEMP', 'C:\TEMP');
getenv('TEMP')
```

% Append the `Perl\bin` folder to your system `PATH` variable:

```
setenv('PATH', [getenv('PATH') ';D:\Perl\bin']);
```

See Also

`getenv` | `system` | `unix` | `dos` | `!`

setfield

Assign values to structure array field

Syntax

```
s = setfield(s,'field',value)
s = setfield(s,{sIndx1,...,sIndxM},'field',
{fIndx1,...,fIndxN},value)
```

Description

`s = setfield(s,'field',value)`, where `s` is a 1-by-1 structure, sets the contents of the specified field, equivalent to `s.field = value`. If `s` does not contain the specified `field`, the `setfield` function creates the field and assigns the specified value. Pass field references as strings.

`s = setfield(s,{sIndx1,...,sIndxM},'field',
{fIndx1,...,fIndxN},value)` sets the contents of the specified field, equivalent to `s(sIndx1,...,sIndxM).field(fIndx1,...,fIndxN) = value`. The `setfield` function supports multiple sets of `field` and `fIndx` inputs. If structure `s` or any of the fields is a nonscalar structure, the `Indx` inputs associated with that input are required. Otherwise, the `Indx` inputs are optional. If you specify a single colon operator for an index input, enclose it in single quotation marks: `':'`.

Examples

Add values to a structure that contains nested fields:

```
grades = [];
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student}
newGrades_Doe = [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];
```

```
grades = setfield(grades, {level}, ...
                  fieldnames{:}, {10, 21:30}, ...
                  newGrades_Doe);

% View the new contents.
grades(level).(semester).(subject).(student)(10, 21:30)
```

Using the structure defined in the previous example, remove the tenth row of the specified field:

```
grades = setfield(grades, {level}, fieldnames{:}, {10,':'}, []);
```

More About

Tips

- For most cases, add data to a structure array by indexing rather than using the `setfield` function. For more information, see "Access Data in a Structure Array" and "Generate Field Names from Variables".
- Call `setfield` to simplify references to structure arrays with nested fields, as shown in the Examples section.

- "Generate Field Names from Variables"
- "Access Data in a Structure Array"

Introduced before R2006a

setpixelposition

Set component position in pixels

Syntax

```
setpixelposition(handle,position)
setpixelposition(handle,position,recursive)
```

Description

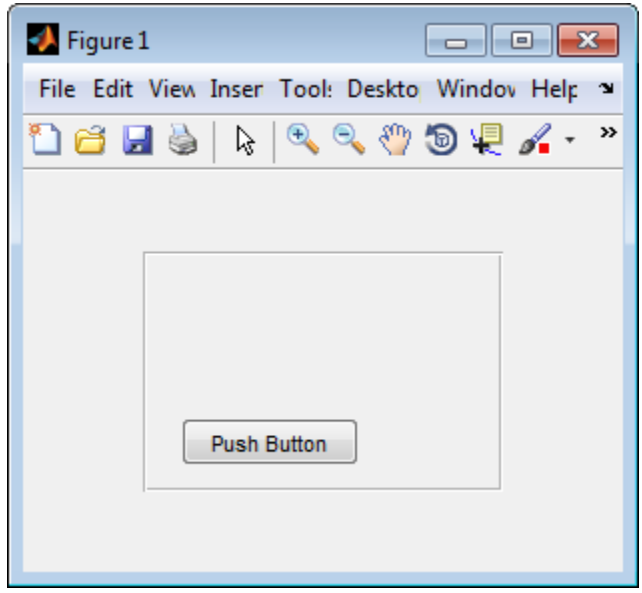
`setpixelposition(handle,position)` sets the position of the component specified by `handle`, to the specified position relative to its parent. `position` is a four-element vector that specifies the location and size of the component: [pixels from left, pixels from bottom, pixels across, pixels high].

`setpixelposition(handle,position,recursive)` sets the position as above. If Boolean `recursive` is true, the position is set relative to the parent figure of `handle`.

Examples

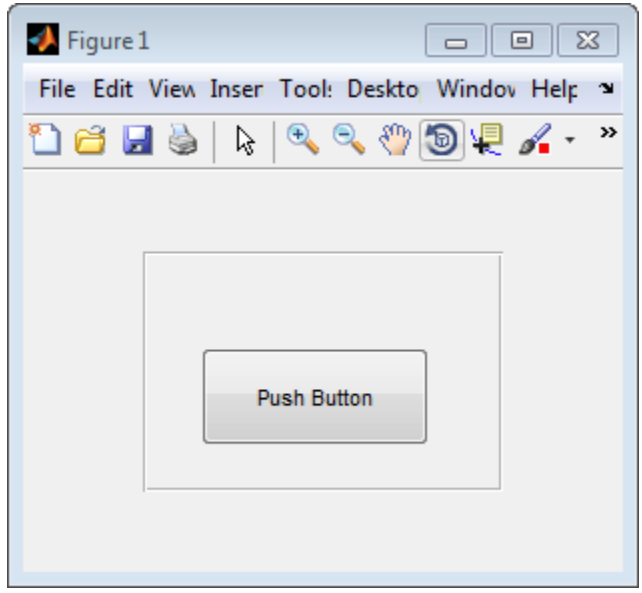
This example first creates a push button within a panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton',...
               'Units','normalized',...
               'String','Push Button',...
               'Position',[.1 .1 .5 .2]);
```



The example then retrieves the position of the push button and changes its position with respect to the panel.

```
pos1 = getpixelposition(h1);
setpixelposition(h1,pos1 + [10 10 25 25]);
```



See Also

`getpixelposition` | `uicontrol` | `uipanel`

setpref

Set preference

Syntax

```
setpref('group','pref',val)
setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})
```

Description

`setpref('group','pref',val)` sets the preference specified by `group` and `pref` to the value `val`. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects. Setting a preference that does not yet exist causes it to be created.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g., `'MathWorks_GUIDE_ApplicationPrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})` sets each preference specified in the cell array of names to the corresponding value.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Use `addpref` to create a preference group called `mytoolbox` and a preference within it called `version`, and then modify the contents of `version` using `setpref`:

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')

ans =
```

```
1.0

setpref('mytoolbox','version',{'1.0','beta'})
getpref('mytoolbox','version')

ans =
    '1.0'    'beta'
```

See Also

addpref | ispref | rmpref | getpref | uigetpref | uisetpref

Introduced before R2006a

setstr

Set string flag

Note: `setstr` is not recommended. Use `char` instead.

Description

This MATLAB 4 function has been renamed `char` in MATLAB 5.

Introduced before R2006a

setSubDirectory

Class: Tiff

Make subIFD specified by byte offset current IFD

Syntax

```
setSubDirectory(tiffobj,offset)
```

Description

`setSubDirectory(tiffobj,offset)` sets the subimage file directory (subIFD) specified by `offset` the current IFD. The offset value is given in bytes. Use this method when you want to access subIFDs linked through the `SubIFD` tag.

Examples

Set Subimage File Directory

Open a TIFF file and read the value of the `SubIFD` tag in the current IFD. The `SubIFD` tag contains byte offsets that specify the location of subIFDs in the IFD. The TIFF file should contain subIFDs.

```
t = Tiff('example.tif','r');
```

Read the value of the SubIFD tag to get subdirectory offsets.

```
offsets = getTag(t,'SubIFD');
```

Set one of the subdirectories (if more than one) as the current directory.

```
setSubDirectory(t,offsets(1))
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

References

This method corresponds to the `TIFFSetSubDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

See Also

`Tiff.setDirectory`

setTag

Class: Tiff

Set value of tag

Syntax

```
setTag(tiffobj,tagId,tagValue)
setTag(tiffobj,tagStruct)
```

Description

`setTag(tiffobj,tagId,tagValue)` sets the value of the TIFF tag specified by `tagId` to the value specified by `tagValue`. You can specify `tagId` as a character string (`'ImageWidth'`) or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

`setTag(tiffobj,tagStruct)` sets the values of all of the tags with name/value fields in `tagStruct`. The names of fields in `tagstruct` must be the name of TIFF tags.

Note: If you are modifying a tag rather than creating it, you must use the `Tiff.rewriteDirectory` method after using the `Tiff.setTag` method.

Examples

Set Tag Values

Write TIFF tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a `Tiff` object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');
```

```
t = Tiff('myfile.tif','w');
```

Set tag values by specifying the numeric tag identifier. Use the `TagID` property to obtain the tag identifier.

```
setTag(t,Tiff.TagID.ImageLength,size(imdata,1))
setTag(t,Tiff.TagID.ImageWidth,size(imdata,2))
```

Set tag values by specifying the tag name.

```
setTag(t,'Photometric', Tiff.Photometric.RGB)
setTag(t,'PlanarConfiguration', Tiff.PlanarConfiguration.Chunky)
```

Create a structure with fields named after TIFF tags and assign values to the fields. Pass this structure to the `setTag` method to set the values of these tags.

```
tagStruct.BitsPerSample = 8;
tagStruct.SamplesPerPixel = 3;
tagStruct.TileWidth = 128;
tagStruct.TileLength = 128;
tagStruct.Compression = Tiff.Compression.JPEG;
tagStruct.Software = 'MATLAB';
setTag(t,tagStruct)
```

Write the image data to the TIFF file.

```
write(t,imdata)
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

References

This method corresponds to the `TIFFSetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

See Also

`Tiff.getTag`

settimeseriesnames

Change name of `timeseries` object in `tscollection`

Syntax

```
tsc = settimeseriesnames(tsc,old,new)
```

Description

`tsc = settimeseriesnames(tsc,old,new)` replaces the `old` name of `timeseries` object with the new name in tsc.

See Also

`tscollection`

Introduced before R2006a

setxor

Set exclusive OR of two arrays

Syntax

```
C = setxor(A,B)
C = setxor(A,B,'rows')
[C,ia,ib] = setxor(A,B)
[C,ia,ib] = setxor(A,B,'rows')

[C,ia,ib] = setxor( ___ ,setOrder)

[C,ia,ib] = setxor(A,B,'legacy')
[C,ia,ib] = setxor(A,B,'rows','legacy')
```

Description

`C = setxor(A,B)` returns the data of `A` and `B` that are not in their intersection (the symmetric difference).

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `setxor` returns the values that occur in `A` or `B`, but not both. The values of `C` are in sorted order.
- If `A` and `B` are tables, then `setxor` returns the rows that occur in one or the other of the two tables, but not both. The rows of table `C` are in sorted order.

`C = setxor(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the rows of matrices `A` and `B` that are not in their intersection. The rows of `C` are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia,ib] = setxor(A,B)` also returns index vectors `ia` and `ib`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `C` is a sorted combination of the elements `A(ia)` and `B(ib)`.

- If A and B are tables, then C is a sorted combination of the rows of A(ia,:) and B(ib,:).

[C,ia,ib] = setxor(A,B,'rows') also returns index vectors ia and ib, such that C is a sorted combination of the rows of A(ia,:) and B(ib,:).

[C,ia,ib] = setxor(___ ,setOrder) returns C in a specific order using any of the input arguments in the previous syntaxes. setOrder='sorted' returns the values (or rows) of C in sorted order. setOrder='stable' returns the values (or rows) of C in the same order as A and B. If no value is specified, the default is 'sorted'.

[C,ia,ib] = setxor(A,B,'legacy') and [C,ia,ib] = setxor(A,B,'rows','legacy') preserve the behavior of the setxor function from R2012b and prior releases.

The 'legacy' option does not support categorical arrays, tables, datetime arrays, or duration arrays.

Examples

Symmetric Difference of Two Vectors

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of A and B that are not in their intersection.

```
C = setxor(A,B)
```

```
C =

     2     3     4     5
```

Symmetric Difference of Two Tables

Define two tables with rows in common.

```
A = table([1:5]',['A';'B';'C';'D';'E'],logical([0;1;0;1;0]))
B = table([1:2:10]',['A';'C';'E';'G';'I'],logical(zeros(5,1)))
```

```
A =
```

```
    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    2       B       true
    3       C       false
    4       D       true
    5       E       false

B =

    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    3       C       false
    5       E       false
    7       G       false
    9       I       false
```

Find the rows of `A` and `B` that are not in their intersection.

```
C = setxor(A,B)
```

```
C =

    Var1    Var2    Var3
    ----    ----    -----
    2       B       true
    4       D       true
    7       G       false
    9       I       false
```

Symmetric Difference of Two Vectors and Indices to Different Values

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of `A` and `B` that are not in their intersection as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B)
```

```
C =
```

```
     2     3     4     5

ia =

     3
     1

ib =

     3
     1
```

`C` is a sorted combination of the elements `A(ia)` and `B(ib)`.

Symmetric Difference of Two Tables and Indices to Different Rows

Define a table, `A`, of gender, age, and height for five people.

```
A = table(['M';'M';'F'],[27;52;31],[74;68;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty'})
```

```
A =

              Gender    Age    Height
              ------    ---    ------
    Ted       M         27     74
    Fred      M         52     68
    Betty     F         31     64
```

Define a table, `B`, with the same variables as `A`.

```
B = table(['F';'M'],[64;68],[31;47],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe'})
```

```
B =

            Gender    Height    Age
            ------    ------    ---
    Meg     F         64        31
    Joe     M         68        47
```

Find the rows of A and B that are not in their intersection, as well as the index vectors ia and ib.

```
[C,ia,ib] = setxor(A,B)
```

```
C =

            Gender    Age    Height
            ------    ---    ------
    Ted     M         27     74
    Joe     M         47     68
    Fred    M         52     68

ia =

     1
     2

ib =

     2
```

C is a sorted combination of the elements A(ia,:) and B(ib,:).

Symmetric Difference of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 8 9; 7 7 1; 7 7 1; 1 2 3; 4 5 6];
B = [1 2 3; 4 5 6; 7 7 2];
```

Find the rows of A and B that are not in their intersection as well as the index vectors ia and ib.

```
[C,ia,ib] = setxor(A,B,'rows')
```

```
C =

     7     7     1
     7     7     2
     7     8     9
```

```
ia =

     2
     1

ib =

     3
```

`C` is a sorted combination of the rows of `A(ia,:)` and `B(ib,:)`.

Symmetric Difference of Two Vectors in Specified Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` if you want the values in `C` to have the same order as `A` and `B`.

```
A = [5 1 3 3 3]; B = [4 1 2];
[C,ia,ib] = setxor(A,B,'stable')
```

```
C =

     5     3     4     2

ia =

     1
     3

ib =

     1
     3
```

Alternatively, you can specify `'sorted'` order.

```
[C,ia,ib] = setxor(A,B,'sorted')
```

```
C =

     2     3     4     5
```

```
ia =

     3
     1

ib =

     3
     1
```

Symmetric Difference of Vectors Containing NaNs

Define two vectors containing `NaN`.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the symmetric difference of vectors `A` and `B`.

```
C = setxor(A,B)
```

```
C =

   NaN   NaN   NaN   NaN
```

The `setxor` function treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, `A`.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, `B`, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings that are not in the intersection of `A` and `B`.

```
[C,ia,ib] = setxor(A,B)
```

```
C =

    'dog'    'dog '    'fish'    'fish '
```

```
ia =

     1
     3

ib =

     1
     3
```

`setxor` treats trailing white space in cell arrays of strings as distinct characters.

Symmetric Difference of Vectors of Different Classes and Shapes

Create a column vector character array.

```
A = ['A';'B';'C'], class(A)
```

```
A =

A
B
C

ans =

char
```

Create a row vector containing elements of numeric type `double`.

```
B = [66 67 68], class(B)
```

```
B =

    66    67    68

ans =

double
```

Find the symmetric difference of `A` and `B`.

```
C = setxor(A,B)

C =

A
D
```

The result is a column vector character array.

```
class(C)

ans =

char
```

Symmetric Difference of Char and Cell Array of Strings

Create a character array, A.

```
A = ['cat';'dog';'fox';'pig'];
class(A)

ans =

char
```

Create a cell array of strings, B.

```
B={'dog','cat','fish','horse'};
class(B)

ans =

cell
```

Find the strings that are not in the intersection of A and B.

```
C = setxor(A,B)

C =

    'fish'
    'fox'
    'horse'
    'pig'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =

cell
```

Preserve Legacy Behavior of setxor

Use the 'legacy' flag to preserve the behavior of setxor from R2012b and prior releases in your code.

Find the symmetric difference of A and B with the current behavior.

```
A = [5 1 3 3 3]; B = [4 1 2 2];
[C1,ia1,ib1] = setxor(A,B)
```

```
C1 =

     2     3     4     5

ia1 =

     3
     1

ib1 =

     3
     1
```

Find the symmetric difference and preserve the legacy behavior.

```
[C2,ia2,ib2] = setxor(A,B,'legacy')
```

```
C2 =

     2     3     4     5

ia2 =
```

```
     5     1

ib2 =

     4     1
```

Input Arguments

A,B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays | duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

`A` and `B` must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of `C` are the sorted union of the categories from `A` and `B`.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

If `A` and `B` are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If `A` and `B` are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, `A` and `B` can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)

- `eq`
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

`setOrder` — Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in `C`.

Order Flag	Meaning
`'sorted'`	The values (or rows) in `C` return in sorted order. For example: `C = setxor([5 1 3],[4 1 2],'sorted')` returns `C = [2 3 4 5]`.
`'stable'`	The values (or rows) in `C` return in the same order as in `A` and `B`. For example: `C = setxor([5 1 3],[4 1 2],'stable')` returns `C = [5 3 4 2]`.

Output Arguments

`C` — Symmetric difference array

vector | matrix | table

Symmetric difference array, returned as a vector, matrix, or table. If the inputs `A` and `B` are tables, the order of the variables in the resulting table, `C`, is the same as the order of the variables in `A`.

The following describes the shape of `C` when the inputs are vector or matrices and when the `'legacy'` flag is not specified:

- If the `'rows'` flag is not specified, then C is a column vector unless both `A` and `B` are row vectors.
- If the `'rows'` flag is not specified and both `A` and `B` are row vectors, then `C` is a row vector.
- If the`'rows'` flag is specified, then `C` is a matrix containing the rows of `A` and `B` that are not in the intersection.

- If all the values (or rows) of A are also in B, then C is an empty matrix.

The class of the inputs A and B determines the class of C:

- If the class of A and B are the same, then C is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then C is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then C is `double`.
- If you combine a cell array of strings with `char`, then C is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then C is a categorical array.
- If you combine a datetime array with a cell array of date strings or single date string, then C is a datetime array.

`ia` — Index to A

column vector

Index to A, returned as a column vector when the `'legacy'` flag is not specified. `ia` identifies the values (or rows) in A that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in A, then `ia` contains the index to the first occurrence of the value (or row).

`ib` — Index to B

column vector

Index to B, returned as a column vector when the `'legacy'` flag is not specified. `ib` identifies the values (or rows) in B that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in B, then `ib` contains the index to the first occurrence of the value (or row).

More About

Tips

- To find the symmetric difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `setxor(A(:,`*`vars`*`),B(:,`*`vars`*`))`, where *`vars`* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

Introduced before R2006a

shading

Set color shading properties

Syntax

```
shading flat
shading faceted
shading interp
shading(axes_handle,...)
```

Description

The `shading` function controls the color shading of surface and patch graphics objects.

`shading flat` each mesh line segment and face has a constant color determined by the color value at the endpoint of the segment or the corner of the face that has the smallest index or indices.

`shading faceted` flat shading with superimposed black mesh lines. This is the default shading mode.

`shading interp` varies the color in each line segment and face by interpolating the colormap index or true color value across the line or face.

`shading(axes_handle,...)` applies the shading type to the objects in the axes specified by `axes_handle`, instead of the current axes. Use quoted strings when using a function form. For example:

```
shading(gca,'interp')
```

Examples

Display Sphere with Different Types of Shading

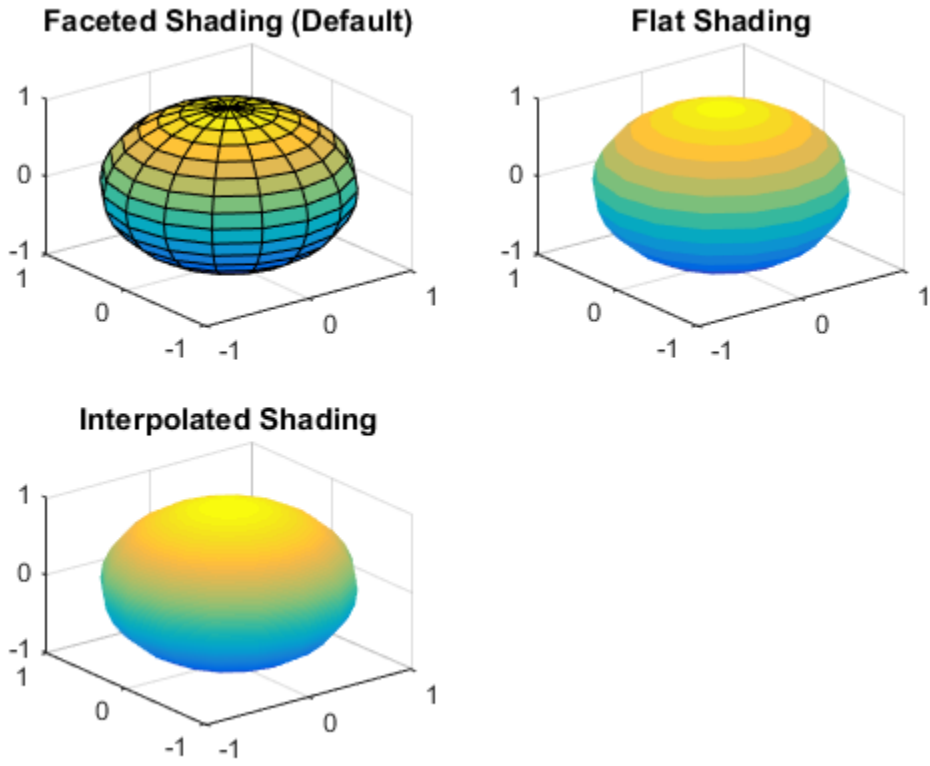
Plot the `sphere` function and use different types of shading.

```
figure
subplot(2,2,1)
```

```
sphere(16)
title('Faceted Shading (Default)')

subplot(2,2,2)
sphere(16)
shading flat
title('Flat Shading')

subplot(2,2,3)
sphere(16)
shading interp
title('Interpolated Shading')
```



More About

Algorithms

`shading` sets the `EdgeColor` and `FaceColor` properties of all surface and patch graphics objects in the current axes. `shading` sets the appropriate values, depending on whether the surface or patch objects represent meshes or solid surfaces.

Introduced before R2006a

shg

Show most recent graph window

Syntax

```
shg
```

Description

`shg` makes the current figure visible and raises it above all other figures on the screen. This is identical to using the command `figure(gcf)`.

See Also

`figure` | `gca` | `gcf`

shiftdim

Shift dimensions

Syntax

```
B = shiftdim(X,n)
[B,nshifts] = shiftdim(X)
```

Description

`B = shiftdim(X,n)` shifts the dimensions of `X` by `n`. When `n` is positive, `shiftdim` shifts the dimensions to the left and wraps the `n` leading dimensions to the end. When `n` is negative, `shiftdim` shifts the dimensions to the right and pads with singletons.

`[B,nshifts] = shiftdim(X)` returns the array `B` with the same number of elements as `X` but with any leading singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. `nshifts` is the number of dimensions that are removed.

If `X` is a scalar, `shiftdim` has no effect.

Examples

The `shiftdim` command is handy for creating functions that, like `sum` or `diff`, work along the first nonsingleton dimension.

```
a = rand(1,1,3,1,2);
[b,n]  = shiftdim(a); % b is 3-by-1-by-2 and n is 2.
c = shiftdim(b,-n);   % c == a.
d = shiftdim(a,3);    % d is 1-by-2-by-1-by-1-by-3.
```

`circshift` | `reshape` | `squeeze` | `permute` | `ipermute`

Introduced before R2006a

showplottool

Show or hide figure plot tool

Syntax

```
showplottool('tool')
showplottool('on','tool')
showplottool('off','tool')
showplottool('toggle','tool')
showplottool(figure_handle,...)
```

Description

`showplottool('tool')` shows the specified plot tool on the current figure. *`tool`* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

`showplottool('on','tool')` shows the specified plot tool on the current figure.

`showplottool('off','tool')` hides the specified plot tool on the current figure.

`showplottool('toggle','tool')` toggles the visibility of the specified plot tool on the current figure.

`showplottool(figure_handle,...)` operates on the specified figure instead of the current figure.

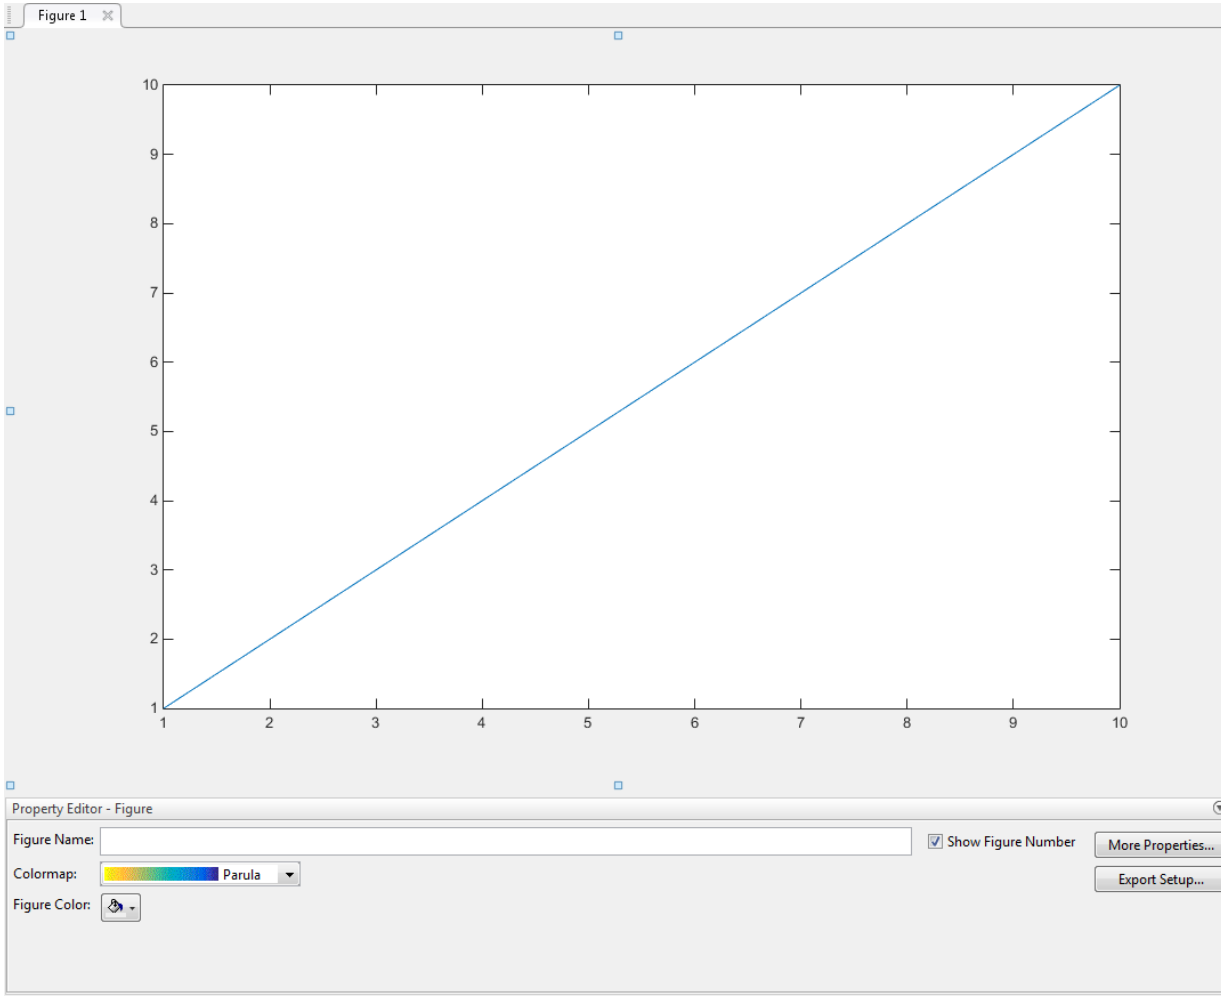
Note: When you dock, undock, resize, or reposition a plotting tool and then close it, it will still be configured as you left it the next time you open it. There is no command to reset plotting tools to their original, default locations.

Examples

Open One of the Plot Tools

Create a simple plot and open the property editor.

```
plot(1:10);
showplottool('propertyeditor')
```



Alternatives

Click the larger Plotting Tools icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select

the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Customize Graph Using Plot Tools”.

`figurepalette` | `plotbrowser` | `plottools` | `propertyeditor`

Introduced before R2006a

shrinkfaces

Reduce size of patch faces

Syntax

```
shrinkfaces(p,sf)
nfv = shrinkfaces(p,sf)
nfv = shrinkfaces(fv,sf)
shrinkfaces(p)
nfv = shrinkfaces(f,v,sf)
[nf,nv] = shrinkfaces(...)
```

Description

`shrinkfaces(p,sf)` shrinks the area of the faces in patch `p` to shrink factor `sf`. A shrink factor of 0.6 shrinks each face to 60% of its original area. If the patch contains shared vertices, the MATLAB software creates nonshared vertices before performing the face-area reduction.

`nfv = shrinkfaces(p,sf)` returns the face and vertex data in the struct `nfv`, but does not set the `Faces` and `Vertices` properties of patch `p`.

`nfv = shrinkfaces(fv,sf)` uses the face and vertex data from the struct `fv`.

`shrinkfaces(p)` and `shrinkfaces(fv)` (without specifying a shrink factor) assume a shrink factor of 0.3.

`nfv = shrinkfaces(f,v,sf)` uses the face and vertex data from the arrays `f` and `v`.

`[nf,nv] = shrinkfaces(...)` returns the face and vertex data in two separate arrays instead of a struct.

Examples

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). Two isosurfaces provide a before and after view of the effects of shrinking the face size.

- First `reducevolume` samples the flow data at every other point and then `isosurface` generates the faces and vertices data.
- The `patch` command accepts the face/vertex struct and draws the first (`p1`) isosurface.
- Use the `daspect`, `view`, and `axis` commands to set up the view and then add a `title`.
- The `shrinkfaces` command modifies the face/vertex data and passes it directly to `patch`.

```
[x,y,z,v] = flow;
[x,y,z,v] = reducevolume(x,y,z,v,2);
fv = isosurface(x,y,z,v,-3);
p1 = patch(fv);
p1.FaceColor = 'red';
p1.EdgeColor = [0.5 0.5 0.5];
daspect([1 1 1]);
view(3);
axis tight
title('Original')

figure
p2 = patch(shrinkfaces(fv,.3));
p2.FaceColor = 'red';
p2.EdgeColor = [0.5 0.5 0.5];
daspect([1 1 1]);
view(3);
axis tight
title('After Shrinking')
```

Introduced before R2006a

sign

Signum function

Syntax

```
Y = sign(X)
```

Description

`Y = sign(X)` returns an array `Y` the same size as `X`, where each element of `Y` is:

- `1` if the corresponding element of `X` is greater than zero
- `0` if the corresponding element of `X` equals zero
- `-1` if the corresponding element of `X` is less than zero

For nonzero complex `X`, `sign(X) = X./abs(X)`.

See Also

`abs` | `conj` | `imag` | `real`

Introduced before R2006a

sin

Sine of argument in radians

Syntax

```
Y = sin(X)
```

Description

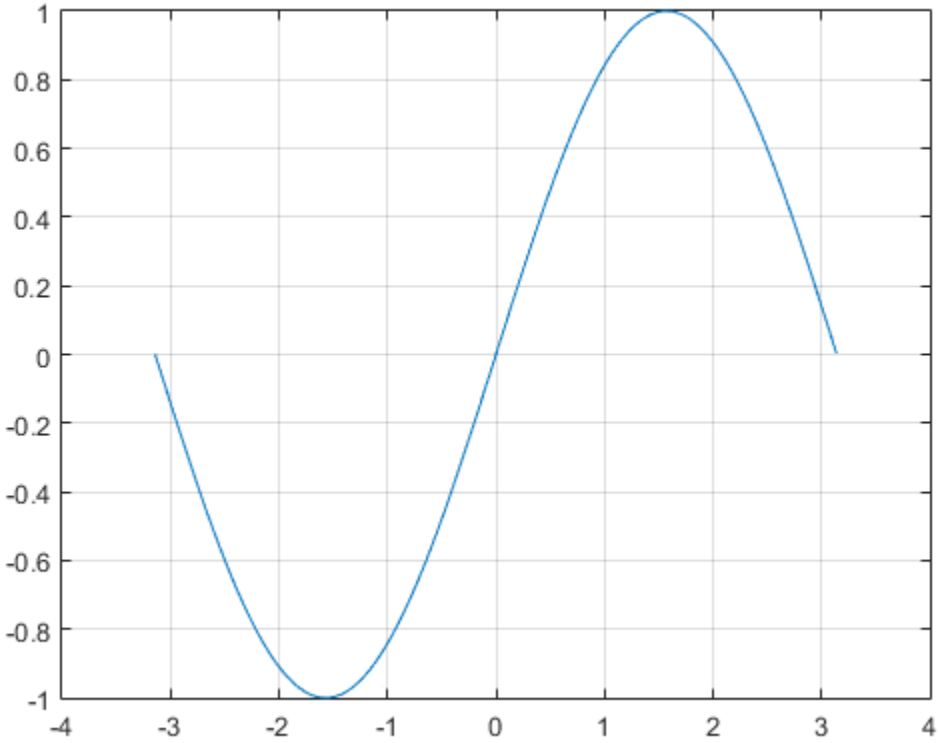
`Y = sin(X)` returns the sine of the elements of `X`. The `sin` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of X in the interval [-Inf, Inf], `sin` returns real values in the interval [-1 ,1]. For complex values of X, `sin` returns complex values. All angles are in radians.

Examples

Plot Sine Function

Plot the sine function over the domain $-\pi \le x \le \pi$.

```
x = -pi:0.01:pi;
plot(x,sin(x)), grid on
```



Sine of Vector of Complex Angles

Calculate the sine of the complex angles in vector `x`.

```
x = [-i pi+i*pi/2 -1+i*4];
y = sin(x)
```

```
y =

   0.0000 - 1.1752i   0.0000 - 2.3013i -22.9791 +14.7448i
```

Input Arguments

X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Sine of input angle

scalar value | vector | matrix | N-D array

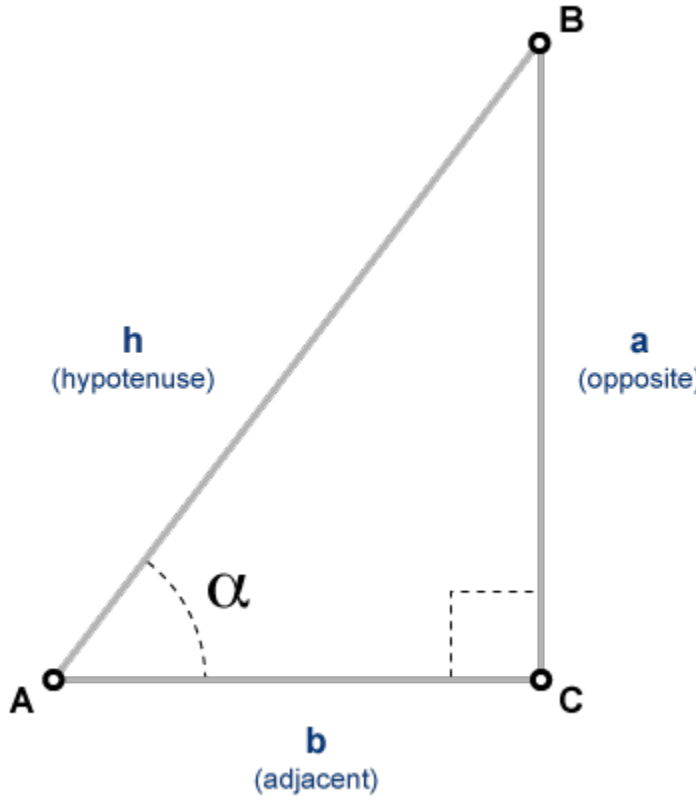
Sine of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

More About

Sine Function

The sine of an angle, α, defined with reference to a right angled triangle is

$$\sin(\alpha) = \frac{\text{opposite side}}{\text{hypotenuse}} = \frac{a}{h}.$$



The sine of a complex angle, α, is

$$\sin(\alpha) = \frac{e^{i\alpha} - e^{-i\alpha}}{2i}.$$

See Also

`asin` | `asind` | `sind` | `sinh`

Introduced before R2006a

sind

Sine of argument in degrees

Syntax

```
Y = sind(X)
```

Description

`Y = sind(X)` returns the sine of the elements in `X`, which are expressed in degrees.

Examples

Sine of 180 degrees compared to sine of π radians

```
sind(180)
```

```
ans =

     0
```

```
sin(pi)
```

```
ans =

   1.2246e-16
```

Sine of vector of complex angles, specified in degrees

```
z = [90+i 15+2i 10+3i];
y = sind(z)
```

```
y =
```

```
   1.0002        0.2590 + 0.0337i   0.1739 + 0.0516i
```

Input Arguments

X — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `sind` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Sine of angle

scalar value | vector | matrix | N-D array

Sine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

See Also

`asin` | `asind` | `sin`

Introduced before R2006a

single

Convert to single precision

Syntax

```
B = single(A)
```

Description

`B = single(A)` converts the matrix `A` to single precision, returning that value in `B`. `A` can be any numeric object (such as a `double`). If `A` is already single precision, `single` has no effect. Single-precision quantities require less storage than double-precision quantities, but have less precision and a smaller range.

The `single` class is primarily meant to be used to store single-precision values. Hence most operations that manipulate arrays without changing their elements are defined. Examples are `reshape`, `size`, the relational operators, subscripted assignment, and subscripted reference.

You can define your own methods for the `single` class by placing the appropriately named method in an `@single` folder within a folder on your path.

Examples

```
a = magic(4);
b = single(a);

whos
  Name      Size         Bytes  Class

  a         4x4            128  double array
  b         4x4             64  single array
```

Introduced before R2006a

sinh

Hyperbolic sine of argument in radians

Syntax

```
Y = sinh(X)
```

Description

The `sinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

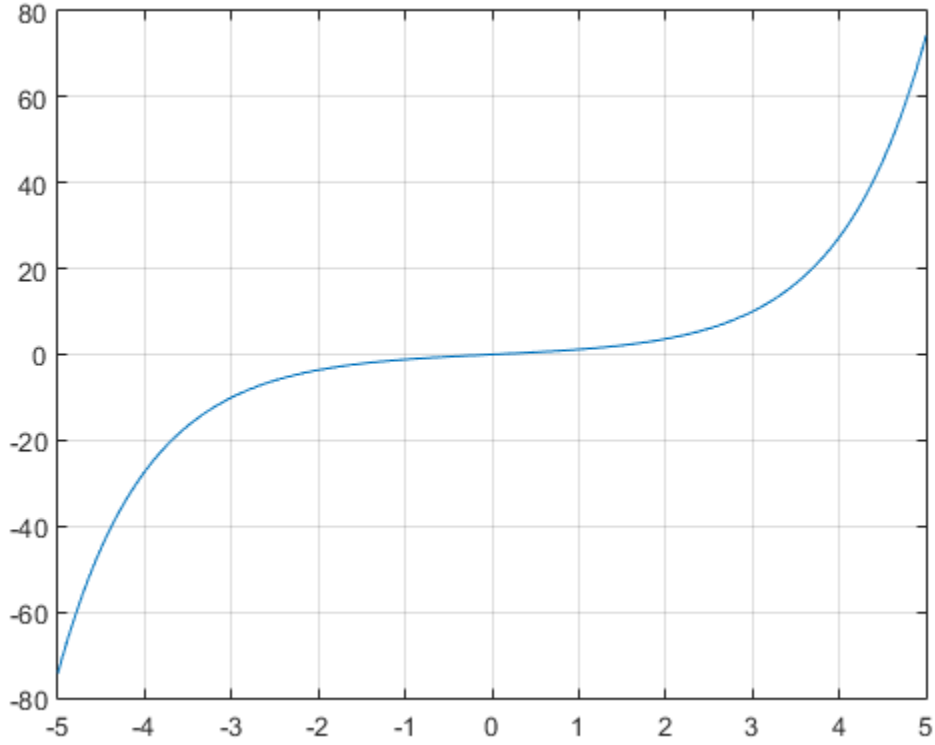
`Y = sinh(X)` returns the hyperbolic sine of the elements of `X`.

Examples

Graph of Hyperbolic Sine Function

Graph the hyperbolic sine over the domain $-5 \le x \le 5$.

```
x = -5:0.01:5;
plot(x,sinh(x)), grid on
```



More About

Hyperbolic Sine

The hyperbolic sine of z is

$$\sinh(z) = \frac{e^z - e^{-z}}{2}.$$

See Also

`sin` | `asinh` | `cosh`

Introduced before R2006a

size

Array dimensions

Syntax

```
d = size(X)
[m,n] = size(X)
m = size(X,dim)
[d1,d2,d3,...,dn] = size(X),
```

Description

`d = size(X)` returns the sizes of each dimension of array `X` in a vector, `d`, with `ndims(X)` elements.

- If `X` is a scalar, then `size(X)` returns the vector `[1 1]`. Scalars are regarded as a 1-by-1 arrays in MATLAB.
- If `X` is a table, `size(X)` returns a two-element row vector consisting of the number of rows and the number of variables in the table. Variables in the table can have multiple columns, but `size` only counts the variables and rows.

`[m,n] = size(X)` returns the size of matrix `X` in separate variables `m` and `n`.

`m = size(X,dim)` returns the size of the dimension of `X` specified by scalar `dim`.

`[d1,d2,d3,...,dn] = size(X),` for `n` > 1, returns the sizes of the dimensions of the array `X` in the variables d1,d2,d3,...,dn, provided the number of output arguments `n` equals `ndims(X)`. If `n` does not equal `ndims(X)`, the following exceptions hold:

`n < ndims(X)`	`di` equals the size of the `i`th dimension of `X` for `0<i<n`, but `dn` equals the product of the sizes of the remaining dimensions of `X`, that is, dimensions `n` through `ndims(X)`.
`n > ndims(X)`	`size` returns ones in the "extra" variables, that is, those corresponding to `ndims(X)+1` through `n`.

Note For a Java array, `size` returns the length of the Java array as the number of rows. The number of columns is always 1. For a Java array of arrays, the result describes only the top level array.

Examples

Size of Dimensions in 3-D Array

Find the size of `rand(2,3,4)`.

```
d = size(rand(2,3,4))
```

```
d =

     2     3     4
```

The size is output as a single vector.

Find the size of the second dimension of `rand(2,3,4)`.

```
m = size(rand(2,3,4),2)
```

```
m =

     3
```

The size is output as a scalar.

Assign the size of each dimension to a separate variable.

```
[m,n,p] = size(rand(2,3,4))
```

```
m =

     2

n =

     3

p =
```

```
     4
```

Size of Table

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

X = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
X =

               Age    Height    Weight     BloodPressure
               ---    ------    ------    ---------------
    Smith      38     71        176       124          93
    Johnson    43     69        163       109          77
    Williams   38     64        131       125          83
    Jones      40     67        133       117          75
    Brown      49     64        119       122          80
```

Find the size of the table.

```
d = size(X)
```

```
d =

     5     4
```

`size` counts four variables, even though the variable `BloodPressure` contains two columns.

Specify Different Number of Outputs than `ndims(X)`

Assign the size of each dimension to a separate variable where the number of outputs matches the number of dimensions.

```
X = ones(3,4,5);
[d1,d2,d3] = size(X)
```

```
d1 =
```

```
     3

d2 =

     4

d3 =

     5
```

There is one output for each dimension of `X`.

Specify fewer output variables than `ndims(X)`.

```
[d1,d2] = size(X)
d1 =

     3

d2 =

    20
```

The “extra” dimensions are collapsed into a single product.

Specify more output variables than `ndims(X)`.

```
[d1,d2,d3,d4,d5,d6] = size(X)
d1 =

     3

d2 =

     4

d3 =
```

```
     5

d4 =

     1

d5 =

     1

d6 =

     1
```

The “extra” variables all represent singleton dimensions.

`exist` | `length` | `ndims` | `numel` | `whos`

Introduced before R2006a

size

Class: containers.Map
Package: containers

Size of `containers.Map` object

Syntax

```
dim = size(mapObj,1)
dimVector = size(mapObj)
[dim1,dim2,...,dimN] = size(mapObj)
```

Description

`dim = size(mapObj,1)` returns a scalar numeric value that indicates the number of key-value pairs in `mapObj`. If you call `size` with a numeric second input argument other than `1`, the `size` method returns the scalar numeric value `1`.

`dimVector = size(mapObj)` returns a two-element vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

`[dim1,dim2,...,dimN] = size(mapObj)` returns `[k,1,...,1]`.

Input Arguments

`mapObj`

Object of class `containers.Map`.

Output Arguments

`dim`

Scalar numeric value that indicates the number of key-value pairs in `mapObj`.

`dimVector`

Two-element numeric vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

`[dim1,dim2,...,dimN]`

Numeric scalar values. Variable `dim1` equals `k`, where `k` is the number of key-value pairs in `mapObj`. All other outputs equal `1`.

Examples

Determine the Size of a Map

Construct a map and find the number of key-value pairs:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);
dim = size(mapObj,1)
```

This code returns a scalar numeric value:

```
dim =
     3
```

If you do not specify a second input argument,

```
dimVector = size(mapObj)
```

then the `size` method returns a vector:

```
dimVector =
     3     1
```

See Also

`isKey` | `keys` | `values` | `containers.Map` | `length`

size

Class: matlab.io.MatFile
Package: matlab.io

Array dimensions

Syntax

```
allDims = size(matObj,variable)
[dim1,...,dimN] = size(matObj,variable)
selectedDim = size(matObj,variable,dim)
```

Description

`allDims = size(matObj,variable)` returns the size of each dimension of the specified variable in the file corresponding to `matObj`. Output `allDims` is a `1`-by-`m` vector, where `m = ndims(variable)`.

`[dim1,...,dimN] = size(matObj,variable)` returns the sizes of each dimension in separate output variables `dim1,...,dimN`.

`selectedDim = size(matObj,variable,dim)` returns the size of the specified dimension.

Tips

- Do not call `size` with the syntax `size(matObj.variable)`. This syntax loads the entire contents of the variable into memory. For very large variables, this load operation results in `Out of Memory` errors.

Input Arguments

`matObj`

Object created by the `matfile` function.

`variable`

String enclosed in single quotation marks that specifies the name of a variable in the MAT-file corresponding to `matObj`.

`dim`

Nonzero positive scalar integer that specifies a dimension of the variable.

Output Arguments

`allDims`

1-by-`m` vector of sizes of the dimensions of the specified variable, where `m = ndims(variable)`.

`dim1,...,dimN`

Scalar numeric values, where `dimK` contains the size of the `K`th dimension of `variable`:

- If `N < ndims(variable)`, then `dimN`, equals the product of the sizes of dimensions `N` through `ndims(variable)`.
- If `N > ndims(variable)`, the `size` method returns ones in the output variables corresponding to dimensions `ndims(variable)+1` through `N`.

`selectedDim`

Scalar numeric value that contains the size of the selected dimension for the specified variable.

Examples

Find the size of the matrix `topo` in `topography.mat` without loading any data:

```
matObj = matfile('topography.mat');
[nrows,ncols] = size(matObj,'topo');
```

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
    avgs(idx) = mean(matObj.stocks(:,idx));
end
```

Create a three-dimensional array, and call the `size` method with different numbers of output arguments:

```
matObj = matfile('temp.mat','Writable',true);
matObj.X = rand(2,3,4);

d = size(matObj,'X')
d2 = size(matObj,'X',2)
[m,n] = size(matObj,'X')
[m1,m2,m3,m4] = size(matObj,'X')
```

This code returns

```
d =
     2     3     4

d2 =
     3

m =
     2
n =
    12

m1 =
     2
m2 =
     3
m3 =
     4
m4 =
     1
```

See Also

`whos` | `matfile`

size (serial)

Size of serial port object array

Syntax

```
d = size(obj)
[m,n] = size(obj)
[m1,m2,m3,...,mn] = size(obj)
m = size(obj,dim)
```

Description

`d = size(obj)` returns the two-element row vector `d` containing the number of rows and columns in the serial port object, `obj`.

`[m,n] = size(obj)` returns the number of rows, `m` and columns, `n` in separate output variables.

`[m1,m2,m3,...,mn] = size(obj)` returns the length of the first `n` dimensions of `obj`.

`m = size(obj,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(obj,1)` returns the number of rows.

See Also

`length`

Introduced before R2006a

size

Class: TriRep

(Will be removed) Size of triangulation matrix

Note: `size(TriRep)` will be removed in a future release. Use `size(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
size(TR)
```

Description

`size(TR)` provides size information for a triangulation matrix. The matrix is of size `mtri`-by-`nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex (triangle/tetrahedron, etc).

Input Arguments

`TR`	Triangulation matrix

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

See Also

`size` | `triangulation` | `delaunayTriangulation`

size (tscollection)

Size of `tscollection` object

Syntax

```
size(tsc)
```

Description

`size(tsc)` returns `[n m]`, where `n` is the length of the time vector and `m` is the number of `tscollection` members.

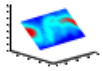
See Also

`length (tscollection)` | `isempty (tscollection)` | `tscollection`

Introduced before R2006a

slice

Volumetric slice plot



Syntax

```
slice(V,sx,sy,sz)
slice(X,Y,Z,V,sx,sy,sz)
slice(V,XI,YI,ZI)
slice(X,Y,Z,V,XI,YI,ZI)
slice(...,'method')
slice(axes_handle,...)
h = slice(...)
```

Description

`slice` displays orthogonal slice planes through volumetric data.

`slice(V,sx,sy,sz)` draws slices along the *x*, *y*, *z* directions in the volume `V` at the points in the vectors `sx`, `sy`, and `sz`. `V` is an *m*-by-*n*-by-*p* volume array containing data values at the default location `X = 1:n`, `Y = 1:m`, `Z = 1:p`. Each element in the vectors `sx`, `sy`, and `sz` defines a slice plane in the *x*-, *y*-, or *z*-axis direction.

`slice(X,Y,Z,V,sx,sy,sz)` draws slices of the volume `V`. `X`, `Y`, and `Z` are three-dimensional arrays specifying the coordinates for `V`. `X`, `Y`, and `Z` must be monotonic and orthogonally spaced (as if produced by the function `meshgrid`). The color at each point is determined by 3-D interpolation into the volume `V`.

`slice(V,XI,YI,ZI)` draws data in the volume `V` for the slices defined by `XI`, `YI`, and `ZI`. `XI`, `YI`, and `ZI` are matrices that define a surface, and the volume is evaluated at the surface points. `XI`, `YI`, and `ZI` must all be the same size.

`slice(X,Y,Z,V,XI,YI,ZI)` draws slices through the volume `V` along the surface defined by the arrays `XI`, `YI`, `ZI`.

`slice(...,'method')` specifies the interpolation method. `'method'` is `'linear'`, `'cubic'`, or `'nearest'`.

- `linear` specifies trilinear interpolation (the default).
- `cubic` specifies tricubic interpolation.
- `nearest` specifies nearest-neighbor interpolation.

`slice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes object (`gca`). The axes `clim` property is set to span the finite values of `V`.

`h = slice(...)` returns a vector of handles to surface graphics objects.

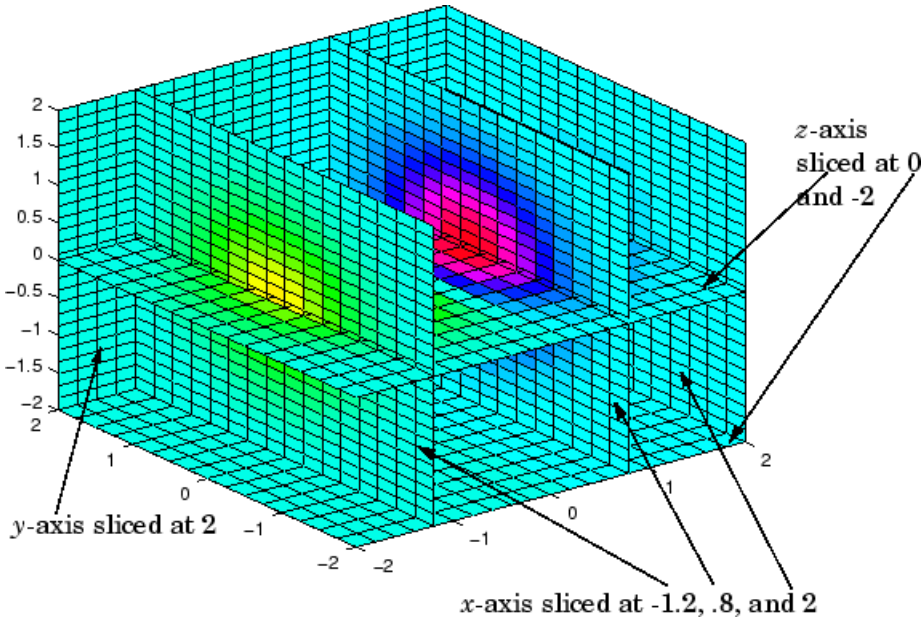
Examples

Visualize the function

$$v = xe^{\left(-x^2-y^2-z^2\right)}$$

over the range $-2 \le x \le 2$, $-2 \le y \le 2$, $-2 \le z \le 2$:

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2);
xslice = [-1.2,.8,2];
yslice = 2;
zslice = [-2,0];
slice(x,y,z,v,xslice,yslice,zslice)
colormap hsv
```



Slicing At Arbitrary Angles

You can also create slices that are oriented in arbitrary planes. To do this,

- Create a slice surface in the domain of the volume (`surf`, `linspace`).
- Orient this surface with respect to the axes (`rotate`).
- Get the `XData`, `YData`, and `ZData` of the surface.
- Use this data to draw the slice plane within the volume.

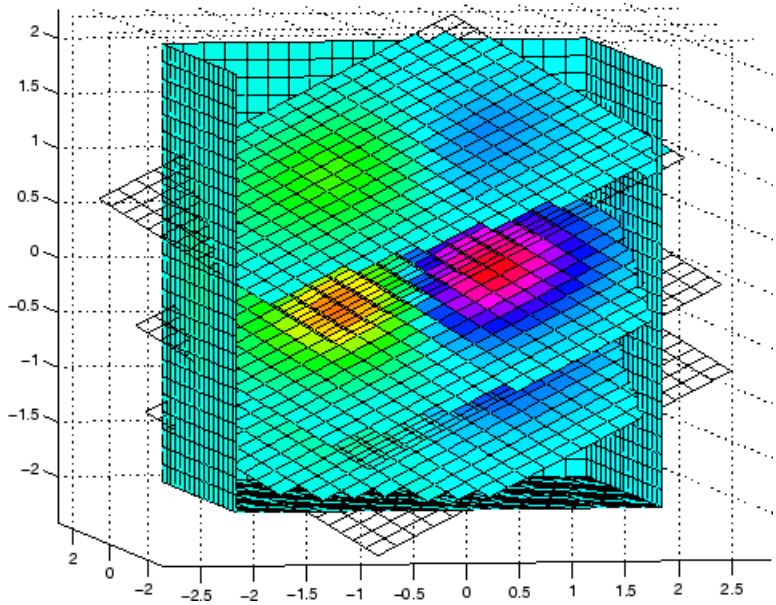
For example, these statements slice the volume in the first example with a rotated plane. Placing these commands within a `for` loop "passes" the plane through the volume along the *z*-axis.

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2);
figure
colormap hsv
for k = -2:.05:2
   hsp = surf(linspace(-2,2,20),linspace(-2,2,20),...
      zeros(20) + k);
```

```
    rotate(hsp,[1,-1,1],30)
    xd = hsp.XData;
    yd = hsp.YData;
    zd = hsp.ZData;
    delete(hsp)

    slice(x,y,z,v,[-2,2],2,-2) % Draw some volume boundaries
    hold on
    slice(x,y,z,v,xd,yd,zd)
    hold off
    view(-5,10)
    axis([-2.5 2.5 -2 2 -2 4])
    drawnow
end
```

The following picture illustrates three positions of the same slice surface as it passes through the volume.

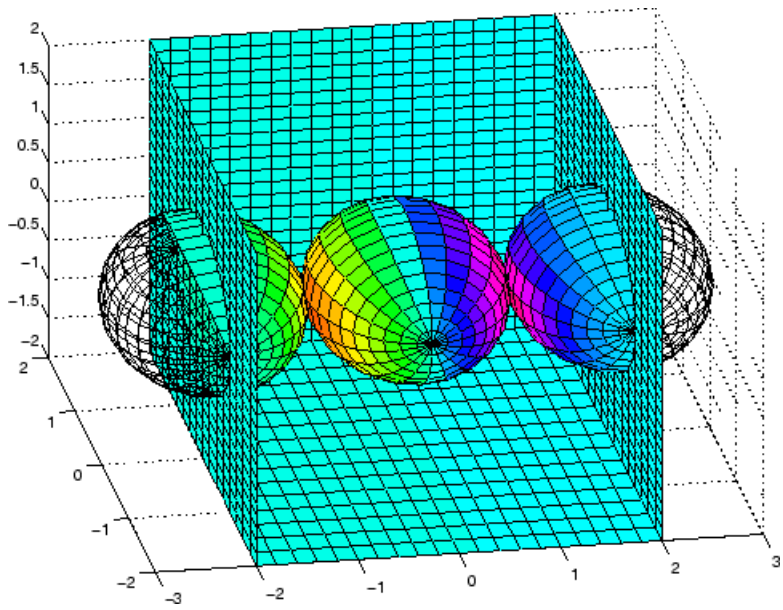


Slicing with a Nonplanar Surface

You can slice the volume with any surface. This example probes the volume created in the previous example by passing a spherical slice surface through the volume.

```
[xsp,ysp,zsp] = sphere;
slice(x,y,z,v,[-2,2],2,-2)
colormap hsv
for i = -3:.2:3
   hsp = surface(xsp+i,ysp,zsp);
   rotate(hsp,[1 0 0],90)
   xd = hsp.XData;
   yd = hsp.YData;
   zd = hsp.ZData;
   delete(hsp)
   hold on
   hslicer = slice(x,y,z,v,xd,yd,zd);
   axis tight
   xlim([-3,3])
   view(-10,35)
   drawnow
   delete(hslicer)
   hold off
end
```

The following picture illustrates three positions of the spherical slice surface as it passes through the volume.



More About

Tips

The color drawn at each point is determined by interpolation into the volume `V`.

- Exploring Volumes with Slice Planes

`interp3` | `meshgrid`

Introduced before R2006a

smooth3

Smooth 3-D data

Syntax

Description

`W = smooth3(V)` smooths the input data `V` and returns the smoothed data in `W`.

`W = smooth3(V,'filter')` *`filter`* determines the convolution kernel and can be the strings

- `'gaussian'`
- `'box'` (default)

`W = smooth3(V,'filter',size)` sets the size of the convolution kernel (default is `[3 3 3]`). If `size` is scalar, then `size` is interpreted as [`size`, `size`, `size`].

`W = smooth3(V,'filter',size,sd)` sets an attribute of the convolution kernel. When *`filter`* is `gaussian`, `sd` is the standard deviation (default is .65).

Examples

This example smooths some random 3-D data and then creates an isosurface with end caps.

```
rng(9,'twister')
data = rand(10,10,10);
data = smooth3(data,'box',5);
patch(isocaps(data,.5),...
   'FaceColor','interp','EdgeColor','none');
p1 = patch(isosurface(data,.5),...
   'FaceColor','blue','EdgeColor','none');
isonormals(data,p1)
view(3);
axis vis3d tight
camlight left;
```

```
colormap jet
lighting gouraud
```

`isocaps` | `isonormals` | `isosurface` | `patch`

Introduced before R2006a

snapnow

Force snapshot of image for inclusion in published document

Syntax

```
snapnow
```

Description

The `snapnow` command forces a snapshot of the image or plot that the code has most recently generated for presentation in a published document. The output appears in the published document at the end of the cell that contains the `snapnow` command. When used outside the context of publishing a file, `snapnow` has the same behavior as `drawnow`. That is, if you run a file that contains the `snapnow` command, the MATLAB software interprets it as though it were a `drawnow` command.

Examples

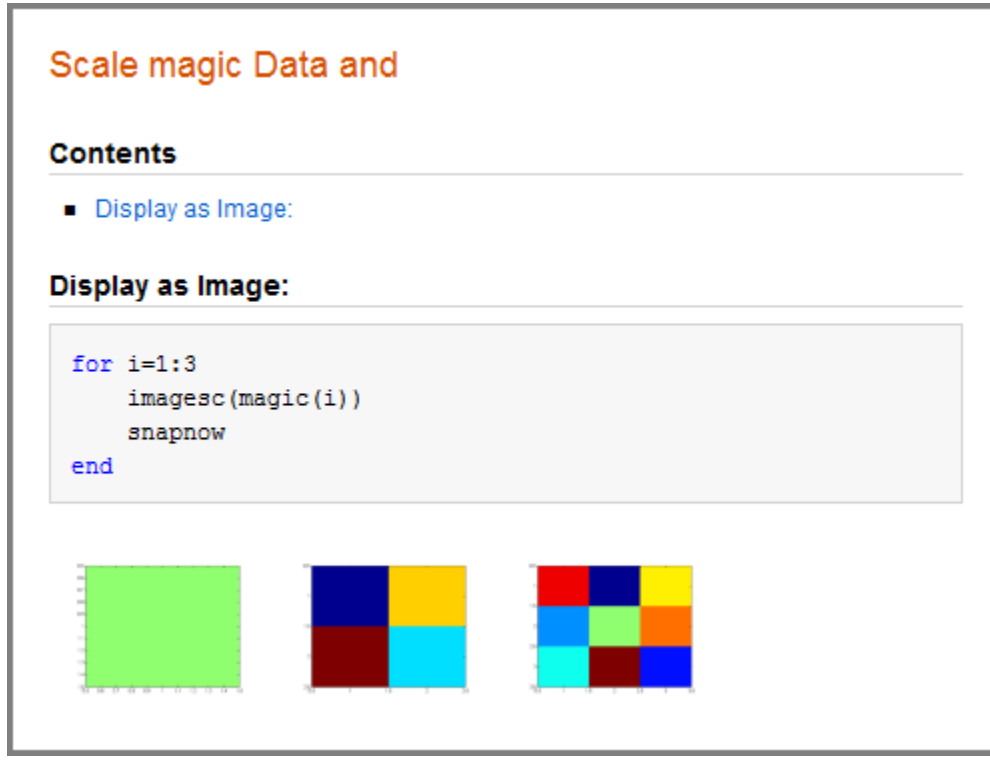
This example demonstrates the difference between publishing code that contains the `snapnow` command and running that code. The first image shows the results of publishing the code and the second image shows the results of running the code.

Suppose you have a file that contains the following code:

```
%% Scale magic Data and
%% Display as Image:

for i=1:3
    imagesc(magic(i))
    snapnow
end
```

When you publish the code to HTML, the published document contains a title, a table of contents, the commented text, the code, and each of the three images produced by the `for` loop. (In the published document shown, the size of the images have been reduced.)



When you run the code, a single Figure window opens and MATLAB updates the image within this window as it evaluates each iteration of the `for` loop. Each successive image replaces the one that preceded it, so that the Figure window appears as follows when the code evaluation completes.

`drawnow`

sort

Sort array elements

Syntax

```
B = sort(A)
B = sort(A,dim)
B = sort( ___ ,mode)
[B,I] = sort( ___ )
```

Description

`B = sort(A)` sorts the elements of `A` in ascending order along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `sort(A)` sorts the vector elements.
- If `A` is a matrix, then `sort(A)` treats the columns of `A` as vectors and sorts each column.
- If `A` is a multidimensional array, then `sort(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors.

`B = sort(A,dim)` returns the sorted elements of `A` along dimension `dim`. For example, if `A` is a matrix, then `sort(A,2)` sorts the elements in each row.

`B = sort( ___ ,mode)` returns sorted elements of `A` in the order specified by `mode` using any of the previous syntaxes. The single string, `'ascend'`, indicates ascending order (default) and `'descend'` indicates descending order.

`[B,I] = sort( ___ )` additionally returns a collection of index vectors for any of the previous syntaxes. `I` is the same size as `A` and describes the arrangement of the elements of `A` into `B` along the sorted dimension. For example, if `A` is a numeric vector, `B = A(I)`.

Examples

Sort Vector in Ascending Order

Create a row vector and sort its elements in ascending order.

```
A = [9 0 -7 5 3 8 -10 4 2];
B = sort(A)

B =

   -10    -7     0     2     3     4     5     8     9
```

Sort Matrix Rows in Ascending Order

Create a matrix and sort each of its rows in ascending order.

```
A = [3 6 5; 7 -2 4; 1 0 -9]

A =

     3     6     5
     7    -2     4
     1     0    -9

B = sort(A,2)

B =

     3     5     6
    -2     4     7
    -9     0     1
```

Sort Matrix Columns in Descending Order

Create a matrix and sort its columns in descending order.

```
A = [10 -12 4 8; 6 -9 8 0; 2 3 11 -2; 1 1 9 3]

A =

    10   -12     4     8
     6    -9     8     0
     2     3    11    -2
     1     1     9     3
```

```
B = sort(A,'descend')
```

```
B =

    10     3    11     8
     6     1     9     3
     2    -9     8     0
     1   -12     4    -2
```

Sort and Index `datetime` Array

Create an array of `datetime` values and sort them in ascending order, that is, from the earliest to the latest calendar date.

```
ds = {'2012-12-22';'2063-04-05';'1992-01-12'};
A = datetime(ds,'Format','yyyy-MM-dd')
```

```
A =

   2012-12-22
   2063-04-05
   1992-01-12
```

```
[B,I] = sort(A)
```

```
B =

   1992-01-12
   2012-12-22
   2063-04-05

I =

     3
     1
     2
```

`B` lists the sorted dates and `I` contains the corresponding indices of `A`.

Access the sorted elements from the original array directly by using the index array `I`.

```
A(I)
```

```
ans =

   1992-01-12
   2012-12-22
   2063-04-05
```

Sort 3-D Array

Create a 2-by-2-by-2 array and sort its elements in ascending order along the third dimension.

```
A(:,:,1) = [2 3; 1 6];
A(:,:,2) = [-1 9; 0 12];
A
```

```
A(:,:,1) =

     2     3
     1     6

A(:,:,2) =

    -1     9
     0    12
```

```
B = sort(A,3)
```

```
B(:,:,1) =

    -1     3
     0     6

B(:,:,2) =
```

```
     2     9
     1    12
```

Use `A(:)`, the column representation of `A`, to sort all of the elements of `A`.

```
B = sort(A(:))
```

```
B =

    -1
     0
     1
     2
     3
     6
     9
    12
```

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

- If `A` is a scalar, then `sort(A)` returns `A`.
- If `A` is an empty 0-by-0 matrix, then `sort(A)` returns an empty 0-by-0 matrix.
- If `A` contains `NaN` values or undefined `categorical` or `datetime` elements, then `sort(A)` places them on the high end of the sort (as if they were large numbers).
- If `A` is complex, then `sort(A)` sorts the elements by magnitude. If more than one element has equal magnitude, the elements are sorted by phase angle on the interval [−π, π].
- If `A` is a string, then `sort(A)` sorts according to the ASCII dictionary order. The sort is case sensitive with uppercase letters appearing in the output before the lowercase letters.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell` | `categorical` | `datetime` | `duration`

Complex Number Support: Yes

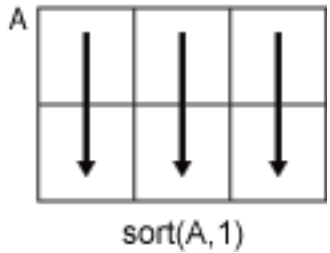
`dim` — Dimension to operate along

positive integer scalar

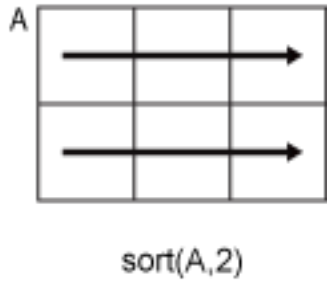
Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`:

- `sort(A,1)` sorts the elements in the columns of `A`.



- `sort(A,2)` sorts the elements in the rows of `A`.



`sort` returns `A` if `dim` is greater than `ndims(A)`. If `A` is a cell array, then `dim` is not supported.

`mode` — Sorting mode

`'ascend'` (default) | `'descend'`

Sorting mode, specified as `'ascend'` or `'descend'`. If `A` is a cell array, then `mode` is not supported.

Example: `sort(A,2,'descend')` sorts the rows of `A` in descending order.

Data Types: `char`

Output Arguments

`B` — Sorted array

vector | matrix | multidimensional array

Sorted array, returned as a vector, matrix, or multidimensional array the same size and type as `A`. The ordering of the elements in `B` preserves the order of any equal elements in `A`.

`I` — Sort index

vector | matrix | multidimensional array

Sort index, returned as a vector, matrix, or multidimensional array the same size as `A`. The index vectors are oriented along the same dimension that `sort` operates on. For example, if `A` is a 2-by-3 matrix, then `[B,I] = sort(A,2)` sorts the elements in each row of `A`. `I` is a collection of 1-by-3 row index vectors describing the rearrangement. If you do not specify `dim`, then `[B,I] = sort(A)` sorts the columns of `A`, and `I` is a collection of 2-by-1 column index vectors.

More About

Tips

- The `sortrows` function provides additional flexibility for subsorting over multiple columns of nonvector input arrays.
- The `sort` function and the relational operators use different orderings for complex numbers. For more information, see “Relational Operations”.
- “Shifting and Sorting Matrices”

See Also

`issorted` | `max` | `mean` | `median` | `min` | `sortrows` | `unique`

sortrows

Sort array rows

Syntax

```
B = sortrows(A)
B = sortrows(A,column)
[B,index] = sortrows( ___ )

tblB = sortrows(tblA)
tblB = sortrows(tblA,'RowNames')
tblB = sortrows(tblA,vars)

tblB = sortrows(tblA,mode)
tblB = sortrows(tblA,'RowNames',mode)
tblB = sortrows(tblA,vars,mode)

[tblB,index] = sortrows(tblA, ___ )
```

Description

`B = sortrows(A)` sorts the rows of `A` in ascending order. For strings, this is the familiar dictionary sort.

`B = sortrows(A,column)` sorts matrix `A` based on the columns specified in the vector, `column`. This input is used to perform multiple column sorts in succession.

`[B,index] = sortrows( ___ )` also returns an index vector using any of the previous syntaxes. The index vector satisfies `B = A(index,:)`.

`tblB = sortrows(tblA)` sorts the rows of table `tblA` in ascending order by the first variable, then by the second variable, and so on.

`tblB = sortrows(tblA,'RowNames')` sorts by the row names.

`tblB = sortrows(tblA,vars)` sorts by the variables specified by `vars`.

`tblB = sortrows(tblA,mode)` and `tblB = sortrows(tblA,'RowNames',mode)` sorts `tblA` in the order specified by `mode`. The single string, `'ascend'`, indicates ascending order (default) and `'descend'` indicates descending order.

`tblB = sortrows(tblA,vars,mode)` uses `mode` to specify the sort order. `mode` can be a single string or a cell array of strings containing `'ascend'` for ascending order (default) or `'descend'` for descending order.

- When `mode` is a single string, `sortrows` sorts in the specified direction for all variables in `vars`.
- When `mode` is a cell array of strings, `sortrows` sorts in the specified direction for each variable in `vars`.

`[tblB,index] = sortrows(tblA, ___ )` also returns an index vector, `index`, such that `tblB = tblA(index,:)`.

Examples

Sort Rows of Matrix

Start with an arbitrary matrix, `A`.

```
A = floor(gallery('uniformdata',[6 7],0)*100);
A(1:4,1) = 95;  A(5:6,1) = 76;  A(2:4,2) = 7;  A(3,3) = 73
```

```
A =
    95    45    92    41    13     1    84
    95     7    73    89    20    74    52
    95     7    73     5    19    44    20
    95     7    40    35    60    93    67
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
```

Sort the rows of `A`.

```
B = sortrows(A)
```

```
B =
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
    95     7    40    35    60    93    67
    95     7    73     5    19    44    20
```

```
    95     7    73    89    20    74    52
    95    45    92    41    13     1    84
```

When called with only a single input argument, `sortrows` bases the sort on the first column of the matrix. For any rows that have equal elements in a particular column, (e.g., `A(1:4,1)` for this matrix), sorting is based on the column immediately to the right, (`A(1:4,2)` in this case).

When called with two input arguments, `sortrows` bases the sort entirely on the column specified in the second argument.

Sort the rows of `A` based on the values in the second column.

```
C = sortrows(A,2)
```

```
C =
    95     7    73    89    20    74    52
    95     7    73     5    19    44    20
    95     7    40    35    60    93    67
    95    45    92    41    13     1    84
    76    61    93    81    27    46    83
    76    79    91     0    19    41     1
```

Rows that have equal elements in the specified column, (e.g., `A(2:4,:)`, if sorting matrix `A` by column 2) remain in their original order.

Specify two columns to sort by: columns 1 and 7.

```
D = sortrows(A,[1 7])
```

```
D =
    76    79    91     0    19    41     1
    76    61    93    81    27    46    83
    95     7    73     5    19    44    20
    95     7    73    89    20    74    52
    95     7    40    35    60    93    67
    95    45    92    41    13     1    84
```

`sortrows` sorts by column 1 first, and then for any rows with equal values in column 1, sorts by column 7.

Sort the rows in descending order using the values in column 4.

```
[E,index] = sortrows(A, -4)
```

```
E =

    95     7    73    89    20    74    52
    76    61    93    81    27    46    83
    95    45    92    41    13     1    84
    95     7    40    35    60    93    67
    95     7    73     5    19    44    20
    76    79    91     0    19    41     1

index =

     2
     5
     1
     4
     3
     6
```

The index vector, `index`, describes the rearrangement of the rows, such that `E = A(index,:)`.

Sort Rows of Cell Array

Create a 6-by-2 cell array of strings.

```
A = {'Germany' 'Lukas'; 'USA' 'William'; 'USA' 'Andrew'; ...
'Germany' 'Andreas'; 'USA' 'Olivia'; 'Germany' 'Julia'}
```

```
A =

    'Germany'    'Lukas'
    'USA'        'William'
    'USA'        'Andrew'
    'Germany'    'Andreas'
    'USA'        'Olivia'
    'Germany'    'Julia'
```

The result is a list of countries and names.

Sort the rows of `A`.

```
B = sortrows(A)
```

```
B =
```

```
    'Germany'    'Andreas'
    'Germany'    'Julia'
    'Germany'    'Lukas'
    'USA'        'Andrew'
    'USA'        'Olivia'
    'USA'        'William'
```

The result is an alphabetized list sorted by both country and name.

Sort the names in the second column in descending order.

```
[C,index] = sortrows(A,[1 -2])
```

```
C =

    'Germany'    'Lukas'
    'Germany'    'Julia'
    'Germany'    'Andreas'
    'USA'        'William'
    'USA'        'Olivia'
    'USA'        'Andrew'

index =

     1
     6
     4
     2
     5
     3
```

The index vector, `index`, describes the rearrangement of the rows, such that `C = A(index,:)`.

Sort Rows of Table

Sort the rows of a table by the variable values in ascending order.

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
```

```
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
tblA =

               Age    Height    Weight     BloodPressure
               ---    ------    ------    ---------------
    Smith      38     71        176       124          93
    Johnson    43     69        163       109          77
    Williams   38     64        131       125          83
    Jones      40     67        133       117          75
    Brown      49     64        119       122          80
```

Sort the rows of the table.

```
tblB = sortrows(tblA)
```

```
tblB =

               Age    Height    Weight     BloodPressure
               ---    ------    ------    ---------------
    Williams   38     64        131       125          83
    Smith      38     71        176       124          93
    Jones      40     67        133       117          75
    Johnson    43     69        163       109          77
    Brown      49     64        119       122          80
```

The `sortrows` function sorts the rows in ascending order first by the variable `Age`, and then it sorts by the variable `Height`.

Sort Rows of Table by Row Names

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
tblA =
```

```
              Age    Height    Weight     BloodPressure
              ---    ------    ------    ---------------
    Smith     38     71        176       124          93
    Johnson   43     69        163       109          77
    Williams  38     64        131       125          83
    Jones     40     67        133       117          75
    Brown     49     64        119       122          80
```

Sort the rows of the table by the row names and return an index vector, such that `tblB = tblA(index,:)`.

```
[tblB,index] = sortrows(tblA,'RowNames')
```

```
tblB =

              Age    Height    Weight     BloodPressure
              ---    ------    ------    ---------------
    Brown     49     64        119       122          80
    Johnson   43     69        163       109          77
    Jones     40     67        133       117          75
    Smith     38     71        176       124          93
    Williams  38     64        131       125          83

index =

     5
     2
     4
     1
     3
```

The `sortrows` function sorts the rows in ascending order by the row names.

Sort Rows of Table by Variables

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
tblA =

               Age    Height    Weight     BloodPressure
               ---    ------    ------    ---------------
    Smith      38     71        176       124           93
    Johnson    43     69        163       109           77
    Williams   38     64        131       125           83
    Jones      40     67        133       117           75
    Brown      49     64        119       122           80
```

Sort the rows of the table in ascending order by `Height`, and then sort in descending order by `Weight`. Also, return an index vector, such that `tblB = tblA(index,:)`.

```
[tblB,index] = sortrows(tblA,{'Height','Weight'},{'ascend','descend'})
```

```
tblB =

               Age    Height    Weight     BloodPressure
               ---    ------    ------    ---------------
    Williams   38     64        131       125           83
    Brown      49     64        119       122           80
    Jones      40     67        133       117           75
    Johnson    43     69        163       109           77
    Smith      38     71        176       124           93

index =

     3
     5
     4
     2
     1
```

Input Arguments

A — Input array

column vector | matrix

Input array, specified as a column vector or matrix. The data type of `A` can be numeric, `logical`, `char`, `cell`, categorical, datetime, or duration. If `A` contains `NaN` values or undefined categorical or datetime elements, `sortrows(A)` places them on the high end of the sort (as if they are large numbers).

When A is complex, sortrows sorts the elements by magnitude, and, where magnitudes are equal, further sorts by phase angle on the interval [−π, π].
Complex Number Support: Yes

column — Column sorting vector
vector of integers

Column sorting vector, specified as a vector of integers. Each integer value indicates a column to sort by. The sign of the integer indicates ascending (positive) or descending (negative) sort order.

Example: sortrows(A,[2 -3]) sorts the rows of A first in ascending order for the second column, and then it sorts by descending order for the third column.

tblA — Input table
table

Input table, specified as a table. Each variable in tblA must be a valid input to sort or sortrows.

Data Types: table

'RowNames' — Row sort input
string

Row sort input, specified as the string 'RowNames'. Specify the 'RowNames' option to sort a table by row names rather than by variables. If tblA.Properties.RowNames is empty, sortrows(tblA,'RowNames') returns tblA.

vars — Sorting variables
integer | vector of integers | variable name | cell array of variable names | logical vector

Sorting variables, specified as an integer, a vector of integers, a variable name, a cell array of variable names, or a logical vector. vars indicates the table variables to sort by. You also can use the mode input to indicate ascending or descending order for each sorting variable.

If an element of vars is a positive integer, sortrows sorts the corresponding variable in tblA in ascending order. If an element of vars is a negative integer, sortrows sorts the corresponding variable in tblA in descending order. If you provide the mode input argument, MATLAB ignores the sign of the integers.

Example: sortrows(tblA,{'Height','Weight'}) sorts the rows of tblA in ascending order, first by the variable Height, and then it sorts by the variable Weight.

Example: `sortrows(tblA,[1 4],{'descend' 'ascend'})` sorts the first variable of `tblA` in descending order, then it sorts the fourth variable in ascending order.

`mode` — Sorting mode

single string | cell array of strings

Sorting mode, specified as a single string or cell array of strings composed of the options `'ascend'` (default), or `'descend'`. If `mode` is a cell array of strings, the number of required entries depends on whether you are sorting by variables or by row names.

- If `tblA` is being sorted by variables, the cell array must have an entry for each variable.
- If `tblA` is being sorted by row names, the cell array must have one entry.

Data Types: `char | cell`

Output Arguments

`B` — Sorted array

array

Sorted array, returned as an array of the same size and class as `A`.

`tblB` — Sorted table

table

Sorted table, returned as a table with the same variables as `tblA`.

`index` — Sort index

index vector

Sort index, returned as an index vector. The sort index describes the rearrangement of elements or rows in the input.

`issorted | sort`

Introduced before R2006a

sound

Convert matrix of signal data to sound

Syntax

```
sound(y)
sound(y,Fs)
sound(y,Fs,nBits)
```

Description

`sound(y)` sends audio signal `y` to the speaker at the default sample rate of 8192 hertz.

`sound(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`sound(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

Examples

Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;
sound(y);
```

Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's “Hallelujah Chorus” at twice the recorded sample rate.

```
load handel.mat;
sound(y, 2*Fs);
```

Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
```

```
sound(y,Fs,nBits);
```

MATLAB plays the audio with a bit depth of 16 bits per sample, if this is supported on your system.

Input Arguments

y — Audio data

column vector | m-by-2 matrix

Audio data, specified as an m-by-1 column vector for single-channel (mono) audio, or an m-by-2 matrix for stereo playback, where m is the number of audio samples. If y is an m-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

Data Types: double

Fs — Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data y, specified as a positive number between 80 and 1000000.

Data Types: single | double

nBits — Bit depth of sample values

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

More About

Tips

- The sound function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

- “Characteristics of Audio Files”
- “Play Audio”

`audioplayer` | `audioread` | `audiowrite` | `soundsc`

Introduced before R2006a

soundsc

Scale data and play as sound

Syntax

```
soundsc(y)
soundsc(y,Fs)
soundsc(y,Fs,nBits)

soundsc( ___ ,yRange)
```

Description

`soundsc(y)` scales the values of audio signal `y` to fit in the range from –1.0 to 1.0, and then sends the data to the speaker at the default sample rate of 8192 hertz. By first scaling the data, `soundsc` plays the audio as loudly as possible without clipping. The mean of the dynamic range of the data is set to zero.

`soundsc(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`soundsc(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

`soundsc( ___ ,yRange)`, where `yRange` is a vector of the form `[low,high]`, linearly scales the values in `y` between `low` and `high` to the full sound range `[-1.0,1.0]`. Values outside `[low,high]` scale beyond `[-1.0,1.0]`. You can use `yRange` with any of the input arguments in the previous syntaxes.

Examples

Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;
```

```
soundsc(y);
```

Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
soundsc(y, 2*Fs);
```

Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
soundsc(y,Fs,nBits);
```

MATLAB plays the scaled audio with a bit depth of 16 bits per sample.

Scale Selected Audio Data

```
load handel.mat;
yRange = [-0.7,0.7];
soundsc(y,yRange);
```

Input Arguments

y — Audio data

column vector | m-by-2 matrix

Audio data, specified as an `m`-by-1 column vector for single-channel (mono) audio, or an `m`-by-2 matrix for stereo playback, where `m` is the number of audio samples. If `y` is an `m`-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

Data Types: `double`

Fs — Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data `y`, specified as a positive number between 80 and 1000000.

Data Types: `single` | `double`

`nBits` — Bit depth of sample values

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

`yRange` — Range of audio data to scale

`[-max(abs(y)),max(abs(y))]` (default) | two-element vector

Range of audio data to scale, specified as a two-element vector of the form `[low,high]`, where `low` and `high` are the lower and upper limits of the range. Values in `y` that are scaled beyond `[-1.0, 1.0]` are clipped when played back on a sound device.

Example: `[-0.8,0.8]`

Data Types: `double`

More About

Tips

- The `sound` function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

Introduced before R2006a

spalloc

Allocate space for sparse matrix

Syntax

```
S = spalloc(m,n,nzmax)
```

Description

`S = spalloc(m,n,nzmax)` creates an all zero sparse matrix `S` of size `m`-by-`n` with room to hold `nzmax` nonzeros. The matrix can then be generated column by column without requiring repeated storage allocation as the number of nonzeros grows.

`spalloc(m,n,nzmax)` is shorthand for

```
sparse([],[],[],m,n,nzmax)
```

Examples

To generate efficiently a sparse matrix that has an average of at most three nonzero elements per column

```
S = spalloc(n,n,3*n);
for j = 1:n
    S(:,j) = [zeros(n-3,1)' round(rand(3,1))']';end
```

Introduced before R2006a

sparse

Create sparse matrix

The `sparse` function generates matrices in the MATLAB sparse storage organization.

Syntax

```
S = sparse(A)

S = sparse(m,n)

S = sparse(i,j,v)
S = sparse(i,j,v,m,n)
S = sparse(i,j,v,m,n,nz)
```

Description

`S = sparse(A)` converts a full matrix into sparse form by squeezing out any zero elements. If a matrix contains many zeros, converting the matrix to sparse storage saves memory.

`S = sparse(m,n)` generates an `m`-by-`n` all zero sparse matrix.

`S = sparse(i,j,v)` generates a sparse matrix `S` from the triplets `i`, `j`, and `v` such that `S(i(k),j(k)) = v(k)`. The `max(i)`-by-`max(j)` output matrix has space allotted for `length(v)` nonzero elements. `sparse` adds together elements in `v` that have duplicate subscripts in `i` and `j`.

If the inputs `i`, `j`, and `v` are vectors or matrices, they must have the same number of elements. Alternatively, the argument `v` and/or one of the arguments `i` or `j` can be scalars.

`S = sparse(i,j,v,m,n)` specifies the size of `S` as `m`-by-`n`.

`S = sparse(i,j,v,m,n,nz)` allocates space for `nz` nonzero elements. Use this syntax to allocate extra space for nonzero values to be filled in after construction.

Examples

Save Memory Using Sparse Storage

Create a 10,000-by-10,000 full storage identity matrix.

```
A = eye(10000);
whos A
```

```
  Name          Size                    Bytes  Class     Attributes

  A         10000x10000             800000000  double
```

This matrix uses 800-megabytes of storage.

Convert the matrix to sparse storage.

```
S = sparse(A);
whos S
```

```
  Name          Size                 Bytes  Class     Attributes

  S         10000x10000             240008  double    sparse
```

In sparse form, the same matrix uses roughly 0.25-megabytes of storage. In this case, you can avoid full storage completely by using the `speye` function, which creates sparse identity matrices directly.

Sparse Matrix of All Zeros

```
S = sparse(10000,5000)
```

```
S =

   All zero sparse: 10000-by-5000
```

Sparse Matrix of Nonzeros with Specified Size

Create a 1500-by-1500 sparse matrix from the triplets `i`, `j`, and `v`.

```
i = [900 1000];
j = [900 1000];
v = [10 100];
S = sparse(i,j,v,1500,1500)

S =

 (900,900)      10
(1000,1000)    100
```

When you specify a size larger than `max(i)` -by- `max(j)`, the `sparse` function pads the output with extra rows and columns of zeros.

```
size(S)

ans =

        1500         1500
```

Preallocate Storage in Sparse Matrix

Create a sparse matrix with 10 nonzero values, but which has space allocated for 100 nonzero values.

```
S = sparse(1:10,1:10,5,20,20,100);
N = nnz(S)

N =

    10

N_alloc = nzmax(S)

N_alloc =

   100
```

The `spalloc` function is a shorthand way to create a sparse matrix with *no* nonzero elements but which has space allotted for some number of nonzeros.

Accumulate Values into Sparse Matrix

Use repeated subscripts to accumulate values into a single sparse matrix that would otherwise require one or more loops.

Create a column vector of data and two column vectors of subscripts.

```
i = [6 6 6 5 10 10 9 9]';
j = [1 1 1 2 3 3 10 10]';
v = [100 202 173 305 410 550 323 121]';
```

Visualize the subscripts and values side-by-side.

```
[i,j,v]
```

```
ans =

     6     1   100
     6     1   202
     6     1   173
     5     2   305
    10     3   410
    10     3   550
     9    10   323
     9    10   121
```

Use the `sparse` function to accumulate the values that have identical subscripts.

```
S = sparse(i,j,v)
```

```
S =

   (6,1)       475
   (5,2)       305
  (10,3)       960
   (9,10)      444
```

Input Arguments

A — Input matrix

full matrix | sparse matrix

Input matrix, specified as a full or sparse matrix. If A is already sparse, then `sparse(A)` returns A.

Data Types: `double` | `logical`
Complex Number Support: Yes

i,j — Subscript pairs (as separate arguments)

scalars | vectors | matrices

Subscript pairs, specified as separate arguments of scalars, vectors, or matrices. Corresponding elements in `i` and `j` specify `S(i,j)` subscript pairs, which determine the placement of the values in `v` into the output. If either `i` or `j` is a vector or matrix, then the other input can be a scalar or can be a vector or matrix with the same number of elements. In that case, `sparse` uses `i(:)` and `j(:)` as the subscripts. If `i` and `j` have identical values for several elements in `v`, then those elements are added together.

Note: If any value in `i` or `j` is larger than `2^31-1` for 32-bit platforms, or `2^48-1` on 64-bit platforms, then the sparse matrix cannot be constructed.

Data Types: `double` | `logical`

v — Values

scalar | vector | matrix

Values, specified as a scalar, vector, or matrix. If `v` is a vector or matrix, then one of the inputs `i` or `j` must also be a vector or matrix with the same number of elements.

Any elements in `v` that are zero are ignored, as are the corresponding subscripts in `i` and `j`. However, if you do not specify the dimension sizes of the output, `m` and `n`, then `sparse` calculates the maxima `m = max(i)` and `n = max(j)` before ignoring any zero elements in `v`.

Data Types: `double` | `logical`

Complex Number Support: Yes

`m,n` — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values. If you specify `m` (the row size), you also must specify `n` (the column size).

If you do not specify `m` and `n`, then `sparse` uses the default values `m = max(i)` and `n = max(j)`. These maxima are computed before any zeros in `v` are removed.

Data Types: `double`

`nz` — Storage allocation for nonzero elements

positive integer scalar

Storage allocation for nonzero elements, specified as a positive integer scalar. `nz` must be greater than or equal to `max([numel(i), numel(j), numel(v)])`.

For a sparse matrix, `S`, the `nnz` function returns the number of nonzero elements in the matrix, and the `nzmax` function returns the amount of storage allocated for nonzero matrix elements. If `nnz(S)` and `nzmax(S)` return different results, then more storage might be allocated than is actually required. For this reason, set `nz` only in anticipation of later fill-in.

If you do not specify `nz`, the `sparse` function uses a default value of `max([numel(i), numel(j), numel(v)])`.

Data Types: `double`

More About

Tips

- The `accumarray` function has similar accumulation behavior to that of `sparse`.
  - `accumarray` groups data into bins using *n*-dimensional subscripts, but `sparse` groups data into bins using 2-D subscripts.
  - `accumarray` adds elements that have identical subscripts into the output by default, but can optionally apply any function to the bins. `sparse` only adds elements that have identical subscripts into the output.

Introduced before R2006a

spaugment

Form least squares augmented system

Syntax

```
S = spaugment(A,c)
S = spaugment(A)
```

Description

`S = spaugment(A,c)` creates the sparse, square, symmetric indefinite matrix `S = [c*I A; A' 0]`. The matrix `S` is related to the least squares problem

```
min norm(b - A*x)
```

by

```
r = b - A*x
S * [r/c; x] = [b; 0]
```

The optimum value of the residual scaling factor `c`, involves `min(svd(A))` and `norm(r)`, which are usually too expensive to compute.

`S = spaugment(A)` without a specified value of `c`, uses `max(max(abs(A)))/1000`.

Note In previous versions of MATLAB product, the augmented matrix was used by sparse linear equation solvers, \ and /, for nonsquare problems. Now, MATLAB software performs a least squares solve using the `qr` factorization of `A` instead.

`spparms`

Introduced before R2006a

spconvert

Import from sparse matrix external format

`spconvert` creates sparse matrices from a simple sparse format produced by sparse programs outside of MATLAB.

Syntax

```
S = spconvert(D)
```

Description

`S = spconvert(D)` constructs sparse matrix `S` from the columns of `D` in a manner similar to the `sparse` function.

- If `D` is of size `N`-by-`3`, then `spconvert` uses the columns `[i,j,re]` of `D` to construct `S`, such that `S(i(k), j(k)) = re(k)`.
- If `D` is of size `N`-by-`4`, then `spconvert` uses the columns `[i,j,re,im]` of `D` to construct `S`, such that `S(i(k), j(k)) = re(k) + 1i*im(k)`.

Examples

Convert Data File to Sparse Matrix

Create an ASCII file, `uphill.dat`, which contains the following values. Save the file in your current directory.

```
1     1     1.000000000000000
1     2     0.500000000000000
2     2     0.333333333333333
1     3     0.333333333333333
2     3     0.250000000000000
3     3     0.200000000000000
1     4     0.250000000000000
2     4     0.200000000000000
```

```
3     4     0.166666666666667
4     4     0.142857142857143
4     4     0.000000000000000
```

It is common to purposefully make the last line of the file include the desired size of the matrix with a value of 0. This practice ensures that the converted sparse matrix has that size.

Load the data into MATLAB and convert it into a sparse matrix.

```
load uphill.dat
H = spconvert(uphill)
```

```
H =

   (1,1)        1.0000
   (1,2)        0.5000
   (2,2)        0.3333
   (1,3)        0.3333
   (2,3)        0.2500
   (3,3)        0.2000
   (1,4)        0.2500
   (2,4)        0.2000
   (3,4)        0.1667
   (4,4)        0.1429
```

In this case, the last line in the file is not necessary because the earlier lines already specify that the matrix is at least 4-by-4.

Input Arguments

`D` — Input matrix

matrix

Input matrix, specified as a matrix with either three or four columns. In both cases, the first two columns of `D` are subscripts and the third column is composed of data values. A four column matrix specifies the real (third column) and imaginary (fourth column) parts of complex numbers.

If `D` is already a sparse matrix, then `spconvert` returns `D`.

Data Types: `single` | `double`

`full` | `sparse`

Introduced before R2006a

spdiags

Extract and create sparse band and diagonal matrices

Syntax

```
B = spdiags(A)
[B,d] = spdiags(A)
B = spdiags(A,d)
A = spdiags(B,d,A)
A = spdiags(B,d,m,n)
```

Description

The `spdiags` function generalizes the function `diag`. Four different operations, distinguished by the number of input arguments, are possible.

`B = spdiags(A)` extracts all nonzero diagonals from the `m`-by-`n` matrix `A`. `B` is a `min(m,n)`-by-`p` matrix whose columns are the `p` nonzero diagonals of `A`.

`[B,d] = spdiags(A)` returns a vector `d` of length `p`, whose integer components specify the diagonals in `A`.

`B = spdiags(A,d)` extracts the diagonals specified by `d`.

`A = spdiags(B,d,A)` replaces the diagonals specified by `d` with the columns of `B`. The output is sparse.

`A = spdiags(B,d,m,n)` creates an `m`-by-`n` sparse matrix by taking the columns of `B` and placing them along the diagonals specified by `d`.

Note In this syntax, if a column of `B` is longer than the diagonal it is replacing, and `m >= n`, `spdiags` takes elements of super-diagonals from the lower part of the column of `B`, and elements of sub-diagonals from the upper part of the column of `B`. However, if `m < n`, then super-diagonals are from the upper part of the column of `B`, and sub-diagonals from the lower part. (See “Example 5A” on page 1-7550 and “Example 5B” on page 1-7551, below).

Arguments

The `spdiags` function deals with three matrices, in various combinations, as both input and output.

A	An `m`-by-`n` matrix, usually (but not necessarily) sparse, with its nonzero or specified elements located on `p` diagonals.
B	A `min(m,n)`-by-`p` matrix, usually (but not necessarily) full, whose columns are the diagonals of `A`.
d	A vector of length `p` whose integer components specify the diagonals in `A`.

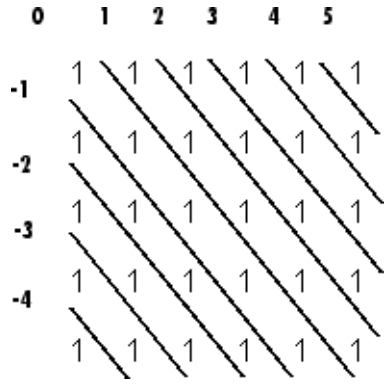
Roughly, `A`, `B`, and `d` are related by

```
for k = 1:p
    B(:,k) = diag(A,d(k))
end
```

Some elements of `B`, corresponding to positions outside of `A`, are not defined by these loops. They are not referenced when `B` is input and are set to zero when `B` is output.

How the Diagonals of A are Listed in the Vector d

An m-by-n matrix `A` has m+n-1diagonals. These are specified in the vector `d` using indices from -m+1 to n-1. For example, if `A` is 5-by-6, it has 10 diagonals, which are specified in the vector `d` using the indices -4, -3 , ... 4, 5. The following diagram illustrates this for a vector of all ones.



Examples

Example 1

For the following matrix,

```
A=[0 5 0 10 0 0;...
0 0 6 0 11 0;...
3 0 0 7 0 12;...
1 4 0 0 8 0;...
0 2 5 0 0 9]
```

```
A =

     0     5     0    10     0     0
     0     0     6     0    11     0
     3     0     0     7     0    12
     1     4     0     0     8     0
     0     2     5     0     0     9
```

the command

```
[B, d]  =spdiags(A)
```

returns

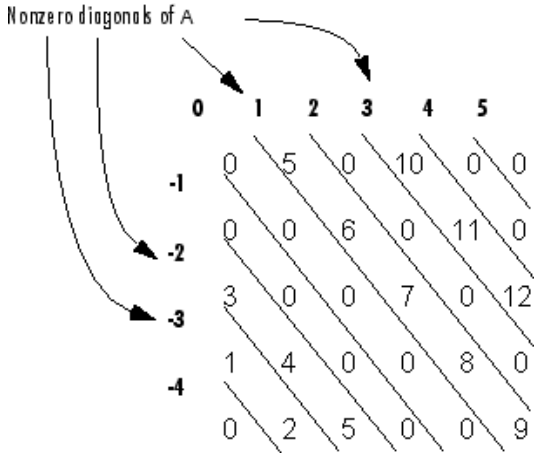
```
B =

     0     0     5    10
     0     0     6    11
     0     3     7    12
     1     4     8     0
     2     5     9     0

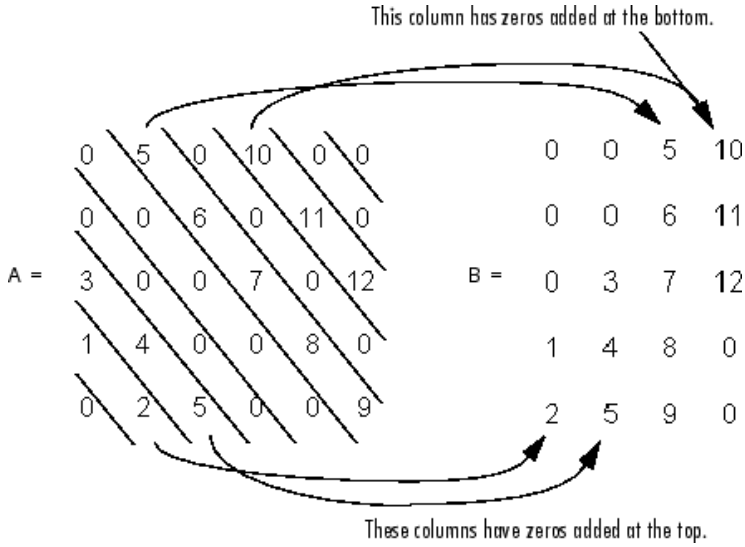
d =

    -3
    -2
     1
     3
```

The columns of the first output B contain the nonzero diagonals of A. The second output d lists the indices of the nonzero diagonals of A, as shown in the following diagram. See “How the Diagonals of A are Listed in the Vector d” on page 1-7545.



Note that the longest nonzero diagonal in A is contained in column 3 of B. The other nonzero diagonals of A have extra zeros added to their corresponding columns in B, to give all columns of B the same length. For the nonzero diagonals below the main diagonal of A, extra zeros are added at the tops of columns. For the nonzero diagonals above the main diagonal of A, extra zeros are added at the bottoms of columns. This is illustrated by the following diagram.



Example 2

This example generates a sparse tridiagonal representation of the classic second difference operator on `n` points.

```
e = ones(n,1);
A = spdiags([e -2*e e], -1:1, n, n)
```

Turn it into Wilkinson's test matrix (see `gallery`):

```
A = spdiags(abs(-(n-1)/2:(n-1)/2)',0,A)
```

Finally, recover the three diagonals:

```
B = spdiags(A)
```

Example 3

The second example is not square.

```
A = [11     0    13     0
       0    22     0    24
       0     0    33     0
```

```
     41     0     0    44
      0    52     0     0
      0     0    63     0
      0     0     0    74]
```

Here `m =7`, `n = 4`, and `p = 3`.

The statement `[B,d] = spdiags(A)` produces `d = [-3 0 2]'` and

```
B = [41    11     0
     52    22     0
     63    33    13
     74    44    24]
```

Conversely, with the above `B` and `d`, the expression `spdiags(B,d,7,4)` reproduces the original `A`.

Example 4

This example shows how `spdiags` creates the diagonals when the columns of `B` are longer than the diagonals they are replacing.

```
B = repmat((1:6)',[1 7])

B =

    1  1  1  1  1  1  1
    2  2  2  2  2  2  2
    3  3  3  3  3  3  3
    4  4  4  4  4  4  4
    5  5  5  5  5  5  5
    6  6  6  6  6  6  6

d = [-4 -2 -1 0 3 4 5];
A = spdiags(B,d,6,6);
full(A)

ans =

  1  0  0  4  5  6
  1  2  0  0  5  6
  1  2  3  0  0  6
  0  2  3  4  0  0
  1  0  3  4  5  0
```

```
  0   2   0   4   5   6
```

Example 5A

This example illustrates the use of the syntax `A = spdiags(B,d,m,n)`, under three conditions:

- `m` is equal to `n`
- `m` is greater than `n`
- `m` is less than `n`

The command used in this example is

```
A = full(spdiags(B, [-2 0 2], m, n))
```

where `B` is the 5-by-3 matrix shown below. The resulting matrix `A` has dimensions `m`-by-`n`, and has nonzero diagonals at `[-2 0 2]` (a sub-diagonal at `-2`, the main diagonal, and a super-diagonal at `2`).

```
B =
    1     6    11
    2     7    12
    3     8    13
    4     9    14
    5    10    15
```

The first and third columns of matrix `B` are used to create the sub- and super-diagonals of `A` respectively. In all three cases though, these two outer columns of `B` are longer than the resulting diagonals of `A`. Because of this, only a part of the columns is used in `A`.

When `m == n` or `m > n`, `spdiags` takes elements of the super-diagonal in `A` from the lower part of the corresponding column of `B`, and elements of the sub-diagonal in `A` from the upper part of the corresponding column of `B`.

When `m < n`, `spdiags` does the opposite, taking elements of the super-diagonal in `A` from the upper part of the corresponding column of `B`, and elements of the sub-diagonal in `A` from the lower part of the corresponding column of `B`.

Part 1 — m is equal to n.

```
A = full(spdiags(B, [-2 0 2], 5, 5))
 Matrix B                      Matrix A
```

```
1    6   11                 6    0   13    0    0
2    7   12                 0    7    0   14    0
3    8   13  == spdiags =>  1    0    8    0   15
4    9   14                 0    2    0    9    0
5   10   15                 0    0    3    0   10
```

`A(3,1)`, `A(4,2)`, and `A(5,3)` are taken from the upper part of `B(:,1)`.

`A(1,3)`, `A(2,4)`, and `A(3,5)` are taken from the lower part of `B(:,3)`.

Part 2 — m is greater than n.

```
A = full(spdiags(B, [-2 0 2], 5, 4))
 Matrix B                      Matrix A

1    6   11                 6    0   13    0
2    7   12                 0    7    0   14
3    8   13  == spdiags =>  1    0    8    0
4    9   14                 0    2    0    9
5   10   15                 0    0    3    0
```

Same as in Part A.

Part 3 — m is less than n.

```
A = full(spdiags(B, [-2 0 2], 4, 5))
 Matrix B                      Matrix A

1    6   11                 6    0   11    0    0
2    7   12                 0    7    0   12    0
3    8   13  == spdiags =>  3    0    8    0   13
4    9   14                 0    4    0    9    0
5   10   15
```

`A(3,1)` and `A(4,2)` are taken from the lower part of `B(:,1)`.

`A(1,3)`, `A(2,4)`, and `A(3,5)` are taken from the upper part of `B(:,3)`.

Example 5B

Extract the diagonals from the first part of this example back into a column format using the command

```
B = spdiags(A)
```

You can see that in each case the original columns are restored (minus those elements that had overflowed the super- and sub-diagonals of matrix A).

Part 1.

```
      Matrix A                        Matrix B

6     0    13     0     0                1    6    0
0     7     0    14     0                2    7    0
1     0     8     0    15  == spdiags =>  3    8   13
0     2     0     9     0                0    9   14
0     0     3     0    10                0   10   15
```

Part 2.

```
    Matrix A                     Matrix B

6     0    13     0                1    6    0
0     7     0    14                2    7    0

diag | speye

Introduced before R2006a

specular

Calculate specular reflectance

Syntax

```
R = specular(Nx,Ny,Nz,S,V)
```

Description

`R = specular(Nx,Ny,Nz,S,V)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` and `V` specify the direction to the light source and to the viewer, respectively. You can specify these directions as three vectors`[x,y,z]` or two vectors `[Theta Phi` (in spherical coordinates).

The specular highlight is strongest when the normal vector is in the direction of `(S+V)/2` where `S` is the source direction, and `V` is the view direction.

The surface spread exponent can be specified by including a sixth argument as in `specular(Nx,Ny,Nz,S,V,spread)`.

speye

Sparse identity matrix

Syntax

```
S = speye(m,n)
S = speye([m n])
S = speye(n)
S = speye
```

Description

`S = speye(m,n)` and `S = speye([m n])` form an `m`-by-`n` sparse matrix with `1`s on the main diagonal.

`S = speye(n)` abbreviates `speye(n,n)`.

`S = speye` returns the sparse form of the 1-by-1 identity matrix.

Examples

`I = speye(1000)` forms the sparse representation of the 1000-by-1000 identity matrix, which requires only about 16 kilobytes of storage. This is the same final result as `I = sparse(eye(1000,1000))`, but the latter requires eight megabytes for temporary storage for the full representation.

`spalloc` | `sprand` | `spones` | `spdiags` | `sprandn`

Introduced before R2006a

spfun

Apply function to nonzero sparse matrix elements

Syntax

```
f = spfun(fun,S)
```

Description

The `spfun` function selectively applies a function to only the *nonzero* elements of a sparse matrix `S`, preserving the sparsity pattern of the original matrix (except for underflow or if `fun` returns zero for some nonzero elements of `S`).

`f = spfun(fun,S)` evaluates `fun(S)` on the elements of `S` that are nonzero. `fun` is a function handle.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

Examples

Given the 4-by-4 sparse diagonal matrix

```
S = spdiags([1:4]',0,4,4)
```

```
S =
   (1,1)         1
   (2,2)         2
   (3,3)         3
   (4,4)         4
```

Because `fun` returns nonzero values for all nonzero element of `S`, `f = spfun(@exp,S)` has the same sparsity pattern as `S`.

```
f =
   (1,1)       2.7183
   (2,2)       7.3891
```

```
   (3,3)       20.0855
   (4,4)       54.5982
```

whereas `exp(S)` has `1`s where `S` has `0`s.

```
full(exp(S))

ans =
    2.7183    1.0000    1.0000    1.0000
    1.0000    7.3891    1.0000    1.0000
    1.0000    1.0000   20.0855    1.0000
    1.0000    1.0000    1.0000   54.5982
```

More About

Tips

Functions that operate element-by-element, like those in the `elfun` directory, are the most appropriate functions to use with `spfun`.

`function_handle`

Introduced before R2006a

sph2cart

Transform spherical coordinates to Cartesian

Syntax

```
[x,y,z] = sph2cart(azimuth,elevation,r)
```

Description

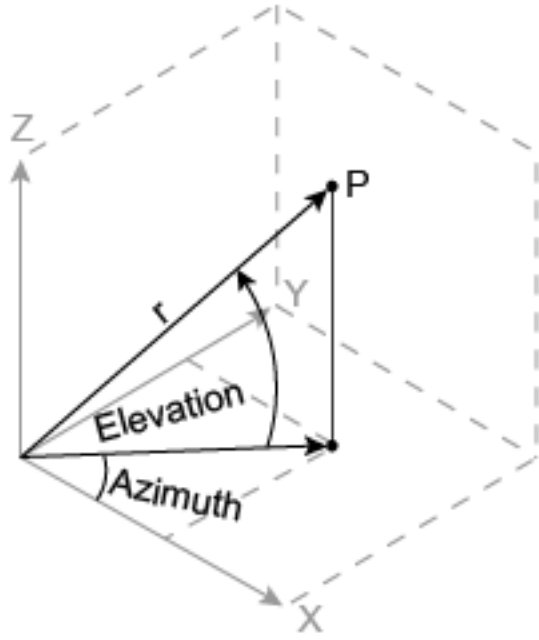
`[x,y,z] = sph2cart(azimuth,elevation,r)` transforms the corresponding elements of spherical coordinate arrays to Cartesian, or *xyz*, coordinates. `azimuth`, `elevation`, and `r` must all be the same size (or any of them can be scalar). `azimuth` and `elevation` are angular displacements in radians. `azimuth` is the counterclockwise angle in the *x*-*y* plane measured from the positive *x*-axis. `elevation` is the elevation angle from the *x*-*y* plane.

More About

Algorithms

The mapping from spherical coordinates to three-dimensional Cartesian coordinates is

```
x = r .* cos(elevation) .* cos(azimuth)
y = r .* cos(elevation) .* sin(azimuth)
z = r .* sin(elevation)
```



See Also

`cart2pol` | `cart2sph` | `pol2cart`

Introduced before R2006a

sphere

Generate sphere

Syntax

```
sphere
sphere(n)
[X,Y,Z] = sphere(n)
```

Description

The `sphere` function generates the *x*-, *y*-, and *z*-coordinates of a unit sphere for use with `surf` and `mesh`.

`sphere` generates a sphere consisting of 20-by-20 faces.

`sphere(n)` draws a `surf` plot of an `n`-by-`n` sphere in the current figure.

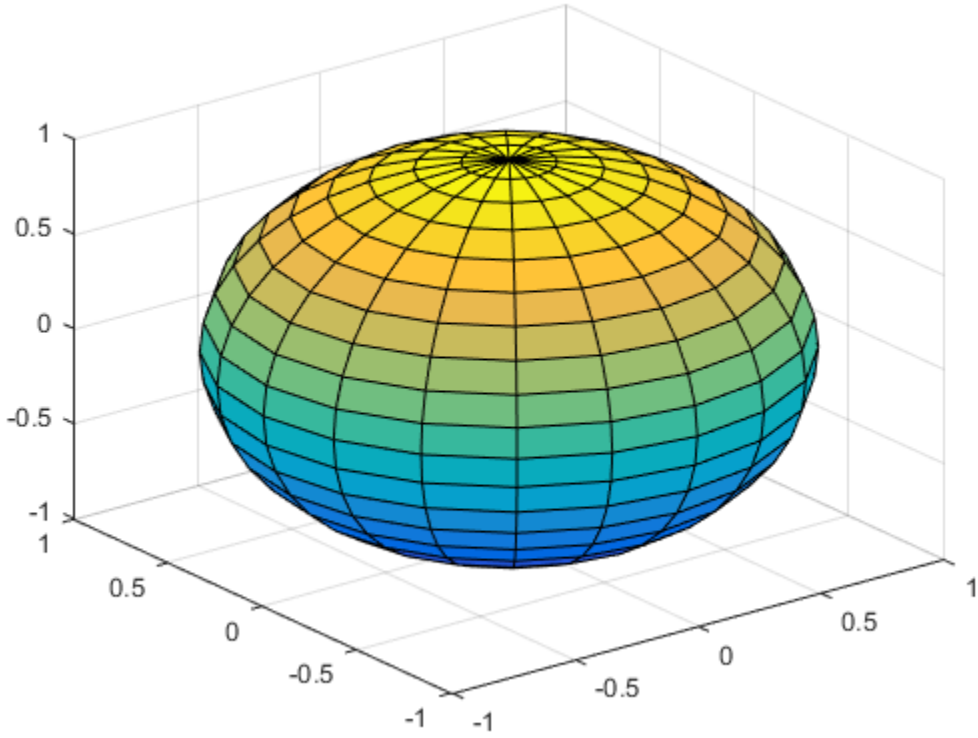
`[X,Y,Z] = sphere(n)` returns the coordinates of a sphere in three matrices that are `(n+1)`-by-`(n+1)` in size. You draw the sphere with `surf(X,Y,Z)` or `mesh(X,Y,Z)`.

Examples

Plot Sphere

Generate and plot a sphere.

```
figure
sphere
```



Plot Multiple Spheres

Define `x`, `y`, and `z` as coordinates of a sphere.

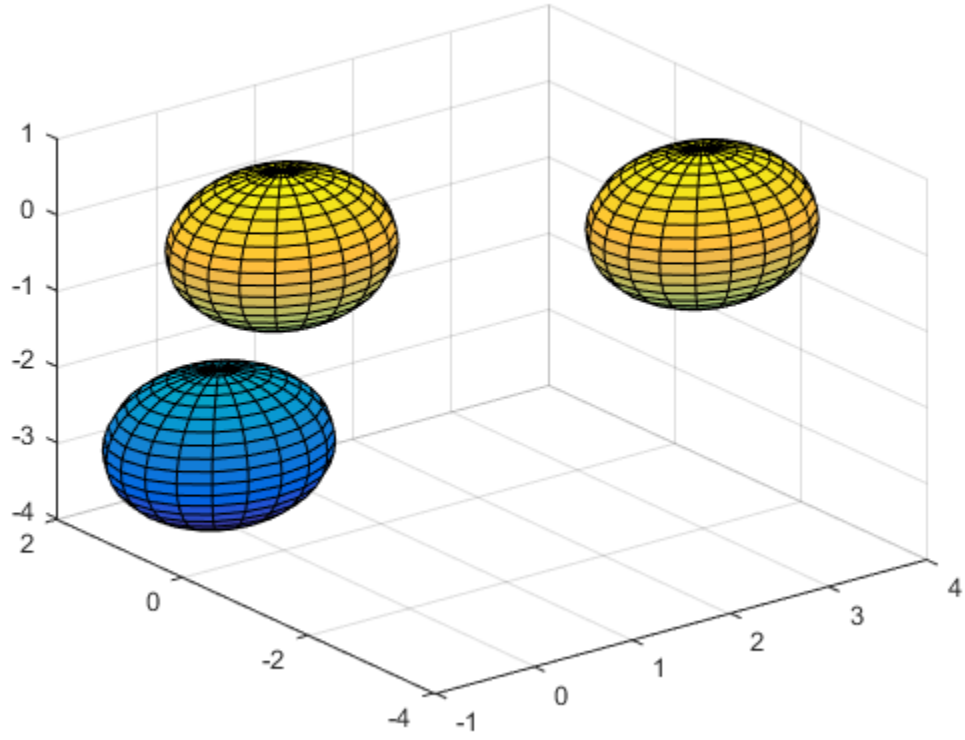
```
[x,y,z] = sphere;
```

Plot a sphere centered at the origin. Plot two more spheres centered at `(3,-2,0)` and `(0,1,-3)`.

```
figure
surf(x,y,z)

hold on
surf(x+3,y-2,z) % centered at (3,-2,0)
```

```
surf(x,y+1,z-3) % centered at (0,1,-3)
```



See Also

`cylinder` | `axis`

Introduced before R2006a

spinmap

Spin colormap

Syntax

```
spinmap
spinmap(t)
spinmap(t,inc)
spinmap('inf')
```

Description

The `spinmap` function shifts the colormap RGB values by some incremental value. For example, if the increment equals 1, color 1 becomes color 2, color 2 becomes color 3, etc.

`spinmap` cyclically rotates the colormap for approximately five seconds using an incremental value of 2.

`spinmap(t)` rotates the colormap for approximately `10*t` seconds. The amount of time specified by `t` depends on your hardware configuration (e.g., if you are running MATLAB software over a network).

`spinmap(t,inc)` rotates the colormap for approximately `10*t` seconds and specifies an increment `inc` by which the colormap shifts. When `inc` is 1, the rotation appears smoother than the default (i.e., 2). Increments greater than 2 are less smooth than the default. A negative increment (e.g., –2) rotates the colormap in a negative direction.

`spinmap('inf')` rotates the colormap for an infinite amount of time. To break the loop, press **Ctrl+C**.

See Also

`colormap` | `colormapeditor`

Introduced before R2006a

spline

Cubic spline data interpolation

Syntax

```
yy = spline(x,Y,xx)
pp = spline(x,Y)
```

Description

`yy = spline(x,Y,xx)` uses a cubic spline interpolation to find `yy`, the values of the underlying function `Y` at the values of the interpolant `xx`. For the interpolation, the independent variable is assumed to be the final dimension of `Y` with the breakpoints defined by `x`. The values in `x` must be distinct.

The sizes of `xx` and `yy` are related as follows:

- If `Y` is a scalar or vector, `yy` has the same size as `xx`.
- If `Y` is an array that is not a vector,
  - If `xx` is a scalar or vector, `size(yy)` equals `[d1, d2, ..., dk, length(xx)]`.
  - If `xx` is an array of size `[m1,m2,...,mj]`, `size(yy)` equals `[d1,d2,...,dk,m1,m2,...,mj]`.

`pp = spline(x,Y)` returns the piecewise polynomial form of the cubic spline interpolant for later use with `ppval` and the spline utility `unmkpp`. `x` must be a vector with distinct values. `Y` can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If `x` and `Y` are vectors of the same size, the not-a-knot end conditions are used.
- If `x` or `Y` is a scalar, it is expanded to have the same length as the other and the not-a-knot end conditions are used. (See Exceptions (1) below).
- If `Y` is a vector that contains two more values than `x` has entries, the first and last value in `Y` are used as the endslopes for the cubic spline. (See Exceptions (2) below.)

Exceptions

1. If `Y` is a vector that contains two more values than `x` has entries, the first and last value in `Y` are used as the endslopes for the cubic spline. If `Y` is a vector, this means
   - `f(x) = Y(2:end-1)`
   - `df(min(x)) = Y(1)`
   - `df(max(x)) = Y(end)`
2. If `Y` is a matrix or an `N`-dimensional array with `size(Y,N)` equal to `length(x)+2`, the following hold:
   - `f(x(j))` matches the value `Y(:,...,:,j+1)` for `j=1:length(x)`
   - `Df(min(x))` matches `Y(:,:,...:,1)`
   - `Df(max(x))` matches `Y(:,:,...:,end)`

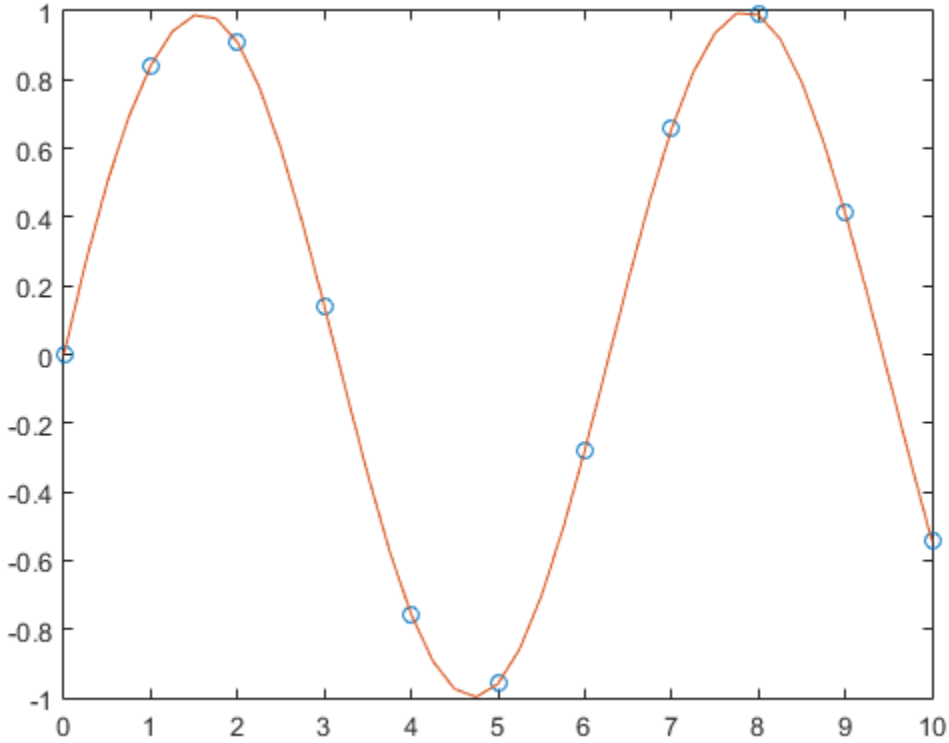
Note You can also perform spline interpolation using the `interp1` function with the command `interp1(x,y,xx,'spline')`. Note that while `spline` performs interpolation on rows of an input matrix, `interp1` performs interpolation on columns of an input matrix.

Examples

Spline Interpolation of Sine Data

This generates a sine curve, then samples the spline over a finer mesh.

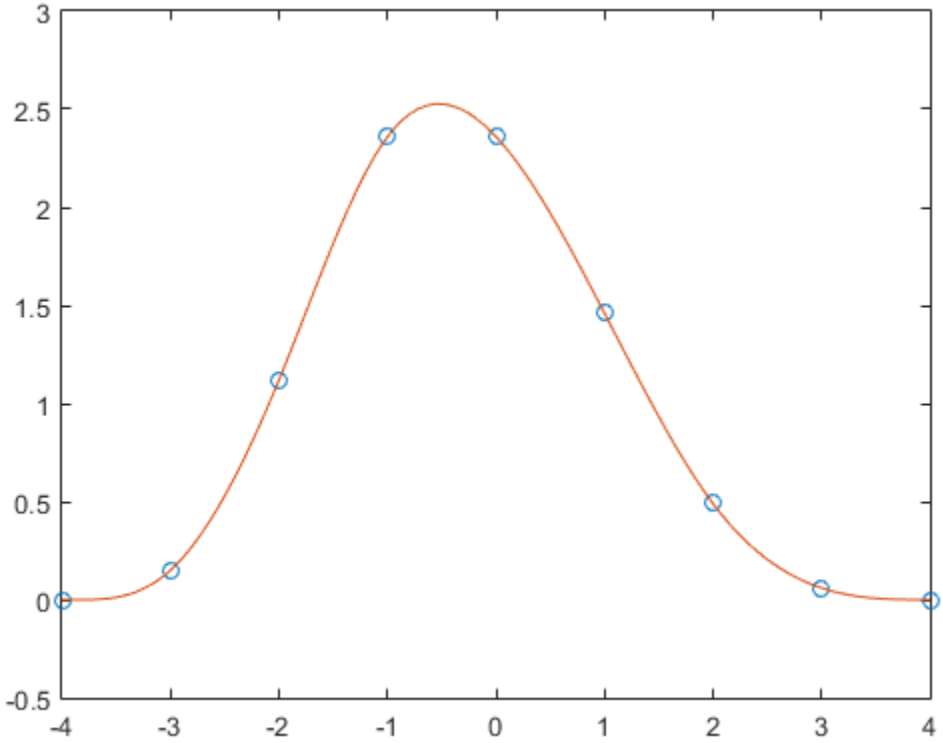
```
x = 0:10;
y = sin(x);
xx = 0:.25:10;
yy = spline(x,y,xx);
plot(x,y,'o',xx,yy)
```



Spline Interpolation of Distribution and Specify Endpoint Slopes

This illustrates the use of clamped or complete spline interpolation where end slopes are prescribed. Zero slopes at the ends of an interpolant to the values of a certain distribution are enforced.

```
x = -4:4;
y = [0 .15 1.12 2.36 2.36 1.46 .49 .06 0];
cs = spline(x,[0 y 0]);
xx = linspace(-4,4,101);
plot(x,y,'o',xx,ppval(cs,xx),'-');
```



Extrapolation Using Cubic Spline

The two vectors

```
t = 1900:10:1990;
p = [ 75.995  91.972  105.711  123.203  131.669 ...
     150.697 179.323  203.212  226.505  249.633 ];
```

represent the census years from 1900 to 1990 and the corresponding United States population in millions of people. The expression

```
spline(t,p,2000)
```

uses the cubic spline to extrapolate and predict the population in the year 2000. The result is

```
ans =

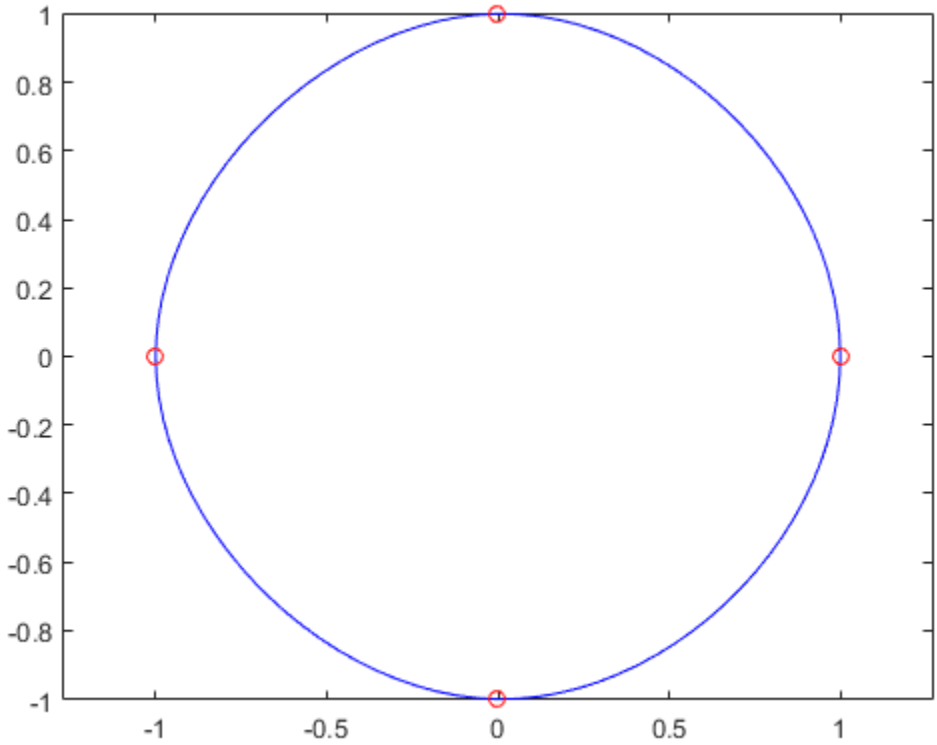
  270.6060
```

Spline Interpolation of Angular Data

The statements

```
x = pi*[0:.5:2];
y = [0  1  0 -1  0  1  0;
     1  0  1  0 -1  0  1];
pp = spline(x,y);
yy = ppval(pp, linspace(0,2*pi,101));
plot(yy(1,:),yy(2,:),'-b',y(1,2:5),y(2,2:5),'or'), axis equal
```

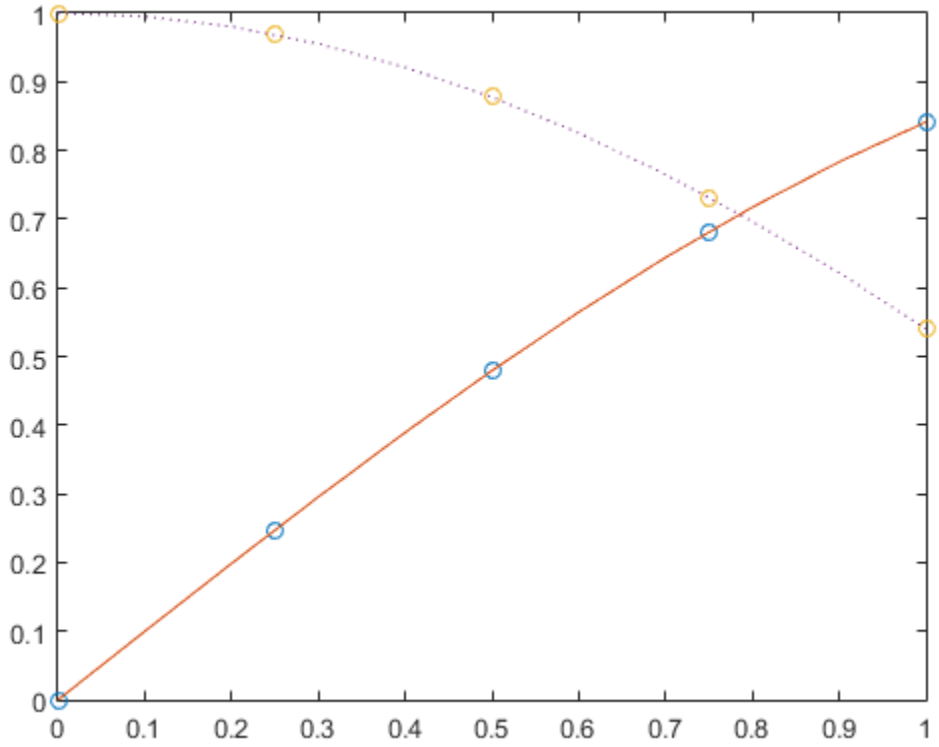
generate the plot of a circle, with the five data points `y(:,2),...,y(:,6)` marked with o's. Note that this `y` contains two more values (i.e., two more columns) than does `x`, hence `y(:,1)` and `y(:,end)` are used as endslopes.



Spline Interpolation of Sine and Cosine Data

The following code generates sine and cosine curves, then samples the splines over a finer mesh.

```
x = 0:.25:1;
Y = [sin(x); cos(x)];
xx = 0:.1:1;
YY = spline(x,Y,xx);
plot(x,Y(1,:),'o',xx,YY(1,:),'-')
hold on
plot(x,Y(2,:),'o',xx,YY(2,:),':')
hold off
```



More About

Algorithms

A tridiagonal linear system (with, possibly, several right sides) is being solved for the information needed to describe the coefficients of the various cubic polynomials which make up the interpolating spline. `spline` uses the functions `ppval`, `mkpp`, and `unmkpp`. These routines form a small suite of functions for working with piecewise polynomials. For access to more advanced features, see the `interp1` reference page, the command-line help for these functions, and the Curve Fitting Toolbox spline functions.

Introduced before R2006a

split

Split calendar duration into numeric and duration units

Syntax

```
[X1,X2,...] = split(t,units)
```

Description

`[X1,X2,...] = split(t,units)` returns the calendar duration values in `t` as separate numeric arrays, one for each of the date or time units specified by `units`. The number of date and time units specified by `units` determines the number of output arguments.

Examples

Split Calendar Duration Array

Create a `calendarDuration` array.

```
T = calmonths(15:17) + caldays(8) + hours(1.2345)
```

```
T =

   1y 3mo 8d 1h 14m 4.2s   1y 4mo 8d 1h 14m 4.2s   1y 5mo 8d 1h 14m 4.2s
```

Get the month, day, and time values.

```
[m,d,t] = split(T,{'months','days','time'})
```

```
m =

    15    16    17
```

```
d =

     8     8     8

t =

   01:14:04   01:14:04   01:14:04
```

Get the year, month, day, and time values

```
[y,m,d,t] = split(T,{'years','months','days','time'})

y =

     1     1     1

m =

     3     4     5

d =

     8     8     8

t =

   01:14:04   01:14:04   01:14:04
```

When you request both the year and month values, `split` carries over month values greater than 12 to the year value.

Input Arguments

`t` — Input calendar duration

`calendarDuration` array

Input calendar duration, specified as a `calendarDuration` array.

`units` — Date and time units

string | cell array of strings

Date and time units, specified as a string or a cell array of strings. The string values can be one or more of the values in this table.

String Value	Split `t` into Units of...
`'years'`	years
`'quarters'`	quarters
`'months'`	months
`'weeks'`	weeks
`'days'`	days
`'time'`	time, in the format hours:minutes:seconds

You must specify date and time units from largest to smallest. For example, `{'years','months'}` is valid, but `{'months','years'}` is not.

Example: `{'years','months','days'}`

Data Types: `char` | `cell`

Output Arguments

`X1,X2,...` — Output arrays

scalar | vector | matrix | multidimensional array

Output arrays, returned as one or more scalars, vectors, matrices, or multidimensional arrays. `split` returns year, month, and day values in numeric arrays and time values in `duration` arrays.

See Also

`caldays` | `calmonths` | `calquarters` | `calweeks` | `calyears` | `time`

Introduced in R2014b

spones

Replace nonzero sparse matrix elements with ones

Syntax

```
R = spones(S)
```

Description

`R = spones(S)` generates a matrix `R` with the same sparsity structure as `S`, but with `1`'s in the nonzero positions.

Examples

`c = sum(spones(S))` is the number of nonzeros in each column.

`r = sum(spones(S'))'` is the number of nonzeros in each row.

`sum(c)` and `sum(r)` are equal, and are equal to `nnz(S)`.

See Also

`nnz` | `spalloc` | `spfun`

Introduced before R2006a

spparms

Set parameters for sparse matrix routines

Syntax

```
spparms('key',value)
spparms
values = spparms
[keys,values] = spparms
spparms(values)
value = spparms('key')
spparms('default')
spparms('tight')
```

Description

`spparms('key',value)` sets one or more of the *tunable* parameters used in the sparse routines. In ordinary use, you should never need to deal with this function.

The meanings of the `key` parameters are

`'spumoni'`	Sparse Monitor flag:
`0`	Produces no diagnostic output, the default
`1`	Produces information about choice of algorithm based on matrix structure, and about storage allocation
`2`	Also produces very detailed information about the sparse matrix algorithms
`'thr_rel'`, `'thr_abs'`	Minimum degree threshold is `thr_rel*mindegree + thr_abs`.
`'exact_d'`	Nonzero to use exact degrees in minimum degree. Zero to use approximate degrees.
`'supernd'`	If positive, minimum degree amalgamates the supernodes every `supernd` stages.

`'rreduce'`	If positive, minimum degree does row reduction every `rreduce` stages.
`'wh_frac'`	Rows with `density > wh_frac` are ignored in `colmmd`.
`'autommd'`	Nonzero to use minimum degree (MMD) orderings with QR-based \ and /.
`'autoamd'`	Nonzero to use `colamd` ordering with the LU-based \ and /, and to use `amd` with Cholesky-based \ and /.
`'piv_tol'`	Pivot tolerance used by the LU-based \ and /.
`'bandden'`	Band density used by \ and / for banded matrices. Band density is defined as (# nonzeros in the band)/(# nonzeros in a full band). If `bandden = 1.0`, never use band solver. If `bandden = 0.0`, always use band solver. Default is `0.5`.
`'umfpack'`	Nonzero to use UMFPACK instead of the v4 LU-based solver in \ and /.
`'sym_tol'`	Symmetric pivot tolerance. See `lu` for more information about the role of the symmetric pivot tolerance.

`spparms`, by itself, prints a description of the current settings.

`values = spparms` returns a vector whose components give the current settings.

`[keys,values] = spparms` returns that vector, and also returns a character matrix whose rows are the keywords for the parameters.

`spparms(values)`, with no output argument, sets all the parameters to the values specified by the argument vector.

`value = spparms('key')` returns the current setting of one parameter.

`spparms('default')` sets all the parameters to their default settings.

`spparms('tight')` sets the minimum degree ordering parameters to their *tight* settings, which can lead to orderings with less fill-in, but which make the ordering functions themselves use more execution time.

The key parameters for `default` and `tight` settings are

	Keyword	Default	Tight
`values(1)`	`'spumoni'`	`0.0`	

	Keyword	Default	Tight
values(2)	'thr_rel'	1.1	1.0
values(3)	'thr_abs'	1.0	0.0
values(4)	'exact_d'	0.0	1.0
values(5)	'supernd'	3.0	1.0
values(6)	'rreduce'	3.0	1.0
values(7)	'wh_frac'	0.5	0.5
values(8)	'autommd'	1.0	
values(9)	'autoamd'	1.0	
values(10)	'piv_tol'	0.1	
values(11)	'bandden'	0.5	
values(12)	'umfpack'	1.0	
values(13)	'sym_tol'	0.001

sprand

Sparse uniformly distributed random matrix

Syntax

```
R = sprand(S)
R = sprand(m,n,density)
R = sprand(m,n,density,rc)
```

Description

`R = sprand(S)` has the same sparsity structure as `S`, but uniformly distributed random entries.

`R = sprand(m,n,density)` is a random, `m`-by-`n`, sparse matrix with approximately `density*m*n` uniformly distributed nonzero entries (`0 <= density <= 1`).

`R = sprand(m,n,density,rc)` also has reciprocal condition number approximately equal to `rc`. `R` is constructed from a sum of matrices of rank one.

If `rc` is a vector of length `lr`, where `lr <= min(m,n)`, then `R` has `rc` as its first `lr` singular values, all others are zero. In this case, `R` is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

More About

Tips

- `sprand` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

See Also

`sprandn` | `sprandsym`

Introduced before R2006a

sprandn

Sparse normally distributed random matrix

Syntax

```
R = sprandn(S)
R = sprandn(m,n,density)
R = sprandn(m,n,density,rc)
```

Description

`R = sprandn(S)` has the same sparsity structure as `S`, but normally distributed random entries with mean `0` and variance `1`.

`R = sprandn(m,n,density)` is a random, `m`-by-`n`, sparse matrix with approximately `density*m*n` normally distributed nonzero entries (`0 <= density <= 1`).

`R = sprandn(m,n,density,rc)` also has reciprocal condition number approximately equal to `rc`. `R` is constructed from a sum of matrices of rank one.

If `rc` is a vector of length `lr`, where `lr <= min(m,n)`, then `R` has `rc` as its first `lr` singular values, all others are zero. In this case, `R` is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

More About

Tips

- `sprandn` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

See Also

`sprand` | `sprandsym`

Introduced before R2006a

sprandsym

Sparse symmetric random matrix

Syntax

```
R = sprandsym(S)
R = sprandsym(n,density)
R = sprandsym(n,density,rc)
R = sprandsym(n,density,rc,kind)
R = sprandsym(S,[],rc,3)
```

Description

`R = sprandsym(S)` returns a symmetric random matrix whose lower triangle and diagonal have the same structure as `S`. Its elements are normally distributed, with mean `0` and variance `1`.

`R = sprandsym(n,density)` returns a symmetric random, `n`-by-`n`, sparse matrix with approximately `density*n*n` nonzeros; each entry is the sum of one or more normally distributed random samples, and (`0 <= density <= 1`).

`R = sprandsym(n,density,rc)` returns a matrix with a reciprocal condition number equal to `rc`. The distribution of entries is nonuniform; it is roughly symmetric about 0; all are in [−1,1].

If `rc` is a vector of length `n`, then `R` has eigenvalues `rc`. Thus, if `rc` is a positive (nonnegative) vector then `R` is a positive (nonnegative) definite matrix. In either case, `R` is generated by random Jacobi rotations applied to a diagonal matrix with the given eigenvalues or condition number. It has a great deal of topological and algebraic structure.

`R = sprandsym(n,density,rc,kind)` is positive definite.

- If kind = 1, `R` is generated by random Jacobi rotation of a positive definite diagonal matrix. `R` has the desired condition number exactly.
- If kind = 2, `R` is a shifted sum of outer products. `R` has the desired condition number only approximately, but has less structure.

`R = sprandsym(S,[],rc,3)` has the same structure as the matrix `S` and approximate condition number `1/rc`.

More About

Tips

`sprandsym` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

See Also

`sprand | sprandn`

Introduced before R2006a

sprank

Structural rank

Syntax

```
r = sprank(A)
```

Description

`r = sprank(A)` is the structural rank of the sparse matrix `A`. For all values of `A`,

```
sprank(A) >= rank(full(A))
```

In exact arithmetic, `sprank(A) == rank(full(sprandn(A)))` with a probability of one.

Examples

```
A = [1    0    2    0
     2    0    4    0 ];

A = sparse(A);

sprank(A)

ans =
     2

rank(full(A))

ans =
     1
```

Introduced before R2006a

sprintf

Format data into string

Syntax

```
str = sprintf(formatSpec,A1,...,An)
[str,errmsg] = sprintf(formatSpec,A1,...,An)
```

Description

`str = sprintf(formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec` in column order, and returns the results to string `str`.

`[str,errmsg] = sprintf(formatSpec,A1,...,An)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is empty.

Examples

Floating-Point Formats

Format a floating-point number using `%e`, `%f`, and `%g` specifiers.

```
A = 1/eps;
str_e = sprintf('%0.5e',A)
str_f = sprintf('%0.5f',A)
str_g = sprintf('%0.5g',A)
```

```
str_e =

4.50360e+15

str_f =

4503599627370496.00000

str_g =
```

```
4.5036e+15
```

Literal Text and Array Inputs

Combine literal text with array values to create a string.

```
formatSpec = 'The array is %dx%d.';
A1 = 2;
A2 = 3;
str = sprintf(formatSpec,A1,A2)
```

```
str =

The array is 2x3.
```

Integer Format with Floating-Point Inputs

Explicitly convert double-precision values to integers.

```
str = sprintf('%d',round(pi))
```

```
str =

3
```

Specify Field Width of a Printed Value

Specify the minimum width of the printed value.

```
str = sprintf('%025d',[123456])
```

```
str =
0000000000000000000123456
```

The `0` flag in the `%025d` format specifier requests leading zeros in the output.

Reorder Inputs Using Position Identifier (n$)

Reorder the input values using the `n$` position identifier.

```
A1 = 'X';
```

```
A2 = 'Y';
A3 = 'Z';
formatSpec = ' %3$s %2$s %1$s';
str = sprintf(formatSpec,A1,A2,A3)

str =
 Z Y X
```

Create a String from Values in Cell Array

```
C = { 1,   2,   3 ;
     'AA','BB','CC'};

str = sprintf(' %d %s',C{:})

str =
 1 AA 2 BB 3 CC
```

The syntax `C{:}` creates a comma-separated list of arrays that contain the contents of each cell from `C` in column order. For example, `C{1}==1` and `C{2}=='AA'`.

Input Arguments

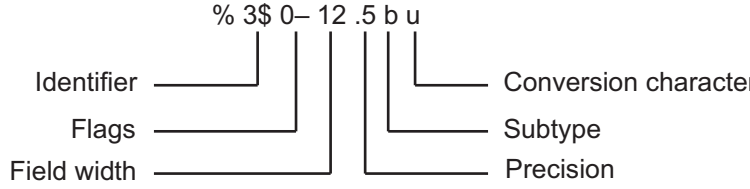
`formatSpec` — Format of output fields

string containing formatting operators

Format of the output fields, specified as a string containing formatting operators. `formatSpec` also can include ordinary text and special characters.

Formatting Operator

A formatting operator starts with a percent sign, `%`, and ends with a conversion character. The conversion character is required. Optionally, you can specify identifier, flags, field width, precision, and subtype operators between `%` and the conversion character. (Spaces are invalid between operators and are shown here only for readability).



Conversion Character

This table shows conversion characters to format numeric and character data as strings.

Value Type	Conversion	Details
Integer, signed	`%d` or `%i`	Base 10
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal), lowercase letters `a`–`f`
	`%X`	Same as `%x`, uppercase letters `A`–`F`
Floating-point number	`%f`	Fixed-point notation (Use a precision operator to specify the number of digits after the decimal point.)
	`%e`	Exponential notation, such as `3.141593e+00` (Use a precision operator to specify the number of digits after the decimal point.)
	`%E`	Same as `%e`, but uppercase, such as `3.141593E+00` (Use a precision operator to specify the number of digits after the decimal point.)
	`%g`	The more compact of `%e` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
	`%G`	The more compact of `%E` or `%f`, with no trailing zeros (Use a precision operator to specify the number of significant digits.)
Characters	`%c`	Single character
	`%s`	String of characters

Optional Operators

The optional identifier, flags, field width, precision, and subtype operators further define the format of the output string.

- **Identifier**

Order for processing values from the input list. Use the syntax *n*$, where *n* represents the position of the value in the input list.

Example: `'%3$s %2$s %1$s %2$s'` prints inputs `'A'`, `'B'`, `'C'` as follows: `C B A B`.

- **Flags**

`'–'`	Left-justify. **Example:** `%-5.2f`
`'+'`	Always print a sign character (+ or –) for any value. **Example:** `%+5.2f`
`' '`	Insert a space before the value. **Example:** `% 5.2f`
`'0'`	Pad to field width with zeros before the value. **Example:** `%05.2f`
`'#'`	Modify selected numeric conversions: • For `%o`, `%x`, or `%X`, print `0`, `0x`, or `0X` prefix. • For `%f`, `%e`, or `%E`, print decimal point even when precision is 0. • For `%g` or `%G`, do not remove trailing zeros or decimal point. **Example:** `%#5.0f`

- **Field Width**

  Minimum number of characters to print. The field width operator can be a number, or an asterisk (`*`) to refer to an argument in the input list.

  Example: The input list `('%12d',intmax)` is equivalent to `('%*d', 12, intmax)`.

  The function pads to field width with spaces before the value unless otherwise specified by flags.

- **Precision**

For `%f`, `%e`, or `%E`	Number of digits to the right of the decimal point **Example:** `'%.4f'` prints `pi` as `'3.1416'`

For `%g` or `%G`	Number of significant digits **Example:** `'%.4g'` prints `pi` as `' 3.142'`

The precision operator can be a number, or an asterisk (`*`) to refer to an argument in the input list.

Example: The input list `('%6.4f', pi)` is equivalent to `('%*.*f', 6, 4, pi)`.

Note: If you specify a precision operator for floating-point values that exceeds the precision of the input numeric data type, the results might not match the input values to the precision you specified. The result depends on your computer hardware and operating system.

- **Subtypes**

  Certain conversion characters can support a subtype. The subtype operator immediately precedes the conversion character. This table shows the conversions that can use subtypes.

Input Value Type	Subtype and Conversion Character	Output Value Type

Floating-point number	`%bx` or `%bX`
	`%bo`
	`%bu`
		Double-precision hexadecimal, octal, or decimal value
		Example: `%bx` prints `pi` as `400921fb54442d18`

	`%tx` or `%tX`
	`%to`
	`%tu`
		Single-precision hexadecimal, octal, or decimal value
		Example: `%tx` prints `pi` as `40490fdb`

Integer	`%ld` or `%li`
	`%lo`
	`%lu`
	`%lx` or `%lX`
		64-bit value

Integer	`%hd` or `%hi`
	`%ho`
	`%hu`
		16-bit value

Input Value Type	Subtype and Conversion Character	Output Value Type
	`%hx` or `%hX`	

Text Before or After Formatting Operators

`formatSpec` can also include additional text before a percent sign, `%`, or after a conversion character. The text can be:

- Ordinary text to print.
- Special characters that you cannot enter as ordinary text. This table shows how to represent special characters in `formatSpec`.

Special Character	Representation
Single quotation mark	`''`
Percent character	`%%`
Backslash	`\\`
Alarm	`\a`
Backspace	`\b`
Form feed	`\f`
New line	`\n`
Carriage return	`\r`
Horizontal tab	`\t`
Vertical tab	`\v`
Character whose ASCII code is the hexadecimal number, `N`	`\xN`
Character whose ASCII code is the octal number, `N`	`\N`

Notable Behavior of Conversions with Formatting Operators

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.

  Example: `'%s'` converts `pi` to `3.141593e+00`.

- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters.

  Example: `'%s'` converts `[65 66 67]` to `ABC`.

`A1,...,An` — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`

Output Arguments

`str` — Formatted text

string

Formatted text, returned as a string.

`errmsg` — Error message

string

Error message, returned as a string, when the operation is unsuccessful. Otherwise, `errmsg` is empty.

More About

Tips

- The `sprintf` function is similar to `fprintf`, but `fprintf` prints to a file or to the Command Window.
- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

spy

Visualize sparsity pattern

Syntax

```
spy(S)
spy(S,markersize)
spy(S,'LineSpec')
spy(S,'LineSpec',markersize)
```

Description

`spy(S)` plots the sparsity pattern of any matrix `S`.

`spy(S,markersize)`, where `markersize` is an integer, plots the sparsity pattern using markers of the specified point size.

`spy(S,'LineSpec')`, where `LineSpec` is a string, uses the specified plot marker type and color.

`spy(S,'LineSpec',markersize)` uses the specified type, color, and size for the plot markers.

`S` is usually a sparse matrix, but full matrices are acceptable, in which case the locations of the nonzero elements are plotted.

Note `spy` replaces `format +`, which takes much more space to display essentially the same information.

Examples

Plot Sparsity Pattern

This example plots the 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster Fuller geodesic dome. This matrix also represents the soccer ball and the carbon-60 molecule.

```
B = bucky;
spy(B)
```

Introduced before R2006a

sqrt

Square root

Syntax

```
B = sqrt(X)
```

Description

`B = sqrt(X)` returns the square root of each element of the array `X`. For the elements of `X` that are negative or complex, `sqrt(X)` produces complex results.

Examples

```
sqrt((-2:2)')
ans =
      0 + 1.4142i
      0 + 1.0000i
      0
 1.0000
 1.4142
```

More About

Tips

See `sqrtm` for the matrix square root.

`nthroot` | `sqrtm` | `realsqrt`

Introduced before R2006a

sqrtm

Matrix square root

Syntax

```
X = sqrtm(A)
[X, resnorm] = sqrtm(A)
[X, alpha, condest] = sqrtm(A)
```

Description

`X = sqrtm(A)` is the principal square root of the matrix `A`, i.e. `X*X = A`.

`X` is the unique square root for which every eigenvalue has nonnegative real part. If `A` has any eigenvalues with negative real parts then a complex result is produced. If `A` is singular then `A` may not have a square root. A warning is printed if exact singularity is detected.

`[X, resnorm] = sqrtm(A)` does not print any warning, and returns the residual, `norm(A-X^2,'fro')/norm(A,'fro')`.

`[X, alpha, condest] = sqrtm(A)` returns a stability factor `alpha` and an estimate `condest` of the matrix square root condition number of `X`. The residual `norm(A-X^2,'fro')/norm(A,'fro')` is bounded approximately by `n*alpha*eps` and the Frobenius norm relative error in `X` is bounded approximately by `n*alpha*condest*eps`, where `n = max(size(A))`.

Examples

Example 1

A matrix representation of the fourth difference operator is

```
A =
     5    -4     1     0     0
```

```
    -4     6    -4     1     0
     1    -4     6    -4     1
     0     1    -4     6    -4
     0     0     1    -4     5
```

This matrix is symmetric and positive definite. Its unique positive definite square root, `Y = sqrtm(A)`, is a representation of the second difference operator.

```
 Y =
     2    -1    -0    -0    -0
    -1     2    -1     0    -0
     0    -1     2    -1     0
    -0     0    -1     2    -1
    -0    -0    -0    -1     2
```

Example 2

The matrix

```
A =
     7    10
    15    22
```

has four square roots. Two of them are

```
Y1 =
    1.5667    1.7408
    2.6112    4.1779
```

and

```
Y2 =
     1     2
     3     4
```

The other two are `-Y1` and `-Y2`. All four can be obtained from the eigenvalues and vectors of `A`.

```
[V,D] = eig(A);
D =
    0.1386         0
         0   28.8614
```

The four square roots of the diagonal matrix `D` result from the four choices of sign in

```
S =
    ±0.3723          0
          0    ±5.3723
```

All four Ys are of the form

```
Y = V*S/V
```

The `sqrtm` function chooses the two plus signs and produces `Y1`, even though `Y2` is more natural because its entries are integers.

More About

Tips

If `A` is real, symmetric and positive definite, or complex, Hermitian and positive definite, then so is the computed matrix square root.

Some matrices, like `A = [0 1; 0 0]`, do not have any square roots, real or complex, and `sqrtm` cannot be expected to produce one.

`expm` | `funm` | `logm`

Introduced before R2006a

squeeze

Remove singleton dimensions

Syntax

```
B = squeeze(A)
```

Description

`B = squeeze(A)` returns an array `B` with the same elements as `A`, but with all singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. Two-dimensional arrays are unaffected by `squeeze`; if `A` is a row or column vector or a scalar (1-by-1) value, then `B = A`.

Examples

Remove Singleton Dimension from Array

Create a 2-by-1-by-3 array and remove the singleton column dimension to form a 2-by-3 matrix.

```
y = rand(2,1,3)
z = squeeze(y)
```

```
y(:,:,1) =

    0.8147
    0.9058

y(:,:,2) =

    0.1270
    0.9134
```

```
y(:,:,3) =

    0.6324
    0.0975

z =

    0.8147    0.1270    0.6324
    0.9058    0.9134    0.0975
```

Create Vector from Array with Singleton Dimensions

Create a 1-by-1-by-5 array of ones.

```
mat = repmat(1,[1,1,5])

mat(:,:,1) =

     1

mat(:,:,2) =

     1

mat(:,:,3) =

     1

mat(:,:,4) =

     1

mat(:,:,5) =

     1
```

Condense the data in the third dimension to create a 5-by-1 column vector.

```
squeeze(mat)

ans =

     1
     1
     1
     1
     1
```

See Also

reshape | shiftdim | permute

Introduced before R2006a

ss2tf

Convert state-space representation to transfer function

Syntax

```
[b,a] = ss2tf(A,B,C,D)
[b,a] = ss2tf(A,B,C,D,ni)
```

Description

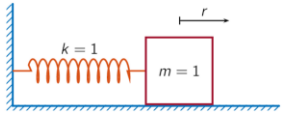
`[b,a] = ss2tf(A,B,C,D)` converts a state-space representation of a system into an equivalent transfer function. `ss2tf` returns the Laplace-transform transfer function for continuous-time systems and the Z-transform transfer function for discrete-time systems.

`[b,a] = ss2tf(A,B,C,D,ni)` returns the transfer function that results when the `ni`th input of a system with multiple inputs is excited by a unit impulse.

Examples

Mass-Spring System

A one-dimensional discrete-time oscillating system consists of a unit mass, m, attached to a wall by a spring of unit elastic constant. A sensor samples the acceleration, a, of the mass at $F_s = 5$ Hz.



Generate 50 time samples. Define the sampling interval $\Delta t = 1/F_s$.

```
Fs = 5;
```

```
dt = 1/Fs;
N = 50;
t = dt*(0:N-1);
```

The oscillator can be described by the state-space equations

$$x(k+1) = Ax(k) + Bu(k),$$
$$y(k) = Cx(k) + Du(k),$$

where $x = (r \quad v)^T$ is the state vector, r and v are respectively the position and velocity of the mass, and the matrices

$$A = \begin{pmatrix} \cos\Delta t & \sin\Delta t \\ -\sin\Delta t & \cos\Delta t \end{pmatrix}, \quad B = \begin{pmatrix} 1-\cos\Delta t \\ \sin\Delta t \end{pmatrix}, \quad C = (-1 \quad 0), \quad D = (1).$$

```
A = [cos(dt) sin(dt);-sin(dt) cos(dt)];
B = [1-cos(dt);sin(dt)];
C = [-1 0];
D = 1;
```

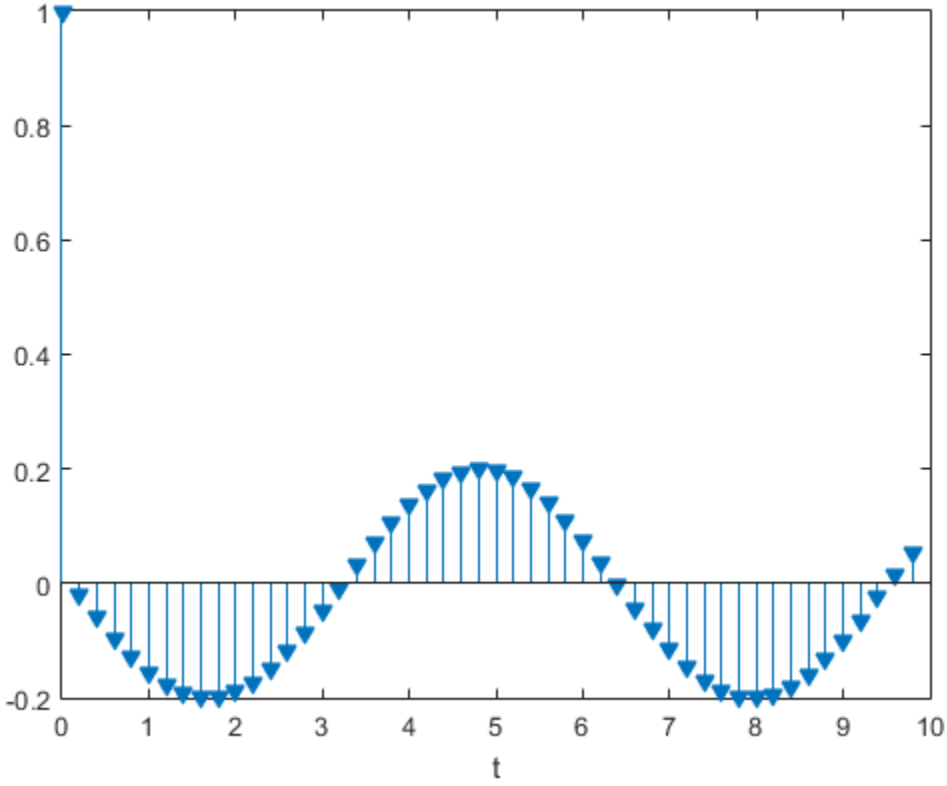
The system is excited with a unit impulse in the positive direction. Use the state-space model to compute the time evolution of the system starting from an all-zero initial state.

```
u = [1 zeros(1,N-1)];

x = [0;0];
for k = 1:N
    y(k) = C*x + D*u(k);
    x = A*x + B*u(k);
end
```

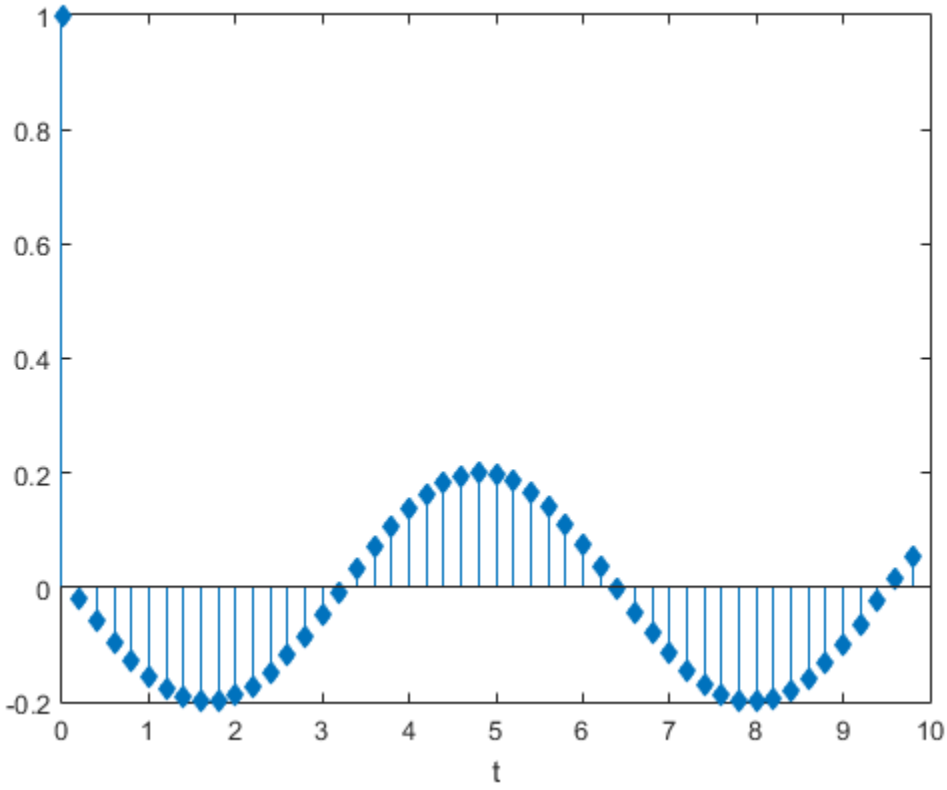
Plot the acceleration of the mass as a function of time.

```
stem(t,y,'v','filled')
xlabel('t')
```



Compute the time-dependent acceleration using the transfer function $H(z)$ to filter the input. Plot the result.

```
[b,a] = ss2tf(A,B,C,D);
yt = filter(b,a,u);
stem(t,yt,'d','filled')
xlabel('t')
```

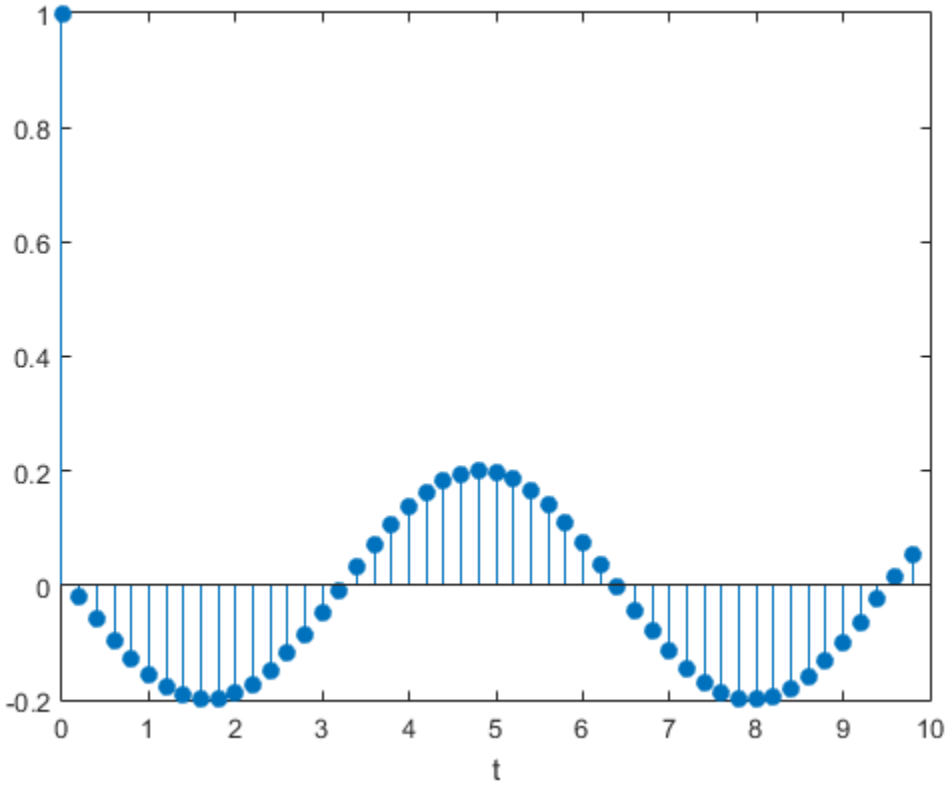


The transfer function of the system has an analytic expression:

$$H(z) = \frac{1 - z^{-1}(1 + \cos \Delta t) + z^{-2} \cos \Delta t}{1 - 2z^{-1} \cos \Delta t + z^{-2}}.$$

Use the expression to filter the input. Plot the response.

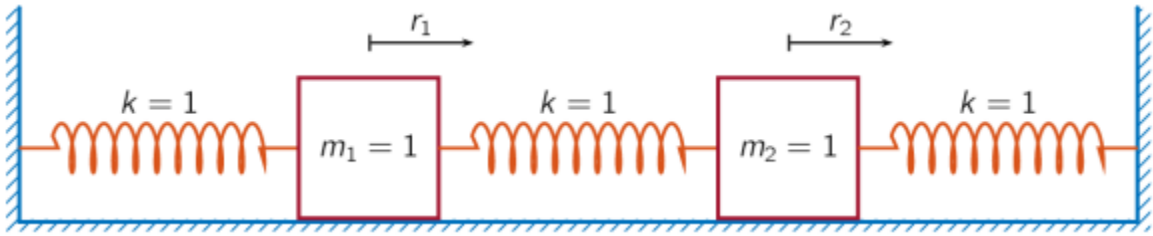
```
bf = [1 -(1+cos(dt)) cos(dt)];
af = [1 -2*cos(dt) 1];
yf = filter(bf,af,u);
stem(t,yf,'o','filled')
xlabel('t')
```



The result is the same in all three cases.

Two-Body Oscillator

An ideal one-dimensional oscillating system consists of two unit masses, m_1 and m_2, confined between two walls. Each mass is attached to the nearest wall by a spring of unit elastic constant. Another such spring connects the two masses. Sensors sample a_1 and a_2, the accelerations of the masses, at $F_s = 16$ Hz.



Specify a total measurement time of 16 s. Define the sampling interval $\Delta t = 1/F_s$.

```
Fs = 16;
dt = 1/Fs;
N = 257;
t = dt*(0:N-1);
```

The system can be described by the state-space model

$$x(n+1) = Ax(n) + Bu(n),$$
$$y(n) = Cx(n) + Du(n),$$

where $x = (r_1 \quad v_1 \quad r_2 \quad v_2)^T$ is the state vector and r_i and v_i are respectively the location and the velocity of the i-th mass. The input vector $u = (u_1 \quad u_2)^T$ and the output vector $y = (a_1 \quad a_2)^T$. The state-space matrices are

$$A = \exp(A_c \Delta t), \quad B = A_c^{-1}(A - I)B_c, \quad C = \begin{pmatrix} -2 & 0 & 1 & 0 \\ 1 & 0 & -2 & 0 \end{pmatrix}, \quad D = I,$$

the continuous-time state-space matrices are

$$A_c = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -2 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & -2 & 0 \end{pmatrix}, \quad B_c = \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix},$$

and I denotes an identity matrix of the appropriate size.

```
Ac = [0 1 0 0;-2 0 1 0;0 0 0 1;1 0 -2 0];
A = expm(Ac*dt);
Bc = [0 0;1 0;0 0;0 1];
B = Ac\(A-eye(4))*Bc;
C = [-2 0 1 0;1 0 -2 0];
D = eye(2);
```

The first mass, m_1, receives a unit impulse in the positive direction.

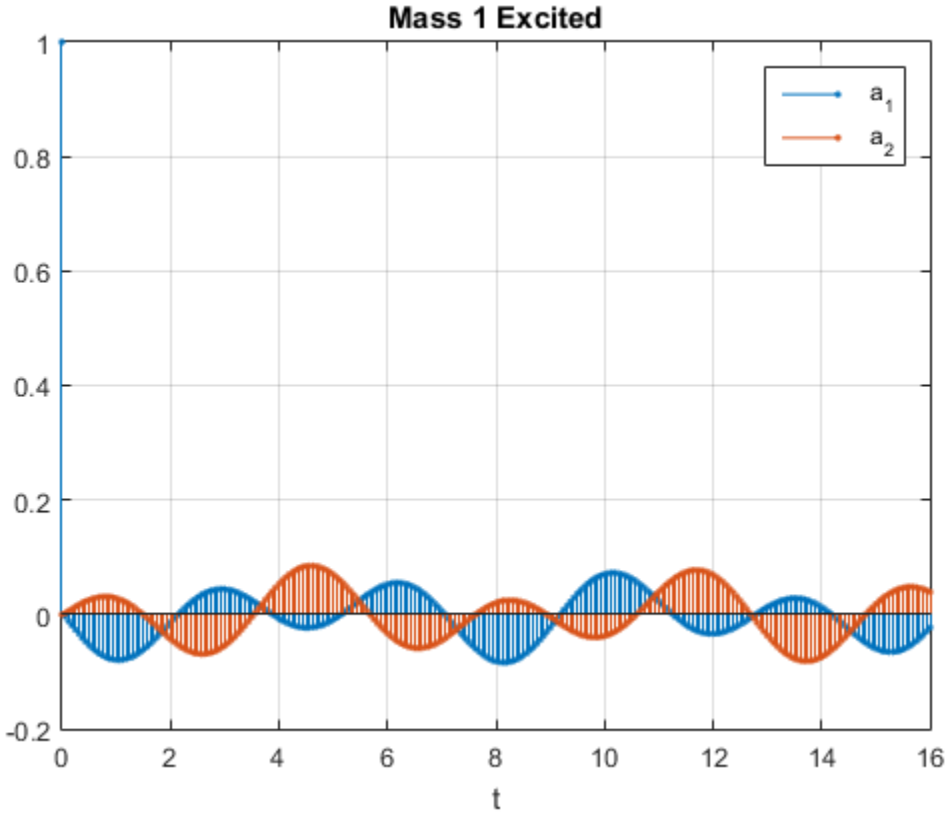
```
ux = [1 zeros(1,N-1)];
u0 = zeros(1,N);
u = [ux;u0];
```

Use the model to compute the time evolution of the system starting from an all-zero initial state.

```
x = [0;0;0;0];
for k = 1:N
    y(:,k) = C*x + D*u(:,k);
    x = A*x + B*u(:,k);
end
```

Plot the accelerations of the two masses as functions of time.

```
stem(t,y','.')
xlabel('t')
legend('a_1','a_2')
title('Mass 1 Excited')
grid
```

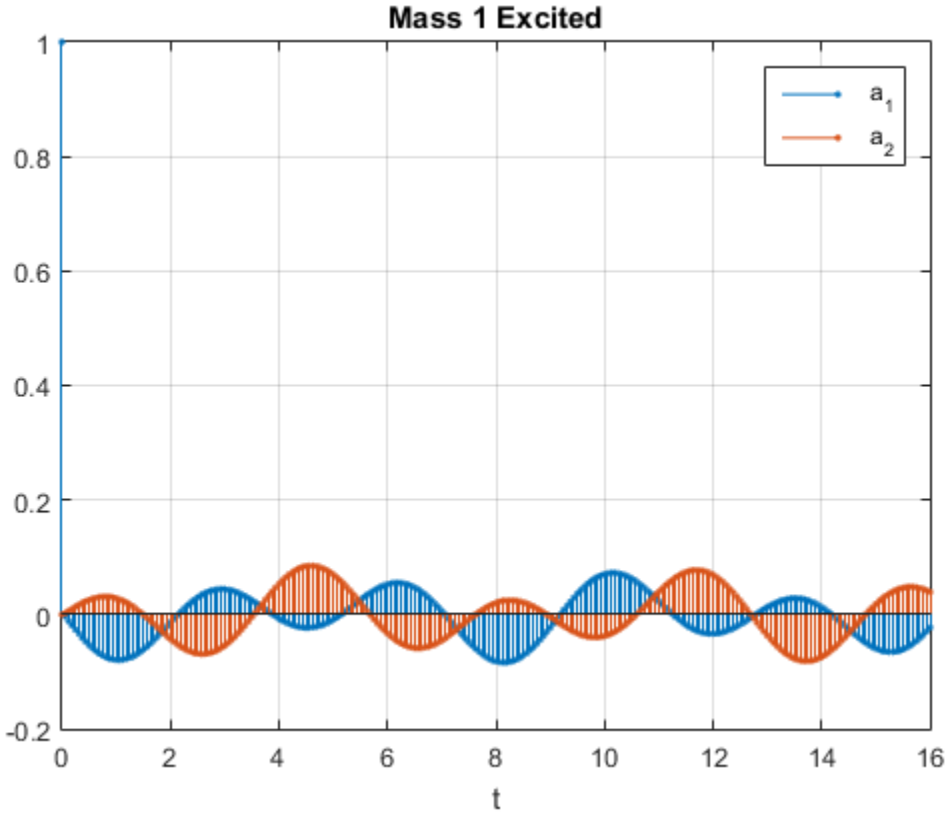


Convert the system to its transfer function representation. Find the response of the system to a positive unit impulse excitation on the first mass.

```
[b1,a1] = ss2tf(A,B,C,D,1);
y1u1 = filter(b1(1,:),a1,ux);
y1u2 = filter(b1(2,:),a1,ux);
```

Plot the result. The transfer function gives the same response as the state-space model.

```
stem(t,[y1u1;y1u2]','.')
xlabel('t')
legend('a_1','a_2')
title('Mass 1 Excited')
grid
```



The system is reset to its initial configuration. Now the other mass, m_2, receives a unit impulse in the positive direction. Compute the time evolution of the system.

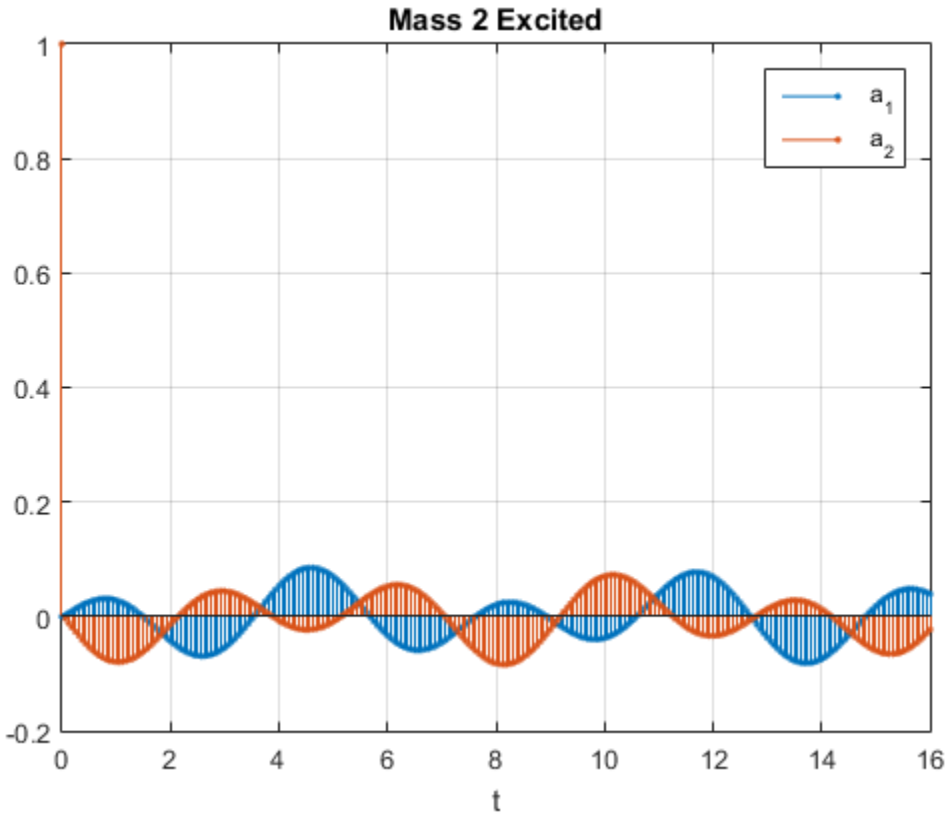
```
u = [u0;ux];

x = [0;0;0;0];
for k = 1:N
    y(:,k) = C*x + D*u(:,k);
    x = A*x + B*u(:,k);
end
```

Plot the accelerations. The responses of the individual masses are switched.

```
stem(t,y','.')
```

```
xlabel('t')
legend('a_1','a_2')
title('Mass 2 Excited')
grid
```



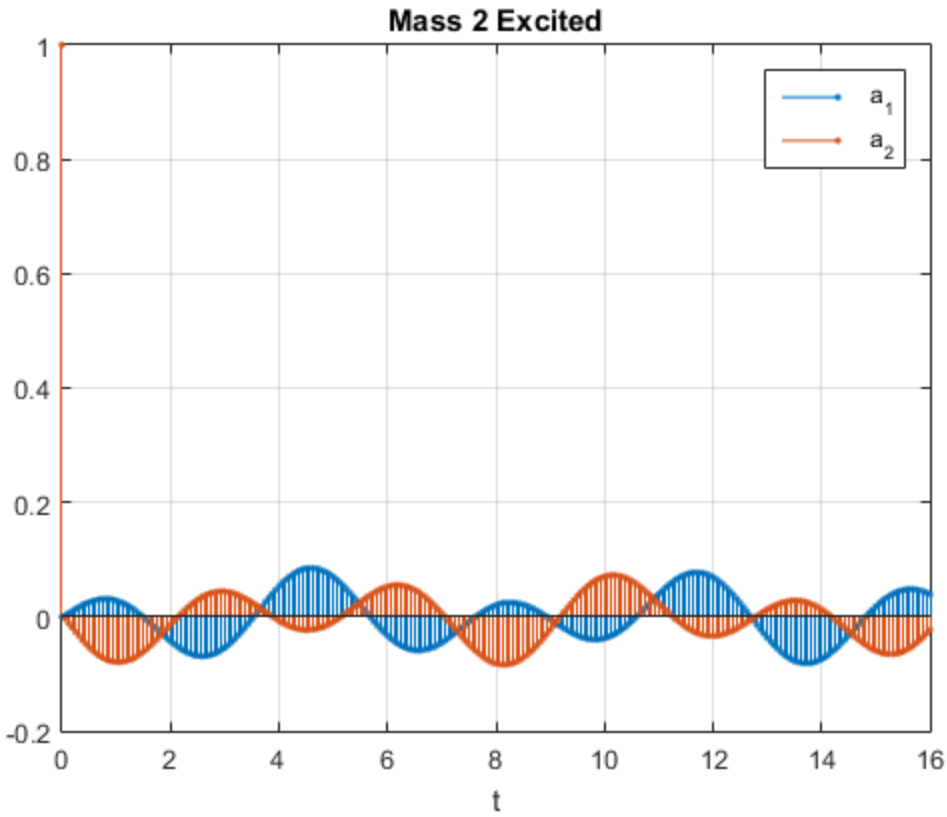
Find the response of the system to a positive unit impulse excitation on the second mass.

```
[b2,a2] = ss2tf(A,B,C,D,2);
y2u1 = filter(b2(1,:),a2,ux);
y2u2 = filter(b2(2,:),a2,ux);
```

Plot the result. The transfer function gives the same response as the state-space model.

```
stem(t,[y2u1;y2u2]','.')
```

```
xlabel('t')
legend('a_1','a_2')
title('Mass 2 Excited')
grid
```



Input Arguments

A — State matrix

matrix

State matrix, specified as a matrix. If the system has p inputs and q outputs and is described by n state variables, then A is n-by-n.

Data Types: `single` | `double`

`B` — Input-to-state matrix
matrix

Input-to-state matrix, specified as a matrix. If the system has p inputs and q outputs and is described by n state variables, then B is n-by-p.

Data Types: `single` | `double`

`C` — State-to-output matrix
matrix

State-to-output matrix, specified as a matrix. If the system has p inputs and q outputs and is described by n state variables, then C is q-by-n.

Data Types: `single` | `double`

`D` — Feedthrough matrix
matrix

Feedthrough matrix, specified as a matrix. If the system has p inputs and q outputs and is described by n state variables, then D is q-by-p.

Data Types: `single` | `double`

`ni` — Input index
1 (default) | integer scalar

Input index, specified as an integer scalar. If the system has p inputs, use `ss2tf` with a trailing argument ni = 1, …, p to compute the response to a unit impulse applied to the nith input.

Data Types: `single` | `double`

Output Arguments

`b` — Transfer function numerator coefficients
vector | matrix

Transfer function numerator coefficients, returned as a vector or matrix. If the system has p inputs and q outputs and is described by n state variables, then b is q-by-$(n + 1)$ for each input. The coefficients are returned in descending powers of s or z.

a — Transfer function denominator coefficients

vector

Transfer function denominator coefficients, returned as a vector. If the system has p inputs and q outputs and is described by n state variables, then a is 1-by-(n + 1) for each input. The coefficients are returned in descending powers of s or z.

More About

Transfer Function

- For discrete-time systems, the state-space matrices relate the state vector x, the input u, and the output y through

  $$x(k+1) = \mathrm{A}\,x(k) + \mathrm{B}\,u(k)$$
  $$y(k) = \mathrm{C}\,x(k) + \mathrm{D}\,u(k).$$

  The transfer function is the Z-transform of the system's impulse response. It can be expressed in terms of the state-space matrices as

  $$\mathrm{H}(z) = \mathrm{C}(z\mathrm{I} - \mathrm{A})^{-1}\mathrm{B} + \mathrm{D}.$$

- For continuous-time systems, the state-space matrices relate the state vector x, the input u, and the output y through

  $$\dot{x} = \mathrm{A}\,x + \mathrm{B}\,u$$
  $$y = \mathrm{C}\,x + \mathrm{D}\,u.$$

  The transfer function is the Laplace transform of the system's impulse response. It can be expressed in terms of the state-space matrices as

  $$\mathrm{H}(s) = \mathrm{C}(s\mathrm{I} - \mathrm{A})^{-1}\mathrm{B} + \mathrm{D}.$$

Introduced before R2006a

sscanf

Read formatted data from string

Syntax

```
A = sscanf(str, format)
A = sscanf(str, format, sizeA)
[A, count] = sscanf(...)
[A, count, errmsg] = sscanf(...)
[A, count, errmsg, nextindex] = sscanf(...)
```

Description

`A = sscanf(str, format)` reads data from string `str`, converts it according to the `format`, and returns the results in array `A`. The `sscanf` function reapplies the `format` until either reaching the end of `str` or failing to match the `format`. If `sscanf` cannot match the `format` to the data, it reads only the portion that matches into `A` and stops processing. If `str` is a character array with more than one row, `sscanf` reads the characters in column order.

`A = sscanf(str, format, sizeA)` reads `sizeA` elements into `A`, where `sizeA` can be an integer or can have the form `[m,n]`.

`[A, count] = sscanf(...)` returns the number of elements that `sscanf` successfully reads.

`[A, count, errmsg] = sscanf(...)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is an empty string.

`[A, count, errmsg, nextindex] = sscanf(...)` returns one more than the number of characters scanned in `str`.

Input Arguments

`format`

String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.

Field Type	Specifier	Details
Integer, signed	`%d`	Base 10
	`%i`	Base determined from the values. Defaults to base 10. If initial digits are `0x` or `0X`, it is base 16. If initial digit is `0`, it is base 8.
	`%ld` or `%li`	64-bit values, base 10, 8, or 16
Integer, unsigned	`%u`	Base 10
	`%o`	Base 8 (octal)
	`%x`	Base 16 (hexadecimal)
	`%lu`, `%lo`, `%lx`	64-bit values, base 10, 8, or 16
Floating-point number	`%f`	Floating-point fields can contain any of the following (not case sensitive): `Inf`, `-Inf`, `NaN`, or `-NaN`.
	`%e`	
	`%g`	
Character string	`%s`	Read series of characters, until find white space.
	`%c`	Read any single character, including white space. (To read multiple characters, specify field length.)
	`%[...]`	Read only characters in the brackets, until the first nonmatching character or white space.

Optionally:

- To skip fields, insert an asterisk (`*`) after the percent sign (`%`). For example, to skip integers, specify `%*d`.
- To specify the maximum width of a field, insert a number. For example, `%10c` reads exactly 10 characters at a time, including white space.

- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from `'pi=3.14159'`, specify a *format* of `'pi=%f'`.

sizeA

Dimensions of the output array *A*. Specify in one of the following forms:

`inf`	Read to the end of the input string. (default)
n	Read at most *n* elements.
`[`*m*`,`*n*`]`	Read at most *m***n* elements in column order. *n* can be `inf`, but *m* cannot.

When the *format* includes `%s`, *A* can contain more than *n* columns. *n* refers to elements, not characters.

str

Character string.

Output Arguments

A

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class `int64`. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class `uint64`. Otherwise, *A* is of class `double`. If *sizeA* is `inf` or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (`%c` or `%s`), *A* is a character array. If *sizeA* is `inf` or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with `char(0)`.
- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of `'%*d %s'`).

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

count

Number of elements sscanf reads into *A*.

errmsg

An error message string when sscanf cannot open the specified file. Otherwise, an empty string.

nextindex

sscanf counts the number of characters sscanf reads from *str*, and then adds one.

Examples

Example 1

Read multiple floating-point values from a string:

```
s = '2.7183  3.1416';
A = sscanf(s,'%f')
A =
    2.7183
    3.1416
```

Example 2

Read an octal integer from a string, identified by the '0' prefix, using %i to preserve the sign:

```
sscanf('-010','%i')
ans =
    -8
```

Example 3

Read numeric values from a two-dimensional character array. By default, `sscanf` reads characters in column order. To preserve the original order of the values, read one row at a time.

```
mixed = ['abc 45 6 ghi'; 'def 7 89 jkl'];

[nrows, ncols] = size(mixed);
for k = 1:nrows
    nums(k,:) = sscanf(mixed(k,:), '%*s %d %d %*s', [1, inf]);
end;

% type the variable name to see the result
nums =
    45     6
     7    89
```

Example 4

`sscanf` finds one match for `%s`

```
[str count] = sscanf('ThisIsOneString', '%s')
str =
    ThisIsOneString
count =
     1
```

`sscanf` finds four matches for `%s`. Because it does not match space characters, there are no spaces in the output string:

```
[str count] = sscanf('These Are Four Strings', '%s')
str =
    TheseAreFourStrings
count =
     4
```

`sscanf` finds five word matches for `%s` and four space character matches for `%c`. Because the `%c` specifier does match a space character, the output string does include spaces:

```
[str count] = sscanf('Five strings and four spaces', '%s%c')
str =
    Five strings and four spaces
```

```
count =
    9
```

`sscanf` finds three word matches for `%s` and two numeric matches for `%d`. Because the format specifier has a mixed %d and %s format, sscanf converts all nonnumeric characters to numeric:

```
[str count] = sscanf('5 strings and 4 spaces', '%d%s%s%d%s');
str'
  Columns 1 through 9
     5   115   116   114   105   110   103   115    97
  Columns 10 through 18
   110   100     4   115   112    97    99   101   115
count
count =
     5
```

Example 5

```
[str, count] = sscanf('one two three', '%c')
str =
    one two three
count =
    13

[str, count] = sscanf('one two three', '%13c')
str =
    one two three
count =
     1

[str, count] = sscanf('one two three', '%s')
str =
    onetwothree
count =
     3

[str, count] = sscanf('one two three', '%1s')
str =
    onetwothree
count =
    11
```

Example 6

```
tempString = '78°F 72°F 64°F 66°F 49°F';

degrees = char(176);
tempNumeric = sscanf(tempString, ['%d' degrees 'F'])'
tempNumeric =
    78    72    64    66    49
```

More About

Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

Introduced before R2006a

stack

Stack data from multiple variables into single variable

Syntax

```
T = stack(W,vars)
T = stack(W,vars,Name,Value)
[T,iw] = stack(___)
```

Description

`T = stack(W,vars)` converts the wide table, `W`, into an equivalent table, `T`, that is in tall format. `stack` stacks up multiple variables from `W`, specified by `vars`, into a single variable in `T`. In general, `T` contains fewer variables, but more rows, than `W`.

The output table, `T`, contains a new categorical variable to indicate which variable in `W` the stacked data in each row came from. `stack` replicates data from the variables in `W` that are not stacked.

`T = stack(W,vars,Name,Value)` converts the table, `W`, to tall format with additional options specified by one or more Name,Value pair arguments.

For example, you can specify variable names for the new and stacked variables in `W`.

`[T,iw] = stack(___)` also returns an index vector, iw, indicating the correspondence between rows in `T` and rows in `W`. You can use any of the previous input arguments.

Examples

Stack Three Variables into One

Create a table containing test scores from three separate tests.

```
Test1 = [93;57;87;89];
Test2 = [89;77;92;86];
Test3 = [95;62;89;91];
```

```
W = table(Test1,Test2,Test3)

W =

    Test1    Test2    Test3
    _____    _____    _____

    93       89       95
    57       77       62
    87       92       89
    89       86       91
```

The table contains four rows and three variables.

Stack the test scores into a single variable.

```
T = stack(W,1:3)

T =

    Test1_Test2_Test3_Indicator    Test1_Test2_Test3
    _______________________________    _________________

    Test1                              93
    Test2                              89
    Test3                              95
    Test1                              57
    Test2                              77
    Test3                              62
    Test1                              87
    Test2                              92
    Test3                              89
    Test1                              89
    Test2                              86
    Test3                              91
```

`T` contains twelve rows and two variables.

The categorical variable, `Test1_Test2_Test3_Indicator`, identifies which test corresponds to the score in the stacked data variable, `Test1_Test2_Test3`.

Stack Variables and Specify Variable Names

Create a table indicating the amount of snowfall at three locations from five separate storms.

```
Storm = [1;2;3;4;5];
Date = {'12/25/11';'1/2/12';'1/23/12';'2/7/12';'2/15/12'};
Natick = [20;5;13;0;17];
Boston = [18;9;21;5;12];
Worcester = [26;10;16;3;15];

W = table(Storm,Date,Natick,Boston,Worcester)
```

```
W =

    Storm       Date       Natick    Boston    Worcester
    _____    __________    ______    ______    _________

    1        '12/25/11'    20        18        26
    2        '1/2/12'       5         9        10
    3        '1/23/12'     13        21        16
    4        '2/7/12'       0         5         3
    5        '2/15/12'     17        12        15
```

The variables `Storm` and `Date` contain data that is constant at each location.

Stack the variables `Natick`, `Boston`, and `Worcester` into a single variable. Name the variable containing the stacked data, `Snowfall`, and name the new indicator variable, `Town`.

```
T = stack(W,{'Natick','Boston','Worcester'},...
    'NewDataVariableName','Snowfall',...
    'IndexVariableName','Town')
```

```
T =

    Storm       Date         Town       Snowfall
    _____    __________    _________    ________

    1        '12/25/11'    Natick       20
    1        '12/25/11'    Boston       18
    1        '12/25/11'    Worcester    26
    2        '1/2/12'      Natick        5
    2        '1/2/12'      Boston        9
    2        '1/2/12'      Worcester    10
    3        '1/23/12'     Natick       13
    3        '1/23/12'     Boston       21
    3        '1/23/12'     Worcester    16
    4        '2/7/12'      Natick        0
    4        '2/7/12'      Boston        5
```

```
    4         '2/7/12'       Worcester      3
    5         '2/15/12'      Natick        17
    5         '2/15/12'      Boston        12
    5         '2/15/12'      Worcester     15
```

`T` contains three rows for each storm, and `stack` repeats the data in the constant variables, `Storm` and `Date`, accordingly.

The categorical variable, `Town`, identifies which variable in `W` contains the corresponding `Snowfall` data.

Stack Variables and Output an Index Vector

Create a table containing estimated influenza rates along the east coast of the United States. Create a different variable for the Northeast, Mid Atlantic, and South Atlantic. Data Source: Google Flu Trends (http://www.google.org/flutrends).

```
Month = {'October';'November';'December';...
    'January';'February';'March'};
Year = [2005*ones(3,1); 2006*ones(3,1)];
NE = [1.1902; 1.3610; 1.5003; 1.7772; 2.1350; 2.2345];
MidAtl = [1.1865; 1.4120; 1.6043; 1.8830; 2.1227; 1.9920];
SAtl = [1.2730; 1.5820; 1.8625; 1.9540; 2.4803; 2.0203];

fluW = table(Month,Year,NE,MidAtl,SAtl)
```

```
fluW =

      Month        Year      NE       MidAtl      SAtl
    ___________    ____    ______    ______    ______

    'October'      2005    1.1902    1.1865     1.273
    'November'     2005     1.361     1.412     1.582
    'December'     2005    1.5003    1.6043    1.8625
    'January'      2006    1.7772     1.883     1.954
    'February'     2006     2.135    2.1227    2.4803
    'March'        2006    2.2345     1.992    2.0203
```

The variables `Month` and `Year` contain data that is constant across the row.

Stack the variables `NE`, `MidAtl`, and `SAtl` into a single variable called `FluRate`. Name the new indicator variable `Region` and output an index vector, `ifluW`, to indicate the correspondence between rows in the input wide table, `fluW`, and the output tall table, `fluT`.

```
[fluT,ifluW] = stack(fluW,3:5,...
    'NewDataVariableName','FluRate',...
    'IndexVariableName','Region')
```

```
fluT =

      Month        Year    Region    FluRate
    ___________    ____    ______    _______

    'October'      2005    NE         1.1902
    'October'      2005    MidAtl     1.1865
    'October'      2005    SAtl        1.273
    'November'     2005    NE          1.361
    'November'     2005    MidAtl      1.412
    'November'     2005    SAtl        1.582
    'December'     2005    NE         1.5003
    'December'     2005    MidAtl     1.6043
    'December'     2005    SAtl       1.8625
    'January'      2006    NE         1.7772
    'January'      2006    MidAtl      1.883
    'January'      2006    SAtl        1.954
    'February'     2006    NE          2.135
    'February'     2006    MidAtl     2.1227
    'February'     2006    SAtl       2.4803
    'March'        2006    NE         2.2345
    'March'        2006    MidAtl      1.992
    'March'        2006    SAtl       2.0203

ifluW =

     1
     1
     1
     2
     2
     2
     3
     3
     3
     4
     4
     4
     5
     5
```

```
5
6
6
6
```

`ifluW(5)` is `2`. The fifth row in the output table, `fluT`, contains data from the second row in the input table `fluW`.

Input Arguments

`W` — Wide table

table

Wide table, specified as a table.

`vars` — Variables in `W` to stack

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in `W` to stack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'NewDataVariableName','StackedData'` names the new data variable `StackedData`.

`'ConstantVariables'` — Variables other than `vars` to include in the output

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables other than `vars` to include in the output, specified as the comma-separated pair consisting of `'ConstantVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. `stack` replicates the data from the constant variables for each stacked entry from a row.

The default is all the variables in W not specified by vars. You can specify the `'ConstantVariables'` name-value pair argument to exclude variables not specified by `vars` or `'ConstantVariables'` from the output table, `T`.

`'NewDataVariableName'` — Name for the new data variable in `T`
string

Name for the new data variable in `T`, specified as the comma-separated pair consisting of `'NewDataVariableName'` and a string. The default is a concatenation of the names of the variables from `W` that are stacked up.

`'IndexVariableName'` — Name for the new indicator variable in `T`
string

Name for the new indicator variable in `T`, specified as the comma-separated pair consisting of `'IndexVariableName'` and a string. The default is a name based on `NewDataVariableName`.

Output Arguments

`T` — Tall table
table

Tall table, returned as a table. `T` contains a stacked data variable, a categorical indicator variable, and any constant variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see `Table Properties`.

`stack` assigns the variable units and variable description property values from the first variable listed in vars to the corresponding `T.Properties.VariableUnits` and `T.Properties.VariableDescrisciptions` values for the new data variable.

`iw` — Index to `W`
column vector

Index to `W`, returned as a column vector. The index vector, `iw`, identifies the row in the input table, `W`, containing the corresponding data. `stack` creates the `j`th row in the output table, `T`, using `W(iw(j),vars)`.

More About

Tips

- You can specify more than one group of data variables in `W`, and each group becomes a stacked data variable in `T`. Use a cell array to contain multiple values for `vars`, and a cell array of strings to contain multiple values for the `'NewDataVariableName'` name-value pair argument. All groups must contain the same number of variables.

See Also

`join` | `unstack`

stairs

Stairstep graph

Syntax

```
stairs(Y)
stairs(X,Y)
stairs( ___ ,LineSpec)
stairs( ___ ,Name,Value)

stairs(ax, ___ )

h = stairs( ___ )

[xb,yb] = stairs( ___ )
```

Description

`stairs(Y)` draws a stairstep graph of the elements in `Y`.

- If `Y` is a vector, then `stairs` draws one line.
- If `Y` is a matrix, then `stairs` draws one line per matrix column.

`stairs(X,Y)` plots the elements in `Y` at the locations specified by `X`. The inputs `X` and `Y` must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

`stairs( ___ ,LineSpec)` specifies a line style, marker symbol, and color. For example, `':*r'` specifies a dotted red line with asterisk markers. Use this option with any of the input argument combinations in the previous syntaxes.

`stairs( ___ ,Name,Value)` specifies stair properties using one or more `Name,Value` pair arguments. For example, `'Marker','o','MarkerSize',8` specifies 8 point circle markers.

`stairs(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in the previous syntaxes.

`h = stairs( ___ )` returns one or more stair objects. Use `h` to make changes to properties of a specific stair object after it is created.

`[xb,yb] = stairs( ___ )` does not create a plot, but returns matrices `xb` and `yb` of the same size, such that `plot(xb,yb)` plots the stairstep graph.

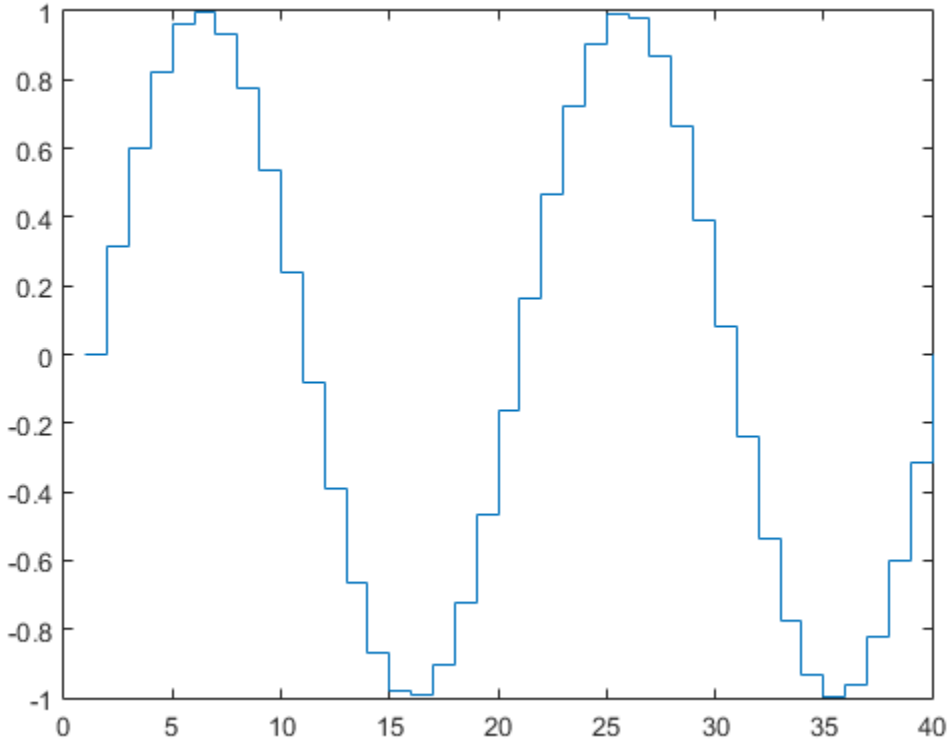
Examples

Plot Single Data Series

Create a stairstep plot of sine evaluated at 40 equally spaced values between 0 and 4π.

```
X = linspace(0,4*pi,40);
Y = sin(X);

figure
stairs(Y)
```



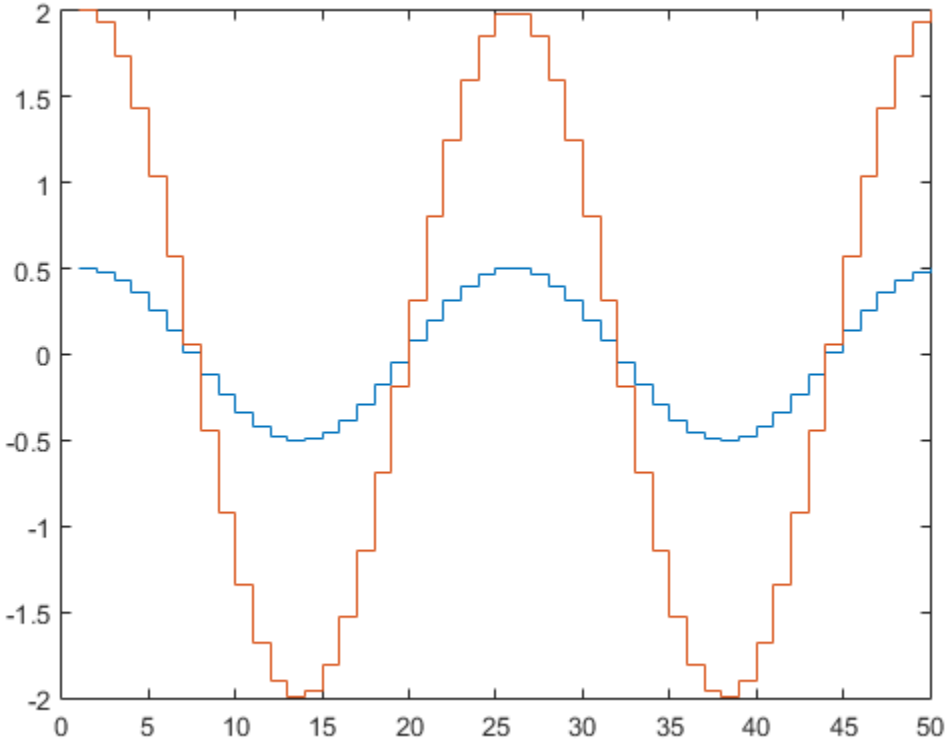
The length of Y automatically determines and generates the *x*-axis scale.

Plot Multiple Data Series

Create a stairstep plot of two cosine functions evaluated at 50 equally spaced values between 0 and 4π.

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];

figure
stairs(Y)
```



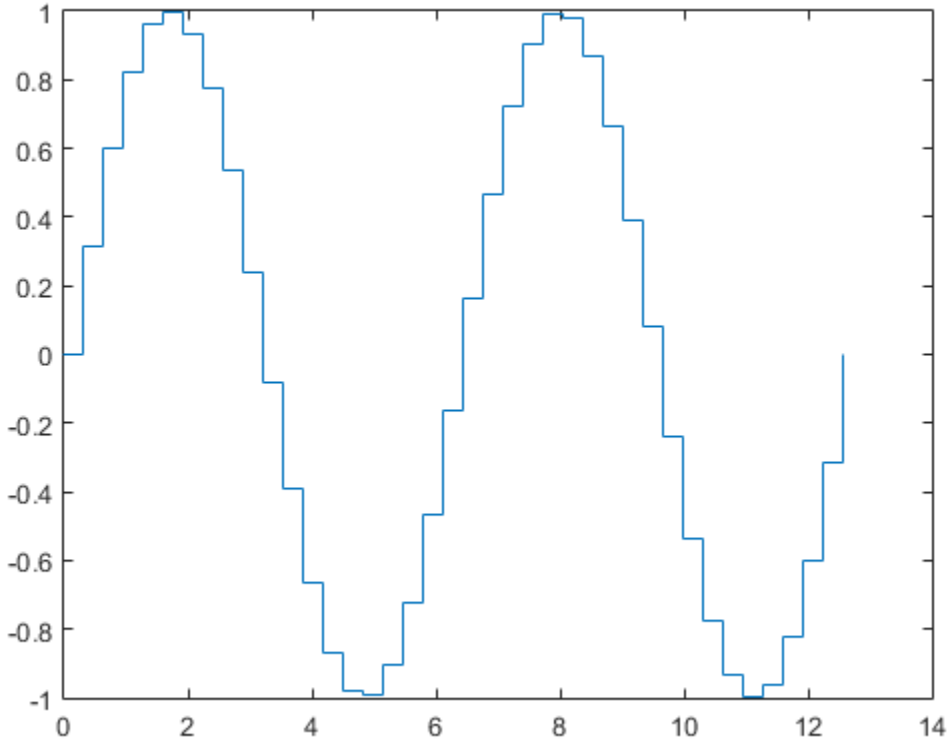
The number of rows in Y automatically determines and generates the *x*-axis scale.

Plot Single Data Series at Specified x-Values

Create a stairstep plot of a sine wave evaluated at equally spaced values between 0 and 4π. Specify the set of *x*-values for the plot.

```
X = linspace(0,4*pi,40);
Y = sin(X);

figure
stairs(X,Y)
```



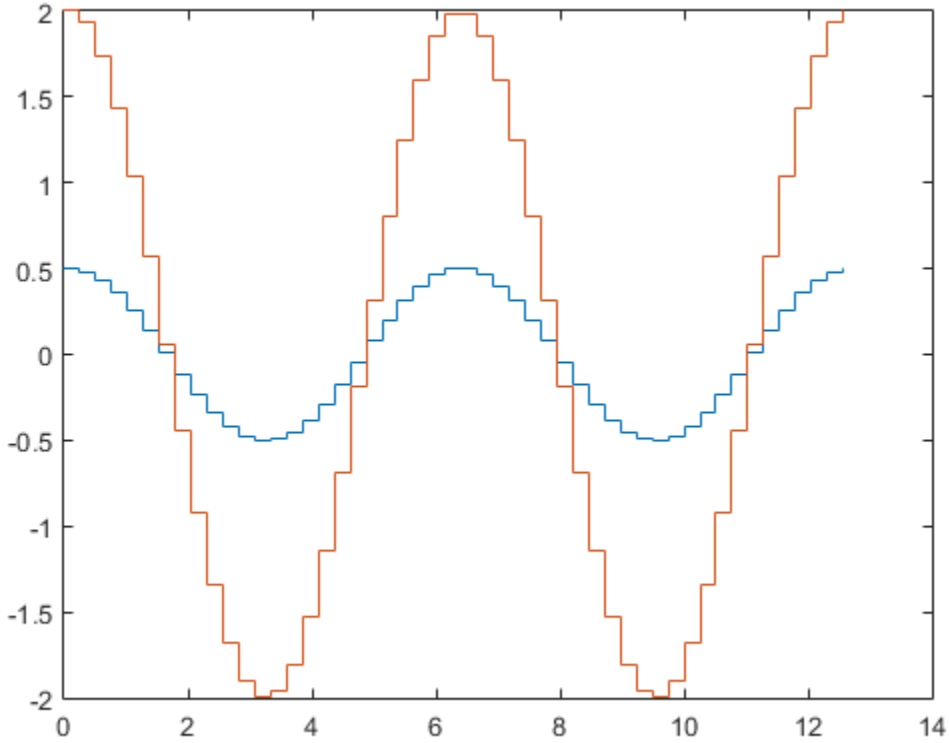
The entries in Y are plotted against the corresponding entries in X.

Plot Multiple Data Series at Specified x-Values

Create a stairstep plot of two cosine waves evaluated at equally spaced values between 0 and 4π. Specify the set of *x*-values for the plot.

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];

figure
stairs(X,Y)
```



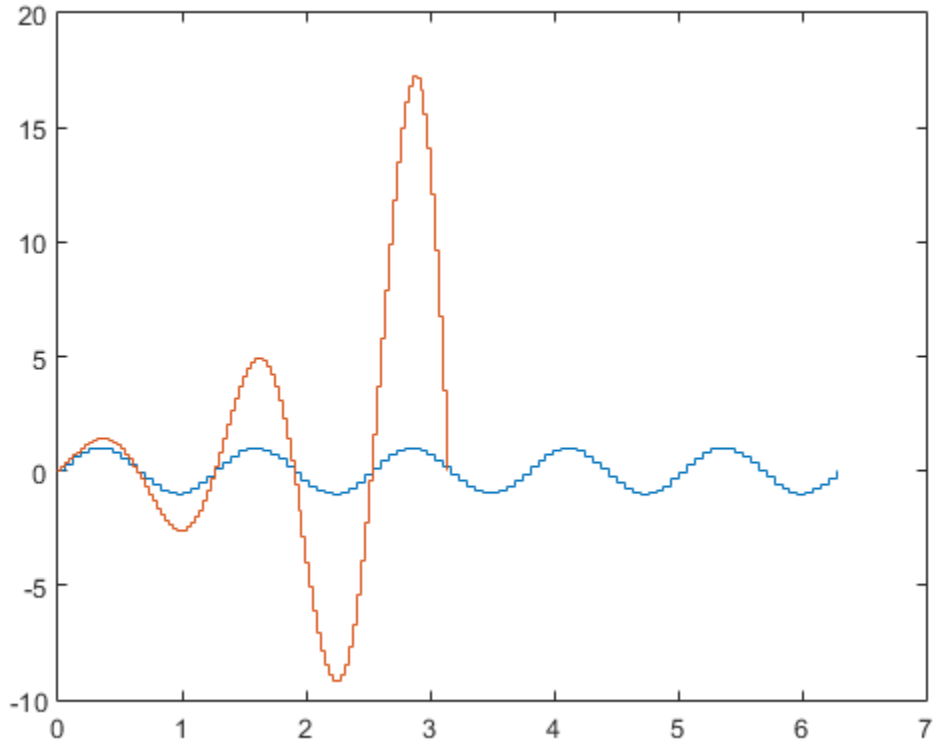
The first vector input, `X`, determines the *x*-axis positions for both data series.

Plot Multiple Data Series at Unique Sets of x-Values

Create a stairstep plot of two sine waves evaluated at different values. Specify a unique set of *x*-values for plotting each data series.

```
x1 = linspace(0,2*pi)';
x2 = linspace(0,pi)';
X = [x1,x2];
Y = [sin(5*x1),exp(x2).*sin(5*x2)];

figure
stairs(X,Y)
```



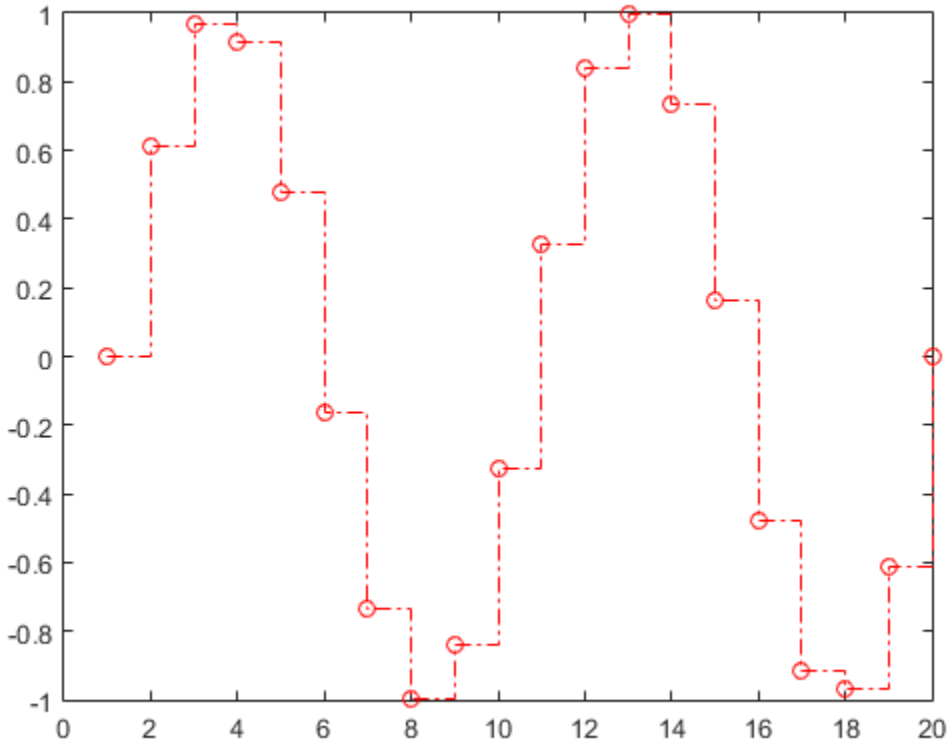
Each column of X is plotted against the corresponding column of Y.

Specify Line Style, Marker Symbol and Color

Create a stairstep plot and set the line style to a dot-dashed line, the marker symbol to circles, and the color to red.

```
X = linspace(0,4*pi,20);
Y = sin(X);

figure
stairs(Y, '-.or')
```

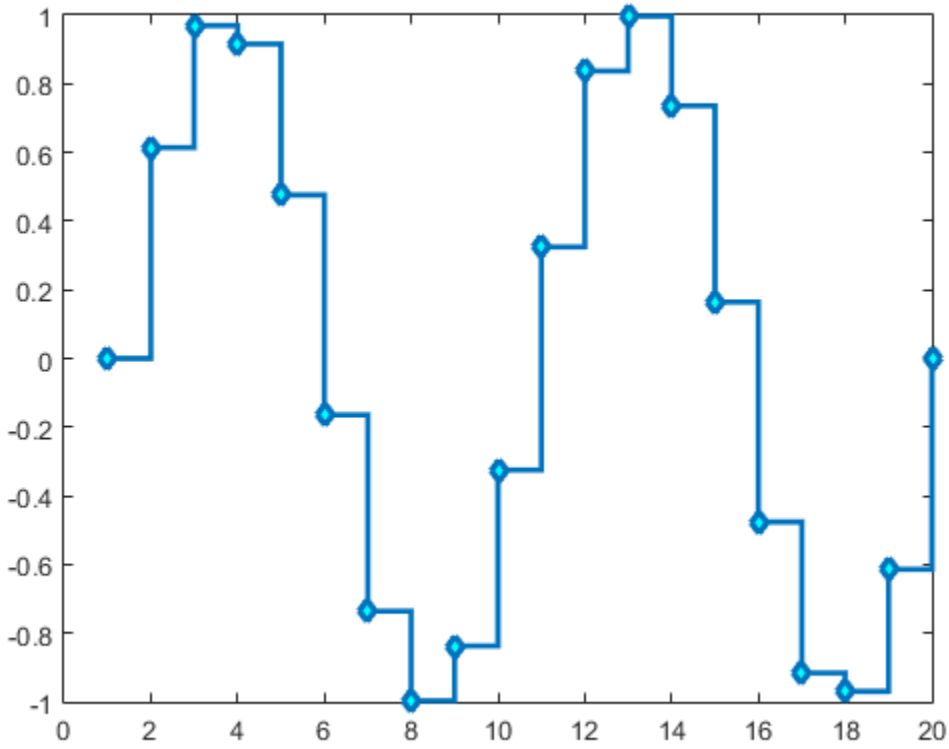


Specify Additional Style Options

Create a stairstep plot and set the line width to 2, the marker symbols to diamonds, and the marker face color to cyan using `Name,Value` pair arguments.

```
X = linspace(0,4*pi,20);
Y = sin(X);

figure
stairs(Y,'LineWidth',2,'Marker','d','MarkerFaceColor','c')
```

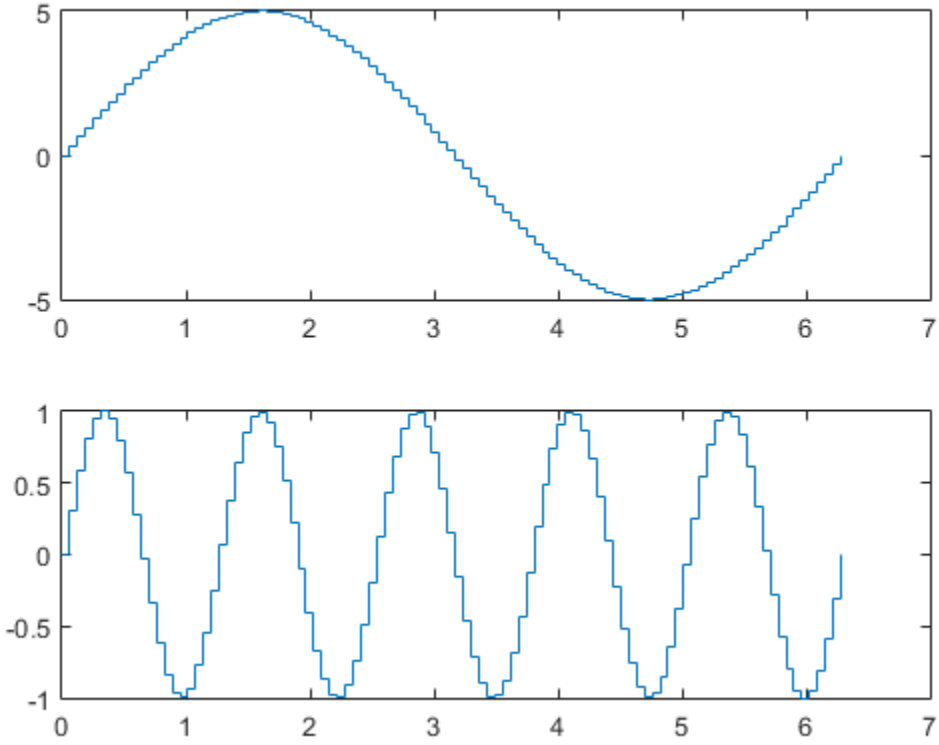


Specify Axes for Stairstep Plots

Create a figure with two subplots and return the two axes handles, `s(1)` and `s(2)`. Create a stairstep plot in each subplot by referring to the axes handles.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

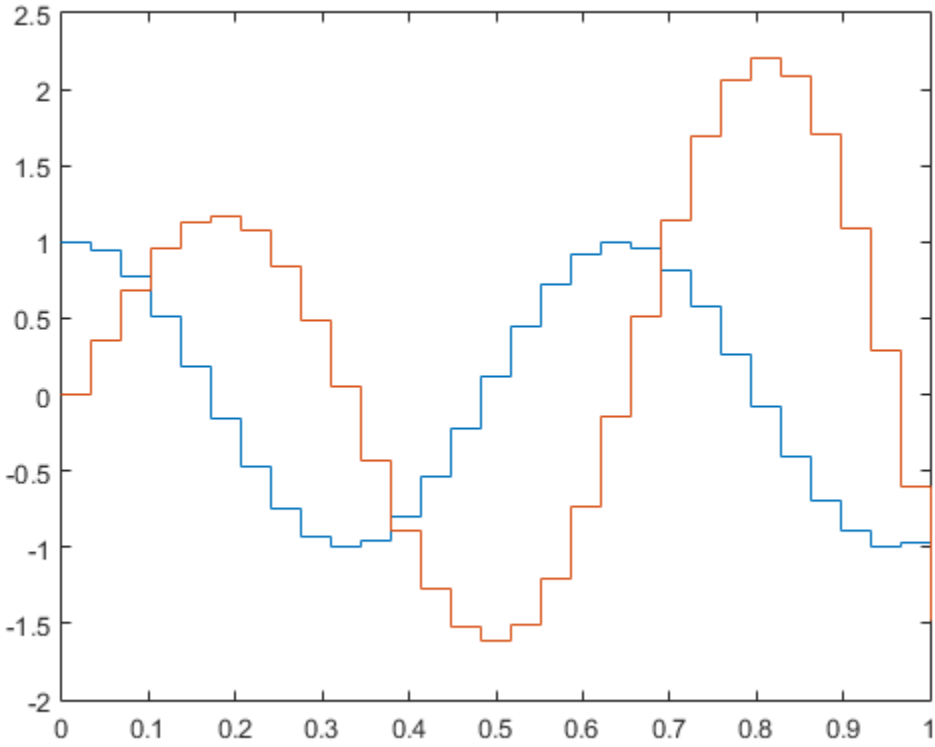
X = linspace(0,2*pi);
Y1 = 5*sin(X);
Y2 = sin(5*X);
stairs(s(1),X,Y1)
stairs(s(2),X,Y2)
```



Modify Stairstep Plot After Creation

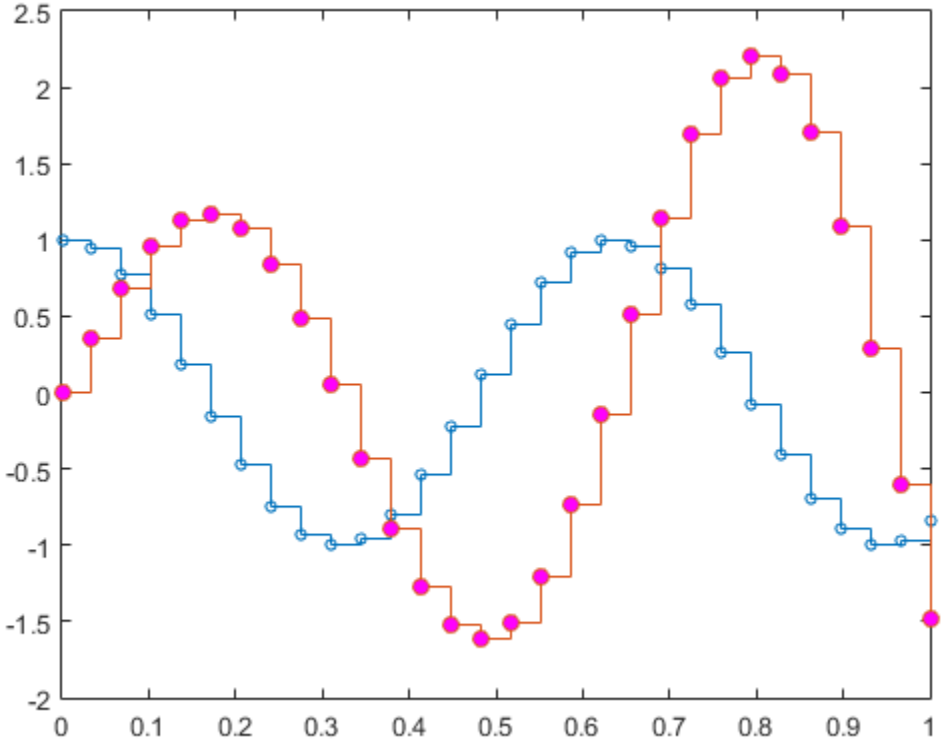
Create a stairstep plot of two data series and return the two stair objects.

```
X = linspace(0,1,30)';
Y = [cos(10*X), exp(X).*sin(10*X)];
h = stairs(X,Y);
```



Use small circle markers for the first data series. Use magenta filled circles for the second series. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
h(1).Marker = 'o';
h(1).MarkerSize = 4;
h(2).Marker = 'o';
h(2).MarkerFaceColor = 'm';
```



Create a Stairstep Plot using plot Function

Evaluate two cosine functions at 50 equally spaced values between 0 and 4π and create a stairstep plot using `plot`.

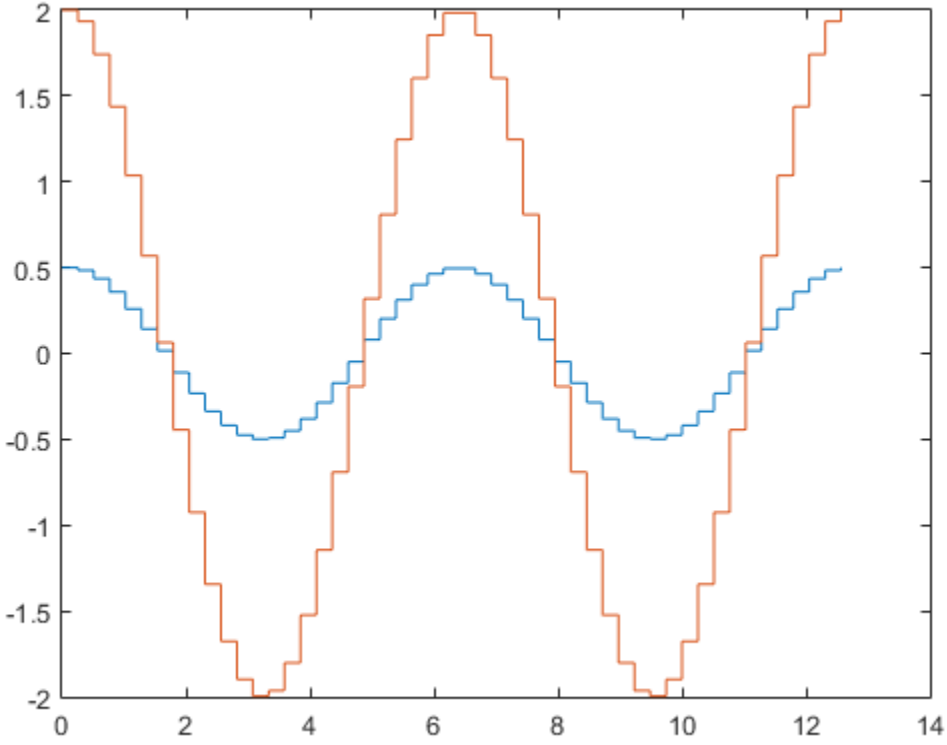
```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
[xb,yb] = stairs(X,Y);
```

`stairs` returns two matrices of the same size, `xb` and `yb`, but no plot.

Use `plot` to create the stairstep plot with `xb` and `yb`.

```
figure
```

```
plot(xb,yb)
```



Input Arguments

Y — y values

vector or matrix

y values, specified as a vector or matrix. When `Y` is a vector, `stairs` creates one stair object. When `Y` is a matrix, `stairs` draws one line per matrix column and creates a separate stair object for each column.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

X — x values
vector or matrix

x values, specified as a vector or matrix. When `Y` is a vector, `X` must be a vector of the same size. When `Y` is a matrix, `X` must be a matrix of the same size, or a vector whose length equals the number of rows in `Y`.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

LineSpec — Line style, marker symbol, and color
string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineSpec`.

Example: `':*r'`

ax — Axes object
axes object

Axes object. If you do not specify an axes, then `stairs` plots into the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Marker','s','MarkerFaceColor','red'` plots the stairstep graph with red square markers.

The properties listed here are only a subset. For a complete list, see Stair Properties.

'LineStyle' — Line style
`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	

String	Line Style	Resulting Line
'--'	Dashed line	- - - - -
':'	Dotted line	.....
'-.'	Dash-dotted line	-.-.-.-
'none'	No line	No line

'LineWidth' — Line width
0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

'Color' — Line color
[0 0.4470 0.7410] (default) | RGB triplet | color string | 'none'

Line color, specified as an RGB triplet, a color string, or 'none'. If you specify the Color as 'none', then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `'blue'`

Example: `[0 0 1]`

`'Marker'` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the stairs object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`'MarkerSize'` — Marker size

`6` (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

'MarkerEdgeColor' — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the Color property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

'MarkerFaceColor' — Marker fill color

'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Output Arguments

h — Stair objects

scalar or column vector

Stair objects, returned as a scalar or a column vector. These are unique identifiers, which you can use to query and modify the properties of a specific stair object after it is created.

xb — x values for use with `plot`

vector or matrix

x values for use with `plot`, specified as a vector or matrix. `xb` contains the appropriate values such that `plot(xb,yb)` creates the stairstep graph.

yb — y values for use with `plot`

vector or matrix

y values for use with `plot`, specified as a vector or matrix. `yb` contains the appropriate values such that `plot(xb,yb)` creates the stairstep graph.

`bar` | `histogram` | `LineSpec` | `stem`

Properties
Stair Properties

Introduced before R2006a

Stair Properties

Control stair appearance and behavior

Stair properties control the appearance and behavior of a stair object. By changing property values, you can modify certain aspects of the stairs.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = stairs(1:10);
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Line

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	`':'`	Dotted line	
`'-.'`	Dash-dotted line	
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`Color` — Line color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the `Color` as `'none'`, then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

Markers

`Marker` — Marker symbol

`'none'` (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the stair object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerSize` — Marker size

`6` (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

Data

XData — x values

[ ] (default) | vector

x values, specified as a vector. The input argument X to the stairs function sets the *x* values. If you do not specify the *x* values, then stairs uses the indices of YData. XData and YData must have equal lengths.

Example: 1:10

YData — y values

[ ] (default) | vector

y values, specified as a vector. The input argument Y to the stairs function sets the *y* values. XData and YData must have equal lengths.

Example: 1:10

XDataSource — Variable linked to XData

'' (default) | string containing MATLAB workspace variable name

Variable linked to XData, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the XData.

By default, there is no linked variable so the value is an empty string, ''. If you link a variable, then MATLAB does not update the XData values immediately. To force an update of the data values, use the refreshdata function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`XDataMode` — Selection mode for `XData`

`'auto'` (default) | `'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the indices of the values in `YData` (or `ZData` for 3-D plots).
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

Visibility

`Visible` — Visibility of stair

`'on'` (default) | `'off'`

Visibility of stair, specified as one of these values:

- `'on'` — Display the stair.

- `'off'` — Hide the stair without deleting it. You still can access the properties of an invisible stair object.

`Clipping` — Clipping of stair to axes limits

`'on'` (default) | `'off'`

Clipping of stair to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the stair that are outside the axes limits.
- `'off'` — Display the entire stair, even if parts of it appear outside the axes limits. Parts of the stair might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the stair that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'stair'`

Type of graphics object, returned as `'stair'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

`Tag` — Tag to associate with stair

`''` (default) | string

Tag to associate with the stair, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with stair

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the stair object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the stair.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the stair object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the stair from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the stair object in the legend as one entry (default).
   - `'off'` — Do not include the stair object in the legend.
   - `'children'` — Include only children of the stair object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of stair
axes object | group object | transform object

Parent of stair, specified as an axes, group, or transform object.

`Children` — Children of stair
empty `GraphicsPlaceholder` array

The stair has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle
`'on'` (default) | `'off'` | `'callback'`

Visibility of stair object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The stair object handle is always visible.
- `'off'` — The stair object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The stair object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the stair at the command-line, but allows callback functions to access it.

If the stair object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback
`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the stair. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stair object — You can access properties of the stair object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the stair. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the stair when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the stair.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the stair that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the stair responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the stair passes the click to the object below it in the current view of the figure window. The HitTest property of the stair has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the stair. If you have defined the UIContextMenu property, then invoke the context menu.

- `'off'` — Trigger the callbacks for the nearest ancestor of the stair that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the stair object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for stair

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for stair, specified as one of these values:

- `'off'` — Click the stair plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the stair plot to select it, that is, anywhere within the rectangle that encloses the stair plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the ButtonDownFcn callback of the stair is the running callback, then the Interruptible property determines if it another callback can interrupt it:

- 'on' — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a drawnow, figure, getframe, waitfor, or pause command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- 'off' — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

BusyAction — Callback queuing
'queue' (default) | 'cancel'

Callback queuing specified as 'queue' or 'cancel'. The BusyAction property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the ButtonDownFcn callback of the stair tries to interrupt a running callback that cannot be interrupted, then the BusyAction property determines if it is discarded or put in the queue. Specify the BusyAction property as one of these values:

- 'queue' — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.

- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the stair. Setting the `CreateFcn` property on an existing stair has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during stair creation. MATLAB executes the callback after creating the stair and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stair object — You can access properties of the stair object from within the callback function. You also can access the stair object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle

- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the stair. MATLAB executes the callback before destroying the stair so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stair object — You can access properties of the stair object from within the callback function. You also can access the stair object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of stair

`'off'` (default) | `'on'`

Deletion status of stair, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the stair begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the stair no longer exists.

Check the value of the BeingDeleted property to verify that the stair is not about to be deleted before querying or modifying it.

standardizeMissing

Insert missing value indicators into table

Syntax

```
B = standardizeMissing(A,id)
B = standardizeMissing(A,id,'DataVariables',vars)
```

Description

`B = standardizeMissing(A,id)` replaces all instances of the values specified in id occurring within table `A` with the standard missing value indicators. `B` is a table.

The standard missing value indicators depend on the data type:

- `NaN` for `double` and `single` floating-point arrays
- `<undefined>` for categorical arrays
- empty string, `{''}`, for cell arrays of strings
- blank string, `[' ']`, for character arrays

`standardizeMissing` checks `double` and `single` variables in `A` against numeric values from `id` and checks string and categorical variables in `A` against strings from `id`. The function `standardizeMissing` ignores integer data types because they cannot contain `NaN`.

`B = standardizeMissing(A,id,'DataVariables',vars)` replaces values only in variables specified by `vars`.

Examples

Replace All Instances of Specified Values

Create a table containing `Inf` and `'N/A'` to represent missing values.

```
dblVar = [NaN;3;Inf;7;9];
```

```
cellstrVar = {'one';'three';'';'NA';'nine'};
charVar = ['A';'C';'E';' ';'I'];
categoryVar = categorical({'red';'yellow';'blue';'violet';''});

A = table(dblVar,cellstrVar,charVar,categoryVar)

A =

    dblVar    cellstrVar    charVar    categoryVar
    ______    __________    _______    ___________

    NaN       'one'         A          red
      3       'three'       C          yellow
    Inf       ''            E          blue
      7       'NA'                     violet
      9       'nine'        I          <undefined>
```

Replace all instances of `Inf` with `NaN` and replace all instances of `'NA'` with the empty string, `''`.

```
B = standardizeMissing(A,{Inf,'NA'})

B =

    dblVar    cellstrVar    charVar    categoryVar
    ______    __________    _______    ___________

    NaN       'one'         A          red
      3       'three'       C          yellow
    NaN       ''            E          blue
      7       ''                       violet
      9       'nine'        I          <undefined>
```

Replace Only Values in Specified Variables

Replace instances of `Inf`, and `'N/A'`, occurring in specified variables of a table, with the standard missing value indicators.

Create a table containing `Inf` and `'N/A'` to represent missing values.

```
a = {'alpha';'bravo';'charlie';'';'N/A'};
x = [1;NaN;3;Inf;5];
y = [57;732;93;1398;Inf];

A = table(a,x,y)
```

```
A =

       a          x       y
    _________    ___    ____

    'alpha'        1      57
    'bravo'      NaN     732
    'charlie'      3      93
    ''           Inf    1398
    'N/A'          5     Inf
```

For the variables `a` and `x`, replace instances of `Inf` with `NaN` and `'N/A'` with the empty string, `''`.

```
B = standardizeMissing(A,{Inf,'N/A'},'DataVariables',{'a','x'})
```

```
B =

       a          x       y
    _________    ___    ____

    'alpha'        1      57
    'bravo'      NaN     732
    'charlie'      3      93
    ''           NaN    1398
    ''             5     Inf
```

`Inf` in the variable `y` remains unchanged because `y` is not included in the `'DataVariables'` name-value pair argument.

Input Arguments

`A` — Input table

table

Input table, specified as a table.

`id` — Nonstandard missing value indicators

numeric vector | string | cell array containing numeric values and strings

Nonstandard missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings.

`vars` — Subset of variables to consider

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Subset of variables to consider, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

Output Arguments

`B` — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

More About

Algorithms

`standardizeMissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `standardizeMissing` does not ignore white space. All strings must match exactly a string specified in `id`.
- For character arrays, `standardizeMissing` ignores trailing white space.
- For categorical arrays, `standardizeMissing` ignores leading and trailing white space.

startup

Startup file for user-defined options

Syntax

```
startup
```

Description

`startup` executes commands of your choosing when the MATLAB program starts.

Create a `startup.m` file in a folder on the MATLAB search path. Add commands you want executed at startup. For example, your `startup.m` file might include physical constants, defaults for Handle Graphics properties, engineering conversion factors, or anything else you want predefined in your workspace.

More About

Tips

- To specify the current folder in MATLAB when it starts, set the **Initial working folder** preference, described in "General Preferences".

Algorithms

At startup, MATLAB automatically executes the file `matlabrc.m` and, if it exists on the MATLAB search path, `startup.m`. The file `matlabrc.m`, which is in the *`matlabroot`*`/toolbox/local` folder, is reserved for use by MathWorks and by system administrators on multiuser systems.

- "Startup Options in MATLAB Startup File"

std

Standard deviation

Syntax

```
S = std(A)
S = std(A,w)
S = std(A,w,dim)
S = std(___,nanflag)
```

Description

`S = std(A)` returns the standard deviation of the elements of `A` along the first array dimension whose size does not equal 1.

- If `A` is a vector of observations, then the standard deviation is a scalar.
- If `A` is a matrix whose columns are random variables and whose rows are observations, then `S` is a row vector containing the standard deviations corresponding to each column.
- If `A` is a multidimensional array, then `std(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors. The size of this dimension becomes `1` while the sizes of all other dimensions remain the same.
- By default, the standard deviation is normalized by `N-1`, where `N` is the number of observations.

`S = std(A,w)` specifies a weighting scheme for any of the previous syntaxes. When `w = 0` (default), `S` is normalized by `N-1`. When `w = 1`, `S` is normalized by the number of observations, `N`. `w` also can be a weight vector containing nonnegative elements. In this case, the length of `w` must equal the length of the dimension over which `std` is operating.

`S = std(A,w,dim)` returns the standard deviation along dimension `dim` for any of the previous syntaxes. To maintain the default normalization while specifying the dimension of operation, set `w = 0` in the second argument.

`S = std(___,nanflag)` specifies whether to include or omit `NaN` values from the calculation for any of the previous syntaxes. For example, `std(A,'includenan')` includes all `NaN` values in `A` while `std(A,'omitnan')` ignores them.

Examples

Standard Deviation of Matrix Columns

Create a matrix and compute the standard deviation of each column.

```
A = [4 -5 1; 2 3 5; -9 1 7];
S = std(A)
```

```
S =

    7.0000    4.1633    3.0551
```

Standard Deviation of 3-D Array

Create a 3-D array and compute the standard deviation along the first dimension.

```
A(:,:,1) = [2 4; -2 1];
A(:,:,2) = [9 13; -5 7];
A(:,:,3) = [4 4; 8 -3];
S = std(A)
```

```
S(:,:,1) =

    2.8284    2.1213

S(:,:,2) =

    9.8995    4.2426

S(:,:,3) =

    2.8284    4.9497
```

Specify Standard Deviation Weights

Create a matrix and compute the standard deviation of each column according to a weight vector `w`.

```
A = [1 5; 3 7; -9 2];
w = [1 1 0.5];
S = std(A,w)
```

```
S =

    4.4900    1.8330
```

Standard Deviation Along Matrix Rows

Create a matrix and calculate the standard deviation along each row.

```
A = [6 4 23 -3; 9 -10 4 11; 2 8 -5 1];
S = std(A,0,2)
```

```
S =

   11.0303
    9.4692
    5.3229
```

Standard Deviation Excluding `NaN`

Create a vector and compute its standard deviation, excluding `NaN` values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
S = std(A,'omitnan')
```

```
S =

    2.2797
```

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. If `A` is a scalar, then `std(A)` returns `0`. If `A` is a `0`-by-`0` empty array, then `std(A)` returns `NaN`.

Data Types: `single` | `double`
Complex Number Support: Yes

`w` — Weight

`0` (default) | `1` | vector

Weight, specified as one of these values:

- `0` — Normalize by `N-1`, where `N` is the number of observations. If there is only one observation, then the weight is 1.
- `1` — Normalize by `N`.
- Vector made up of nonnegative scalar weights corresponding to the dimension of `A` along which the standard deviation is calculated.

Data Types: `single` | `double`

`dim` — Dimension to operate along

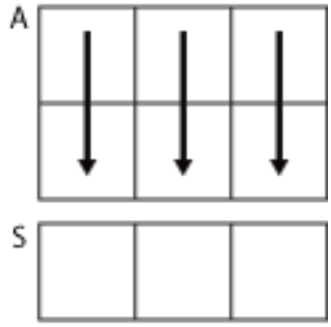
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(S,dim)` is `1`, while the sizes of all other dimensions remain the same.

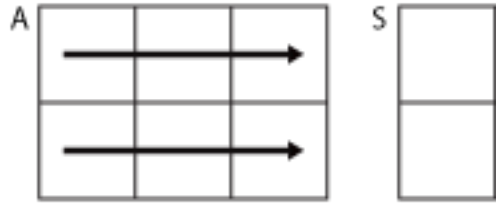
Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `std(A,0,1)` returns a row vector containing the standard deviation of the elements in each column.



std(A,0,1)

- If `dim = 2`, then `std(A,0,2)` returns a column vector containing the standard deviation of the elements in each row.



std(A,0,2)

If `dim` is greater than `ndims(A)`, then `std(A)` returns an array of zeros the same size as `A`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`nanflag` — `NaN` condition

`'includenan'` (default) | `'omitnan'`

`NaN` condition, specified as one of these values:

- `'includenan'` — Include `NaN` values when computing the standard deviation, resulting in `NaN`.
- `'omitnan'` — Ignore `NaN` values appearing in either the input array or weight vector.

Data Types: `char`

More About

Standard Deviation

For a random variable vector A made up of N scalar observations, the standard deviation is defined as

$$S = \sqrt{\frac{1}{N-1}\sum_{i=1}^{N}|A_i - \mu|^2},$$

where μ is the mean of A:

$$\mu = \frac{1}{N}\sum_{i=1}^{N}A_i.$$

The standard deviation is the square root of the variance. Some definitions of standard deviation use a normalization factor of N instead of $N-1$, which you can specify by setting `w` to `1`.

`corrcoef` | `cov` | `mean` | `median` | `var`

stem

Plot discrete sequence data

Syntax

```
stem(Y)
stem(X,Y)
stem(___,'filled')
stem(___,LineSpec)
stem(___,Name,Value)

stem(ax,___)

h = stem(___)
```

Description

`stem(Y)` plots the data sequence, `Y`, as stems that extend from a baseline along the *x*-axis. The data values are indicated by circles terminating each stem.

- If `Y` is a vector, then the *x*-axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stem` plots all elements in a row against the same *x* value, and the *x*-axis scale ranges from 1 to the number of rows in `Y`.

`stem(X,Y)` plots the data sequence, `Y`, at values specified by `X`. The `X` and `Y` inputs must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

- If `X` and `Y` are both vectors, then `stem` plots entries in `Y` against corresponding entries in `X`.
- If `X` is a vector and `Y` is a matrix, then `stem` plots each column of `Y` against the set of values specified by `X`, such that all elements in a row of `Y` are plotted against the same value.
- If `X` and `Y` are both matrices, then `stem` plots columns of `Y` against corresponding columns of `X`.

`stem( ___ ,'filled')` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

`stem( ___ ,LineSpec)` specifies the line style, marker symbol, and color.

`stem( ___ ,Name,Value)` specifies stem series properties using one or more `Name,Value` pair arguments.

`stem(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in the previous syntaxes.

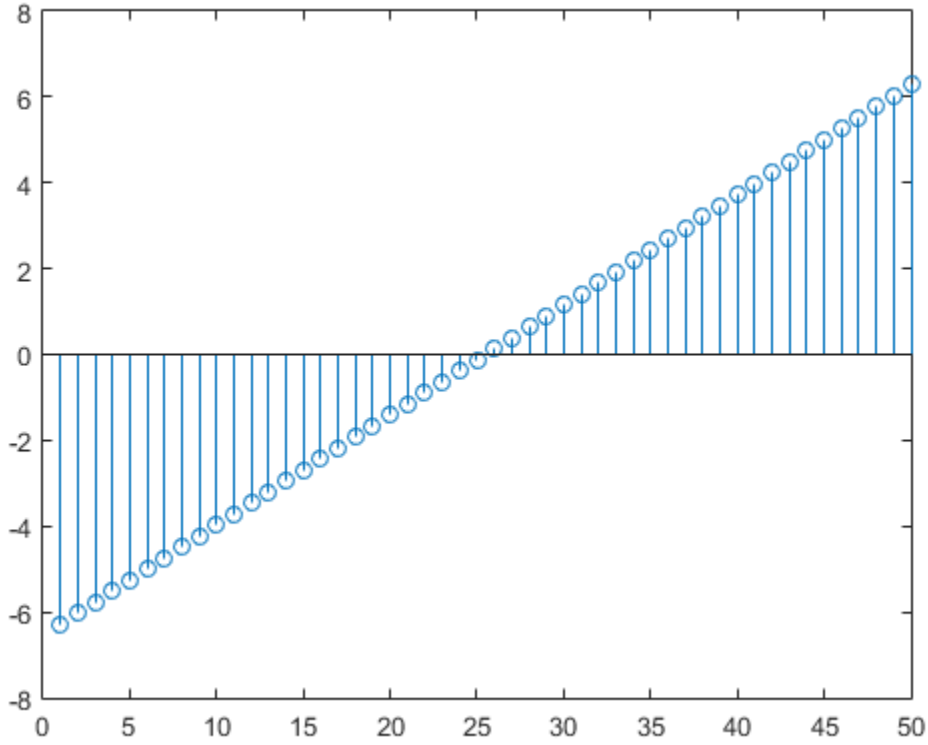
`h = stem( ___ )` returns a vector of stem series handles in `h`. When multiple stem series are present, you can make changes to properties of a specific stem series by specifying a particular handle.

Examples

Plot Single Data Series

Create a stem plot of 50 data values between -2π and 2π.

```
figure
Y = linspace(-2*pi,2*pi,50);
stem(Y)
```

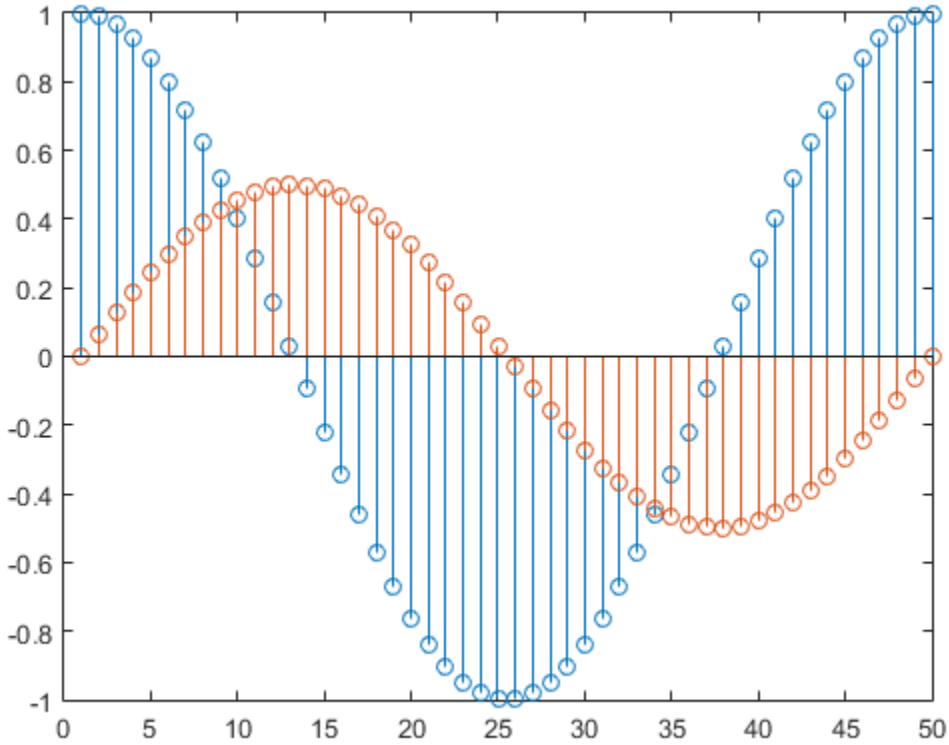


Data values are plotted as stems extending from the baseline and terminating at the data value. The length of `Y` automatically determines the position of each stem on the *x*-axis.

Plot Multiple Data Series

Plot two data series using a two-column matrix.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
stem(Y)
```

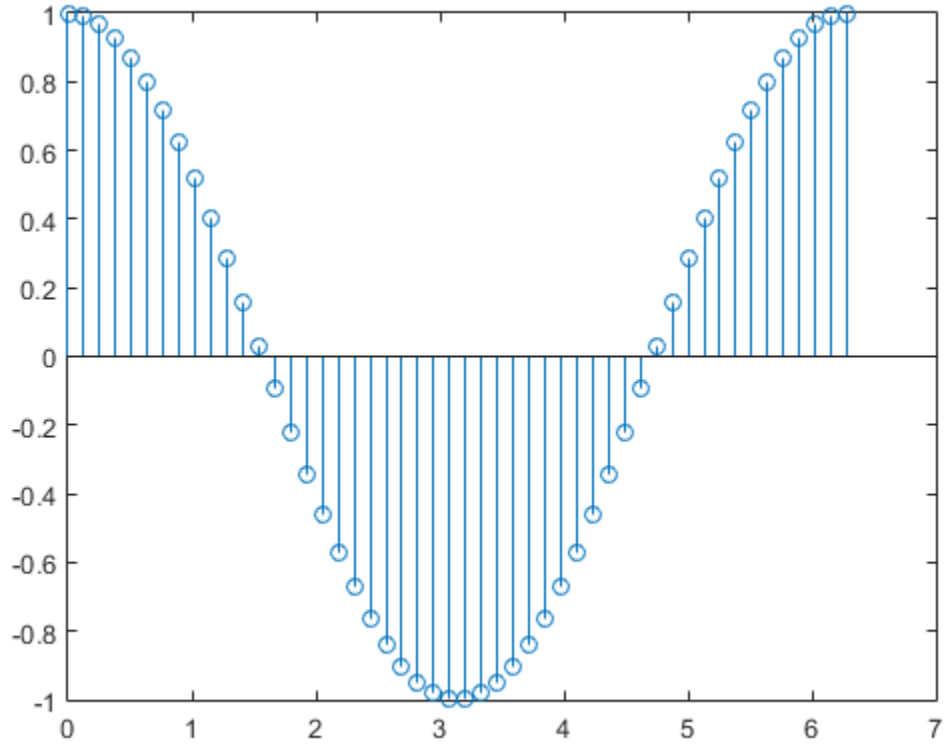


Each column of Y is plotted as a separate series, and entries in the same row of Y are plotted against the same *x* value. The number of rows in Y automatically generates the position of each stem on the *x*-axis.

Plot Single Data Series at Specified x values

Plot 50 data values of cosine evaluated between 0 and 2π and specify the set of *x* values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = cos(X);
stem(X,Y)
```

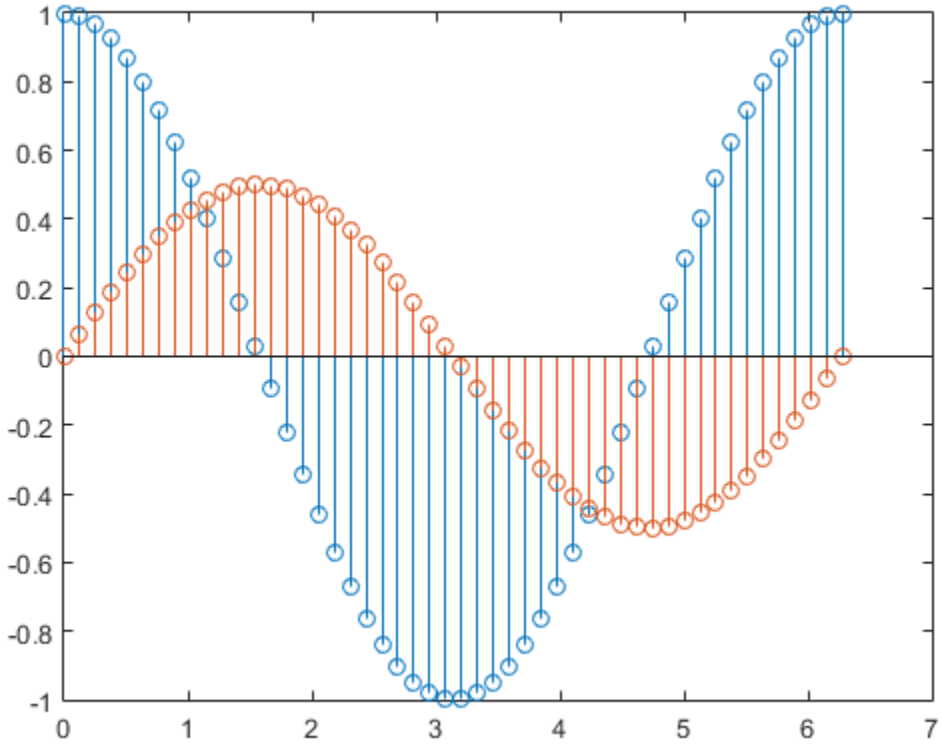


The first vector input determines the position of each stem on the x-axis.

Plot Multiple Data Series at Specified x values

Plot 50 data values of sine and cosine evaluated between 0 and 2π and specify the set of x values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
stem(X,Y)
```

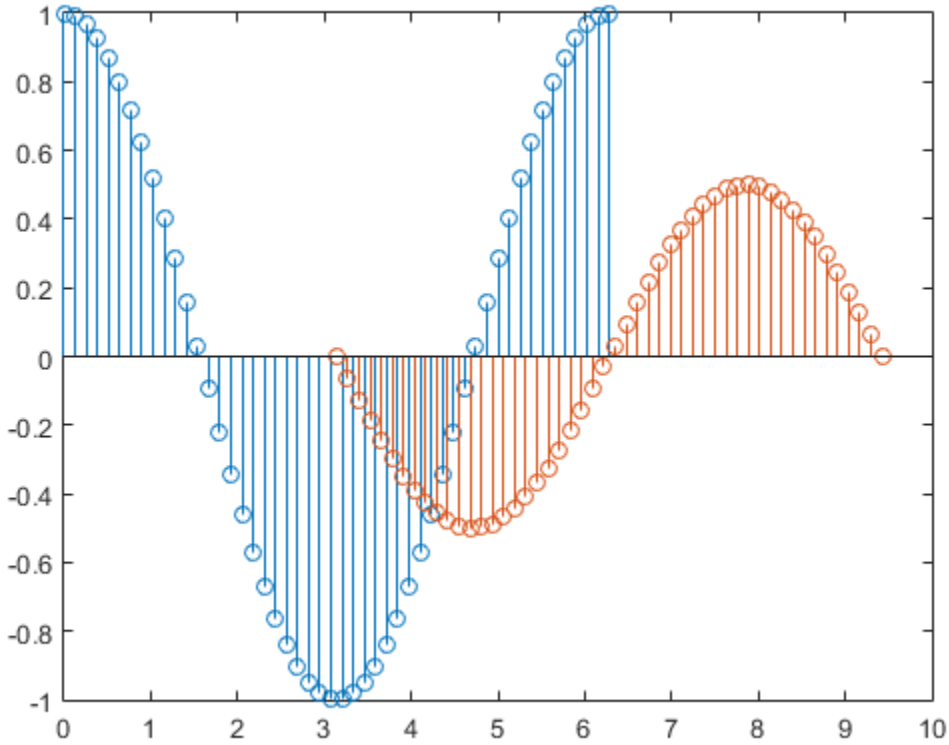


The vector input determines the *x*-axis positions for both data series.

Plot Multiple Data Series at Unique Sets of x values

Plot 50 data values of sine and cosine evaluated at different sets of *x* values. Specify the corresponding sets of *x* values for each series.

```
figure
x1 = linspace(0,2*pi,50)';
x2 = linspace(pi,3*pi,50)';
X = [x1, x2];
Y = [cos(x1), 0.5*sin(x2)];
stem(X,Y)
```

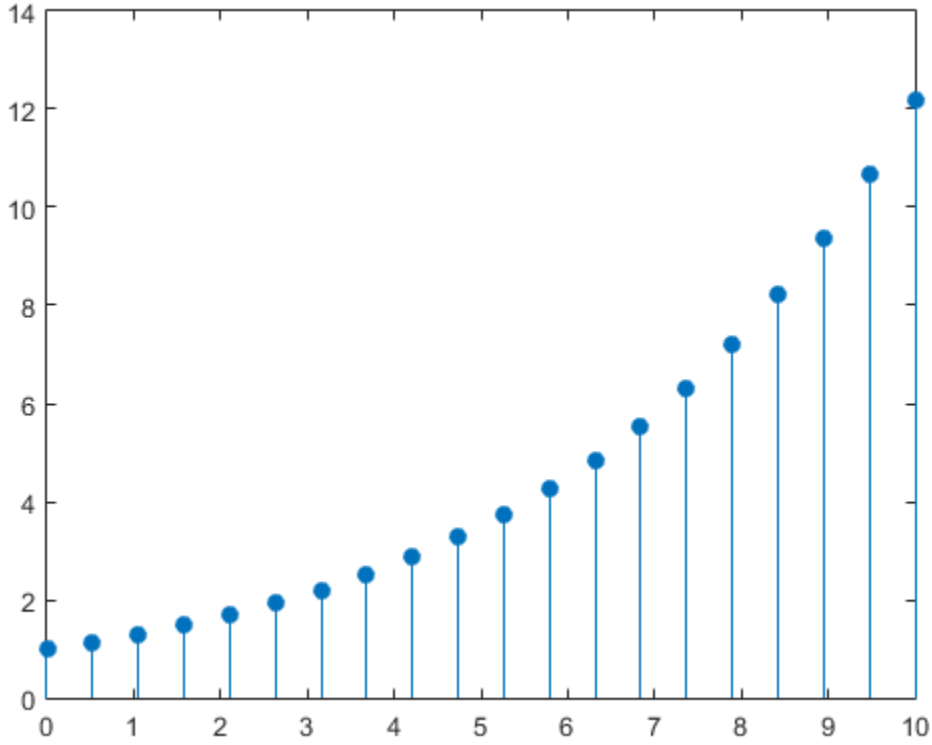


Each column of `X` is plotted against the corresponding column of `Y`.

Fill in Plot Markers

Create a stem plot and fill in the circles that terminate each stem.

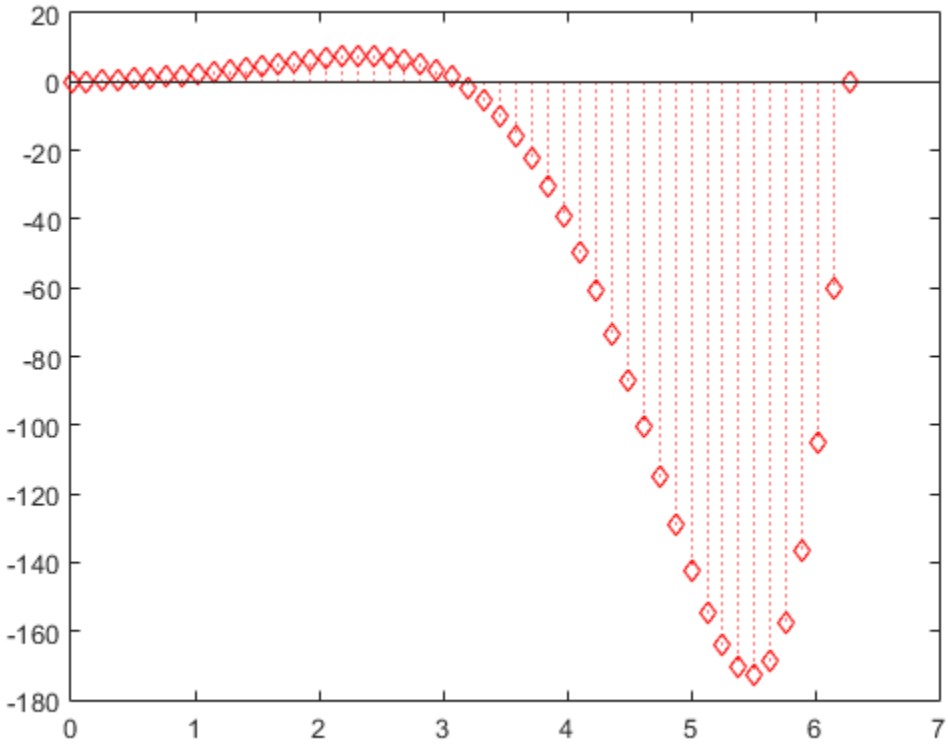
```
X = linspace(0,10,20)';
Y = (exp(0.25*X));
stem(X,Y,'filled')
```



Specify Stem and Marker Options

Create a stem plot and set the line style to a dotted line, the marker symbols to diamonds, and the color to red using the `LineSpec` option.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(X).*sin(X));
stem(X,Y,':diamondr')
```

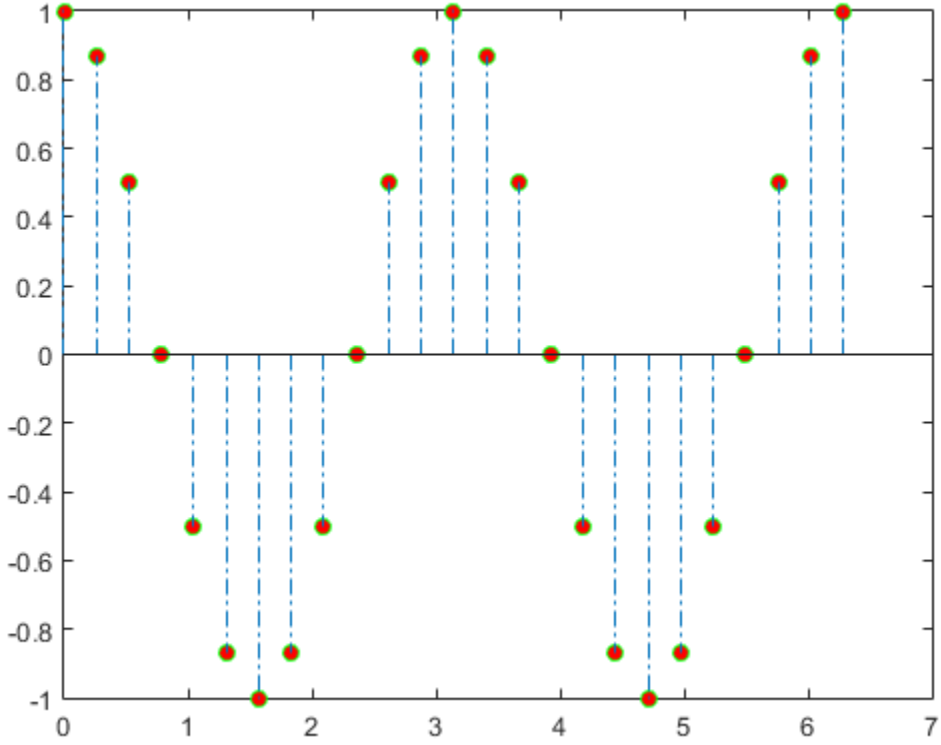


To color the inside of the diamonds, use the `'fill'` option.

Specify Additional Stem and Marker Options

Create a stem plot and set the line style to a dot-dashed line, the marker face color to red, and the marker edge color to green using `Name,Value` pair arguments.

```
figure
X = linspace(0,2*pi,25)';
Y = (cos(2*X));
stem(X,Y,'LineStyle','-.',...
     'MarkerFaceColor','red',...
     'MarkerEdgeColor','green')
```



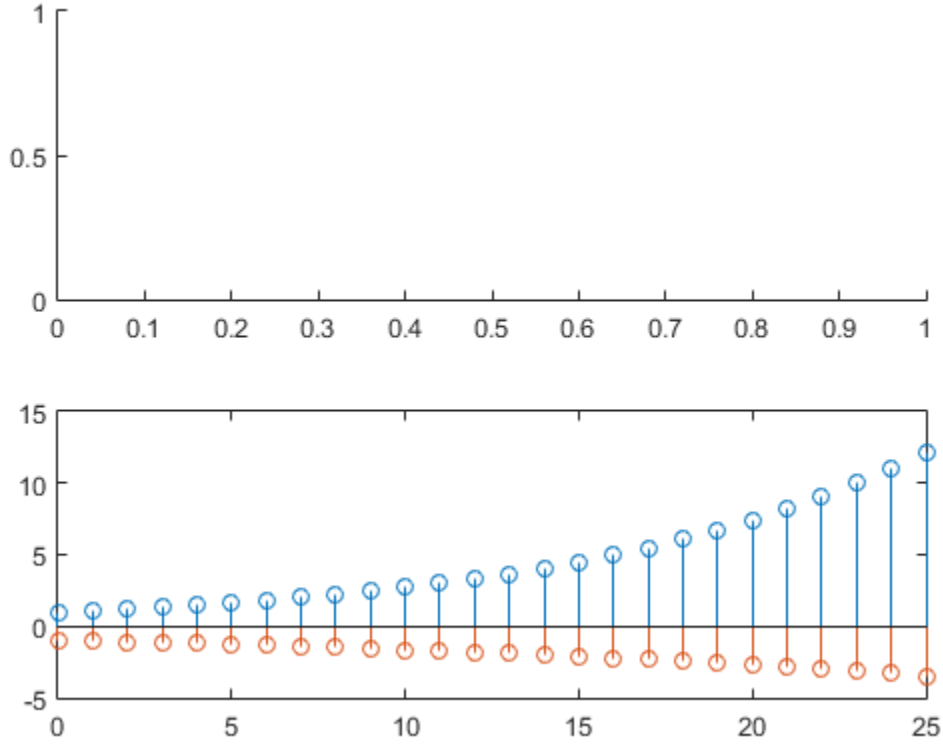
The stem remains the default color.

Specify Axes for Stem Plot

Create a figure with two subplots and return the handles to each axes, `s(1)` and `s(2)`. Create a stem plot in the lower subplot by referring to its axes handle, `s(2)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

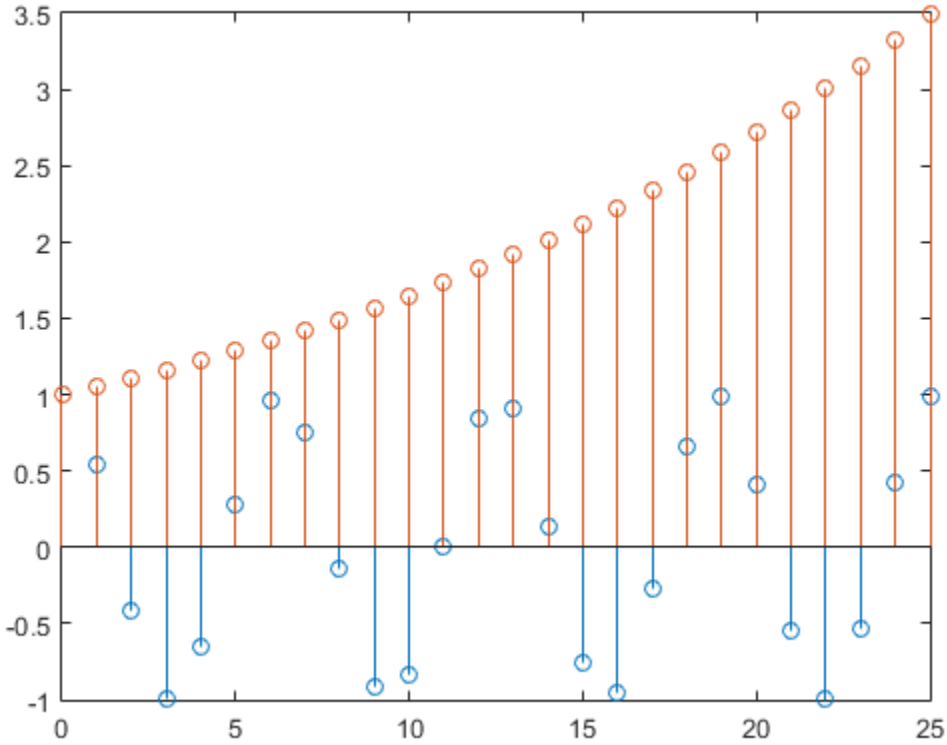
X = 0:25;
Y = [exp(0.1*X); -exp(.05*X)]';
stem(s(2),X,Y)
```



Modify Stem Series After Creation

Create a stem plot.

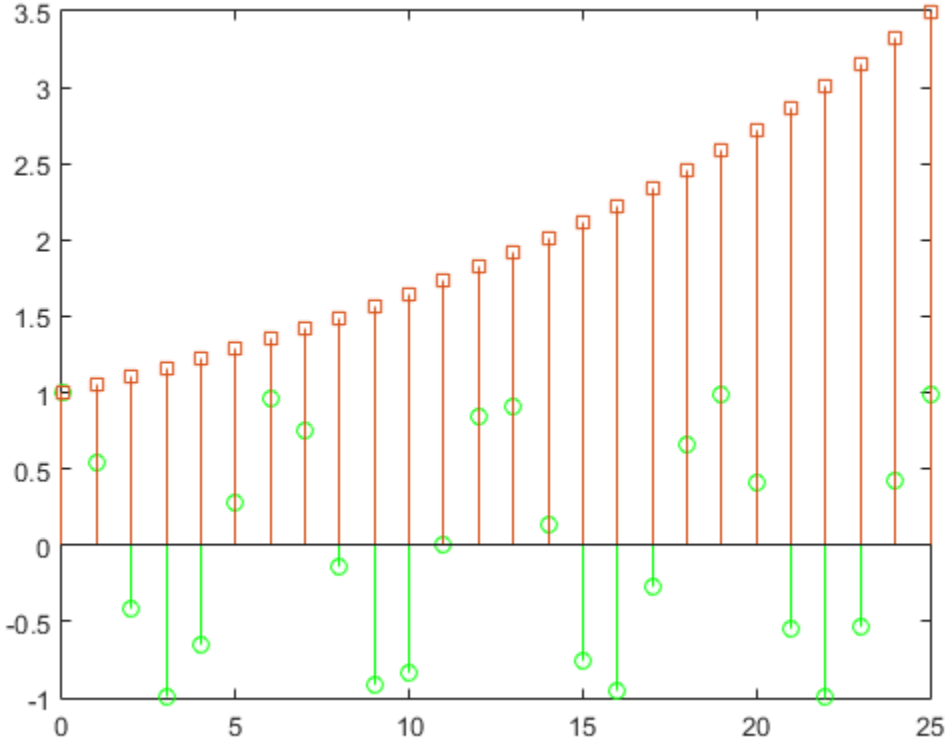
```
X = 0:25;
Y = [cos(X); exp(0.05*X)]';
h = stem(X,Y);
```



The `stem` function creates a stem series object for each column of data. The output argument, `h`, contains the two stem series objects.

Set the first stem series color to green. Change the markers of the second stem series to squares. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

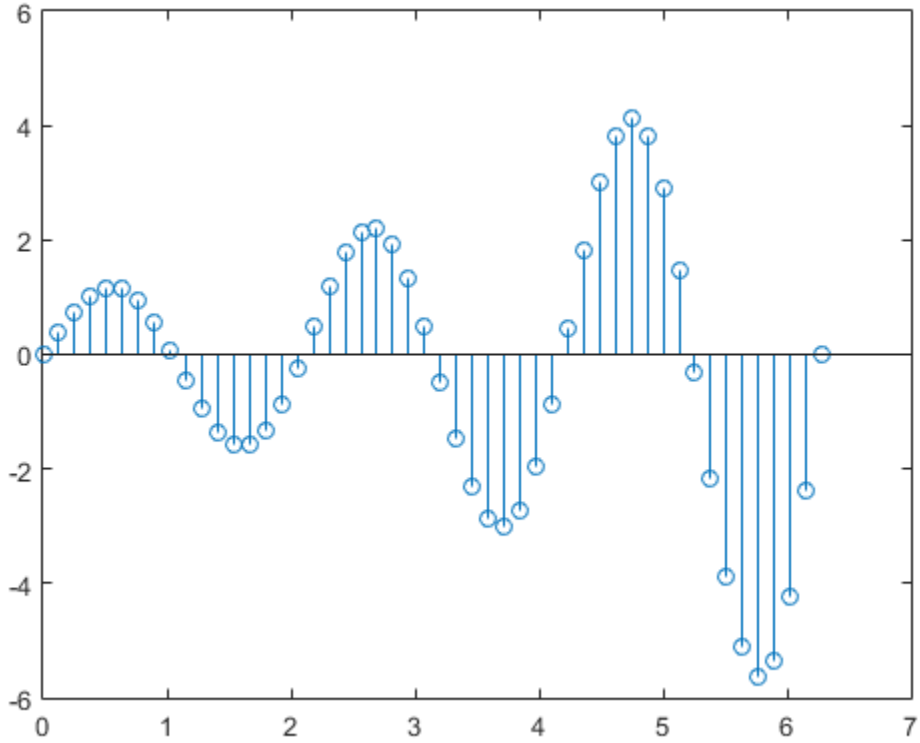
```
h(1).Color = 'green';
h(2).Marker = 'square';
```



Adjust Baseline Properties

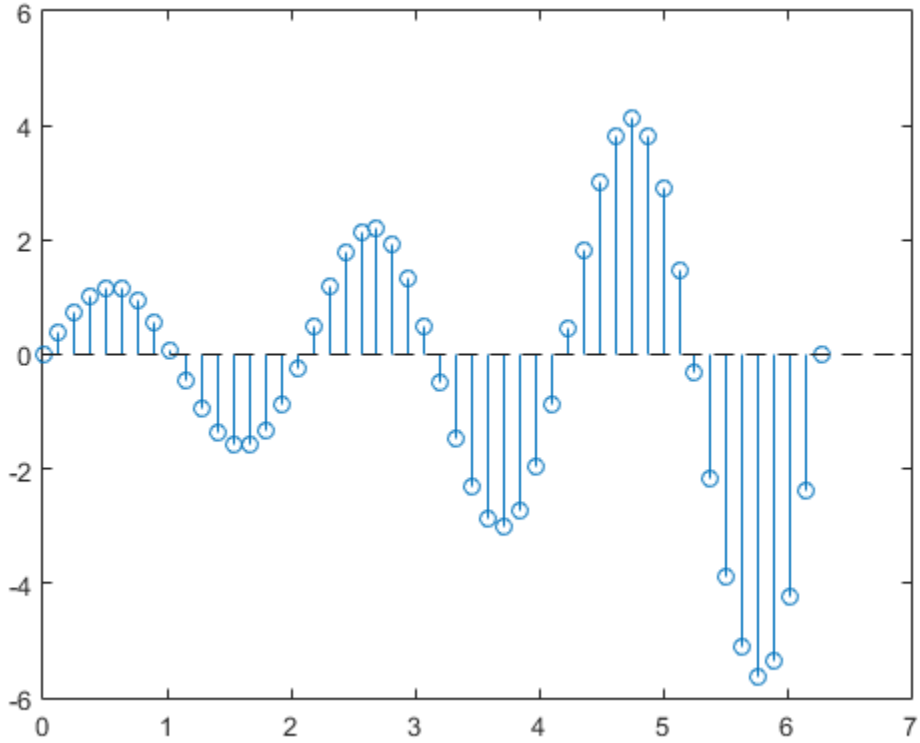
Create a stem plot and change properties of the baseline.

```
X = linspace(0,2*pi,50);
Y = exp(0.3*X).*sin(3*X);
h = stem(X,Y);
```



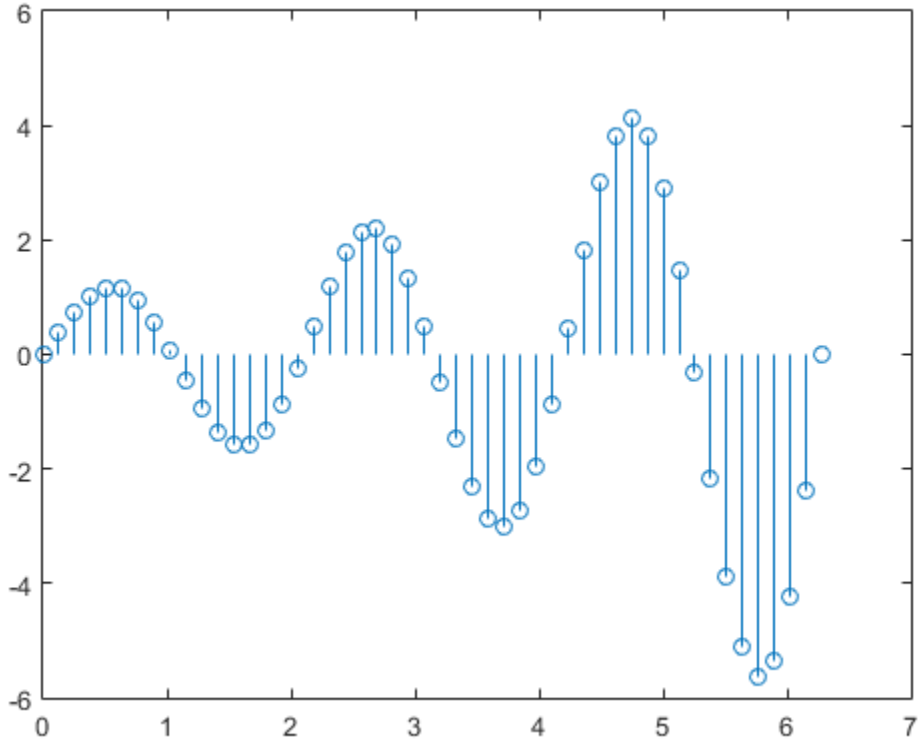
Change the line style of the baseline. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
hbase = h.BaseLine;
hbase.LineStyle = '--';
```



Hide the baseline by setting its `Visible` property to `'off'` .

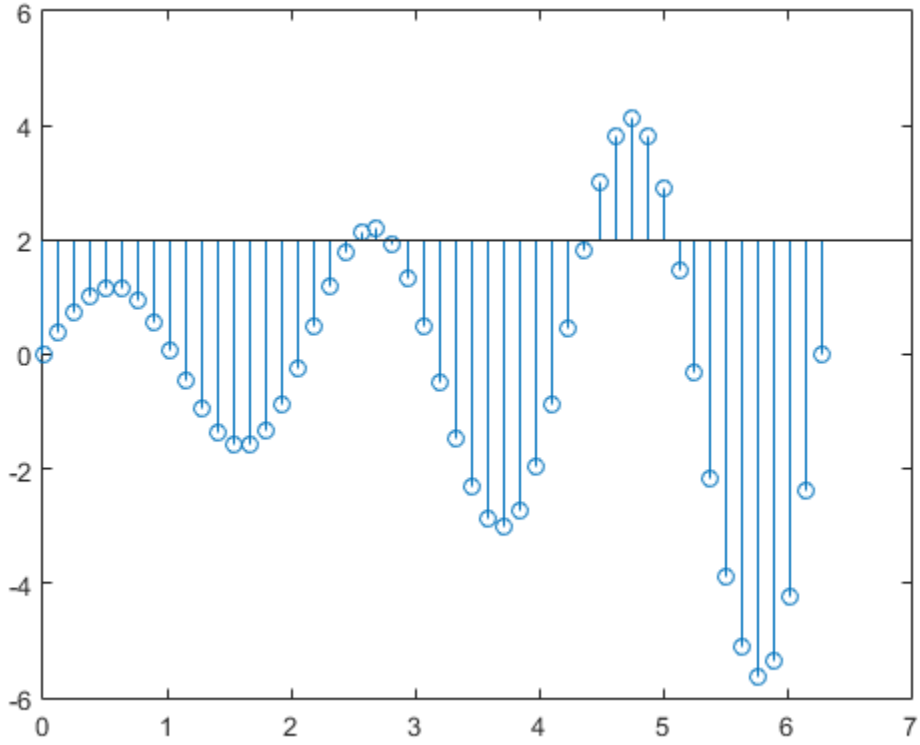
```
hbase.Visible = 'off';
```



Change Baseline Level

Create a stem plot with a baseline level at 2.

```
X = linspace(0,2*pi,50)';
Y = (exp(0.3*X).*sin(3*X));
stem(X,Y,'BaseValue',2);
```



- “Combine Stem Plot and Line Plot”

Input Arguments

Y — Data sequence to display

vector or matrix

Data sequence to display, specified as a vector or matrix. When `Y` is a vector, `stem` creates one stem series. When `Y` is a matrix, `stem` creates a separate stem series for each column.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

X — Locations to plot data values in Y

vector or matrix

Locations to plot data values in Y, specified as a vector or matrix. When Y is a vector, X must be a vector of the same size. When Y is a matrix, X must be a matrix of the same size, or a vector whose length equals the number of rows in Y.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

LineSpec — Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineSpec`.

Example: `':*r'`

ax — Axes object

object

Axes object. Use `ax` to modify the stem series after it is created.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'LineStyle',':','MarkerFaceColor','red'` plots the stem as a dotted line and colors the marker face red.

The stem series properties listed here are only a subset. For a complete list, see Stem Series Properties.

'LineStyle' — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
String	Line Style	Resulting Line
'--'	Dashed line	':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

'LineWidth' — Line width
0.5 (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: 0.75

'Color' — Stem color
[0 0 0] (default) | RGB triplet | color string | 'none'

Stem color, specified as an RGB triplet, a color string, or 'none'. If you specify the Color as 'none', then the stems are invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `'blue'`

Example: `[0 0 1]`

`'Marker'` — Marker symbol

`'o'` (default) | `'+'` | `'*'` | `'.'` | `'x'` | ...

Marker symbol, specified as one of the marker strings listed in this table.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `‘diamond’`

`'MarkerSize'` — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`'MarkerEdgeColor'` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`'MarkerFaceColor'` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `[0.3 0.2 0.1]`

Example: `'green'`

Output Arguments

h — Stem series object

scalar or column vector

Stem series objects, returned as a scalar or column vector. This is a unique identifier, which you can use to modify the properties of a specific stem series after it is created.

Functions

`bar` | `LineSpec` | `plot` | `stairs`

Properties

Stem Series Properties

Introduced before R2006a

stem3

Plot 3-D discrete sequence data

Syntax

```
stem3(Z)
stem3(X,Y,Z)
stem3(___,'filled')
stem3(___,LineSpec)
stem3(___,Name,Value)

stem3(ax,___)

h = stem3(___)
```

Description

`stem3(Z)` plots entries in `Z` as stems extending from the *xy*-plane and terminating with circles at the entry values. The stem locations in the *xy*-plane are automatically generated.

`stem3(X,Y,Z)` plots entries in `Z` as stems extending from the *xy*-plane where `X` and `Y` specify the stem locations in the *xy*-plane. The inputs `X`, `Y`, and `Z` must be vectors or matrices of the same size.

`stem3(___,'filled')` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

`stem3(___,LineSpec)` specifies the line style, marker symbol, and color.

`stem3(___,Name,Value)` specifies stem series properties using one or more `Name,Value` pair arguments.

`stem3(ax,___)` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in the previous syntaxes.

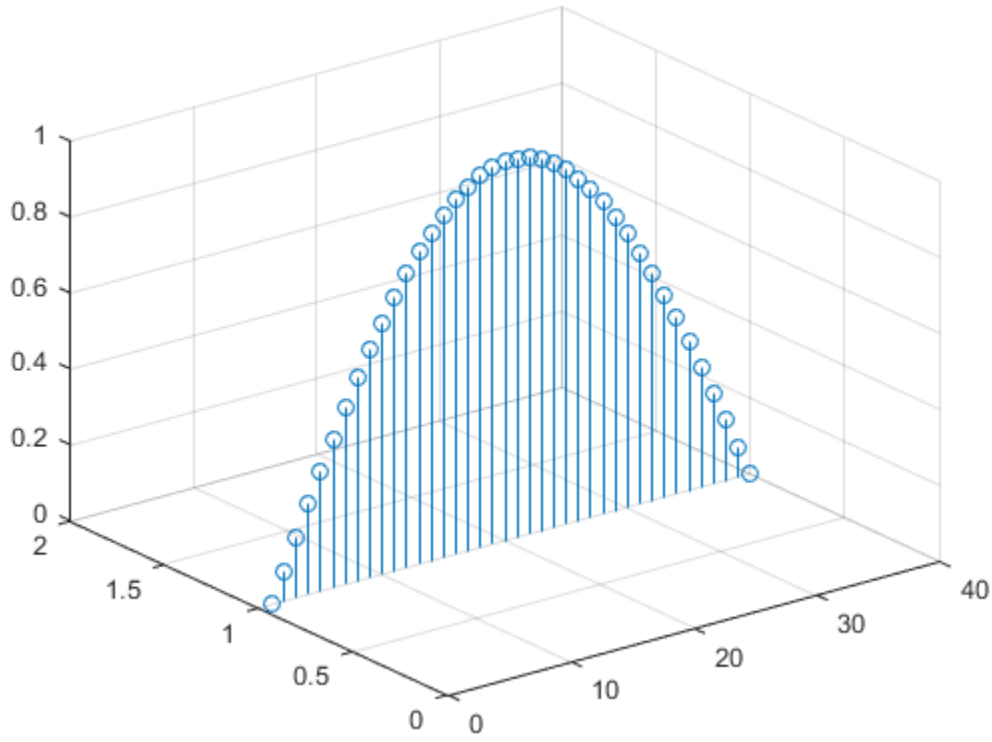
`h = stem3( ___ )` returns the stem series object `h`.

Examples

Row Vector Input

Create a 3-D stem plot of cosine values between $-\pi/2$ and $\pi/2$ with a row vector input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = cos(X);
stem3(Z)
```

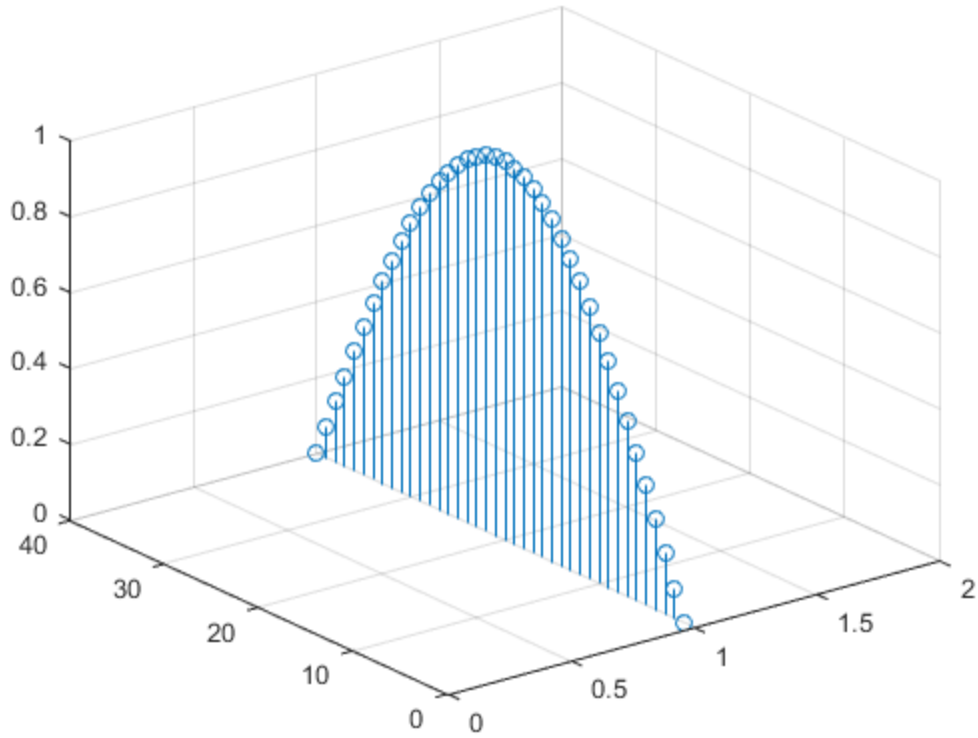


`stem3` plots elements of `Z` against the same *y* value at equally space *x* values.

Column Vector Input

Create a 3-D stem plot of cosine values between $-\pi/2$ and $\pi/2$ with a column vector input.

```
figure
X = linspace(-pi/2,pi/2,40)';
Z = cos(X);
stem3(Z)
```

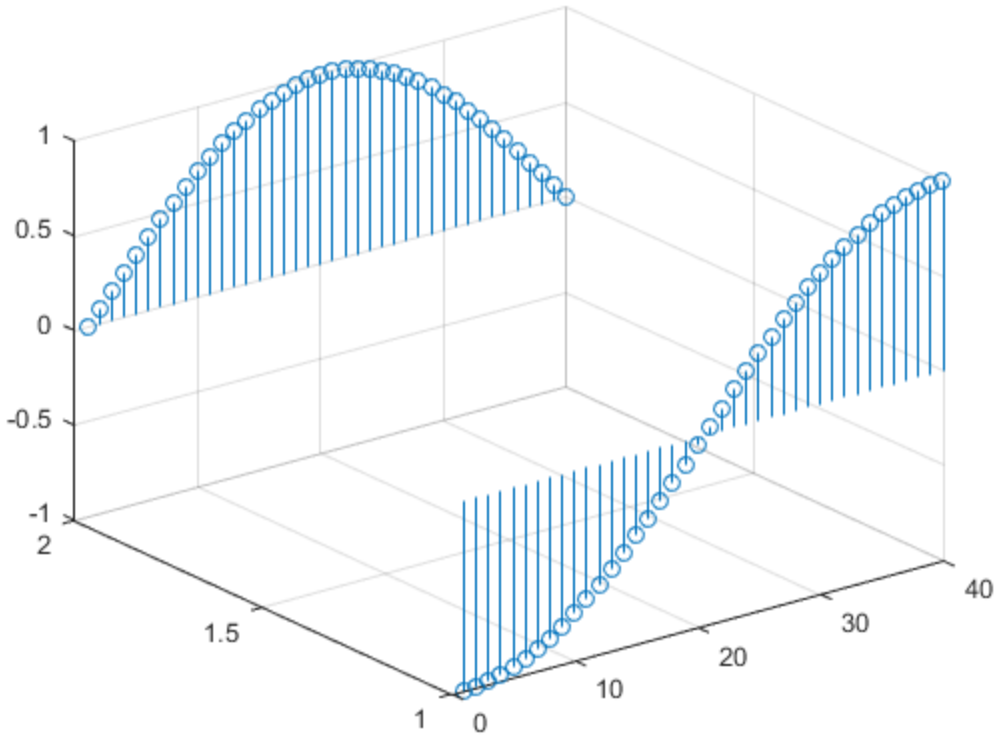


`stem3` plots elements of `Z` against the same *x* value at equally space *y* values.

Matrix Input

Create a 3-D stem plot of sine and cosine values between $-\pi/2$ and $\pi/2$ with a matrix input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = [sin(X); cos(X)];
stem3(Z)
```

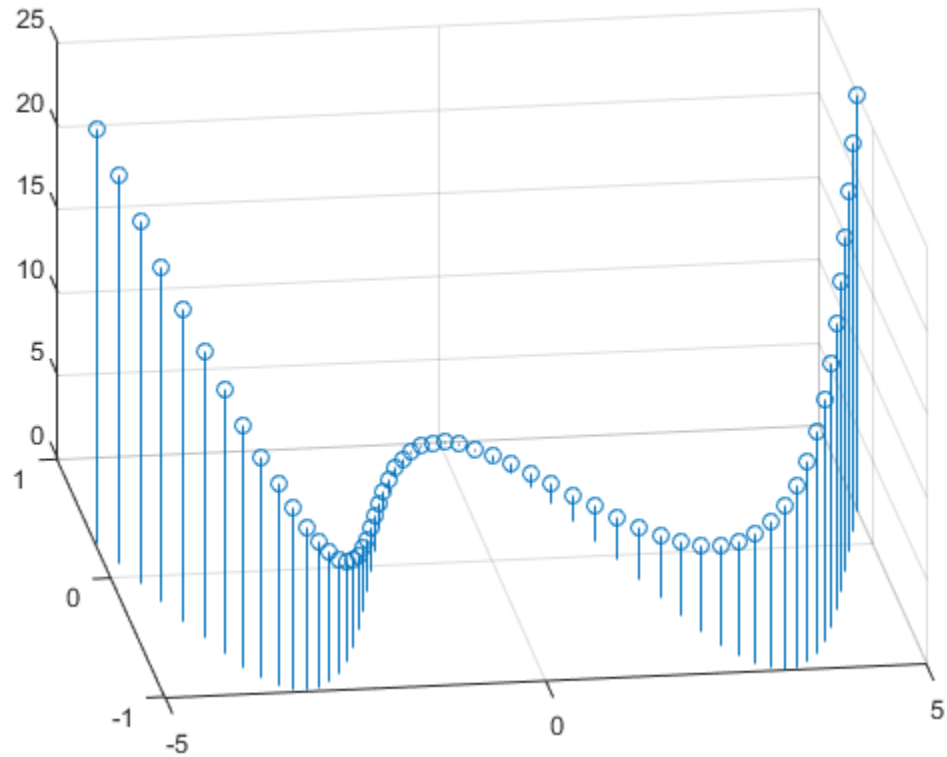


`stem3` plots each row of `Z` against the same *y* value at equally space *x* values.

Specify Stem Locations with Vector Inputs

Create a 3-D stem plot and specify the stem locations along a curve. Use `view` to adjust the angle of the axes in the figure.

```
figure
X = linspace(-5,5,60);
Y = cos(X);
Z = X.^2;
stem3(X,Y,Z)
view(-8,30)
```

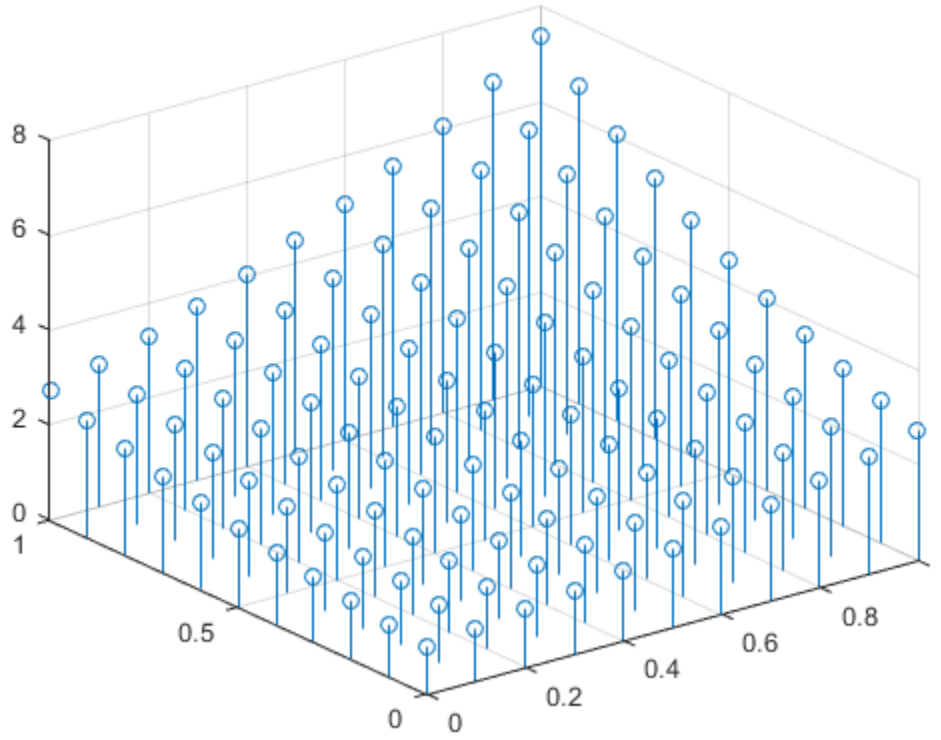


`X` and `Y` determine the stem locations. `Z` determines the marker heights.

Specify Stem Locations with Matrix Inputs

Create a 3-D stem plot with matrix data and specify the stem locations in the *xy*-plane.

```
figure
[X,Y] = meshgrid(0:.1:1);
Z = exp(X+Y);
stem3(X,Y,Z)
```

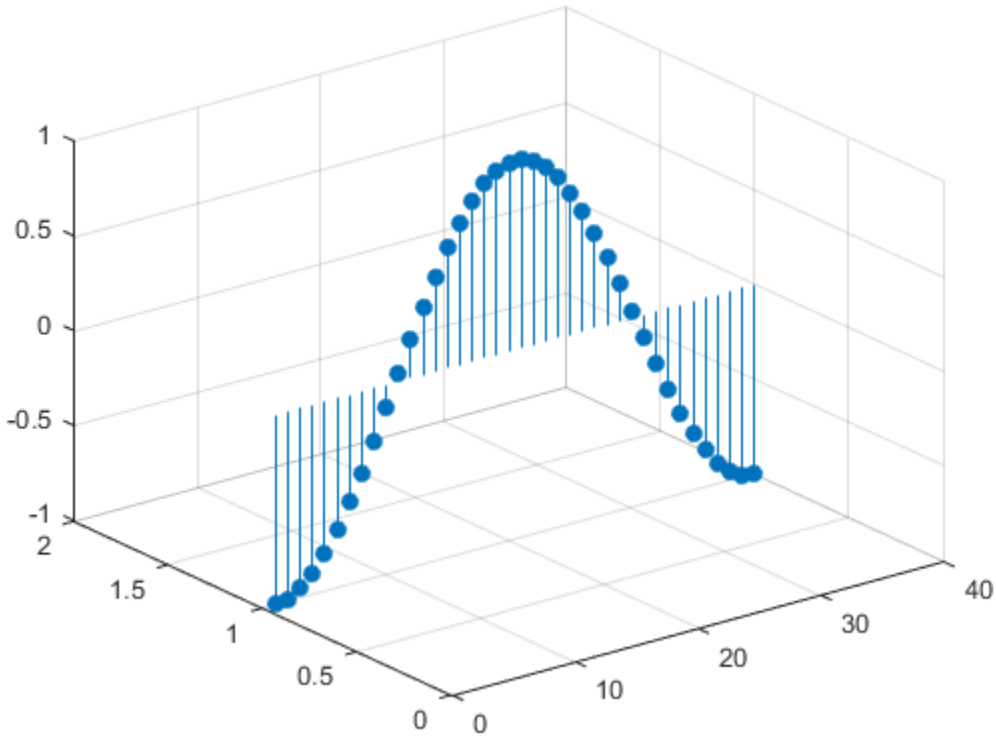


X and Y determine the stem locations. Z determines the marker heights.

Fill in Markers

Create a 3-D stem plot of cosine values between $-\pi$ and π and fill in the markers.

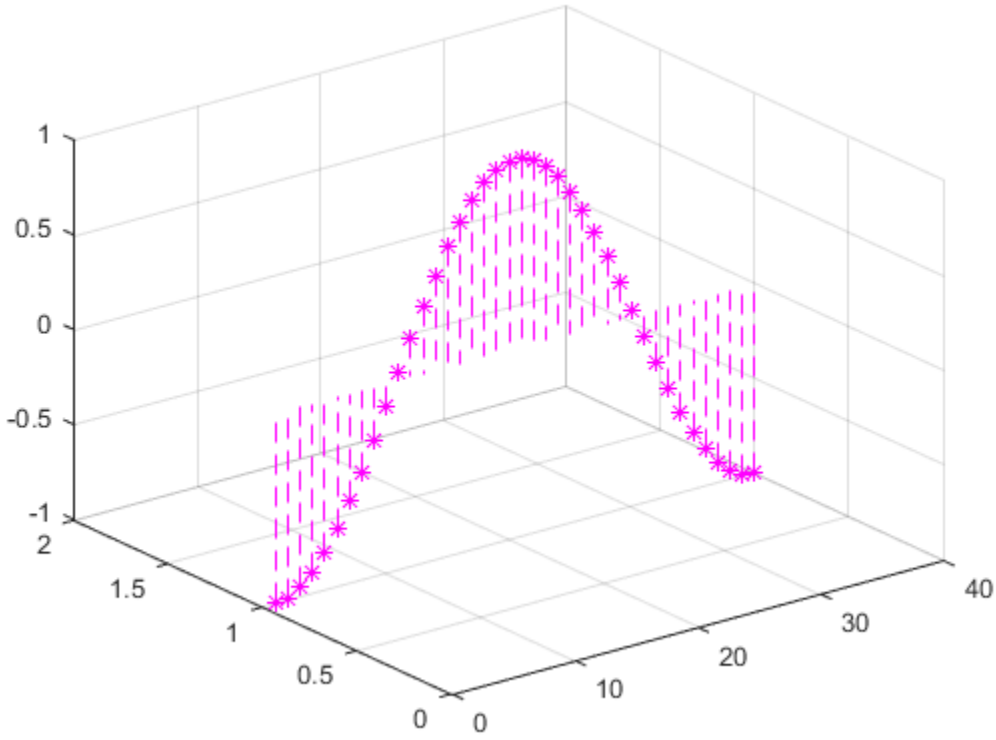
```
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'filled')
```



Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot of cosine values between $-\pi$ and π. Use a dashed line style for the stem, set the marker symbols to stars, and set the color to magenta.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'--*m')
```



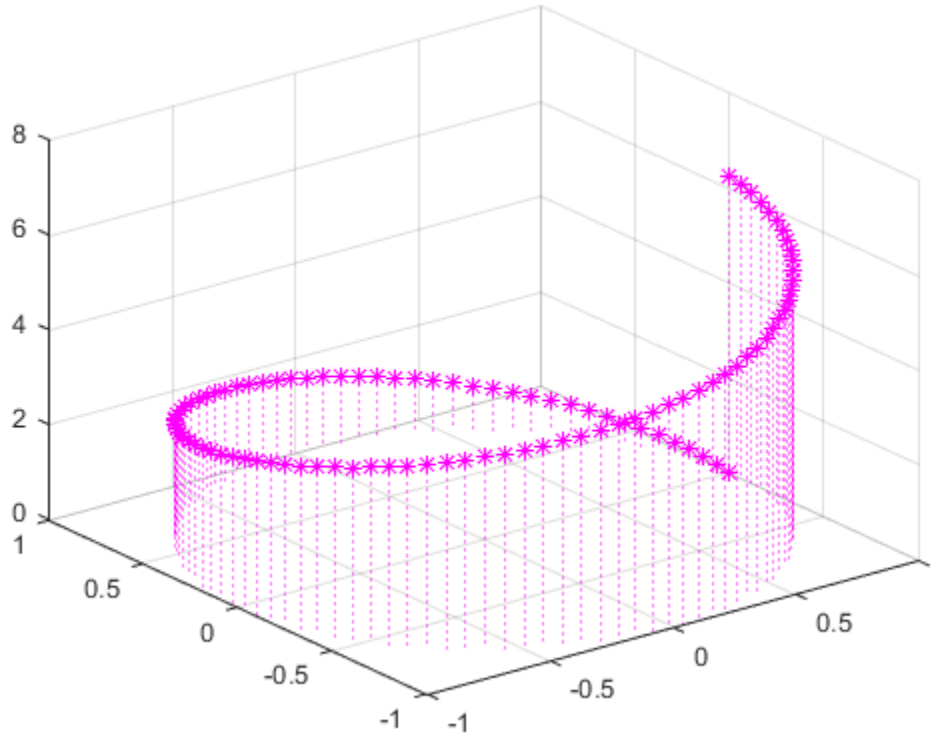
To specify only two of the three `LineSpec` options, omit the third option from the string. For example, `'*m'` sets the marker symbol and the color and uses the default line style.

Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot and specify the stem locations along a circle. Set the stem to a dotted line style, the marker symbols to stars, and the color to magenta.

```
figure
```

```
theta = linspace(0,2*pi);
X = cos(theta);
Y = sin(theta);
Z = theta;
stem3(X,Y,Z,':*m')
```



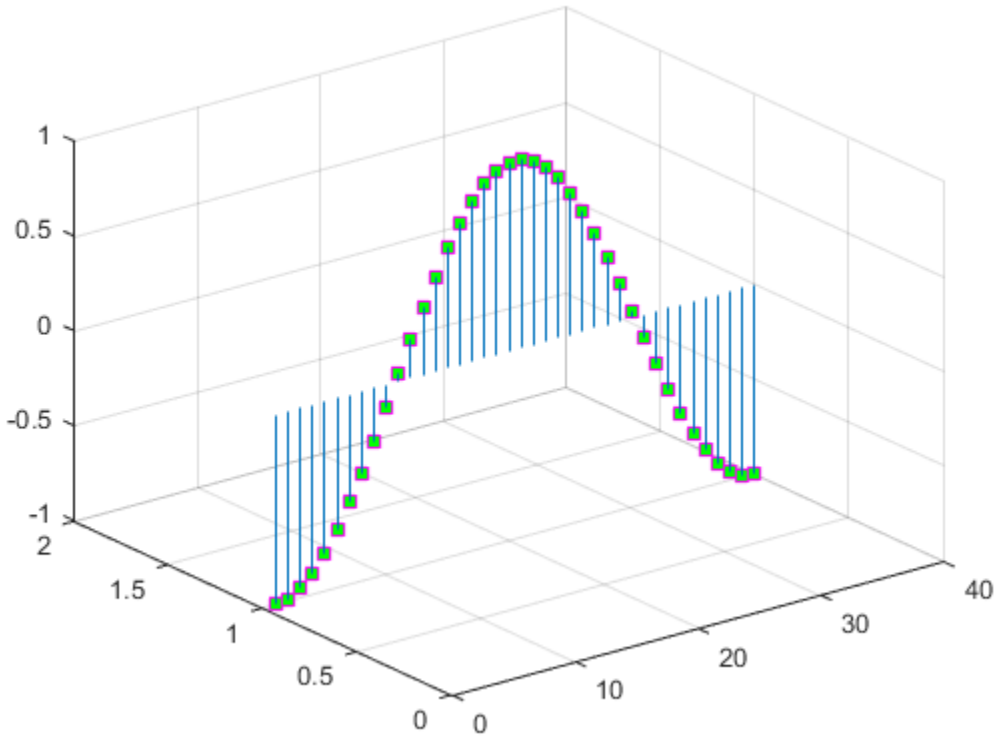
X and Y determine the stem locations. Z determines the marker heights.

Additional Style Options

Create a 3-D stem plot of cosine values between $-\pi$ and π. Set the marker symbols to squares with green faces and magenta edges.

```
figure
```

```
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'Marker','s',...
      'MarkerEdgeColor','m',...
      'MarkerFaceColor','g')
```



Axes Handles

Specify the axes for a 3-D stem plot.

Define vectors `X`, `Y` and `Z`.

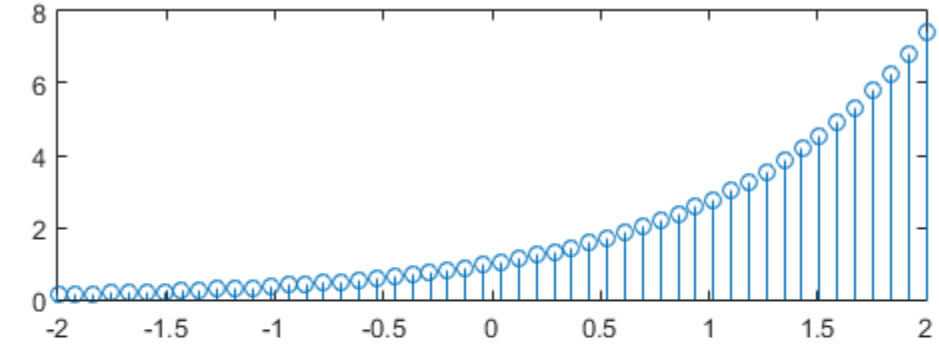
```
X = linspace(-2,2,50);
```

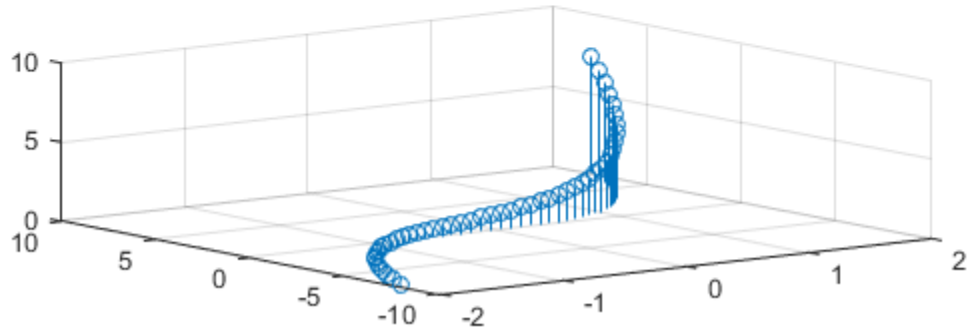
```
Y = X.^3;
Z = exp(X);
```

Create a figure with two subplots and return the handles to each axes, `s(1)` and `s(2)`. Plot a 3-D stem plot in the lower subplot by referring to its axes handle, `s(2)`. For comparison, plot a 2-D stem plot in the upper subplot by referring to its axes handle, `s(1)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

stem(s(1),X,Z)
stem3(s(2),X,Y,Z)
```

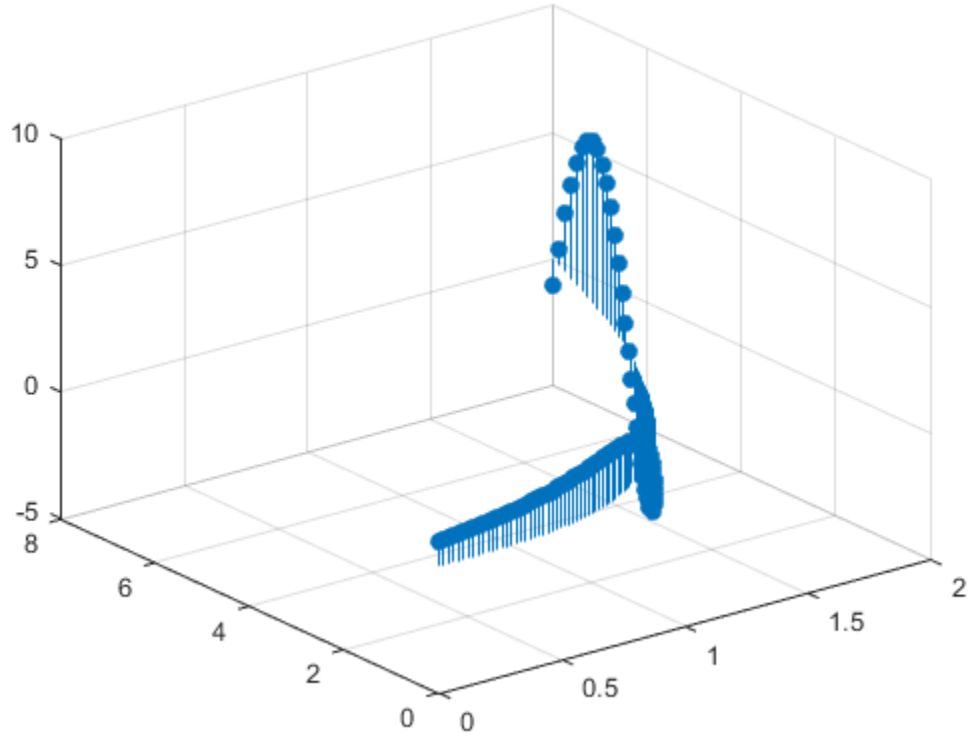




Modify Stem Series After Creation

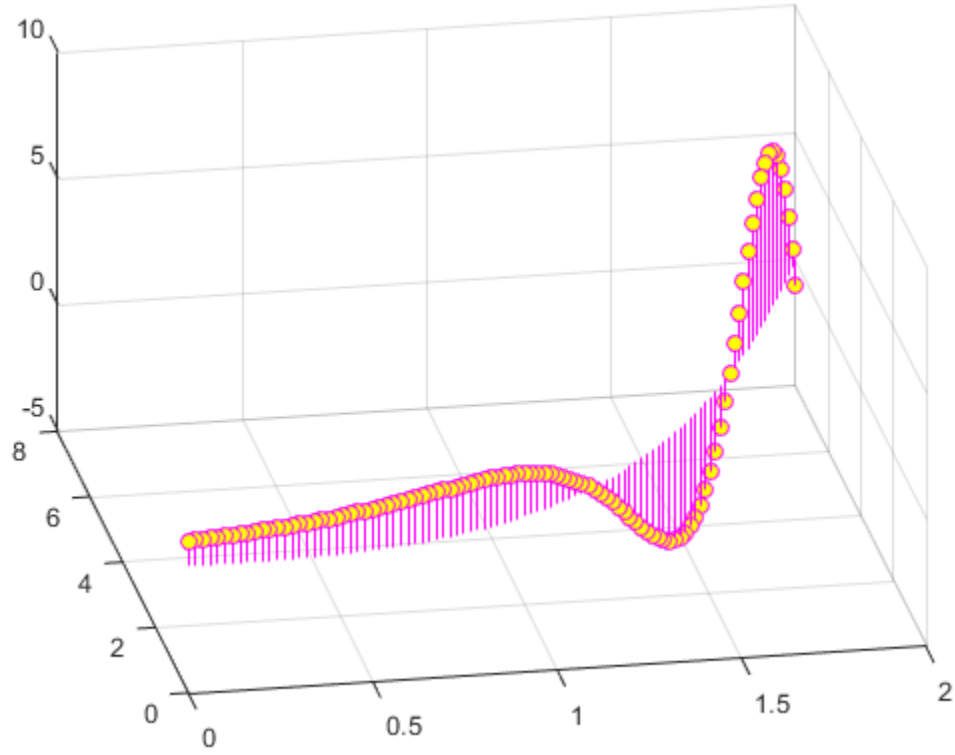
Create a 3-D stem plot and return the stem series object.

```
X = linspace(0,2);
Y = X.^3;
Z = exp(X).*cos(Y);
h = stem3(X,Y,Z,'filled');
```



Change the color to magenta and set the marker face color to yellow. Use `view` to adjust the angle of the axes in the figure. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
h.Color = 'm';
h.MarkerFaceColor = 'y';
view(-10,35)
```



- “Combine Stem Plot and Line Plot”

Input Arguments

Z — Data sequence to display

vector or matrix

Data sequence to display, specified as a vector or matrix. `stem3` plots each element in `Z` as a stem extending from the *xy*-plane and terminating at the data value.

- If `Z` is a row vector, `stem3` plots all elements against the same *y* value at equally spaced *x* values.

- If `Z` is a column vector, `stem3` plots all elements against the same *x* value at equally spaced *y* values.
- If `Z` is a matrix, `stem3` plots each row of `Z` against the same *y* value at equally spaced *x* values.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

`X` — Locations to plot values of `Z`

vector or matrix

Locations to plot values of`Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

`Y` — Locations to plot values of `Z`

vector or matrix

Locations to plot values of `Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical`

`LineSpec` — Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineSpec`.

Example: `':*r'`

Data Types: `char`

`ax` — Axes object

axes object

Axes object. If you do not specify an axes, then `stem` plots into the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'LineStyle',':','MarkerFaceColor','red'` plots the stem as a dotted line and sets the marker face color to red.

The properties listed here are only a subset. For a complete list, see Stem Series Properties.

`'LineStyle'` — Line style
`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	————
`'--'`	Dashed line	- - - - -
`':'`	Dotted line	.....
`'-.'`	Dash-dotted line	_._._._.-
`'none'`	No line	No line

`'LineWidth'` — Line width of stem and marker edge
`0.5` (default) | positive value

Line width of stem and marker edge, specified as a positive value in point units.

Example: `0.75`

`'Color'` — Stem color
`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Stem color, specified as an RGB triplet, a color string, or `'none'`. If you specify the `Color` as `'none'`, then the stems are invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`'Marker'` — Marker symbol

`'o'` (default) | `'+'` | `'*'` | `'.'` | `'x'` | ...

Marker symbol, specified as one of the marker strings listed in this table.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle

String	Marker Symbol
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

'MarkerSize' — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

'MarkerEdgeColor' — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the Color property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.5 0.5 0.5]

Example: 'blue'

'MarkerFaceColor' — Marker fill color
'none' (default) | 'auto' | RGB triplet | color string

Marker fill color, specified as one of these values:

- 'none' — Use no color, which makes the interior invisible.
- 'auto' — Use the same color as the Color property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: `'green'`

Output Arguments

h — Stem series object
scalar

Stem series object, specified as a scalar. This is a unique identifier, which you can use to modify the properties of the stem series after it is created.

See Also

Functions
`bar` | `plot` | `stairs` | `stem`

Properties
Stem Series Properties

Introduced before R2006a

Stem Series Properties

Control stem series appearance and behavior

Stem series properties control the appearance and behavior of a stem series object. By changing property values, you can modify certain aspects of the stem series.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = stem(1:10);
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Stems

`Color` — Stem color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Stem color, specified as an RGB triplet, a color string, or `'none'`. If you specify the `Color` as `'none'`, then the stems are invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`LineStyle` — Stem line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Stem line style, specified as one of the strings listed in this table.

String	Line Style
`'-'`	Solid line
`'--'`	Dashed line
`':'`	Dotted line
`'-.'`	Dash-dotted line
`'none'`	No stems

Example: `'--'`

`LineWidth` — Line width of stem and marker edge

`0.5` (default) | scalar numeric value greater than 0

Line width of stem and marker edge, specified as a scalar numeric value greater than 0 in point units. The default line width is `0.5` points.

Example: `0.75`

Markers

`Marker` — Marker symbol

`'o'` (default) | `'+'` | `'*'` | `'.'` | `'x'` | ...

Marker symbol, specified as one of the marker strings listed in this table.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk

String	Marker Symbol
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: '+'

Example: 'diamond'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: 10

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | color string

Marker outline color, specified as one of these values:

- 'auto' — Use the same color as the Color property.
- 'none' — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]

Long Name	Short Name	RGB Triplet
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

Baseline

BaseValue — Baseline location

0 (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

ShowBaseLine — Baseline visibility

'on' (default) | 'off'

Baseline visibility, specified as one of these values:

- 'on' — Show the baseline.
- 'off' — Hide the baseline.

BaseLine — Baseline

baseline object

Baseline object. For a list of baseline properties, see Baseline Properties.

Data

XData — Values along x-axis

[ ] (default) | vector

Values along the *x*-axis, specified as a vector.

- For 2-D stem charts, the input argument X to the stem function determines the *x*-values. If you do not specify X, then stem uses the indices of YData as the *x*-values. XData and YData must have equal lengths.

- For 3-D stem charts, the input argument `X` to the `stem3` function determines the *x*-values. If you do not specify `X`, then `stem3` uses the indices of `ZData` as the *x*-values. `XData`, `YData`, and `ZData` must have equal lengths.

`YData` — Values along y-axis

`[ ]` (default) | vector

Values along the *y*-axis, specified as a vector.

- For 2-D stem charts, the input argument `Y` to the `stem` function determines the *y*-values. `YData` defines the stem heights. `XData` and `YData` must have equal lengths.
- For 3-D stem charts, the input argument `Y` to the `stem3` function determines the *y*-values. `YData` defines the locations of the stems along the *y*-axis. `XData`, `YData`, and `ZData` must have equal lengths.

`ZData` — Values along z-axis

`[ ]` (default) | vector

Values along the *z*-axis, specified as a vector.

- For 2-D stem charts, `ZData` is empty by default.
- For 3-D stem charts, the input argument `Z` to the `stem3` function determines the *z*-values. `XData`, `YData`, and `ZData` must have equal lengths.

`XDataSource` — Variable linked to `XData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

YDataSource — Variable linked to YData

'' (default) | string containing MATLAB workspace variable name

Variable linked to YData, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the YData.

By default, there is no linked variable so the value is an empty string, ''. If you link a variable, then MATLAB does not update the YData values immediately. To force an update of the data values, use the refreshdata function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: 'y'

ZDataSource — Variable linked to ZData

'' (default) | string containing MATLAB workspace variable name

Variable linked to ZData, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the ZData.

By default, there is no linked variable so the value is an empty string, ''. If you link a variable, then MATLAB does not update the ZData values immediately. To force an update of the data values, use the refreshdata function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: 'z'

XDataMode — Selection mode for XData

'auto' (default) | 'manual'

Selection mode for XData, specified as one of these values:

- 'auto' — Use the indices of the values in YData (or ZData for 3-D plots).

- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

Visibility

`Visible` — Visibility of stem series

`'on'` (default) | `'off'`

Visibility of stem series, specified as one of these values:

- `'on'` — Display the stem series.
- `'off'` — Hide the stem series without deleting it. You still can access the properties of an invisible stem series object.

`Clipping` — Clipping of stem series to axes limits

`'on'` (default) | `'off'`

Clipping of stem series to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the stem series that are outside the axes limits.
- `'off'` — Display the entire stem series, even if parts of it appear outside the axes limits. Parts of the stem series might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the stem series that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.

- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'stem'` (default)

Type of graphics object, returned as `'stem'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

`Tag` — Tag to associate with stem series

`''` (default) | string

Tag to associate with the stem series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: `char`

`UserData` — Data to associate with stem series

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the stem series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the stem series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the stem series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the stem series from a legend.

1. Query the `Annotation` property to get the `Annotation` object.

2 Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.

3 Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:

- `'on'` — Include the stem series object in the legend as one entry (default).
- `'off'` — Do not include the stem series object in the legend.
- `'children'` — Include only children of the stem series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of stem series

axes object | group object | transform object

Parent of stem series, specified as an axes, group, or transform object.

`Children` — Children of stem series

empty `GraphicsPlaceholder` array

The stem series has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of stem series object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The stem series object handle is always visible.
- `'off'` — The stem series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The stem series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the stem series at the command-line, but allows callback functions to access it.

If the stem series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the stem series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stem series object — You can access properties of the stem series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

UIContextMenu — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the stem series. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

Selected — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the stem series when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the stem series.
- `'off'` — Not selected.

SelectionHighlight — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

PickableParts — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the stem series that has a defined color. You

cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the stem series responds to the click or if an ancestor does.

- `'none'` — Cannot capture mouse clicks. Clicking the stem series passes the click to the object below it in the current view of the figure window. The HitTest property of the stem series has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the stem series. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the stem series that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the stem series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for stem series

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for stem series, specified as one of these values:

- `'off'` — Click the stem series plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the stem series plot to select it, that is, anywhere within the rectangle that encloses the stem series plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the stem series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the stem series tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the stem series. Setting the `CreateFcn` property on an existing stem series has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during stem series creation. MATLAB executes the callback after creating the stem series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stem series object — You can access properties of the stem series object from within the callback function. You also can access the stem series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the stem series. MATLAB executes the callback before destroying the stem series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The stem series object — You can access properties of the stem series object from within the callback function. You also can access the stem series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of stem series

`'off'` (default) | `'on'`

Deletion status of stem series, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the stem series begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the stem series no longer exists.

Check the value of the BeingDeleted property to verify that the stem series is not about to be deleted before querying or modifying it.

stopasync

Stop asynchronous read and write operations

Syntax

```
stopasync(obj)
```

Description

`stopasync(obj)` stops any asynchronous read or write operation that is in progress for the serial port object, `obj`.

More About

Tips

You can write data asynchronously using the `fprintf` or `fwrite` function. You can read data asynchronously using the `readasync` function, or by configuring the `ReadAsyncMode` property to `continuous`. In-progress asynchronous operations are indicated by the `TransferStatus` property.

If `obj` is an array of serial port objects and one of the objects cannot be stopped, the remaining objects in the array are stopped and a warning is returned. After an object stops:

- Its `TransferStatus` property is configured to `idle`.
- Its `ReadAsyncMode` property is configured to `manual`.
- The data in its output buffer is flushed.

Data in the input buffer is not flushed. You can return this data to the MATLAB workspace using any of the synchronous read functions. If you execute the `readasync` function, or configure the `ReadAsyncMode` property to `continuous`, then the new data is appended to the existing data in the input buffer.

See Also

`fwrite` | `readasync` | `fprintf` | `ReadAsyncMode` | `TransferStatus`

Introduced before R2006a

str2double

Convert string to double-precision value

Syntax

```
X = str2double('str')
X = str2double(C)
```

Description

`X = str2double('str')` converts the string `str`, which should be an ASCII character representation of a real or complex scalar value, to the MATLAB double-precision representation. The string can contain digits, a comma (thousands separator), a decimal point, a leading `+` or `-` sign, an `e` preceding a power of 10 scale factor, and an `i` for a complex unit.

If `str` does not represent a valid scalar value, `str2double` returns `NaN`.

`X = str2double(C)` converts the strings in the cell array of strings `C` to double precision. The matrix `X` returned will be the same size as `C`.

Examples

Here are some valid `str2double` conversions, for numbers and cell arrays.

```
str2double('123.45e7')
str2double('123 + 45i')
str2double('3.14159')
str2double('2.7i - 3.14')
str2double({'2.71' '3.1415'})
str2double('1,200.34')
```

`char` | `hex2num` | `num2str` | `str2num` | `cast`

Introduced before R2006a

str2func

Construct function handle from function name string

Syntax

```
str2func('str')
```

Description

`str2func('str')` constructs a function handle `fhandle` for the function named in the string `'str'`. The contents of `str` can be the name of a file that defines a MATLAB function, or the name of an anonymous function.

You can create a function handle `fh` using any of the following four methods:

- Create a handle to a named function:

  ```
  fh = @functionName;
  fh = str2func('functionName');
  ```

- Create a handle to an anonymous function:

  ```
  fh = @(x)functionDef(x);
  fh = str2func('@(x)functionDef(x)');
  ```

You can create an array of function handles from strings by creating the handles individually with `str2func`, and then storing these handles in a cell array.

Examples

Example 1

To convert the string, `'sin'`, into a handle for that function, type

```
fh = str2func('sin')
fh =
```

```
    @sin
```

Example 2

If you pass a function name string in a variable, the function that receives the variable can convert the function name to a function handle using `str2func`. The example below passes the variable, `funcname`, to function `makeHandle`, which then creates a function handle. Here is the function:

```
function fh = makeHandle(funcname)
fh = str2func(funcname);
```

This is the code that calls `makeHandle` to construct the function handle:

```
makeHandle('sin')
ans =
    @sin
```

Example 3

To call `str2func` on a cell array of strings, use the `cellfun` function. This returns a cell array of function handles:

```
fh_array = cellfun(@str2func, {'sin' 'cos' 'tan'}, ...
                   'UniformOutput', false);

fh_array{2}(5)
ans =
   0.2837
```

Example 4

In the following example, the `myminbnd` function expects to receive either a function handle or string in the first argument. If you pass a string, `myminbnd` constructs a function handle from it using `str2func`, and then uses that handle in a call to `fminbnd`:

```
function myminbnd(fhandle, lower, upper)
if ischar(fhandle)
   disp 'converting function string to function handle ...'
   fhandle = str2func(fhandle);
end
fminbnd(fhandle, lower, upper)
```

Whether you call `myminbnd` with a function handle or function name string, the function can handle the argument appropriately:

```
myminbnd('humps', 0.3, 1)
converting function string to function handle ...
ans =
    0.6370
```

Example 5

The `dirByType` function shown here creates an anonymous function called `dirCheck`. What the anonymous function does depends upon the value of the `dirType` argument passed in to the primary function. The example demonstrates one possible use of `str2func` with anonymous functions:

```
function dirByType(dirType)
switch(dirType)
   case 'class', leadchar = '@';
   case 'package', leadchar = '+';
   otherwise disp('ERROR: Unrecognized type'), return;
end

dirfile = @(fs)isdir(fs.name);
dirCheckStr = ['@(fs)strcmp(fs.name(1,1),''', leadchar, ''')'];
dirCheckFun = str2func(dirCheckStr);
s = dir;   filecount = length(s);

for k=1:filecount
   fstruct = s(k);
   if dirfile(fstruct) && dirCheckFun(fstruct)
       fprintf('%s folder: %s\n', dirType, fstruct.name)
   end
end
```

Generate a list of class and package folders:

```
dirByType('class')
class folder: @Point
class folder: @asset
class folder: @bond

dirByType('package')
package folder: +containers
package folder: +event
```

```
package folder: +mypkg
```

More About

Tips

Nested functions are not accessible to `str2func`. To construct a function handle for a nested function, you must use the function handle constructor, `@`.

Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

`function_handle` | `func2str` | `functions`

Introduced before R2006a

str2mat

Form blank-padded character matrix from strings

Note: `str2mat` is not recommended. Use `char` instead.

Syntax

```
S = str2mat(T1, T2, T3, ...)
```

Description

`S = str2mat(T1, T2, T3, ...)` forms the matrix `S` containing the text strings `T1, T2, T3, ...` as rows. The function automatically pads each string with blanks in order to form a valid matrix. Each text parameter, `Ti`, can itself be a string matrix. This allows the creation of arbitrarily large string matrices. Empty strings are significant.

Examples

```
x = str2mat('36842', '39751', '38453', '90307');

whos x
  Name      Size         Bytes  Class

  x         4x5             40  char array

x(2,3)

ans =

    7
```

More About

Tips

`str2mat` differs from `strvcat` in that empty strings produce blank rows in the output. In `strvcat`, empty strings are ignored.

See Also

`char`

Introduced before R2006a

str2num

Convert string to number

Syntax

```
x = str2num('str')
[x, status] = str2num('str')
```

Description

Note `str2num` uses the `eval` function to convert the input argument. Side effects can occur if the string contains calls to functions. Using `str2double` can avoid some of these side effects.

`x = str2num('str')` converts the string `str`, which is an ASCII character representation of a numeric value, to numeric representation. `str2num` also converts string matrices to numeric matrices. If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

The input string can contain one or more numbers separated by spaces, commas, or semicolons, such as '`5`', '`10,11,12`', or '`5,10;15,20`'. In addition to numerical values and delimiters, the input string can also include a decimal point, leading + or - signs, the letter `e` or `d` preceding a power of 10 scale factor, or the letter `i` or `j` indicating a complex or imaginary number.

The following table shows several examples of valid inputs to `str2num`:

String Input	Numeric Output	Output Class
`'500'`	500	`double`
`'500 250 125 67'`	500 250 125 67	1-by-4 row vector of `double`
`'500; 250; 125; 62.5'`	500.0000 250.0000 125.0000 62.5000	4-by-1 column vector of `double`

String Input	Numeric Output	Output Class
'1 23 6 21; 53:56'	1 23 6 21 53 54 55 56	2-by-4 matrix of double
'12e-3 5.9e-3'	0.0120 0.0059	1-by-2 row vector of double
'uint16(500)'	500	16–bit unsigned integer

Note: str2num does not operate on cell arrays. To convert a cell array of strings to a numeric value, use str2double.

If the input string does not represent a valid number or matrix, str2num(str) returns the empty matrix in x.

[x, status] = str2num('str') returns the status of the conversion in logical status, where status equals logical 1 (true) if the conversion succeeds, and logical 0 (false) otherwise.

Space characters can be significant. For instance, str2num('1+2i') and str2num('1 + 2i') produce x = 1+2i, while str2num('1 +2i') produces x = [1 2i]. You can avoid these problems by using the str2double function.

Examples

Input a character string that contains a single number. The output is a scalar double:

```
A = str2num('500')
A =
   500

class(A)
ans =
   double
```

Repeat this operation, but this time using an unsigned 16–bit integer:

```
A = str2num('uint16(500)')
A =
    500
```

```
class(A)
ans =
   uint16
```

Try three different ways of specifying a row vector. Each returns the same answer:

```
str2num('2 4 6 8')              % Separate with spaces.
ans =
     2     4     6     8

str2num('2,4,6,8')              % Separate with commas.
ans =
     2     4     6     8

str2num('[2 4 6 8]')            % Enclose in brackets.
ans =
     2     4     6     8
```

Note that the first two of these commands do not need the MATLAB square bracket operator to create a matrix. The `str2num` function inserts the brackets for you if they are needed.

Use a column vector this time:

```
str2num('2; 4; 6; 8')
ans =
     2
     4
     6
     8
```

And now a 2-by-2 matrix:

```
str2num('2 4; 6 8')
ans =
     2     4
     6     8
```

Introduced before R2006a

strcat

Concatenate strings horizontally

Syntax

```
s = strcat(s1,...,sN)
```

Description

`s = strcat(s1,...,sN)` horizontally concatenates strings `s1,...,sN`. Each input argument can be a single string, a collection of strings in a cell array, or a collection of strings in a character array.

If any input argument is a cell array, the result is a cell array of strings. Otherwise, the result is a character array.

For character array inputs, `strcat` removes trailing ASCII white-space characters: space, tab, vertical tab, newline, carriage return, and form feed. For cell array inputs, `strcat` does not remove trailing white space.

Examples

Concatenate Two Strings

```
s1 = 'Good';
s2 = 'morning';
s = strcat(s1,s2)
```

```
s =

Goodmorning
```

Concatenate Two Cell Arrays

```
s1 = {'abcde','fghi'};
s2 = {'jkl','mn'};
```

```
s = strcat(s1,s2)

s =

    'abcdejkl'    'fghimn'
```

Concatenate Two Cell Arrays with Scalar Cell Array

```
firstnames = {'Abraham'; 'George'};
lastnames = {'Lincoln'; 'Washington'};
names = strcat(lastnames, {', '}, firstnames)

names =

    'Lincoln, Abraham'
    'Washington, George'
```

Input Arguments

`s1, . . . , sN` — Input strings

character arrays | cell array of strings

Input strings, specified as cell arrays of strings or character arrays with the same number of rows. When combining nonscalar cell arrays and multirow character arrays, cell arrays must be column vectors with the same number of rows as the character arrays.

Data Types: `char` | `cell`

More About

Tips

- Strings also can be concatenated using left and right square brackets.

  ```
  s1 = 'Good ';
  s2 = 'Morning';
  s = [s1 s2]

  s =

  Good Morning
  ```

See Also

`cat` | `cellstr` | `horzcat` | `strjoin` | `vertcat`

Introduced before R2006a

strcmp

Compare strings

Syntax

```
tf = strcmp(s1,s2)
```

Description

`tf = strcmp(s1,s2)` compares strings `s1` and `s2` and returns 1 (true) if the two are identical. Otherwise, `strcmp` returns 0 (false). Strings are considered identical if the size and content of each are the same. The return result, `tf`, is of data type `logical`.

Inputs can be combinations of single strings, strings in scalar cell arrays, character arrays, and cell arrays of strings.

Examples

Compare Two Strings

Compare two different strings.

```
s1 = 'Yes';
s2 = 'No';
tf = strcmp(s1,s2)
```

```
tf =

     0
```

`strcmp` returns 0 because the two strings are not equal.

Compare two equal strings.

```
s1 = 'Yes';
s2 = 'Yes';
tf = strcmp(s1,s2)
```

```
tf =
```

```
     1
```

`strcmp` returns 1 because the two strings are equal.

Compare String and Cell Array of Strings

Compare a string, `'upon'`, to each element of a cell array of strings.

```
s1 = 'upon';
s2 = {'Once','upon';
      'a','time'};
tf = strcmp(s1,s2)
```

```
tf =

     0     1
     0     0
```

There is only one occurrence of string `s1` in array `s2`, and it occurs at element `s2(1,2)`.

Compare Two Cell Arrays of Strings

Compare each element in a cell array of strings to the corresponding element in a second cell array of strings.

```
s1 = {'Time','flies','when';
      'you''re','having','fun.'};
s2 = {'Time','drags','when';
      'you''re','anxiously','waiting.'};
tf = strcmp(s1,s2)
```

```
tf =

     1     0     1
     1     0     0
```

There are three instances of equal strings between `s1` and `s2`. These are `'Time'` at indices `(1,1)`, `'when'` at indices`(1,3)`, and `'you''re'` at indices `(2,1)`.

Input Arguments

`s1,s2` — Input strings

character array | cell array of strings

Input strings, specified as a cell array of strings, or character array with one or more rows. The order of the inputs does not affect the comparison results.

- If both s1,s2 are nonscalar cell arrays, then s1,s2 must be the same size.
- If both s1,s2 are character arrays, then s1,s2 can have different numbers of rows.
- When comparing a nonscalar cell array and a multirow character array, the cell array must be a column vector with the same number of rows as the character array.

Data Types: `char` | `cell`

Output Arguments

`tf` — True or false

1 | 0 | logical array

True or false result, returned as a 1 or 0 of data type `logical`.

- If both inputs are character arrays, `tf` is a scalar.
- If at least one input is a cell array of strings, `tf` is an array the same size as the cell array.
- If `s1` and `s2` are a string in a scalar cell and a character array with multiple rows, then `tf` is an `n`-by-1 array, where `n` is the number of rows in the character array.

More About

Tips

- Use the `strcmp` function for comparison of strings. If you use `strcmp` on numeric arrays, it always returns 0.
- For case-insensitive string comparison, use `strcmpi` instead of `strcmp`.
- The value that `strcmp` returns is not the same as the C language convention.

`regexp` | `regexpi` | `strcmpi` | `strfind` | `strncmp` | `strncmpi`

Introduced before R2006a

strcmpi

Compare strings (case insensitive)

Syntax

```
TF = strcmpi(string,string)
TF = strcmpi(string,cellstr)
TF = strcmpi(cellstr,cellstr)
```

Description

`TF = strcmpi(string,string)` compares two strings for equality, ignoring any differences in letter case. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strcmpi(string,cellstr)` compares a string with each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the input arguments is not important.

`TF = strcmpi(cellstr,cellstr)` compares each element of one cell array of strings with the same element of the other, ignoring letter case. The function returns a logical array the same size as the input arrays.

Input Arguments

`string`

A single character string or n-by-1 array of strings.

`cellstr`

A cell array of strings.

Output Arguments

TF

When both inputs are character arrays, `TF` is a scalar logical value. This value is logical 1 (`true`) if the size and content of both arrays are equal, and logical 0 (`false`) if they are not.

When either or both inputs are a cell array of strings, `TF` is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (`true`) for those elements of the input arrays that are a match, and logical 0 (`false`) for those elements that are not.

Examples

Perform a simple case-insensitive comparison of two strings:

```
strcmpi('Yes', 'No')
ans =
     0
strcmpi('Yes', 'yes')
ans =
     1
```

Create two cell arrays of strings and call `strcmpi` to compare them:

```
A = {'Handle Graphics', 'Statistics';   ...
     '  Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing';    ...
     'Toolboxes', 'MATHWORKS'};

match = strcmpi(A, B)
match =
     1     0
     0     1
```

The result of comparing the two cell arrays is:

- `match{1,1}` is 1 because “Handle Graphics” in `A{1,1}` matches the same text in `B{1,1}`.

- `match{1,2}` is 0 because “Statistics” in `A{1,2}` does not match “Signal Processing” in `B{1,2}`.
- `match{2,1}` is 0 because “ Toolboxes”, in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
- `match{2,2}` is 1 because even though “MathWorks” in `A{2,2}` uses different letter case than “MATHWORKS” in `B{2,2}`, `strcmpi` performs the comparison without sensitivity to letter case.

More About

Tips

- The `strcmpi` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strcmp` for case-sensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strcmpi` is not the same as the C language convention.
- `strcmpi` supports international character sets.

Introduced before R2006a

stream2

Compute 2-D streamline data

Syntax

```
XY = stream2(x,y,u,v,startx,starty)
XY = stream2(u,v,startx,starty)
XY = stream2(...,options)
```

Description

`XY = stream2(x,y,u,v,startx,starty)` computes streamlines from vector data `u` and `v`.

The arrays `x` and `y`, which define the coordinates for `u` and `v`, must be monotonic, but do not need to be uniformly spaced. `x` and `y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XY` contains a cell array of vertex arrays.

`XY = stream2(u,v,startx,starty)` assumes the arrays `x` and `y` are defined as `[x,y] = meshgrid(1:n,1:m)` where `[m,n] = size(u)`.

`XY = stream2(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify a value, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream2`.

Examples

This example draws 2-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx,sy] = meshgrid(80,20:10:50);
streamline(stream2(x(:,:,5),y(:,:,5),u(:,:,5),v(:,:,5),sx,sy));
```

More About

- Specifying Starting Points for Stream Plots

`coneplot` | `stream3` | `streamline`

Introduced before R2006a

stream3

Compute 3-D streamline data

Syntax

```
XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)
XYZ = stream3(U,V,W,startx,starty,startz)
XYZ = stream3(...,options)
```

Description

`XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)` computes streamlines from vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XYZ` contains a cell array of vertex arrays.

`XYZ = stream3(U,V,W,startx,starty,startz)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)` where `[M,N,P] = size(U)`.

`XYZ = stream3(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream3`.

Examples

This example draws 3-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamline(stream3(x,y,z,u,v,w,sx,sy,sz))
view(3)
```

More About

- Specifying Starting Points for Stream Plots

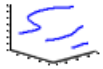
`coneplot` | `stream2` | `streamline`

Introduced before R2006a

streamline

Plot streamlines from 2-D or 3-D vector data



Syntax

```
streamline(X,Y,Z,U,V,W,startx,starty,startz)
streamline(U,V,W,startx,starty,startz)
streamline(XYZ)
streamline(X,Y,U,V,startx,starty)
streamline(U,V,startx,starty)
streamline(XY)
streamline(...,options)
streamline(axes_handle,...)
h = streamline(...)
```

Description

`streamline(X,Y,Z,U,V,W,startx,starty,startz)` draws streamlines from 3-D vector data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, `startz` define the starting positions of the streamlines. The section Specifying Starting Points for Stream Plots provides more information on defining starting points.

`streamline(U,V,W,startx,starty,startz)` assumes the arrays `X`, `Y`, and `Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)`, where `[M,N,P] = size(U)`.

`streamline(XYZ)` assumes `XYZ` is a precomputed cell array of vertex arrays (as produced by `stream3`).

`streamline(X,Y,U,V,startx,starty)` draws streamlines from 2-D vector data `U`, `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The output argument `h` contains a vector of line handles, one handle for each streamline.

`streamline(U,V,startx,starty)` assumes the arrays `X` and `Y` are defined as `[X,Y] = meshgrid(1:N,1:M)`, where `[M,N] = size(U)`.

`streamline(XY)` assumes `XY` is a precomputed cell array of vertex arrays (as produced by `stream2`).

`streamline(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 1000

`streamline(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of the into current axes object (`gca`).

`h = streamline(...)` returns a vector of line handles, one handle for each streamline.

Examples

Draw Streamlines

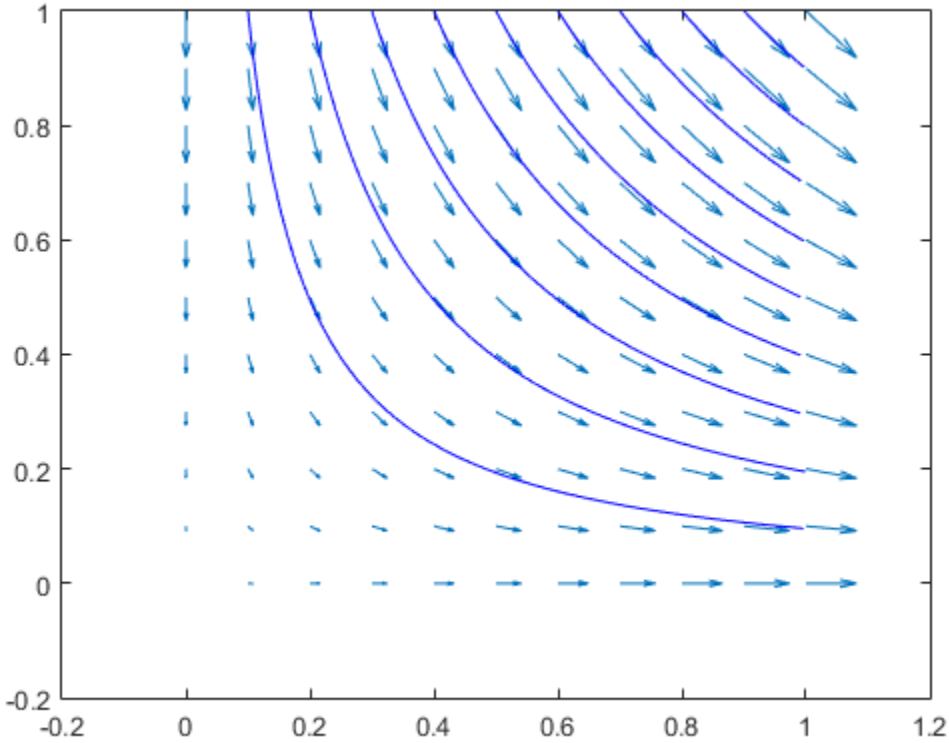
Define arrays `x`, `y`, `u`, and `v`.

```
[x,y] = meshgrid(0:0.1:1,0:0.1:1);
u = x;
v = -y;
```

Create a quiver plot of the data. Plot streamlines that start at different points along the line $y = 1$.

```
figure
quiver(x,y,u,v)

startx = 0.1:0.1:1;
starty = ones(size(startx));
streamline(x,y,u,v,startx,starty)
```



More About

- Specifying Starting Points for Stream Plots

- Stream Line Plots of Vector Data

See Also

`coneplot` | `stream2` | `stream3` | `streamparticles` | `meshgrid`

Introduced before R2006a

streamparticles

Plot stream particles

Syntax

```
streamparticles(vertices)
streamparticles(vertices,n)
streamparticles(...,'PropertyName',PropertyValue,...)
streamparticles(line_handle,...)
h = streamparticles(...)
```

Description

`streamparticles(vertices)` draws stream particles of a vector field. Stream particles are usually represented by markers and can show the position and velocity of a streamline. `vertices` is a cell array of 2-D or 3-D vertices (as if produced by `stream2` or `stream3`).

`streamparticles(vertices,n)` uses `n` to determine how many stream particles to draw. The `ParticleAlignment` property controls how `n` is interpreted.

- If `ParticleAlignment` is set to `off` (the default) and `n` is greater than `1`, approximately `n` particles are drawn evenly spaced over the streamline vertices.

  If `n` is less than or equal to `1`, `n` is interpreted as a fraction of the original stream vertices; for example, if `n` is `0.2`, approximately 20% of the vertices are used.

  `n` determines the upper bound for the number of particles drawn. The actual number of particles can deviate from `n` by as much as a factor of 2.
- If `ParticleAlignment` is `on`, `n` determines the number of particles on the streamline having the most vertices and sets the spacing on the other streamlines to this value. The default value is `n = 1`.

`streamparticles(...,'PropertyName',PropertyValue,...)` controls the stream particles using named properties and specified values. Any unspecified properties have default values. MATLAB ignores the case of property names.

Stream Particle Properties

`Animate` — Stream particle motion [nonnegative integer]

The number of times to animate the stream particles. The default is `0`, which does not animate. `Inf` animates until you enter **Ctrl+C**.

`FrameRate` — Animation frames per second [nonnegative integer]

This property specifies the number of frames per second for the animation. `Inf`, the default, draws the animation as fast as possible. Note that the speed of the animation might be limited by the speed of the computer. In such cases, the value of `FrameRate` cannot necessarily be achieved.

`ParticleAlignment` — Align particles with streamlines [`on` | `{off}`]

Set this property to `on` to draw particles at the beginning of each streamline. This property controls how `streamparticles` interprets the argument `n` (number of stream particles).

Stream particles are primitive line objects. In addition to stream particle properties, you can specify any line property, such as `Marker`. `streamparticles` sets the following line properties when called.

Line Property	Value Set by streamparticles
`LineStyle`	`'none'`
`Marker`	`'o'`
`MarkerEdgeColor`	`'none'`
`MarkerFaceColor`	`'red'`

You can override any of these properties by specifying a property name and value as arguments to `streamparticles`. For example, this statement uses RGB values to set the `MarkerFaceColor` to medium gray:

```
streamparticles(vertices,'MarkerFaceColor',[.5 .5 .5])
```

`streamparticles(line_handle,...)` uses the line object identified by `line_handle` to draw the stream particles.

`h = streamparticles(...)` returns a vector of handles to the primitive line objects it creates. For a list of properties, see Primitive Line Properties.

Examples

Animate Flow Without Displaying Streamlines

This example uses streamlines in the `z = 5` plane to animate the flow along these lines with stream particles.

```
load wind
figure
daspect([1,1,1]);
view(2)
[verts,averts] = streamslice(x,y,z,u,v,w,[],[],[5]);
sl = streamline([verts averts]);
axis tight manual off;
ax = gca;
ax.Position = [0,0,1,1];
set(sl,'Visible','off')
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.05);
zlim([4.9,5.1]);
streamparticles(iverts, 200, ...
    'Animate',15,'FrameRate',40, ...
    'MarkerSize',10,'MarkerFaceColor',[0 .5 0])
```

- Creating Stream Particle Animations
- Specifying Starting Points for Stream Plots

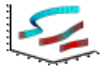
See Also

`interpstreamspeed` | `stream3` | `streamline` | `stream2`

Introduced before R2006a

streamribbon

3-D stream ribbon plot from vector volume data



Syntax

```
streamribbon(X,Y,Z,U,V,W,startx,starty,startz)
streamribbon(U,V,W,startx,starty,startz)
streamribbon(vertices,X,Y,Z,cav,speed)
streamribbon(vertices,cav,speed)
streamribbon(vertices,twistangle)
streamribbon(...,width)
streamribbon(axes_handle,...)
h = streamribbon(...)
```

Description

`streamribbon(X,Y,Z,U,V,W,startx,starty,startz)` draws stream ribbons from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the stream ribbons at the center of the ribbons. The section Specifying Starting Points for Stream Plots provides more information on defining starting points.

The twist of the ribbons is proportional to the curl of the vector field. The width of the ribbons is calculated automatically.

`streamribbon(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamribbon(vertices,X,Y,Z,cav,speed)` assumes precomputed streamline vertices, curl angular velocity, and flow speed. `vertices` is a cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, `cav`, and `speed` are 3-D arrays.

`streamribbon(vertices,cav,speed)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(cav)`.

`streamribbon(vertices,twistangle)` uses the cell array of vectors `twistangle` for the twist of the ribbons (in radians). The size of each corresponding element of `vertices` and `twistangle` must be equal.

`streamribbon(...,width)` sets the width of the ribbons to `width`.

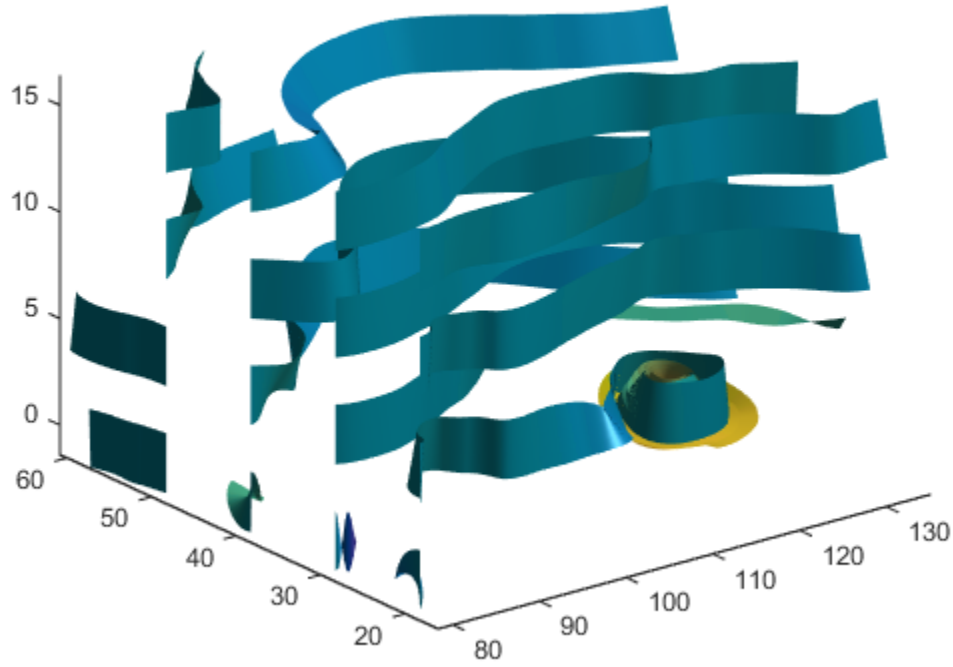
`streamribbon(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamribbon(...)` returns a vector of handles (one per start point) to `surface` objects.

Examples

This example uses stream ribbons to indicate the flow in the `wind` data set. Inputs include the coordinates, vector field components, and starting location for the stream ribbons.

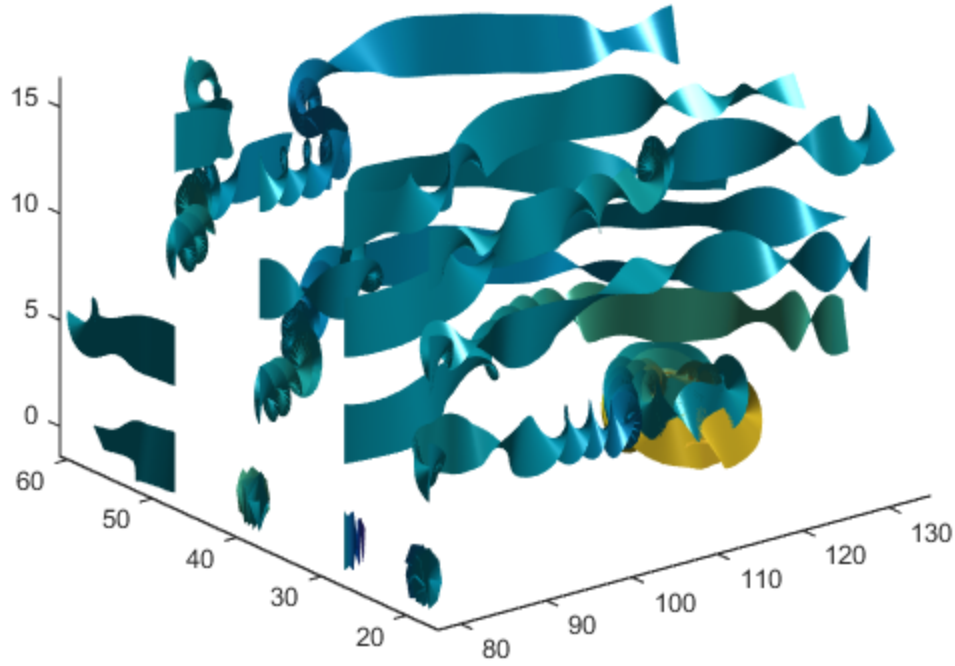
```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
axis tight
shading interp;
view(3);
camlight
lighting gouraud
```



This example uses precalculated vertex data (`stream3`), curl average velocity (`curl`), and speed $\sqrt{u^2 + v^2 + w^2}$. Using precalculated data enables you to use values other than those calculated from the single data source. In this case, the speed is reduced by a factor of 10 compared to the previous example.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
cav = curl(x,y,z,u,v,w);
spd = sqrt(u.^2 + v.^2 + w.^2).*.1;
streamribbon(verts,x,y,z,cav,spd);
% Define viewing and lighting
```

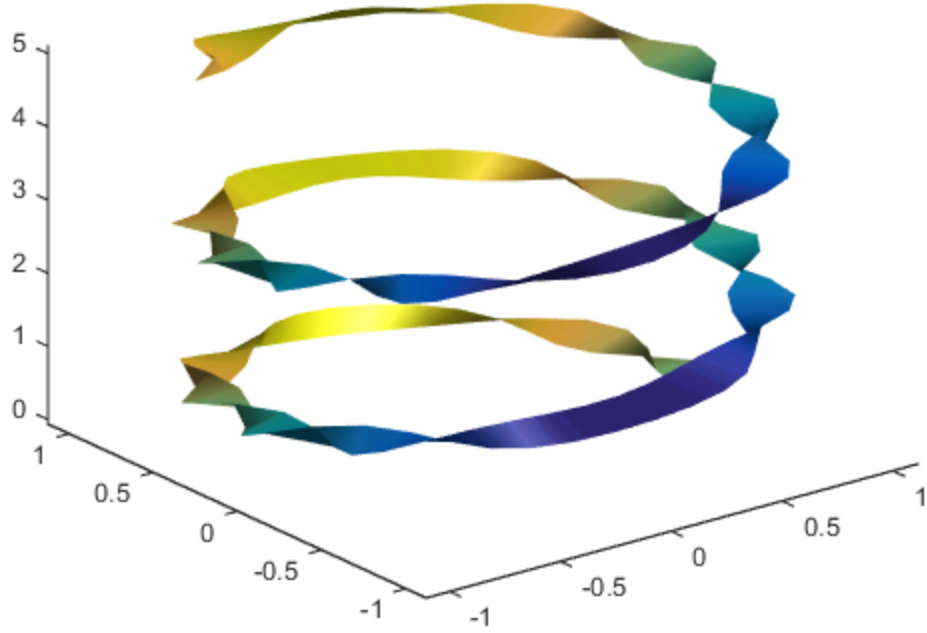
```
axis tight
shading interp
view(3)
camlight;
lighting gouraud
```



This example specifies a twist angle for the stream ribbon.

```
figure
t = 0:.15:15;
verts = {[cos(t)' sin(t)' (t/3)']};
twistangle = {cos(t)'};
streamribbon(verts,twistangle)
% Define viewing and lighting
axis tight
```

```
shading interp
view(3)
camlight
lighting gouraud
```



This example combines cone plots (`coneplot`) and stream ribbon plots in one graph.

```
figure
% Define 3-D arrays x, y, z, u, v, w
xmin = -7; xmax = 7;
ymin = -7; ymax = 7;
zmin = -7; zmax = 7;
x = linspace(xmin,xmax,30);
y = linspace(ymin,ymax,20);
z = linspace(zmin,zmax,20);
```

```
[x y z] = meshgrid(x,y,z);
u = y; v = -x; w = 0*x+1;
[cx cy cz] = meshgrid(linspace(xmin,xmax,30),...
   linspace(ymin,ymax,30),[-3 4]);
h = coneplot(x,y,z,u,v,w,cx,cy,cz,'quiver');
set(h,'Color','k');

% Plot two sets of streamribbons
[sx sy sz] = meshgrid([-1 0 1],[-1 0 1],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
[sx sy sz] = meshgrid([1:6],[0],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);

% Define viewing and lighting
shading interp
view(-30,10) ; axis off tight
camproj perspective; camva(66); camlookat;
camdolly(0,0,.5,'fixtarget')
camlight
```

- Specifying Starting Points for Stream Plots

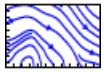
See Also

`curl` | `streamtube` | `streamline` | `stream3` | `meshgrid` | `coneplot`

Introduced before R2006a

streamslice

Plot streamlines in slice planes



Syntax

```
streamslice(X,Y,Z,U,V,W,startx,starty,startz)
streamslice(U,V,W,startx,starty,startz)
streamslice(X,Y,U,V)
streamslice(U,V)
streamslice(...,density)
streamslice(...,'arrowsmode')
streamslice(...,'method')
streamslice(axes_handle,...)
h = streamslice(...)
[vertices arrowvertices] = streamslice(...)
```

Description

`streamslice(X,Y,Z,U,V,W,startx,starty,startz)` draws well-spaced streamlines (with direction arrows) from vector data `U`, `V`, `W` in axis aligned *x*-, *y*-, *z*-planes at the points in the vectors `startx`, `starty`, `startz`. The section Specifying Starting Points for Stream Plots provides more information on defining starting points.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`. `U`, `V`, `W` must be m-by-n-by-p volume arrays.

Do not assume that the flow is parallel to the slice plane. For example, in a stream slice at a constant `z`, the `z` component of the vector field `W` is ignored when you are calculating the streamlines for that plane.

Stream slices are useful for determining where to start streamlines, stream tubes, and stream ribbons.

`streamslice(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(X,Y,U,V)` draws well-spaced streamlines (with direction arrows) from vector volume data `U`, `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`streamslice(U,V)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(...,density)` modifies the automatic spacing of the streamlines. `density` must be greater than `0`. The default value is `1`; higher values produce more streamlines on each plane. For example, `2` produces approximately twice as many streamlines, while `0.5` produces approximately half as many.

`streamslice(...,'arrowsmode')` determines if direction arrows are present or not. `arrowmode` can be

- `arrows` — Draw direction arrows on the streamlines (default).
- `noarrows` — Do not draw direction arrows.

`streamslice(...,'method')` specifies the interpolation method to use. `method` can be

- `linear` — Linear interpolation (default)
- `cubic` — Cubic interpolation
- `nearest` — Nearest-neighbor interpolation

See `interp3` for more information on interpolation methods.

`streamslice(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamslice(...)` returns a vector of handles to the line objects created.

`[vertices arrowvertices] = streamslice(...)` returns two cell arrays of vertices for drawing the streamlines and the arrows. You can pass these values to any of the streamline drawing functions (`streamline`, `streamribbon`, `streamtube`).

Examples

Plot Streamlines in Slice Plane

Load the `wind` data set. Draw a stream slice at `z = 5`.

```
load wind

figure
streamslice(x,y,z,u,v,w,[],[],[5])
axis tight
```

Introduced before R2006a

streamtube

Create 3-D stream tube plot

Syntax

```
streamtube(X,Y,Z,U,V,W,startx,starty,startz)
streamtube(U,V,W,startx,starty,startz)
streamtube(vertices,X,Y,Z,divergence)
streamtube(vertices,divergence)
streamtube(vertices,width)
streamtube(vertices)
streamtube(...,[scale n])
streamtube(axes_handle,...)
h = streamtube(...z)
```

Description

`streamtube(X,Y,Z,U,V,W,startx,starty,startz)` draws stream tubes from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the streamlines at the center of the tubes. The section Specifying Starting Points for Stream Plots provides more information on defining starting points.

The width of the tubes is proportional to the normalized divergence of the vector field.

`streamtube(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamtube(vertices,X,Y,Z,divergence)` assumes precomputed streamline vertices and divergence. `vertices` is a cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, and `divergence` are 3-D arrays.

`streamtube(vertices,divergence)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(divergence)`.

`streamtube(vertices,width)` specifies the width of the tubes in the cell array of vectors, `width`. The size of each corresponding element of `vertices` and `width` must be equal. `width` can also be a scalar, specifying a single value for the width of all stream tubes.

`streamtube(vertices)` selects the width automatically.

`streamtube(...,[scale n])` scales the width of the tubes by `scale`. The default is `scale = 1`. When the stream tubes are created, using start points or divergence, specifying `scale = 0` suppresses automatic scaling. `n` is the number of points along the circumference of the tube. The default is `n = 20`.

`streamtube(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

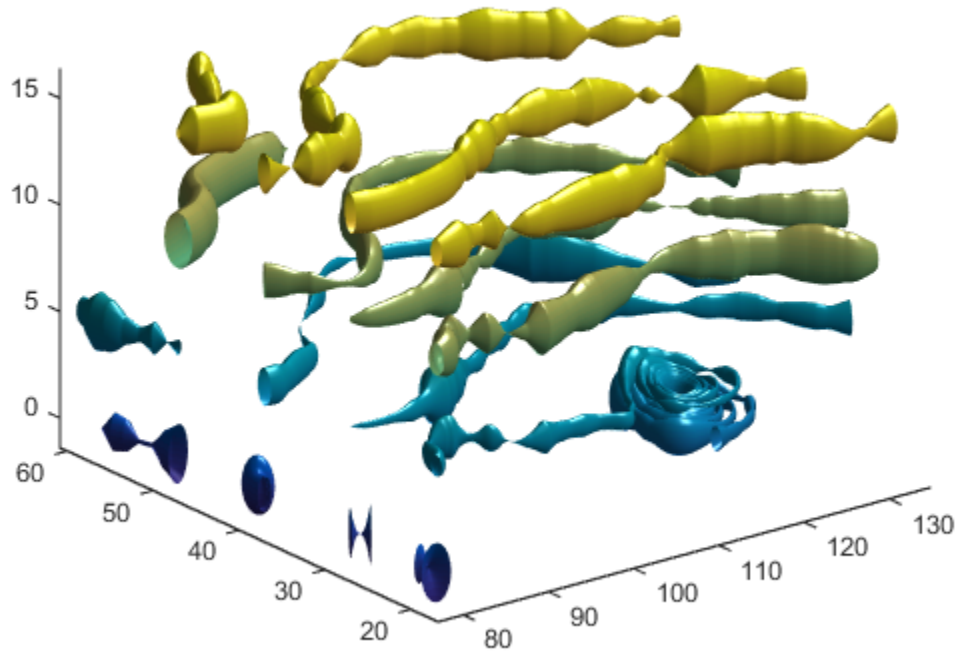
`h = streamtube(...z)` returns a vector of handles (one per start point) to `surface` objects used to draw the stream tubes.

Examples

This example uses stream tubes to indicate the flow in the `wind` data set. Inputs include the coordinates, vector field components, and starting location for the stream tubes.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
```

```
streamtube(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
view(3)
axis tight
shading interp;
camlight; lighting gouraud
```



This example uses precalculated vertex data (`stream3`) and divergence (`divergence`).

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
div = divergence(x,y,z,u,v,w);
```

```
streamtube(verts,x,y,z,-div);
% Define viewing and lighting
view(3)
axis tight
shading interp
camlight
lighting gouraud
```

Introduced before R2006a

strfind

Find one string within another

Syntax

```
k = strfind(str, pattern)
```

Description

`k = strfind(str, pattern)` searches str for occurrences of pattern. The output, k, indicates the starting index of each occurrence of pattern in str. If pattern is not found `strfind` returns an empty array, `[]`. The `strfind` function executes a case sensitive search.

- If str is a string, `strfind` returns a vector of type `double`.
- If str is a cell array, `strfind` returns a cell array of vectors of type `double`.

Examples

Find String Pattern

Define string `S` as follows:

```
S = 'Find the starting indices of the pattern string';
```

Find the pattern `in` in string `S`.

```
k = strfind(S, 'in')
```

```
k =

     2    15    19    45
```

There are four instances of the substring, `in`, found in `S`.

Find the pattern `In` in string `S`.

```
k = strfind(S, 'In')

k =

     []
```

Since `strfind` is case sensitive, the string, `In`, is not found in `S`, k is an empty array.

Find the blank spaces in string `S`.

```
k = strfind(S, ' ')

k =

     5     9    18    26    29    33    41
```

There are seven occurrences of blank spaces in the string `S`.

Find String in Cell Array of Strings

Define the cell array of strings, `cstr`, as follows:

```
cstr = {'How much wood would a woodchuck chuck';
        'if a woodchuck could chuck wood?'};
```

Find the pattern, `wood`, in cell array `cstr`.

```
idx = strfind(cstr, 'wood')

idx =

    [1x2 double]
    [1x2 double]
```

Examine the output cell array to find the instances of `wood`.

```
idx{:,:}

ans =

    10    23

ans =

     6    28
```

The pattern, `wood`, occurs at indices 10 and 23 in the first string and at indices 6 and 28 in the second string.

Input Arguments

`str` — Data to be searched

string | cell array of strings

Data to be searched, specified as a string or cell array of strings.

Data Types: `char` | `cell`

`pattern` — Search pattern

string

Search pattern, specified as a string.

Data Types: `char`

Output Arguments

`k` — Indices of occurrences of `pattern`

array

Indices of occurrences of pattern, returned as an array. If pattern is not found, then k is an empty array, `[]`.

- If str is a string, k is an array of doubles indicating the index of each occurrence of pattern.
- If str is a cell array of strings, k is a cell array with each element being an array of type `double` corresponding to the indices of each occurrence of pattern in the corresponding element of str.

More About

Tips

- The `strfind` function does not find a pattern of empty strings, `''`, within str.

Introduced before R2006a

strings

String handling

Syntax

```
S = 'Any Characters'
S = [S1 S2 ...]
C = {S1 S2 ...}
S = strcat(S1, S2, ...)
S = char(S1, S2, ...)
S = char(X)
X = double(S)
```

Description

`S = 'Any Characters'` creates a character array, or string. The string is actually a vector that contains the numeric codes for the characters (codes 0 to 127 are ASCII). The length of `S` is the number of characters. A quotation within the string is indicated by two quotation marks.

`S = [S1 S2 ...]` concatenates character arrays `S1`, `S2`, etc. into a new character array, `S`.

`C = {S1 S2 ...}` creates a cell array of strings. Separate each row of the cell array with a semicolon (`;`).

`S = strcat(S1, S2, ...)` horizontally concatenates `S1`, `S2`, etc., which can be character arrays or cell arrays of strings. If the inputs are character arrays, `strcat` removes trailing white space. For more information, see the `strcat` reference page.

`S = char(S1, S2, ...)` vertically concatenates character arrays `S1`, `S2`, etc., padding each input string as needed so that each row contains the same number of characters.

`S = char(X)` converts an array that contains positive integers representing numeric codes into a MATLAB character array.

`X = double(S)` converts the string to its equivalent integer numeric codes.

Examples

Create a simple string that includes a single quote.

```
msg = 'You''re right!'

msg =
You're right!
```

Create the string `name` using two methods of concatenation.

```
name = ['Thomas' ' R. ' 'Lee']
name = strcat('Thomas',' R.',' Lee')
```

Create a character array of strings.

```
C = char('Hello','Goodbye','Yes','No')

C =
Hello
Goodbye
Yes
No
```

Create a cell array of strings.

```
S = {'Hello' 'Goodbye'; 'Yes' 'No'}

S =
    'Hello'    'Goodbye'
    'Yes'      'No'
```

More About

Tips

- To convert between character arrays and cell arrays of strings, use `char` and `cellstr`. Most string functions support both types.
- To determine whether `S` is a character array or cell array, call `ischar(S)` or `iscellstr(S)`.
- “Cell Arrays of Strings”

See Also

`char` | `isstrprop` | `ischar` | `cellstr` | `isletter` | `isspace` | `iscellstr` | `sprintf` | `sscanf` | `text` | `input`

strjoin

Join strings in cell array into single string

Syntax

```
str = strjoin(C)
str = strjoin(C,delimiter)
```

Description

`str = strjoin(C)` constructs the string, `str`, by linking each string in the cell array, C, with a single space.

`str = strjoin(C,delimiter)` constructs the string, `str`, by linking each string of C with the elements in delimiter.

Examples

Join List of Words with Whitespace

Join individual strings in a cell array of strings, `C`, with a single space.

```
C = {'one','two','three'};
str = strjoin(C)
```

```
str =

one two three
```

Join Cell Array of Strings

```
C = {'Newton','Gauss','Euclid','Lagrange'};
str = strjoin(C,', ')
```

```
str =
```

```
Newton, Gauss, Euclid, Lagrange
```

Join Strings with Multiple Different Delimiters

Specify multiple different delimiters in a cell array of strings. The `delimiter` cell array must have one fewer element than `C`.

```
C = {'one','two','three'};
str = strjoin(C,{' + ',' = '})
```

```
str =

one + two = three
```

Input Arguments

`C` — Input text

1-by-n cell array of strings

Input text, specified as a 1-by-n cell array of strings. Each element in the cell array must contain a single string in a single row.

Example: `{'The','rain','in','Spain'}`

Data Types: `cell`

`delimiter` — Delimiting characters

string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings.

- If `delimiter` is a single string, then `strjoin` forms `str` by inserting `delimiter` between each element of `C`. The `delimiter` input can include any of these escape sequences:

`\\`	Backslash
`\0`	Null
`\a`	Alarm
`\b`	Backspace
`\f`	Form feed

`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab

- If `delimiter` is a cell array of strings, then it must contain one fewer element than `C`. Each element in the cell array must contain a single string in a single row. `strjoin` forms `str` by interleaving the elements of `delimiter` and `C`. All characters in `delimiter` are inserted as literal text, and escape sequences are not supported.

Example: `', '`

Example: `{',',' '}`

Data Types: `char` | `cell`

See Also

`cellstr` | `regexp` | `strcat` | `strsplit`

strjust

Justify character array

Syntax

```
T = strjust(S)
T = strjust(S, 'right')
T = strjust(S, 'left')
T = strjust(S, 'center')
```

Description

`T = strjust(S)` or `T = strjust(S, 'right')` returns a right-justified version of the character array `S`.

`T = strjust(S, 'left')` returns a left-justified version of `S`.

`T = strjust(S, 'center')` returns a center-justified version of `S`.

See Also

`deblank` | `strtrim`

Introduced before R2006a

strmatch

Find possible matches for string

Note: `strmatch` is not recommended. Use `strncmp` or `validatestring`, depending on your requirements, instead. `strncmp` returns a logical array indicating which array elements begin with the specified string, whereas `validatestring` returns a single string that represents the best match to the specified string. See Example 2, below.

To find an exact match for a string, use `strcmp`.

Syntax

```
x = strmatch(str, strarray)
x = strmatch(str, strarray, 'exact')
```

Description

`x = strmatch(str, strarray)` looks through the rows of the character array or cell array of strings `strarray` to find strings that begin with the text contained in `str`, and returns the matching row indices. If `strmatch` does not find `str` in `strarray`, `x` is an empty matrix (`[ ]`). Any trailing space characters in `str` or `strarray` are ignored when matching. `strmatch` is fastest when `strarray` is a character array.

`x = strmatch(str, strarray, 'exact')` compares `str` with each row of `strarray`, looking for an exact match of the entire strings. Any trailing space characters in `str` or `strarray` are ignored when matching.

Examples

Example 1

The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'))
```

returns `x = [1; 3]` since rows 1 and 3 begin with `'max'`. The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'),'exact')
```

returns `x = 1`, since only row 1 matches `'max'` exactly.

Example 2

This example shows how to replace use of the `strmatch` function with `validatestring` or `strncmp`.

To start with, use `strmatch` to return the index of those elements for which there is a match:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = strmatch('max',list)
x =
     1
     3
     4
```

`validatestring` returns the string representing the best match. If multiple or no matches exist, this statement would return an error:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = validatestring('max', list)
x =
   max
```

`strncmp` returns a logical array indicating which strings match the specified string:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = strncmp('max', list, 3)
x =
     1     0     1     1
```

If you prefer that MATLAB return the numeric indices of `list`, use `find` as follows:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = find(strncmp(list, 'max', 3))
```

If your input to `strmatch` is a character matrix, then first convert the matrix to a cell array using `cellstr`. Then, pass the output from `cellstr` to `strncmp` or `validatestring`

See Also

`strcmp` | `strcmpi` | `strncmp` | `strncmpi` | `strfind` | `regexp` | `regexpi` | `regexprep`

Introduced before R2006a

strncmp

Compare first `n` characters of strings (case sensitive)

Syntax

```
TF = strncmp(string,string,n)
TF = strncmp(string,cellstr,n)
TF = strncmp(cellstr,cellstr,n)
```

Description

`TF = strncmp(string,string,n)` compares the first `n` characters of two strings for equality. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strncmp(string,cellstr,n)` compares the first `n` characters of a string with the first `n` characters of each element of a cell array of strings. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the first two input arguments is not important.

`TF = strncmp(cellstr,cellstr,n)` compares each element of one cell array of strings with the same element of the other. `strncmp` attempts to match only the first `n` characters of these strings. The function returns a logical array the same size as either input array.

Input Arguments

`string`

Single character string or n-by-1 array of strings.

`cellstr`

Cell array of strings.

n

Maximum number of characters to compare. Must be a scalar, integer-valued double.

Output Arguments

TF

When both inputs are character arrays, `TF` is a scalar logical value. This value is logical 1 (`true`) if the size and content of both arrays are equal, and logical 0 (`false`) if they are not.

When either or both inputs are a cell array of strings, `TF` is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (`true`) for those elements of the input arrays that are a match, and logical 0 (`false`) for those elements that are not.

Examples

Before trying the `strncmp` function, use `strcmp` to perform a simple comparison of the two input strings. Because only the first 13 characters are the same, `strcmp` returns logical 0:

```
strcmp('Kansas City, KS', 'Kansas City, MO')
ans =
     0
```

Do the comparison again, but this time using `strncmp` and specifying the number of characters to compare:

```
chars2compare = length('Kansas City, KS') - 2
ans =
    13
strncmp('Kansas City, KS', 'Kansas City, MO', chars2compare)
ans =
     1
```

From a list of 10 MATLAB functions, find those that apply to using a camera:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
                 'caxis' 'camtarget' 'cast' 'camorbit' ...
```

```
               'callib' 'cart2sph'};

strncmp(function_list, 'cam', 3)
ans =
    0    0    1    0    0    1    0    1    0    0

function_list{strncmp(function_list, 'cam', 3)}
ans =
   camdolly
ans =
   camtarget
ans =
   camorbit
```

Create two 5-by-10 string arrays `str1` and `str2` that are equal, except for the element at row 4, column 3. Using linear indexing, this is element 14:

```
str1 = ['AAAAAAAAAA'; 'BBBBBBBBBB'; 'CCCCCCCCCC'; ...
        'DDDDDDDDDD'; 'EEEEEEEEEE']
str1 =
    AAAAAAAAAA
    BBBBBBBBBB
    CCCCCCCCCC
    DDDDDDDDDD
    EEEEEEEEEE

str2 = str1;
str2(4,3) = '-'
str2 =
    AAAAAAAAAA
    BBBBBBBBBB
    CCCCCCCCCC
    DD-DDDDDDD
    EEEEEEEEEE
```

Because MATLAB compares the arrays in linear order (that is, column by column rather than row by row), `strncmp` finds only the first 13 elements to be the same:

```
str1   A B C D E A B C D E A B C D E
str2   A B C D E A B C D E A B C - E
                                 |
                              element 14

strncmp(str1, str2, 13)
ans =
     1
```

```
strncmp(str1, str2, 14)
ans =
     0
```

More About

Tips

- The `strncmp` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strncmpi` for case-insensitive string comparisons.
- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strncmp` is not the same as the C language convention.
- `strncmp` supports international character sets.

See Also

`strcmp` | `strncmpi` | `strcmpi` | `strfind` | `regexp` | `regexpi`

Introduced before R2006a

strncmpi

Compare first `n` characters of strings (case insensitive)

Syntax

```
TF = strncmpi(string,string,n)
TF = strncmpi(string,cellstr,n)
TF = strncmpi(cellstr,cellstr,n)
```

Description

`TF = strncmpi(string,string,n)` compares the first `n` characters of two strings for equality, ignoring any differences in letter case. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

`TF = strncmpi(string,cellstr,n)` compares the first `n` characters of a string with the first `n` characters of each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the `cellstr` input in which logical 1 represents equality. The order of the input arguments is not important.

`TF = strncmpi(cellstr,cellstr,n)` compares each element of one cell array of strings with the same element of the other, ignoring letter case. `strncmpi` attempts to match only the first `n` characters of these strings. The function returns a logical array the same size as either input array.

Input Arguments

`string`

A single character string or n-by-1 array of strings.

`cellstr`

A cell array of strings.

`n`

Maximum number of characters to compare. Must be a scalar, integer-valued double.

Output Arguments

TF

When both inputs are character arrays, `TF` is a scalar logical value. This value is logical 1 (`true`) if the size and content of both arrays are equal, and logical 0 (`false`) if they are not.

When either or both inputs are a cell array of strings, `TF` is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (`true`) for those elements of the input arrays that are a match, and logical 0 (`false`) for those elements that are not.

Examples

From a list of 10 MATLAB functions, find those that apply to using a camera. Do the comparison without sensitivity to letter case:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
                 'caxis' 'Camtarget' 'cast' 'camorbit' ...
                 'callib' 'cart2sph'};

strncmpi(function_list, 'CAM', 3)
ans =
    0    0    1    0    0    1    0    1    0    0

function_list{strncmpi(function_list, 'CAM', 3)}
ans =
   camdolly
ans =
   Camtarget
ans =
   camorbit
```

More About

Tips

- The `strncmpi` function is intended for comparison of character data. When used to compare numeric data, it returns logical `0`.
- Use `strncmp` for case-sensitive string comparisons.

- Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
- The value returned by `strncmpi` is not the same as the C language convention.
- `strncmpi` supports international character sets.

Introduced before R2006a

strread

Read formatted data from string

Note `strread` is not recommended. Use `textscan` instead.

Syntax

```
A = strread('str')
[A, B, ...] = strread('str')
[A, B, ...] = strread('str', 'format')
[A, B, ...] = strread('str', 'format', N)
[A, B, ...] = strread('str', 'format', N, param, value, ...)
```

Description

`A = strread('str')` reads numeric data from input string `str` into a 1-by-`N` vector `A`, where `N` equals the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 1” on page 1-7811 below.

`[A, B, ...] = strread('str')` reads numeric data from the string input `str` into scalar output variables `A`, `B`, and so on. The number of output variables must equal the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 2” on page 1-7811 below.

`[A, B, ...] = strread('str', 'format')` reads data from `str` into variables `A`, `B`, and so on using the specified `format`. The number of output variables `A`, `B`, etc. must be equal to the number of format specifiers (e.g., `%s` or `%d`) in the `format` argument. You can read all of the data in `str` to a single output variable as long as you use only one format specifier in the command. See “Example 4” on page 1-7811 and “Example 5” on page 1-7812 below.

The table Formats for strread lists the valid format specifiers. More information on using formats is available under “Formats” on page 1-7814 in the “Tips” on page 1-7814 section below.

`[A, B, ...] = strread('str', 'format', N)` reads data from `str` reusing the `format` string `N` times, where `N` is an integer greater than zero. If `N` is -1, `strread` reads the entire string. When `str` contains only numeric data, you can set `format` to the empty string (`''`). See "Example 3" on page 1-7811 below.

`[A, B, ...] = strread('str', 'format', N, param, value, ...)` customizes `strread` using `param/value` pairs, as listed in the table Parameters and Values for strread below. When `str` contains only numeric data, you can set `format` to the empty string (`''`). The `N` argument is optional and may be omitted entirely. See "Example 7" on page 1-7813 below.

Formats for strread

Format	Action	Output
Literals (ordinary characters)	Ignore the matching characters. For example, in a string that has `Dept` followed by a number (for department number), to skip the `Dept` and read only the number, use `'Dept'` in the `format` string.	None
`%d`	Read a signed integer value.	Double array
`%u`	Read an integer value.	Double array
`%f`	Read a floating-point value.	Double array
`%s`	Read a white-space separated string.	Cell array of strings
`%q`	Read a double quoted string, ignoring the quotes.	Cell array of strings
`%c`	Read characters, including white space.	Character array
`%[...]`	Read the longest string containing characters specified in the brackets.	Cell array of strings
`%[^...]`	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
`%*...`	Ignore the characters following `*`. See "Example 8" on page 1-7813 below.	No output

Format	Action	Output
`%w...`	Read field width specified by `w`. The `%f` format supports `%w.pf`, where `w` is the field width and `p` is the precision.	

Parameters and Values for strread

param	value		Action
`whitespace`	Any from the list below:		Treats vector of characters, `*`, as white space. Default is `\b \r\n\t`.
	`\b`	Backspace	
	`\n`	New line	
	`\r`	Carriage return	
	`\t`	Horizontal tab	
	`\\`	Backslash	
	`%%`	Percent sign	
	`''`	Single quotation mark	
`delimiter`	Delimiter character		Specifies delimiter character. Default is one or more whitespace characters.
`expchars`	Exponent characters		Default is `eEdD`.
`bufsize`	Positive integer		Specifies the maximum string length, in bytes. Default is `4095`.
`commentstyle`	`matlab`		Ignores characters after `%`.
`commentstyle`	`shell`		Ignores characters after `#`.
`commentstyle`	`c`		Ignores characters between `/*` and `*/`.
`commentstyle`	`c++`		Ignores characters after `//`.
`emptyvalue`	Value to return for empty numeric fields in delimited files		Default is NaN.

Examples

Example 1

Read numeric data into a 1-by-5 vector:

```
a = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100    8.2400    3.5700    6.2400    9.2700
```

Example 2

Read numeric data into separate scalar variables:

```
[a b c d e] = strread('0.41 8.24 3.57 6.24 9.27')
a =
    0.4100
b =
    8.2400
c =
    3.5700
d =
    6.2400
e =
    9.2700
```

Example 3

Read the only first three numbers in the string, also formatting as floating point:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%4.2f', 3)

a =
    0.4100
    8.2400
    3.5700
```

Example 4

Truncate the data to one decimal digit by specifying format `%3.1f`. The second specifier, `%*1d`, tells `strread` not to read in the remaining decimal digit:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%3.1f %*1d')

a =
    0.4000
    8.2000
    3.5000
    6.2000
    9.2000
```

Example 5

Read six numbers into two variables, reusing the format specifiers:

```
[a b] = strread('0.41 8.24 3.57 6.24 9.27 3.29', '%f %f')

a =
    0.4100
    3.5700
    9.2700
b =
    8.2400
    6.2400
    3.2900
```

Example 6

Read string and numeric data to two output variables. Ignore commas in the input string:

```
str = 'Section 4, Page 7, Line 26';

[name value] = strread(str, '%s %d,')
name =
    'Section'
    'Page'
    'Line'
value =
     4
     7
    26
```

Example 7

Read the string used in the last example, but this time delimiting with commas instead of spaces:

```
str = 'Section 4, Page 7, Line 26';

[a b c] = strread(str, '%s %s %s', 'delimiter', ',')
a =
    'Section 4'
b =
    'Page 7'
c =
    'Line 26'
```

Example 8

Read selected portions of the input string:

```
str = '<table border=5 width="100%" cellspacing=0>';

[border width space] = strread(str, ...
   '%*s%*s %c %*s "%4s" %*s %c', 'delimiter', '= ')
border =
     5
width =
    '100%'
space =
     0
```

Example 9

Read the string into two vectors, restricting the `Answer` values to `T` and `F`. Also note that two delimiters (comma and space) are used here:

```
str = 'Answer_1: T, Answer_2: F, Answer_3: F';

[a b] = strread(str, '%s %[TF]', 'delimiter', ', ')
a =
    'Answer_1:'
    'Answer_2:'
    'Answer_3:'
b =
```

```
    'T'
    'F'
    'F'
```

More About

Tips

If you terminate the input string with a newline character (`\n`), `strread` returns arrays of equal size by padding arrays of lesser size with the `emptyvalue` character:

```
[A,B,C] = strread(sprintf('5,7,1,9\n'),'%d%d%d', ...
              'delimiter', ',', 'emptyvalue',NaN)
A =
     5
     9
B =
     7
   NaN
C =
     1
   NaN
```

If you remove the `\n` from the input string of this example, array `A` continues to be a 2-by-1 array, but `B` and `C` are now 1-by-1.

Delimiters

If your data uses a character other than a space as a delimiter, you must use the `strread` parameter `'delimiter'` to specify the delimiter. For example, if the string `str` used a semicolon as a delimiter, you would use this command:

```
[names, types, x, y, answer] = strread(str,'%s %s %f ...
    %d %s','delimiter',';')
```

Formats

The `format` string determines the number and types of return arguments. The number of return arguments must match the number of conversion specifiers in the `format` string.

The `strread` function continues reading `str` until the entire string is read. If there are fewer format specifiers than there are entities in `str`, `strread` reapplies the format specifiers, starting over at the beginning. See “Example 5” on page 1-7812 below.

The `format` string supports a subset of the conversion specifiers and conventions of the C language `fscanf` routine. White-space characters in the `format` string are ignored.

Preserving White-Space

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
str = '   An  example      of preserving     spaces      ';

strread(str, '%s', 'whitespace', '')
ans =
    '   An  example      of preserving     spaces      '
```

See Also

`textscan` | `sscanf`

Introduced before R2006a

strrep

Find and replace substring

Syntax

```
modifiedStr = strrep(origStr, oldSubstr, newSubstr)
```

Description

`modifiedStr = strrep(origStr, oldSubstr, newSubstr)` replaces all occurrences of the string `oldSubstr` within string `origStr` with the string `newSubstr`.

Examples

Replace text in a character array:

```
claim = 'This is a good example.';
new_claim = strrep(claim, 'good', 'great')
```

MATLAB returns:

```
new_claim =
This is a great example.
```

Replace text in a cell array:

```
c_files = {'c:\cookies.m'; ...
           'c:\candy.m';   ...
           'c:\calories.m'};
d_files = strrep(c_files, 'c:', 'd:')
```

MATLAB returns:

```
d_files =
    'd:\cookies.m'
    'd:\candy.m'
```

```
    'd:\calories.m'
```

Replace text in a cell array with values in a second cell array:

```
missing_info = {'Start: __'; ...
                'End: __'};

dates = {'01/01/2001'; ...
         '12/12/2002'};

complete = strrep(missing_info, '__', dates)
```

MATLAB returns:

```
complete =
    'Start: 01/01/2001'
    'End: 12/12/2002'
```

Compare the use of `strrep` and `regexprep` to replace a string with a repeated pattern:

```
repeats = 'abc 2 def 22 ghi 222 jkl 2222';
indices = strfind(repeats, '22')

using_strrep = strrep(repeats, '22', '*')
using_regexprep = regexprep(repeats, '22', '*')
```

MATLAB returns:

```
indices =
    11    18    19    26    27    28

using_strrep =
abc 2 def * ghi ** jkl ***

using_regexprep =
abc 2 def * ghi *2 jkl **
```

More About

Tips

- `strrep` accepts input combinations of single strings, strings in scalar cells, and same-sized cell arrays of strings. If any inputs are cell arrays, `strrep` returns a cell array.

- The `strrep` function does not find empty strings for replacement. That is, when *`origStr`* and *`oldSubstr`* both contain the empty string (`''`), `strrep` does not replace `''` with the contents of *`newSubstr`*.
- Before replacing strings, `strrep` finds all instances of *`oldSubstr`* in *`origStr`*, like the `strfind` function. For overlapping patterns, `strrep` performs multiple replacements. See the final example in the Examples section.

Introduced before R2006a

strsplit

Split string at specified delimiter

Syntax

```
C = strsplit(str)
C = strsplit(str,delimiter)
C = strsplit(str,delimiter,Name,Value)

[C,matches] = strsplit( ___ )
```

Description

`C = strsplit(str)` splits the string, `str`, at whitespace into the cell array of strings, `C`. A whitespace character is equivalent to any sequence in the set `{' ','\f','\n','\r','\t','\v'}`.

`C = strsplit(str,delimiter)` splits `str` at the delimiters specified by `delimiter`.

`C = strsplit(str,delimiter,Name,Value)` specifies additional delimiter options using one or more name-value pair arguments.

`[C,matches] = strsplit( ___ )` additionally returns a cell array of strings, `matches`, using any of the input arguments in the previous syntaxes. `matches` contains all occurrences of delimiters upon which `strsplit` splits `str`.

Examples

Split String on Whitespace

```
str = 'The rain in Spain.';
C = strsplit(str)
```

```
C =

    'The'    'rain'    'in'    'Spain.'
```

`C` is a cell array containing 4 strings.

Split String of Values on Specific Delimiter

Split a string of comma-separated values.

```
data = '1.21, 1.985, 1.955, 2.015, 1.885';
C = strsplit(data,', ')
```

```
C =

    '1.21'    '1.985'    '1.955'    '2.015'    '1.885'
```

Split a string of values, `data`, which contains the units `m/s` with an arbitrary number of white-space on either side of the text. The regular expression, `\s*`, matches any white-space character appearing zero or more times.

```
data = '1.21m/s1.985m/s 1.955 m/s2.015 m/s 1.885m/s';
[C,matches] = strsplit(data,'\s*m/s\s*',...
    'DelimiterType','RegularExpression')
```

```
C =

    '1.21'    '1.985'    '1.955'    '2.015'    '1.885'    ''

matches =

    'm/s'    'm/s '    ' m/s'    ' m/s '    'm/s'
```

In this case, the last string in `C` is empty. This empty string is the string that follows the last matched delimiter.

Split Path String on File Separator

```
myPath = 'C:\work\matlab';
C = strsplit(myPath,'\')
```

```
C =

    'C:'    'work'    'matlab'
```

Split Text String with Multiple Delimiters

Split a string on `' '` and `'ain'`, treating multiple delimiters as one. Specify multiple delimiters in a cell array of strings.

```
str = 'The rain in Spain stays mainly in the plain.';
[C,matches] = strsplit(str,{' ','ain'},'CollapseDelimiters',true)
```

```
C =

    'The'    'r'    'in'    'Sp'    'stays'    'm'    'ly'    'in'    'the'    'pl'

matches =

    ' '    'ain '    ' '    'ain '    ' '    'ain'    ' '    ' '    ' '    'ain'
```

Split the same string on whitespace and on `'ain'`, using regular expressions and treating multiple delimiters separately.

```
[C,matches] = strsplit(str,{'\s','ain'},'CollapseDelimiters',...
    false, 'DelimiterType','RegularExpression')
```

```
C =

    'The'    'r'    ''    'in'    'Sp'    ''    'stays'    'm'    'ly'    'in'    'the

matches =

    ' '    'ain'    ' '    ' '    'ain'    ' '    ' '    'ain'    ' '    ' '    ' '
```

In this case, `strsplit` treats the two delimiters separately, so empty strings appear in output `C` between the consecutively matched delimiters.

Split Text with Multiple, Overlapping Delimiters

Split text on the strings `', '` and `', and '`.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{', ',', and '})
```

```
C =

    'bacon'    'lettuce'    'and tomato'

matches =

    ', '    ', '
```

Because the command lists `', '` first and `', and '` contains `', '`, the `strsplit` function splits `str` on the first delimiter and never proceeds to the second delimiter.

If you reverse the order of delimiters, `', and '` takes priority.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{', and ',', '})
```

```
C =

    'bacon'    'lettuce'    'tomato'

matches =

    ', '    ', and '
```

Input Arguments

`str` — Input text

string

Input text, specified as a string.

Data Types: `char`

`delimiter` — Delimiting characters

string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings. Strings specified in delimiter do not appear in the string fragments of the output C.

Specify multiple delimiters in a cell array of strings. Each element of the cell array must contain a single string in a single row. The `strsplit` function splits str on the elements of delimiter in the order in which they appear in the cell array.

`delimiter` can include the following escape sequences:

`\\`	Backslash
`\0`	Null
`\a`	Alarm

`\b`	Backspace
`\f`	Form feed
`\n`	New line
`\r`	Carriage return
`\t`	Horizontal tab
`\v`	Vertical tab

Example: `','`

Example: `{'-',','}`

Data Types: `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DelimiterType','RegularExpression'` instructs `strsplit` to treat `delimiter` as a regular expression.

`'CollapseDelimiters'` — Multiple delimiter handling

`1 (true)` (default) | `0 (false)`

Multiple delimiter handling, specified as the comma-separated pair consisting of `'CollapseDelimiters'` and either `true` or `false`. If `true`, then consecutive delimiters in `str` are treated as one. If `false`, then consecutive delimiters are treated as separate delimiters, resulting in empty string `''` elements between matched delimiters.

Example: `'CollapseDelimiters',true`

`'DelimiterType'` — Delimiter type

`'Simple'` (default) | `'RegularExpression'`

Delimiter type, specified as the comma-separated pair consisting of `'DelimiterType'` and one of the following strings.

`'Simple'`	Except for escape sequences, `strsplit` treats `delimiter` as a literal string.

`'RegularExpression'`	`strsplit` treats `delimiter` as a regular expression.

In both cases, `delimiter` can include escape sequences.

Output Arguments

`C` — Parts of original string

cell array of strings

Parts of the original string, returned as a cell array of strings. C always contains one more element than matches contains. Consequently, if the original string, `str`, ends with a delimiter, then the last cell in `C` contains an empty string.

`matches` — Identified delimiters

cell array of strings

Identified delimiters, returned as a cell array of strings. matches always contains one fewer element than output C contains.

`regexp` | `strfind` | `strjoin`

strtok

Selected parts of string

Syntax

```
token = strtok(str)
token = strtok(str, delimiter)
[token, remain] = strtok(str, ...)
```

Description

`token = strtok(str)` parses input string `str` from left to right, returning part or all of that string in `token`. Using the white-space character as a delimiter, the `token` output begins at the start of `str`, skipping any delimiters that might appear at the start, and includes all characters up to either the next delimiter or the end of the string. White-space characters include space (ASCII 32), tab (ASCII 9), and carriage return (ASCII 13).

The `str` argument can be a string of characters enclosed in single quotation marks, a cell array of strings each enclosed in single quotation marks, or a variable representing either of the two. If `str` is a cell array of `N` strings, then `token` is a cell array of `N` tokens, with `token{1}` derived from `str{1}`, `token{2}` from `str{2}`, and so on.

`token = strtok(str, delimiter)` is the same as the above syntax except that you specify the delimiting character(s) yourself using the `delimiter` character vector input. White-space characters are not considered to be delimiters when using this syntax unless you include them in the `delimiter` argument. If the `delimiter` input specifies more than one character, MATLAB treats each character as a separate delimiter; it does not treat the multiple characters as a delimiting string. The number and order of characters in the `delimiter` argument is unimportant. Do not use escape sequences as delimiters. For example, use `char(9)` rather than `'\t'` for tab.

`[token, remain] = strtok(str, ...)` returns in `remain` that part of `str`, if any, that follows `token`. The delimiter is included in `remain`. If no delimiters are found in the body of the input string, then the entire string (excluding any leading delimiting characters) is returned in `token`, and `remain` is an empty string (`''`). If `str` is a cell array of strings, `token` is a cell array of tokens and `remain` is a cell array of string remainders.

Examples

Example 1

This example uses the default white-space delimiter. Note that space characters at the start of the string are not included in the `token` output, but the space character that follows `token` is included in `remain`:

```
s = '  This is a simple example.';
[token, remain] = strtok(s)

token =
This
remain =
 is a simple example.
```

Example 2

Take a string of HTML code and break it down into segments delimited by the < and > characters. Write a `while` loop to parse the string and print each segment:

```
s = sprintf('%s%s%s%s', ...
'<ul class=continued><li class=continued>', ...
'<pre><a name="13474"></a>token = strtok', ...
'(''str'', delimiter)<a name="13475"></a>', ...
'token = strtok(''str'')');

remain = s;

while true
   [str, remain] = strtok(remain, '<>');
   if isempty(str),  break;  end
   disp(sprintf('%s', str))
end
```

Here is the output:

```
ul class=continued
li class=continued
pre
a name="13474"
/a
token = strtok('str', delimiter)
```

```
a name="13475"
/a
token = strtok('str')
```

Example 3

Using `strtok` on a cell array of strings returns a cell array of strings in `token` and a character array in `remain`:

```
s = {'all in good time'; ...
     'my dog has fleas'; ...
     'leave no stone unturned'};

remain = s;

for k = 1:4
   [token, remain] = strtok(remain);
   token
end
```

Here is the output:

```
token =
    'all'
    'my'
    'leave'
token =
    'in'
    'dog'
    'no'
token =
    'good'
    'has'
    'stone'
token =
    'time'
    'fleas'
    'unturned'
```

See Also

`strfind` | `strcmp` | `strncmp` | `textscan` | `strsplit`

Introduced before R2006a

strtrim

Remove leading and trailing white space from string

Syntax

```
S = strtrim(str)
C = strtrim(cstr)
```

Description

`S = strtrim(str)` returns a copy of string `str` with all leading and trailing white-space characters removed. A white-space character is one for which the `isspace` function returns logical `1` (`true`).

`C = strtrim(cstr)` returns a copy of the cell array of strings `cstr` with all leading and trailing white-space characters removed from each string in the cell array.

Examples

Remove the leading white-space characters (spaces and tabs) from `str`:

```
str = sprintf('  \t   Remove    leading white-space')
str =
        Remove    leading white-space

str = strtrim(str)
str =
Remove    leading white-space
```

Remove leading and trailing white-space from the cell array of strings:

```
cstr = {'     Trim leading white-space';
        'Trim trailing white-space     '};

cstr = strtrim(cstr)
cstr =
    'Trim leading white-space'
```

```
    'Trim trailing white-space'
```

See Also

isspace | cellstr | deblank | strjust

Introduced before R2006a

struct

Create structure array

Syntax

```
s = struct
s = struct(field,value)
s = struct(field1,value1,...,fieldN,valueN)
s = struct([])

s = struct(obj)
```

Description

`s = struct` creates a scalar (1-by-1) structure with no fields.

`s = struct(field,value)` creates a structure array with the specified field and values. The `value` input argument can be any data type, such as a numeric, logical, character, or cell array.

- If `value` is *not* a cell array, then `s` is a scalar structure, where `s.(field) = value`.
- If `value` is a cell array, then `s` is a structure array with the same dimensions as `value`. Each element of `s` contains the corresponding element of `value`. For example, `s = struct('f',{'a','b'})` returns `s(1).f = 'a'` and `s(2).f = 'b'`.
- If `value` is an empty cell array `{}`, then `s` is an empty (0-by-0) structure.

`s = struct(field1,value1,...,fieldN,valueN)` creates a structure array with multiple fields. Any nonscalar cell arrays in the set `value1,...,valueN` must have the same dimensions.

- If none of the `value` inputs is a cell array, or if all `value` inputs that are cell arrays are scalars, then `s` is a scalar structure.
- If any of the `value` inputs is a nonscalar cell array, then `s` has the same dimensions as the nonscalar cell array. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.

- If any `value` input is an empty cell array, `{}`, then output `s` is an empty (0-by-0) structure. To specify an empty field and keep the values of the other fields, use `[]` as a `value` input instead.

`s = struct([])` creates an empty (0-by-0) structure with no fields.

`s = struct(obj)` creates a scalar structure with field names and values that correspond to properties of `obj`. The `struct` function does not convert `obj`, but rather creates `s` as a new structure. This structure does not retain the class information, so private, protected, and hidden properties become public fields in `s`. The `struct` function issues a warning when you use this syntax.

Examples

Structure with One Field

Create a nonscalar structure with one field.

```
field = 'f';
value = {'some text';
         [10, 20, 30];
         magic(5)};
s = struct(field,value)
```

```
s =
3x1 struct array with fields:
    f
```

View the contents of each element.

```
s.f
```

```
ans =
some text

ans =
    10    20    30

ans =
    17    24     1     8    15
    23     5     7    14    16
```

```
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

When you access a field of a nonscalar structure, such as `s.f`, MATLAB returns a comma-separated list. In this case, `s.f` is equivalent to `s(1).f, s(2).f, s(3).f`.

Structure with Multiple Fields

Create a nonscalar structure with several fields.

```
field1 = 'f1';  value1 = zeros(1,10);
field2 = 'f2';  value2 = {'a', 'b'};
field3 = 'f3';  value3 = {pi, pi.^2};
field4 = 'f4';  value4 = {'fourth'};

s = struct(field1,value1,field2,value2,field3,value3,field4,value4)

s =
1x2 struct array with fields:
    f1
    f2
    f3
    f4
```

The cell arrays for `value2` and `value3` are 1-by-2, so `s` is also 1-by-2. Because `value1` is a numeric array and not a cell array, both `s(1).f1` and `s(2).f1` have the same contents. Similarly, because the cell array for `value4` has a single element, `s(1).f4` and `s(2).f4` have the same contents.

```
s(1)

ans =
    f1: [0 0 0 0 0 0 0 0 0 0]
    f2: 'a'
    f3: 3.1416
    f4: 'fourth'

s(2)

ans =
    f1: [0 0 0 0 0 0 0 0 0 0]
    f2: 'b'
    f3: 9.8696
```

```
    f4: 'fourth'
```

Structure with Empty Field

Create a structure with an empty field. Use `[]` to specify the value of the empty field.

```
s = struct('f1','a','f2',[])

s =

    f1: 'a'
    f2: []
```

Fields That Contain Cell Arrays

Create a structure with a field that contains a cell array.

```
field = 'mycell';
value = {{'a','b','c'}};
s = struct(field,value)

s =
    mycell: {'a'  'b'  'c'}
```

Empty Structure

Create an empty structure with several fields.

```
s = struct('a',{},'b',{},'c',{})

s =
0x0 struct array with fields:
    a
    b
    c
```

Assign a value to a field in an empty structure.

```
s(1).a = 'a'

s =

    a: 'a'
    b: []
```

```
    c: []
```

Nested Structure

Create a nested structure. `a` is a structure with a field which contains another structure.

```
a.b = struct('c',{},'d',{})
```

```
a =
    b: [0x0 struct]
```

View the names of the fields of `a.b`.

```
fieldnames(a.b)
```

```
ans =
    'c'
    'd'
```

- "Create a Structure Array"
- "Access Data in a Structure Array"
- "Generate Field Names from Variables"

Input Arguments

`field` — Field name

string

Field name, specified as a string. Valid field names begin with a letter, and can contain letters, digits, and underscores. The maximum length of a field name is the value that the `namelengthmax` function returns.

`value` — Values within structure field

cell array | scalar | vector | multidimensional array

Values within a structure field, specified as a cell array or as a scalar, vector, or multidimensional array of any other data type.

If none of the `value` inputs is a cell array, or if all `value` inputs that are cell arrays are scalars, then output `s` is a scalar structure. Otherwise, `value` inputs that are nonscalar cell arrays must have the same dimensions, and output `s` also has those dimensions. For

any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.

If any `value` input is an empty cell array, `{}`, then output `s` is an empty structure array. To specify an empty field and keep the values of the other fields, use `[]` as a `value` input instead.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell` | `function_handle` | `categorical` | `datetime` | `duration` | `calendarDuration`
Complex Number Support: Yes

`obj` — Object

object of any nonfundamental class

Object. `struct` copies the properties of `obj` to the fields of a new scalar structure. `obj` cannot be an object of a fundamental data type, such as `double` or `char`. See "Fundamental MATLAB Classes" for the list of fundamental data types.

See Also

`cell2struct` | `fieldnames` | `isfield` | `isstruct` | `orderfields` | `rmfield` | `struct2cell` | `struct2table` | `substruct` | `table` | `table2struct`

Introduced before R2006a

struct2cell

Convert structure to cell array

Syntax

```
c = struct2cell(s)
```

Description

`c = struct2cell(s)` converts the `m`-by-`n` structure `s` (with `p` fields) into a `p`-by-`m`-by-`n` cell array `c`.

If structure `s` is multidimensional, cell array `c` has size `[p size(s)]`.

Examples

The commands

```
clear s, s.category = 'tree';
s.height = 37.4; s.name = 'birch';
```

create the structure

```
s =
    category: 'tree'
      height: 37.4000
        name: 'birch'
```

Converting the structure to a cell array,

```
c = struct2cell(s)

c =
    'tree'
    [37.4000]
    'birch'
```

More About

Tips

- Use `fieldnames` to obtain structure field names in the same order as `struct2cell` returns structure values.
- dynamic field names

See Also

`cell2struct` | `struct2table` | `table2cell` | `cell` | `iscell` | `struct` | `isstruct` | `fieldnames`

Introduced before R2006a

struct2table

Convert structure array to table

Syntax

```
T = struct2table(S)
T = struct2table(S,Name,Value)
```

Description

`T = struct2table(S)` converts the structure array, `S`, to a table, `T`. Each field of `S` becomes a variable in `T`.

`T = struct2table(S,Name,Value)` creates a table from a structure array, `S`, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify row names to include in the table.

Examples

Convert Scalar Structure to Table

Convert a scalar structure to a table using the default options.

Create a structure array, `S`.

```
S.Name = {'CLARK';'BROWN';'MARTIN'};
S.Gender = {'M';'F';'M'};
S.SystolicBP = [124;122;130];
S.DiastolicBP = [93;80;92];

S
```

```
S =

           Name: {3x1 cell}
         Gender: {3x1 cell}
```

```
     SystolicBP: [3x1 double]
    DiastolicBP: [3x1 double]
```

The scalar structure, `S`, has four fields, each with three rows.

Convert the structure array to a table.

```
T = struct2table(S)
```

```
T =

      Name       Gender    SystolicBP    DiastolicBP
    _________    ______    __________    ___________

    'CLARK'      'M'       124           93
    'BROWN'      'F'       122           80
    'MARTIN'     'M'       130           92
```

The structure field names in `S` become the variable names in the output table. The size of `T` is 3-by-4.

Change `Name` from a variable to row names by modifying the table property, `T.Properties.RowNames`, and then deleting the variable `Name`.

```
T.Properties.RowNames = T.Name;
T.Name = [];
```

```
T
```

```
T =

                Gender    SystolicBP    DiastolicBP
                ______    __________    ___________

    CLARK       'M'       124           93
    BROWN       'F'       122           80
    MARTIN      'M'       130           92
```

Convert Nonscalar Structure Array to Table

Create a nonscalar structure array, `S`.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
```

```
S(1,1).DiastolicBP = 93;

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;

S
```

```
S =

3x1 struct array with fields:

    Name
    Gender
    SystolicBP
    DiastolicBP
```

`S` is a 3-by-1 structure array with four fields.

Convert the structure array to a table.

```
T = struct2table(S)
```

```
T =

      Name       Gender    SystolicBP    DiastolicBP
    _________    _______    __________    ___________

    'CLARK'      'M'        124           93
    'BROWN'      'F'        122           80
    'MARTIN'     'M'        130           92
```

The structure field names in `S` become the variable names in the output table. The size of `T` is 3-by-4.

Treat Scalar Stucture As Array

Use `'AsArray',true` to create a table from a scalar structure whose fields have different numbers of rows.

Create a scalar structure, `S`, with fields `name`, `billing`, and `test`.

```
S.name = 'John Doe';
S.billing = 127.00;
S.test = [79, 75, 73; 180, 178, 177.5; 220, 210, 205];
S
```

```
S =

       name: 'John Doe'
    billing: 127
       test: [3x3 double]
```

The fields have a different number of rows. Therefore, you cannot use `struct2table(S)`, which uses `'AsArray',false` by default.

Treat the scalar structure as an array and convert it to a table.

```
T = struct2table(S,'AsArray',true)
```

```
T =

       name       billing        test
    __________    _______    _____________

    'John Doe'    127        [3x3 double]
```

`T` contains one row.

- "Access Data in a Table"

Input Arguments

S — Structure array

structure array

Structure array, specified as a scalar structure array.

- If `S` is a scalar structure with `n` fields, all of which have `m` rows, then `T` is an `m`-by-`n` table.
- If `S` is a nonscalar `m`-by-`1` structure array with `n` fields, then `T` is an `m`-by-`n` table.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `RowNames','{'row1','row2','row3'}` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

`'RowNames'` — Row names for `T`

`{}` (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings.

`'AsArray'` — Indicator for how to treat scalar structure

`false` (default) | `true` | `0` | `1`

Indicator for how to treat scalar structure, specified as the comma-separated pair consisting of `'AsArray'` and either `false`, `true`, `0`, or `1`.

`true`	`struct2table` converts `S` to a table with one row and `n` variables. The variables can be different sizes.
`false`	`struct2table` converts a scalar structure array with `n` fields into an `m`-by-`n` table. Each field must have `m` rows. This is the default behavior

Output Arguments

`T` — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

See Also

`array2table` | `cell2table` | `table` | `table2struct`

structfun

Apply function to each field of scalar structure

Syntax

```
[A1,...,An] = structfun(func,S)
[A1,...,An] = structfun(func,S,Name,Value)
```

Description

`[A1,...,An] = structfun(func,S)` applies the function specified by function handle `func` to each field of scalar structure `S`. Output arrays `A1,...,An`, where `n` is the number of outputs from function `func`, contain the outputs from the function calls.

`[A1,...,An] = structfun(func,S,Name,Value)` calls function `func` with additional options specified by one or more Name,Value pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

Input Arguments

`func`

Handle to a function that accepts a single input argument and returns `n` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

`S`

Scalar structure.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'UniformOutput'`

Logical value, as follows:

`true (1)`	Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type and size. The `structfun` function combines the outputs in arrays `A1,...,An`, where `n` is the number of function outputs. Each output array is of the same type as the individual function outputs.
`false (0)`	Requests that the `structfun` function combine the outputs into scalar structures `A1,...,An`, with the same fields as input structure `S`. The outputs of function `func` can be of any size or type.

Default: `true`

`'ErrorHandler'`

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

`identifier`	Error identifier.
`message`	Error message text.
`index`	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments

`A1,...,An`

Arrays that collect the `n` outputs from function `func`.

If `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each input. The class of the corresponding output array is the same as the class of the individual outputs from function `func`.
- Each array `A` is a column vector whose length equals the number of fields in `S`. The `structfun` function applies function `func` to the fields of `S` in the same order as that returned by the `fieldnames` function.

If `UniformOutput` is `false`, each array `A` is a scalar structure with the same fields as input `S`.

Examples

Create a scalar structure, and count the number of characters in each field.

```
s.f1 = 'Sunday';
s.f2 = 'Monday';
s.f3 = 'Tuesday';
s.f4 = 'Wednesday';
s.f5 = 'Thursday';
s.f6 = 'Friday';
s.f7 = 'Saturday';

lengths = structfun(@numel, s)
```

Shorten the text in each field of `s`, created in the previous example. Because the output is nonscalar, set `UniformOutput` to `false`.

```
shortNames = structfun(@(x) ( x(1:3) ), s, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function.

Define and call a custom error handling function.

```
function result = errorfun(errorinfo, field)
   warning(errorinfo.identifier, errorinfo.message);
   result = NaN;
end
```

```
mystruct.f1 = 'text';
myresult = structfun(@(x) x^2, mystruct, 'ErrorHandler', @errorfun)
```

See Also

cellfun | arrayfun | function_handle | cell2mat | spfun

Introduced before R2006a

strvcat

Concatenate strings vertically

Note: `strvcat` is not recommended. Use `char` instead. Unlike `strvcat`, the `char` function does not ignore empty strings.

Syntax

```
S = strvcat(t1, t2, t3, ...)
S = strvcat(c)
```

Description

`S = strvcat(t1, t2, t3, ...)` forms the character array `S` containing the text strings (or string matrices) `t1,t2,t3,...` as rows. Spaces are appended to each string as necessary to form a valid matrix. Empty arguments are ignored.

`S = strvcat(c)` when `c` is a cell array of strings, passes each element of `c` as an input to `strvcat`. Empty strings in the input are ignored.

Examples

The command `strvcat('Hello','Yes')` is the same as `['Hello';'Yes ']`, except that `strvcat` performs the padding automatically.

```
t1 = 'first'; t2 = 'string'; t3 = 'matrix'; t4 = 'second';

S1 = strvcat(t1, t2, t3)        S2 = strvcat(t4, t2, t3)

S1 =                            S2 =

first                           second
string                          string
```

```
matrix                          matrix

S3 = strvcat(S1, S2)

S3 =
first
string
matrix
second
string
matrix
```

More About

Tips

If each text parameter, `ti`, is itself a character array, `strvcat` appends them vertically to create arbitrarily large string matrices.

Introduced before R2006a

sub2ind

Convert subscripts to linear indices

Syntax

```
linearInd = sub2ind(matrixSize, rowSub, colSub)
linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)
```

Description

`linearInd = sub2ind(matrixSize, rowSub, colSub)` returns the linear index equivalents to the row and column subscripts `rowSub` and `colSub` for a matrix of size `matrixSize`. The `matrixSize` input is a 2-element vector that specifies the number of rows and columns in the matrix as [`nRows`, `nCols`]. The `rowSub` and `colSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscript pairs for the matrix. Example 3 demonstrates the use of vectors for the `rowSub` and `colSub` inputs.

`linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)` returns the linear index equivalents to the specified subscripts for each dimension of an N-dimensional array of size `arraySize`. The `arraySize` input is an n-element vector that specifies the number of dimensions in the array. The `dimNSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscripts for the matrix.

All subscript inputs can be `single`, `double`, or any integer type. The `linearInd` output is always of class `double`.

If needed, `sub2ind` assumes that unspecified trailing subscripts are 1. See Example 2, below.

Examples

Example 1

This example converts the subscripts (2, 1, 2) for three-dimensional array `A` to a single linear index. Start by creating a 3-by-4-by-2 array `A`:

```
rng(0,'twister');   % Initialize random number generator.
A = rand(3, 4, 2)

A(:,:,1) =
    0.8147    0.9134    0.2785    0.9649
    0.9058    0.6324    0.5469    0.1576
    0.1270    0.0975    0.9575    0.9706
A(:,:,2) =
    0.9572    0.1419    0.7922    0.0357
    0.4854    0.4218    0.9595    0.8491
    0.8003    0.9157    0.6557    0.9340
```

Find the linear index corresponding to (2, 1, 2):

```
linearInd = sub2ind(size(A), 2, 1, 2)
linearInd =
    14
```

Make sure that these agree:

```
A(2, 1, 2)            A(14)
ans =                 and =
     0.4854               0.4854
```

Example 2

Using the 3-dimensional array `A` defined in the previous example, specify only 2 of the 3 subscript arguments in the call to `sub2ind`. The third subscript argument defaults to 1.

The command

```
linearInd = sub2ind(size(A), 2, 4)
ans =
    11
```

is the same as

```
linearInd = sub2ind(size(A), 2, 4, 1)
ans =
    11
```

Example 3

Using the same 3-dimensional input array `A` as in Example 1, accomplish the work of five separate `sub2ind` commands with just one.

Replace the following commands:

```
sub2ind(size(A), 3, 3, 2);
sub2ind(size(A), 2, 4, 1);
sub2ind(size(A), 3, 1, 2);
sub2ind(size(A), 1, 3, 2);
sub2ind(size(A), 2, 4, 1);
```

with a single command:

```
sub2ind(size(A), [3 2 3 1 2], [3 4 1 3 4], [2 1 2 2 1])
ans =
    21    11    15    19    11
```

Verify that these linear indices access the same array elements as their subscripted counterparts:

```
[A(3,3,2),   A(2,4,1),   A(3,1,2),   A(1,3,2),   A(2,4,1)]
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576

A([21, 11, 15, 19, 11])
ans =
    0.6557    0.1576    0.8003    0.7922    0.1576
```

See Also

`ind2sub` | `find` | `size`

Introduced before R2006a

subplot

Create axes in tiled positions

Syntax

```
subplot(m,n,p)
subplot(m,n,p,'replace')
subplot(m,n,p,'align')
subplot('Position',positionVector)
subplot(m,n,p,ax)
subplot(___,Name,Value)

h = subplot(___)

subplot(h)
```

Description

`subplot(m,n,p)` divides the current figure into an `m`-by-`n` grid and creates an axes for a subplot in the position specified by `p`. MATLAB numbers its subplots by row, such that the first subplot is the first column of the first row, the second subplot is the second column of the first row, and so on. If the axes already exists, then the command `subplot(m,n,p)` makes the subplot in position `p` the current axes.

`subplot(m,n,p,'replace')` deletes any existing axes in position `p` and creates a new axes.

`subplot(m,n,p,'align')` creates a new axes so that the plot boxes are aligned. This is the default behavior.

`subplot('Position',positionVector)` creates a new axes at the position specified by `positionVector`. The `positionVector` is a four-element vector of the form `[left,bottom,width,height]`, such that the entries are normalized values between 0.0 to 1.0. If the position vector specifies an axes that overlaps any previous axes, then the new axes replaces the existing ones.

`subplot(m,n,p,ax)` converts the existing axes, `ax`, into a subplot axes in the same figure.

`subplot(___,Name,Value)` specifies properties for the axes using any of the input argument combinations in the previous syntaxes and one or more `Name,Value` pair arguments.

`h = subplot(___)` returns the axes object created by the `subplot` function.

`subplot(h)` makes the axes with handle `h` the current axes of its figure, but does not make its figure the current figure if it is not already the current figure.

Examples

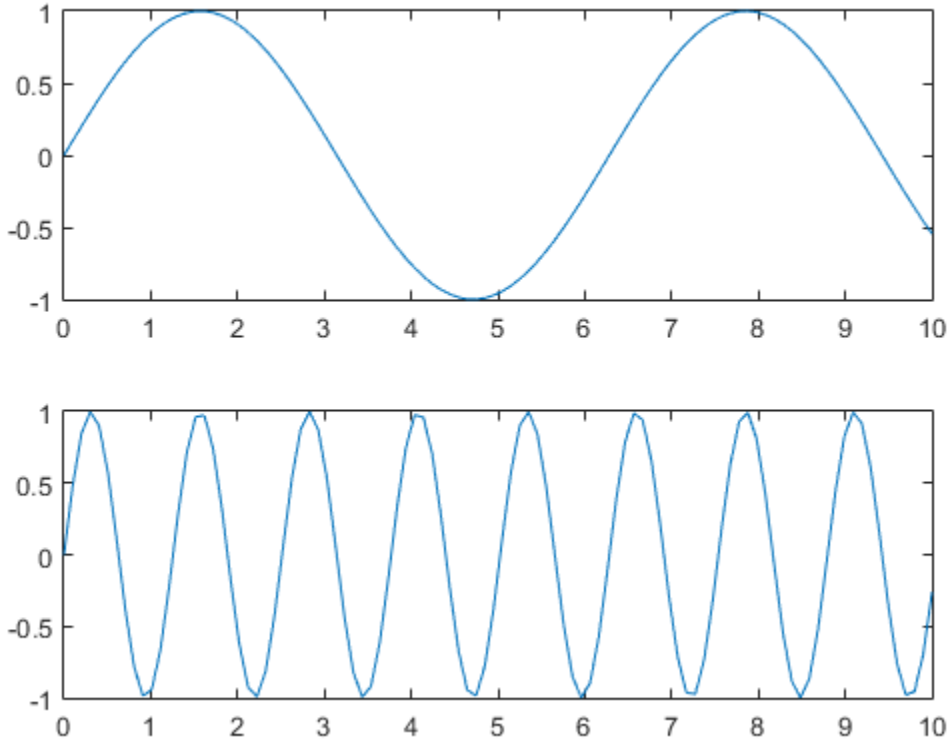
Upper and Lower Subplots

Create a figure with two stacked subplots. Plot a sine wave in each axes.

```
x = linspace(0,10);
y1 = sin(x);
y2 = sin(5*x);

figure
subplot(2,1,1);
plot(x,y1)

subplot(2,1,2);
plot(x,y2)
```



Quadrant of Subplots

Create a figure divided into four subplots.

Define the data.

```
x = linspace(0,10);
y1 = sin(x);
y2 = sin(2*x);
y3 = sin(4*x);
y4 = sin(8*x);
```

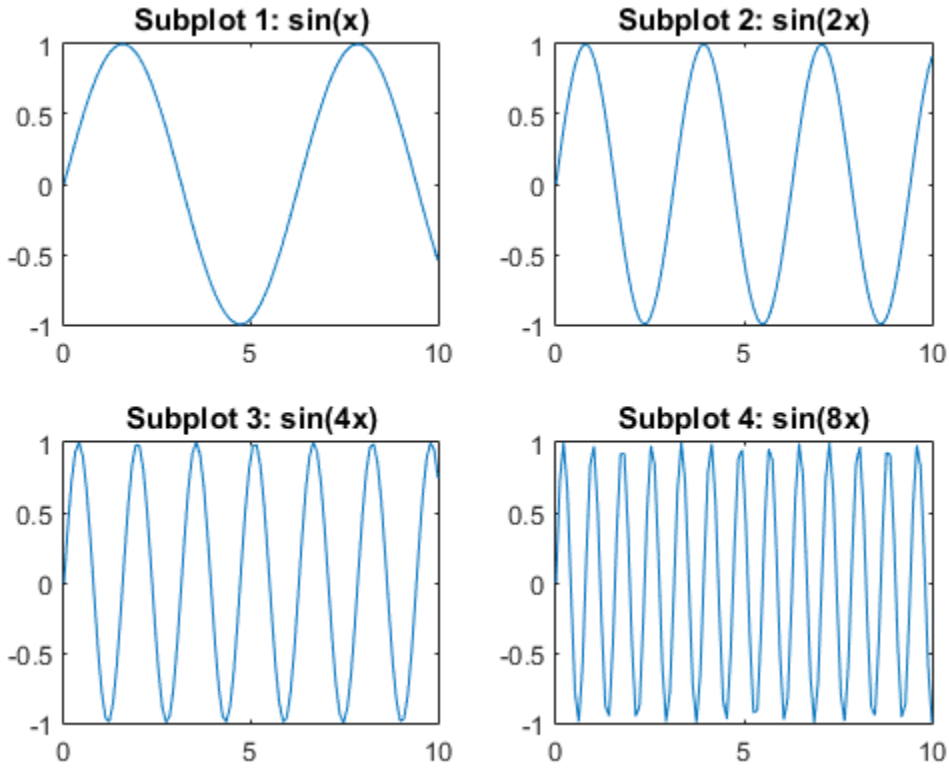
Plot the four sine waves and title each subplot.

```
figure
subplot(2,2,1)
plot(x,y1)
title('Subplot 1: sin(x)')

subplot(2,2,2)
plot(x,y2)
title('Subplot 2: sin(2x)')

subplot(2,2,3)
plot(x,y3)
title('Subplot 3: sin(4x)')

subplot(2,2,4)
plot(x,y4)
title('Subplot 4: sin(8x)')
```



Subplots with Different Sizes

Create a figure containing subplots with different sizes.

Define a vector of sine values and a vector of polynomial values.

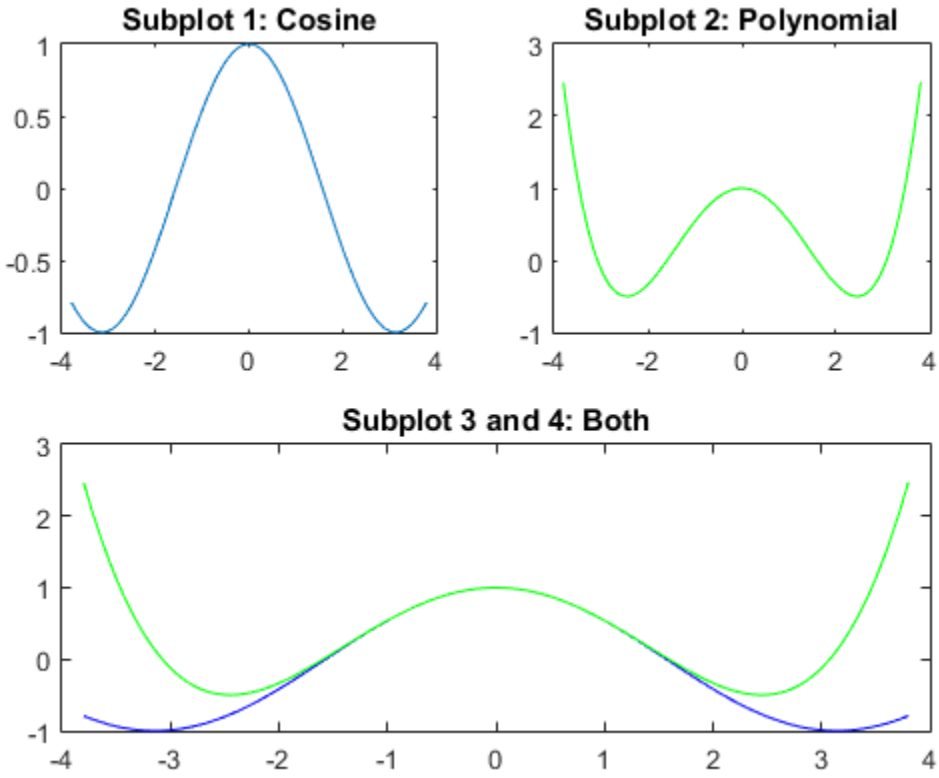
```
x = linspace(-3.8,3.8);
y_cos = cos(x);
y_poly = 1 - x.^2./2 + x.^4./24;
```

Plot the sine wave in the first subplot and the polynomial in the second subplot. Create a third subplot that spans the lower half of the figure and plot both vectors together. Add titles to each subplot.

```
figure
subplot(2,2,1);
plot(x,y_cos);
title('Subplot 1: Cosine')

subplot(2,2,2);
plot(x,y_poly,'g');
title('Subplot 2: Polynomial')

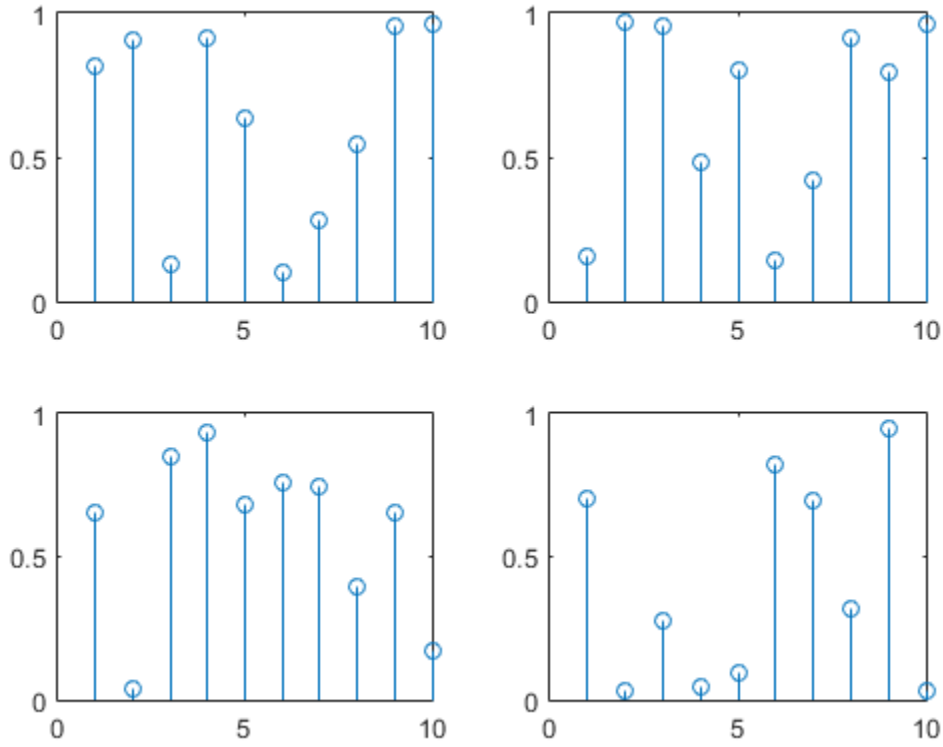
subplot(2,2,[3,4]);
plot(x,y_cos,'b',x,y_poly,'g');
title('Subplot 3 and 4: Both')
```



Replace Subplot with Empty Axes

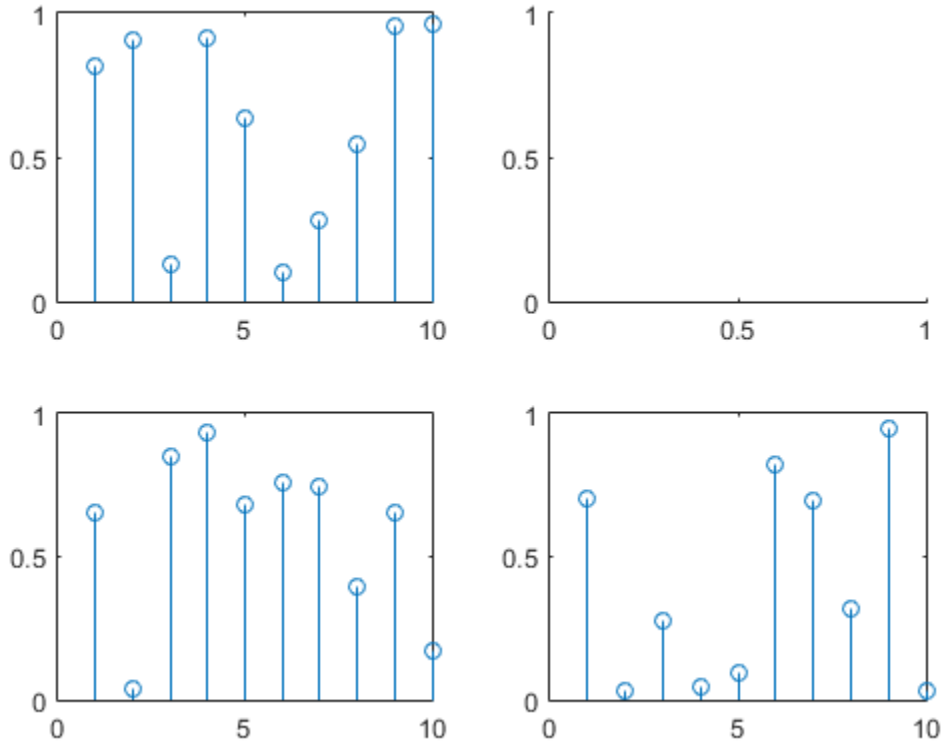
Initialize the random number generator. Use a loop to create a figure with four stem plots of random data.

```
rng default
figure
for k = 1:4
    data = rand(1,10);
    subplot(2,2,k)
    stem(data)
end
```



Replace the second subplot with an empty axes.

```
subplot(2,2,2,'replace')
```



Subplots at Specified Positions

Create a figure with two subplots that are not aligned.

Define `y` as data from the `magic` function.

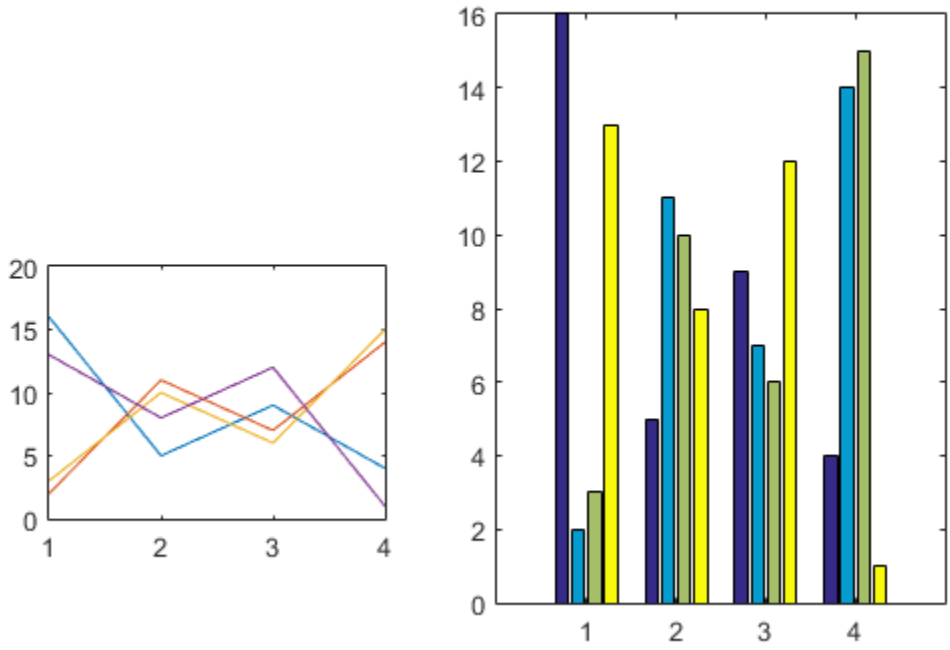
```
y = magic(4);
```

Plot `y` in one subplot. Create a bar graph of `y` in a second subplot. Specify a custom position for each subplot.

```
figure
positionVector1 = [0.1, 0.2, 0.3, 0.3];
```

```
subplot('Position',positionVector1)
plot(y)

positionVector2 = [0.5, 0.1, 0.4, 0.7];
subplot('Position',positionVector2)
bar(y)
```



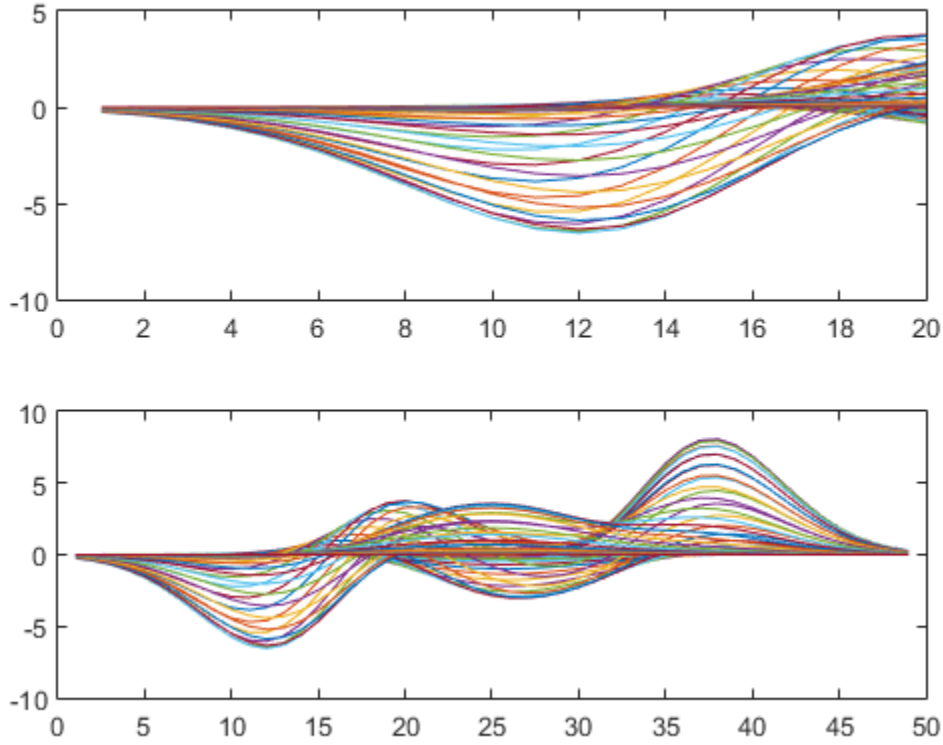
Return Subplot Axes Handle

Create a figure with two subplots. Plot the first 20 rows of the `peaks` function in the upper subplot. Plot the entire data set in the lower subplot.

```
ax1 = subplot(2,1,1);
```

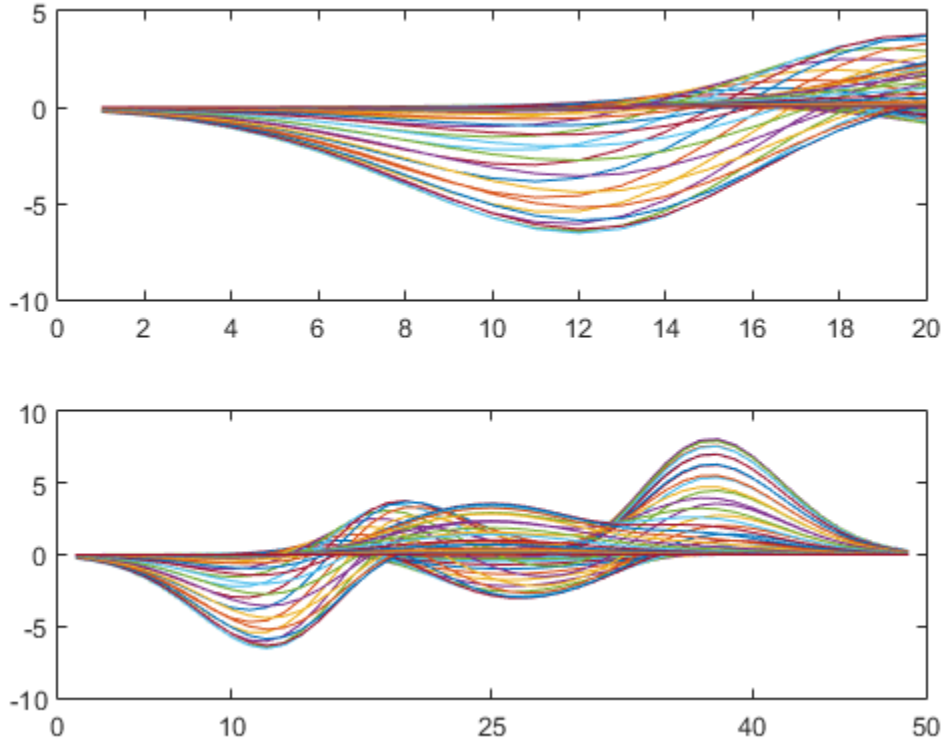
```
Z = peaks;
plot(ax1,Z(1:20,:))

ax2 = subplot(2,1,2);
plot(ax2,Z)
```



Change the tick marks for the lower subplot. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
ax2.XTick = [0,10,25,40,50];
```



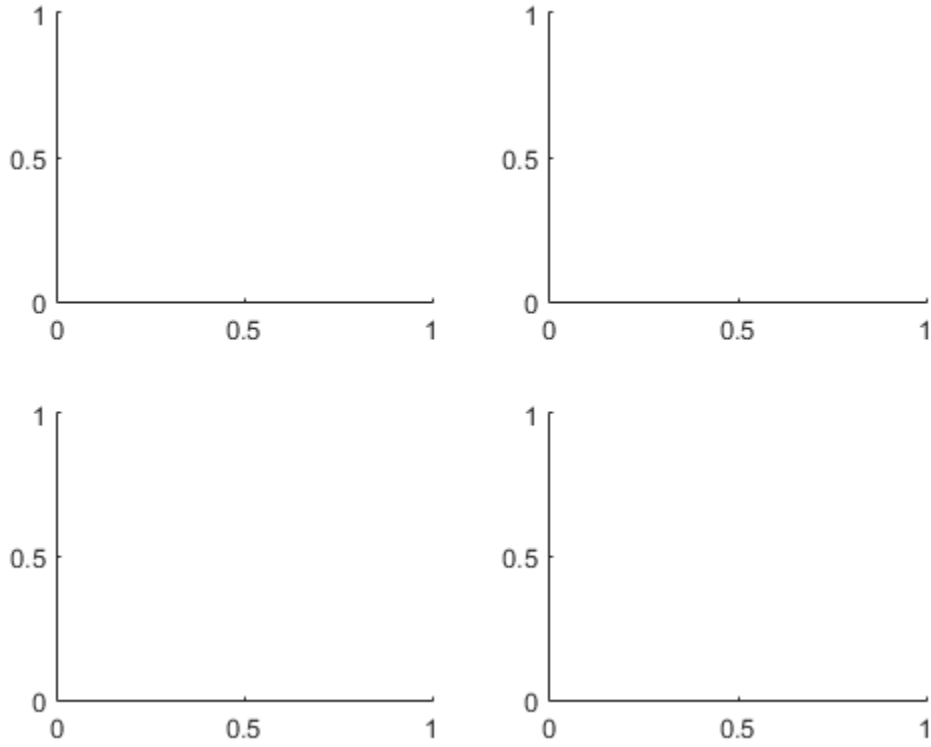
Some plotting functions set axes properties. Execute plotting functions before specifying axes properties to avoid overriding existing axes property settings.

Make Subplot Axes the Current Axes

Make a subplot the current axes using its axes handle.

Create a figure with multiple subplots. Store the subplot axes handles in vector `h`.

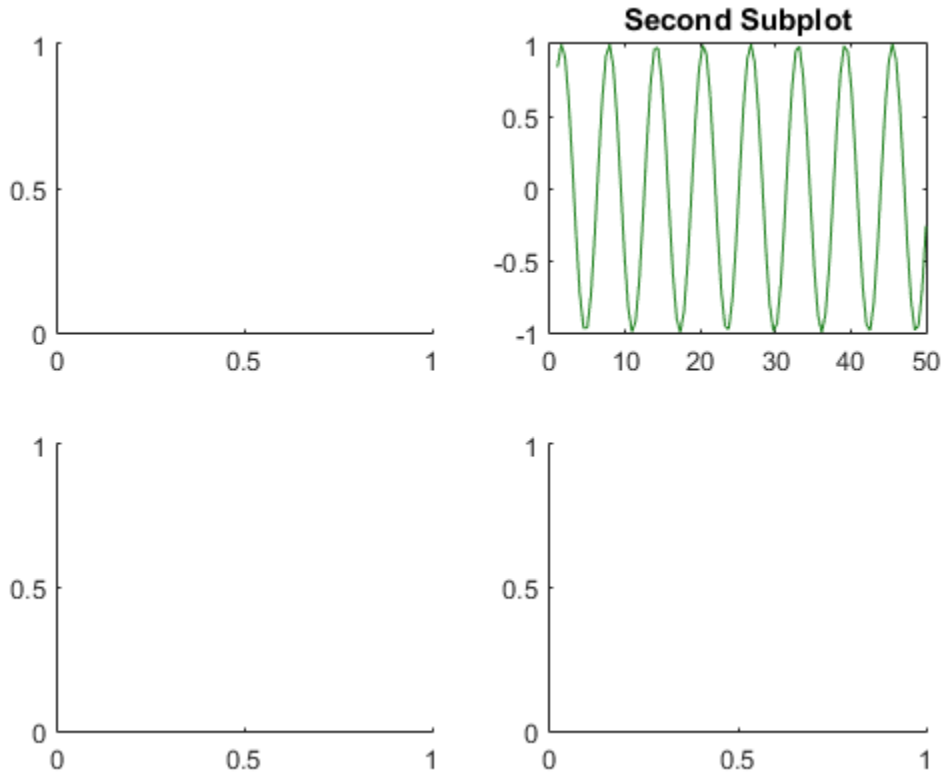
```
figure;
for k = 1:4
    h(k) = subplot(2,2,k);
end
```



Make the second subplot the current axes. Plot a sine wave and change the axis limits.

```
x = linspace(1,50);
y = sin(x);

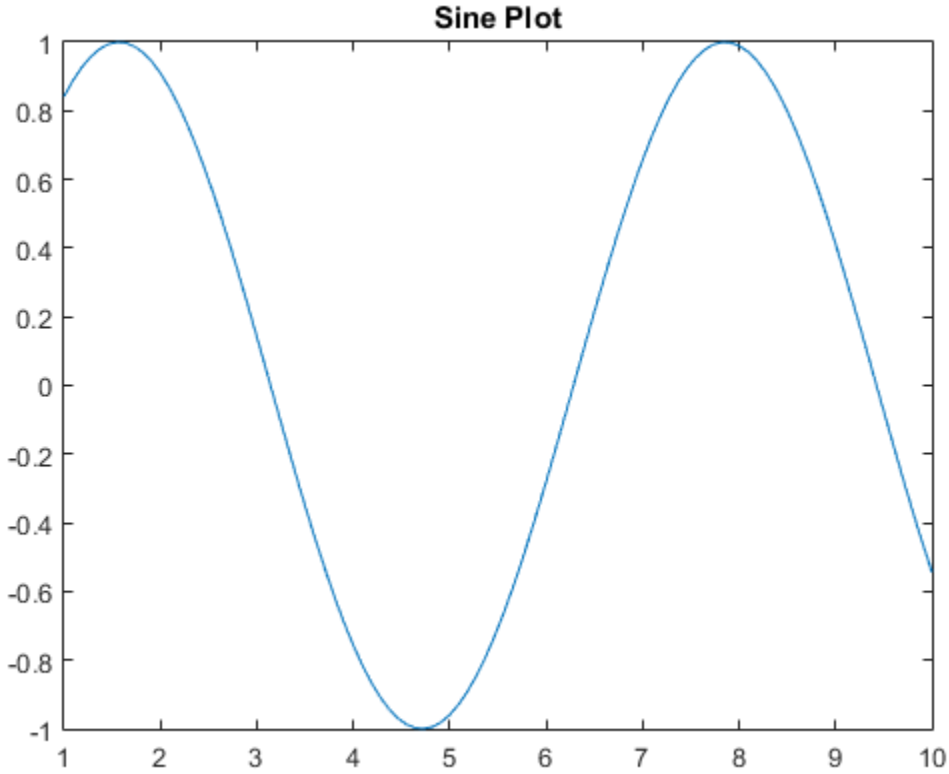
subplot(h(2))
plot(x,y,'Color',[0.1, 0.5, 0.1])
title('Second Subplot')
axis([0,50,-1,1])
```



Convert Existing Axes to Subplot

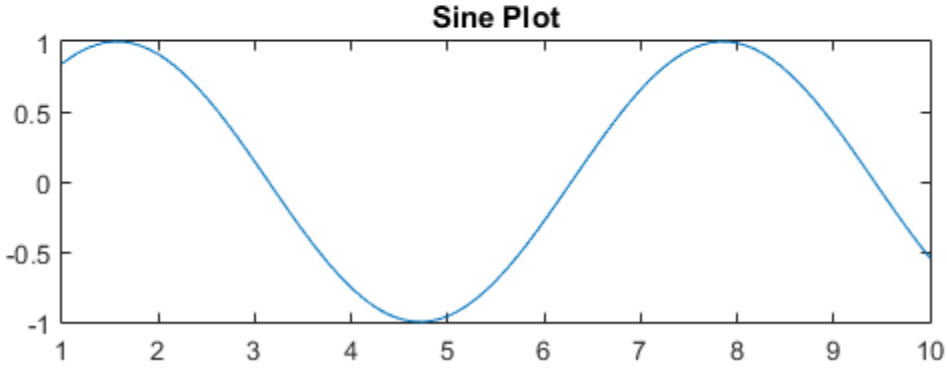
Create a plot with a title.

```
x = linspace(1,10);
y = sin(x);
plot(x,y)
title('Sine Plot')
```



Get the current axes object using `gca`. Convert the current axes so that it is the lower subplot of the figure.

```
ax1 = gca;
subplot(2,1,2,ax1)
```



The `subplot` function uses the figure in which the original axes existed.

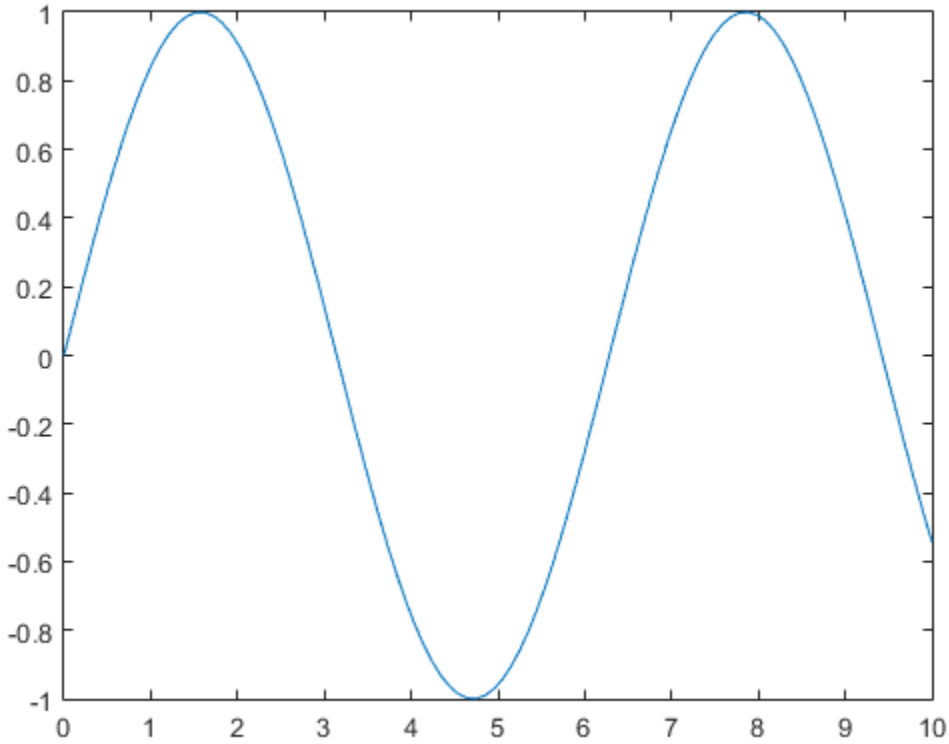
Combine Two Axes Into Single Figure With Subplots

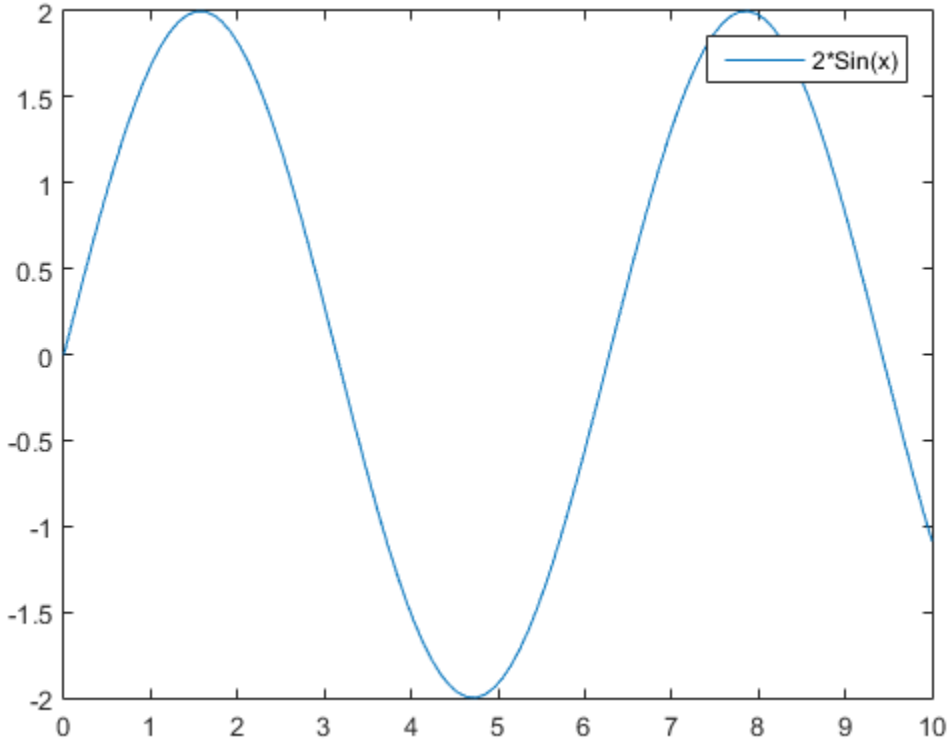
Create two plots in two different figures and store the axes objects.

```
x = linspace(0,10);
y1 = sin(x);
figure
plot(x,y1)
ax1 = gca;

y2 = 2*sin(x);
```

```
figure
plot(x,y2)
leg = legend('2*Sin(x)');
ax2 = gca;
```

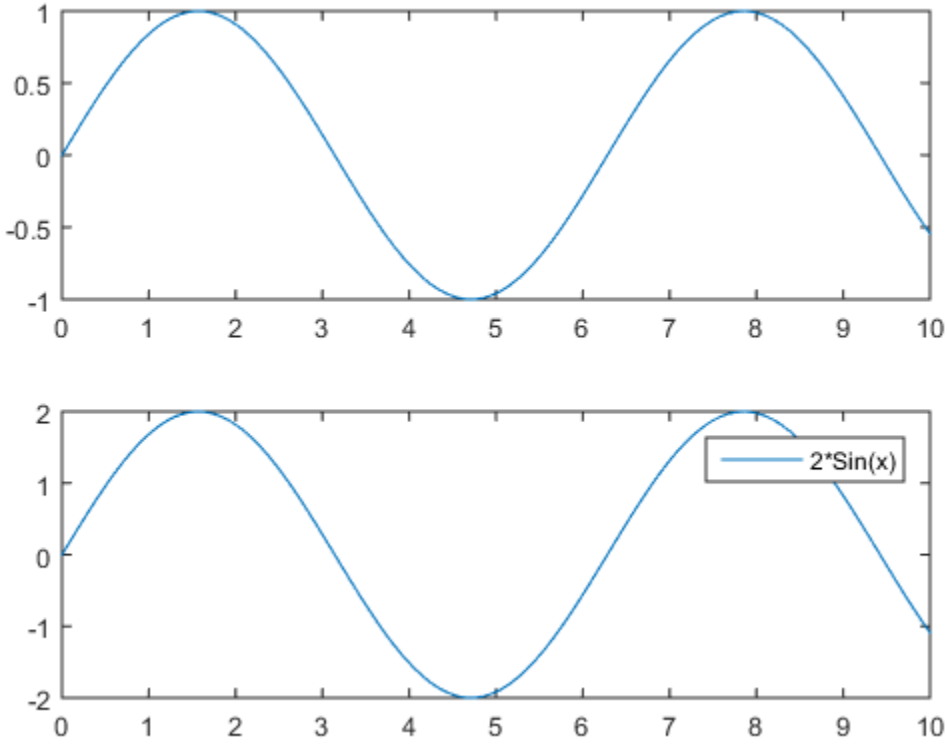




Create copies of the two axes objects using `copyobj`. Set the parent of the copied axes to a third figure. Since legends and colorbars objects do not get copied with the associated axes, copy the legend with the axes.

```
f3 = figure;
ax1_copy = copyobj(ax1,f3);
subplot(2,1,1,ax1_copy)

copies = copyobj([ax2,leg],f3);
ax2_copy = copies(1);
subplot(2,1,2,ax2_copy)
```



Input Arguments

`m` — Number of grid rows

1 (default) | positive integer

Number of grid rows, specified as a positive integer.

Data Types: `single` | `double`

`n` — Number of grid columns

1 (default) | positive integer

Number of grid columns, specified as a positive integer.

Data Types: `single | double`

`p` — Grid position for new axes

positive integer | vector

Grid position for the new axes, specified as a positive integer or a vector of positive integers.

- If `p` is a positive integer, then `subplot` creates a new axes in grid position `p`.
- If `p` is a vector of positive integers, then `subplot` creates a new axes that spans the grid positions listed in `p`. For example, `subplot(2,3,[2,5])` creates one axes spanning positions 2 and 5. Use `subplot(2,3,[2,6])` to create one axes spanning positions 2, 3, 5, and 6.

Data Types: `single | double`

`positionVector` — Normalized position for new axes

four-element vector of values between 0.0 and 1.0

Normalized position for the new axes, specified as a four-element vector of values between 0.0 and 1.0 with the form `[left,bottom,width,height]`. The values are normalized with respect to the interior of the figure. The first two elements specify the position of the bottom-left corner of the axes in relation to the bottom-left corner of the figure. The last two elements specify the width and height of the new axes. Use this syntax to position an axes that does not align with grid positions.

Example: [0.1, 0.1, 0.35, 0.35]

Data Types: `single | double`

`ax` — Existing axes to convert to subplot

axes object

Existing axes to convert to a subplot axes, specified as an axes object. Use `gca` to refer to the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

You can set any axes properties for a subplot. Some plotting functions override existing axes property settings. Execute plotting functions before specifying axes properties to avoid overriding them. For a list of axes properties see Axes Properties.

Example: `'XGrid','on'`

Output Arguments

h — Axes object

scalar

Axes object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific axes.

More About

Tips

- `subplot(111)` is an exception and not identical in behavior to `subplot(1,1,1)`. For reasons of backwards compatibility, `subplot(111)` is a special case of subplot that does not immediately create an axes, but sets up the figure so that the next graphics command executes `clf reset`. The next graphics command deletes all the figure children and creates a new axes in the default position. `subplot(111)` does not return a handle and an error occurs if code specifies a return argument.
- If a new subplot axes overlaps an existing axes, then MATLAB deletes the existing axes. To overlay a new axes on top of existing subplots, use the `axes` command. For example, `subplot('Position',[.35 .35 .3 .3])` deletes any underlying subplots, but `axes('Position',[.35 .35 .3 .3])` positions a new axes in the middle of the figure without deleting any underlying axes.
- When using a script to create subplots, MATLAB does not finalize the `Position` property value until either a `drawnow` command is issued or MATLAB returns to await a user command. The `Position` property value for a subplot is subject to change until the script either refreshes the plot or exits.

subsasgn

Subscripted assignment

Syntax

```
A = subsasgn(A, S, B)
```

Description

`A = subsasgn(A, S, B)` is called by MATLAB for the syntax `A(i) = B`, `A{i} = B`, or `A.i = B` when `A` is an object.

MATLAB uses the built-in `subsasgn` function to interpret indexed assignment statements. Modify the indexed assignment behavior of classes by overloading `subsasgn` in the class.

If `A` is a fundamental class (see "Fundamental MATLAB Classes"), then an indexed reference to `A` calls the built-in `subsasgn` function. It does not call a `subsasgn` method that you have overloaded for that class. Therefore, if `A` is an array of class `double`, and there is an `@double/subsasgn` method on your MATLAB path, the statement `A(I) = B` calls the MATLAB built-in `subsasgn` function.

Input Arguments

A

Object

Default:

S

`struct` array with two fields, `type` and `subs`.

- `type` is a string containing `'()'`, `'{}'`, or `'.'`, where `'()'` specifies integer subscripts, `'{}'` specifies cell array subscripts, and `'.'` specifies subscripted structure fields.

- `subs` is a cell array or string containing the actual subscripts.

Default:

`B`

Assignment value (right-hand side)

Default:

Output Arguments

`A`

Result of evaluating assignment.

Examples

See how MATLAB calls `subsasgn` for the expression:

```
A(1:2,:) = B;
```

The syntax `A(1:2,:) = B` calls `A = subsasgn(A,S,B)` where `S` is a 1-by-1 structure with `S.type = '()'` and `S.subs = {1:2,':'}`. The string `':'` indicates a colon used as a subscript.

See how MATLAB calls `subsasgn` for the expression:

```
A{1:2} = B;
```

The syntax `A{1:2} = B` calls `A = subsasgn(A,S,B)` where `S.type = '{}'` and `S.subs = {[1 2]}`.

See how MATLAB calls `subsasgn` for the expression:

```
A.field = B;
```

The syntax `A.field = B` calls `A = subsasgn(A,S,B)` where `S.type = '.'` and `S.subs = 'field'`.

See how MATLAB calls `subsasgn` for the expression:

```
A(1,2).name(3:5)=B;
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscripting levels. For instance, `A(1,2).name(3:5)=B` calls `A=subsasgn(A,S,B)` where `S` is a 3-by-1 structure array with the following values:

```
S(1).type = '()'       S(2).type = '.'        S(3).type = '()'
S(1).subs = {1,2}      S(2).subs = 'name'     S(3).subs = {[3 4 5]}
```

More About

Tips

Within a class's own methods, MATLAB calls the built-in `subsasgn`, not the class defined `subsasgn`. This behavior enables to use the default `subsasgn` behavior when defining specialized indexing for your class. See "Built-In subsref and subsasgn Called In Methods" for more information.

Algorithms

In the assignment `A(J,K,...) = B(M,N,...)`, subscripts `J`, `K`, `M`, `N`, and so on, can be scalar, vector, or arrays, when all the following are true:

- The number of subscripts specified for `B`, excluding trailing subscripts equal to 1, does not exceed the value returned by `ndims(B)`.
- The number of nonscalar subscripts specified for `A` equals the number of nonscalar subscripts specified for `B`. For example, `A(5,1:4,1,2) = B(5:8)` is valid because both sides of the equation use one nonscalar subscript.
- The order and length of all nonscalar subscripts specified for `A` matches the order and length of nonscalar subscripts specified for `B`. For example, `A(1:4, 3, 3:9) = B(5:8, 1:7)` is valid because both sides of the equation (ignoring the one scalar subscript `3`) use a 4-element subscript followed by a 7-element subscript.

  See `numel` for information concerning the use of `numel` with regards to the overloaded `subsasgn` function.

  For information on the syntax to use when overloading `subsasgn`, see "Overloading numel, subsref, and subsasgn"

- “Overloading numel, subsref, and subsasgn”

See Also

`subsref` | `substruct`

Introduced before R2006a

subsindex

Subscript indexing with object

Syntax

```
ind = subsindex(A)
```

Description

`ind = subsindex(A)` called by MATLAB for the expression `X(A)` when `A` is an object, unless such an expression results in a call to an overloaded `subsref` or `subsasgn` method for `X`. `subsindex` must return the value of the object as a zero-based integer index. (`ind` must contain integer values in the range `0` to `prod(size(X))-1`.) Call `subsindex` directly from an overloaded `subsref` or `subsasgn` method.

MATLAB invokes `subsindex` separately on all the subscripts in an expression, such as `X(A,B)`.

- “Objects In Index Expressions”

Introduced before R2006a

subspace

Angle between two subspaces

Syntax

```
theta = subspace(A,B)
```

Description

`theta = subspace(A,B)` finds the angle between two subspaces specified by the columns of `A` and `B`. If `A` and `B` are column vectors of unit length, this is the same as `acos(abs(A'*B))`.

Examples

Consider two subspaces of a Hadamard matrix, whose columns are orthogonal.

```
H = hadamard(8);
A = H(:,2:4);
B = H(:,5:8);
```

Note that matrices `A` and `B` are different sizes — `A` has three columns and `B` four. It is not necessary that two subspaces be the same size in order to find the angle between them. Geometrically, this is the angle between two hyperplanes embedded in a higher dimensional space.

```
theta = subspace(A,B)
theta =
    1.5708
```

That `A` and `B` are orthogonal is shown by the fact that `theta` is equal to $\pi/2$.

```
theta - pi/2
ans =
     0
```

More About

Tips

If the angle between the two subspaces is small, the two spaces are nearly linearly dependent. In a physical experiment described by some observations `A`, and a second realization of the experiment described by `B`, `subspace(A,B)` gives a measure of the amount of new information afforded by the second experiment not associated with statistical errors of fluctuations.

Introduced before R2006a

subsref

Redefine subscripted reference for objects

Syntax

```
B = subsref(A,S)
```

Description

`B = subsref(A,S)` is called by MATLAB for the syntax `A(i)`, `A{i}`, or `A.i` when `A` is an object. `S` is a `struct` array with two fields, `type` and `subs`.

The `type` field is string containing `'()'`, `'{}'`, or `'.'`, where `'()'` specifies integer subscripts, `'{}'` specifies cell array subscripts, and `'.'` specifies subscripted structure fields. The subs field is a cell array or a string containing the actual subscripts.

`B` is the result of the indexed expression.

MATLAB uses the built-in `subsref` function to interpret indexed references to objects. To modify the indexed reference behavior of objects, overload `subsref` in the class.

If `A` is a fundamental class (see "Fundamental MATLAB Classes"), then an indexed reference to `A` calls the built-in `subsref` function. It does not call a `subsref` method that you have overloaded for that class. Therefore, if `A` is an array of class `double`, and there is an `@double/subsref` method on your MATLAB path, the statement `A(I)` calls the MATLAB built-in `subsref` function.

Examples

See how MATLAB calls `subsref` for the expression:

```
A(1:2,:)
```

The syntax `A(1:2,:)` calls `B = subsref(A,S)` where `S` is a 1-by-1 structure with `S.type='()'` and `S.subs={1:2,':'}`. The string `':'` indicates a colon used as a subscript.

See how MATLAB calls `subsref` for the expression:

```
A{1:2}
```

The syntax `A{1:2}` calls `B = subsref(A,S)` where `S.type='{}'` and `S.subs={[1 2]}`.

See how MATLAB calls `subsref` for the expression:

```
A.field
```

The syntax `A.field` calls `B = subsref(A,S)` where `S.type='.'` and `S.subs='field'`.

See how MATLAB calls `subsref` for the expression:

```
A(1,2).name(3:5)
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscript levels. For instance, `A(1,2).name(3:5)` calls `subsref(A,S)` where `S` is a 3-by-1 structure array with the following values:

```
S(1).type='()'          S(2).type='.'           S(3).type='()'
S(1).subs={1,2}         S(2).subs='name'        S(3).subs={[3 4 5]}
```

More About

Tips

Within a class's own methods, MATLAB calls the built-in `subsref`, not the class defined `subsref`. This behavior enables to use the default `subsref` behavior when defining specialized indexing for your class. See “Built-In subsref and subsasgn Called In Methods” for more information.

- “Overloading numel, subsref, and subsasgn”

See Also

`numel` | `subsasgn` | `substruct`

Introduced before R2006a

substruct

Create structure argument for `subsasgn` or `subsref`

Syntax

```
S = substruct(type1, subs1, type2, subs2, ...)
```

Description

`S = substruct(type1, subs1, type2, subs2, ...)` creates a structure with the fields required by an overloaded `subsref` or `subsasgn` method. Each `type` string must be one of `'.'`, `'()'`, or `'{}'`. The corresponding `subs` argument must be either a field name (for the `'.'` type) or a cell array containing the index vectors (for the `'()'` or `'{}'` types).

Output Arguments

S

`struct` with these fields:

- `type`: one of `'.'`, `'()'`, or `'{}'`
- `subs`: subscript values (field name or cell array of index vectors)

Examples

Call `subsref` with arguments equivalent to the syntax:

```
B = A(3,5).field;
```

where `A` is an object of a class that implements a `subsref` method

Use `substruct` to form the input `struct`, `S`:

```
S = substruct('()',{3,5},'.','field');
```

Call the class method:

```
B = subsref(A,S);
```

The `struct` created by `substruct` in this example contains:

```
S(1)

ans =

    type: '()'
    subs: {[3]  [5]}

S(2)

ans =

    type: '.'
    subs: 'field'
```

`subsasgn` | `subsref`

Introduced before R2006a

subvolume

Extract subset of volume data set

Syntax

```
[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)
[Nx,Ny,Nz,Nv] = subvolume(V,limits)
Nv = subvolume(...)
```

Description

`[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)` extracts a subset of the volume data set `V` using the specified axis-aligned `limits`. `limits = [xmin,xmax,ymin, ymax,zmin,zmax]` (Any `NaN`s in the limits indicate that the volume should not be cropped along that axis.)

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The subvolume is returned in `NV` and the coordinates of the subvolume are given in `NX`, `NY`, and `NZ`.

`[Nx,Ny,Nz,Nv] = subvolume(V,limits)` assumes the arrays `X`, `Y`, and `Z` are defined as

```
[X,Y,Z] = meshgrid(1:N,1:M,1:P)
```

where `[M,N,P] = size(V)`.

`Nv = subvolume(...)` returns only the subvolume.

Examples

This example uses a data set that is a collection of MRI slices of a human skull. The data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then a subset of the data is extracted (`subvolume`).

- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with interpolated face color draws the end caps (`FaceColor`, `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).
- A 100-element grayscale colormap provides coloring for the end caps (`colormap`).
- Adding lights to the right and left of the camera illuminates the object (`camlight`, `lighting`).

```
load mri
D = squeeze(D);
[x,y,z,D] = subvolume(D,[60,80,nan,80,nan,nan]);
p1 = patch(isosurface(x,y,z,D, 5),...
     'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
     'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight right; camlight left; lighting gouraud
```

Introduced before R2006a

sum

Sum of array elements

Syntax

```
S = sum(A)
S = sum(A,dim)
S = sum( ___ ,outtype)
S = sum( ___ ,nanflag)
```

Description

`S = sum(A)` returns the sum of the elements of A along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `sum(A)` returns the sum of the elements.
- If `A` is a matrix, then `sum(A)` returns a row vector containing the sum of each column.
- If `A` is a multidimensional array, then `sum(A)` operates along the first array dimension whose size does not equal 1, treating the elements as vectors. This dimension becomes `1` while the sizes of all other dimensions remain the same.

`S = sum(A,dim)` returns the sum along dimension `dim`. For example, if `A` is a matrix, then `sum(A,2)` is a column vector containing the sum of each row.

`S = sum( ___ ,outtype)` returns the sum with a specified data type, using any of the input arguments in the previous syntaxes. `outtype` can be `'default'`, `'double'`, or `'native'`.

`S = sum( ___ ,nanflag)` specifies whether to include or omit `NaN` values from the calculation for any of the previous syntaxes. `sum(A,'includenan')` includes all `NaN` values in the calculation while `sum(A,'omitnan')` ignores them.

Examples

Sum of Vector Elements

Create a vector and compute the sum of its elements.

```
A = 1:10;
S = sum(A)

S =

    55
```

Sum of Matrix Columns

Create a matrix and compute the sum of the elements in each column.

```
A = [1 3 2; 4 2 5; 6 1 4]

A =

     1     3     2
     4     2     5
     6     1     4

S = sum(A)

S =

    11     6    11
```

Sum of Matrix Rows

Create a matrix and compute the sum of the elements in each row.

```
A = [1 3 2; 4 2 5; 6 1 4]

A =

     1     3     2
     4     2     5
     6     1     4

S = sum(A,2)
```

```
S =

     6
    11
    11
```

Sum of 3-D Array

Create a 4-by-2-by-3 array of ones and compute the sum along the third dimension.

```
A = ones(4,2,3);
S = sum(A,3)
```

```
S =

     3     3
     3     3
     3     3
     3     3
```

Integer Output Type Saturation

Create a vector of 8-bit integers and compute the `int8` sum of its elements by specifying the output type as `native`.

```
A = int8(1:20);
S = sum(A,'native')
```

```
S =

  127
```

Compute the sum using the default `double` output type (equivalent to `S = sum(A,'default')`).

```
S = sum(A)
```

```
S =
```

```
   210
```

The two sums differ because the `int8` output is saturated while the `double` output reflects the expected sum of elements.

Sum Excluding `NaN`

Create a vector and compute its sum, excluding `NaN` values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
S = sum(A,'omitnan')
```

```
S =

    3.3250
```

If you do not specify `'omitnan'`, then `sum(A)` returns `NaN`.

Input Arguments

`A` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

- If `A` is a scalar, then `sum(A)` returns `A`.
- If `A` is an empty 0-by-0 matrix, then `sum(A)` returns `0`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `duration`
Complex Number Support: Yes

`dim` — Dimension to operate along

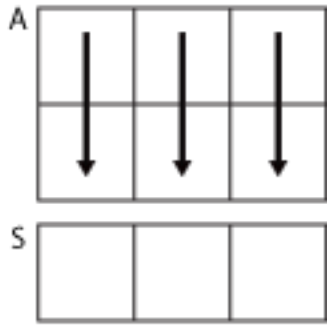
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(S,dim)` is `1`, while the sizes of all other dimensions remain the same.

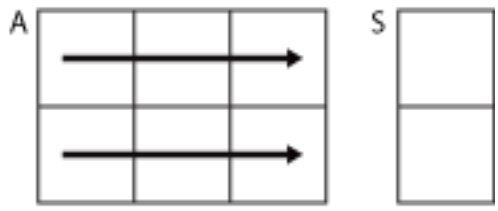
Consider a two-dimensional input array, `A`:

- `sum(A,1)` operates on successive elements in the columns of `A` and returns a row vector of the sums of each column.



sum(A,1)

- `sum(A,2)` operates on successive elements in the rows of `A` and returns a column vector of the sums of each row.



sum(A,2)

`sum` returns `A` when `dim` is greater than `ndims(A)` or when `size(A,dim)` is `1`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`outtype` — Output data type

`'default'` (default) | `'double'` | `'native'`

Output data type, specified as `'default'`, `'double'`, or `'native'`. These options also specify the data type in which the operation is performed.

`outtype`	Output data type
`'default'`	`double`, unless the input data type is `single` or `duration`, in which case, the output is `'native'`
`'double'`	`double`, unless the data type is `duration`, in which case, `'double'` is not supported
`'native'`	same data type as the input, unless the input data type is `char`, in which case, `'native'` is not supported

Data Types: `char`

`nanflag` — `NaN` condition

'`includenan`' (default) | '`omitnan`'

`NaN` condition, specified as one of these values:

- `'includenan'` — Include `NaN` values when computing the sum, resulting in `NaN`.
- `'omitnan'` — Ignore all `NaN` values in the input.

The `sum` function does not support the `nanflag` option for `duration` arrays.

Data Types: `char`

`cumsum` | `diff` | `mean` | `prod`

summary

Print summary of table or categorical array

Syntax

```
summary(T)
```

```
summary(A)
summary(A,dim)
```

Description

`summary(T)` prints a summary of the table, `T`. The table summary displays the table description from `T.Properties.Description` followed by a summary of the table variables.

`summary(A)` prints a summary of the categorical array, `A`.

- If `A` is a vector, then `sumamry(A)` displays the category names along with the number of elements in each category (the category counts). Furthermore, the summary contains the number of elements that are undefined.
- If `A` is a matrix, then `summary` treats the columns of `A` as vectors and displays the category counts for each column of `A`.
- If `A` is a multidimensional array, then `summary` acts along the first array dimension whose size does not equal `1`.

`summary(A,dim)` prints the category counts of the categorical array, `A`, along dimension dim.

For example, you can display the counts of each row in a categorical array using `counts(A,2)`.

Examples

Summary of Table

Create a table.

```
load patients
BloodPressure = [Systolic Diastolic];
T = table(Gender,Age,Smoker,BloodPressure,'RowNames',LastName);
```

Add descriptions and units to table `T`.

```
T.Properties.Description = 'Simulated patient data';
T.Properties.VariableUnits =  {''  'Yrs' ''  'mm Hg'};
T.Properties.VariableDescriptions{4} = 'Systolic/Diastolic';
```

Print a summary of table `T`.

```
format compact

summary(T)
```

```
Description:  Simulated patient data
Variables:
    Gender: 100x1 cell string
    Age: 100x1 double
        Units:  Yrs
        Values:
            min       25
            median    39
            max       50
    Smoker: 100x1 logical
        Values:
            true     34
            false    66
    BloodPressure: 100x2 double
        Units:  mm Hg
        Description:  Systolic/Diastolic
        Values:
                      BloodPressure_1    BloodPressure_2
                      _______________    _______________
            min       109                  68
            median    122                81.5
            max       138                  99
```

`summary` displays the minimum, median, and maximum values for each column of the variable `BloodPressure`.

Summary of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =

     plane      car      train      car      plane
```

A has three categories, `car`, `plane`, and `train`.

Print a summary of A.

```
summary(A)
```

```
     car      plane      train
       2          2          1
```

`car` appears in two elements of A, `plane` appears in two elements, and `train` appears in one element.

Since A is a row vector, `summary` lists the occurrences of each category horizontally.

Summary of Each Column in Categorical Array

Create a 3-by-2 categorical array, A, from a numeric array.

```
X = [1 3; 2 1; 3 1; 4 2];
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical(X,valueset,catnames)
```

```
A =

     red              blue
     green            red
     blue             red
     <undefined>      green
```

A has three categories, `red`, `green`, and `blue`. The value, `4`, was not included in the `valueset` input to the `categorical` function. Therefore, the corresponding element, `A(4,1)`, does not have a corresponding category and is undefined.

Print a summary of A.

```
summary(A)
```

```
     red              1      2
     green            1      1
```

```
blue              1       1
<undefined>       1       0
```

`red` appears in one element in the first column of `A` and two in the second column.

`green` appears in one element in the first column of `A` and none in the second column.

`blue` appears in one element in the first column of `A` and one in the second column.

`A` contains only one undefined element. It occurs in the first column.

Category Counts of Each Row in Categorical Array

Create a 3-by-2 categorical array, `A`, from a numeric array.

```
A = categorical([1 3; 2 1; 3 1],1:3,{'red' 'green' 'blue'})
```

```
A =

     red         blue
     green       red
     blue        red
```

`A` has three categories, `red`, `green`, and `blue`.

Print a summary of `A` along the second dimension.

```
summary(A,2)
```

```
     red       green       blue
       1           0          1
       1           1          0
       1           0          1
```

`red` appears in one element in the first row of `A`, one in the second row, and one in the third row.

`green` appears in only one element. It occurs in the second row of `A`.

`blue` appears in one element in the first row of `A` and one in the third column.

Input Arguments

`T` — Input table

table

Input table, specified as a table.

`A` — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

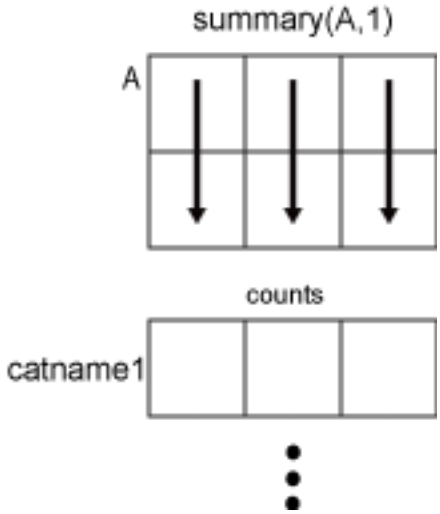
`dim` — Dimension of `A` to operate along

positive integer scalar

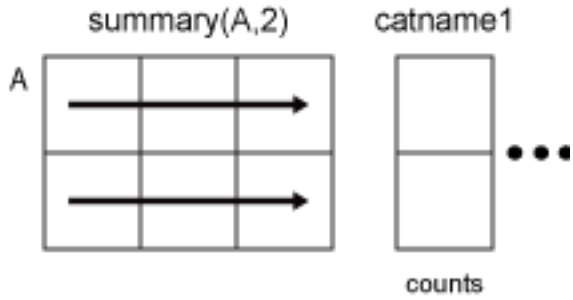
Dimension of `A` to operate to along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional categorical array, `A`:

If `dim = 1`, then `summary(A,1)` displays the category counts for each column of `A`.



If `dim = 2`, then `sumary(A,2)` returns the category counts of each row of `A`.



If `dim` is greater than `ndims(A)`, then`summary(A)` returns an array the same size as `A` for each category. `summary` returns `1` for elements in the corresponding category and `0` otherwise.

More About

Table Summary

The table summary displays the table description from `T.Properties.Description` followed by information on the variables of T.

The summary contains the following information on the variables:

- Name: Size and Data Type — variable name from `T.Properties.VariableNames`, the size of the variable, and the data type of the variable.
- Units — variable's units from `T.Properties.VariableUnits`.
- Description — variable's description from `T.Properties.VariableDescriptions`.
- Values — only included for numeric variables, logical variables, or categorical variables.
  - numeric variables — minimum, median, and maximum values.
  - logical variables — number of values that are `true` and the number of values that are `false`.
  - categorical variables — number of elements from each category.

See Also

`categorical` | `categories` | `countcats` | `table`

superclasses

Superclass names

Syntax

```
superclasses('ClassName')
superclasses(obj)
s = superclasses(...)
```

Description

`superclasses('ClassName')` displays the names of all visible superclasses of the MATLAB class with the name *`ClassName`*. Visible classes have a `Hidden` attribute value of `false` (the default).

`superclasses(obj)` `obj` is an instance of a MATLAB class. `obj` can be either a scalar object or an array of objects.

`s = superclasses(...)` returns the superclass names in a cell array of strings.

Examples

Get the name of the `matlab.mixin.SetGet` class superclass:

```
superclasses('matlab.mixin.SetGet')

Superclasses for class matlab.mixin.SetGet:

    handle
```

See Also

`properties` | `methods` | `events` | `classdef`

superiorto

Establish superior class relationship

Syntax

```
superiorto('class1', 'class2', ...)
```

Description

`superiorto('class1', 'class2', ...)` establishes that the class invoking this function in its constructor has higher precedence than the classes in the argument list.

The `superiorto` function establishes a precedence that determines which object method MATLAB calls. Use this function only from a constructor that calls the `class` function to create an object. For classes defined with `classdef` statements, see "Class Precedence".

Examples

Show function dispatching:

`a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. The constructor method for `class_c` contains the statement `superiorto('class_a')`. Then, either of the following two statements:

```
e = fun(a,c);
e = fun(c,a);
```

invokes `class_c/fun`.

If you call a function with two objects having an unspecified relationship, MATLAB considers the two objects to have equal precedence. In this case, MATLAB calls the left-most object method. So `fun(b,c)` calls `class_b/fun`, while `fun(c,b)` calls `class_c/fun`.

support

Open MathWorks Technical Support Web page

Note: `support` will be removed in a future release.

Syntax

```
support
```

Description

`support` opens the MathWorks Technical Support Web page, http://www.mathworks.com/support, in a Web browser.

This Web page contains resources including

- A search engine, including an option for solutions to common problems
- Information about installation and licensing
- A patch archive for bug fixes you can download
- Other useful resources

Support Package Installer

Install support for third-party hardware or software

Description

Use Support Package Installer to install support packages. The support packages add support for specific third-party hardware or software to specific MathWorks products.

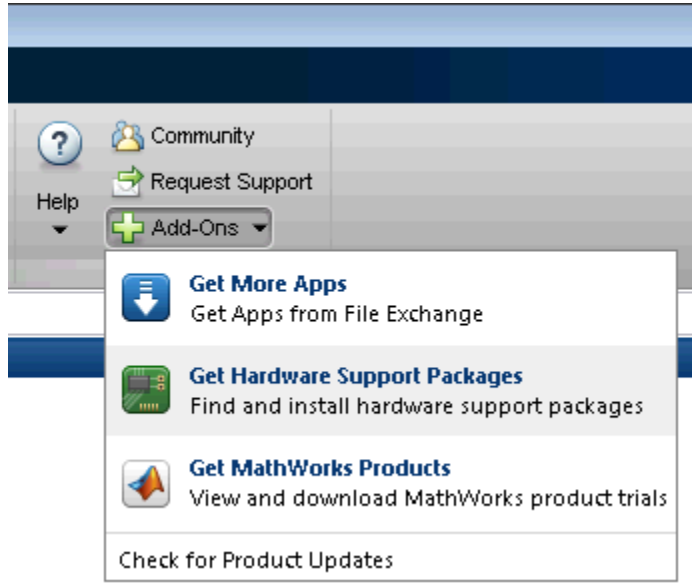
Support Package Installer can:

- Display a list of available, installable, installed, or updatable support packages.
- Install, update, download, or uninstall a support package.
- Update the firmware on specific third-party hardware.

If the support package installs third-party software, Support Package Installer displays a list of the software and licenses for you to review before continuing with the installation.

Open the Support Package Installer App

- On the MATLAB toolstrip, click **Add-Ons > Get Hardware Support Packages**.



- In the MATLAB Command Window, enter `supportPackageInstaller`.
- Double-click a support package installation file (`*.mlpkginstall`).

See Also

Functions

`matlabshared.supportpkg.checkForUpdate` | `matlabshared.supportpkg.getInstalled` | `supportPackageInstaller` | `targetupdater`

supportPackageInstaller

Install support for third-party hardware or software

Syntax

```
supportPackageInstaller
```

Description

The `supportPackageInstaller` function opens *Support Package Installer*.

Use Support Package Installer to install support packages. The support packages add support for specific third-party hardware or software to specific MathWorks products.

Support Package Installer can:

- Display a list of available, installable, installed, or updatable support packages.
- Install, update, download, or uninstall a support package.
- Update the firmware on specific third-party hardware.

If the support package installs third-party software, Support Package Installer displays a list of the software and licenses for you to review before continuing with the installation.

Examples

Use the supportPackageInstaller Function

Enter the function in the MATLAB Command Window:

```
supportPackageInstaller
```

This action starts the Support Package Installer.

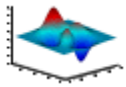
surf

3-D shaded surface plot



Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

Description

`surf(Z)` creates a three-dimensional shaded surface from the *z* components in matrix `Z`, using `x = 1:n` and `y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a geometrically rectangular grid. `Z` specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of `Z`, a single-valued function defined over a geometrically rectangular grid, and uses matrix `C`, assumed to be the same size as `Z`, to color the surface. See Coloring Mesh and Surface Plots for information on defining `C`.

`surf(X,Y,Z)` uses `Z` for the color data and surface height. `X` and `Y` are vectors or matrices defining the `x` and `y` components of a surface. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, the vertices of the surface faces are *(X(j), Y(i), Z(i,j))* triples. To create X and Y matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses `C` to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface properties along with the data. For a list or properties, see Chart Surface Properties.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a chart surface graphics object.

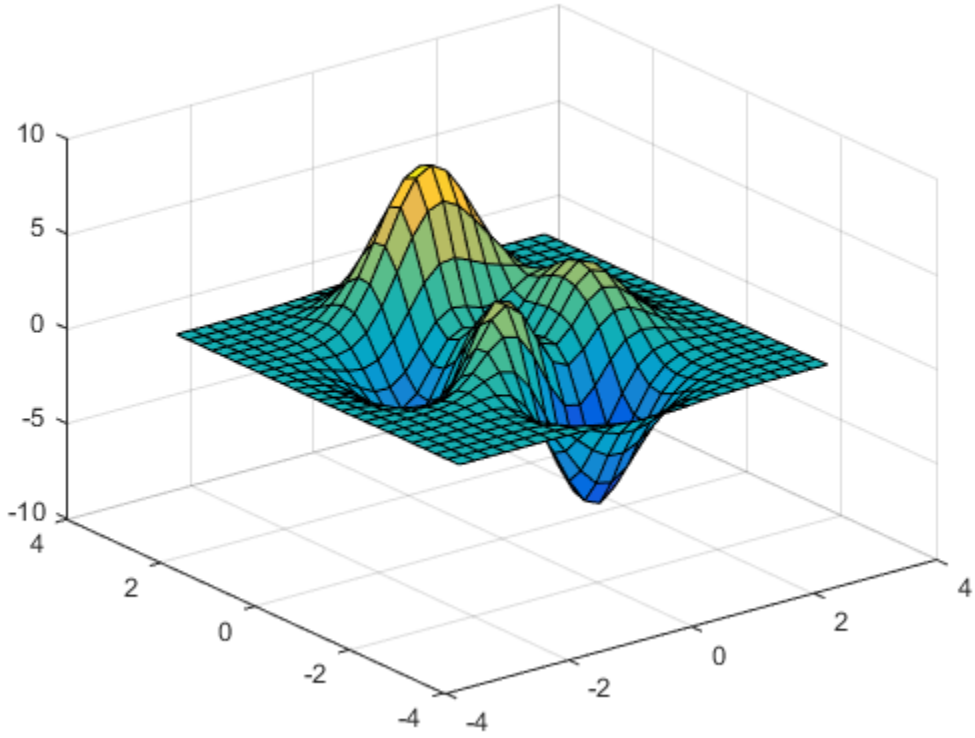
Examples

Surface Plot of Peaks Function

Use the `peaks` function to define `X`, `Y`, and `Z` as 25-by-25 matrices. Then, create a surface plot.

```
[X,Y,Z] = peaks(25);

figure
surf(X,Y,Z);
```



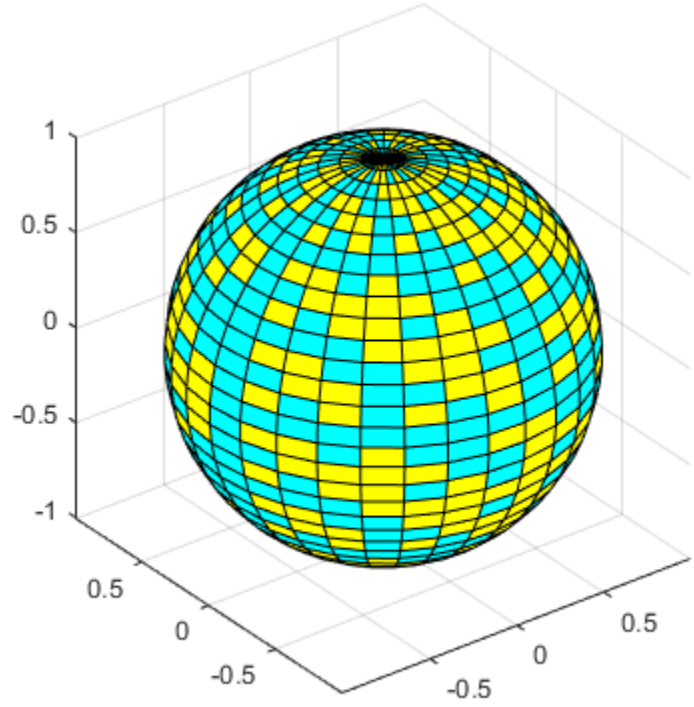
`surf` creates the surface plot from corresponding values in `X`, `Y`, and `Z`. If you do not define the color data `C`, then `surf` uses `Z` to determine the color, so color is proportional to surface height.

Sphere With Two Colors

Create a sphere and color it using the pattern from a Hadamard matrix, which is a matrix that contains the values `1` and `-1`. Change the colors used in the plot by setting the colormap to an array of two RGB triplet values.

```
k = 5;
n = 2^k-1;
[x,y,z] = sphere(n);
c = hadamard(2^k);
```

```
figure
surf(x,y,z,c);
colormap([1  1  0; 0  1  1])
axis equal
```



More About

Tips

`surf` does not accept complex inputs.

Algorithms

Consider a parametric surface parameterized by two independent variables, `i` and `j`, which vary continuously over a rectangle; for example, $1 \le i \le m$ and $1 \le j \le n$. The three functions `x(i,j)`, `y(i,j)`, and `z(i,j)` specify the surface. When `i` and `j` are integer values, they define a rectangular grid with integer grid points. The functions `x(i,j)`, `y(i,j)`, and `z(i,j)` become three `m`-by-`n` matrices, `X`, `Y`, and `Z`. Surface color is a fourth function, `c(i,j)`, denoted by matrix `C`.

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

```
       i-1,j
         |
i,j-1 - i,j - i,j+1
         |
       i+1,j
```

This underlying rectangular grid induces four-sided patches on the surface. To express this another way, `[X(:) Y(:) Z(:)]` returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of `x` and `y`. Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The `shading` function sets the shading. If the shading is `interp`, `C` must be the same size as `X`, `Y`, and `Z`; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local coordinates. If the shading is `faceted` (the default) or `flat`, `C(i,j)` specifies the constant color in the surface patch:

```
 (i,j)   -   (i,j+1)
   |   C(i,j)  |
(i+1,j)  -  (i+1,j+1)
```

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of `XLimMode`, `YLimMode`, and `ZLimMode` axes properties determines the axis labels. You can also set these properties using `axis` function.

The range of `C` or the current setting of the `CLim` and `CLimMode` axes properties determines the color scaling. You can also set the properties using `caxis` function. The scaled color values are indices into the current colormap.

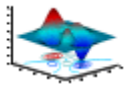
surfc

Contour plot under a 3-D shaded surface plot



Syntax

```
surfc(Z)
surfc(Z,C)
surfc(X,Y,Z)
surfc(X,Y,Z,C)
surfc(...,'PropertyName',PropertyValue)
surfc(axes_handles,...)
h = surfc(...)
```

Description

`surfc(Z)` creates a contour plot under the three-dimensional shaded surface from the *z* components in matrix `Z`, using `x = 1:n` and `y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a geometrically rectangular grid. `Z` specifies the color data, as well as surface height, so color is proportional to surface height.

`surfc(Z,C)` plots the height of `Z`, a single-valued function defined over a geometrically rectangular grid, and uses matrix `C`, assumed to be the same size as `Z`, to color the surface.

`surfc(X,Y,Z)` uses `Z` for the color data and surface height. `X` and `Y` are vectors or matrices defining the `x` and `y` components of a surface. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, the vertices of the surface faces are *(X(j), Y(i), Z(i,j))* triples. To create X and Y matrices for arbitrary domains, use the `meshgrid` function.

`surfc(X,Y,Z,C)` uses `C` to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surfc(...,'PropertyName',PropertyValue)` specifies surface properties along with the data.

`surfc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

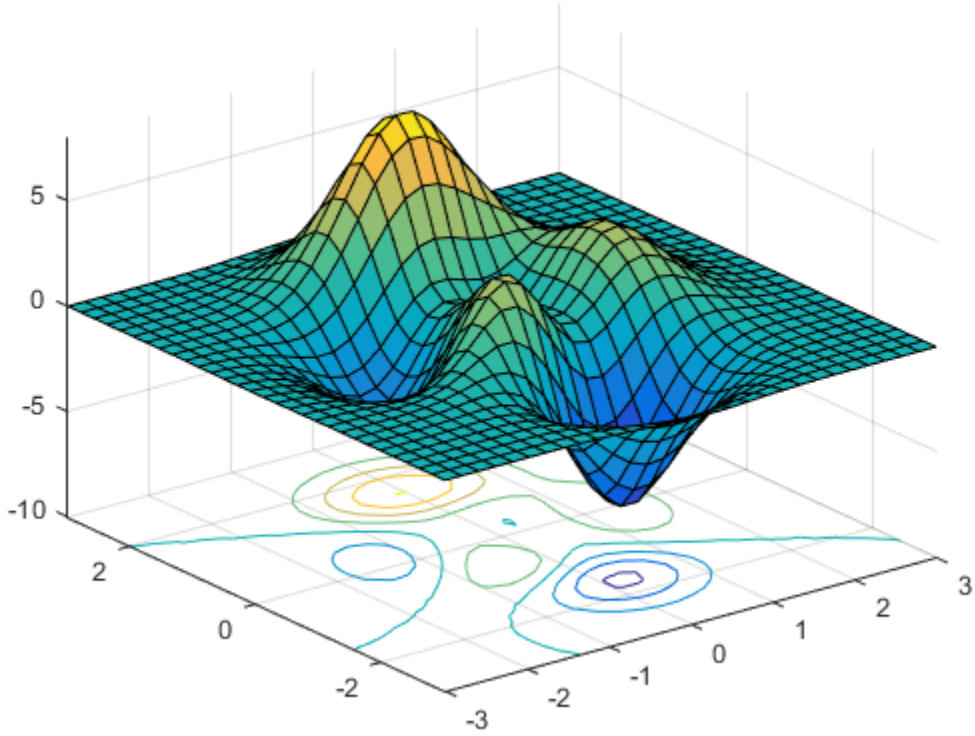
`h = surfc(...)` returns handles to a chart surface and a contour object.

Examples

Display Contour Plot Under Surface Plot

Display a contour plot under a surface plot of the `peaks` function.

```
[X,Y,Z] = peaks(30);
figure
surfc(X,Y,Z)
```



More About

Tips

`surfc` does not accept complex inputs.

Algorithms

Consider a parametric surface parameterized by two independent variables, `i` and `j`, which vary continuously over a rectangle; for example, $1 \le i \le m$ and $1 \le j \le n$. The three functions `x(i,j)`, `y(i,j)`, and `z(i,j)` specify the surface. When `i` and `j` are integer

values, they define a rectangular grid with integer grid points. The functions `x(i,j)`, `y(i,j)`, and `z(i,j)` become three `m`-by-`n` matrices, `X`, `Y`, and `Z`. Surface color is a fourth function, `c(i,j)`, denoted by matrix `C`.

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

```
       i-1,j
         |
i,j-1 - i,j - i,j+1
         |
       i+1,j
```

This underlying rectangular grid induces four-sided patches on the surface. To express this another way, `[X(:) Y(:) Z(:)]` returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of `x` and `y`. Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The `shading` function sets the shading. If the shading is `interp`, `C` must be the same size as `X`, `Y`, and `Z`; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local coordinates. If the shading is `faceted` (the default) or `flat`, `C(i,j)` specifies the constant color in the surface patch:

```
 (i,j)   -   (i,j+1)
   |   C(i,j)  |
(i+1,j)  -  (i+1,j+1)
```

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surfc` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties (also set by the `axis` function) determines the axis labels.

The range of `C` or the current setting of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function) determines the color scaling. The scaled color values are used as indices into the current colormap.

Properties

Chart Surface Properties | Contour Properties

Introduced before R2006a

surf2patch

Convert surface data to patch data

Syntax

```
fvc = surf2patch(Z)
fvc = surf2patch(Z,C)
fvc = surf2patch(X,Y,Z)
fvc = surf2patch(X,Y,Z,C)
fvc = surf2patch(...,'triangles')
[f,v,c] = surf2patch(...)
```

Description

```
fvc = surf2patch(h)
```

converts the geometry and color data from the `surface` object identified by the handle `h` into patch format and returns the face, vertex, and color data in the struct `fvc`. You can pass this struct directly to the `patch` command.

`fvc = surf2patch(Z)` calculates the patch data from the surface's `ZData` matrix `Z`.

`fvc = surf2patch(Z,C)` calculates the patch data from the surface's `ZData` and `CData` matrices `Z` and `C`.

`fvc = surf2patch(X,Y,Z)` calculates the patch data from the surface's `XData`, `YData`, and `ZData` matrices `X`, `Y`, and `Z`.

`fvc = surf2patch(X,Y,Z,C)` calculates the patch data from the surface's `XData`, `YData`, `ZData`, and `CData` matrices `X`, `Y`, `Z`, and `C`.

`fvc = surf2patch(...,'triangles')` creates triangular faces instead of the quadrilaterals that compose surfaces.

`[f,v,c] = surf2patch(...)` returns the face, vertex, and color data in the three arrays `f`, `v`, and `c` instead of a struct.

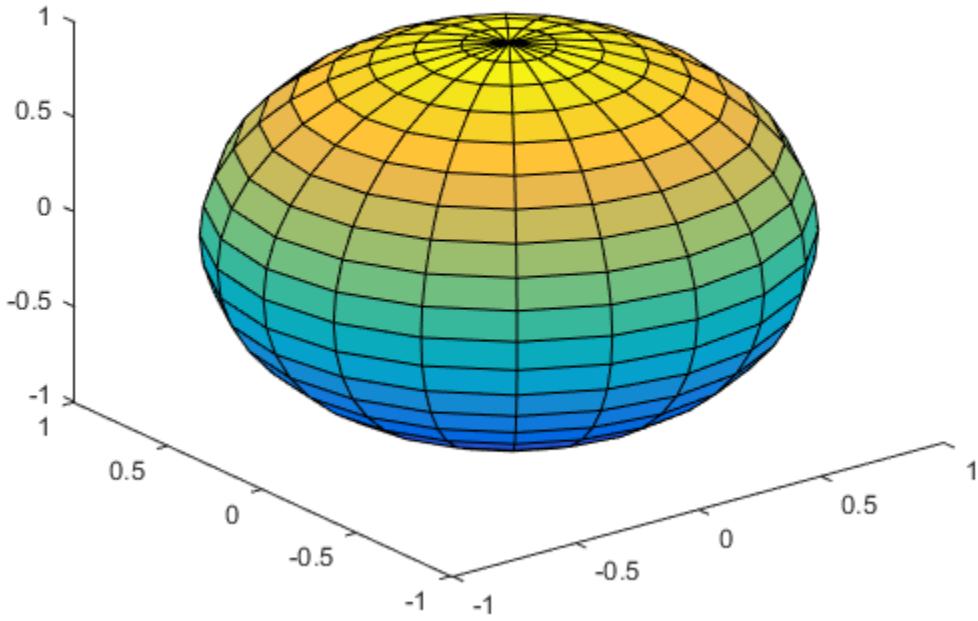
Examples

Calculate Patch Data from Surface Data

Use the `sphere` command to generate the `XData`, `YData`, and `ZData` of a surface. Then, calculate the patch data. Pass the `ZData` (`z`) to `surf2patch` as both the third and fourth arguments - the third argument is the `ZData` and the fourth argument is taken as the `CData`. You must do this since the `patch` command does not automatically use the z-coordinate data for the color data, as does the surface command.

Since patch is a low-level command, you must set the view and shading to produce the same results produced by the `surf` command.

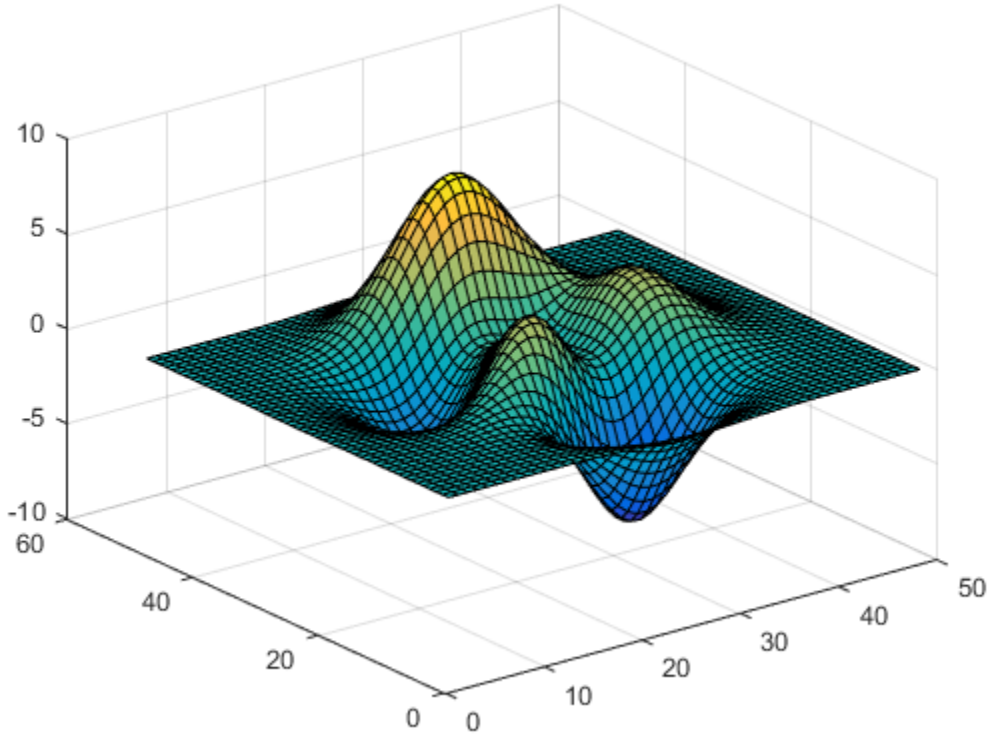
```
[x,y,z] = sphere;
figure
patch(surf2patch(x,y,z,z));
shading faceted;
view(3)
```



Calculate Patch Data Using Surface Object

Calculate face, vertex, and color data from a surface whose handle has been passed as an argument.

```
figure
s = surf(peaks);
patch(surf2patch(s));
delete(s)
shading faceted;
view(3)
```



See Also

`patch` | `reducepatch` | `shrinkfaces` | `surface` | `surf`

surface

Create surface object

Syntax

```
surface(Z)
surface(Z,C)
surface(X,Y,Z)
surface(X,Y,Z,C)
surface(x,y,Z)
surface(...'PropertyName',PropertyValue,...)
h = surface(...)
```

Properties

For a list of properties, see Primitive Surface Properties.

Description

`surface` is the low-level function for creating surface graphics objects. Surfaces are plots of matrix data created using the row and column indices of each element as the *x*- and *y*-coordinates and the value of each element as the *z*-coordinate.

`surface(Z)` plots the surface specified by the matrix `Z`. Here, `Z` is a single-valued function, defined over a geometrically rectangular grid.

`surface(Z,C)` plots the surface specified by `Z` and colors it according to the data in `C` (see "Examples").

`surface(X,Y,Z)` uses `C = Z`, so color is proportional to surface height above the *x*-*y* plane.

`surface(X,Y,Z,C)` plots the parametric surface specified by `X`, `Y`, and `Z`, with color specified by `C`.

`surface(x,y,Z)`, surface(x,y,Z,C) replaces the first two matrix arguments with vectors and must have `length(x) = n` and `length(y) = m` where `[m,n] = size(Z)`. In this case, the vertices of the surface facets are the triples `(x(j),y(i),Z(i,j))`. Note that `x` corresponds to the columns of `Z` and `y` corresponds to the rows of `Z`. For a complete discussion of parametric surfaces, see the `surf` function.

`surface(...'PropertyName',PropertyValue,...)` follows the `X`, `Y`, `Z`, and `C` arguments with property name/property value pairs to specify additional surface properties. For a description of the properties, see Primitive Surface Properties.

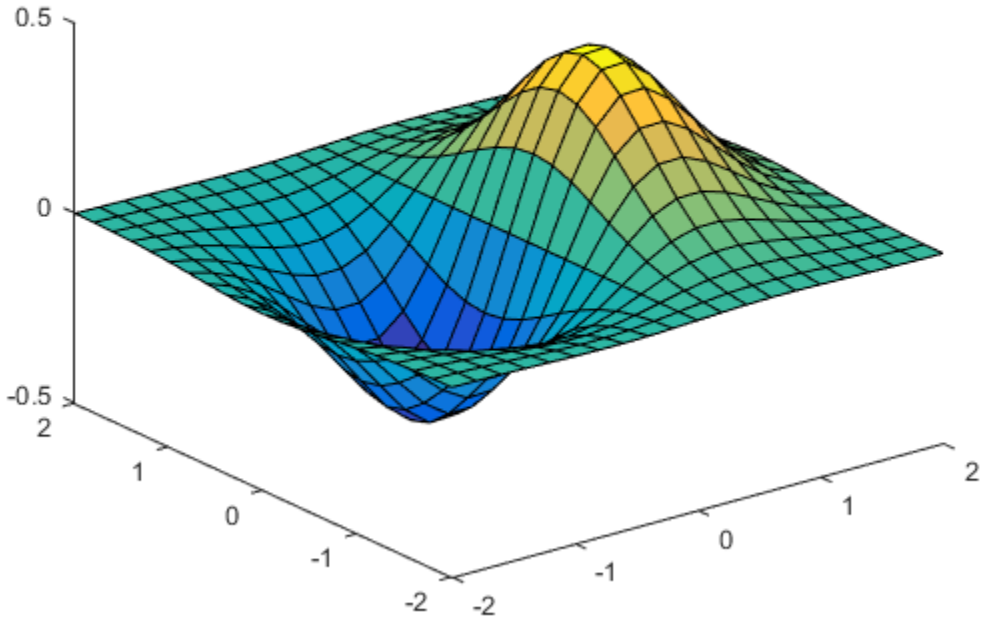
`h = surface(...)` returns a handle to the created primitive surface object.

Examples

Create Surface Plot

Plot the function $z = xe^{-x^2-y^2}$ on the domain $-2 \le x \le 2$ and $-2 \le y \le 2$. Use `meshgrid` to define `X` and `Y`. Then, define `Z` and create a surface plot. Change the view of the plot using `view`.

```
[X,Y] = meshgrid(-2:0.2:2,-2:0.2:2);
Z = X.*exp(-X.^2 - Y.^2);
figure
surface(X,Y,Z)
view(3)
```



`surface` creates the plot from corresponding values in `X`, `Y`, and `Z`. If you do not define the color data `C`, then `surface` uses `Z` to determine the color, so color is proportional to surface height.

Display Image Along Surface Plot

Use the `peaks` function to define `XD`, `YD`, and `ZD` as 25-by-25 matrices.

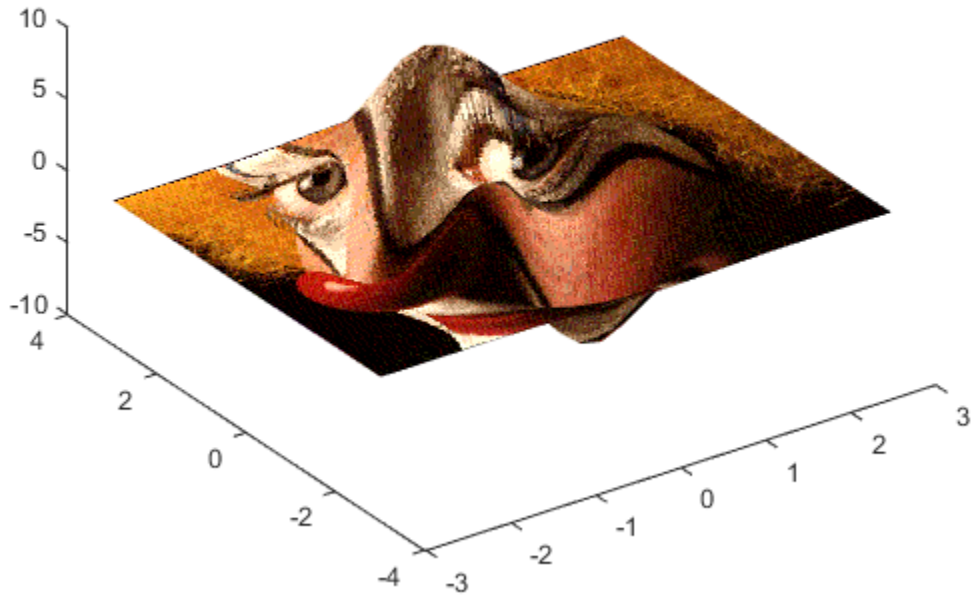
```
[XD,YD,ZD] = peaks(25);
```

Load the `clown` data set to get the image data `X` and its associated colormap, `map`. Flip `X` using the `flipud` function and define the flipped image as the color data for the surface, `C`.

```
load clown
C = flipud(X);
```

Create a surface plot and display the image along the surface. Since the surface data `ZD` and the color data `C` have different dimensions, you must set the surface `FaceColor` to `'texturemap'`.

```
figure
surface(XD,YD,ZD,C,...
    'FaceColor','texturemap',...
    'EdgeColor','none',...
    'CDataMapping','direct')
colormap(map)
view(-35,45)
```



The clown data is typically viewed with the `image` function, which uses `'ij'` axis numbering. This example reverses the image data in the vertical direction using `flipud`.

Tutorials

For examples, see Representing a Matrix as a Surface.

More About

Tips

`surface` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds the surface object to the current axes.

If you do not specify separate color data (`C`), MATLAB uses the matrix (`Z`) to determine the coloring of the surface. In this case, color is proportional to values of `Z`. You can specify a separate matrix to color the surface independently of the data defining the area of the surface.

You can specify properties as property name/property value pairs or using dot notation.

`surface` provides convenience forms that allow you to omit the property name for the `XData`, `YData`, `ZData`, and `CData` properties. For example,

```
surface('XData',X,'YData',Y,'ZData',Z,'CData',C)
```

is equivalent to

```
surface(X,Y,Z,C)
```

When you specify only a single matrix input argument,

```
surface(Z)
```

MATLAB assigns the data properties as if you specified

```
surface('XData',[1:size(Z,2)],...
   'YData',[1:size(Z,1)],...
   'ZData',Z,...
   'CData',Z)
```

The `axis`, `caxis`, `colormap`, `hold`, `shading`, and `view` commands set graphics properties that affect surfaces. You can also set and query surface property values after creating them using dot notation.

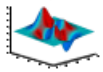
Primitive Surface Properties

Introduced before R2006a

surfl

Surface plot with colormap-based lighting



Syntax

```
surfl(Z)
surfl(...,'light')
surfl(...,s)
surfl(X,Y,Z,s,k)
h = surfl(...)
```

Description

The surfl function displays a shaded surface based on a combination of ambient, diffuse, and specular lighting models.

`surfl(Z)` and `surfl(X,Y,Z)` create three-dimensional shaded surfaces using the default direction for the light source and the default lighting coefficients for the shading model. `X`, `Y`, and `Z` are vectors or matrices that define the *x*, *y*, and *z* components of a surface.

`surfl(...,'light')` produces a colored, lighted surface using a MATLAB light object. This produces results different from the default lighting method, `surfl(...,'cdata')`, which changes the color data for the surface to be the reflectance of the surface.

`surfl(...,s)` specifies the direction of the light source. `s` is a two- or three-element vector that specifies the direction from a surface to a light source. `s = [sx sy sz]` or `s = [azimuth elevation]`. The default `s` is 45° counterclockwise from the current view direction.

`surfl(X,Y,Z,s,k)` specifies the reflectance constant. `k` is a four-element vector defining the relative contributions of ambient light, diffuse reflection, specular reflection, and the specular shine coefficient. `k = [ka kd ks shine]` and defaults to `[.55,.6,.4,10]`.

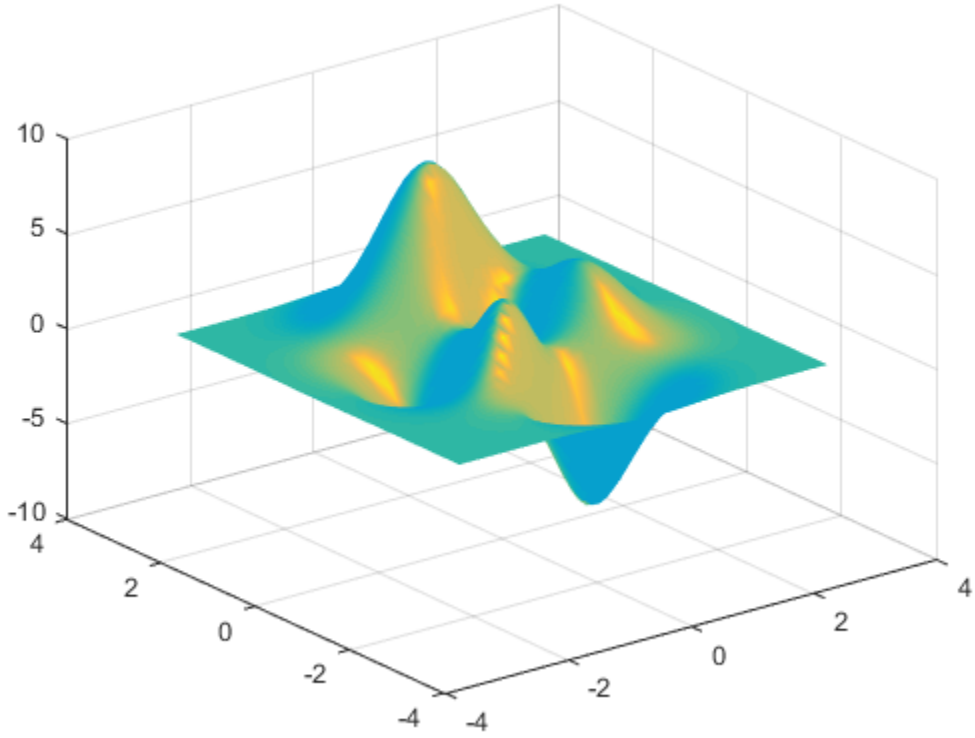
`h = surfl(...)` returns a handle to a surface graphics object. If you specify the `'light'` option, `h` contains the handle to the surface and the light objects.

Examples

Create Surface Plot With Colormap-Based Lighting

Create a surface plot of the `peaks` function using colormap-based lighting. Set the `shading` to `interp` to interpolate the colors across lines and faces.

```
[x,y] = meshgrid(-3:1/8:3);
z = peaks(x,y);
surfl(x,y,z)
shading interp
```



More About

Tips

`surfl` does not accept complex inputs.

For smoother color transitions, use colormaps that have linear intensity variations (e.g., `gray`, `copper`, `bone`, `pink`).

The ordering of points in the `X`, `Y`, and `Z` matrices defines the inside and outside of parametric surfaces. If you want the opposite side of the surface to reflect the light

source, use `surfl(X',Y',Z')`. Because of the way surface normal vectors are computed, `surfl` requires matrices that are at least 3-by-3.

`colormap` | `light` | `shading`

Introduced before R2006a

surfnorm

Compute and display 3-D surface normals

Syntax

```
surfnorm(Z)
surfnorm(X,Y,Z)
surfnorm(axes_handle, ___ )
surfnorm( ___ ,Name,Value)
[Nx,Ny,Nz] = surfnorm( ___ )
```

Description

`surfnorm(Z)` plots a surface of the matrix Z with `surf` and displays its surface normals as radiating vectors.

`surfnorm(X,Y,Z)` plots a surface and its surface normals from the vectors or matrices X, Y, and matrix Z. `X`, `Y`, and `Z` must be the same size.

`surfnorm(axes_handle, ___ )` plots into `axes_handle` instead of `gca` and it can include any of the input arguments in previous syntaxes.

`surfnorm( ___ ,Name,Value)` can be used to set the value of the specified Chart Surface Properties properties.

`[Nx,Ny,Nz] = surfnorm( ___ )` returns the components of the 3-D surface normals for the surface without plotting the surface or surface normals.

Input Arguments

Z

2–D array of real numbers representing a surface

Default:

`X`

2–D array of real numbers that defines the *x* component of the surface grid

`Y`

2–D array of real numbers that defines the *y* component of the surface grid

`axes_handle`

Handle to the target axes in which to plot the surface

If you do not specify `axes_handle`, MATLAB uses current axes.

`Name,Value`

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Property names and values of the surface object

See Chart Surface Properties for description of property names and values.

Output Arguments

`[Nx,Ny,Nz]`

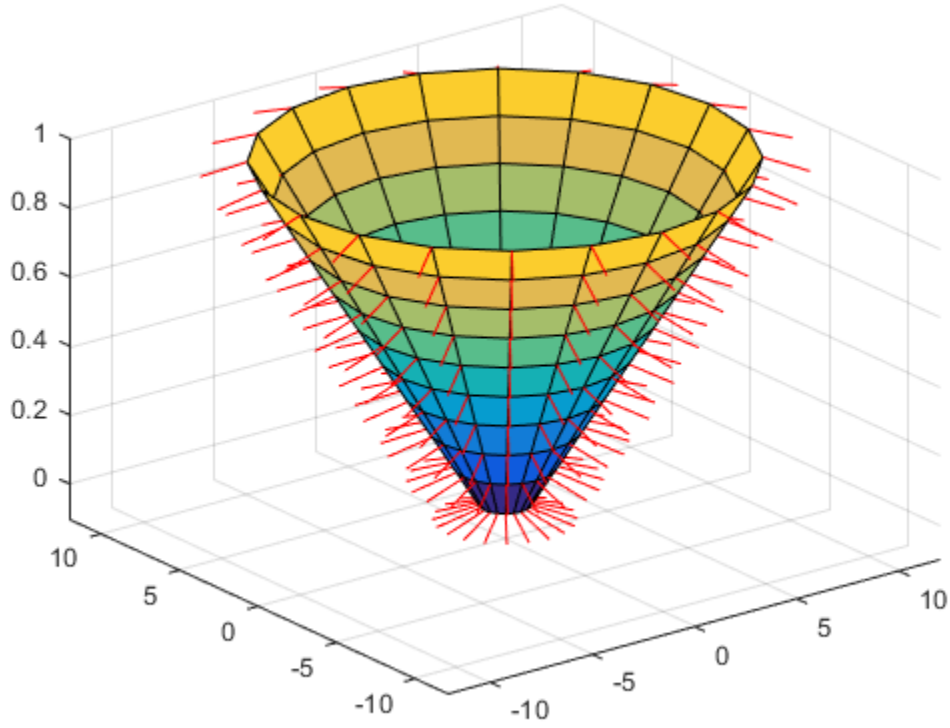
x, *y*, and *z* components of the three-dimensional surface normals for the surface

Examples

Display 3-D Surface Normals for Cone Plot

Compute and plot the normal vectors for a truncated cone. Set the axis limits using the `axis` function.

```
[x,y,z] = cylinder(1:10);
figure
surfnorm(x,y,z)
axis([-12 12 -12 12 -0.1 1])
```



Use Computed Surface Normals for Lighting

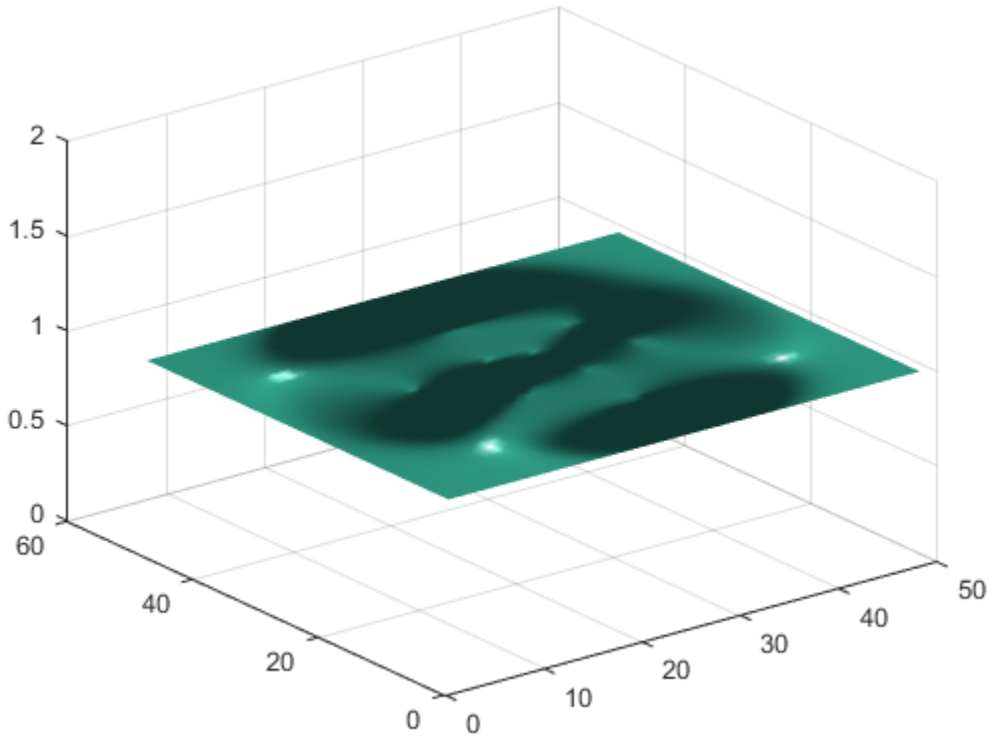
Compute the normal vectors of an expression representing a surface.

```
[nx, ny, nz] = surfnorm(peaks);
```

Assign these normals to the `VertexNormals` property which MATLAB® uses to calculate the surface lighting. Set the lighting algorithm to `gouraud` and add a light using `camlight`.

```
b = reshape([nx ny nz], 49,49,3);
figure
surf(ones(49),'VertexNormals',b,'EdgeColor','none');
lighting gouraud
```

```
camlight
```



More About

Surface Normal

An imaginary line perpendicular to a flat surface or perpendicular to the tangent plane at a point on a non-flat surface

Tips

- `surfnorm` does not accept complex inputs.

- Reverse the direction of the normals by calling `surfnorm` with transposed arguments:

  ```
  surfnorm(X',Y',Z')
  ```
- The surface normals represent conditions at vertices and are not normalized. Normals for surface elements that face away from the viewer do not display.
- `surfl` uses `surfnorm` to compute surface normals when calculating the reflectance of a surface.

Algorithms

After performing a bicubic fit of the data in the *x*, *y*, and *z* directions, diagonal vectors are computed and crossed to form the normal at each vertex.

Introduced before R2006a

svd

Singular value decomposition

Syntax

```
s = svd(X)
[U,S,V] = svd(X)
[U,S,V] = svd(X,0)
[U,S,V] = svd(X,'econ')
```

Description

The `svd` command computes the matrix singular value decomposition.

`s = svd(X)` returns a vector of singular values.

`[U,S,V] = svd(X)` produces a diagonal matrix `S` of the same dimension as `X`, with nonnegative diagonal elements in decreasing order, and unitary matrices `U` and `V` so that `X = U*S*V'`.

`[U,S,V] = svd(X,0)` produces the "economy size" decomposition. If `X` is m-by-n with m > n, then `svd` computes only the first `n` columns of `U` and `S` is n-by-n.

`[U,S,V] = svd(X,'econ')` also produces the "economy size" decomposition. If `X` is m-by-n with m >= n, it is equivalent to `svd(X,0)`. For m < n, only the first m columns of `V` are computed and `S` is m-by-m.

Examples

For the matrix

```
X =
     1     2
     3     4
     5     6
     7     8
```

the statement

```
[U,S,V] = svd(X)
```

produces

```
U =
    -0.1525   -0.8226   -0.3945   -0.3800
    -0.3499   -0.4214    0.2428    0.8007
    -0.5474   -0.0201    0.6979   -0.4614
    -0.7448    0.3812   -0.5462    0.0407

S =
     14.2691         0
           0    0.6268
           0         0
           0         0

V =
    -0.6414    0.7672
    -0.7672   -0.6414
```

The economy size decomposition generated by

```
[U,S,V] = svd(X,0)
```

produces

```
U =
    -0.1525   -0.8226
    -0.3499   -0.4214
    -0.5474   -0.0201
    -0.7448    0.3812
S =
    14.2691         0
          0    0.6268
V =
    -0.6414    0.7672
    -0.7672   -0.6414
```

Diagnostics

If the limit of 75 QR step iterations is exhausted while seeking a singular value, this message appears:

```
Solution will not converge.
```

Introduced before R2006a

svds

Find singular values and vectors

Syntax

```
s = svds(A)
s = svds(A,k)
s = svds(A,k,sigma)
s = svds(A,k,'L')
s = svds(A,k,sigma,options)
[U,S,V] = svds(A,...)
[U,S,V,flag] = svds(A,...)
```

Description

`s = svds(A)` computes the six largest singular values and associated singular vectors of matrix `A`. If `A` is `m`-by-`n`, `svds(A)` manipulates eigenvalues and vectors returned by `eigs(B)`, where `B = [sparse(m,m) A; A' sparse(n,n)]`, to find a few singular values and vectors of `A`. The positive eigenvalues of the symmetric matrix `B` are the same as the singular values of `A`.

`s = svds(A,k)` computes the `k` largest singular values and associated singular vectors of matrix `A`.

`s = svds(A,k,sigma)` computes the `k` singular values closest to the scalar shift sigma. For example, `s = svds(A,k,0)` computes the `k` smallest singular values and associated singular vectors.

`s = svds(A,k,'L')` computes the `k` largest singular values (the default).

`s = svds(A,k,sigma,options)` sets some parameters (see `eigs`):

Option Structure Fields and Descriptions

Field name	Parameter	Default
`options.tol`	Convergence tolerance: `norm(AV-US,1)<=tol*norm(A,1)`	`1e-10`

Field name	Parameter	Default
`options.maxit`	Maximum number of iterations	300
`options.disp`	Number of values displayed each iteration	0

`svds` checks the accuracy of the computed singular vectors. If the vectors are not accurate enough, then `svds` returns fewer singular values than requested. To obtain the requested number of singular values, try decreasing the error tolerance in the options structure.

`[U,S,V] = svds(A,...)` returns three output arguments, and if `A` is `m`-by-`n`:

- `U` is `m`-by-`k` with orthonormal columns
- `S` is `k`-by-`k` diagonal
- `V` is `n`-by-`k` with orthonormal columns
- `U*S*V'` is the closest rank `k` approximation to `A`

`[U,S,V,flag] = svds(A,...)` returns a convergence flag. If `eigs` converged, then `norm(A*V-U*S,1) <= tol*norm(A,1)` and `flag` is `0`. If `eigs` did not converge, then `flag` is `1`.

Note `svds` is best used to find a few singular values of a large, sparse matrix. To find all the singular values of such a matrix, `svd(full(A))` will usually perform better than `svds(A,min(size(A)))`.

Examples

Singular Values of Sparse Matrix

`west0479` is a real 479-by-479 sparse matrix. `svd` calculates all 479 singular values. `svds` picks out only the largest and smallest singular values.

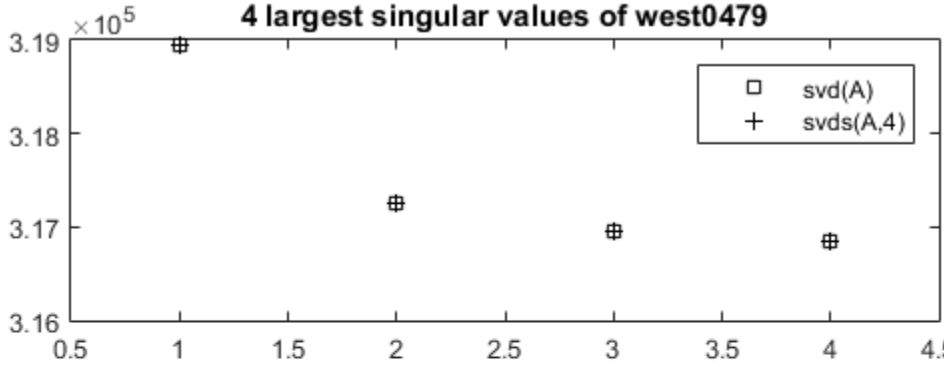
```
load west0479
s = svd(full(west0479));
sl = svds(west0479,4);
ss = svds(west0479,6,0);
```

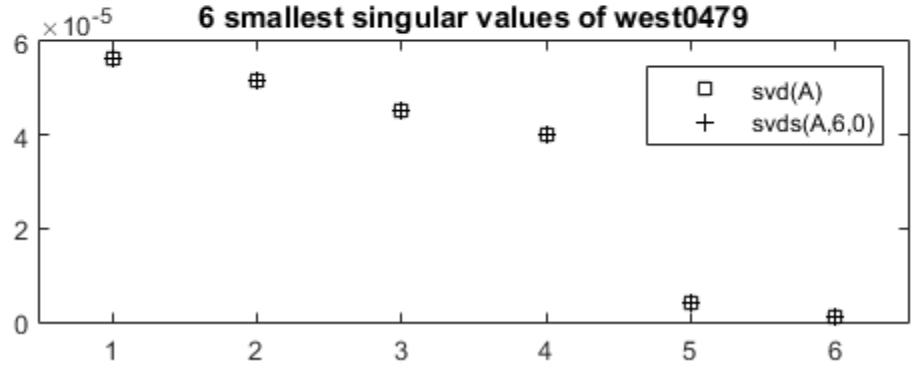
```
Warning: NORMEST did not converge for 100 iterations with tolerance 1e-06
```

These plots show some of the singular values of west0479 as computed by `svd` and `svds`.

```
subplot(2,1,1)
plot(s(1:4),'ks')
hold on
plot(sl,'k+')
hold off
title('4 largest singular values of west0479')
legend('svd(A)','svds(A,4)')
xlim([0.5 4.5])

subplot(2,1,2)
plot(s(end-5:end),'ks')
hold on
plot(ss,'k+')
hold off
title('6 smallest singular values of west0479')
legend('svd(A)','svds(A,6,0)')
xlim([0.5 6.5])
```





The largest singular value of `west0479` can be computed a few different ways:

```
svds(west0479,1)
max(svd(full(west0479)))
norm(full(west0479))
```

```
ans =

   3.1895e+05

ans =
```

```
   3.1895e+05

ans =

   3.1895e+05
```

Or, to estimate the largest singular value:

```
normest(west0479)

Warning: NORMEST did not converge for 100 iterations with tolerance 1e-06

ans =

   3.1854e+05
```

More About

Algorithms

`svds(A,k)` uses `eigs` to find the `k` largest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`.

`svds(A,k,0)` uses `eigs` to find the `2k` smallest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`, and then selects the `k` positive eigenvalues and their eigenvectors.

See Also

`svd` | `eigs`

Introduced before R2006a

swapbytes

Swap byte ordering

Syntax

```
Y = swapbytes(X)
```

Description

`Y = swapbytes(X)` reverses the byte ordering of each element in array `X`, converting little-endian values to big-endian (and vice versa). The input array must contain all full, noncomplex, numeric elements.

Examples

Example 1

Reverse the byte order for a scalar 32-bit value, changing hexadecimal `12345678` to `78563412`:

```
A = uint32(hex2dec('12345678'));

B = dec2hex(swapbytes(A))
B =
    78563412
```

Example 2

Reverse the byte order for each element of a 1-by-4 matrix:

```
X = uint16([0 1 128 65535])
X =
      0      1    128  65535
```

```
Y = swapbytes(X);
Y =
      0    256  32768  65535
```

Examining the output in hexadecimal notation shows the byte swapping:

```
format hex

X, Y
X =
   0000   0001   0080   ffff
Y =
   0000   0100   8000   ffff
```

Example 3

Create a three-dimensional array A of 16-bit integers and then swap the bytes of each element:

```
format hex

A = uint16(magic(3) * 150);
A(:,:,2) = A * 40;

A
A(:,:,1) =
   04b0   0096   0384
   01c2   02ee   041a
   0258   0546   012c
A(:,:,2) =
   bb80   1770   8ca0
   4650   7530   a410
   5dc0   d2f0   2ee0

swapbytes(A)
ans(:,:,1) =
   b004   9600   8403
   c201   ee02   1a04
   5802   4605   2c01
ans(:,:,2) =
   80bb   7017   a08c
   5046   3075   10a4
   c05d   f0d2   e02e
```

See Also

`typecast`

Introduced before R2006a

switch, case, otherwise

Execute one of several groups of statements

Syntax

```
switch switch_expression
   case case_expression
      statements
   case case_expression
      statements
    ...
   otherwise
      statements
end
```

Description

`switch` *`switch_expression`*`, case` *`case_expression`*`, end` evaluates an expression and chooses to execute one of several groups of statements. Each choice is a case.

The `switch` block tests each case until one of the case expressions is true. A case is true when:

- For numbers, *`case_expression`* `==` *`switch_expression`*.
- For strings, `strcmp(`*`case_expression`*`,`*`switch_expression`*`) == 1`.
- For objects that support the `eq` function, *`case_expression`* `==` *`switch_expression`*.
- For a cell array *`case_expression`*, at least one of the elements of the cell array matches *`switch_expression`*, as defined above for numbers, strings, and objects.

When a case expression is true, MATLAB executes the corresponding statements and exits the `switch` block.

An evaluated *`switch_expression`* must be a scalar or string. An evaluated *`case_expression`* must be a scalar, a string, or a cell array of scalars or strings.

The `otherwise` block is optional. MATLAB executes the statements only when no case is true.

Examples

Compare Single Values

Display different text conditionally, depending on a value entered at the command prompt.

```
n = input('Enter a number: ');

switch n
    case -1
        disp('negative one')
    case 0
        disp('zero')
    case 1
        disp('positive one')
    otherwise
        disp('other value')
end
```

At the command prompt, enter the number 1.

```
positive one
```

Repeat the code and enter the number 3.

```
other value
```

Compare Against Multiple Values

Determine which type of plot to create based on the value of the string `plottype`. If `plottype` is either `'pie'` or `'pie3'`, create a 3-D pie chart. Use a cell array to contain both values.

```
x = [12 64 24];
plottype = 'pie3';

switch plottype
    case 'bar'
```

```
        bar(x)
        title('Bar Graph')
    case {'pie','pie3'}
        pie3(x)
        title('Pie Chart')
    otherwise
        warning('Unexpected plot type. No plot created.')
end
```

More About

Tips

- A *`case_expression`* cannot include relational operators such as < or > for comparison against the *`switch_expression`*. To test for inequality, use `if`, `elseif`, `else` statements.
- The MATLAB `switch` statement does not fall through like a C language `switch` statement. If the first `case` statement is `true`, MATLAB does not execute the other `case` statements. For example:

  ```
  result = 52;

  switch(result)
     case 52
        disp('result is 52')
     case {52, 78}
        disp('result is 52 or 78')
  end
  ```

  ```
  result is 52
  ```

- Define all variables necessary for code in a particular case within that case. Since MATLAB executes only one case of any `switch` statement, variables defined within one case are not available for other cases. For example, if your current workspace does not contain a variable `x`, only cases that define `x` can use it:

  ```
  switch choice
     case 1
        x = -pi:0.01:pi;
     case 2
        % does not know anything about x
  end
  ```

- Do not use a `break` statement within a `switch` block. `break` is not defined outside a `for` or `while` loop.

`end` | `for` | `if` | `while`

Introduced before R2006a

sylvester

Solve Sylvester equation $AX + XB = C$ for X

Syntax

```
X = sylvester(A,B,C)
```

Description

`X = sylvester(A,B,C)` returns the solution, `X`, to the Sylvester equation.

Input `A` is an m-by-m matrix, input `B` is an n-by-n matrix, and both `C` and `X` are m-by-n matrices.

Examples

Solve Sylvester Equation with 3-by-3 Output

Create the coefficient matrices `A` and `B`.

```
A = [1 -1 1; 1 1 -1; 1 1 1];
B = magic(3);
```

Define `C` as the 3-by-3 identity matrix.

```
C = eye(3);
```

Use the `sylvester` function to solve the Sylvester equation for these values of `A`, `B`, and `C`.

```
X = sylvester(A,B,C)
```

```
X =

    0.1223   -0.0725    0.0131
   -0.0806   -0.0161    0.1587
   -0.0164    0.1784   -0.1072
```

The result is a 3-by-3 matrix.

Solve Sylvester Equation with 4-by-2 Output

Create a 4-by-4 coefficient matrix, `A`, and 2-by-2 coefficient matrix, `B`.

```
A = [1 0 2 3; 4 1 0 2; 0 5 5 6; 1 7 9 0];
B = [0 -1; 1 0];
```

Define `C` as a 4-by-2 matrix to match the corresponding sizes of `A` and `B`.

```
C = [1 0; 2 0; 0 3; 1 1]
```

```
C =

     1     0
     2     0
     0     3
     1     1
```

Use the `sylvester` function to solve the Sylvester equation for these values of `A`, `B`, and `C`.

```
X = sylvester(A,B,C)
```

```
X =

    0.4732   -0.3664
   -0.4006    0.3531
    0.3305   -0.1142
    0.0774    0.3560
```

The result is a 4-by-2 matrix.

Input Arguments

`A,B,C` — Input matrices

matrices

Input matrices, specified as matrices. Input `A` is an m-by-m square matrix, input `B` is an n-by-n square matrix, and input `C` is an m-by-n rectangular matrix. The function returns an error if any input matrix is sparse.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

`X` — Solution

matrix

Solution, returned as a matrix of the same size as `C`. The function returns an error if the eigenvalues of `A` and `-B` are not distinct (in this case, the solution, `X`, is singular or not unique).

More About

Sylvester Equation

The Sylvester equation is

$$AX + XB = C.$$

The equation has a unique solution when the eigenvalues of `A` and `-B` are distinct. In terms of the Kronecker tensor product, $\otimes$, the equation is

$$\left[I \otimes A + B^T \otimes I\right] X(:) = C(:),$$

where `I` is the identity matrix, and `X(:)` and `C(:)` denote the matrices `X` and `C` as single column vectors.

Introduced in R2014a

symamd

Symmetric approximate minimum degree permutation

Syntax

```
p = symamd(S)
p = symamd(S,knobs)
[p,stats] = symamd(...)
```

Description

`p = symamd(S)` for a symmetric positive definite matrix `S`, returns the permutation vector `p` such that `S(p,p)` tends to have a sparser Cholesky factor than `S`. To find the ordering for `S`, `symamd` constructs a matrix `M` such that `spones(M'*M) = spones (S)`, and then computes `p = colamd(M)`. The `symamd` function may also work well for symmetric indefinite matrices.

`S` must be square; only the strictly lower triangular part is referenced.

`p = symamd(S,knobs)` where `knobs` is a scalar. If `S` is `n`-by-`n`, rows and columns with more than `knobs*n` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs = spparms('wh_frac')`.

`[p,stats] = symamd(...)` produces the optional vector `stats` that provides data about the ordering and the validity of the matrix `S`.

`stats(1)`	Number of dense or empty rows ignored by `symamd`
`stats(2)`	Number of dense or empty columns ignored by `symamd`
`stats(3)`	Number of garbage collections performed on the internal data structure used by `symamd` (roughly of size `8.4*nnz(tril(S,-1)) + 9n` integers)
`stats(4)`	`0` if the matrix is valid, or `1` if invalid

`stats(5)`	Rightmost column index that is unsorted or contains duplicate entries, or `0` if no such column exists
`stats(6)`	Last seen duplicate or out-of-order row index in the column index given by `stats(5)`, or `0` if no such row index exists
`stats(7)`	Number of duplicate and out-of-order row indices

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `symamd`. For this reason, `symamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `symamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `symamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `symamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

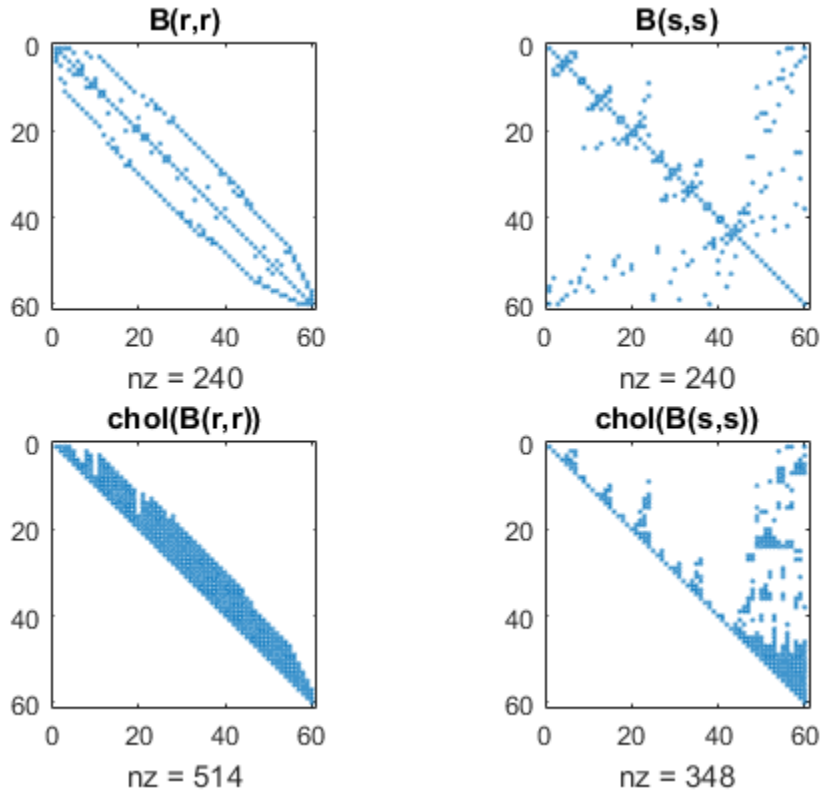
The ordering is followed by a symmetric elimination tree post-ordering.

Examples

Compare Reverse Cuthill-McKee and Minimum Degree

Here is a comparison of reverse Cuthill-McKee and minimum degree on the Bucky ball example mentioned in the `symrcm` reference page.

```
B = bucky+4*speye(60);
r = symrcm(B);
p = symamd(B);
R = B(r,r);
S = B(p,p);
subplot(2,2,1), spy(R,4), title('B(r,r)')
subplot(2,2,2), spy(S,4), title('B(s,s)')
subplot(2,2,3), spy(chol(R),4), title('chol(B(r,r))')
subplot(2,2,4), spy(chol(S),4), title('chol(B(s,s))')
```



Even though this is a very small problem, the behavior of both orderings is typical. RCM produces a matrix with a narrow bandwidth which fills in almost completely during the Cholesky factorization. Minimum degree produces a structure with large blocks of contiguous zeros which do not fill in during the factorization. Consequently, the minimum degree ordering requires less time and storage for the factorization.

References

The authors of the code for `symamd` are Stefan I. Larimore and Timothy A. Davis (`davis@cise.ufl.edu`), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National

Laboratory. Sparse Matrix Algorithms Research at the University of Florida: http://www.cise.ufl.edu/research/sparse/

Introduced before R2006a

symbfact

Symbolic factorization analysis

Syntax

```
count = symbfact(A)
count = symbfact(A,'sym')
count = symbfact(A,'col')
count = symbfact(A,'row')
count = symbfact(A,'lo')
[count,h,parent,post,R] = symbfact(...)
[count,h,parent,post,L] = symbfact(A,type,'lower')
```

Description

`count = symbfact(A)` returns the vector of row counts of `R=chol(A)`. `symbfact` should be much faster than `chol(A)`.

`count = symbfact(A,'sym')` is the same as `count = symbfact(A)`.

`count = symbfact(A,'col')` returns row counts of `R=chol(A'*A)` (without forming it explicitly).

`count = symbfact(A,'row')` returns row counts of `R=chol(A*A')`.

`count = symbfact(A,'lo')` is the same as `count = symbfact(A)` and uses `tril(A)`.

`[count,h,parent,post,R] = symbfact(...)` has several optional return values.

The flop count for a subsequent Cholesky factorization is `sum(count.^2)`

Return Value	Description
`h`	Height of the elimination tree
`parent`	The elimination tree itself
`post`	Postordering of the elimination tree

Return Value	Description
`R`	0-1 matrix having the structure of `chol(A)` for the symmetric case, `chol(A'*A)` for the `'col'` case, or `chol(A*A')` for the `'row'` case.

`symbfact(A)` and `symbfact(A,'sym')` use the upper triangular part of `A (triu(A))` and assume the lower triangular part is the transpose of the upper triangular part. `symbfact(A,'lo')` uses `tril(A)` instead.

`[count,h,parent,post,L] = symbfact(A,type,'lower')` where `type` is one of `'sym'`,`'col'`, `'row'`, or`'lo'` returns a lower triangular symbolic factor `L=R'`. This form is quicker and requires less memory.

symmlq

Symmetric LQ method

Syntax

```
x = symmlq(A,b)
symmlq(A,b,tol)
symmlq(A,b,tol,maxit)
symmlq(A,b,tol,maxit,M)
symmlq(A,b,tol,maxit,M1,M2)
symmlq(A,b,tol,maxit,M1,M2,x0)
[x,flag] = symmlq(A,b,...)
[x,flag,relres] = symmlq(A,b,...)
[x,flag,relres,iter] = symmlq(A,b,...)
[x,flag,relres,iter,resvec] = symmlq(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)
```

Description

`x = symmlq(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be symmetric but need not be positive definite. It should also be large and sparse. The column vector `b` must have length `n`. You can specify `A` as a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `symmlq` converges, a message to that effect is displayed. If `symmlq` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`symmlq(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `symmlq` uses the default, `1e-6`.

`symmlq(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `symmlq` uses the default, `min(n,20)`.

`symmlq(A,b,tol,maxit,M)` and `symmlq(A,b,tol,maxit,M1,M2)` use the symmetric positive definite preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(sqrt(M))*A*inv(sqrt(M))*y = inv(sqrt(M))*b` for `y` and then return `x = in(sqrt(M))*y`. If `M` is `[]` then `symmlq` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`symmlq(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `symmlq` uses the default, an all-zero vector.

`[x,flag] = symmlq(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`symmlq` converged to the desired tolerance `tol` within `maxit` iterations.
1	`symmlq` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`symmlq` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `symmlq` became too small or too large to continue computing.
5	Preconditioner `M` was not symmetric positive definite.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = symmlq(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = symmlq(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = symmlq(A,b,...)` also returns a vector of estimates of the `symmlq` residual norms at each iteration, including `norm(b-A*x0)`.

`[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)` also returns a vector of estimates of the conjugate gradients residual norms at each iteration.

Examples

Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50; M1 = spdiags(4*on,0,n,n);

x = symmlq(A,b,tol,maxit,M1);
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in the function `run_symmlq` that:

- Calls `symmlq` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_symmlq` are available to `afun`.

The following shows the code for `run_symmlq`:

```
function x1 = run_symmlq
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = symmlq(@afun,b,tol,maxit,M1);

       function y = afun(x)
          y = 4 * x;
          y(2:n) = y(2:n) - 2 * x(1:n-1);
          y(1:n-1) = y(1:n-1) - 2 * x(2:n);
       end
```

```
end
```

When you enter

```
x1=run_symmlq;
```

MATLAB software displays the message

```
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

Example 3

Use a symmetric indefinite matrix that fails with `pcg`.

```
A = diag([20:-1:1,-1:-1:-20]);
b = sum(A,2);      % The true solution is the vector of all ones.
x = pcg(A,b);      % Errors out at the first iteration.
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, `symmlq` can handle the indefinite matrix `A`.

```
x = symmlq(A,b,1e-6,40);
symmlq converged at iteration 39 to a solution with relative
residual 1.3e-007
```

symrcm

Sparse reverse Cuthill-McKee ordering

Syntax

```
r = symrcm(S)
```

Description

`r = symrcm(S)` returns the symmetric reverse Cuthill-McKee ordering of `S`. This is a permutation `r` such that `S(r,r)` tends to have its nonzero elements closer to the diagonal. This is a good preordering for LU or Cholesky factorization of matrices that come from long, skinny problems. The ordering works for both symmetric and nonsymmetric `S`.

For a real, symmetric sparse matrix, `S`, the eigenvalues of `S(r,r)` are the same as those of `S`, but `eig(S(r,r))` probably takes less time to compute than `eig(S)`.

Examples

Reverse Cuthill-McKee Ordering

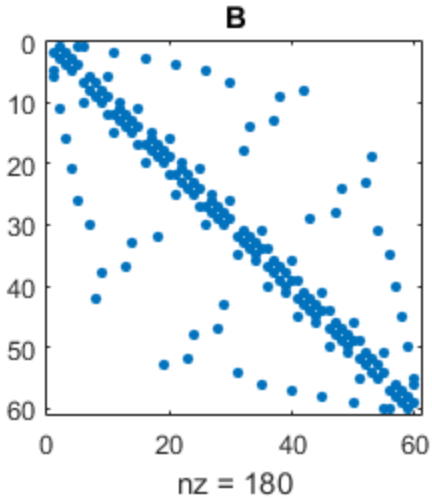
The statement

```
B = bucky;
```

uses a function in the `demos` toolbox to generate the adjacency graph of a truncated icosahedron. This is better known as a soccer ball, a Buckminster Fuller geodesic dome (hence the name `bucky`), or, more recently, as a 60-atom carbon molecule. There are 60 vertices. The vertices have been ordered by numbering half of them from one hemisphere, pentagon by pentagon; then reflecting into the other hemisphere and gluing the two halves together.

With this numbering, the matrix does not have a particularly narrow bandwidth, as the first spy plot shows:

```
figure();
subplot(1,2,1),spy(B),title('B')
```

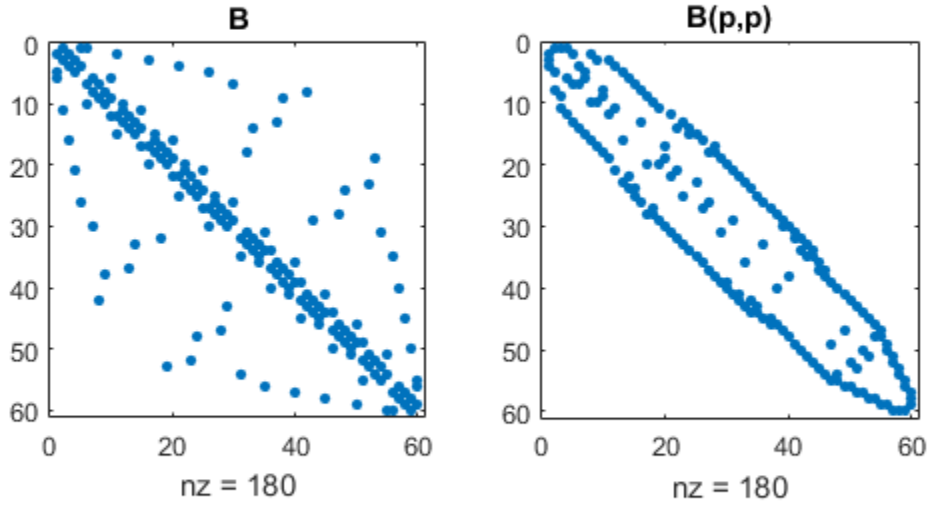


The reverse Cuthill-McKee ordering is obtained with:

```
p = symrcm(B);
R = B(p,p);
```

The `spy` plot shows a much narrower bandwidth.

```
subplot(1,2,2),spy(R),title('B(p,p)')
```



This example is continued in the reference page for `symamd`.

The bandwidth can also be computed with:

```
[i,j] = find(B);
bw = max(i-j) + 1;
```

The bandwidths of `B` and `R` are 35 and 12, respectively.

More About

Algorithms

The algorithm first finds a pseudoperipheral vertex of the graph of the matrix. It then generates a level structure by breadth-first search and orders the vertices by decreasing distance from the pseudoperipheral vertex. The implementation is based closely on the SPARSPAK implementation described by George and Liu.

Introduced before R2006a

symvar

Determine symbolic variables in expression

Syntax

```
symvar 'expr'
s = symvar('expr')
```

Description

`symvar 'expr'` searches the expression, `expr`, for identifiers other than `i`, `j`, `pi`, `inf`, `nan`, `eps`, and common functions. `symvar` displays those variables that it finds or, if no such variable exists, displays an empty cell array, `{}`.

`s = symvar('expr')` returns the variables in a cell array of strings, `s`. If no such variable exists, `s` is an empty cell array.

Examples

`symvar` finds variables `beta1` and `x`, but skips `pi` and the `cos` function.

```
symvar 'cos(pi*x - beta1)'

ans =

    'beta1'
    'x'
```

`strfind`

Introduced before R2006a

syntax

Two ways to call MATLAB functions

Description

You can call MATLAB functions using either *command syntax* or *function syntax*, as described below.

Command Syntax

A function call in this syntax consists of the function name followed by one or more arguments separated by spaces:

```
functionname arg1 arg2 ... argn
```

Command syntax does not allow you to obtain any values that might be returned by the function. Attempting to assign output from the function to a variable using command syntax generates an error. Use function syntax instead.

Examples of command syntax:

```
save mydata.mat x y z
import java.awt.Button java.lang.String
```

Arguments are treated as string literals. See the examples below, under “Argument Passing” on page 1-7974.

Function Syntax

A function call in this syntax consists of the function name followed by one or more arguments separated by commas and enclosed in parentheses:

```
functionname(arg1, arg2, ..., argn)
```

You can assign the output of the function to one or more output values. When assigning to more than one output variable, separate the variables by commas or spaces and enclose them in square brackets (`[ ]`):

```
[out1,out2,...,outn] = functionname(arg1, arg2, ..., argn)
```

Examples of function syntax:

```
copyfile('srcfile', '..\mytests', 'writable')
[x1,x2,x3,x4] = deal(A{:})
```

Arguments are passed to the function by value. See the examples below, under "Argument Passing" on page 1-7974.

Argument Passing

When calling a function using command syntax, MATLAB passes the arguments as string literals. When using function syntax, arguments are passed by value.

In the following example, assign a value to `A` and then call `disp` on the variable to display the value passed. Calling `disp` with command syntax passes the variable name, `'A'`:

```
A = pi;
disp A
   A
```

while function syntax passes the value assigned to `A`:

```
A = pi;
disp(A)
   3.1416
```

The next example passes two strings to `strcmp` for comparison. Calling the function with command syntax compares the variable names, `'str1'` and `'str2'`:

```
str1 = 'one';    str2 = 'one';
strcmp str1 str2
ans =
     0        (unequal)
```

while function syntax compares the values assigned to the variables, `'one'` and `'one'`:

```
str1 = 'one';    str2 = 'one';
strcmp(str1, str2)
ans =
     1        (equal)
```

Passing Strings

When using the function syntax to pass a string literal to a function, you must enclose the string in single quotes, (`'string'`). For example, to create a new folder called `myapptests`, use

```
mkdir('myapptests')
```

On the other hand, variables that contain strings do not need to be enclosed in quotes:

```
folder = 'myapptests';
mkdir(folder)
```

`mlint`

system

Execute operating system command and return output

Syntax

```
status = system(command)
[status,cmdout] = system(command)
[status,cmdout] = system(command,'-echo')
```

Description

`status = system(command)` calls the operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = system(command)` additionally returns the output of the command to `cmdout`. This syntax is most useful for commands that do not require user input, such as `dir`.

`[status,cmdout] = system(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

Examples

Display Windows Operating System Command Status and Output

On a Windows system, display the current folder using the `cd` command.

```
command = 'cd';
[status,cmdout] = system(command)
```

```
status =
     0
cmdout =
C:\matlab\myfiles
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the current folder in `cmdout`.

Save UNIX Command Exit Status and Output

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = system(command);
status
```

```
status =

     0
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

Input Arguments

`command` — Operating system command

string

Operating system command, specified as a string. The `command` executes in a system shell, which might not be the shell from which you launched MATLAB.

Example: `'dir'`

Example: `'ls'`

Output Arguments

`status` — Command exit status

0 | nonzero integer

Command exit status, returned as either `0` or a nonzero integer. When the command is successful, `status` is `0`. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (`&`), then `status` is the exit status upon command launch.

- If `command` does not include the ampersand character (`&`), then `status` is the exit status upon command completion.

`cmdout` — Output of operating system command
string

Output of the operating system command, returned as a string.

Limitations

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `system` with a DOS `command` that relies on the current folder fails. To work around this limitation, change the folder to a mapped drive before calling `system`.

More About

Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'notepad &'` on a Windows platform, or `'emacs &'` on UNIX). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

  Note: If `command` includes the trailing `&` character, `cmdout` is empty.

- On a UNIX system, the `system` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while the `system` function executes. This can lead to corrupted output when `system` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

Algorithms

On UNIX, MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB

first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

- "Run External Commands, Scripts, and Programs"

Introduced before R2006a

table

Create table from workspace variables

Syntax

```
T = table(var1,...,varN)
T = table(var1,...,varN,Name,Value)
T = table
```

Description

`T = table(var1,...,varN)` creates a table from the input variables, var1,...,varN . Variables can be of different sizes and data types, but all variables must have the same number of rows.

For more information on creating and using the `table` data type, see “Tables”.

`T = table(var1,...,varN,Name,Value)` includes additional options specified by one or more Name,Value pair arguments.

For example, you can specify row names or variable names to include in the table.

`T = table` creates an empty 0-by-0 table.

Examples

Create Table from Workspace Variables

Define workspace variables with the same number of rows.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

Create a table, T, as a container for the workspace variables.

```
T = table(Age,Height,Weight,BloodPressure,...
    'RowNames',LastName)
```

```
T =

                Age    Height    Weight     BloodPressure
                ___    ______    ______    _______________

    Smith       38     71        176       124          93
    Johnson     43     69        163       109          77
    Williams    38     64        131       125          83
    Jones       40     67        133       117          75
    Brown       49     64        119       122          80
```

`table` names the variables with the workspace variable names.

Create Table and Specify Variable Names

Create a table from arrays with different data types.

```
T = table(['M';'F';'M'],[45;32;34],...
    {'NY';'CA';'MA'},logical([1;0;0]),...
    'VariableNames',{'Gender' 'Age' 'State' 'Vote'})
```

```
T =

    Gender    Age    State    Vote
    ______    ___    _____    _____

    M         45     'NY'     true
    F         32     'CA'     false
    M         34     'MA'     false
```

Each variable in T contains 3 rows.

`Gender` is a character array, `Age` is a double-precision array, `State` is a cell array of strings, and `Vote` is a logical array. You can use the function `summary` to print the data type and other information about the variables in the table.

- “Create a Table”
- “Modify Units, Descriptions and Table Variable Names”
- “Access Data in a Table”

Input Arguments

`var1,...,varN` — Input variables
arrays with the same number of rows

Input variables, specified as arrays with the same number of rows. The input variables can be of different sizes and different data types.

Common input variables are numeric arrays, logical arrays, character arrays, structure arrays, or cell arrays. Furthermore, input variables can be objects that are arrays that support indexing of the form `var(index1,...indexN)`, where `index1` is a numeric or logical vector that corresponds to rows of the variable `var`. In addition, the array must implement a `vertcat` method and a `size` method with a `dim` argument.

Example: `table([1:4]',ones(4,3,2),eye(4,2))` creates a table from variables with 4 rows, but different sizes.

Example: `table([1:3]',{'one';'two';'three'},['A';'B';'C'])` creates a table from variables with 3 rows, but different data types.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'RowNames',{'row1','row2','row3'}` names the rows `row1`, `row2`, and `row3`.

`'RowNames'` — Row names
`{}` (default) | cell array of nonempty, distinct strings

Row names, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows in the table.

`'VariableNames'` — Variable names
cell array of nonempty, distinct strings

Variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the

number of variables. The strings must be valid MATLAB variable names. You can determine valid variable names using the function `isvarname`.

Output Arguments

`T` — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

Unless you specify the table variable names using the `VariableNames` name-value pair argument, the `table` function generates them automatically. If an input argument is a variable in the current workspace, `table` uses that variable's name as the table variable name. Otherwise, it generates a string from `Var` followed by an integer, such as `Var2`.

`array2table` | `cell2table` | `isvarname` | `readtable` | `struct2table` | `summary`

table2array

Convert table to homogeneous array

Syntax

```
A = table2array(T)
```

Description

`A = table2array(T)` converts the table, `T`, to a homogeneous array, `A`.

Examples

Convert Table of Numeric Data to Array

Create a table, `T`, consisting of numeric data.

```
T = table([1;2;3],[2 8; 4 10; 6 12],[3 12 21; 6 15 24; 9 18 27],...
    'VariableNames',{'One' 'Two' 'Three'})
```

```
T = 

    One        Two              Three        
    ___    ________    ________________

    1      2       8    3     12     21
    2      4      10    6     15     24
    3      6      12    9     18     27
```

Convert table, `T`, to an array.

```
A = table2array(T)
```

```
A =

     1     2     8     3    12    21
     2     4    10     6    15    24
```

```
     3     6    12     9    18    27
```

A contains two columns from variable Two and three columns from variable Three.

Convert Numeric Subset of Table to Array

Define the numeric subset of a table to convert to an array.

Create a table with nonnumeric data in the first variable.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
    [71;69;64;67;64],[176;163;131;133;119],...
    'VariableNames',{'Gender' 'Age' 'Height' 'Weight'})
```

```
T =

    Gender    Age    Height    Weight
    ______    ___    ______    ______

    M         38     71        176
    M         43     69        163
    F         38     64        131
    F         40     67        133
    F         49     64        119
```

Convert T(:,2:4) to an array.

```
A = table2array(T(:,2:4))
```

```
A =

    38    71   176
    43    69   163
    38    64   131
    40    67   133
    49    64   119
```

A does not include data from the variable Gender.

Convert Table with Three-Dimensional Variables to Array

Create a table, T, with two rows and three variables where each variable has three dimensions.

```
T = table(ones(2,1,3),2*ones(2,2,3),3*ones(2,3,3),...
```

```
    'VariableNames',{'One' 'Two' 'Three'})
T =

        One               Two               Three
    ______________    ______________    ______________

    [1x1x3 double]    [1x2x3 double]    [1x3x3 double]
    [1x1x3 double]    [1x2x3 double]    [1x3x3 double]
```

The size of the table is 2-by-3.

Convert table `T` to an array.

```
A = table2array(T)
```

```
A(:,:,1) =

     1     2     2     3     3     3
     1     2     2     3     3     3

A(:,:,2) =

     1     2     2     3     3     3
     1     2     2     3     3     3

A(:,:,3) =

     1     2     2     3     3     3
     1     2     2     3     3     3
```

The size of `A` is 2-by-6-by-3.

Input Arguments

`T` — Input table

table

Input table, specified as a table. All variables in `T` must have sizes and data types that are compatible for horizontal concatenation. Specifically, the size of all variable dimensions greater than `2` must match.

- If `T` is an `m`-by`n` table with variables that each have one column, then each variable becomes one column in `A`, and `A` is an `m`-by-`n` array.
- If `T` contains variables that consist of more than one column, those variables become multiple columns in `A`, and the size of `A` is greater than the size of `T`.
- If `T` contains variables with more than two dimensions, the number of dimensions of `A` is the same as the number of variable dimensions.

More About

Tips

- `table2array` horizontally concatenates the variables in `T` to create `A`. If the variables in `T` are cell arrays, `table2array` does not concatenate their contents, and `A` is a cell array, equivalent to `table2cell(T)`. To create an array containing the contents of variables that are all cell arrays, use `cell2mat(table2cell(T))`.
- `table2array(T)` is equivalent to `T{:,:}`.

Algorithms

If `T` contains variables with different data types that are compatible for horizontal concatenation, `table2array` creates a homogeneous array, `A`, of the dominant data type. For example, if `T` contains `double` and `single` numeric data, `table2array(T)` returns an array with data type `single`.

See Also

`array2table` | `table` | `table2cell` | `table2struct`

table2cell

Convert table to cell array

Syntax

```
C = table2cell(T)
```

Description

`C = table2cell(T)` converts the table, `T`, to a cell array, `C`. Each variable in `T` becomes a column of cells in `C`.

Examples

Convert Table to Cell Array

Create a table, `T`, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
    [124 93;109 77; 125 83; 117 75; 122 80],...
    'VariableNames',{'Gender' 'Age' 'BloodPressure'},...
    'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

```
T =

                Gender    Age    BloodPressure
                ______    ___    _____________

    Smith       M         38     124          93
    Johnson     M         43     109          77
    Williams    F         38     125          83
    Jones       F         40     117          75
    Brown       F         49     122          80
```

Convert `T` to a cell array.

```
C = table2cell(T)
```

```
C =

    'M'    [38]    [1x2 double]
    'M'    [43]    [1x2 double]
    'F'    [38]    [1x2 double]
    'F'    [40]    [1x2 double]
    'F'    [49]    [1x2 double]
```

`C` is a 5-by-3 cell array.

Vertically concatenate the table property, `T.Properties.VariableNames`, with `C` to include column headings for the cell array.

```
[T.Properties.VariableNames;C]
```

```
ans =

    'Gender'    'Age'    'BloodPressure'
    'M'         [ 38]       [1x2 double]
    'M'         [ 43]       [1x2 double]
    'F'         [ 38]       [1x2 double]
    'F'         [ 40]       [1x2 double]
    'F'         [ 49]       [1x2 double]
```

`T.Properties.VariableNames` is a cell array of strings.

Input Arguments

`T` — Input table

table

Input table, specified as a table.

If `T` is an `m`-by`n` table, then `C` is an `m`-by-`n` cell array.

See Also

`cell2table` | `table` | `table2array` | `table2struct`

table2struct

Convert table to structure array

Syntax

```
S = table2struct(T)
S = table2struct(T,'ToScalar',true)
```

Description

`S = table2struct(T)` converts the table, `T`, to a structure array, `S`. Each variable of `T` becomes a field in `S`. If `T` is an `m`-by-`n` table, then `S` is a `m`-by-1 structure array with `n` fields.

`S = table2struct(T,'ToScalar',true)` converts the table, `T`, to a scalar structure `S`. Each variable of `T` becomes a field in `S`. If `T` is a `m`-by-`n` table, then `S` has `n` fields, each of which has `m` rows.

Examples

Convert Table to Structure Array

Create a table, `T`, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
    [124 93;109 77; 125 83; 117 75; 122 80],...
    'VariableNames',{'Gender' 'Age' 'BloodPressure'})
```

```
T =

    Gender    Age    BloodPressure
    ______    ___    _____________

    M         38     124          93
    M         43     109          77
    F         38     125          83
    F         40     117          75
```

```
    F         49     122          80
```

Convert T to a structure array.

```
S = table2struct(T)
```

```
S =

5x1 struct array with fields:

    Gender
    Age
    BloodPressure
```

The structure is 5-by-1, corresponding to the five rows of the table, T. The three fields of S correspond to the three variables from T.

Display the field data for the first element of S.

```
S(1)
```

```
ans =

           Gender: 'M'
              Age: 38
    BloodPressure: [124 93]
```

The information corresponds to the first row of the table.

Convert Table to Scalar Structure

Create a table, T, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
    [124 93;109 77; 125 83; 117 75; 122 80],...
    'VariableNames',{'Gender' 'Age' 'BloodPressure'})
```

```
T =

    Gender    Age     BloodPressure
    ______    ___    ______________

    M         38     124          93
    M         43     109          77
    F         38     125          83
```

```
    F          40      117           75
    F          49      122           80
```

Convert `T` to a scalar structure.

```
S = table2struct(T,'ToScalar',true)
```

```
S =

           Gender: [5x1 char]
              Age: [5x1 double]
    BloodPressure: [5x2 double]
```

The data in the fields of the scalar structure are 5-by-1, corresponding to the five rows in the table `T`.

Display the data for the field `BloodPressure`.

```
S.BloodPressure
```

```
ans =

   124    93
   109    77
   125    83
   117    75
   122    80
```

The structure field `BloodPressure` contains all of the data that was in the variable of the same name from table `T`.

Convert Table with Row Names to Structure

Create a table, `T`, that includes row names.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
    [124 93;109 77; 125 83; 117 75; 122 80],...
    'VariableNames',{'Gender' 'Age' 'BloodPressure'},...
    'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

```
T =

                Gender    Age    BloodPressure
                ______    ___    _____________
```

```
    Smith       M          38      124          93
    Johnson     M          43      109          77
    Williams    F          38      125          83
    Jones       F          40      117          75
    Brown       F          49      122          80
```

Convert `T` to a scalar structure.

```
S = table2struct(T,'ToScalar',true)
```

```
S =

           Gender: [5x1 char]
              Age: [5x1 double]
    BloodPressure: [5x2 double]
```

Add a field for the row names from the table.

```
S.RowNames = T.Properties.RowNames
```

```
S =

           Gender: [5x1 char]
              Age: [5x1 double]
    BloodPressure: [5x2 double]
         RowNames: {5x1 cell}
```

If `S` is a nonscalar structure, use `[S.RowNames] = T.Properties.RowNames{:}` to include a field with the row names from the table.

Input Arguments

T — Input table

table

Input table, specified as a table.

See Also

`struct2table` | `table` | `table2array` | `table2cell`

Table Properties

Access and modify table metadata properties

Access and Modify Properties

A table, `T`, has properties that store metadata such as its variable names, row names, descriptions, and variable units. `T.Properties` returns a summary of all of the table properties.

You can access a property using *`T`*`.Properties.`*`PropName`*, where *`T`* is the name of the table and *`PropName`* is one of the table properties. For example, to access the `VariableDescriptions` property of a table named `Patients`, use `Patients.Properties.VariableDescriptions`.

You can modify a property value using *`T`*`.Properties.`*`PropName = P` where *`T`* is the name of the table, *`PropName`* is one of the table properties, and *`P`* is the desired property value. For example, to modify the `VariableUnits` property of a table named `Patients`, use `Patients.Properties.VariableUnits = P` where *`P`* is a cell array of strings containing the specified information.

In contrast, you can access and modify variables within a table using *`T.Variable`* or *`T.Variable = V`*, where *`T`* is the name of the table, *`Variable`* is the name of the variable you want to access or modify, and *`V`* is the variable value you want.

Properties

`VariableNames` — Variable names

cell array of nonempty, distinct strings

Variable names, specified as a cell array of nonempty, distinct strings. Variable names must be valid MATLAB variable names. The number of strings must equal the number of variables. MATLAB removes any leading or trailing white space from the strings.

If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of `N` strings of the form `{'Var1' ... 'Var`*`N`*`'}` where *`N`* is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

The variable names are visible when viewing the table and when using the `summary` function. Furthermore, you can use the variable names within parentheses, within curly braces, or with dot indexing to access table data.

Example

```
%% Create a table
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
    [71;69;64;67;64],[176;163;131;133;119])
```

```
T =

    Var1    Var2    Var3    Var4
    ____    ____    ____    ____

    M       38      71      176
    M       43      69      163
    F       38      64      131
    F       40      67      133
    F       49      64      119
```

```
%% Modify variable names
T.Properties.VariableNames = {'Gender' 'Age' 'Height' 'Weight'}
```

```
T =

    Gender    Age    Height    Weight
    ______    ___    ______    ______

    M         38     71        176
    M         43     69        163
    F         38     64        131
    F         40     67        133
    F         49     64        119
```

```
%% Create a subtable
%
% Use variable names within parentheses to create a subtable.
% Include al the rows, but only the variables Age and Gender.
T(:,{'Age','Gender'})
```

```
ans =

    Age    Gender
    ___    ______
```

```
    38     M
    43     M
    38     F
    40     F
    49     F

%% Extract data from the table
%
% Use variable names within curly braces to extract the
% numeric data from the variables Height and Weight.
T{:,{'Height','Weight'}}

ans =

    71   176
    69   163
    64   131
    67   133
    64   119

% Use variable names with dot indexing to extract
% all the data from the variable Gender.
T.Gender

ans =

M
M
F
F
F
```

`RowNames` — Row names

`{}` (default) | cell array of nonempty, distinct strings

Row names, specified as a cell array of nonempty, distinct strings. This property can be empty, but if not empty, the number of strings must equal the number of rows in the table. MATLAB removes any leading or trailing white space from the strings. The default property value is an empty cell array.

The row names are visible when you view the table. Furthermore, you can use the row names within parentheses or curly braces to access the table data.

Example

```
% Create a table
load patients
T = table(Gender,Age,Height,Weight,Smoker,Systolic,Diastolic);

% Add row names
T.Properties.RowNames = LastName;

% Remove row names
T.Properties.RowNames = {};
```

`DimensionNames` — Dimension names

`{'Row' 'Variable'}` (default) | two-element cell array of strings

Dimension names, specified as a two-element cell array of strings.

Example

```
% Create a table
load patients
T = table(Gender,Age,Height,Weight,Smoker,Systolic,Diastolic,...
    'RowNames',LastName);

% Add dimension names
T.Properties.DimensionNames = {'Patient' 'Data'};
```

`Description` — Table description

`''` (default) | string

Table description, specified as a string. This string is visible when using the `summary` function.

Example

```
% Create a table
load patients
T = table(Gender,Age,Height,Weight);

% Add a table description
T.Properties.Description = 'Simulated patient data';

%View the summary
format compact
summary(T)
```

```
Description:  Simulated patient data
```

```
Variables:
    Gender: 100x1 char
    Age: 100x1 double
        Values:
            min       25
            median    39
            max       50
    Height: 100x1 double
        Values:
            min       60
            median    67
            max       72
    Weight: 100x1 double
        Values:
            min         111
            median    142.5
            max         202
```

`VariableDescriptions` — Variable descriptions

{} (default) | cell array of strings

Variable descriptions, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have a description.

The variable descriptions are visible when using the `summary` function.

Example

```
% Create a table
load patients
T = table(Gender,Age,Height,Weight,Smoker,Systolic,Diastolic);

% Add variable descriptions
T.Properties.VariableDescriptions = {'' '' '' '' ...
    'Has the patient ever been a smoker' ...
    'Systolic Pressure' 'Diastolic Pressure'};

% View the summary
format compact
summary(T)

Variables:
```

```
    Gender: 100x1 char
    Age: 100x1 double
        Values:
            min       25
            median    39
            max       50
    Height: 100x1 double
        Values:
            min       60
            median    67
            max       72
    Weight: 100x1 double
        Values:
            min         111
            median    142.5
            max         202
    Smoker: 100x1 logical
        Description:  Has the patient ever been a smoker
        Values:
            true     34
            false    66
    Systolic: 100x1 double
        Description:  Systolic Pressure
        Values:
            min       109
            median    122
            max       138
    Diastolic: 100x1 double
        Description:  Diastolic Pressure
        Values:
            min         68
            median    81.5
            max         99
```

```
% Remove all the variable descriptions
T.Properties.VariableDescriptions = {};
```

`VariableUnits` — Variable units

{} (default) | cell array of strings

Variable units, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have units.

The variable units are visible when using the `summary` function.

Example

```
% Create a table
load patients
T = table(Gender,Age,Height,Weight,Smoker,Systolic,Diastolic);

% Add variable units
T.Properties.VariableUnits = {'' 'Yrs' 'In' 'Lbs' '' 'mm Hg' 'mm Hg'};

% View the summary
format compact
summary(T)

Variables:
    Gender: 100x1 char
    Age: 100x1 double
        Units:  Yrs
        Values:
            min       25
            median    39
            max       50
    Height: 100x1 double
        Units:  In
        Values:
            min       60
            median    67
            max       72
    Weight: 100x1 double
        Units:  Lbs
        Values:
            min         111
            median    142.5
            max         202
    Smoker: 100x1 logical
        Values:
            true     34
            false    66
    Systolic: 100x1 double
        Units:  mm Hg
        Values:
            min       109
            median    122
            max       138
```

```
    Diastolic: 100x1 double
        Units:  mm Hg
        Values:
            min         68
            median    81.5
            max         99
```

```
% Remove all the variable units
T.Properties.VariableUnits = {};
```

`UserData` — Additional table information

{} (default) | variable containing information in any data type

Additional table information, specified as a variable containing information in any data type.

Example

```
% Create a table
load patients
T = table(Gender,Age,Height,Weight,Smoker,Systolic,Diastolic);

% Add an anonymous function to the table metadata
formula = @(x) x.^2;
T.Properties.UserData = formula;
```

TabularTextDatastore Properties

Access and modify `TabularTextDatastore` properties

`TabularTextDatastore` properties describe the files associated with a `TabularTextDatastore` object. Specifically, the properties describe the format of the data in the files and control how the data should be read from the datastore. By changing property values, you can modify certain aspects of the datastore. Use dot notation to view or modify a particular property of a `TabularTextDatastore` object:

```
ds = datastore('airlinesmall.csv');
ds.TreatAsMissing = 'NA';
ds.MissingValue = 0;
```

You also can specify the value of `TabularTextDatastore` properties using name-value pair arguments when you create a datastore using the `datastore` function:

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'MissingValue',0)
```

The first file specified by the `Files` property determines the variable names and format information. The `datastore` function reevaluates this information when you change any of the following properties of a `TabularTextDatastore`:

`Files`	`Delimiter`	`CommentStyle`
`ReadVariableNames`	`RowDelimiter`	`Whitespace`
`NumHeaderLines`	`TreatAsMissing`	`MultipleDelimitersAsOne`

File Properties

`Files` — Files included in datastore

cell array of strings

Files included in the datastore, specified as a cell array of strings, where each string is a full path to a file.

The first file specified by the `Files` property determines the variable names and format information for all files in the datastore.

Example: `{'C:\dir\data\mydata1.csv','C:\dir\data\mydata2.csv'}`

`ReadVariableNames` — Indicator for reading first row of first file as variable names

`true` (default) | `false` | `1` | `0`

Indicator for reading first row of the first file in the datastore as variable names, specified as either `true` (`1`) or `false` (`0`).

- If `true`, then the first nonheader row of the first file determines the variable names for the data.
- If `false`, then the first nonheader row of the first file contains the first row of data. The data is assigned default variable names, `Var1`, `Var2`, and so on.

Data Types: `logical`

`VariableNames` — Names of variables

cell array of strings

Names of variables in the datastore, specified as a cell array of strings. Specify the variable names in the order in which they appear in the files. If you do not specify the variable names, they are detected from the first nonheader line in the first file of the datastore. When modifying the `VariableNames` property, the number of new variable names must match the number of original variable names.

If `ReadVariableNames` is `false`, then `VariableNames` defaults to `{'Var1','Var2', ...}`.

Example: `{'Time','Name','Quantity'}`

Text Format Properties

`NumHeaderLines` — Number of lines to skip at beginning of file

`0` (default) | positive integer

Number of lines to skip at the beginning of the file, specified as a positive integer.

`datastore` ignores the specified number of header lines before reading the variable names or data.

Data Types: `double`

`Delimiter` — Field delimiter characters

`','` (default) | string | cell array of strings

Field delimiter characters, specified as a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

Example: `'|'`

Example: `{';','*'}`

Repeated delimiter characters in a file are interpreted as separate delimiters with empty fields between them.

When you specify one of the following escape sequences as a delimiter, it is converted to the corresponding control character:

`\b`	Backspace
`\n`	Newline
`\r`	Carriage return
`\t`	Tab
`\\`	Backslash (\)

`RowDelimiter` — Row delimiter character

`\r\n` (default) | string

Row delimiter character, specified as a string. The string must be a single character or one of the strings, `'\r'`, `'\n'`, or `'\r\n'`.

Example: `':'`

`TreatAsMissing` — Numeric values to treat as missing values

`''` (default) | string | cell array of strings

Numeric values to treat as missing values, specified as a single string or cell array of strings. This option only applies to numeric fields. This property is equivalent to the `TreatAsEmpty` name-value pair argument for the `textscan` function.

Example: `'NA'`

Example: `{'-',''}`

Data Types: `char` | `cell`

`MissingValue` — Value for missing numeric fields

`NaN` (default) | scalar

Value for missing numeric fields in delimited text files, specified as a scalar. This property is equivalent to the `EmptyValue` name-value pair argument for the `textscan` function.

Data Types: `double`

Advanced Text Format Properties

`TextscanFormats` — Format of the data fields

cell array of strings

Format of the data fields, specified as a cell array of strings, where each string contains one conversion specifier.

When you specify or modify the `TextscanFormats` property, you can use the same conversion specifiers that the `textscan` function accepts, including specifiers that skip fields using an asterisk (*) character and specifiers that skip literal text. The number of conversion specifiers must match the number of variables in the `VariableNames` property.

If the value of `TextscanFormats` includes conversion specifiers that skip fields using asterisk characters (*), then the value of the `SelectedVariableNames` property automatically updates. MATLAB uses the `%*q` conversion specifier to skip fields omitted by the `SelectedVariableNames` property and treats the field contents as literal strings. For fixed width files, indicate a skipped field using the appropriate conversion specifier along with the field width. For example, `%*52c` skips a field that contains 52 characters.

If you do not specify a value for `TextscanFormats`, then `datastore` determines the format of the data fields by scanning text from the first non-header line in the first file of the datastore.

Example: `{'%s','%s','%f'}`

`ExponentCharacters` — Exponent characters

`'eEdD'` (default) | string

Exponent characters, specified as a string. The default exponent characters are `e`, `E`, `d`, and `D`.

`CommentStyle` — Style of comments

`''` (default) | string | cell array of strings

Style of comments in the file, specified as a string or cell array of strings.

For example, specify a string such as `'%'` to ignore characters following the string on the same line. Specify a cell array of two strings, such as `{'/*', '*/'}`, to ignore characters between the strings.

When reading from a `TabularTextDatastore`, the `read` function checks for comments only at the start of each field, not within a field.

Example: `'CommentStyle',{'/*', '*/'}`

Data Types: `char` | `cell`

`Whitespace` — White-space characters

`' \b\t'` (default) | string

White-space characters, specified as a string of one or more characters.

When you specify one of the following escape sequences as any white-space character, `datastore` converts that sequence to the corresponding control character:

`\b`	Backspace
`\n`	Newline
`\r`	Carriage return
`\t`	Tab
`\\`	Backslash (\)

Example: `' \b\t'`

Data Types: `char`

`MultipleDelimitersAsOne` — Multiple delimiter handling

`0 (false)` (default) | `1 (true)`

Multiple delimiter handling, specified as either `true` or `false`. If `true`, then `datastore` treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter.

Properties that Control the Table Returned by `preview`, `read`, `readall` Functions

`SelectedVariableNames` — Variables to read

cell array of strings

Variables to read from the file, specified as a cell array of strings, where each string contains the name of one variable. You can specify the variable names in any order.

Example: `{'Var3','Var7','Var4'}`

`SelectedFormats` — Formats of selected variables

cell array of strings

Formats of the selected variables to read, specified as a cell array of strings, where each string contains one conversion specifier. The variables to read are indicated by the `SelectedVariableNames` property. The number of strings in `SelectedFormats` must match the number of variables to read.

You can use the same conversion specifiers that the `textscan` function accepts, including specifiers that skip literal text. However, you cannot use a conversion specifier that skips a field. That is, the conversion specifier cannot include an asterisk character (*).

Example: `{'%d','%d'}`

`ReadSize` — Amount of data to read

20000 (default) | positive scalar | `'file'`

Amount of data to read in a call to the `read` function, specified as a positive scalar or the string, `'file'`.

- If `ReadSize` is a positive integer, then each call to `read` reads up to the specified number of rows from the datastore.
- If `ReadSize` is `'file'`, then each call to `read` reads all of the data in one file.

When you change `ReadSize` from a numeric scalar to `'file'` or vice versa, MATLAB resets the datastore to the state where no data has been read from it.

`RowsPerRead` — Upper limit on number of rows to read

20000 (default) | positive scalar

Note: `RowsPerRead` will be removed in a future release. Use `ReadSize` instead.

Upper limit on number of rows to read from a file in a call to the `read` function, specified as a positive scalar.

See Also

`datastore` | `reset` | `textscan`

More About

- Using TabularTextDatastore Objects

tan

Tangent of argument in radians

Syntax

```
Y = tan(X)
```

Description

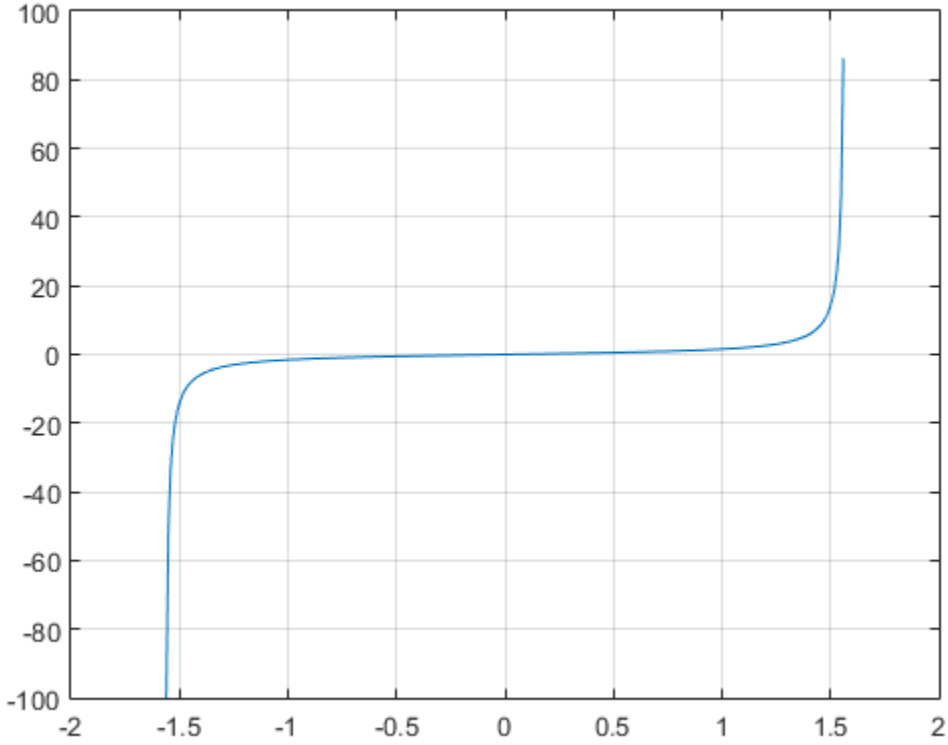
`Y = tan(X)` returns the tangent of each element of `X`. The `tan` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of X in the interval [-Inf, Inf], `tan` returns real values in the interval [-Inf ,Inf]. For complex values of X, `tan` returns complex values. All angles are in radians.

Examples

Plot Tangent Function

Plot the tangent function over the domain $-\pi/2 \le x \le \pi/2$.

```
x = (-pi/2)+0.01:0.01:(pi/2)-0.01;
plot(x,tan(x)), grid on
```



Tangent of Vector of Complex Angles

Calculate the tangent of the complex angles in vector `x`.

```
x = [-i pi+i*pi/2 -1+i*4];
y = tan(x)
```

```
y =

   0.0000 - 0.7616i  -0.0000 + 0.9172i  -0.0006 + 1.0003i
```

Input Arguments

X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Tangent of input angle

scalar value | vector | matrix | N-D array

Tangent of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

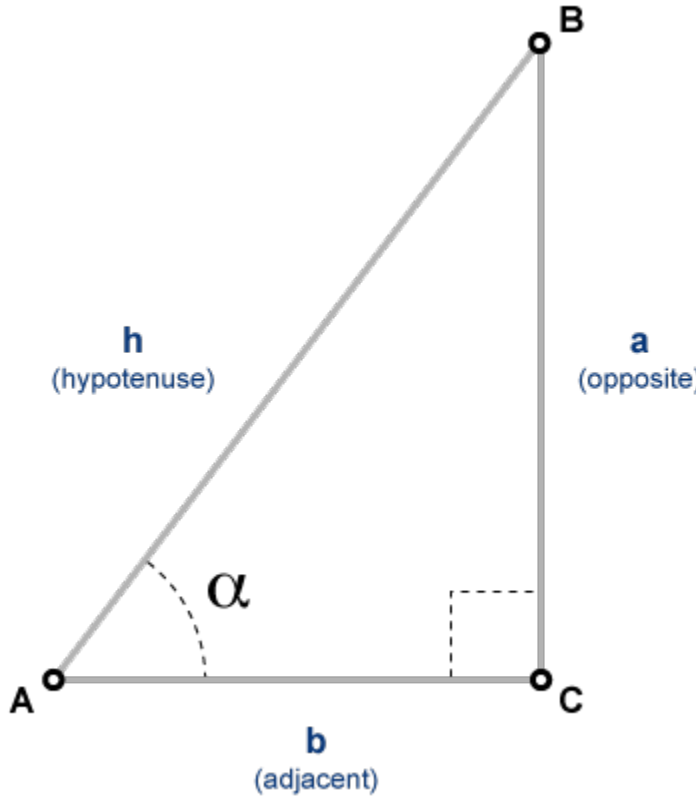
More About

Tangent Function

The tangent of an angle, α, defined with reference to a right angled triangle is

$$\tan(\alpha) = \frac{\text{opposite side}}{\text{adjacent side}} = \frac{a}{b}.$$

.



The tangent of a complex angle, α, is

$$\tan(\alpha) = \frac{e^{i\alpha} - e^{-i\alpha}}{i\left(e^{i\alpha} + e^{-i\alpha}\right)}.$$

.

See Also

`atan` | `atan2` | `atan2d` | `atand` | `tand` | `tanh`

Introduced before R2006a

tand

Tangent of argument in degrees

Syntax

```
Y = tand(X)
```

Description

`Y = tand(X)` returns the tangent of the elements of `X`, which are expressed in degrees.

Examples

Tangent of 90 degrees compared to tangent of π/2 radians

```
tand(90)
```

```
ans =

   Inf
```

```
tan(pi/2)
```

```
ans =

   1.6331e+16
```

`tand(90)` is infinite, whereas `tan(pi/2)` is large but finite.

Tangent of vector of complex angles, specified in degrees

```
z = [180+i 15+2i 10+3i];
y = tand(z)
```

```
y =
```

```
   0 + 0.0175i   0.2676 + 0.0374i   0.1758 + 0.0539i
```

Input Arguments

X — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `tand` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Tangent of angle

scalar value | vector | matrix | N-D array

Tangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

See Also

`atan` | `atand` | `tan`

Introduced before R2006a

tanh

Hyperbolic tangent

Syntax

```
Y = tanh(X)
```

Description

The `tanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

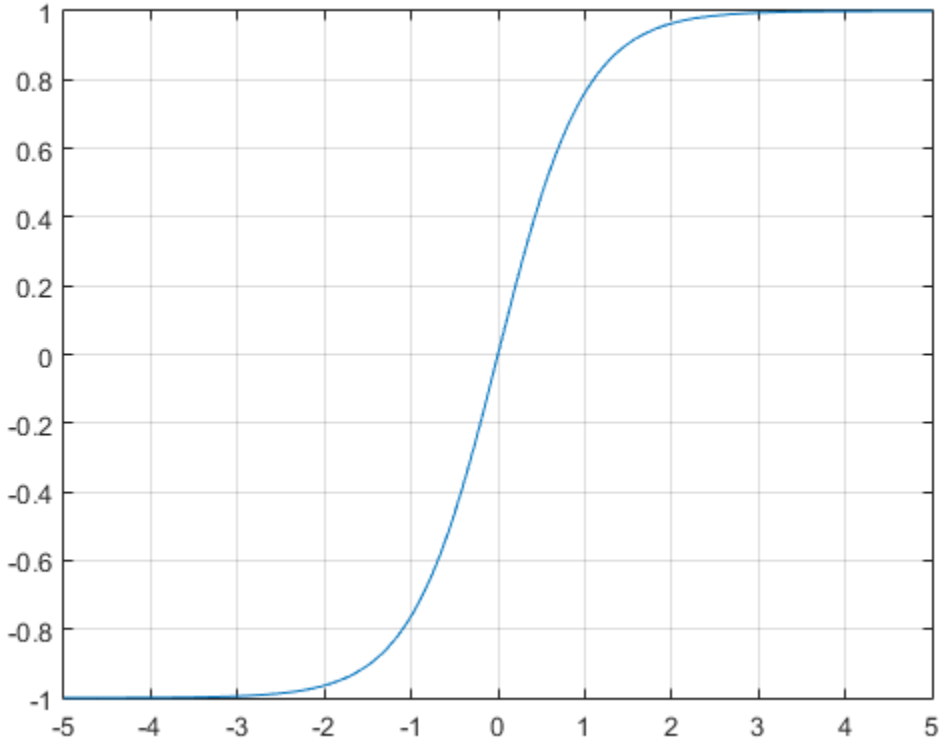
`Y = tanh(X)` returns the hyperbolic tangent of each element of `X`.

Examples

Graph Hyperbolic Tangent Function

Graph the hyperbolic tangent function over the domain $-5 \le x \le 5$.

```
x = -5:0.01:5;
plot(x,tanh(x)), grid on
```



More About

Hyperbolic Tangent

The hyperbolic tangent of z is

$$\tanh(z) = \frac{\sinh(z)}{\cosh(z)}.$$

`atan` | `atan2` | `tan` | `atanh` | `sinh` | `cosh`

Introduced before R2006a

tar

Compress files into tar file

Syntax

```
tar(tarfilename,files)
tar(tarfilename,files,rootfolder)
entrynames = tar(...)
```

Description

`tar(tarfilename,files)` creates a tar file named *`tarfilename`* from the list of files and folders specified in *`files`*. Folders recursively include all of their content. If *`files`* includes relative paths, the tar file also contains relative paths. The tar file does not include absolute paths.

`tar(tarfilename,files,rootfolder)` specifies the path for *`files`* relative to *`rootfolder`* rather than the current folder. Relative paths in the tar file reflect the relative paths in *`files`*, and do not include path information from *`rootfolder`*.

`entrynames` `= tar(...)` returns a string cell array of the names of the files contained in *`tarfilename`*. If *`files`* includes relative paths, *`entrynames`* also contains relative paths.

Input Arguments

`tarfilename`

String specifying the name of the tar file. If *`tarfilename`* has no extension, MATLAB appends the `.tar` extension. The *`tarfilename`* extension can end in `.tgz` or `.gz`. In this case, *`tarfilename`* is gzipped.

`files`

String or cell array of strings containing the list of files or folders included in *`tarfilename`*.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`rootfolder`

String specifying the path for *`files`*.

Examples

Tar all files in the current folder to the file `backup.tgz`.

```
tar('backup.tgz','.');
```

More About

Tips

`tar` cannot compress folders larger than 2 GB.

`gzip` | `gunzip` | `untar` | `unzip` | `zip`

Introduced before R2006a

targetupdater

Set up support package that is already installed

Syntax

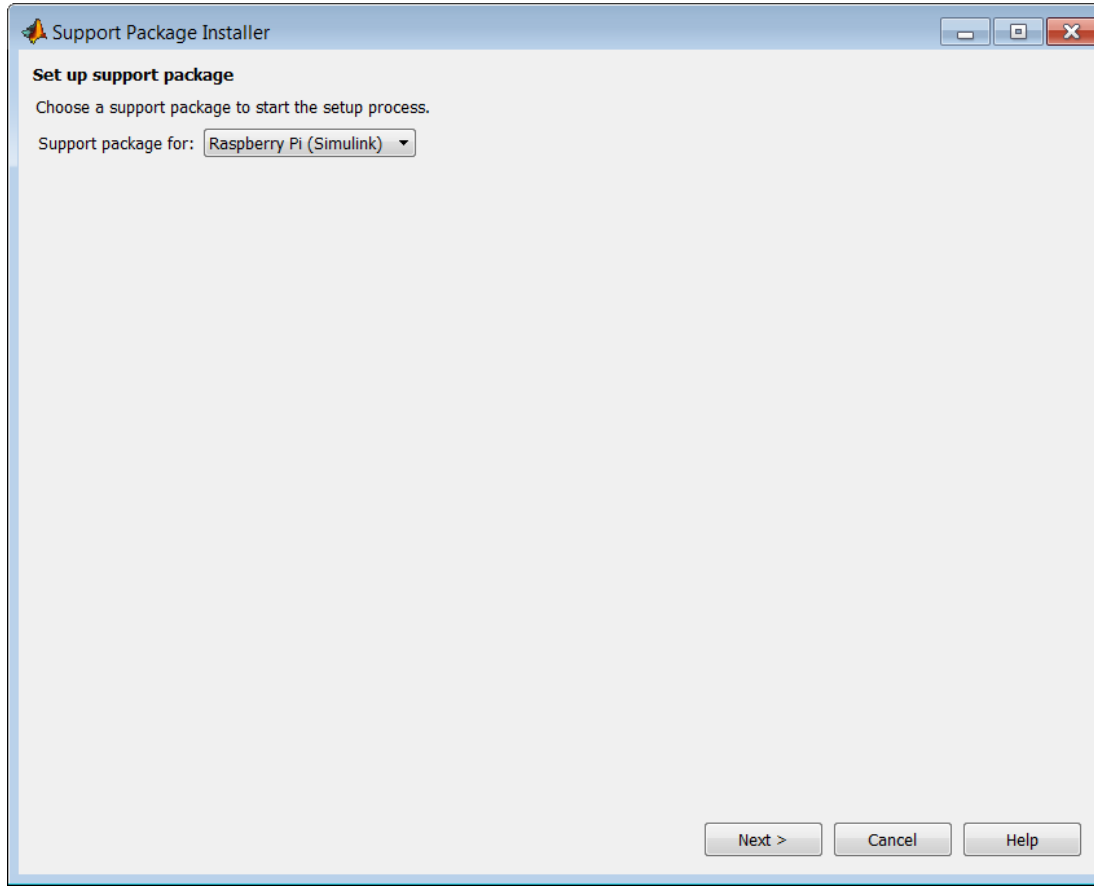
Description

To set up a support package that is already installed, use `targetupdater`.

Setting up a support package can include:

- Updating firmware on the target hardware.
- Validating the installation folder of third-party software.
- Validating licenses.

The `targetupdater` function starts Support Package Installer at the **Set up support package** screen.



Tip Some support packages do not require set up. If the **Set up support package** screen does not display an installed support package, the support package does not require set up.

To check whether a support package is installed, use the `matlabshared.supportpkg.getInstalled` function.

See Also

`matlabshared.supportpkg.checkForUpdate` | `matlabshared.supportpkg.getInstalled` | `supportPackageInstaller`

tcpclient

Create TCP/IP client object to communicate over TCP/IP

Syntax

```
t = tcpclient('Address',Port)
t = tcpclient('Address',Port,'Timeout',<timeout_value>)
```

Description

`t = tcpclient('Address',Port)` constructs a TCP/IP object, `t`, associated with remote host, `Address`, and remote port value, `Port`. The address can be either a remote host name or a remote IP address. The port must be a positive integer between `1` and `65535`.

If an invalid address or port is specified, or the connection to the server cannot be established, the object will not be created.

`t = tcpclient('Address',Port,'Timeout',<timeout_value>)` additionally sets a timeout value. The `Timeout` property specifies the waiting time to complete read and write operations in seconds, and the default is `10`.

Examples

Create Object Using Host Name

Create a TCP/IP object called `t`, using the host address shown, and Port of `4012`.

```
t = tcpclient('www.mathworks.com', 4012)
```

```
t =

   tcpclient with properties:

          Address: 'www.mathworks.com'
             Port: 4012
          Timeout: 10
```

```
   BytesAvailable: 0
```

Create Object Using IP Address

Create a TCP/IP object called `t`, using the IP address shown, and Port of `4012`.

```
t = tcpclient('172.28.154.231', 4012)

t =

   tcpclient with properties:

          Address: '172.28.154.231'
             Port: 4012
          Timeout: 10
   BytesAvailable: 0
```

Create Object Setting the Timeout Property

Create a TCP/IP object called `t`, and increase the `Timeout` to `20` seconds.

```
t = tcpclient('172.28.154.231', 4012, 'Timeout', 20)

t =

   tcpclient with properties:

          Address: '172.28.154.231'
             Port: 4012
          Timeout: 20
   BytesAvailable: 0
```

The output reflects the `Timeout` property change.

Input Arguments

`Address` — Remote host name or IP address for connection

character string

Remote host name or IP address for connection, specified as a character string. Specify address as the first argument when you create the `tcpclient` object.

Example: `t = tcpclient('www.mathworks.com', 4012)`

Data Types: `char`

`Port` — Remote host port for connection

numeric scalar

Remote host port for connection, specified as a numeric scalar. Specify port number as the second argument when you create the `tcpclient` object. The `Port` must be a positive integer between `1` and `65535`.

Example: `t = tcpclient('www.mathworks.com', 4012)`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `t = tcpclient('172.28.154.231', 120, 'Timeout', 15)`

`'Timeout'` — Timeout for read/write operation

10 (default) | numeric scalar

Timeout for read/write operation specified as the comma-separated pair consisting of 'Timeout" and a positive value of type `double`. You can change the value either during object creation or after you create the object.

For information on how to change the timeout value after object creation, see Configure Properties for TCP/IP Communication.

Example: `t = tcpclient('172.28.154.231', 4012, 'Timeout', 20)`

Data Types: `double`

tempdir

Name of system's temporary folder

Syntax

```
tmp_folder = tempdir
```

Description

`tmp_folder = tempdir` returns the name of the system's temporary folder, if one exists. This function does not create a new folder.

More About

- "Create Temporary Files"

See Also

`delete` | `recycle` | `tempname`

Introduced before R2006a

tempname

Unique name for temporary file

Syntax

```
tmpName = tempname
```

Description

`tmpName = tempname` returns a string, `tmpName`, suitable for use as a temporary file path in your system's temporary folder.

Examples

Create Temporary File Name with Extension

Create a temporary file name that has the extension, `.dat`, by concatenating two strings.

```
tmpName = [tempname,'.dat'];
```

Write Data to Temporary File

Create a temporary file name.

```
filename = tempname;
```

Create a new file with the temporary file name, and write data to the file.

```
fileID = fopen(filename,'w');
fwrite(fileID,magic(5));
fclose(fileID);
```

Limitations

- In most cases, `tempname` generates a universally unique identifier (UUID). However, if you run MATLAB without JVM software, then `tempname` generates a random

string using the CPU counter and time, and this string is not guaranteed to be unique. For more information about the MATLAB startup option that does not load JVM software, see “Commonly Used Startup Options”.

More About

- “Create Temporary Files”

`tempdir`

Introduced before R2006a

tetramesh

Tetrahedron mesh plot

Syntax

```
tetramesh(T,X,c)
tetramesh(T,X)
tetramesh(TR)
h = tetramesh(...)
tetramesh(...,'param','value','param','value'...)
```

Description

`tetramesh(T,X,c)` displays the tetrahedrons defined in the `m`-by-4 matrix `T` as mesh. `T` is usually the output of a Delaunay triangulation of a 3-D set of points. A row of `T` contains indices into `X` of the vertices of a tetrahedron. `X` is an `n`-by-3 matrix, representing `n` points in 3 dimension. The tetrahedron colors are defined by the vector `C`, which is used as indices into the current colormap.

`tetramesh(T,X)` uses `C = 1:m` as the color for the `m` tetrahedra. Each tetrahedron has a different color (modulo the number of colors available in the current colormap).

`tetramesh(TR)` displays the tetrahedra in a triangulation representation.

`h = tetramesh(...)` returns a vector of tetrahedron handles. Each element of `h` is a handle to the set of patches forming one tetrahedron. You can use these handles to view a particular tetrahedron by turning the patch `'Visible'` property `'on'` or `'off'`.

`tetramesh(...,'param','value','param','value'...)` allows additional patch property name/property value pairs to be used when displaying the tetrahedrons. For example, the default transparency parameter is set to `0.9`. You can overwrite this value by using the property name/property value pair `('FaceAlpha',value)` where `value` is a number between `0` and `1`. See Patch Properties for information about the available properties.

Examples

Plot Tetrahedrons of 3-D Delaunay Triangulation

Generate a 3-D Delaunay triangulation, then use `tetramesh` to visualize the tetrahedrons.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d); % a cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
```

`[x,y,z]` are corners of a cube plus the center.

```
DT = delaunayTriangulation(x,y,z);
tetramesh(DT);
camorbit(20,0)
```

Introduced before R2006a

matlab.unittest.Test class

Package: matlab.unittest
Superclasses: matlab.unittest.TestSuite

Specification of a single test method

Description

The `matlab.unittest.Test` class holds the information needed for the `TestRunner` object to be able to run a single `Test` method of a `TestCase` class. A scalar `Test` instance is the fundamental element contained in `TestSuite` arrays. A simple array of `Test` instances is a commonly used form of a `TestSuite` array.

Properties

`Name`

Name of the `Test` element.

`Parameterization`

Row vector of parameters required for the `Test`. The `Parameterization` property contains all the parameterized data needed by the `TestRunner`.

`SharedTestFixtures`

Row vector of fixtures required for the `Test`. The `SharedTestFixtures` property contains all the fixtures specified by the `SharedTestFixtures` class-level attribute of the `TestCase` class.

Examples

Show Class of a TestSuite Array

Create a suite of `Test` objects of all test methods in the `BankAccountTest` class.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?BankAccountTest);

whos suite
```

```
  Name       Size            Bytes  Class                    Attributes

  suite      1x5              1636  matlab.unittest.Test
```

Each test is a `matlab.unittest.Test` object.

Display test method names.

```
{suite.Name}'
```

```
ans =

    'BankAccountTest/testConstructor'
    'BankAccountTest/testConstructorNotEnoughInputs'
    'BankAccountTest/testDesposit'
    'BankAccountTest/testWithdraw'
    'BankAccountTest/testNotifyInsufficientFunds'
```

See Also

`matlab.unittest.TestSuite` | `matlab.unittest.TestRunner` | `matlab.unittest.TestCase` | `matlab.unittest.fixtures`

matlab.unittest.TestCase class

Package: matlab.unittest

Superclass of all `matlab.unittest` test classes

Description

The `TestCase` class is the means by which a test is written in the `matlab.unittest` framework. It provides the means to write and identify test content, as well as test fixture setup and teardown routines. Creating such a test requires deriving from `TestCase` to produce a `TestCase` subclass. Then, subclasses can leverage the metadata attributes to specify tests and test fixtures.

Construction

Note: The ability to directly construct `TestCase` instances by calling the `matlab.unittest.TestCase` constructor will be removed in a future release. For interactive, command line use, instantiate a `TestCase` using the `forInteractiveUse` static method.

Use the `forInteractiveUse` static method to create a `TestCase` for interactive, command line use. When tests are run in the framework, `TestCase` instances are constructed by the `matlab.unittest.TestRunner`.

Methods

addTeardown	Dynamically add teardown routine
applyFixture	Use fixture with `TestCase`
forInteractiveUse	Create TestCase for interactive use

getSharedTestFixtures	Provide access to shared test fixtures
log	Record diagnostic information
run	Run `TestCase` test

Inherited Methods

The `TestCase` class inherits methods from the following classes:

matlab.unittest.qualifications.Assertable	Qualification to validate preconditions of a test
matlab.unittest.qualifications.Assumable	Qualification to filter test content
matlab.unittest.qualifications.FatalAssertable	Qualification to abort test execution
matlab.unittest.qualifications.Verifiable	Qualification to produce soft-failure conditions

Attributes

Class Attributes

`TestCase` objects support the following class level attributes. Specify class-level attributes in the `classdef` block before the class name.

`SharedTestFixtures`	Class block to contain shared test fixtures. You must define `SharedTestFixtures` as a cell array of `matlab.unittest.fixtures.Fixture` instances.

`TestTags`	Class block to contain tests tagged with a specified value. You must define `TestTags` as a cell array of non-empty strings, where each string is a tag for the test.

Method Attributes

Classes that derive from `TestCase` can define `methods` blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

`Test`	Method block to contain test methods.
`TestMethodSetup`	Method block to contain setup code.
`TestMethodTeardown`	Method block to contain teardown code.
`TestClassSetup`	Method block to contain class level setup code.
`TestClassTeardown`	Method block to contain class level teardown code.
`ParameterCombination`	Method block to contain parameterized testing code. This attribute accepts the following values: • `'exhaustive'` (default): Test methods are invoked for all combinations of parameters. • `'sequential'`: Test methods are invoked with corresponding values from each parameter. Each parameter must contain the same number of values. • `'pairwise'`: Test methods are invoked for every pair of parameter values at least once.
`TestTags`	Method block to contain tests tagged with a specified value. You must define `TestTags` as a cell array of non-empty strings, where each string is a tag for the test.

Property Attributes

Classes that derive from `TestCase` can define `properties` blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

`ClassSetupParameter`	Property block to define parameterized testing properties for methods in the `TestClassSetup` block
`MethodSetupParameter`	Property block to define parameterized testing properties for methods in the`MethodSetup` block
`TestParameter`	Property block to define parameterized testing properties for methods in the `Test` block

Events

`VerificationFailed`	Triggered upon failing verification. A `QualificationEventData` object is passed to listener callback functions.
`VerificationPassed`	Triggered upon passing verification. A `QualificationEventData` object is passed to listener callback functions.
`AssertionFailed`	Triggered upon failing assertion. A `QualificationEventData` object is passed to listener callback functions.
`AssertionPassed`	Triggered upon passing assertion. A `QualificationEventData` object is passed to listener callback functions.
`FatalAssertionFailed`	Triggered upon failing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.
`FatalAssertionPassed`	Triggered upon passing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.

`AssumptionFailed`	Triggered upon failing assumption. A `QualificationEventData` object is passed to listener callback functions.
`AssumptionPassed`	Triggered upon passing assumption. A `QualificationEventData` object is passed to listener callback functions.
`ExceptionThrown`	Triggered by the `TestRunner` when an exception is thrown. An `ExceptionEventData` object is passed to listener callback functions.
`DiagnosticLogged`	Triggered by the `TestRunner` upon a call to the `log` method. A `LoggedDiagnosticEventData` object is passed to the listener callback functions.

Examples

Create Test Case Class

Create a test case class, `FigurePropertiesTest`, with `TestMethodSetup` and `TestMethodTeardown` methods.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

    properties
        TestFigure
    end

    methods(TestMethodSetup)
        function createFigure(testCase)
            testCase.TestFigure = figure;
        end
    end

    methods(TestMethodTeardown)
        function closeFigure(testCase)
            close(testCase.TestFigure)
        end
    end
```

```
    methods(Test)

        function defaultCurrentPoint(testCase)

            cp = testCase.TestFigure.CurrentPoint;
            testCase.verifyEqual(cp, [0 0], ...
                'Default current point is incorrect')
        end

        function defaultCurrentObject(testCase)
            import matlab.unittest.constraints.IsEmpty

            co = testCase.TestFigure.CurrentObject;
            testCase.verifyThat(co, IsEmpty, ...
                'Default current object should be empty')
        end

    end

end
```

More About

- “Method Attributes”
- “Class Attributes”

Introduced in R2013a

addTeardown

Class: matlab.unittest.TestCase
Package: matlab.unittest

Dynamically add teardown routine

Syntax

```
addTeardown(testCase,tearDownFcn)
addTeardown(testCase,tearDownFcn,arg1,...,argN)
```

Description

`addTeardown(testCase,tearDownFcn)` adds the tearDownFcn function handle that defines fixture teardown code to the testCase instance. The teardown code is executed in the reverse order to which it is added. This is known as LIFO (or Last-In-First-Out).

`addTeardown(testCase,tearDownFcn,arg1,...,argN)` provides input arguments to the `tearDownFcn`.

Input Arguments

`testCase`

`matlab.unittest.TestCase` instance

Default:

`tearDownFcn`

Function, specified as a function handle, that defines the fixture teardown code

Default:

`arg1,...,argN`

Input arguments, 1 through N (if any), required by tearDownFcn, specified by any type. The argument type is specified by the function argument list.

Default:

Examples

Call addTeardown in a TestMethodSetup Method

```
classdef SomeTest < matlab.unittest.TestCase

    methods(TestMethodSetup)
        function createFixture(testCase)
            p = path;
            testCase.addTeardown(@path, p);
            addpath(fullfile(pwd,'testHelpers'));
        end
    end
end
```

applyFixture

Class: matlab.unittest.TestCase
Package: matlab.unittest

Use fixture with `TestCase`

Syntax

```
applyFixture(testCase,fixture)
```

Description

`applyFixture(testCase,fixture)` prepares the specified fixture for use with the `TestCase`. This method enables the use of a fixture within the scope of a single `Test` method or `TestCase` class. The life cycle of the fixture is tied to the `TestCase`. When the `TestCase` goes out of scope, the test framework tears down the fixture.

Call `applyFixture` within a `Test` method or `TestMethodSetup` method to use a fixture for the current test method alone. Use `applyFixture` within a `TestClassSetup` method to set up a fixture for the entire class.

Input Arguments

`testCase`

`matlab.unittest.TestCase` instance

`fixture`

`matlab.unittest.fixtures.Fixture` instance

Examples

Apply Fixtures to `TestCase` Class

Create a temporary folder and make it the current working folder.

```
classdef applyFixtureTest < matlab.unittest.TestCase
    methods(TestMethodSetup)
        function addHelpers(testCase)
            import matlab.unittest.fixtures.TemporaryFolderFixture;
            import matlab.unittest.fixtures.CurrentFolderFixture;

            % Create a temporary folder and make it the current working
            % folder.
            tempFolder = testCase.applyFixture(TemporaryFolderFixture);
            testCase.applyFixture(CurrentFolderFixture(tempFolder.Folder));
        end
    end
end
```

Each test method can write files to the current working folder, which is the temporary folder. After each test method runs, the test framework restores the working folder to its previous state and deletes the temporary folder.

`matlab.unittest.fixtures`

matlab.unittest.TestCase.forInteractiveUse

Class: matlab.unittest.TestCase
Package: matlab.unittest

Create TestCase for interactive use

Syntax

```
tc = matlab.unittest.TestCase.forInteractiveUse
```

Description

`tc = matlab.unittest.TestCase.forInteractiveUse` creates a `TestCase` instance for interactive use. The `TestCase` is configured for experimentation at the command prompt. It reacts to qualification tests by printing messages to the screen for both passing and failing conditions.

Examples

Verify Values Using Interactive TestCase

Create a `TestCase` for interactive use.

```
import matlab.unittest.TestCase;
testCase = TestCase.forInteractiveUse;
```

Produce a passing verification.

```
testCase.verifyTrue(true, 'true should be true');
```

```
Interactive verification passed.
```

Produce a failing verification.

```
testCase.verifyTrue(false);
```

```
Interactive verification failed.
```

```
---------------------
Framework Diagnostic:
---------------------
verifyTrue failed.
--> The value must evaluate to "true".

Actual Value:
         0
```

`matlab.unittest.TestCase` | `matlab.unittest.qualifications`

Introduced in R2014a

getSharedTestFixtures

Class: matlab.unittest.TestCase
Package: matlab.unittest

Provide access to shared test fixtures

Syntax

```
fixtures = getSharedTestFixtures(testCase)
fixtures = getSharedTestFixtures(testCase,fixtureClassName)
```

Description

`fixtures = getSharedTestFixtures(testCase)` provides access to the array of all shared test fixtures for `testCase`. `getSharedTestFixtures` returns an array of fixture objects, `fixtures`. Specify shared fixtures are using the `SharedTestFixtures` attribute for the `testCase` class.

`fixtures = getSharedTestFixtures(testCase,fixtureClassName)` returns only the shared fixtures that have the class name `fixtureClassName`.

Input Arguments

`testCase`

`matlab.unittest.TestCase` instance

Default:

`fixtureClassName`

Name of test fixture class, specified as a string

Examples

Obtain Array of All Shared Fixtures

Create the following class, `myTest`, on your MATLAB path. Two shared fixtures are used within the test method. This example assumes that the subfolder `helperFiles` exists in your working folder. Create the subfolder `helperFiles` in your working folder if it does not exist.

```
classdef (SharedTestFixtures={...
matlab.unittest.fixtures.PathFixture('helperFiles'),...
        matlab.unittest.fixtures.TemporaryFolderFixture}) ...
        myTest < matlab.unittest.TestCase
    methods(Test)
        function accessFixtures(testCase)
            myFixtures = testCase.getSharedTestFixtures
        end
    end
end
```

At the command prompt, run the test.

```
run(myTest);
```

```
Setting up PathFixture.
Description: Adds 'H:\Documents\doc_examples\helperFiles' to the path.
__________

Setting up TemporaryFolderFixture.
Description: Creates a temporary folder.
__________

Running myTest

myFixtures =

  1x2 heterogeneous Fixture (PathFixture, TemporaryFolderFixture) array with no propert

.
Done myTest
__________

Tearing down TemporaryFolderFixture.
```

```
Description: Deletes the temporary folder and all its contents.
__________

Tearing down PathFixture.
Description: Restores the path to its previous state.
__________
```

Access Shared Fixtures of Particular Class

Create the class, `mySecondTest`, on your MATLAB path.

```
classdef (SharedTestFixtures={...
        matlab.unittest.fixtures.TemporaryFolderFixture})...
        mySecondTest < matlab.unittest.TestCase
    methods(Test)
        function accessTemporaryFolderFixture(testCase)
            tempFolderFixture = testCase.getSharedTestFixtures...
                ('matlab.unittest.fixtures.TemporaryFolderFixture');
            temporaryFolder = tempFolderFixture.Folder
        end
    end
end
```

At the command prompt, run the test. The name of the temporary folder varies.

```
run(mySecondTest);
```

```
Setting up TemporaryFolderFixture.
Description: Creates a temporary folder.
__________

Running mySecondTest

temporaryFolder =

C:\Temp\tpb92c9c67_02fa_4714_bfb0_b2127df0f31d

.
Done mySecondTest
__________

Tearing down TemporaryFolderFixture.
Description: Deletes the temporary folder and all its contents.
```

More About

- Class Attributes

log

Class: matlab.unittest.TestCase
Package: matlab.unittest

Record diagnostic information

Syntax

```
log(testCase,diagnostic)
log(testCase,v,diagnostic)
```

Description

`log(testCase,diagnostic)` logs the supplied diagnostic. The log method provides a means for tests to log information during their execution. The testing framework displays logged messages only if you configure it to do so by adding an appropriate plugin, such as the `matlab.unittest.plugins.LoggingPlugin`.

`log(testCase,v,diagnostic)` logs the diagnostic at the specified verbosity level, `v`.

Input Arguments

`testCase` — Instance of test case

`matlab.unittest.TestCase` instance

Instance of test case, specified as a `matlab.unittest.TestCase`.

`diagnostic` — Diagnostic information to display upon a failure

string | function handle | `matlab.unittest.diagnostics.Diagnostic` instance

Diagnostic information to display upon a failure, specified as a string, function handle, or `matlab.unittest.diagnostics.Diagnostic` instance.

`v` — Verbosity level

2 (default) | 1 | 3 | 4 | `matlab.unittest.Verbosity` enumeration

Verbosity level, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The default verbosity level for diagnostic messages is `Concise`. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Member	Verbosity Description
1	`matlab.unittest.Verbosity.Terse`	minimal amount of information
2	`matlab.unittest.Verbosity.Concis`	typical amount of information
3	`matlab.unittest.Verbosity.Detail`	supplemental amount of information
4	`matlab.unittest.Verbosity.Verbos`	surplus of information

Examples

Log Diagnostic Information

Create a function-based test in a file, `sampleLogTest.m`, in your working folder.

```
function tests = sampleLogTest
tests = functiontests(localfunctions);

function svdTest(testCase)
import matlab.unittest.Verbosity

log(testCase,'Generating matrix.');
m = rand(1000);

log(testCase,1,'About to call SVD.');
[U,S,V] = svd(m);

log(testCase,Verbosity.Terse,'SVD finished.');

verifyEqual(testCase,U*S*V',m,'AbsTol',1e-6)
```

At the command prompt, run the test.

```
results = run(sampleLogTest);
```

```
Running sampleLogTest
   [Terse] Diagnostic logged (2014-04-14T14:20:59): About to call SVD.
   [Terse] Diagnostic logged (2014-04-14T14:20:59): SVD finished.
.
Done sampleLogTest
__________
```

The default runner reports the diagnostics at level 1 (`Terse`).

Create a test runner to report the diagnostics at levels 1 and 2, and rerun the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.plugins.LoggingPlugin

runner = TestRunner.withNoPlugins;
p = LoggingPlugin.withVerbosity(2);
runner.addPlugin(p);

results = runner.run(sampleLogTest);
```

```
 [Concise] Diagnostic logged (2014-04-14T14:28:14): Generating matrix.
   [Terse] Diagnostic logged (2014-04-14T14:28:14): About to call SVD.
   [Terse] Diagnostic logged (2014-04-14T14:28:15): SVD finished.
```

`matlab.unittest.plugins.LoggingPlugin` | `matlab.unittest.Verbosity`

Introduced in R2014b

run

Class: matlab.unittest.TestCase
Package: matlab.unittest

Run `TestCase` test

Syntax

```
result = run(testCase)
result = run(testCase,testMethod)
```

Description

`result = run(testCase)` uses testCase as a prototype to run a `TestSuite` array created from all test methods in the class defining testCase. This suite is run using a `TestRunner` object configured for text output.

`result = run(testCase,testMethod)` uses testCase as a prototype to run a `TestSuite` array created from testMethod. This test is run using a `TestRunner` object configured for text output.

This is a convenience method to allow interactive experimentation of `TestCase` classes in MATLAB, yet running the tests contained in them using a supported `TestRunner` object.

Input Arguments

`testCase`

`matlab.unittest.TestCase` instance

Default:

`testMethod`

Name of desired test method, specified as one of the following:

- string
- `meta.method` instance

The method must correspond to a valid `Test` method of the testCase instance.

Default:

Output Arguments

`result`

A `matlab.unittest.TestResult` object containing the result of the test run.

Examples

Run Test Directly from Test Case

Add the `FigurePropertiesTest.m` test case file to a folder on your MATLAB path.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

    properties
        TestFigure
    end

    methods(TestMethodSetup)
        function createFigure(testCase)
            % comment
            testCase.TestFigure = figure;
        end
    end

    methods(TestMethodTeardown)
        function closeFigure(testCase)
            close(testCase.TestFigure)
        end
    end

    methods(Test)
```

```
        function defaultCurrentPoint(testCase)

            cp = testCase.TestFigure.CurrentPoint;
            testCase.verifyEqual(cp, [0 0], ...
                'Default current point is incorrect')
        end

        function defaultCurrentObject(testCase)
            import matlab.unittest.constraints.IsEmpty

            co = testCase.TestFigure.CurrentObject;
            testCase.verifyThat(co, IsEmpty, ...
                'Default current object should be empty')
        end

    end

end
```

Create a testcase object.

```
tc = FigurePropertiesTest;
```

Run the tests.

```
tc.run;
```

```
Running FigurePropertiesTest
..
Done FigurePropertiesTest
__________
```

All tests passed.

See Also

`matlab.unittest.TestSuite.run` | `matlab.unittest.TestRunner.run`

matlab.unittest.TestResult class

Package: matlab.unittest

Result of running test suite

Description

The `matlab.unittest.TestResult` class holds the information describing the result of running a test suite using the `matlab.unittest` framework. The results include information describing whether the test passed, failed, or ran to completion, as well as the duration of each test.

Construction

`TestResult` arrays are created and returned by the test runner, and are of the same size as the suite which was run.

Properties

`Duration`

Time elapsed running test.

The `Duration` property indicates the amount of time taken to run a particular test, including the time taken setting up and tearing down any test fixtures.

Fixture setup time is accounted for in the duration of the first test suite array element that uses the fixture. Fixture teardown time is accounted for in the duration of the last test suite array element that uses the fixture.

The total run time for a suite of tests exceeds the sum of the durations for all the elements of the suite because the `Duration` property does not include all the overhead of the `TestRunner` object, nor any of the time consumed by test runner plugins.

`Failed`

Logical value showing if test failed.

A TRUE `Failed` property indicates some form of test failure. When `Failed` is FALSE, then no failing conditions were encountered. A failing result can occur with a failure condition either in a test or in setting up and tearing down test fixtures. Failures can occur due to the following:

- Verification failures
- Assertion failures
- Uncaught MExceptions

Fatal assertions are also failing conditions, but in the event of a fatal assertion failure, the entire framework aborts and a `TestResult` object is never produced.

`Incomplete`

Logical value showing if test did not run to completion.

A TRUE `Incomplete` property indicates a test did not run to completion. When it is FALSE, then no conditions were encountered that prevented the test from completing. In other words, when FALSE there were no stack disruptions out of the running test content. An incomplete result can occur with a stack disruption in either a test or when setting up and tearing down test fixtures. Incomplete tests can occur due to the following:

- Assertion failures
- Tests filtered through assumption
- Uncaught MExceptions

Fatal assertions are also conditions that prevent the completion of tests, but in the event of a fatal assertion failure the entire framework aborts and a `TestResult` object is never produced.

`Name`

The name of the `TestSuite` object for the result.

The `Name` property is a string that holds the name of the test corresponding to this result.

`Passed`

Logical value showing if the test passed.

When the `Passed` property is TRUE, then the test completed as expected without any failure. When it is FALSE, then the test did not run to completion and/or encountered a failure condition.

Tips

- Create a table from the `TestResult` object for access to `table` functionality such as sorting rows, displaying a summary, and writing the table to a file. For example,

  ```
  rt = table(results);
  ```

Examples

Use TestResult Object to Identify and Rerun Failed Tests

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

Result display method provides a summary of the results

```
suite = TestSuite.fromClass(?SomeTestClass)
results = run(suite)

results =

  matlab.unittest.TestResult

  Test Suite Summary:
    12 Passed, 4 Failed, 0 Not Run To Completion.
    5.5091 seconds testing time.
```

Rerun only the failed tests.

```
failedTests = suite([results.Failed]);
failedResults = run(failedTests)

failedResults =

  matlab.unittest.TestResult

  Test Suite Summary:
    0 Passed, 4 Failed, 0 Not Run To Completion.
    1.2894 seconds testing time.
```

Make the fix and rerun results.

```
newResults = run(failedTests)

newResults =

  matlab.unittest.TestResult

  Test Suite Summary:
    4 Passed, 0 Failed, 0 Not Run To Completion.
    1.1607 seconds testing time.
```

`table` | `TestRunner` | `TestSuite`

More About

- Property Attributes

matlab.unittest.TestRunner class

Package: matlab.unittest

Class for running tests in `matlab.unittest` framework

Description

The `matlab.unittest.TestRunner` class is the fundamental API used to run a suite of tests in the `matlab.unittest` framework. It runs and operates on `TestSuite` arrays. Use this class to customize running tests.

The `TestRunner` class is a sealed class; you cannot derive classes from the `TestRunner` class.

Construction

To create a simple, silent `TestRunner` object, call the static `withNoPlugins` method.

```
runner = matlab.unittest.TestRunner.withNoPlugins
```

To create a `TestRunner` object to run tests from the MATLAB Command Window, call the static `withTextOutput` method.

```
runner = matlab.unittest.TestRunner.withTextOutput
```

To create a customized `TestRunner` object, call the `addPlugin` method.

```
runner = TestRunner.withNoPlugins;
runner.addPlugin(SomePlugin())
```

Properties

`PrebuiltFixtures` — Fixtures set up outside the test runner

scalar `Fixture` instance | row vector of `Fixture` instances

Fixtures that are set up outside the test runner, specified as a scalar or row vector of `matlab.unittest.fixture.Fixture` instances. Use this property to specify that the

environmental configuration is performed manually instead of automatically during fixture setup and teardown.

The test runner considers these fixtures as already set up and never attempts to set up or tear down any fixtures specified by the `PrebuiltFixtures` property. If a test suite requires a shared test fixture and that test fixture is specified as a prebuilt fixture, the test runner does not perform set up or tear down actions.

Note: The test runner uses a prebuilt fixture only if it is specified by the `PrebuiltFixtures` property and is listed as a `SharedTestFixture` in the test class definition. The test runner does not use a prebuilt fixture if the fixture is registered using the `TestCase.applyFixture` method.

Methods

addPlugin	Add plugin to `TestRunner` object
run	Run all tests in `TestSuite` array
runInParallel	Run all tests in `TestSuite` array in parallel
withNoPlugins	Create simplest runner possible
withTextOutput	Create `TestRunner` object for command window output

Examples

Create TestRunner Object Configured for Text Output

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
```

```
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create the `TestRunner` object and run the suite.

```
runner = TestRunner.withTextOutput;
result = run(runner,suite);
```

Include Prebuilt Fixture

This example uses a shared test fixture and then specifies the fixture as prebuilt. The test runner does not set up and tear down the prebuilt fixture. Since the test assumes that the fixture exists, you must manually perform the setup work that the fixture ordinarily performs.

Create a test class in a file in your working folder. The test class uses a `PathFixture` as a shared test fixture. This example assumes that the subfolder, `helperFiles`, exists in your working folder.

```
classdef (SharedTestFixtures={ ...
        matlab.unittest.fixtures.PathFixture('helperFiles')}) ...
        SampleTest < matlab.unittest.TestCase
    methods(Test)
        function test1(testCase)
            f = testCase.getSharedTestFixtures;

            import matlab.unittest.constraints.ContainsSubstring
            testCase.assertThat(path,ContainsSubstring(f.Folder))
        end
    end
end
```

Create a test suite and test runner at the command prompt.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?SampleTest);
runner = TestRunner.withTextOutput;
```

Run the tests using the shared test fixture. In this case, the fixture is not prebuilt.

```
runner.run(suite);
```

```
Setting up PathFixture
Done setting up PathFixture: Added 'C:\Work\helperFiles' to the path.
__________

Running SampleTest
.
Done SampleTest
__________

Tearing down PathFixture
Done tearing down PathFixture: Restored the path to its original state.
__________
```

The test runner sets up and tears down the shared test fixture.

Create an instance of the fixture and add it to the test runner.

```
f = matlab.unittest.fixtures.PathFixture('helperFiles');
runner.PrebuiltFixtures = f;
```

Manually add the `'helperFiles'` folder to your path. The `PathFixture` adds the specified folder to your path, and the tests rely on this setup action. However, since the fixture is defined as prebuilt, the test runner does not perform set up or tear down actions, and you must perform them manually. In this case, if you do not manually add it to your path, the test fails.

```
p = fullfile(pwd,'helperFiles');
oldPath = addpath(p);
```

Run the tests.

```
runner.run(suite);
```

```
Running SampleTest
.
Done SampleTest
__________
```

The test runner assumes that the fixture is prebuilt and does not set it up or tear it down.

Manually reset your path.

```
path(oldPath)
```

`TestResult` | `TestSuite`

Introduced in R2013a

addPlugin

Class: matlab.unittest.TestRunner
Package: matlab.unittest

Add plugin to `TestRunner` object

Syntax

```
addPlugin(runner,plugin)
```

Description

`addPlugin(runner,plugin)` adds plugin to runner.

Input Arguments

`runner`

`matlab.unittest.TestRunner` object.

Default:

`plugin`

Mechanism provided to customize the manner in which a `TestSuite` array is run, specified as a `TestRunnerPlugin` object.

Default:

Examples

Run Test with Custom Plugin

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a `TestRunner` object.

```
runner = TestRunner.withNoPlugins;
```

Add a custom plugin.

```
import matlab.unittest.plugins.DiagnosticsValidationPlugin;
runner.addPlugin(DiagnosticsValidationPlugin);
```

Run the test.

```
result = run(runner,suite);
```

run

Class: matlab.unittest.TestRunner
Package: matlab.unittest

Run all tests in `TestSuite` array

Syntax

```
result = run(runner,suite)
```

Description

`result = run(runner,suite)` runs the `TestSuite` array defined by suite using the `TestRunner` object provided in runner, and returns the result in result.

This method runs all of the appropriate methods of the `TestCase` class to set up fixtures and run test content. It handles errors and qualification failures and records the information in result.

Input Arguments

`runner`

`matlab.unittest.TestRunner` object.

Default:

`suite`

Set of tests, specified as a `matlab.unittest.TestSuite` array.

Output Arguments

`result`

A `matlab.unittest.TestResult` object containing the result of the test run. result is the same size as suite and each element is the result of the corresponding element in suite.

Examples

Run All Tests in a Package

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a test suite, and a test runner that displays text.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
runner = TestRunner.withTextOutput;
```

Run the test suite.

```
result = runner.run(suite)
```

See Also

`matlab.unittest.TestSuite.run` | `matlab.unittest.TestCase.run`

runInParallel

Class: matlab.unittest.TestRunner
Package: matlab.unittest

Run all tests in `TestSuite` array in parallel

Syntax

```
result = runInParallel(runner,suite)
```

Description

`result = runInParallel(runner,suite)` runs all tests in the `TestSuite` array in parallel and returns the results in a `TestResult` object. The `runInParallel` method divides `suite` into separate groups and uses `runner` to run each group on the current parallel pool.

Note: The `runInParallel` method requires the Parallel Computing Toolbox. The testing framework might vary the order and number of groups or which tests it includes in each group.

When you select a test suite to run in parallel, consider possible resource contention. For example, if your test fixtures access global resources, such as a shared file on the same network, the parallel sessions could conflict with each other. In such cases, consider using a prebuilt shared test fixture.

Input Arguments

`runner` — Test runner for parallel test groups

`matlab.unittest.TestRunner` instance

Test runner for parallel test groups, specified as a `matlab.unittest.TestRunner` instance.

Consider your test runner configuration before running tests in parallel. Since the `runInParallel` method runs separate groups of tests on different workers, some plugins, such as `StopOnFailuresPlugin` or `CodeCoveragePlugin`, are not well suited for parallelization. The framework does not support running parallelized tests using a test runner with a custom plugin.

`suite` — Set of tests to run in parallel
`matlab.unittest.Test` array

Set of tests to run in parallel, specified as a `matlab.unittest.Test` array.

Examples

Run Tests in Parallel

Create the following parameterized test in a file in your current working folder.

```
classdef TestRand < matlab.unittest.TestCase
    properties (TestParameter)
        dim1 = createDimensionSizes;
        dim2 = createDimensionSizes;
        dim3 = createDimensionSizes;
        type = {'single','double'};
    end

    methods (Test)
        function testRepeatable(testCase,dim1,dim2,dim3)
            state = rng;
            firstRun = rand(dim1,dim2,dim3);
            rng(state)
            secondRun = rand(dim1,dim2,dim3);
            testCase.verifyEqual(firstRun,secondRun);
        end
        function testClass(testCase,dim1,dim2,type)
            testCase.verifyClass(rand(dim1,dim2,type),type)
        end
    end
end

function sizes = createDimensionSizes
% Create logarithmicly spaced sizes up to 100
sizes = num2cell(round(logspace(0,2,10)));
end
```

At the command prompt, create a suite from `TestRand.m` and a test runner that displays text in the Command Window.

```
suite = matlab.unittest.TestSuite.fromClass(?TestRand);
runner = matlab.unittest.TestRunner.withTextOutput();
```

The suite contains 1200 test elements.

Run the test suite in parallel.

```
result = runInParallel(runner,suite)
```

```

More About

- “Key Problems Addressed by Parallel Computing”

Introduced in R2015a

matlab.unittest.TestRunner.withNoPlugins

Class: matlab.unittest.TestRunner
Package: matlab.unittest

Create simplest runner possible

Syntax

```
runner = matlab.unittest.TestRunner.withNoPlugins
```

Description

`runner = matlab.unittest.TestRunner.withNoPlugins` creates a TestRunner that is guaranteed to have no plugins installed and returns it in runner. It is the method one can use to create the simplest runner possible without violating the guarantees a test writer has when writing TestCase classes. This runner is a silent runner, meaning that regardless of passing or failing tests, this runner produces no command window output, although the results returned after running a test suite are accurate.

This method can also be used when it is desirable to have complete control over which plugins are installed and in what order. It is the only method guaranteed to produce the minimal TestRunner with no plugins, so one can create it and add additional plugins as desired.

Output Arguments

`runner`

`matlab.unittest.TestRunner` object.

Default:

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Create a Silent TestRunner Object with no Plugins

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a `TestRunner` object.

```
runner = TestRunner.withNoPlugins;

% Run the suite silently
result = run(runner,suite)
```

Control Plugins

Using the `TestRunner` object created in the previous example, control which plugins are installed and in what order they are installed.

Add `matlab.unittest` class to the current import list.

```
import matlab.unittest.plugins;
```

Add specific plugins.

```
runner.addPlugin(DiagnosticsValidationPlugin);
runner.addPlugin(TestRunProgressPlugin.withVerbosity(2));
```

Rerun the tests.

```
result = run(runner,suite)
```

matlab.unittest.TestRunner.withTextOutput

Class: matlab.unittest.TestRunner
Package: matlab.unittest

Create `TestRunner` object for command window output

Syntax

```
runner = matlab.unittest.TestRunner.withTextOutput
runner = matlab.unittest.TestRunner.withTextOutput('Verbosity',v)
```

Description

`runner = matlab.unittest.TestRunner.withTextOutput` creates a `TestRunner` object that is configured for running tests from the MATLAB Command Window and returns it in runner. The output produced includes test progress as well as diagnostics in the event of test failures.

`runner = matlab.unittest.TestRunner.withTextOutput('Verbosity',v)` reacts to messages logged at or below the specified verbosity level and controls the level of detail about the test run that is displayed in the Command Window.

Input Arguments

v — Verbosity levels supported by test runner

`1 | 2 | 3 | 4 | matlab.unittest.Verbosity` enumeration

Verbosity levels supported by the test runner, specified as an integer value between 1 and 4 or a `matlab.unittest.Verbosity` enumeration object. The runner reacts to diagnostics that are logged at this level and lower. Integer values correspond to the members of the `matlab.unittest.Verbosity` enumeration.

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
1	`matlab.unittest.Verbosity.Terse`	Minimal amount of information

Numeric Representation	Corresponding Enumeration Object	Verbosity Description
2	`matlab.unittest.Verbosity.Concise`	Typical amount of information
3	`matlab.unittest.Verbosity.Detailed`	Supplemental amount of information
4	`matlab.unittest.Verbosity.Verbose`	Surplus of information

Output Arguments

`runner`

`matlab.unittest.TestRunner` object.

Default:

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Display Test Results in Command Window

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a `TestSuite` array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a `TestRunner` object that produced output to the Command Window.

```
runner = TestRunner.withTextOutput;

% Run the suite
result = run(runner,suite)
```

Specify Output Verbosity

Create the follow class In a file in your current working folder, `ExampleLogTest.m`.

```
classdef ExampleLogTest < matlab.unittest.TestCase
    methods(Test)
        function testOne(testCase)
            log(testCase,matlab.unittest.Verbosity.Detailed,'Starting Test')
            log(testCase,'Testing 5==5')
            testCase.verifyEqual(5,5)
            log(testCase,matlab.unittest.Verbosity.Verbose,'Test Complete')
        end
    end
end
```

At the command prompt, run the test.

```
result = run(ExampleLogTest);
```

```
Running ExampleLogTest
.
Done ExampleLogTest
__________
```

Create a test runner to display logged messages at verbosity level 4 and lower, and then run the test.

```
import matlab.unittest.TestRunner
import matlab.unittest.TestSuite
suite = TestSuite.fromClass(?ExampleLogTest);
runner = TestRunner.withTextOutput('Verbosity',4);

results = runner.run(suite);
```

```
 Running ExampleLogTest
  Setting up ExampleLogTest
  Done setting up ExampleLogTest in 0 seconds
   Running ExampleLogTest/testOne
    Evaluating Test: testOne
[Detailed] Diagnostic logged (2014-04-18T14:28:19): Starting Test
```

```
 [Concise] Diagnostic logged (2014-04-18T14:28:19): Testing 5==5
 [Verbose] Diagnostic logged (2014-04-18T14:28:20): Test Complete
   Done ExampleLogTest/testOne in 0.21106 seconds
  Tearing down ExampleLogTest
  Done tearing down ExampleLogTest in 0 seconds
 Done ExampleLogTest in 0.21106 seconds
```

matlab.unittest.Verbosity | matlab.unittest.fixtures.Fixture.log | matlab.unittest.TestCase.log | run

matlab.unittest.TestSuite class

Package: matlab.unittest

Class for grouping tests to run

Description

The `matlab.unittest.TestSuite` class is the fundamental interface used to group and run a set of tests in the unit test framework. The `matlab.unittest.TestRunner` object can only run arrays of `TestSuite` objects.

Construction

`TestSuite` arrays are created using static methods of the `TestSuite` class. These methods may return subclasses of the `TestSuite` class depending on the method call and context.

Methods

fromClass	Create suite from `TestCase` class
fromFile	Create `TestSuite` array from test file
fromFolder	Create `TestSuite` array from all tests in folder
fromMethod	Create `TestSuite` array from single test method
fromName	Create `Test` object from name of test element

fromPackage	Create `TestSuite` array from all tests in package
run	Run `TestSuite` array using `TestRunner` object configured for text output
selectIf	Select test suite elements that satisfy conditions

Examples

Create Test Suite of Every Type of Test Set

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

Create test suites using each method.

```
fileSuite    = TestSuite.fromFile('SomeTestFile.m');
folderSuite  = TestSuite.fromFolder(pwd);
packageSuite = TestSuite.fromPackage('mypackage.subpackage');
classSuite   = TestSuite.fromClass(?mypackage.MyTestClass);
methodSuite  = TestSuite.fromMethod(?SomeTestClass,'testMethod');
```

Concatenate the suites.

```
largeSuite = [fileSuite, folderSuite, packageSuite, classSuite, methodSuite];
```

Run the full suite.

```
result = run(largeSuite)
```

See Also

`Test` | `TestResult` | `TestRunner`

matlab.unittest.TestSuite.fromClass

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Create suite from `TestCase` class

Syntax

```
suite = matlab.unittest.TestSuite.fromClass(testClass)
suite = matlab.unittest.TestSuite.fromClass(testClass,s)
suite = matlab.unittest.TestSuite.fromClass( ___ ,Name,Value)
```

Description

`suite = matlab.unittest.TestSuite.fromClass(testClass)` creates a `TestSuite` array from all of the `Test` methods contained in testClass and returns that array in suite.

`suite = matlab.unittest.TestSuite.fromClass(testClass,s)` creates a `TestSuite` array from all of the `Test` methods contained in testClass that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromClass( ___ ,Name,Value)` creates a `TestSuite` array with additional options specified by one or more Name,Value pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

Tips

- testClass must be on the MATLAB path when using this method to create suite, as well as when suite is run.

Input Arguments

`testClass`

Class containing test methods, specified as a `meta.class` instance. Use the `?` operator to create a `meta.class` instance. testClass must derive from `matlab.unittest.TestCase`.

`s`

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

Name-Value Pair Arguments

`'Name'`

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterProperty'`

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterName'`

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'BaseFolder'`

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one

character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

`'Tag'`

String indicating the name of the tag applied to the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character.

Output Arguments

`suite`

Set of tests, specified as a `matlab.unittest.Test` array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run Tests in a Package Class

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
result = run(suite)
```

Run Tests in a Class Without a Package

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

```
suite = TestSuite.fromClass(?MyTestClass);
result = run(suite)
```

Create Suite of Test Elements Using Selector

In your working folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
        type = {'single','double','uint16'};
        outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the test elements that tests the `'double'` data type.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromClass(?testZeros, ...
```

```
    HasParameter('Property','type','Name','double'));
{suite.Name}'

ans =

    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
```

Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from the test elements that tests the `'double'` data type.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?testZeros, ...
    'ParameterProperty','type', 'ParameterName','double');
{suite.Name}'

ans =

    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
```

See Also

`fromMethod` | `fromPackage` | `matlab.unittest.selectors` | `TestRunner`

Introduced in R2013a

matlab.unittest.TestSuite.fromFile

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Create `TestSuite` array from test file

Syntax

```
suite = matlab.unittest.TestSuite.fromFile(file)
suite = matlab.unittest.TestSuite.fromFile(file,s)
suite = matlab.unittest.TestSuite.fromFile( ___ ,Name,Value)
```

Description

`suite = matlab.unittest.TestSuite.fromFile(file)` creates a `TestSuite` array from all of the tests in file. When the test suite is run, MATLAB changes the current folder to the folder that defines the test content, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFile(file,s)` creates a `TestSuite` array from all of the tests in file that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromFile( ___ ,Name,Value)` creates a `TestSuite` array with additional options specified by one or more Name,Value pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

Input Arguments

`file`

Test file, specified as a string.

`s`

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Name'`

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterProperty'`

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterName'`

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'BaseFolder'`

String indicating the name of the folder that contains the file defining the tests. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

`'Tag'`

String indicating the name of the tag applied to the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character.

Output Arguments

`suite`

Set of tests, specified as a `matlab.unittest.Test` array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run Tests in Class File

Function for unit testing:

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.')
end
res = x + 5;
end
```

`TestCase` class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
    methods (Test)
        function testDoubleOut(testCase)
            actOutput = add5(1);
            testCase.verifyClass(actOutput,'double')
        end
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric')
        end
    end
```

```
end
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m')
```

```
result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
__________
```

Create Suite of Test Elements Using Selector

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
        type = {'single','double','uint16'};
        outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized test methods in `testZeros.m` using the `HasParameter` selector.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromFile('testZeros.m', HasParameter)
```

```
suite =

  1x8 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   5 Unique Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

Create a test suite from only the test elements from the `testSize` method using the `HasName` selector with the `StartsWithSubstring` constraint.

```
import matlab.unittest.selectors.HasName;
import matlab.unittest.constraints.StartsWithSubstring;

suite = TestSuite.fromFile('testZeros.m',...
    HasName(StartsWithSubstring('testZeros/testSize')));
{suite.Name}'
```

```
ans =

    'testZeros/testSize(outSize=s2d)'
    'testZeros/testSize(outSize=s3d)'
```

The test suite contains the two parameterized tests from the `testSize` method.

Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all test methods in `testZeros.m` that have a name starting with `'testZeros/testSize'`. This test suite contains parameterized tests from the `testSize` method.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFile('testZeros.m', 'Name', 'testZeros/testSize*');
{suite.Name}'

ans =

    'testZeros/testSize(outSize=s2d)'
    'testZeros/testSize(outSize=s3d)'
```

To ensure that a test suite is comprised of test elements associated with one particular test method, use the `fromMethod` method of `TestSuite`.

At the command prompt, create a test suite from all test methods in `testZeros.m` that have a name ending in `'Size'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFile('testZeros.m', 'Name', '*Size');
{suite.Name}'

ans =

    'testZeros/testDefaultSize'
```

Note that elements from the `testSize` method are not included in the test suite. The name of these elements contains information about the parameterization, and therefore it does not end with `'Size'`.

Create a test suite of all tests that use the parameter name `'double'`.

```
suite = TestSuite.fromFile('testZeros.m', 'ParameterName', 'double');
{suite.Name}'

ans =

    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
```

To construct the same test suite using selectors, use `suite = TestSuite.fromFile('testZeros.m', HasParameter('Name','double'))`.

`fromFolder` | `matlab.unittest.selectors` | `TestRunner`

Introduced in R2013a

matlab.unittest.TestSuite.fromFolder

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Create `TestSuite` array from all tests in folder

Syntax

```
suite = matlab.unittest.TestSuite.fromFolder(folder)
suite = matlab.unittest.TestSuite.fromFolder(folder,s)
suite = matlab.unittest.TestSuite.fromFolder( ___ ,Name,Value)
```

Description

`suite = matlab.unittest.TestSuite.fromFolder(folder)` creates a `TestSuite` array from all of the `Test` methods of all concrete `TestCase` classes contained in folder and returns that array in suite. If tests are function-based or script-based, a `Test` file is included in the `TestSuite` array if it follows the naming convention of starting or ending in the word 'test', which is case-insensitive. Class-based tests do not need to follow this naming convention. The method is not recursive, returning only those tests directly in the specified folder.

When the test suite is run, MATLAB changes the current folder to the folder that defines the test content, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFolder(folder,s)` creates a `TestSuite` array from all of the `Test` methods contained in folder that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromFolder( ___ ,Name,Value)` creates a `TestSuite` array with additional options specified by one or more Name,Value pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

Input Arguments

`folder`

Folder containing tests, specified as a string. folder can be either an absolute or relative path to the desired folder.

`s`

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

Name-Value Pair Arguments

`'IncludingSubfolders'`

Indicator for whether to include tests from any folder subfolders, excluding package, class, and private folders, specified as `false` or `true` (`logical 0` or `1`). This property is `false` by default. You can specify it as `true` during construction.

`'Name'`

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterProperty'`

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterName'`

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'BaseFolder'`

String indicating the name of the folder that contains the file defining the tests. For a test element to be included in the suite, the test element must be contained in the

specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

`'Tag'`

String indicating the name of the tag applied to the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character.

Output Arguments

`suite`

Set of tests, specified as a `matlab.unittest.Test` array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run Tests in Current Folder

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder(pwd);
result = run(suite);
```

Run Tests in Subfolders

```
suite = TestSuite.fromFolder(pwd, 'IncludingSubfolders', true);
```

```
result = run(suite);
```

Create Suite of Test Elements Using Selector

In your working folder, create a new folder, `myTests`. In that folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
        type = {'single','double','uint16'};
        outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests that use the parameter name `'double'`.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromFolder('myTests', HasParameter('Name','double'));
{suite.Name}'
```

```
ans =

    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
```

Create Suite of Test Elements Using Name-Value Arguments

Create the `myTests` folder and `testZeros.m` class from the previous example.

Create a test suite of all tests that use the parameter name `'double'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder('myTests', 'ParameterName', 'double');
{suite.Name}'
```

```
ans =

    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
```

See Also

`fromFile` | `matlab.unittest.selectors` | `TestRunner`

Introduced in R2013a

matlab.unittest.TestSuite.fromMethod

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Create `TestSuite` array from single test method

Syntax

```
suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod)
suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod,s)
suite = matlab.unittest.TestSuite.fromMethod( ___ ,Name,Value)
```

Description

`suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod)` creates a `TestSuite` array from the test class described by testClass and the test method described by testMethod and returns it in suite.

`suite = matlab.unittest.TestSuite.fromMethod(testClass,testMethod,s)` creates a `TestSuite` array from all of the `Test` methods contained in testMethod that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromMethod( ___ ,Name,Value)` creates a `TestSuite` array with additional options specified by one or more Name,Value pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

Tips

- testClass must be on the MATLAB path when using this method to create suite, as well as when suite is run.

Input Arguments

`testClass`

Class describing the test methods, specified as a `meta.class` instance which must derive from `matlab.unittest.TestCase`.

`testMethod`

Test method, specified by either the `meta.method` instance or the name as a string. The method must be defined with a `Test` method attribute.

`s`

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

Name-Value Pair Arguments

`'Name'`

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterProperty'`

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterName'`

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'BaseFolder'`

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be

contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

`'Tag'`

String indicating the name of the tag applied to the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character.

Output Arguments

`suite`

Set of tests, specified as a `matlab.unittest.Test` array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run a Single Test Method

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

cls = ?mypackage.MyTestClass;

% Create the suite using the method name
suite = TestSuite.fromMethod(cls, 'testMethod');
result = run(suite)
```

```
% Create the suite using the meta.method instance
metaMethod = findobj(cls.MethodList, 'Name', 'testMethod');
suite = TestSuite.fromMethod(cls, metaMethod);
result = run(suite)
```

Create Suite of Test Elements Using Selector

In your working folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
        type = {'single','double','uint16'};
        outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests from the `testClass` method that use the parameter name `'single'`.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;
```

```
suite = TestSuite.fromMethod(?testZeros,'testClass', ...
    HasParameter('Name','single'));
{suite.Name}'

ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=single,outSize=s3d)'
```

Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all parameterized tests from the `testClass` method that use the parameter name `'single'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromMethod(?testZeros,'testClass', ...
    'ParameterName','single');
{suite.Name}'

ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=single,outSize=s3d)'
```

See Also

`fromClass` | `fromPackage` | `matlab.unittest.selectors` | `TestRunner`

Introduced in R2013a

matlab.unittest.TestSuite.fromName

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Create `Test` object from name of test element

Syntax

```
testObj = matlab.unittest.TestSuite.fromName(name)
```

Description

`testObj = matlab.unittest.TestSuite.fromName(name)` creates a scalar `Test` object, `testObj`, from the name of the test element, name.

Input Arguments

`name`

Name of the `matlab.unittest.Test` element, specified as a string. For class-based tests, `name` contains the name of the `TestCase` class and the test method, as well as information about parameterization. For function-based tests, `name` contains the name of the main function and the local test function. For script-based tests, `name` contains the name of the script and the title of the test section or cell. If the section does not have a title, MATLAB assigns one. The `name` argument corresponds to the `Name` property of the `Test` object.

The test class, function or script described by `name` must be on the MATLAB path when you are creating and running the `TestSuite`.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Create and Run Test from Test Suite Element

Create a function to test, `add5`, in a file on your MATLAB path.

```
function res = add5(x)
% ADD5 Increment input by 5.
if ~isa(x,'numeric')
    error('add5:InputMustBeNumeric','Input must be numeric.')
end
res = x + 5;
end
```

Create a file, `Add5Test.m`, on your MATLAB path that contains the following `TestCase` class.

```
classdef Add5Test < matlab.unittest.TestCase
    properties (TestParameter)
        Type = {'double','single','int8','int32'};
    end

    methods (Test)
        function testNonNumericInput(testCase)
            testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric')
        end
        function testResultType(testCase, Type)
            actOutput = add5(cast(1,Type));
            testCase.verifyClass(actOutput, Type)
        end

    end
end
```

At the command prompt, create a test object for the `testNonNumericInput` method in the `Add5Test` class.

```
import matlab.unittest.TestSuite
testObj = TestSuite.fromName('Add5Test/testNonNumericInput');
```

Run the test

```
result = run(testObj);
```

```
Running Add5Test
.
Done Add5Test
__________
```

Create a parameterized test for the `testResultType` method in the `Add5Test` class, and run the test.

```
testObj = TestSuite.fromName('Add5Test/testResultType(Type=single)');
result = run(testObj);
```

```
Running Add5Test
.
Done Add5Test
__________
```

`TestRunner`

matlab.unittest.TestSuite.fromPackage

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Create `TestSuite` array from all tests in package

Syntax

```
suite = matlab.unittest.TestSuite.fromPackage(package)
suite = matlab.unittest.TestSuite.fromPackage(package,s)
suite = matlab.unittest.TestSuite.fromPackage( ___ ,Name,Value)
```

Description

`suite = matlab.unittest.TestSuite.fromPackage(package)` creates a `TestSuite` array from all of the `Test` methods of all the tests contained in package and returns that array in suite. The method is not recursive, returning only those tests directly in the package specified.

`suite = matlab.unittest.TestSuite.fromPackage(package,s)` creates a `TestSuite` array from all the tests contained in package that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromPackage( ___ ,Name,Value)` creates a `TestSuite` array with additional options specified by one or more Name,Value pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

Tips

- The root folder(s) where package is defined must be on the MATLAB path when creating suite using this method as well as when suite is run.

Input Arguments

`package`

The name of the desired package to find tests, specified as a string.

`s`

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

Name-Value Pair Arguments

`'IncludingSubpackages'`

Indicator for whether to include subpackages in the `TestSuite` array, specified as `false` or `true` (`logical 0` or `1`). This property is `false` by default. You can specify it as `true` during construction.

`'Name'`

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterProperty'`

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterName'`

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'BaseFolder'`

String indicating the name of the folder that contains the tests. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use

the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

`'Tag'`

String indicating the name of the tag applied to the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character.

Output Arguments

`suite`

Set of tests, specified as a `matlab.unittest.Test` array.

Attributes

`Static`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Examples

Run All Tests in a Package

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

```
suite = TestSuite.fromPackage('mypackage.subpackage');
result = run(suite)
```

Run tests in `mypackage` including all subpackages.

```
suite = TestSuite.fromPackage('mypackage','IncludingSubpackages',true);
```

```
result = run(suite)
```

Create Suite of Test Elements Using Selector

In your working folder, create a new package by creating a new folder, `+myPackage`. In that folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
        type = {'single','double','uint16'};
        outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests that use the parameter property `'outSize'`.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;
```

```
suite = TestSuite.fromPackage('myPackage', ...
    HasParameter('Property','outSize'));
{suite.Name}'

ans =

    'myPackage.testZeros/testClass(type=single,outSize=s2d)'
    'myPackage.testZeros/testClass(type=single,outSize=s3d)'
    'myPackage.testZeros/testClass(type=double,outSize=s2d)'
    'myPackage.testZeros/testClass(type=double,outSize=s3d)'
    'myPackage.testZeros/testClass(type=uint16,outSize=s2d)'
    'myPackage.testZeros/testClass(type=uint16,outSize=s3d)'
    'myPackage.testZeros/testSize(outSize=s2d)'
    'myPackage.testZeros/testSize(outSize=s3d)'
```

Create Suite of Test Elements Using Name-Value Arguments

Create the `+myPackage` folder and `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all parameterized tests that use the parameter property `'outSize'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromPackage('myPackage', ...
    'ParameterProperty', 'outSize');
{suite.Name}'

ans =

    'myPackage.testZeros/testClass(type=single,outSize=s2d)'
    'myPackage.testZeros/testClass(type=single,outSize=s3d)'
    'myPackage.testZeros/testClass(type=double,outSize=s2d)'
    'myPackage.testZeros/testClass(type=double,outSize=s3d)'
    'myPackage.testZeros/testClass(type=uint16,outSize=s2d)'
    'myPackage.testZeros/testClass(type=uint16,outSize=s3d)'
    'myPackage.testZeros/testSize(outSize=s2d)'
    'myPackage.testZeros/testSize(outSize=s3d)'
```

See Also

`fromClass` | `fromMethod` | `matlab.unittest.selectors` | `TestRunner`

Introduced in R2013a

run

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Run `TestSuite` array using `TestRunner` object configured for text output

Syntax

```
result = run(suite)
```

Description

`result = run(suite)` runs the `TestSuite` object defined by suite using a `TestRunner` object configured for text output.

Tips

- This is a convenience method which is equivalent to using a `TestRunner` object created from the `TestRunner.withTextOutput` method to run suite.

Input Arguments

`suite`

Set of tests, specified as a `matlab.unittest.TestSuite` array.

Output Arguments

`result`

A `matlab.unittest.TestResult` object containing the result of the test run. result is the same size as suite and each element is the result of the corresponding element in suite.

Examples

Compare TestSuite.run with TestRunner.run

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a test suite and a test runner.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
runner = TestRunner.withTextOutput;
```

The following test results are equivalent.

```
result = runner.run(suite)
result = run(suite)
```

See Also

`matlab.unittest.TestRunner.run` | `matlab.unittest.TestCase.run`

selectIf

Class: matlab.unittest.TestSuite
Package: matlab.unittest

Select test suite elements that satisfy conditions

Syntax

```
newsuite = selectIf(suite,s)
newsuite = selectIf(suite,Name,Value)
```

Description

`newsuite = selectIf(suite,s)` selects from `suite` the test elements that satisfy the conditions specified by the selector, `s`, and returns them in the `TestSuite` array, `newsuite`.

`newsuite = selectIf(suite,Name,Value)` creates a `TestSuite` array with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`suite`

Set of tests, specified as a `matlab.unittest.TestSuite` array.

`s`

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Name'`

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterProperty'`

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'ParameterName'`

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

`'BaseFolder'`

String indicating the name of the folder that contains the tests. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For tests defined in packages, the base folder is the parent of the top-level package folder.

`'Tag'`

String indicating the name of the tag applied to the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match exactly one character.

Examples

Select Test Elements Using Selector

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef (SharedTestFixtures={...
        matlab.unittest.fixtures.PathFixture(fullfile(...
        matlabroot, 'help', 'techdoc', 'matlab_oop', 'examples'))})...
        ExampleTest < matlab.unittest.TestCase
    methods(Test)
        function testPathAdd(testCase)
            % test code
        end
        function testOne(testCase)
            % test code
        end
         function testTwo(testCase)
            % test code
        end
    end
end
```

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasSharedTestFixture;
import matlab.unittest.selectors.HasName;
import matlab.unittest.fixtures.PathFixture;
import matlab.unittest.constraints.EndsWithSubstring;
import matlab.unittest.constraints.ContainsSubstring;

suite = TestSuite.fromClass(?ExampleTest)
```

```
suite =

  1x3 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   0 Parameterizations, 1 Unique Shared Test Fixture Class, 0 Tags.
```

The test suite contains three test elements.

Create a filtered test suite of tests comprising tests with names that contain the case-insensitive substring `'pAtH'`.

```
newSuite = selectIf(suite,HasName(ContainsSubstring('pAtH','IgnoringCase',true)))

newSuite =

  Test with properties:

                 Name: 'ExampleTest/testPathAdd'
      Parameterization: []
    SharedTestFixtures: [1x1 matlab.unittest.fixtures.PathFixture]
                 Tags: {0x1 cell}

Tests Include:
   0 Parameterizations, 1 Unique Shared Test Fixture Class, 0 Tags.
```

Only the `testPathAdd` test is part of the suite.

Alternatively, create the same suite using a name-value pair.

```
newSuite = selectIf(suite,'Name','*Path*');
```

However, unlike the `ContainsSubstring` constraint, the name-value pair does not have an option to ignore case.

Create a filtered suite of tests comprising tests that use a shared path fixture and do not have names ending with `'One'`.

```
newSuite = suite.selectIf(~HasName(EndsWithSubstring('One')) ...
    & HasSharedTestFixture(PathFixture(fullfile(matlabroot, 'help',...
    'techdoc', 'matlab_oop', 'examples'))));
{newSuite.Name}

ans =

    'ExampleTest/testPathAdd'    'ExampleTest/testTwo'
```

The test suite contains two tests. All of the tests use the specified path fixture, but the test named `'testOne'` is excluded from the suite.

Select Test Elements Using Parameterization

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
    properties (TestParameter)
```

```
        type = {'single','double','uint16'};
        outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
    end

    methods (Test)
        function testClass(testCase, type, outSize)
            testCase.verifyClass(zeros(outSize,type), type);
        end

        function testSize(testCase, outSize)
            testCase.verifySize(zeros(outSize), outSize);
        end

        function testDefaultClass(testCase)
            testCase.verifyClass(zeros, 'double');
        end
        function testDefaultSize(testCase)
            testCase.verifySize(zeros, [1 1]);
        end

        function testDefaultValue(testCase)
            testCase.verifyEqual(zeros,0);
        end
    end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the file.

```
s = matlab.unittest.TestSuite.fromFile('testZeros.m');
{s.Name}'
```

```
ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=single,outSize=s3d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s3d)'
    'testZeros/testSize(outSize=s2d)'
    'testZeros/testSize(outSize=s3d)'
    'testZeros/testDefaultClass'
    'testZeros/testDefaultSize'
```

```
    'testZeros/testDefaultValue'
```

The suite contains 11 test elements. Six from the parameterized `testClass` method, two from the parameterized `testSize` method, and one from each of the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

Select all of the test elements from parameterized test methods.

```
import matlab.unittest.selectors.HasParameter;

s1 = s.selectIf(HasParameter);
{s1.Name}'

ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=single,outSize=s3d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s3d)'
    'testZeros/testSize(outSize=s2d)'
    'testZeros/testSize(outSize=s3d)'
```

The suite contains the eight test elements from the two parameterized test methods.

Select all of the test elements from non-parameterized test methods.

```
s2 = s.selectIf(~HasParameter);
{s2.Name}'

ans =

    'testZeros/testDefaultClass'
    'testZeros/testDefaultSize'
    'testZeros/testDefaultValue'
```

Select all test elements that are parameterized and have a property named `'type'` with a parameter name `'double'`.

```
s3 = s.selectIf('ParameterProperty','type', 'ParameterName','double');
{s3.Name}'

ans =
```

```
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
```

The resulting suite contains two elements. The `testClass` method is the only method in `testZeros` that uses the `'type'` property, and selecting only `'double'` from the parameters results in two test elements — one for each value of `'outSize'`.

Select all test elements that are parameterized and have a parameters defined by a property starting with `'t'`.

```
s4 = s.selectIf('ParameterProperty','t*');
{s4.Name}'
```

```
ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=single,outSize=s3d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s3d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s3d)'
```

The resulting suite contains the six parameterized test elements from the `testClass` method. The `testSize` method is parameterized, but the elements from the method are not included in the suite because the method does not use a property that starts with `'t'`.

Select all test elements that are parameterized and test the `zeros` function with a `2-D` array. A parameter value representing a `2-D` array will have a length of `1` (e.g. `zeros(3)`) or `2` (e.g. `zeros(2,3)`).

```
import matlab.unittest.constraints.HasLength;

s5 = s.selectIf(HasParameter('Property','outSize',...
    'Value', HasLength(1)|HasLength(2)));
{s5.Name}'
```

```
ans =

    'testZeros/testClass(type=single,outSize=s2d)'
    'testZeros/testClass(type=double,outSize=s2d)'
    'testZeros/testClass(type=uint16,outSize=s2d)'
    'testZeros/testSize(outSize=s2d)'
```

Select only the test element that tests that the output is a `double` data type and the has the correct size for a `2-D` array.

```
s6 = s.selectIf(HasParameter('Property','type','Name','double')...
    & HasParameter('Property','outSize','Name','s2d'))
```

```
s6 =

  Test with properties:

                  Name: 'testZeros/testClass(type=double,outSize=s2d)'
      Parameterization: [1x2 matlab.unittest.parameters.TestParameter]
    SharedTestFixtures: []
                  Tags: {0x1 cell}

Tests Include:
   2 Unique Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

Select Test Elements Using Tags

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
    methods (Test)
        function testA (testCase)
            % test code
        end
    end
    methods (Test, TestTags = {'Unit'})
        function testB (testCase)
            % test code
        end
        function testC (testCase)
            % test code
        end
    end
    methods (Test, TestTags = {'Unit','FeatureA'})
        function testD (testCase)
            % test code
        end
    end
    methods (Test, TestTags = {'System','FeatureA'})
        function testE (testCase)
            % test code
        end
```

```
    end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and examine the contents.

```
import matlab.unittest.TestSuite
import matlab.unittest.selectors.HasTag

suite = TestSuite.fromClass(?ExampleTest)
```

```
suite =

  1x5 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 3 Unique Tags.
```

Click the hyperlink for `3 Unique Tags` to display all the tags in the suite.

```
       Tag
    __________

    'FeatureA'
    'System'
    'Unit'
```

Select all the test suite elements that have the tag `'Unit'`.

```
s1 = suite.selectIf(HasTag('Unit'))
```

```
s1 =

  1x3 Test array with properties:

    Name
    Parameterization
    SharedTestFixtures
    Tags
```

```
Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 2 Unique Tags.
```

Select all the test suite elements that do not contain the tag `'FeatureA'`.

```
s2 =  suite.selectIf(~HasTag('FeatureA'));
{s2.Name}

ans =

    'ExampleTest/testB'    'ExampleTest/testC'    'ExampleTest/testA'
```

Select all the test suite elements that have no tags.

```
s3 =  suite.selectIf(~HasTag)

s3 =

  Test with properties:

                 Name: 'ExampleTest/testA'
      Parameterization: []
    SharedTestFixtures: []
                 Tags: {0x1 cell}

Tests Include:
   0 Parameterizations, 0 Shared Test Fixture Classes, 0 Tags.
```

See Also

`matlab.unittest.constraints` | `matlab.unittest.selectors`

Introduced in R2014a

texlabel

Format text into TeX string

Syntax

```
TeXString = texlabel(f)
TeXString = texlabel(f,'literal')
```

Description

`TeXString = texlabel(f)` converts the MATLAB expression `f` into the TeX equivalent for use in text strings. `texlabel` converts Greek variable names (for example, lambda, delta, and so on) into a string that is displayed as Greek letters. The `TeXString` output is useful as an argument to annotation functions such as `title`, `xlabel`, and `text`.

If `TeXString` is too long to fit into a figure window, then the center of the expression is replaced with a tilde ellipsis (~~~).

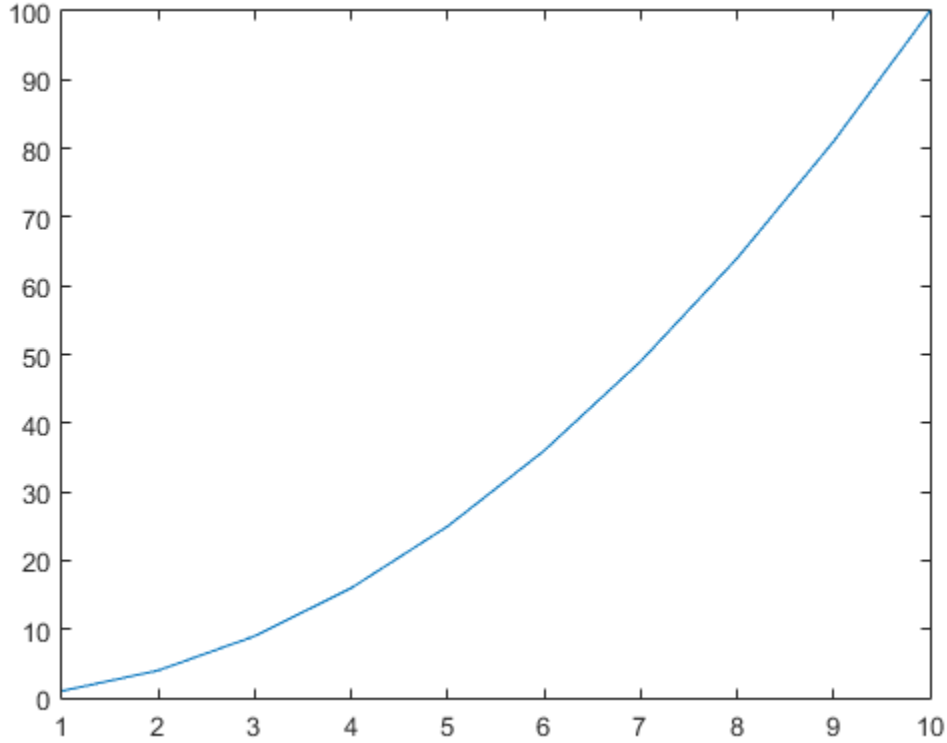
`TeXString = texlabel(f,'literal')` interprets Greek variable names literally.

Examples

Insert TeX String in Figure

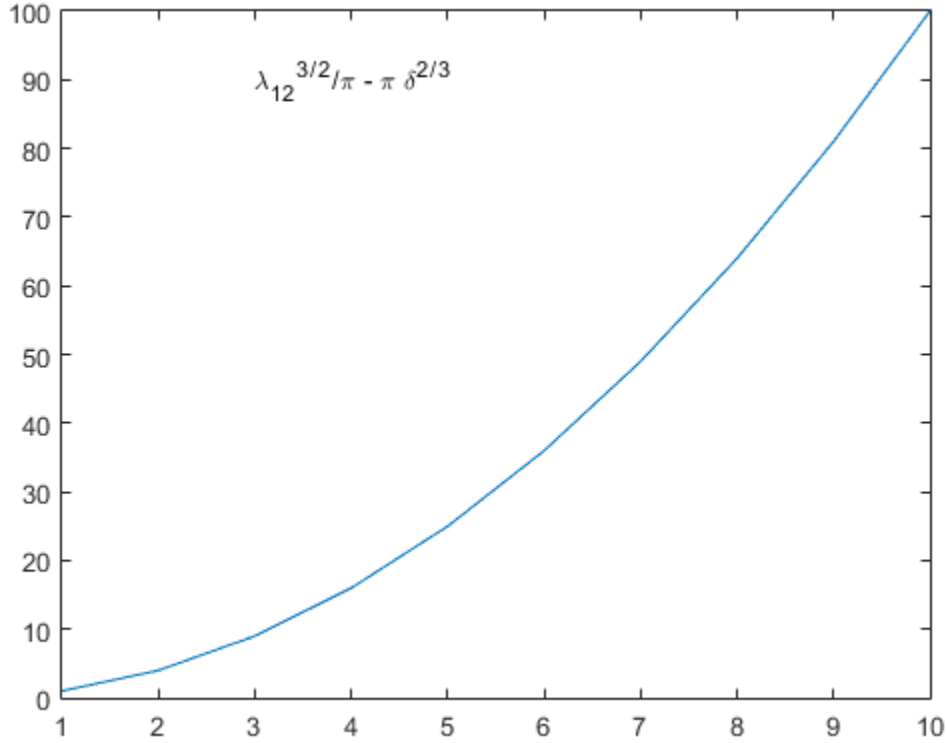
Create a figure and a TeX string for use in a text graphics object.

```
figure
plot((1:10).^2)
TeXString = texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)');
```



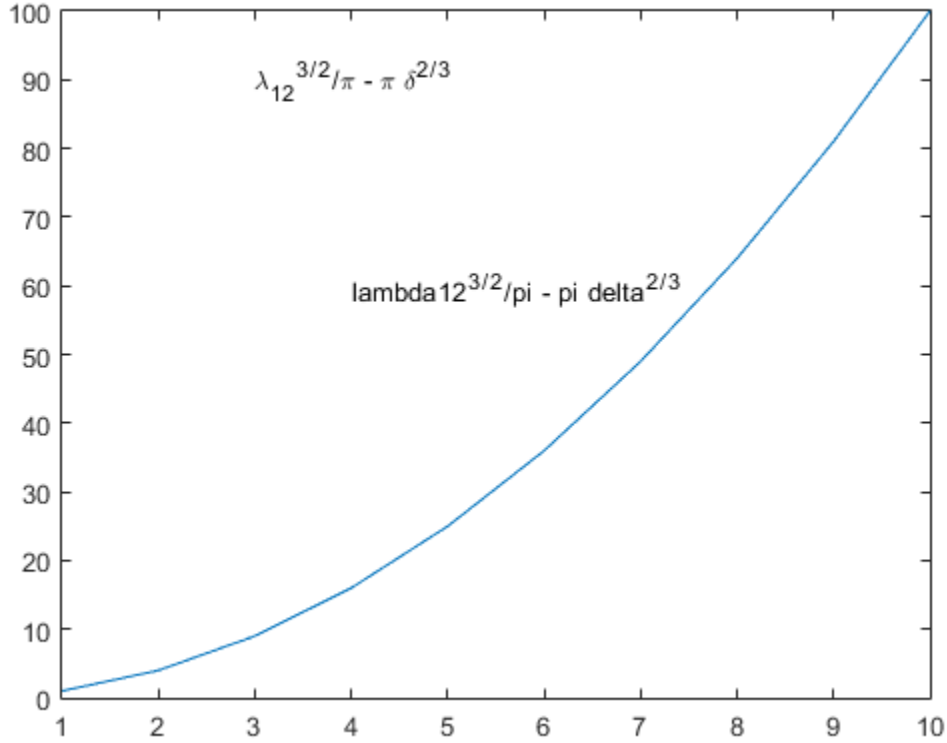
Add a text object containing the TeX string to the figure.

```
text(3,90,TeXString)
```



If you include the `'literal'` argument, `texlabel` interprets Greek variable names literally. Add a text object containing the literal string.

```
text(4,60,texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)','literal'))
```



Input Arguments

`f` — Input MATLAB expression

string

Input MATLAB expression, specified as a string.

Example: `'theta (degrees)'`

Data Types: `char`

See Also

`text` | `title` | `xlabel` | `ylabel` | `zlabel`

Introduced before R2006a

text

Create text object in current axes

Syntax

```
text(x,y,'string')
text(x,y,z,'string')
text(x,y,z,'string','PropertyName',PropertyValue....)
text('PropertyName',PropertyValue....)
h = text(...)
```

Properties

For a list of properties, see Text Properties.

Description

`text` is the low-level function for creating text graphics objects. Use `text` to place character strings at specified locations.

`text(x,y,'string')` adds the string in quotes to the location specified by the point `(x,y)` `x` and `y` must be numbers of class `double`.

`text(x,y,z,'string')` adds the string in 3-D coordinates. `x`, `y` and `z` must be numbers of class `double`.

`text(x,y,z,'string','PropertyName',PropertyValue....)` adds the string in quotes to the location defined by the coordinates and uses the values for the specified text properties. For a description of the properties, see Text Properties.

`text('PropertyName',PropertyValue....)` omits the coordinates entirely and specifies all properties using property name/property value pairs.

`h = text(...)` returns a column vector of handles to text objects, one handle per object. All forms of the `text` function optionally return this output argument.

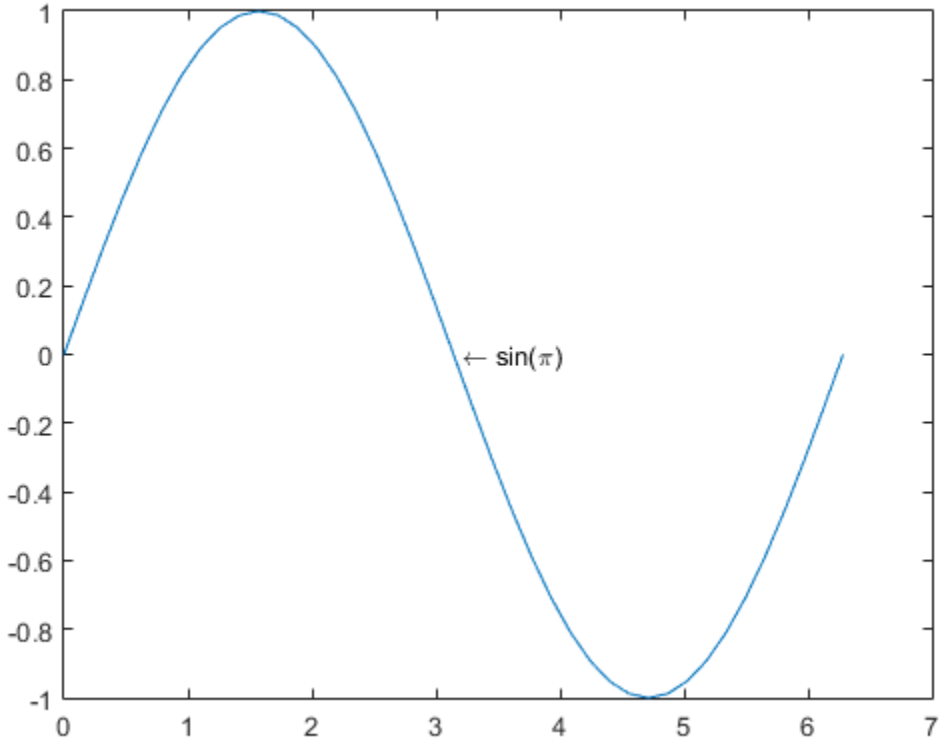
Examples

Label Point on Graph

Annotate the point $(\pi, 0)$ with the string $\sin(\pi)$.

```
x = 0:pi/20:2*pi;
y = sin(x);

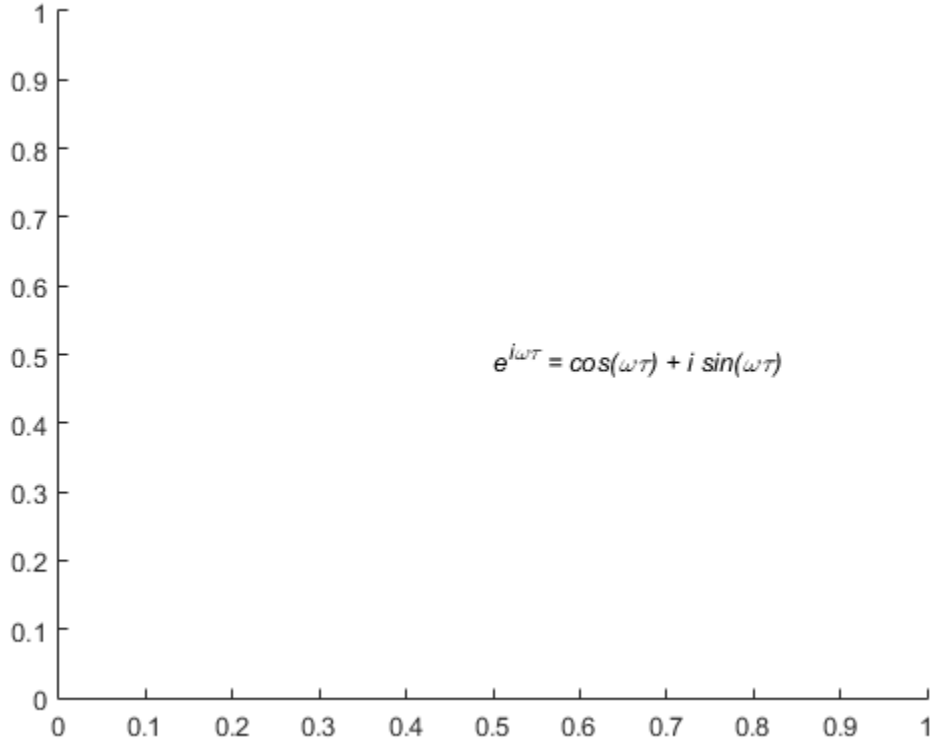
figure % new figure window
plot(x,y)
text(pi,0,' \leftarrow sin(\pi)')
```



Display Equation with Greek Symbols

Use embedded TeX sequences to display an equation in an empty axes.

```
axes
text(0.5,0.5,'\ite^{i\omega\tau} = cos(\omega\tau) + i sin(\omega\tau)')
```



Setting Default Properties

You can set default text properties on the axes, figure, and root levels:

```
set(0,'DefaulttextProperty',PropertyValue...)
set(gcf,'DefaulttextProperty',PropertyValue...)
set(gca,'DefaulttextProperty',PropertyValue...)
```

Where *`Property`* is the name of the text property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access text properties.

More About

Tips

Position Text Within the Axes

The default text units are the units used to plot data in the graph. Specify the text location coordinates (the `x`, `y`, and `z` arguments) in the data units of the current graph. You can use other units to position the text by setting the text `Units` property to `normalized` or one of the nonrelative units (`pixels`, `inches`, `centimeters`, `points`, or `characters`).

Note that the Axes Units property controls the positioning of the Axes within the figure and is not related to the axes data units used for graphing.

The `Extent`, `VerticalAlignment`, and `HorizontalAlignment` properties control the positioning of the character string with regard to the text location point.

If the coordinates are vectors, `text` writes the string at all locations defined by the list of points. If the character string is an array the same length as `x`, `y`, and `z`, `text` writes the corresponding row of the string array at each point specified.

Multiline Text

When specifying strings for multiple text objects, the string can be:

- A cell array of strings
- A padded string matrix

Each element of the specified string array creates a different text object.

When specifying the string for a single text object, cell arrays of strings and padded string matrices result in a text object with a multiline string, while vertical slash characters are not interpreted as separators and result in a single line string containing vertical slashes.

Behavior of the Text Function

`text` is a low-level function that accepts property name/property value pairs as input arguments. However, the convenience form:

```
text(x,y,z,'string')
```

is equivalent to:

```
text('Position',[x,y,z],'String','string')
```

You can specify other properties only as property name/property value pairs. You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

`text` does not respect the setting of the figure or axes `NextPlot` property. This allows you to add text objects to an existing axes without setting `hold` to `on`.

See Also

Functions

`annotation` | `int2str` | `num2str` | `title` | `xlabel` | `ylabel` | `zlabel`

Properties

Text Properties

Introduced before R2006a

Text Properties

Control text appearance and behavior

Text properties control the appearance and behavior of a text object. By changing property values, you can modify certain aspects of the text.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = text(0.5,0.5,'text here');
s = h.FontSize;
h.FontSize = 12;
```

If you are using an earlier release, use the `get` and `set` functions instead.

Text

`String` — Text to display

`''` (default) | character array | cell array | numeric value

Text to display, specified as a character array, cell array, or numeric value.

Example: `'my label'`

Example: `{'first line','second line'}`

Example: `123`

To include numeric variables with text, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the Interpreter property.

To create multiline text:

- Use a cell array, where each cell contains a line of text, such as `{'first line','second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.

- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`. This property converts strings with new line characters to cell arrays.

Text that contains only a numeric value is converted to a string using `sprintf('%g',value)`. For example, `12345678` displays as `1.23457e+07`.

Note: The words `default`, `factory`, and `remove` are reserved words that will not appear in text when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

`Interpreter` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`

Modifier	Description	Example of String
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
`\alpha`	α	`\upsilon`	υ	`\sim`	~
`\angle`	∠	`\phi`	Φ	`\leq`	≤

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

Font Style

`Color` — Text color
`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default color is black with an RGB triplet value of `[0 0 0]`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`FontName` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`FontSize` — Font size

`10` (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. One point equals `1/72` inch. To change the font units, use the `FontUnits` property.

Example: `12`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`FontUnits` — Font size units

`'points'` (default) | `'inches'` | `'centimeters'` | `'normalized'` | `'pixels'`

Font size units, specified as one of the values in this table.

`Units`	Description
`'points'`	1 point equals `1/72` inch.
`'inches'`	Inches
`'centimeters'`	Centimeters
`'normalized'`	Font size is interpreted as a fraction of the axes height. If you resize the axes, MATLAB modifies the font size accordingly.

Units	Description
'pixels'	Pixel size depends on the screen resolution.

This property affects the FontSize property. If you set both the FontSize and the FontUnits property in the same function call, then you must set the FontUnits property first for MATLAB to interpret the specified FontSize correctly.

FontAngle — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

Note: The 'oblique' value has been removed. Use 'italic' instead.

FontWeight — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

FontSmoothing — Smooth font character appearance

'on' (default) | 'off'

Smooth font character appearance, specified as one of these values:

- 'on' — Apply font smoothing. Reduce the appearance of jaggedness in the text characters to make the text easier to read.
- 'off' — Do not apply font smoothing.

Text Box

`EdgeColor` — Color of box outline

`'none'` (default) | RGB triplet | color string

Color of box outline, specified as `'none'`, a three-element RGB triplet, or a color string. The default edge color of `'none'` makes the box outline invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`BackgroundColor` — Color of text box background

`'none'` (default) | RGB triplet | color string

Color of text box background, specified as `'none'`, a three-element RGB triplet, or a color string. The default background color of `'none'` makes the text box background transparent.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

Margin — Space around text within the text box

3 (default) | scalar numeric value

The space around the text within the text box, specified as scalar numeric value in point units.

MATLAB uses the Extent property value plus the Margin property value to determine the size of the text box.

Example: 8

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

LineStyle — Line style of box outline

'-' (default) | '--' | ':' | '-.' | 'none'

Line style of box outline, specified as one of the strings in this table.

String	Line Style	Resulting Line
'-'	Solid line	————
'--'	Dashed line	- — — — —
':'	Dotted line	.....

String	Line Style	Resulting Line
`'-.'`	Dash-dotted line	
`'none'`	Line is invisible	

`LineWidth` — Width of box outline

`0.5` (default) | scalar numeric value

Width of box outline, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: `1.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Location and Size

`Position` — Location of text

`[0 0 0]` (default) | two-element vector of form `[x y]` | three-element vector of form `[x y z]`

Location of the text, specified as a two-element vector of the form `[x y]` or a three-element vector of the form `[x y z]`. If you omit the third element, `z`, then MATLAB sets it to `0`.

By default, the position value is defined in data units. To change the units, use the Units property.

Example: `[0.5 0.5 0]`

`Extent` — Size and location of rectangle that encloses text string

four-element vector

Size and location of the rectangle that encloses the text string, not including the margin, returned as a four-element vector of the form `[left bottom width height]`. The first two elements, `left` and `bottom`, define the position of the lower left corner of the rectangle. The last two elements, `width` and `height`, define the dimensions of the rectangle.

By default, the extent value is defined in data units. To change the units, use the Units property.

Example: `[0.5 0.5 0.4 0.2]`

`Units` — Position and extent units

`'data'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

`Units`	Description
`'data'` (default)	Data coordinates.
`'normalized'`	Normalized with respect to the axes. The lower left corner of the axes maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units, except for `'data'`, are measured from the lower left corner of the axes. This property affects the Position and Extent properties.

If you specify the `Position` and `Units` properties as `Name,Value` pairs when creating the text object, then the order of specification matters. If you want to define the position with particular units, then you must set the `Units` property before the `Position` property.

`Rotation` — Text orientation

0 (default) | scalar value in degrees

Text orientation, specified as a scalar value in degrees. The default rotation of 0 degrees makes the text horizontal. For vertical text, set this property to `90` or `-90`. Positive values rotate the text counterclockwise. Negative values rotate the text clockwise.

Example: `90`

Example: `-90`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`HorizontalAlignment` — Horizontal alignment of text with respect to position point

`'left'` (default) | `'center'` | `'right'`

Horizontal alignment of the text with respect to the `x` value in the `Position` property, specified as one of the values in this table. The vertical line indicates where the `x` value lies in relation to the text.

Value	Result
`'left'` (default)	
`'center'`	
`'right'`	

`VerticalAlignment` — Vertical alignment of text with respect to position point

`'middle'` (default) | `'top'` | `'bottom'` | `'baseline'` | `'cap'`

Vertical alignment of the text with respect to the `y` value in the `Position` property, specified as one of the values in this table. The horizontal line indicates where the `y` value lies in relation to the text.

Value	Result
`'middle'`	`'top'`	
Value	Result
`'cap'`	`'bottom'`	`'baseline'`	
Visibility

`Visible` — Visibility of text

`'on'` (default) | `'off'`

Visibility of text, specified as one of these values:

- `'on'` — Display the text.
- `'off'` — Hide the text without deleting it. You still can access the properties of an invisible text object.

`Clipping` — Clipping of text to axes plot box

`'off'` (default) | `'on'`

Clipping of the text to the axes plot box, which is the box defined by the axis limits, specified as one of these values:

- `'off'` — Do not clip the text. Portions of it might appear outside the axes plot box.
- `'on'` — Clips the text to the axes plot box.
  - If the axes `ClippingStyle` property is set to `'3dbox'`, which is the default, then MATLAB either displays the entire text or none of the text, depending on the text position. If the point defined by the text `Position` property lies inside the axes, then MATLAB displays the entire text. If the point lies outside the axes, then MATLAB displays none of it.
  - If the axes `ClippingStyle` property is set to `'rectangle'`, then MATLAB displays portions of the text lying inside the axes plot box and does not display portions of the text lying outside the axes plot box.

Note: If the `Clipping` property of the associated axes is set to `'on'`, which is the default, then each individual object controls its own clipping behavior. If the `Clipping` property of the axes is set to `'off'`, then MATLAB does not clip any objects in the axes, regardless of the `Clipping` property of the individual object.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object
`'text'`

Type of graphics object, returned as `'text'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — Tag to associate with text
`''` (default) | string

Tag to associate with the text, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with text
`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the text object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent of text
axes object | group object | transform object

Parent of text, specified as an axes, group, or transform object.

`Children` — Children of text
empty `GraphicsPlaceholder` array

The text has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of text object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The text object handle is always visible.
- `'off'` — The text object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The text object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the text at the command-line, but allows callback functions to access it.

If the text object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`Editing` — Interactive edit mode

`'off'` (default) | `'on'`

Interactive edit mode, specified as one of these values:

- `'off'` — Do no allow interactive string editing. To change the text string you must set the String property. This is the default value.
- `'on'` — Allow interactive string editing. MATLAB places an insert cursor within the text and typing changes the text. To apply the new text string, do any of the following:
  - Press the **Esc** key.
  - Click anywhere away from the text string.

- Reset the `Editing` property to `'off'`.

MATLAB updates the String property to contain the new text and resets the `Editing` property to `'off'`.

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the text. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The text object — You can access properties of the text object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the text. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the text when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the text.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The Visible property must be set to `'on'`. The HitTest property determines if the text responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'`. The HitTest property determines if the text responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the text passes the click to the object below it in the current view of the figure window, which is typically the axes or the figure. The HitTest property has no effect.

If you want an object to be clickable when it is underneath other objects that you do not want to be clickable, then set the `PickableParts` property of the other objects to `'none'` so that the click passes through them.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the text. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the text that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the text object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the text is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the text tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the text. Setting the `CreateFcn` property on an existing text has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during text creation. MATLAB executes the callback after creating the text and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The text object — You can access properties of the text object from within the callback function. You also can access the text object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the text. MATLAB executes the callback before destroying the text so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The text object — You can access properties of the text object from within the callback function. You also can access the text object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of text

`'off'` (default) | `'on'`

Deletion status of text, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the text begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the text no longer exists.

Check the value of the BeingDeleted property to verify that the text is not about to be deleted before querying or modifying it.

- "Graphics Object Properties"

textread

Read data from text file; write to multiple outputs

Note: `textread` is not recommended. Use `textscan` instead.

Syntax

```
[A,B,C,...] = textread(filename,format)
[A,B,C,...] = textread(filename,format,N)
[...] = textread(...,param,value,...)
```

Description

`[A,B,C,...] = textread(filename,format)` reads data from the file `filename` into the variables `A`, `B`, `C`, and so on, using the specified `format`, until the entire file is read. The `filename` and `format` inputs are strings, each enclosed in single quotes. `textread` is useful for reading text files with a known format. `textread` handles both fixed and free format files.

Note When reading large text files, reading from a specific point in a file, or reading file data into a cell array rather than multiple outputs, you might prefer to use the `textscan` function.

`textread` matches and converts groups of characters from the input. Each input field is defined as a string of non-white-space characters that extends to the next white-space or delimiter character, or to the maximum field width. Repeated delimiter characters are significant, while repeated white-space characters are treated as one.

The `format` string determines the number and types of return arguments. The number of return arguments is the number of items in the `format` string. The `format` string supports a subset of the conversion specifiers and conventions of the C language

`fscanf` routine. Values for the `format` string are listed in the table below. White-space characters in the `format` string are ignored.

format	Action	Output
Literals (ordinary characters)	Ignore the matching characters. For example, in a file that has `Dept` followed by a number (for department number), to skip the `Dept` and read only the number, use `'Dept'` in the `format` string.	None
`%d`	Read a signed integer value.	Double array
`%u`	Read an integer value.	Double array
`%f`	Read a floating-point value.	Double array
`%s`	Read a white-space or delimiter-separated string.	Cell array of strings
`%q`	Read a double quoted string, ignoring the quotes.	Cell array of strings
`%c`	Read characters, including white space.	Character array
`%[...]`	Read the longest string containing characters specified in the brackets.	Cell array of strings
`%[^...]`	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
`%*...` `instead of %`	Ignore the matching characters specified by `*`.	No output
`%w...` `instead of %`	Read field width specified by `w`. The `%f` format supports `%w.pf`, where `w` is the field width and `p` is the precision.	

`[A,B,C,...] = textread(filename,format,N)` reads the data, reusing the `format` string `N` times, where `N` is an integer greater than zero. If `N` is smaller than zero, `textread` reads the entire file.

`[...] = textread(...,param,value,...)` customizes `textread` using `param`/`value` pairs, as listed in the table below.

param	value	Action
`bufsize`	Positive integer	Specifies the maximum string length, in bytes. Default is `4095`.

param	value		Action
`commentstyle`	`matlab`		Ignores characters after `%`.
`commentstyle`	`shell`		Ignores characters after `#`.
`commentstyle`	`c`		Ignores characters between `/*` and `*/`.
`commentstyle`	`c++`		Ignores characters after `//`.
`delimiter`	One or more characters		Act as delimiters between elements. Default is none.
`emptyvalue`	Scalar double		Value given to empty cells when reading delimited files. Default is 0.
`endofline`	Single character or `'\r\n'`		Character that denotes the end of a line. Default is determined from file
`expchars`	Exponent characters		Default is `eEdD`.
`headerlines`	Positive integer		Ignores the specified number of lines at the beginning of the file.
`whitespace`	Any from the list below:		Treats vector of characters as white space. Default is `' \b\t'`.
	`' '`	Space	
	`\b`	Backspace	
	`\n`	Newline	
	`\r`	Carriage return	
	`\t`	Horizontal tab	

Note When `textread` reads a consecutive series of `whitespace` values, it treats them as one white space. When it reads a consecutive series of `delimiter` values, it treats each as a separate delimiter.

Examples

Example 1 — Read All Fields in Free Format File Using %

The first line of `mydata.dat` is

```
Sally    Level1 12.34 45 Yes
```

Read the first line of the file as a free format file using the `%` format.

```
[names, types, x, y, answer] = textread('mydata.dat', ...
'%s %s %f %d %s', 1)
```

returns

```
names =
    'Sally'
types =
    'Level1'
x =
  12.34000000000000
y =
    45
answer =
    'Yes'
```

Example 2 — Read as Fixed Format File, Ignoring the Floating Point Value

The first line of `mydata.dat` is

```
Sally    Level1 12.34 45 Yes
```

Read the first line of the file as a fixed format file, ignoring the floating-point value.

```
[names, types, y, answer] = textread('mydata.dat', ...
'%9c %6s %*f %2d %3s', 1)
```

returns

```
names =
Sally
types =
    'Level1'
y =
    45
answer =
    'Yes'
```

`%*f` in the `format` string causes `textread` to ignore the floating point value, in this case, `12.34`.

Example 3 — Read Using Literal to Ignore Matching Characters

The first line of `mydata.dat` is

```
Sally    Type1 12.34 45 Yes
```

Read the first line of the file, ignoring the characters `Type` in the second field.

```
[names, typenum, x, y, answer] = textread('mydata.dat', ...
'%s Type%d %f %d %s', 1)
```

returns

```
names =
    'Sally'
typenum =
    1
x =
  12.34000000000000
y =
    45
answer =
    'Yes'
```

`Type%d` in the `format` string causes the characters `Type` in the second field to be ignored, while the rest of the second field is read as a signed integer, in this case, `1`.

Example 4 — Specify Value to Fill Empty Cells

For files with empty cells, use the `emptyvalue` parameter. Suppose the file `data.csv` contains:

```
1,2,3,4,,6
7,8,9,,11,12
```

Read the file using `NaN` to fill any empty cells:

```
data = textread('data.csv', '', 'delimiter', ',', ...
                'emptyvalue', NaN);
```

Example 5 — Read File into a Cell Array of Strings

Read the file `fft.m` into cell array of strings.

```
file = textread('fft.m', '%s', 'delimiter', '\n', ...
                'whitespace', '');
```

More About

Tips

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
textread('myfile.txt', '%s', 'whitespace', '')
ans =
    '   An  example      of preserving    spaces      '
```

`textscan` | `fscanf` | `dlmread`

Introduced before R2006a

textscan

Read formatted data from text file or string

Syntax

```
C = textscan(fileID,formatSpec)
C = textscan(fileID,formatSpec,N)

C = textscan(str,formatSpec)
C = textscan(str,formatSpec,N)

C = textscan( ___ ,Name,Value)

[C,position] = textscan( ___ )
```

Description

`C = textscan(fileID,formatSpec)` reads data from an open text file into a cell array, `C`. The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading from a file, close the file by calling `fclose(fileID)`.

`textscan` attempts to match the data in the file to `formatSpec`, which is a string of conversion specifiers. `textscan` reapplies `formatSpec` throughout the entire file and stops when it cannot match `formatSpec` to the data.

`C = textscan(fileID,formatSpec,N)` reads file data using the `formatSpec` `N` times, where `N` is a positive integer. To read additional data from the file after `N` cycles, call `textscan` again using the original `fileID`. If you resume a text scan of a file by calling `textscan` with the same file identifier (`fileID`), then `textscan` automatically resumes reading at the point where it terminated the last read.

`C = textscan(str,formatSpec)` reads data from a string, `str`, into cell array `C`. For strings, repeated calls to `textscan` restart the scan from the beginning each time. To restart a scan from the last position, request a `position` output.

`textscan` attempts to match the data in the string, `str`, to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(str,formatSpec,N)` reads string data using the `formatSpec` `N` times, where `N` is a positive integer.

`C = textscan( ___ ,Name,Value)` specifies options using one or more `Name,Value` pair arguments, in addition to any of the input arguments in the previous syntaxes.

`[C,position] = textscan( ___ )` returns the file or string position at the end of the scan as the second output argument, using any of the input arguments in the previous syntaxes. For a file, this is the value that `ftell(fileID)` would return after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

Examples

Read a String

Read a string of floating-point numbers.

```
str = '0.41 8.24 3.57 6.24 9.27';
C = textscan(str,'%f');
```

The `formatSpec` string `'%f'` tells `textscan` to match each field in `str` to a double-precision floating-point number.

Display the contents of cell array `C`.

```
celldisp(C)
```

```
C{1} =

    0.4100
    8.2400
    3.5700
    6.2400
    9.2700
```

Read the same string, truncating each value to one decimal digit.

```
C = textscan(str,'%3.1f %*1d');
```

The specifier `%3.1f` indicates a field width of 3 digits and a precision of 1. `textscan` reads a total of 3 digits, including the decimal point and the 1 digit after the decimal point. The specifier, `%*1d`, tells `textscan` to skip the remaining digit.

Display the contents of cell array `C`.

```
celldisp(C)
```

```
C{1} =

    0.4000
    8.2000
    3.5000
    6.2000
    9.2000
```

Read Different Types of Data

Using a text editor, create a file `scan1.dat` that contains data in the following form:

```
09/12/2005 Level1 12.34 45 1.23e10 inf Nan Yes 5.1+3i
10/12/2005 Level2 23.54 60 9e19 -inf  0.001 No 2.2-.5i
11/12/2005 Level3 34.90 12 2e5   10  100   No 3.1+.1i
```

Open the file, and read each column with the appropriate conversion specifier.

```
fileID = fopen('scan1.dat');
C = textscan(fileID,'%s %s %f32 %d8 %u %f %f %s %f');
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =

09/12/2005

C{1}{2} =

10/12/2005

C{1}{3} =
```

```
11/12/2005

C{2}{1} =

Level1

C{2}{2} =

Level2

C{2}{3} =

Level3

C{3} =

   12.3400
   23.5400
   34.9000

C{4} =

   45
   60
   12

C{5} =

  4294967295
  4294967295
      200000

C{6} =
```

```
   Inf
  -Inf
    10

C{7} =

       NaN
    0.0010
  100.0000

C{8}{1} =

Yes

C{8}{2} =

No

C{8}{3} =

No

C{9} =

   5.1000 + 3.0000i
   2.2000 - 0.5000i
   3.1000 + 0.1000i
```

`textscan` returns a 1-by-9 cell array `C`.

View the MATLAB data type of each of the cells in `C`.

```
C
```

```
C =

  Columns 1 through 5
```

```
    {3x1 cell}    {3x1 cell}    [3x1 single]    [3x1 int8]    [3x1 uint32]

  Columns 6 through 9

    [3x1 double]    [3x1 double]    {3x1 cell}    [3x1 double]
```

For example, `C{1}` and `C{2}` are cell arrays. `C{5}` is of data type `uint32`, so the first two elements of `C{5}` are the maximum values for a 32-bit unsigned integer, or `intmax('uint32')`.

Remove a Literal String

Remove the text `'Level'` from each field in the second column of the data from the previous example.

Match the literal string in the `formatSpec` input.

```
fileID = fopen('scan1.dat');
C = textscan(fileID,'%s Level%d %f32 %d8 %u %f %f %s %f');
fclose(fileID);
C{2}
```

```
ans =

           1
           2
           3
```

View the MATLAB data type of the second cell in `C`.

```
class(C{2})
```

```
ans =

int32
```

The second cell of the 1-by-9 cell array, `C`, is now of data type `int32`.

Skip the Remainder of a Line

Read the first column of the file in the previous example into a cell array, skipping the rest of the line.

```
fileID = fopen('scan1.dat');
dates = textscan(fileID,'%s %*[^\n]');
```

```
fclose(fileID);
dates{1}

ans =

    '09/12/2005'
    '10/12/2005'
    '11/12/2005'
```

`textscan` returns a 1-by-1 cell array `dates`.

Specify Delimiter and Empty Value Conversion

Using a text editor, create a comma-delimited file, `data.csv`, that contains

```
1,  2,  3,  4,   ,  6
7,  8,  9,   , 11, 12
```

Read the file, converting empty cells to `-Inf`.

```
fileID = fopen('data.csv');
C = textscan(fileID,'%f %f %f %f %u8 %f',...
'Delimiter',',','EmptyValue',-Inf);
fclose(fileID);
column4 = C{4}, column5 = C{5}

column4 =

     4
  -Inf

column5 =

    0
   11
```

`textscan` returns a 1-by-6 cell array, `C`. The `textscan` function converts the empty value in `C{4}` to `-Inf`, where `C{4}` is associated with a floating-point format. Because MATLAB represents unsigned integer `-Inf` as `0`, `textscan` converts the empty value in `C{5}` to `0`, and not `-Inf`.

Read Custom Empty Value Strings and Comments

Using a text editor, create a comma-delimited file, `data2.csv`, that contains the lines

```
abc, 2, NA, 3, 4
// Comment Here
def, na, 5, 6, 7
```

Designate the input that `textscan` should treat as comments or empty values.

```
fileID = fopen('data2.csv');
C = textscan(fileID,'%s %n %n %n %n','Delimiter',',',...
'TreatAsEmpty',{'NA','na'},'CommentStyle','//');
fclose(fileID);
celldisp(C)

C{1}{1} =
abc

C{1}{2} =
def

C{2} =
     2
   NaN

C{3} =
   NaN
     5

C{4} =
     3
     6

C{5} =
     4
     7
```

Treat Repeated Delimiters as One

Using a text editor, create a file, `data3.csv`, that contains

```
1,2,3,,4
5,6,7,,8
```

To treat the repeated commas as a single delimiter, use the `MultipleDelimsAsOne` parameter, and set the value to `1 (true)`.

```
fileID = fopen('data3.csv');
```

```
C = textscan(fileID,'%f %f %f %f','Delimiter',',',...
'MultipleDelimsAsOne',1);
fclose(fileID);
celldisp(C)

C{1} =
     1
     5

C{2} =
     2
     6

C{3} =
     3
     7

C{4} =
     4
     8
```

Specify Repeated Conversion Specifiers and Collect Numeric Data

Using a text editor, create a file, `grades.txt`, that contains:

```
Student_ID  | Test1  | Test2  | Test3
   1          91.5     89.2     77.3
   2          88.0     67.8     91.0
   3          76.3     78.1     92.5
   4          96.4     81.2     84.6
```

Read the column headers using the format `'%s'` four times.

```
fileID = fopen('grades.txt');

formatSpec = '%s';
N = 4;
C_text = textscan(fileID,formatSpec,N,'Delimiter','|');
```

Read the numeric data in the file.

```
C_data0 = textscan(fileID,'%d %f %f %f')

C_data0 =
  [4x1 int32]    [4x1 double]    [4x1 double]    [4x1 double]
```

The default value for `CollectOutput` is 0 `(false)`, so `textscan` returns each column of the numeric data in a separate array.

Set the file position indicator to the beginning of the file.

```
frewind(fileID);
```

Reread the file and set `CollectOutput` to `1 (true)` to collect the consecutive columns of the same class into a single array. You can use the `repmat` function to indicate that the `%f` conversion specifier should appear three times. This technique is useful when a format repeats many times.

```
C_text = textscan(fileID,'%s',N,'Delimiter','|');
```

```
C_data1 = textscan(fileID,['%d',repmat('%f',[1,3])],'CollectOutput',1)
```

```
C_data1 =
    [4x1 int32]    [4x3 double]
```

The test scores, which are all `double`, are collected into a single 4-by-3 array.

Close the file, `grades.txt`.

```
fclose(fileID);
```

Read or Skip Quoted Strings and Numeric Fields

Read the first and last columns of data from a text file. Skip a column of strings and a column of integer data.

In a text editor, create a comma-delimited text file called `names.txt` that contains:

```
"Smith, J.","M",38,71.1
"Bates, G.","F",43,69.3
"Curie, M.","F",38,64.1
"Murray, G.","F",40,133.0
"Brown, K.","M",49,64.9
```

Read the first and last columns of data in the file. Use the conversion specifier, `%q` to read a string enclosed by double quotation marks ("). `%*q` skips a quoted string, `%*d` skips an integer field, and `%f` reads a floating-point number. Specify the comma delimiter using the `'Delimiter'` name-value pair argument.

```
fileID = fopen('names.txt','r');
C = textscan(fileID,'%q %*q %*d %f','Delimiter',',');
```

```
fclose(fileID);
celldisp(C)

C{1}{1} =

Smith, J.

C{1}{2} =

Bates, G.

C{1}{3} =

Curie, M.

C{1}{4} =

Murray, G.

C{1}{5} =

Brown, K.

C{2} =

   71.1000
   69.3000
   64.1000
  133.0000
   64.9000
```

`textscan` returns a 1-by-2 cell array, `C`. Double quotation marks enclosing the strings are removed.

Read Foreign-Language Dates

Create a sample file named `myfile.txt` that contains comma-separated values. The first column of values contains dates in German and the second and third columns are numeric values.

```
fileID = fopen('myfile.txt','w','n','ISO-8859-15');
fprintf(fileID,'1 Januar 2014, 20.2, 100.5 \n');
fprintf(fileID,'1 Februar 2014, 21.6, 102.7 \n');
fprintf(fileID,'1 März 2014, 20.7, 99.8 \n');
fclose(fileID);
```

The sample file looks like this:

```
1 Januar 2014, 20.2, 100.5
1 Februar 2014, 21.6, 102.7
1 März 2014, 20.7, 99.8
```

Open the file. Specify the character encoding scheme associated with the file as the last input to `fopen`.

```
fileID = fopen('myfile.txt','r','n','ISO-8859-15');
```

Read the file. Specify the format of the dates in the file using the `%{dd % MMMM yyyy}D` specifier. Specify the locale of the dates using the `DateLocale` name-value pair argument.

```
C = textscan(fileID,'%{dd MMMM yyyy}D %f %f',...
    'DateLocale','de_DE','Delimiter',',');
fclose(fileID);
```

View the contents of the first cell in `C`.

```
C{1}
```

```
ans =

   01 January 2014
   01 February 2014
   01 March 2014
```

The dates display in the language MATLAB uses depending on your system locale.

Read Nondefault Control Characters

Use `sprintf` to convert nondefault escape sequences in your data.

Create a string that includes a form feed character, `\f`. Then, to read the string using `textscan`, call `sprintf` to explicitly convert the form feed.

```
lyric = sprintf('Blackbird\fsinging\fin\fthe\fdead\fof\fnight');
C = textscan(lyric,'%s','delimiter',sprintf('\f'));
C{1}

ans =

    'Blackbird'
    'singing'
    'in'
    'the'
    'dead'
    'of'
    'night'
```

`textscan` returns a 1-by-1 cell array, `C`.

Resume a Text Scan of a String

Resume a scan of a string from a position other than the beginning.

If you resume a text scan of a string, `textscan` reads from the beginning of the string each time. To resume a scan from any other position in the string, use the two-output argument syntax in your initial call to `textscan`.

For example, create a string called `lyric`. Read the first word of the string, and then resume the scan.

```
lyric = 'Blackbird singing in the dead of night';
[firstword,pos] = textscan(lyric,'%9c',1);
lastpart = textscan(lyric(pos+1:end),'%s');
```

- “Import Data from a Nonrectangular Text File”
- “Import Large Text File Data in Blocks”
- “Access Data in a Cell Array”

Input Arguments

`fileID` — File identifier

numeric scalar

File identifier of an open text file, specified as a number. Before reading a file with `textscan`, you must use `fopen` to open the file and obtain the `fileID`.

Data Types: `double`

`formatSpec` — Format of the data fields

string

Format of the data fields, specified as a string of one or more conversion specifiers. When `textscan` reads a file or string, it attempts to match the data to the `formatSpec` string. If `textscan` fails to match a data field, it stops reading and returns all fields read before the failure.

The number of conversion specifiers determines the number of cells in output array, `C`.

Numeric Fields

This table lists available conversion specifiers for numeric inputs.

Numeric Input Type	Conversion Specifier	Output Class
Integer, signed	`%d`	`int32`
	`%d8`	`int8`
	`%d16`	`int16`
	`%d32`	`int32`
	`%d64`	`int64`
Integer, unsigned	`%u`	`uint32`
	`%u8`	`uint8`
	`%u16`	`uint16`
	`%u32`	`uint32`
	`%u64`	`uint64`
Floating-point number	`%f`	`double`
	`%f32`	`single`
	`%f64`	`double`
	`%n`	`double`

Nonnumeric Fields

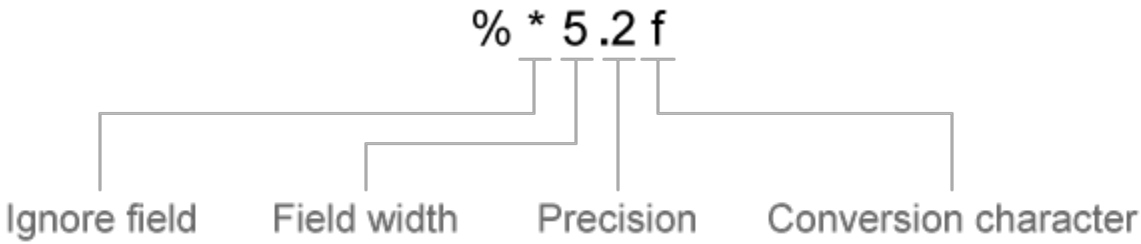
This table lists available conversion specifiers for inputs that include nonnumeric characters.

Strings	Conversion Specifier	Details
Character	`%c`	Read any single character, including a delimiter.
Text string	`%s`	Read a string.
	`%q`	Read a string. If the string begins with a double quotation mark ("), omit the leading quotation mark and its accompanying closing mark, which is the second instance of a lone double quotation mark. Replace escaped double quotation marks (for example, `""abc""`) with lone double quotation marks (`"abc"`). `%q` ignores any double quotation marks that appear after the closing double quotation mark. Example: `'%q'` reads `'"Joe ""Lightning"" Smith, Jr."'` as `'Joe "Lightning" Smith, Jr.'`.
Dates and time	`%D`	Read a string in the same way as `%q` above, and then convert to a datetime value.
	`%{`*`fmt`*`}D`	Read a string in the same way as `%q` above, and then convert to a datetime value. *`fmt`* describes the format of the input string. The *`fmt`* input is a string of letter identifiers that is a valid value for the `Format` property of a datetime. `textscan` converts strings that do not match this format to `NaT` values. For more information about datetime display formats, see the `Format` property for datetime arrays. Example: `'%{dd-MMM-yyyy}D'` specifies the format of a date such as `'01-Jan-2014'` .

Strings	Conversion Specifier	Details
Category string	`%C`	Read a string in the same way as `%q`, and then convert to a category name in a categorical array. `textscan` converts the string, `<undefined>` to an undefined value in the output categorical array.
Pattern-matching strings	`%[...]`	Read only the characters inside the brackets up to the first nonmatching character. To include `]` in the set, specify it first: `%[]...]`. Example: `%[mus]` reads `'summer '` as `'summ'`.
	`%[^...]`	Exclude characters inside the brackets, reading until the first matching character. To exclude `]`, specify it first: `%[^]...]`. Example: `%[^xrg]` reads `'summer '` as `'summe'`.

Optional Operators

Conversion specifiers in `formatSpec` can include optional operators, which appear in the following order (includes spaces for clarity):



Optional operators include:

- Fields and Characters to Ignore

  `textscan` reads all characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field.

Insert an asterisk character (*) after the percent character (%) to skip a field or a portion of a character field.

Operator	Action Taken
`%*k`	Skip the field. *k* is any conversion specifier identifying the field to skip. `textscan` does not create an output cell for any such fields. Example: `'%s %*s %s %s %*s %*s %s'` (spaces are optional) converts the string `'Blackbird singing in the dead of night'` to four output cells with the strings `'Blackbird' 'in' 'the' 'night'`
`'%*ns'`	Skip up to *n* characters, where *n* is an integer less than or equal to the number of characters in the field. Example: `'%*3s %s'` converts `'abcdefg'` to `'defg'`. When the delimiter is a comma, the same delimiter converts `'abcde,fghijkl'` to a cell array containing `'de';'ijkl'`.
`'%*nc'`	Skip *n* characters, including delimiter characters.

- Field Width

  `textscan` reads the number of characters or digits specified by the field width or precision, or up to the first delimiter, whichever comes first. A decimal point, sign (+ or -), exponent character, and digits in the numeric exponent are counted as characters and digits within the field width. For complex numbers, the field width refers to the individual widths of the real part and the imaginary part. For the imaginary part, the field width includes + or − but not `i` or `j`. Specify the field width by inserting a number after the percent character (%) in the conversion specifier.

  Example: `%5f` reads `'123.456'` as `123.4`.

  Example: `%5c` reads `'abcdefg'` as `'abcde'`.

  When the field width operator is used with single characters (`%c`), `textscan` also reads delimiter, white-space, and end-of-line characters.
  Example: `%7c` reads 7 characters, including white-space, so `'Day and night'` reads as `'Day and'`.

- Precision

For floating-point numbers (`%n`, `%f`, `%f32`, `%f64`), you can specify the number of decimal digits to read.

Example: `%7.2f` reads `'123.456'` as `123.45`.

- Literal Text to Ignore

  `textscan` ignores specified text appended to the `formatSpec` string.

  Example: `Level%u8` reads `'Level1'` as `1`.

  Example: `%u8Step` reads `'2Step'` as `2`.

`N` — Number of times to apply `formatSpec`

`Inf` (default) | positive integer

Number of times to apply `formatSpec`, specified as a positive integer.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`str` — Input string

string

Input string to read.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Names are not case sensitive.

Example: `C = textscan(fileID,formatSpec,'HeaderLines',3,'Delimiter',',')` skips the first three lines of the data, and then reads the remaining data, treating commas as a delimiter.

`'CollectOutput'` — Logical indicator determining data concatenation

`false` (default) | `true`

Logical indicator determining data concatenation, specified as the comma-separated pair consisting of `'CollectOutput'` and either `true` or `false`. If `true`, then `textscan` concatenates consecutive output cells of the same fundamental MATLAB class into a single array.

`'CommentStyle'` — Symbols designating text to ignore

string | cell array of strings

Symbols designating text to ignore, specified as the comma-separated pair consisting of `'CommentStyle'` and a string or cell array of strings.

For example, specify a string such as `'%'` to ignore characters following the string on the same line. Specify a cell array of two strings, such as `{'/*', '*/'}`, to ignore characters between the strings.

`textscan` checks for comments only at the start of each field, not within a field.

Example: `'CommentStyle',{'/*', '*/'}`

`'DateLocale'` — Locale for reading dates

string

Locale for reading dates, specified as the comma-separated pair consisting of `'DateLocale'` and a string in the form *`xx_YY`*, where *`xx`* is a lowercase ISO 639-1 two-letter code that specifies a language, and *`YY`* is an uppercase ISO 3166-1 alpha-2 code that specifies a country. For a list of common values for the locale, see the `Locale` name-value pair argument for the `datetime` function.

Use `DateLocale` to specify the locale in which textscan should interpret month and day of week names and abbreviations when reading text as dates using the `%D` format specifier.

Example: `'DateLocale','ja_JP'`

`'Delimiter'` — Field delimiter characters

string | cell array of strings

Field delimiter characters, specified as the comma-separated pair consisting of `'Delimiter'` and a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

Example: `'Delimiter',{';','*'}`

`textscan` interprets repeated delimiter characters as separate delimiters, and returns an empty value to the output cell.

Within each row of data, the default field delimiter is white-space. White-space can be any combination of space (`' '`), backspace (`'\b'`), or tab (`'\t'`) characters. If you do not specify a delimiter, then:

- the delimiter characters are the same as the white-space characters. The default white-space characters are `' '`, `'\b'`, and `'\t'`. Use the `'Whitespace'` name-value pair argument to specify alternate white-space characters.
- `textscan` interprets repeated white-space characters as a single delimiter.

When you specify one of the following escape sequences as a delimiter, `textscan` converts that sequence to the corresponding control character:

`\b`	Backspace
`\n`	Newline
`\r`	Carriage return
`\t`	Tab
`\\`	Backslash (\)

`'EmptyValue'` — Returned value for empty numeric fields

`NaN` (default) | scalar

Returned value for empty numeric fields in delimited text files, specified as the comma-separated pair consisting of `'EmptyValue'` and a scalar.

`'EndOfLine'` — End-of-line characters

string

End-of-line characters, specified as the comma-separated pair consisting of `'EndOfLine'` and a string. The string must specify a single character or be `'\r\n'`. The default end-of-line sequence depends on the format of your file and can include a newline character (`'\n'`), a carriage return (`'\r'`), or a combination of the two (`'\r\n'`).

If there are missing values and an end-of-line sequence at the end of the last line in a file, then `textscan` returns empty values for those fields. This ensures that individual cells in output cell array, `C`, are the same size.

Example: `'EndOfLine',':'`

'ExpChars' — Exponent characters
'eEdD' (default) | string

Exponent characters, specified as the comma-separated pair consisting of 'ExpChars' and a string. The default exponent characters are e, E, d, and D.

'HeaderLines' — Number of header lines
0 (default) | positive integer

Number of header lines, specified as the comma-separated pair consisting of 'HeaderLines' and a positive integer. textscan skips the header lines, including the remainder of the current line.

'MultipleDelimsAsOne' — Multiple delimiter handling
0 (false) (default) | 1 (true)

Multiple delimiter handling, specified as the comma-separated pair consisting of 'MultipleDelimsAsOne' and either true or false. If true, textscan treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter. You must also specify the Delimiter option.

Example: 'MultipleDelimsAsOne',1

'ReturnOnError' — Behavior when textscan fails to read or convert
1 (true) (default) | 0 (false)

Behavior when textscan fails to read or convert, specified as the comma-separated pair consisting of 'ReturnOnError' and either true or false. If true, textscan terminates without an error and returns all fields read. If false, textscan terminates with an error and does not return an output cell array.

'TreatAsEmpty' — Strings to treat as empty value
string | cell array of strings

Strings to treat as empty values, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a single string or cell array of strings. This option only applies to numeric fields.

'Whitespace' — White-space characters
' \b\t' (default) | string

White-space characters, specified as the comma-separated pair consisting of 'Whitespace' and a string of one or more characters. textscan adds a space

character, `char(32)`, to any specified `Whitespace`, unless `Whitespace` is empty (`''`) and `formatSpec` includes any string conversion specifier.

When you specify one of the following escape sequences as any white-space character, `textscan` converts that sequence to the corresponding control character:

`\b`	Backspace
`\n`	Newline
`\r`	Carriage return
`\t`	Tab
`\\`	Backslash (\)

Output Arguments

`C` — File or string data

cell array

File or string data, returned as a cell array.

For each numeric conversion specifier in `formatSpec`, the `textscan` function returns a `K`-by-1 MATLAB numeric vector to the output cell array, `C`, where `K` is the number of times that `textscan` finds a field matching the specifier.

For each string conversion specifier in `formatSpec`, the `textscan` function returns a `K`-by-1 cell vector of strings, where `K` is the number of times that `textscan` finds a field matching the specifier. For each character conversion that includes a field width operator, `textscan` returns a `K`-by-`M` character array, where `M` is the field width.

For each datetime or categorical conversion specifier in `formatSpec`, the `textscan` function returns a `K`-by-1 datetime or categorical vector to the output cell array, `C`, where `K` is the number of times that `textscan` finds a field matching the specifier.

`position` — File or string position

integer

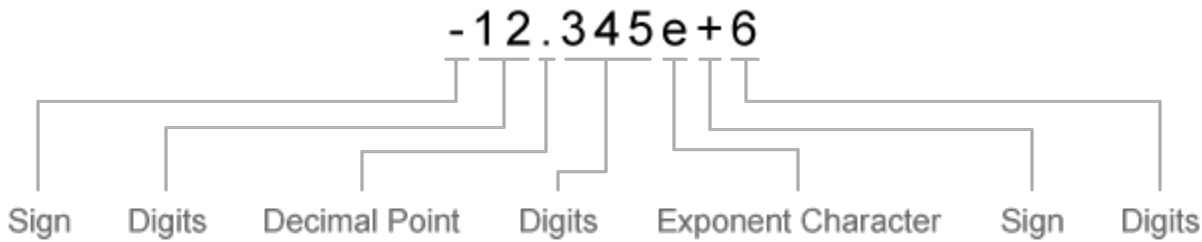
File or string position at the end of the scan, returned as an integer of class `double`. For a file, `ftell(fileID)` would return the same value after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

More About

Algorithms

`textscan` converts numeric fields to the specified output type according to MATLAB rules regarding overflow, truncation, and the use of `NaN`, `Inf`, and `-Inf`. For example, MATLAB represents an integer `NaN` as zero. If `textscan` finds an empty field associated with an integer format specifier (such as `%d` or `%u`), it returns the empty value as zero and not `NaN`.

When matching data to a string conversion specifier, `textscan` reads until it finds a delimiter or an end-of-line character. When matching data to a numeric conversion specifier, `textscan` reads until it finds a nonnumeric character. When `textscan` can no longer match the data to a particular conversion specifier, it attempts to match the data to the next conversion specifier in the `formatSpec` string. Sign (`+` or `-`), exponent characters, and decimal points are considered numeric characters.



Sign	Digits	Decimal Point	Digits	Exponent Character	Sign	Digits
Read one sign character if it exists.	Read one or more digits.	Read one decimal point if it exists.	If there is a decimal point, read one or more digits that immediately follow it.	Read one exponent character if it exists.	If there is an exponent character, read one sign character.	If there is an exponent character, read one or more digits that follow it.

`textscan` imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type (such as `%d` or `%f`). Valid forms for a complex number are:

`±<real>±<imag>i|j`	Example: `5.7-3.1i`
`±<imag>i|j`	Example: `-7j`

Do not include embedded white space in a complex number. `textscan` interprets embedded white space as a field delimiter.

textwrap

Wrapped string matrix for given uicontrol

Syntax

```
outstring = textwrap(h,instring)
outstring = textwrap(h,instring,columns)
[outstring,position] = textwrap(...)
```

Description

`outstring = textwrap(h,instring)` returns a wrapped string cell array, `outstring`, that fits inside the uicontrol with handle `h`. `instring` is a cell array, with each cell containing a single line of text. `outstring` is the wrapped string matrix in cell array format. Each cell of the input string is considered a paragraph.

`outstring = textwrap(h,instring,columns)` returns an `outstring` with each line wrapped at `columns` characters. Spaces are included in the character count.

`[outstring,position] = textwrap(...)` returns the recommended position of the uicontrol in the units of the uicontrol. `position` considers the extent of the multiline text in the *x* and *y* directions.

`textwrap` maintains the original line breaks in the input cell array and adds new ones. It can calculate uicontrol positions with any type of `Units`, including normalized units.

Examples

Place two text-wrapped strings in text uicontrols. The left one has a `Position` calculated by `textwrap` in `Units` of `pixels`; the right one's `Position` is calculated manually in `Units` of `characters`:

```
figure('Position',[560 528 350 250]);
% Make a text uicontrol to wrap in Units of Pixels
% Create it in Units of Pixels, 100 wide, 10 high
pos = [10 100 100 10];
ht = uicontrol('Style','Text','Position',pos);
```

```
string = {'This is a string for the left text uicontrol.',...
          'to be wrapped in Units of Pixels,',...
          'with a position determined by TEXTWRAP.'};
% Wrap string, also returning a new position for ht
[outstring,newpos] = textwrap(ht,string) %#ok<NOPRT>

outstring =
    'This is a string for'
    'the left text'
    'uicontrol.'
    'to be wrapped in'
    'Units of Pixels,'
    'with a position'
    'determined by'
    'TEXTWRAP.'

newpos =
    10   100    91   124

set(ht,'String',outstring,'Position',newpos)

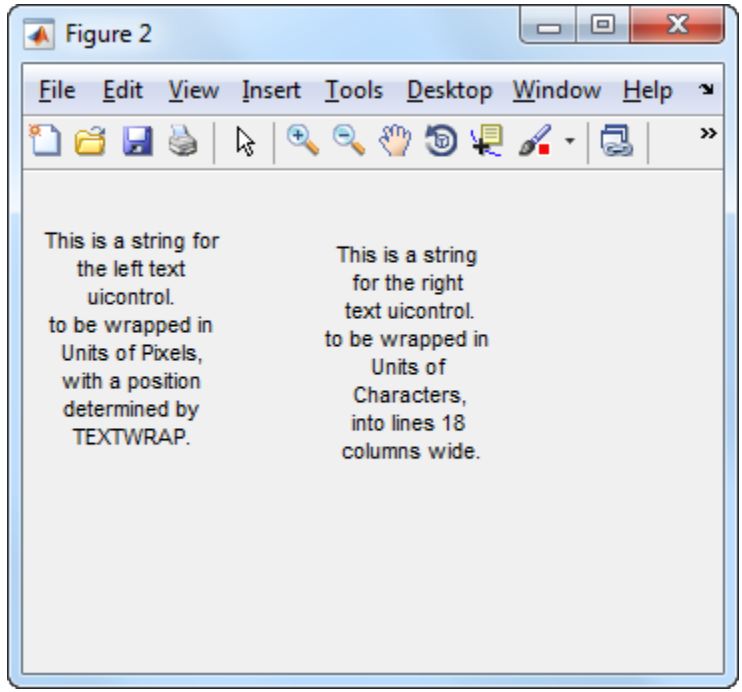
% Make another text uicontrol to wrap to a column width of 18
colwidth = 18;
% Create it in Units of Pixels, 100 wide, 10 high
pos1 = [150 100 100 10];
ht1 = uicontrol('Style','Text','Position',pos1);
string1 = {'This is a string for the right text uicontrol.',...
          'to be wrapped in Units of Characters,',...
          'into lines 18 columns wide.'};
outstring1 = textwrap(ht1,string1,colwidth);
% Reset Units of ht1 to Characters to use the result
set(ht1,'Units','characters')
newpos1 = get(ht1,'Position')

newpos1 =
   29.8000    7.6154   20.0000    0.7692

% Set new Position in Characters to be specified colwidth
% with height the length of the outstring1 cell array + 1.
newpos1(3) = colwidth;
newpos1(4) = length(outstring1)+1

newpos1 =
   29.8000    7.6154   15.0000   10.0000
```

```
set(ht1,'String',outstring1,'Position',newpos1)
```



More About

Tips

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uicontrol object fires the CreateFcn callback repeatedly, which raises a series of error messages.

Introduced before R2006a

tfqmr

Transpose-free quasi-minimal residual method

Syntax

```
x = tfqmr(A,b)
x = tfqmr(afun,b)
x = tfqmr(a,b,tol)
x = tfqmr(a,b,tol,maxit)
x = tfqmr(a,b,tol,maxit,m)
x = tfqmr(a,b,tol,maxit,m1,m2,x0)
[x,flag] = tfqmr(A,B,...)
[x,flag,relres] = tfqmr(A,b,...)
[x,flag,relres,y]y(A,b,...)
[x,flag,relres,iter,resvec] = tfqmr(A,b,...)
```

Description

`x = tfqmr(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and the right-hand side column vector `b` must have length `n`.

`x = tfqmr(afun,b)` accepts a function handle, `afun`, instead of the matrix `A`. The function, `afun(x)`, accepts a vector input `x` and returns the matrix-vector product `A*x`. In all of the following syntaxes, you can replace `A` by `afun`. "Parameterizing Functions" explains how to provide additional parameters to the function `afun`.

`x = tfqmr(a,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `tfqmr` uses the default, 1e-6.

`x = tfqmr(a,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `tfqmr` uses the default, `min(N,20)`.

`x = tfqmr(a,b,tol,maxit,m)` and `x = tfqmr(a,b,tol,maxit,m1,m2)` use preconditioners `m` or `m=m1*m2` and effectively solve the system `A*inv(M)*x = B` for `x`. If

M is [] then a preconditioner is not applied. M may be a function handle mfun such that mfun(x) returns m\x.

x = tfqmr(a,b,tol,maxit,m1,m2,x0) specifies the initial guess. If x0 is [] then tfqmr uses the default, an all zero vector.

[x,flag] = tfqmr(A,B,...) also returns a convergence flag:

Flag	Convergence
0	tfqmr converged to the desired tolerance tol within maxit iterations.
1	tfqmr iterated maxit times but did not converge.
2	Preconditioner m was ill-conditioned.
3	tfqmr stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during tfqmr became too small or too large to continue computing.

[x,flag,relres] = tfqmr(A,b,...) also returns the relative residual norm(b-A*x)/norm(b). If flag is 0, then relres <= tol.

[x,flag,relres,y]y(A,b,...) also returns the iteration number at which x was computed: 0 <= iter <= maxit.

[x,flag,relres,iter,resvec] = tfqmr(A,b,...) also returns a vector of the residual norms at each iteration, including norm(b-A*x0).

Examples

Using tfqmr with Matrix or Function Handle Input

This example shows how to use tfqmr with a matrix input and with a function input.

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
```

```
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = tfqmr(A,b,tol,maxit,M1,M2,[]);
```

You can also use a matrix-vector product function as input:

```
function y = afun(x,n)
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
y(1:n-1) = y(1:n-1) - x(2:n);
x1 = tfqmr(@(x)afun(x,n),b,tol,maxit,M1,M2);
```

If `applyOp` is a function suitable for use with `qmr`, it may be used with `tfqmr` by wrapping it in an anonymous function:

```
x1 = tfqmr(@(x)applyOp(x,'notransp'),b,tol,maxit,M1,M2);
```

Using tfqmr with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

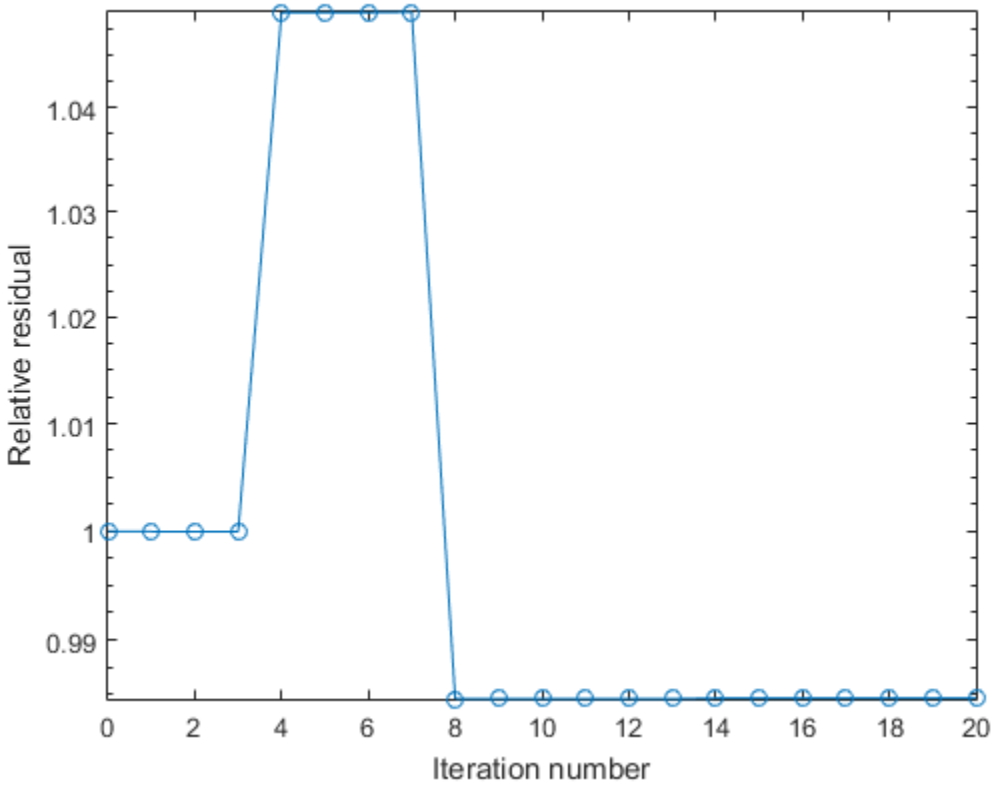
Use `tfqmr` to find a solution at the requested tolerance and number of iterations.

```
[x0,fl0,rr0,it0,rv0] = tfqmr(A,b,tol,maxit);
```

`fl0` is 1 because `tfqmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `tfqmr`.

```
semilogy(0:maxit,rv0(1:maxit+1)/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



Note that like `bicgstab`, `tfqmr` keeps track of half iterations. The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

```
Error using ilu
```

```
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = tfqmr(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `tfqmr` drives the relative residual to `4.1410e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

You can follow the progress of `tfqmr` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

`bicg` | `bicgstab` | `bicgstabl` | `cgs` | `function_handle` | `gmres` | `ilu` | `lsqr` | `minres` | `mldivide` | `pcg` | `qmr` | `symmlq`

tic

Start stopwatch timer

Syntax

```
tic
timerVal = tic
```

Description

`tic` starts a stopwatch timer to measure performance. The function records the internal time at execution of the `tic` command. Display the elapsed time with the `toc` function.

`timerVal = tic` returns the value of the internal timer at the execution of the `tic` command, so that you can record time for simultaneous time spans.

Output Arguments

`timerVal`

Value of the internal timer at the execution of the `tic` command. This value is used as an input argument for a subsequent call to `toc`. You should not rely on the meaning of this value.

Examples

Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.

```
tic
A = rand(12000, 4400);
B = rand(12000, 4400);
toc
C = A'.*B';
```

```
toc
```

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
    A = rand(n,n);
    b = rand(n,1);
    tic;
    x = A\b;
    t(n) = toc;
end
plot(t)
```

Measure multiple time spans simultaneously using two pairs of `tic/toc` calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000;   minTime = Inf;   nsum = 10;
tic;  % TIC, pair 1

for i=1:REPS
   tStart = tic;  % TIC, pair 2
   total = 0;
   for j=1:nsum
      total = total + besselj(j,REPS);
   end

   tElapsed = toc(tStart);  % TOC, pair 2
   minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS;  % TOC, pair 1
```

More About

Tips

- Consecutive `tic` commands overwrite the internally recorded starting time.
- The `clear` function does not reset the starting time recorded by a `tic` command.
- The following actions result in unexpected output:
  - Using `tic` and `toc` to time `timeit`

- Using `tic` and `toc` within a function timed by `timeit`

See Also

`clock` | `cputime` | `etime` | `profile` | `timeit` | `toc`

Introduced before R2006a

timeit

Measure time required to run function

Syntax

```
t = timeit(f)
t = timeit(f,numOutputs)
```

Description

`t = timeit(f)` measures the typical time (in seconds) required to run the function specified by the function handle `f`.

`t = timeit(f,numOutputs)` calls `f` with the desired number of outputs, `numOutputs`. By default, `timeit` calls the function `f` with one output (or no outputs, if the function does not return any outputs).

Examples

Determine Time to Obtain Current Date

Use `timeit` to time a function call to `date`. This example uses a handle to a function that accepts no input.

```
f = @date;
t = timeit(f)
```

```
t =

   4.1257e-05
```

Determine Time to Compute Matrix Summation

Time the combination of several mathematical matrix operations: matrix transposition, element-by-element multiplication, and summation of columns.

```
A = rand(12000,400);
B = rand(400,12000);
f = @() sum(A.'.*B, 1);
timeit(f)
```

```
ans =

    0.0659
```

Compare Time to Run svd with Multiple Outputs

Determine how long it takes to run `svd` with one output argument, `s = svd(X)`.

```
X = rand(100);
f = @() svd(X);
t1 = timeit(f)
```

```
t1 =

    0.0021
```

Compare the results to `svd` with three output arguments, `[U,S,V] = svd(X)`.

```
t2 = timeit(f,3)
```

```
t2 =

    0.0043
```

Compare Time to Execute Custom Preallocation to Calling `zeros`

Create a short function to allocate a matrix using nested loops. Preallocating an array using a nested loop is inefficient, but is shown here for illustrative purposes.

```
function mArr = preAllocFcn(x,y)
for m = 1:x
    for n = 1:y
        mArr(m,n) = 0;
    end
```

```
end
end
```

Compare the time to allocate zeros to a matrix using nested loops and using the `zeros` function.

```
x = 1000;
y = 500;
g = @() preAllocFcn(x,y);
h = @() zeros(x,y);
diffRunTime = timeit(g)-timeit(h)
```

```
diffRunTime =

    0.2004
```

Input Arguments

`f` — function to be measured

function handle

Function to be measured, specified as a function handle. `f` is either a handle to a function that takes no input, or a handle to an anonymous function with an empty argument list.

`numOutputs` — Number of desired outputs from `f`

integer

Number of desired outputs from `f`, specified as an integer. If the function specified by `f` has a variable number of outputs, `numOutputs` specifies which syntax `timeit` uses to call the function. For example, the `svd` function returns a single output, `s`, or three outputs, `[U,S,V]`. Set `numOutputs` to `1` to time the `s = svd(X)` syntax, or set it to `3` to time the `[U,S,V] = svd(X)` syntax.

More About

Tips

- The following actions result in unexpected output:
  - Using `timeit` between `tic` and `toc`

- Using `timeit` to time a function that includes calls to `tic` and `toc`
- Using `timeit` recursively

Algorithms

`timeit` calls the specified function multiple times, and computes the median of the measurements.

- Anonymous Functions
- Analyzing Your Program's Performance
- MATLAB Performance Measurement White Paper on MATLAB Central File Exchange

See Also

`cputime` | `function_handle` | `tic` | `toc`

toc

Read elapsed time from stopwatch

Syntax

```
toc
elapsedTime = toc
toc(timerVal)
elapsedTime = toc(timerVal)
```

Description

`toc` reads the elapsed time from the stopwatch timer started by the `tic` function. The function reads the internal time at the execution of the `toc` command, and displays the elapsed time since the most recent call to the `tic` function that had no output, in seconds.

`elapsedTime = toc` returns the elapsed time in a variable.

`toc(timerVal)` displays the time elapsed since the `tic` command corresponding to `timerVal`.

`elapsedTime = toc(timerVal)` returns the elapsed time since the `tic` command corresponding to `timerVal`.

Input Arguments

`timerVal`

Value of the internal timer saved from a previous call to the `tic` command.

Output Arguments

`elapsedTime`

Scalar `double` representing the time elapsed between `tic` and `toc` commands, in seconds.

Examples

Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.

```
tic
A = rand(12000, 4400);
B = rand(12000, 4400);
toc
C = A'.*B';
toc
```

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
    A = rand(n,n);
    b = rand(n,1);
    tic;
    x = A\b;
    t(n) = toc;
end
plot(t)
```

Measure multiple time spans simultaneously using two pairs of `tic/toc` calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000;   minTime = Inf;   nsum = 10;
tic;  % TIC, pair 1

for i=1:REPS
   tStart = tic;  % TIC, pair 2
   total = 0;
   for j=1:nsum
```

```
      total = total + besselj(j,REPS);
   end

   tElapsed = toc(tStart);  % TOC, pair 2
   minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS;  % TOC, pair 1
```

More About

Tips

- Consecutive calls to the `toc` function with no input return the elapsed since the most recent `tic`. Therefore, you can take multiple measurements from a single point in time.

  Consecutive calls to the `toc` function with the same `timerVal` input return the elapsed time since the `tic` function call that corresponds to that input.
- The following actions result in unexpected output:
  - Using `tic` and `toc` to time `timeit`
  - Using `tic` and `toc` within a function timed by `timeit`

Introduced before R2006a

Tiff class

MATLAB Gateway to LibTIFF library routines

Description

The `Tiff` class represents a connection to a Tagged Image File Format (TIFF) file and provides access to many of the capabilities of the LibTIFF library. Use the methods of the `Tiff` object to call routines in the LibTIFF library. While you can use the `imread` and `imwrite` functions to read and write TIFF files, the `Tiff` class offers capabilities that these functions don't provide, such as reading subimages, writing tiles and strips of image data, and modifying individual TIFF tags.

In most cases, the syntax of the `Tiff` method is similar to the syntax of the corresponding LibTIFF library function. To get the most out of the `Tiff` object, you must be familiar with the LibTIFF API, as well as the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

MATLAB supports LibTIFF version 4.0.0.

For copyright information, see the `libtiffcopyright.txt` file.

Construction

`obj = Tiff(filename,mode)` creates a `Tiff` object associated with the TIFF file `filename`. `mode` specifies the type of access to the file.

A TIFF file is made up of one or more image file directories (IFDs). An IFD contains image data and associated metadata. IFDs can also contain subIFDs which also contain image data and metadata. When you open a TIFF file for reading, the Tiff object makes the first IFD in the file the *current* IFD. `Tiff` methods operate on the current IFD. You can use `Tiff` object methods to navigate among the IFDs and the subIFDs in a TIFF file.

When you open a TIFF file for writing or appending, the `Tiff` object automatically creates a IFD in the file for writing subsequent data. This IFD has all the default values specified in TIFF Revision 6.0.

When creating a new TIFF file, before writing any image to the file, you must create certain required fields (tags) in the file. These tags include `ImageWidth`, `ImageHeight`,

`BitsPerSample`, `SamplesPerPixel`, `Compression`, `PlanarConfiguration`, and `Photometric`. If the image data has a stripped layout, the IFD contains the `RowsPerStrip` tag. If the image data has a tiled layout, the IFD contains the `TileWidth` and `TileHeight` tags. Use the `setTag` method to define values for these tags.

Input Arguments

`filename`

Text string specifying name of file.

`mode`

One of the following text strings specifying the type of access to the TIFF file.

Supported Values

Parameter	Description
`'r'`	Open file for reading (default)
`'w'`	Open file for writing; discard existing contents
`'w8'`	Open file for writing a BigTIFF file; discard existing contents
`'a'`	Open or create file for writing; append data to end of file.
`'r+'`	Open (do not create) file for reading and writing

Properties

`Compression`

Specify scheme used to compress image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

`None`
`CCITTRLE (Read-only)`

CCITTFax3
CCITTFax4
LZW
JPEG
CCITTRLEW (Read-only)
PackBits
SGILog
SGILog24
Deflate
AdobeDeflate (Same as deflate)

Example: Set the `Compression` tag to the value `JPEG`. Note how you use the property to specify the value.

```
tiffobj.setTag('Compression', Tiff.Compression.JPEG);
```

`ExtraSamples`

Describe extra components

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This field is required if there are extra channels in addition to the usual colormetric channels.

Supported Values

Value of `ExtraSamples`	Description
`Unspecified`	Unspecified data
`AssociatedAlpha`	Associated alpha (pre-multiplied)
`UnassociatedAlpha`	Unassociated alpha data

Example: Set the `ExtraSamples` tag to the value `AssociatedAlpha`. Note how you use the property to specify the value.

```
tiffobj.setTag('ExtraSamples', Tiff.ExtraSamples.AssociatedAlpha);
```

See Also “Specify Tiff object properties and describe alpha channel” on page 1-8221

Group3Options

Options for Group 3 Fax Compression

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property is also referred to as `Fax3` and `T4Options`. This value is a bit mask controlled by the first three bits.

Supported Values

Supported values include the following.

`Encoding2D`	Bit 0 is 1. This specifies two-dimensional coding. If more than one strip is specified, each strip must begin with a one-dimensionally coded line. That is, `RowsPerStrip` should be a multiple of Parameter K, as documented in the CCITT specification.
`Uncompressed`	Bit 1 is 1. This specifies an uncompressed mode when encoding.
`FillBits`	Bit 2 is 1. Fill bits are added as necessary before EOL codes such that EOL always ends on a byte boundary. This ensures an EOL-sequence of 1 byte preceded by a zero nibble, for example, `xxxx-0000 0000-0001`.

Example:

```
mask = bitor(Tiff.Group3Options.Encoding2D,Tiff.Group3Options.Uncompressed)
tiffobj.setTag('Group3Options',mask);
```

InkSet

Specify set of inks used in separated image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

In this context, separated refers to photometric interpretation, not the planar configuration.

Supported Values

`CMYK`	Order of components: cyan, magenta, yellow, black. Usually, a value of 0 represents 0% ink coverage and a value of 255 represents 100% ink coverage for that component, but consult the TIFF specification for `DotRange`. When you specify CMYK, do not set the `InkNames` tag.
`MultiInk`	Any ordering other than CMYK. Consult the TIFF specification for `InkNames` field for a description of the inks used.

Example:

```
tiffobj.setTag('InkSet', Tiff.InkSet.CMYK);
```

`JPEGColorMode`

Specify control of YCbCr/RGB conversion

Use these values only when the photometric interpretation is YCbCr.

This property should not be used for the purpose of reading YCbCr imagery as RGB. In this case, use the RGBA interface provided by the `readRGBAImage`, `readRGBAStrip`, and `readRGBATile` methods.

Supported Values

`Raw` (default)	Keep input as separate Y, Cb, and Cr matrices.
`RGB`	Convert RGB input to YCbCr.

Example:

```
tiffobj.setTag('JPEGColorMode',Tiff/JPEGColorMode.RGB);
```

See also “Create YCbCr/JPEG image from RGB data” on page 1-8222

`Orientation`

Specify visual orientation of the image data.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

The first row represents the top of the image, and the first column represents the left side. Support for this tag is for informational purposes only, and it does not affect how MATLAB reads or writes the image data.

Supported Values

`TopLeft`
`TopRight`
`BottomRight`
`BottomLeft`
`LeftTop`
`RightTop`
`RightBottom`
`LeftBottom`

Example:

```
tiffobj.setTag('Orientation', Tiff.Orientation.TopRight);
```

`Photometric`

Specify color space of image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

`MinIsWhite`
`MinIsBlack`
`RGB`
`Palette`
`Mask`
`Separated (CMYK)`
`YCbCr`
`CIELab`

ICCLab
ITULab
LogL
LogLUV
CFA
LinearRaw

Example:

```
tiffobj.setTag('Photometric', Tiff.Photometric.RGB);
```

PlanarConfiguration

Specifies how image data components are stored on disk

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

Chunky	Store component values for each pixel contiguously. For example, in the case of RGB data, the first three pixels would be stored in the file as RGBRGBRGB etc. Almost all TIFF images have contiguous planar configurations.
Separate	Store component values for each pixel separately. For example, in the case of RGB data, the red component would be stored separately in the file from the green and blue components.

Example:

```
tiffobj.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.Chunky);
```

ResolutionUnit

Specify unit of measure used to interpret the `XResolution` and `YResolution` tags.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

`None` (default)
`Inch`
`Centimeter`

Example: Set `ResolutionUnit` tag to the value `Inch`. Then, setting `XResolution` tag to 300 means pixels per inch.

```
tiffObj.setTag('ResolutionUnit', Tiff.ResolutionUnit.Inch);
tiffObj.setTag('XResolution', 300);
tiffObj.setTag('YResolution', 300);
```

`SampleFormat`

Specify how to interpret each pixel sample

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the examples.

Supported Values

`UInt` (default)
`Int`
`IEEEFP`

`Void`, `ComplexInt`, and `ComplexIEEEFP` are not supported.

Example:

```
tiffobj.setTag('SampleFormat', Tiff.SampleFormat.IEEEFP);
```

`SGILogDataFmt`

Specify control of client data for SGILog codec

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

These enumerated values should only be used when the photometric interpretation value is `LogL` or `LogLUV`. The `BitsPerSample`, `SamplesPerPixel`, and `SampleFormat` tags should not be set if the image type is `LogL` or `LogLuv`. The choice of `SGILogDataFmt` will set these tags automatically. The `Float` and `Bits8` settings imply a `SamplesPerPixel` value of 3 for `LogLUV` images, but only 1 for `LogL` images.

Supported Values

`Float`	Single precision samples
`Bits8`	`uint8` samples (read only)

This tag can be set only once per instance of a `LogL`/`LogLuv` Tiff image object instance.

Example:

```
tiffobj = Tiff('example.tif','r');
tiffobj.setDirectory(3); % image three is a LogLuv image
tiffobj.setTag('SGILogDataFmt', Tiff.SGILogDataFmt.Float);
imdata = tiffobj.read();
```

`SubFileType`

Specify type of image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

`SubFileType` is a bitmask that indicates the type of the image.

Supported Values

`Default`	Default value for single image file or first image.
`ReducedImage`	The current image is a thumbnail or reduced-resolution image that typically would be found in a sub-IFD.
`Page`	The image is a single image of a multi-image (or multipage) file.
`Mask`	The image is a transparency mask for another image in the file. The photometric interpretation value must be Photometric.Mask.

Example:

```
tiffobj.setTag('SubFileType', Tiff.SubFileType.Mask);
```

TagID

List of recognized TIFF tag names with their ID numbers

This property identifies all the supported TIFF tags with their ID numbers. Use this property to specify a tag when using the `setTag` method. For example, `Tiff.TagID.ImageWidth` returns the ID of the `ImageWidth` tag. To get a list of the names of supported tags, use the `getTagNames` method.

Example:

```
tiffobj.setTag(Tiff.TagID.ImageWidth, 300);
```

Thresholding

Specifies technique used to convert from gray to black and white pixels.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

Supported Values

`BiLevel` (default)
`HalfTone`
`ErrorDiffuse`

Example:

```
tiffobj.setTag('Thresholding', Tiff.Thresholding.HalfTone);
```

YCbCrPositioning

Specify relative positioning of chrominance samples

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property identifies all supported values for the `YCbCrPositioning` tag.

Supported Values

`Centered`	Specify for compatibility with industry standards such as PostScript Level 2

`Cosited`	Specify for compatibility with most digital video standards such as CCIR Recommendation 601-1.

Example:

```
tiffobj.setTag('YCbCrPositioning', Tiff.YCbCrPositioning.Centered);
```

Methods

close	Close Tiff object
computeStrip	Index number of strip containing specified coordinate
computeTile	Index number of tile containing specified coordinates
currentDirectory	Index of current IFD
getTag	Value of specified tag
getTagNames	List of recognized TIFF tags
getVersion	LibTIFF library version
isTiled	Determine if tiled image
lastDirectory	Determine if current IFD is last in file
nextDirectory	Make next IFD current IFD
numberOfStrips	Total number of strips in image
numberOfTiles	Total number of tiles in image

read	Read entire image
readEncodedStrip	Read data from specified strip
readEncodedTile	Read data from specified tile
readRGBAImage	Read image using RGBA interface
readRGBAStrip	Read strip data using RGBA interface
readRGBATile	Read tile data using RGBA interface
rewriteDirectory	Write modified metadata to existing IFD
setDirectory	Make specified IFD current IFD
setSubDirectory	Make subIFD specified by byte offset current IFD
setTag	Set value of tag
write	Write entire image
writeDirectory	Create new IFD and make it current IFD
writeEncodedStrip	Write data to specified strip
writeEncodedTile	Write data to specified tile

Examples

Create New TIFF File Using `Tiff` object

Create a new file called `myfile.tif`. To run this example, your directory must be writable.

```
t = Tiff('myfile.tif', 'w');
```

Close the Tiff object.

```
t.close();
```

Specify Tiff object properties and describe alpha channel

Create an array of data, `data`, that contains colormetric channels and an alpha channel.

```
rgb = imread('example.tif');
numrows = size(rgb,1);
numcols = size(rgb,2);
alpha = 255*ones([numrows numcols], 'uint8');
data = cat(3,rgb,alpha);
```

Create a `Tiff` object, `t`, and set the object properties. Set the value of the `ExtraSamples` tag because the data contains the alpha channel in addition to the colormetric channels.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.RGB);
t.setTag('Compression',Tiff.Compression.None);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',4);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ExtraSamples',Tiff.ExtraSamples.Unspecified);
t.setTag('ImageLength',numrows);
t.setTag('ImageWidth',numcols);
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write the data to the `Tiff` object.

```
t.write(data);
```

```
t.close();
```

Create YCbCr/JPEG image from RGB data

Get RGB data.

```
rgb = imread('example.tif');
```

Create a `Tiff` object, `t`, and set the object properties. Specify RGB input data using the `JPEGColorMode` property.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.YCbCr);
t.setTag('Compression',Tiff.Compression.JPEG);
t.setTag('YCbCrSubSampling',[2 2]);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',3);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ImageLength',size(rgb,1));
t.setTag('ImageWidth',size(rgb,2));
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
t.setTag('JPEGColorMode',Tiff.JPEGColorMode.RGB);
t.setTag('JPEGQuality',75);
```

Write the data to the `Tiff` object.

```
t.write(rgb);
t.close();
```

- “Reading Image Data and Metadata from TIFF Files”

See Also

`imread` | `imwrite` | `imfinfo`

time

Convert time of calendar duration to duration

Syntax

```
t = time(d)
```

Description

`t = time(d)` returns the time components of the calendar duration values in `d` as durations. The `t` output is the same size as `d`.

Examples

Convert Time of Calendar Durations to Durations

Create an array of calendar durations.

```
d = caldays(8:10) + hours(1.2345)
```

```
d =

    8d 1h 14m 4.2s    9d 1h 14m 4.2s   10d 1h 14m 4.2s
```

Convert the time components of the array to durations.

```
t = time(d)
```

```
t =

   01:14:04   01:14:04   01:14:04
```

View the data type of `t`.

```
whos t
  Name      Size            Bytes  Class       Attributes

  t         1x3               144  duration
```

Input Arguments

d — Input calendar duration

scalar | vector | matrix | multidimensional array

Input calendar duration, specified as a scalar, vector, matrix, or multidimensional `calendarDuration` array.

See Also

`caldays` | `calmonths` | `calquarters` | `calweeks` | `calyears` | `duration`

Introduced in R2014b

timeofday

Convert time of datetime to duration

Syntax

```
d = timeofday(t)
```

Description

`d = timeofday(t)` returns an array of durations equal to the time components of the datetime values in `t`. The `d` output is the same size as `t`.

```
timeofday(t) = t - dateshift(t,'start','day')
```

Examples

Convert Time of Datetimes to Durations

Create a `datetime` array.

```
t = datetime('now') + hours(1:3)
```

```
t =

   23-Feb-2015 10:58:45   23-Feb-2015 11:58:45   23-Feb-2015 12:58:45
```

Convert the time components of the array to durations.

```
d = timeofday(t)
```

```
d =

   10:58:45   11:58:45   12:58:45
```

View the data type of `d`.

```
whos d
```

```
  Name      Size            Bytes  Class       Attributes

  d         1x3               144  duration
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

See Also

`dateshift` | `duration` | `hms` | `hour` | `minute` | `second`

Introduced in R2014b

timer class

Create object to schedule execution of MATLAB commands

Description

Use a `timer` object to schedule the execution of MATLAB commands one or multiple times. If you schedule the timer to execute multiple times, you can define the time between executions and how to handle queuing conflicts.

The `timer` object uses callback functions to execute commands. Callback functions execute code during some event. For the `timer` object, you can specify the callback function as a function handle or as a string. If the callback function is a string, MATLAB evaluates it as executable code. The timer object supports callback functions when a timer starts (`StartFcn`), executes (`TimerFcn`), stops (`StopFcn`), or encounters an error (`ErrorFcn`).

Note: The `timer` object is subject to the limitations of your hardware, operating system, and software. Avoid using timer objects for real-time applications.

Construction

`t = timer` creates an empty `timer` object to schedule execution of MATLAB commands. An error occurs if the timer starts and `TimerFcn` is not defined.

`t = timer(Name,Value)` creates a `timer` object with additional options that you specify using one or more Name,Value pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

The argument name, `Name`, corresponds to a `timer` property name. In the constructor, the property values are specified using Name,Value pair arguments.

`'BusyMode'`

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
`'drop'`	Adds task to queue	Drops task	Possible skipping of `TimerFcn` calls
`'error'`	Adds task to queue	Completes task; throws error specified by `ErrorFcn`; stops timer	Stops timer after completing task in execution queue
`'queue'`	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts `Period` property to manage tasks in execution queue

See "Handling Timer Queuing Conflicts" for more information.

Default: `'drop'`

`'ErrorFcn'`

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.

- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

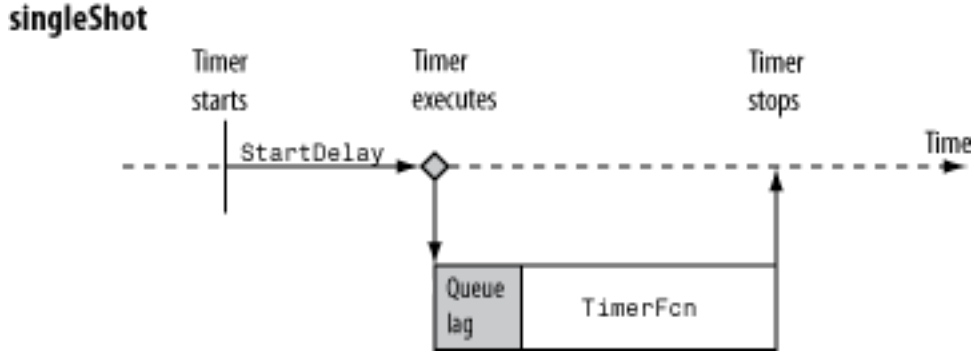
For more information, see "Timer Callback Functions".

`'ExecutionMode'`

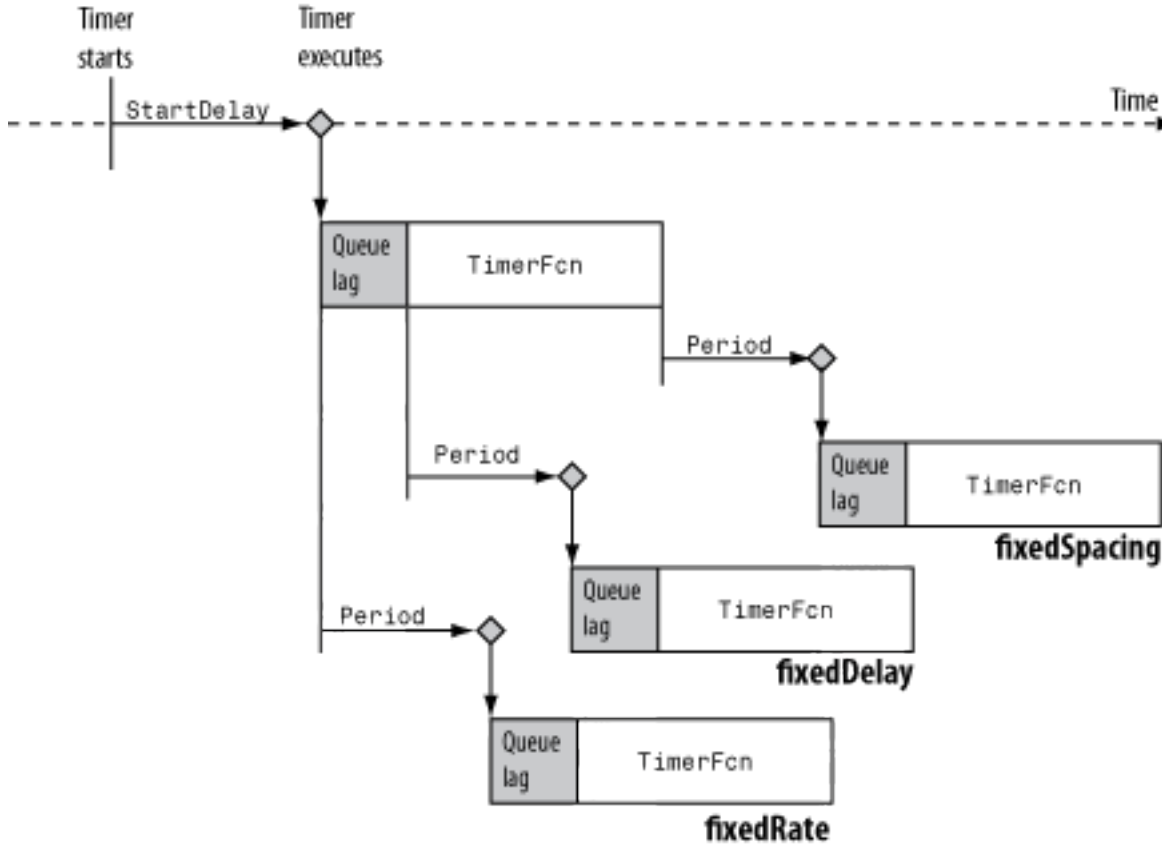
String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time `Period` Start Point
`'singleShot'`	In this mode, the timer callback function is only executed once. Therefore, the `Period` property has no effect. This is the default execution mode.
`'fixedRate'`	Starts immediately after the timer callback function is added to the MATLAB execution queue
`'fixedDelay'`	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
`'fixedSpacing'`	Starts when the timer callback function finishes executing.

- `'singleShot'` is the single execution mode for the `timer` class, and is the default value.



- `'fixedDelay'`, `'fixedRate'`, and `'fixedSpacing'` are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.



Default: `'singleShot'`

`'Name'`

String representing the `timer` name.

Default: `'timer-`*`i`*`'`, where *`i`* is a number indicating the *`i`*th timer object created this session. To reset *`i`* to 1, execute the `clear classes` command.

`'ObjectVisibility'`

String with possible values of `'on'` or `'off'`, that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function

does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

Default: `'on'`

`'Period'`

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

Default: 1.0

`'StartDelay'`

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

Default: 0

`'StartFcn'`

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

`'StopFcn'`

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

`'Tag'`

String that represents a label for the object.

`'TasksToExecute'`

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

Default: `Inf`

`'TimerFcn'`

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

`'UserData'`

Generic field for data that you want to add to the object.

Properties

`AveragePeriod`

Average time in seconds between `TimerFcn` executions since the timer started. Value is `NaN` until timer executes two timer callbacks.

`InstantPeriod`

The time in seconds between the last two executions of `TimerFcn`. Value is `NaN` until timer executes two timer callbacks.

`Running`

String defined as `'off'` or `'on'`, indicating whether the timer is currently executing callback functions.

`TasksExecuted`

The number of times the timer called `TimerFcn` since the timer started.

`Type`

String that identifies the object type.

Methods

delete	Remove timer object from memory
get	Query property values for timer object
isvalid	Determine timer object validity
set	Set property values for timer object
start	Start timer object
startat	Schedule timer to fire at specified time
stop	Stop timer object
timerfind	Find timer object
timerfindall	Find timer object, regardless of visibility
wait	Block command prompt until timer stops running

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Display Message Using Timer

Display a message using an anonymous function as a callback function. It is important to note that the first two arguments the callback function passes are a handle to the

timer object and an event structure. Even if the function doesn't use these arguments, the function definition requires them.

Wait 3 seconds, and then display the message '3 seconds have elapsed'.

```
t = timer;
t.StartDelay = 3;
t.TimerFcn = @(myTimerObj, thisEvent)disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Suppose the function does not require the timer or event object. Use the tilde (~) operator to ignore the inputs.

```
t.TimerFcn = @(~,~) disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Delete the timer object.

```
delete(t)
```

Execute Callback Function Multiple Times

Display the event and date/time output when the timer starts, fires, and stops. The timer callback function will be executed 3 times with 2 seconds between calls. The first two arguments the callback function passes are a handle to the timer object and an event structure. The event structure contains two fields: `Type` is a string that identifies the type of event that caused the callback, and `Data` is a structure that contains a date time vector of when the event occurred.

```
t = timer;
t.StartFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
    datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.TimerFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
     datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.StopFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
    datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.Period = 2;
t.TasksToExecute = 3;
t.ExecutionMode = 'fixedRate';
start(t)
```

```
StartFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:52.865
TimerFcn executed 14-Mar-2013 09:08:54.866
StopFcn executed 14-Mar-2013 09:08:54.869
```

Delete the timer object.

```
delete(t)
```

Define Custom Callback Functions

Create a timer object to remind yourself to take 30-second ergonomic breaks every 10 minutes over the course of 8 hours.

Create a function in a file named `createErgoTimer.m` that returns a timer object. Have this file include three local functions to handle timer start, execute, and stop tasks.

```
function t = createErgoTimer()
secondsBreak = 30;
secondsBreakInterval = 600;
secondsPerHour = 60^2;
secondsWorkTime = 8*secondsPerHour;

t = timer;
t.UserData = secondsBreak;
t.StartFcn = @ergoTimerStart;
t.TimerFcn = @takeBreak;
t.StopFcn = @ergoTimerCleanup;
t.Period = secondsBreakInterval+secondsBreak;
t.StartDelay = t.Period-secondsBreak;
t.TasksToExecute = ceil(secondsWorkTime/t.Period);
t.ExecutionMode = 'fixedSpacing';
end
```

Using `StartDelay` allows the timer to start without directing you to take a break immediately. Set the execution mode to `'fixedSpacing'` so that `10` minutes and `30` seconds (`t.Period`) elapses after the completion of a `TimerFcn` execution. This allows you to stretch for `30` seconds before the start of the next `10` minute interval.

In the `createErgoTimer.m` file, add a local function to handle the tasks associated with starting the timer. By default, the `timer` object passes itself and event data to the callback function. The function disregards the event data.

```
function ergoTimerStart(mTimer,~)
secondsPerMinute = 60;
secondsPerHour = 60*secondsPerMinute;
str1 = 'Starting Ergonomic Break Timer.  ';
str2 = sprintf('For the next %d hours you will be notified',...
    round(mTimer.TasksToExecute*(mTimer.Period + ...
    mTimer.UserData)/secondsPerHour));
str3 = sprintf(' to take a %d second break every %d minutes.',...
    mTimer.UserData, (mTimer.Period - ...
    mTimer.UserData)/secondsPerMinute);
disp([str1 str2 str3])
end
```

Add a local function to handle the tasks associated with executing the timer. The `TimerFcn` callback should tell you to take a 30 second break.

```
function takeBreak(mTimer,~)
disp('Take a 30 second break.')
end
```

Add a local function to handle the tasks associated with stopping the timer.

```
function ergoTimerCleanup(mTimer,~)
disp('Stopping Ergonomic Break Timer.')
delete(mTimer)
end
```

Deleting the timer object removes it from memory.

From the command line, call the `createErgoTimer` function to create and start a timer.

```
t = createErgoTimer;
start(t)
```

```
Starting Ergonomic Break Timer.  For the next 8 hours you will be notified to take a 30
```

Every 10 minutes, you will be reminded to take a 30 second break.

```
Take a break.
```

You can leave the timer running for 8 hours or stop it manually. Recall that you included the task of deleting the timer from memory in the `StopFcn` callback.

```
stop(t)
```

```
Stopping Ergonomic Break Timer.
```

Tips

- To force the execution of the callback functions in the event queue, include a call to the `drawnow` function in your code. The `drawnow` function flushes the event queue.

Introduced before R2006a

delete

Class: timer

Remove timer object from memory

Syntax

```
delete(t)
```

Description

`delete(t)` removes the timer object, `t`, from memory. If `t` is an array of timer objects, `delete` removes all the objects from memory.

When you delete a timer object, it becomes invalid and you cannot reuse it. If multiple references to a timer object exist in the workspace, deleting the timer object invalidates the remaining references. To remove invalid timer objects references from the workspace, use the `clear` command.

Tips

- Use the `isvalid` method to determine if a timer object exists in memory, but is not cleared from the workspace.
- Use the `timerfind` and `timerfindall` methods to return timer objects currently existing in memory. This approach is useful if the reference to the timer object is cleared from the workspace (using the `clear` command), but not deleted from memory.

Input Arguments

`t`

Object of class `timer`.

Examples

Delete a Timer

Create and start a timer that generates a 10-by-10 array of random numbers.

```
t = timer('TimerFcn','rand(10);');
start(t)
```

Delete the timer from memory.

```
delete(t)
```

Call the `whos` function to see if a reference still exists in the workspace.

```
whos
```

```
  Name        Size              Bytes  Class     Attributes

  ans        10x10               800  double
  t           1x1                104  timer
```

Try to restart the timer.

```
start(t)
```

```
Error using timer/start (line 27)
Invalid timer object. This object has been deleted and should be removed from your work
```

The timer cannot be restarted.

Clear the timer object reference from the workspace.

```
clear t
```

Delete Multiple Timers Using timerfind

Use `delete` with the `timerfind` method to remove all visible timers from memory. This is an alternative to deleting individual timers by variable name.

Create and start three timers that compute the sine, cosine and tangent of `pi/4`.

```
t1 = timer('TimerFcn','sin(pi/4);');
t2 = timer('TimerFcn','cos(pi/4);');
t3 = timer('TimerFcn','tan(pi/4);');
```

Delete the timers from memory using `timerfind`. This removes all visible timer objects from memory.

```
delete(timerfind)
```

See Also

`timer` | `isvalid` | `timerfind` | `timerfindall`

Introduced before R2006a

get

Class: timer

Query property values for timer object

Syntax

```
get(t)
V = get(t)
V = get(t,propName)
```

Description

`get(t)` queries property values for timer object, `t`, and displays all property names and current values. `t` must be a scalar timer object.

`V = get(t)` queries property values for timer object, `t` and returns a structure, `V`, where each field name is the name of a property of `t` and each field contains the value of that property. If `t` is an M-by-1 vector of timer objects, `V` is an M-by-1 array of structures.

`V = get(t,propName)` returns the value, `V`, of the timer object property specified in `propName`. If `propNames` is a vector cell array of N property names, and `t` is a vector of M timer objects, `v` is an M-by-N cell array of property values.

Input Arguments

`t`

Object of class `timer`.

`propName`

String enclosed in single quotation marks that specifies a `timer` property.

Examples

Display All Properties of Timer

```
t = timer;
get(t)
```

```
       AveragePeriod: NaN
            BusyMode: 'drop'
            ErrorFcn: ''
       ExecutionMode: 'singleShot'
       InstantPeriod: NaN
                Name: 'timer-1'
    ObjectVisibility: 'on'
              Period: 1
             Running: 'off'
          StartDelay: 0
            StartFcn: ''
             StopFcn: ''
                 Tag: ''
       TasksExecuted: 0
      TasksToExecute: Inf
            TimerFcn: ''
                Type: 'timer'
            UserData: []
```

Delete the timer from memory.

```
delete(t)
```

Obtain Properties for Array of Timers

Create three timers.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Get properties of an array of timers.

```
V = get([t1,t2,t3])
```

```
V =
```

```
3x1 struct array with fields:

    AveragePeriod
    BusyMode
    ErrorFcn
    ExecutionMode
    InstantPeriod
    Name
    ObjectVisibility
    Period
    Running
    StartDelay
    StartFcn
    StopFcn
    Tag
    TasksExecuted
    TasksToExecute
    TimerFcn
    Type
    UserData
```

Delete the timers from memory.

```
delete([t1,t2,t3])
```

Obtain Single Property for Timer

Create a timer and determine if it is running.

```
t = timer;
get(t,'Running')
```

```
ans =

off
```

Delete the timer from memory.

```
delete(t)
```

Obtain Specified Properties for Array of Timers

Create three timers.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Obtain name, period, and running property values from the array of timers.

```
V = get([t1,t2,t3],{'Name','Running','Period'})
```

```
V =

    'timer-1'    'off'    [1]
    'timer-2'    'off'    [1]
    'timer-3'    'off'    [1]
```

Delete the timers

```
delete([t1,t2,t3])
```

Alternatives

You can also use dot notation can also be used to query timer object properties. For example, `t.Running` returns the same value as `get(t,'Running')`.

See Also

`timer` | `set`

Introduced before R2006a

isvalid

Class: timer

Determine timer object validity

Syntax

```
validCheck = isvalid(t)
```

Description

`validCheck = isvalid(t)` determines timer object validity and returns a logical array, `validCheck`, that contains a `0` where the elements of `t` are invalid timer objects and a `1` where the elements of `t` are valid timer objects.

An invalid timer object is an object that is deleted from memory using `delete` and cannot be reused. Use the `clear` command to remove an invalid timer object from the workspace.

Tips

- To return timer objects existing in memory, use the `timerfind` and `timerfindall` methods. This practice is useful if the reference to the timer object is cleared from the workspace (using the `clear` function), but the object has not been deleted from memory.

Input Arguments

`t`

Object or array of objects of class `timer`

Examples

Check Timer Object Validity

Create a timer object. While this timer object is valid, it cannot start because a `TimerFcn` is not defined.

```
t = timer;
out = isvalid(t)
```

```
out =

     1
```

Delete the timer object, making it invalid.

```
delete(t)
out1 = isvalid(t)
```

```
out1 =

     0
```

Introduced before R2006a

set

Class: timer

Set property values for timer object

Syntax

```
set(t)
propStruct = set(t)

set(t,Name)
propCell = set(t,Name)
```

Description

`set(t)` displays the property names and their possible values for all configurable properties of timer object `t`.

`propStruct = set(t)` returns the values in a `struct`.

`set(t,Name)` displays the possible values for the specified property, `Name`, of timer object, `t`.

`propCell = set(t,Name)` returns the values in a cell.

`set(t,Name,Value)` sets the properties specified by one or more Name,Value pair arguments. `t` can be a single timer object or a vector of timer objects, in which case `set` configures the property values for all timer objects, `t`.

`set(t,S)` configures the properties of `t`, with the values specified in `S`, where `S` is a structure whose field names are object property names.

`set(t,PN,PV)` configures the properties specified in the cell array of strings, `PN`, to the corresponding values in the cell array `PV`, for the timer object `t`.

Input Arguments

`t`

Object of class `timer`.

`S`

Structure whose field names are `timer` property names.

`PN,PV`

Cell array of strings, `PN`, and corresponding cell array of values, `PV`. The cell array of `PN` must be a 1-by-N or N-by-1 array. If `t` is an array of timer objects, `PV` can be an M-by-N cell array, where M is equal to the length of `t` and N is equal to the length of `PN`. In this case, each timer object is updated with a different set of values for the list of property names contained in `PN`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BusyMode'`

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

`BusyMode` Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
`'drop'`	Adds task to queue	Drops task	Possible skipping of `TimerFcn` calls
`'error'`	Adds task to queue	Completes task; throws error specified by `ErrorFcn`; stops timer	Stops timer after completing task in execution queue

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts Period property to manage tasks in execution queue

See "Handling Timer Queuing Conflicts" for more information.

Default: 'drop'

'ErrorFcn'

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls StopFcn.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the timer object and an event structure to the callback function. The event structure contains the type of event in the Type field and the time of the event in the Data field.
- If your callback function accepts arguments in addition to the timer object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

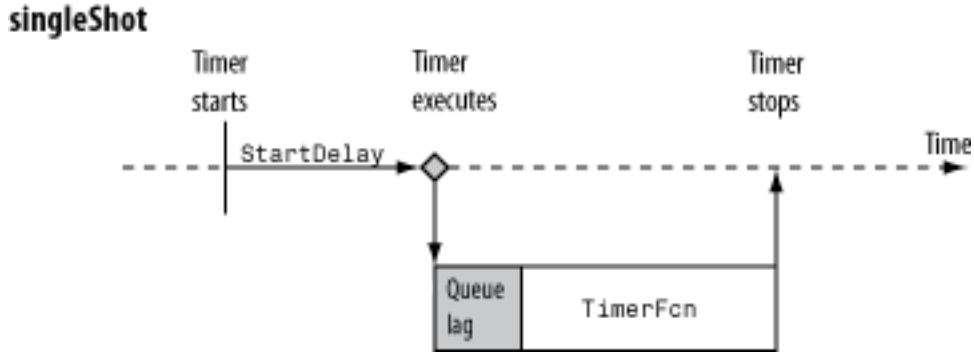
'ExecutionMode'

String that defines how the timer object schedules timer events. When Running='on', ExecutionMode is read only. This table summarizes the execution modes.

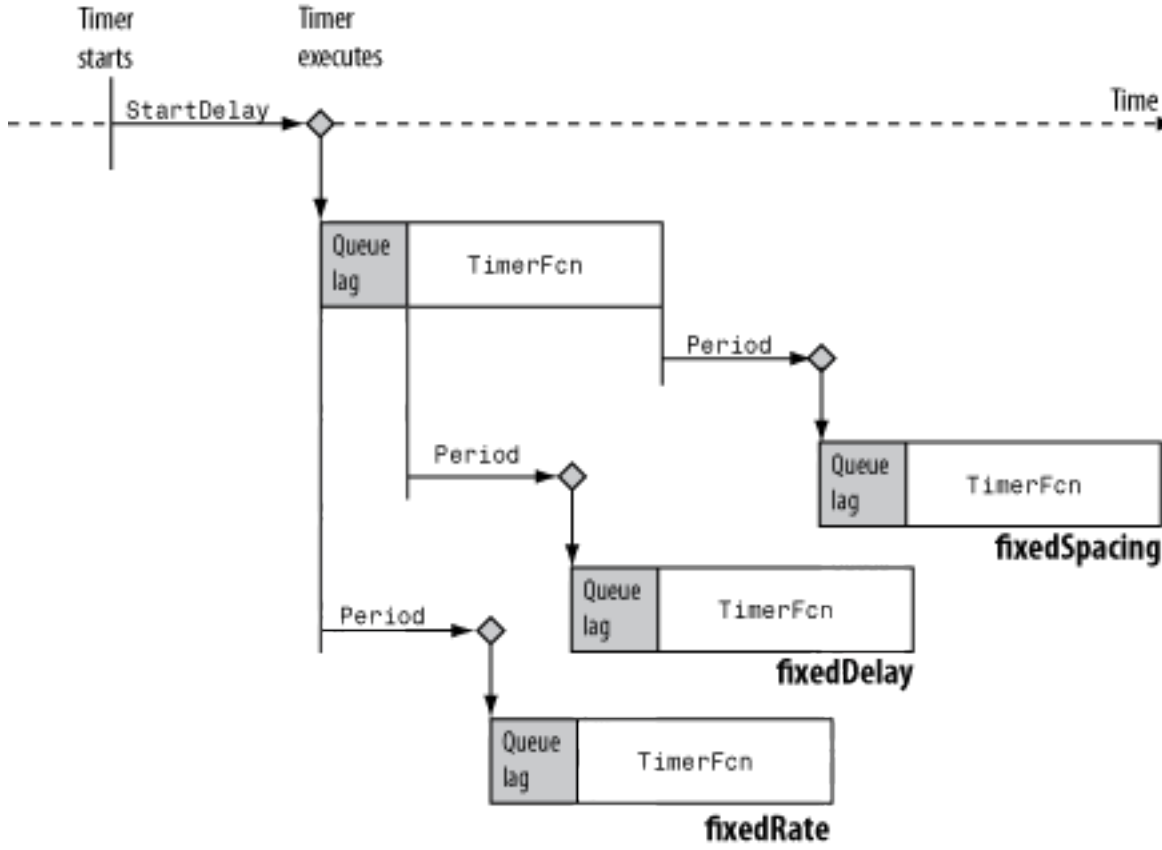
Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the Period property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue

Execution Mode	Time `Period` Start Point
`'fixedDelay'`	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
`'fixedSpacing'`	Starts when the timer callback function finishes executing.

- `'singleShot'` is the single execution mode for the `timer` class, and is the default value.



- `'fixedDelay'`, `'fixedRate'`, and `'fixedSpacing'` are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.



Default: `'singleShot'`

`'Name'`

String representing the `timer` name.

Default: `'timer-`*`i`*`'`, where *`i`* is a number indicating the *`i`*th timer object created this session. To reset *`i`* to 1, execute the `clear classes` command.

`'ObjectVisibility'`

String with possible values of `'on'` or `'off'`, that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function

does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

Default: `'on'`

`'Period'`

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

Default: 1.0

`'StartDelay'`

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

Default: 0

`'StartFcn'`

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

`'StopFcn'`

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

`'Tag'`

String that represents a label for the object.

`'TasksToExecute'`

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

Default: `Inf`

`'TimerFcn'`

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

`'UserData'`

Generic field for data that you want to add to the object.

Output Arguments

`propStruct`

Configurable properties of `t`, returned as a structure. The field names of `propStruct` are the property names of `t`, and the associated values of `propStruct` are cell arrays of the possible property values. If the property in `t` does not have a finite set of possible values, the property value in `propStruct` is an empty cell array.

`propCell`

Possible values of a given property name, returned as cell array of strings. If the property does not have a finite set of possible string values, `set` returns an empty cell array.

Examples

Display Configurable Timer Object Properties

Instantiate a timer object and call the `set` method.

```
t = timer;
set(t)
```

```
    BusyMode: [ {drop} | queue | error ]
```

```
    ErrorFcn: string -or- function handle -or- cell array
    ExecutionMode: [ {singleShot} | fixedSpacing | fixedDelay | fixedRate ]
    Name
    ObjectVisibility: [ {on} | off ]
    Period
    StartDelay
    StartFcn: string -or- function handle -or- cell array
    StopFcn: string -or- function handle -or- cell array
    Tag
    TasksToExecute
    TimerFcn: string -or- function handle -or- cell array
    UserData
```

Some of the timer properties, such as `Running`, are not displayed because they are read only.

Use the `set` method to output a structure.

```
out = set(t)
```

```
out =

            BusyMode: {3x1 cell}
            ErrorFcn: {}
       ExecutionMode: {4x1 cell}
                Name: {}
    ObjectVisibility: {2x1 cell}
              Period: {}
          StartDelay: {}
            StartFcn: {}
             StopFcn: {}
                 Tag: {}
      TasksToExecute: {}
             TimerFcn: {}
             UserData: {}
```

Delete the timer object from memory.

```
delete(t)
```

Display Possible Property Values

Instantiate a timer object and display possible values for the `BusyMode` property.

```
t = timer;
set(t,'BusyMode')
```

```
[ {drop} | queue | error ]
```

The output shows the three possible values for `BusyMode`. The default value, `drop`, is indicated by curly braces.

Display the possible values for `ErrorFcn`.

```
set(t,'ErrorFcn')
```

```
string -or- function handle -or- cell array
```

A description of the possible values is displayed since `ErrorFcn` does not have a set list of possible values.

Output the possible property values.

```
out1 = set(t,'BusyMode')
out2 = set(t,'ErrorFcn')
```

```
out1 =

    'drop'
    'queue'
    'error'

out2 =

     {}
```

While `set(t,'ErrorFcn')` displays a description of the possible values, `out2 = set(t,'ErrorFcn')` returns an empty cell.

Delete the timer from memory.

```
delete(t)
```

Set Timer Object Property

Instantiate a timer object and make the object invisible. Display the objects's visibility and delete the object.

```
t = timer;
set(t,'ObjectVisibility','off')
get(t,'ObjectVisibility')
delete(t)
```

```
ans =

off
```

Set Timer Object Properties Using Structure

Construct a structure to modify several timer object properties.

```
s.BusyMode = 'queue';
s.ExecutionMode = 'fixedDelay';
s.ObjectVisibility = 'off'
```

```
s =

            BusyMode: 'queue'
       ExecutionMode: 'fixedDelay'
    ObjectVisibility: 'off'
```

Create a timer, display the properties in `s`, modify the timer, display the new values of the properties, and delete the timer.

```
t = timer;
get(t,{'BusyMode','ExecutionMode','ObjectVisibility'})
set(t,s)
get(t,{'BusyMode','ExecutionMode','ObjectVisibility'})
delete(t)
```

```
ans =

    'drop'    'singleShot'    'on'

ans =

    'queue'    'fixedDelay'    'off'
```

Set Timer Objects Using Cell Arrays

Create a cell array of properties to modify, and a cell array of the values of the corresponding properties. Instantiate a timer, and display the initial values of the properties in the property name cell array, `nameArr`.

```
nameArr = {'BusyMode','ExecutionMode','Period'};
valArr = {'queue','fixedDelay',3};
t = timer;
get(t,nameArr)
```

```
ans =

    'drop'    'singleShot'    [1]
```

Modify the timer object and display the new property values. Delete the timer.

```
set(t,nameArr,valArr)
get(t,nameArr)
delete(t)
```

```
ans =

    'queue'    'fixedDelay'    [3]
```

Instantiate an array of three timers. Create a new property name cell array to modify the `BusyMode`, `ExecutionMode`, and `UserData` properties. Display the initial values of the properties for each timer.

```
tArr = [timer timer timer];
nameArr = {'BusyMode','ExecutionMode','UserData'};
get(tArr,nameArr)
```

```
ans =

    'drop'    'singleShot'    []
    'drop'    'singleShot'    []
    'drop'    'singleShot'    []
```

Assign each property a different value in each timer. Create a cell array containing the new values. Each row indicates the values for the properties in the corresponding timer.

```
valArr = {'queue','fixedDelay',3;...
            'error','fixedSpacing',42;...
            'drop','fixedRate','hello'};
```

Modify the timer object properties and display the updated values.

```
set(tArr,nameArr,valArr)
get(tArr,nameArr)
```

```
ans =

    'queue'    'fixedDelay'      [    3]
    'error'    'fixedSpacing'    [   42]
    'drop'     'fixedRate'       'hello'
```

Delete the timers from memory.

```
delete(tArr)
```

Alternatives

You can also use dot notation to set timer object properties. For example, `t.ObjectVisibility = 'off'` sets the property to the same value as `set(t,'ObjectVisibility','off')`.

See Also

`timer` | `get`

Introduced before R2006a

start

Class: timer

Start timer object

Syntax

```
start(t)
```

Description

`start(t)` starts the timer object, `t`. If `t` is an array of timer objects, `start` starts all the timers.

The `start` method sets the `Running` property of the timer object to `'on'`, executes the `StartFcn` callback, and initiates `TimerFcn` callback .

Input Arguments

`t`

Object of class `timer`.

Examples

Start Timer

Create and start a timer that displays the message 'timer started.' as the `StartFcn` callback and generates a random number as the `TimerFcn` callback. Delete the timer.

```
t = timer('StartFcn',@(~,~)disp('timer started.'),'TimerFcn',@(~,~)disp(rand(1)));
start(t)
delete(t)
```

```
timer started.
```

```
    0.9706
```

Your output from `rand` will vary.

Start Several Timers

Create and start three timers that displays a message for the `StartFcn` callbacks and compute the sine, cosine, and tangent of `pi/4` as the `TimerFcn` callbacks. Delete the timers.

```
t1 = timer('StartFcn',@(~,~)disp('t1 started.'),'TimerFcn',@(~,~)sin(pi/4));
t2 = timer('StartFcn',@(~,~)disp('t2 started.'),'TimerFcn',@(~,~)cos(pi/4));
t3 = timer('StartFcn',@(~,~)disp('t3 started.'),'TimerFcn',@(~,~)tan(pi/4));
start([t1 t2 t3]);
delete([t1 t2 t3]);
```

```
t1 started.
t2 started.
t3 started.
```

startat

Class: timer

Schedule timer to fire at specified time

Syntax

```
startat(t,firingTime)
startat(t,Y,M,D)
startat(t,Y,M,D,H,MI,S)
```

Description

`startat(t,firingTime)` schedules timer, `t`, to fire at specified time, `firingTime`. A timer fires by executing the callback function, `timerFcn`. `firingTime` must be within 25 days of the current time.

- If `t` is an array of timer objects and `firingTime` is a scalar, `startat` sets all the timers to fire at the specified time.
- If `t` is an array of timer objects and `firingTime` is an array of the same size as `t`, `startat` sets each timer to fire at the corresponding time.

`startat(t,Y,M,D)` starts the timer and schedules execution of `TimerFcn` at the year (`Y`), month (`M`), and day (`D`) specified.

`startat(t,Y,M,D,H,MI,S)` also specifies the hour (`H`), minute (`MI`), and second (`S`) specified.

Algorithms

- The `startat` method specifies when the timer object executes the `TimerFcn` callback, not when the timer starts running. The timer starts running with the call to the `startat` method.
- Based on the specified time, `startat` computes and sets the required `StartDelay` property of the timer object, `t`. Additionally, it sets the `Running` property of the timer object to `'on'`, and executes the `StartFcn` callback.

- `startat` modifies the `timer` object's `startDelay` property. As such, `startat` overrides specified values of the timer's `startDelay` property.

Input Arguments

`t`

Object of class `timer`.

`firingTime`

Time at which the timer object is to fire, specified as a serial date number, date string, or a date vector. `firingTime` can be a single date or an array of dates with the same number of rows as timer objects in `t`.

- A serial date number indicates the number of days that have elapsed since 1-Jan-0000 (starting at 1). See `datenum` for additional information about serial date numbers.
- To specify date strings, use the following date formats defined by the `datestr` function: 0, 1, 2, 6, 13, 14, 15, 16, or 23. These numeric identifiers correspond to formats defined by the `formatOut` property of the `datestr` function. Date strings with two-character years are interpreted to be within the 100 years centered on the current year.
- Date vectors are specified as an `m-by-6` or `m-by-3` matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements indicating year, month, day, hour, minute, and second, in that order. A partial date vector has three elements indicating year, month, and day, in that order.

`Y,M,D`

Time at which the timer object is to fire, specified as numbers indicating the year (`Y`), month (`M`), and day (`D`). Month values less than 1 are set to 1; other arguments can wrap and have negative values.

`Y,M,D,H,MI,S`

Time at which the timer object is to fire, specified as numbers indicating the year (`Y`), month (`M`), day (`D`), hour (`H`), minute (`MI`), and second (`S`) specified. Month values less than 1 are set to 1; other arguments can wrap and have negative values.

Examples

Start Timer in 2 Seconds

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
    'StartFcn', @(~,~)disp('Started.'));
```

Set the timer to fire 2 seconds from the present time using a serial date. A serial date is specified in days.

```
two = 2/(60^2*24); % two seconds in serial time
fTime = now + two
startat(t,fTime);
```

```
fTime =

   7.3527e+05

Started.
Fired.
```

Wait for the timer to fire, and then delete the timer.

```
delete(t)
```

Start Timer Using Year, Month, Day

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
    'StartFcn', @(~,~)disp('Started.'));
```

Schedule the timer to start 2 days from present at 00:00:00

```
[Y, M, D, H, MI, S] = datevec(now+2);
startat(t,Y,M,D)
```

```
Started.
```

Manually stop and delete the timer.

```
stop(t)
```

```
delete(t)
```

See Also

`timer` | `delete` | `start` | `stop`

More About

- “Carryover in Date Vectors and Strings”

Introduced before R2006a

stop

Class: timer

Stop timer object

Syntax

```
stop(t)
```

Description

`stop(t)` stops the timer object, `t`. If `t` is an array of timer objects, the `stop` method stops each timer.

The `stop` method sets the `Running` property of the timer object to `'off'` and executes the `StopFcn` callback .

Tips

- Use the `stop` method to stop a timer manually. The timer automatically stops when the `TimerFcn` callback executes the number of times specified by the `ExecutionMode` and `TasksToExecute` properties or when an error occurs while executing a `TimerFcn` callback.

Input Arguments

`t`

Object of class `timer`.

Examples

Stop Timer

Create a timer object that generates 100 random numbers and executes one million times. Define a `StopFcn` callback that displays the message 'Timer has stopped.' Start the timer and verify the timer is running

```
t = timer('TimerFcn','rand(100,1);',...
    'ExecutionMode','fixedSpacing','TasksToExecute',1e6,...
    'StopFcn','disp(''Timer has stopped.'')');
start(t)
t.Running
```

```
ans =

on
```

Manually stop the timer and verify it is no longer running. Delete the timer.

```
stop(t)
t.Running
delete(t)
```

```
Timer has stopped.

ans =

off
```

`timer` | `delete` | `start` | `startat`

Introduced before R2006a

timerfind

Class: timer

Find timer object

Syntax

```
out = timerfind
out = timerfind(Name,Value)
out = timerfind(t,Name,Value)
out = timerfind(S)
```

Description

`out = timerfind` finds the "visible timer objects" on page 1-8277and returns an array, `out`.

`out = timerfind(Name,Value)` finds "visible timer objects" on page 1-8277 with property values matching those passed as Name,Value pair arguments and returns an array, `out`.

`out = timerfind(t,Name,Value)` matches Name,Value pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfind(S)` matches property values defined in the structure, `S`, and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

Tips

- `timerfind` only finds "visible timer objects" on page 1-8277. Visible timer objects are those that are in memory and have the `ObjectVisibility` property set to `'on'`. To find objects that are hidden, but still valid, use `timerfindall`.

Input Arguments

`t`

Array of objects of class `timer`

`s`

Structure with field names corresponding to `timer` object property names. Field values are the corresponding property values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'BusyMode'`

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

`BusyMode` Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
`'drop'`	Adds task to queue	Drops task	Possible skipping of `TimerFcn` calls
`'error'`	Adds task to queue	Completes task; throws error specified by `ErrorFcn`; stops timer	Stops timer after completing task in execution queue
`'queue'`	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts `Period` property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

Default: `'drop'`

`'ErrorFcn'`

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

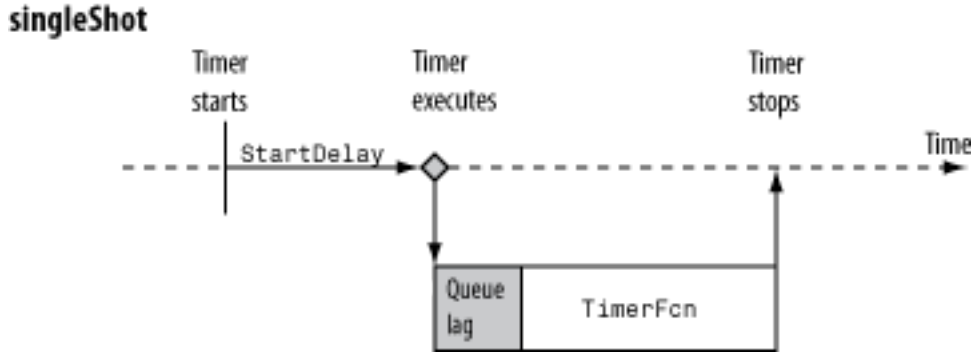
For more information, see “Timer Callback Functions”.

`'ExecutionMode'`

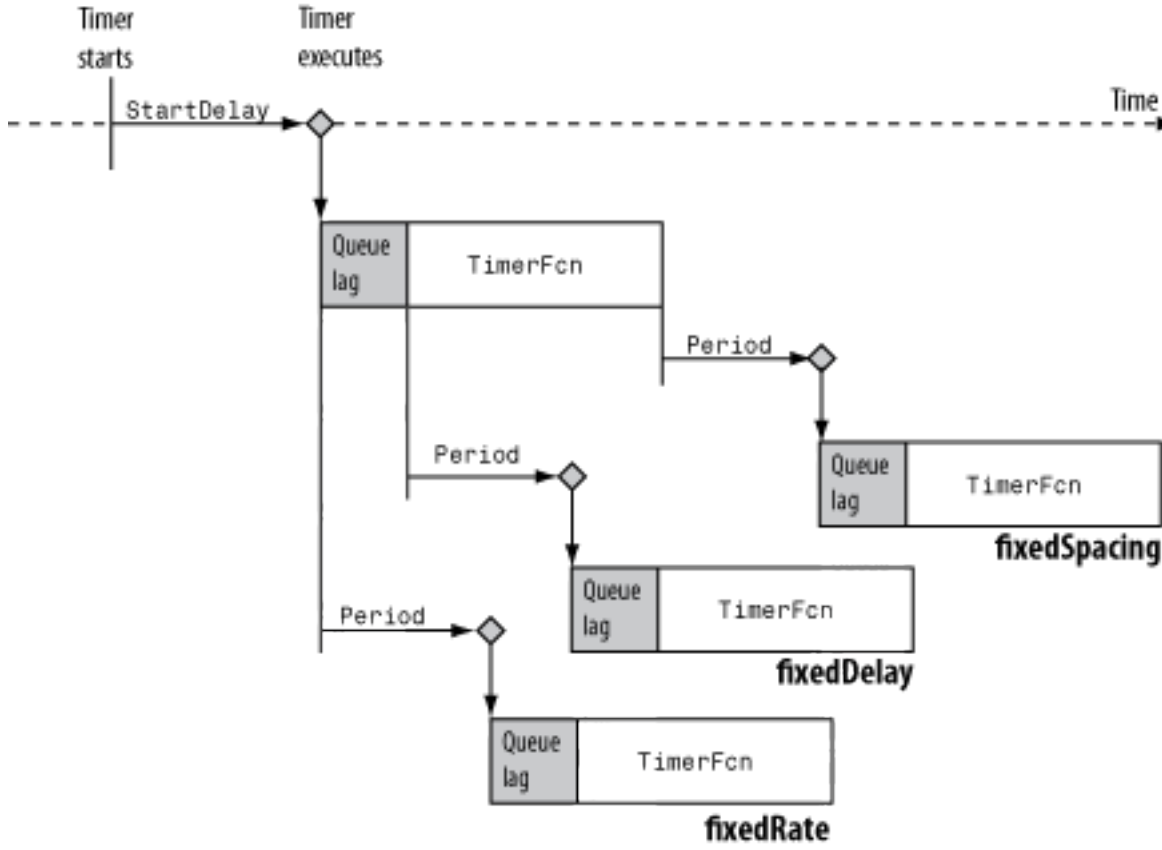
String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time `Period` Start Point
`'singleShot'`	In this mode, the timer callback function is only executed once. Therefore, the `Period` property has no effect. This is the default execution mode.
`'fixedRate'`	Starts immediately after the timer callback function is added to the MATLAB execution queue
`'fixedDelay'`	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
`'fixedSpacing'`	Starts when the timer callback function finishes executing.

- `'singleShot'` is the single execution mode for the `timer` class, and is the default value.



- `'fixedDelay'`, `'fixedRate'`, and `'fixedSpacing'` are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.



Default: `'singleShot'`

`'Name'`

String representing the `timer` name.

Default: `'timer-`*`i`*`'`, where *`i`* is a number indicating the *`i`*th timer object created this session. To reset *`i`* to 1, execute the `clear classes` command.

`'ObjectVisibility'`

String with possible values of `'on'` or `'off'`, that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function

does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

Default: `'on'`

`'Period'`

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

Default: 1.0

`'StartDelay'`

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

Default: 0

`'StartFcn'`

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

`'StopFcn'`

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

`'Tag'`

String that represents a label for the object.

`'TasksToExecute'`

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

Default: `Inf`

`'TimerFcn'`

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

`'UserData'`

Generic field for data that you want to add to the object.

Read Only Name-Value Pair Arguments

`AveragePeriod`

Average time in seconds between `TimerFcn` executions since the timer started. Value is `NaN` until timer executes two timer callbacks.

`InstantPeriod`

The time in seconds between the last two executions of `TimerFcn`. Value is `NaN` until timer executes two timer callbacks.

`Running`

String defined as `'off'` or `'on'`, indicating whether the timer is currently executing callback functions.

`TasksExecuted`

The number of times the timer called `TimerFcn` since the timer started.

`Type`

String that identifies the object type.

Definitions

visible timer objects

Visible timer objects are timer objects that are in memory and have the `ObjectVisibility` property set to 'on'.

Examples

Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag','broadcastProgress','UserData','Monday');
t2 = timer('Tag','displayProgress','UserData','Monday');
timerArr = [timer('Tag','broadcastProgress','UserData','Tuesday');
    timer('Tag','displayProgress','UserData','Tuesday');
    timer('Tag','displayProgress','UserData','Wednesday');];
```

Find all the timers in memory.

```
out1 = timerfind
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                    timer-1
   2       singleShot      1        ''                    timer-2
   3       singleShot      1        ''                    timer-3
   4       singleShot      1        ''                    timer-4
   5       singleShot      1        ''                    timer-5
```

Find only those timers in memory that have the string value, `'displayProgress'`, as the `Tag` property.

```
out2 = timerfind('Tag','displayProgress')
```

```
Timer Object Array
```

```
   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                    timer-2
   2       singleShot      1        ''                    timer-4
   3       singleShot      1        ''                    timer-5
```

Limit the search for timers with the string value, `'displayProgress'`, as the `Tag` property to timer objects in `timerArr`.

```
out3 = timerfind(timerArr,'Tag','displayProgress')
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                    timer-4
   2       singleShot      1        ''                    timer-5
```

Define a `struct` containing the `Tag` and `UserData` properties of interest.

```
searchStruct = struct('Tag','broadcastProgress','UserData','Monday')
```

```
searchStruct =

         Tag: 'broadcastProgress'
    UserData: 'Monday'
```

Use the `struct` as the search criteria to find timer objects in memory.

```
out4 = timerfind(searchStruct)
```

```
   Timer Object: timer-1

   Timer Settings
      ExecutionMode: singleShot
             Period: 1
          BusyMode: drop
           Running: off

   Callbacks
```

```
          TimerFcn: ''
          ErrorFcn: ''
          StartFcn: ''
           StopFcn: ''
```

Delete the timer objects.

```
delete(t1)
delete(t2)
delete(timerArr)
```

Delete Timer by Name

Simulate having existing timers in memory by creating an array of timers. Create a new timer with a custom name. List all visible timers.

```
existingTimers = [timer timer timer];

myTimerName = 'myTimer';
anotherTimer = timer('Name',myTimerName);

timerfind
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                     timer-1
   2       singleShot      1        ''                     timer-2
   3       singleShot      1        ''                     timer-3
   4       singleShot      1        ''                     myTimer
```

Delete the specified timer and list all visible timers.

```
delete(timerfind('Name',myTimerName));
timerfind
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                     timer-1
   2       singleShot      1        ''                     timer-2
   3       singleShot      1        ''                     timer-3
```

Delete all visible timers from memory.

```
delete(timerfind)
```

Find Valid Timer Objects Cleared from Workspace

Use `timerfind` to find 'lost' timer object references. References are lost when you clear the timer object from the workspace, but do not delete it from memory.

Create two timer objects. Since the callback function does not require the timer or event object, you can use the tilde (~) operator to ignore the inputs in the function handle.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
whos
```

```
  Name      Size            Bytes  Class    Attributes

  t1        1x1               104  timer
  t2        1x1               104  timer
```

Clear one of the timer objects from the workspace. To actually remove the timer from memory, you need to both clear it and delete it.

```
clear t1
whos
```

```
  Name      Size            Bytes  Class    Attributes

  t2        1x1               104  timer
```

Try to delete the timer, `t1`.

```
delete(t1)
```

```
Undefined function or variable 't1'.
```

The timer, `t1`, can not be removed from memory using delete because its reference has been cleared.

Find valid timer objects in memory.

```
out = timerfind
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:               Name:
   1       singleShot      1        1x1 function_handle arraytimer-1
```

```
   2       singleShot      1        1x1 function_handle arraytimer-2
```

Since two timers were found, determine which timer does not exist in the workspace.

```
out ~= t2
```

```
ans =

     1     0
```

The first timer object in `out` is not equal to `t2`. This was previously `t1`. It is reassigned to `t1`. Since it is still valid, the timer can be started.

```
t1 = out(1);
start(t1)
```

```
Timer 1 Fired!
```

Delete timer objects. `timerfind` provides a way of accessing timer objects in memory. It does not copy the objects; therefore you do not need to delete `out` from memory. To verify, use `timerfind`.

```
delete(t1)
delete(t2)
timerfind
```

```
ans =

     []
```

Delete All Timer Objects in Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Clear two timers from the workspace.

```
clear t2 t3
```

Pass `timerfind` to `delete` to remove all timer objects from memory, whether or not they exist in the workspace.

```
delete(timerfind)
timerfind

ans =

     []
```

See Also

`timer` | `delete` | `timerfindall`

Introduced before R2006a

timerfindall

Class: timer

Find timer object, regardless of visibility

Syntax

```
out = timerfindall
out = timerfindall(Name,Value)
out = timerfindall(t,Name,Value)
out = timerfindall(S)
```

Description

`out = timerfindall` finds timer objects existing in memory, regardless of visibility and returns an array, `out`. Use the `ObjectVisibility` property to set the object's visibility.

`out = timerfindall(Name,Value)` finds timer objects existing in memory, regardless of visibility whose property values match those passed as Name,Value pair arguments and returns an array, `out`.

`out = timerfindall(t,Name,Value)` matches Name,Value pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfindall(S)` matches property values defined in the structure, `S` and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

Tips

- `timerfindall` finds timer objects in memory, regardless of the value of the `ObjectVisibility` property. To limit the search to objects with `ObjectVisibility` set to `'on'`, use `timerfind`. .

Input Arguments

t

Array of objects of class `timer`.

s

Structure with field names corresponding to `timer` object property names. Field values are the corresponding property values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'BusyMode'

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
`'drop'`	Adds task to queue	Drops task	Possible skipping of `TimerFcn` calls
`'error'`	Adds task to queue	Completes task; throws error specified by `ErrorFcn`; stops timer	Stops timer after completing task in execution queue
`'queue'`	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts `Period` property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

Default: `'drop'`

`'ErrorFcn'`

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

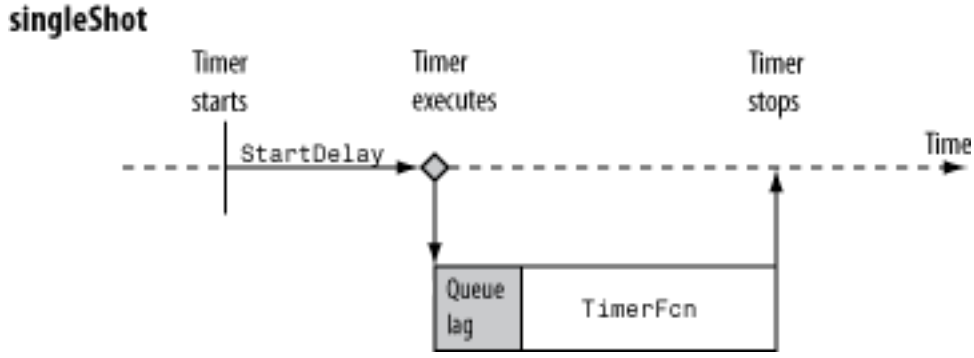
For more information, see “Timer Callback Functions”.

`'ExecutionMode'`

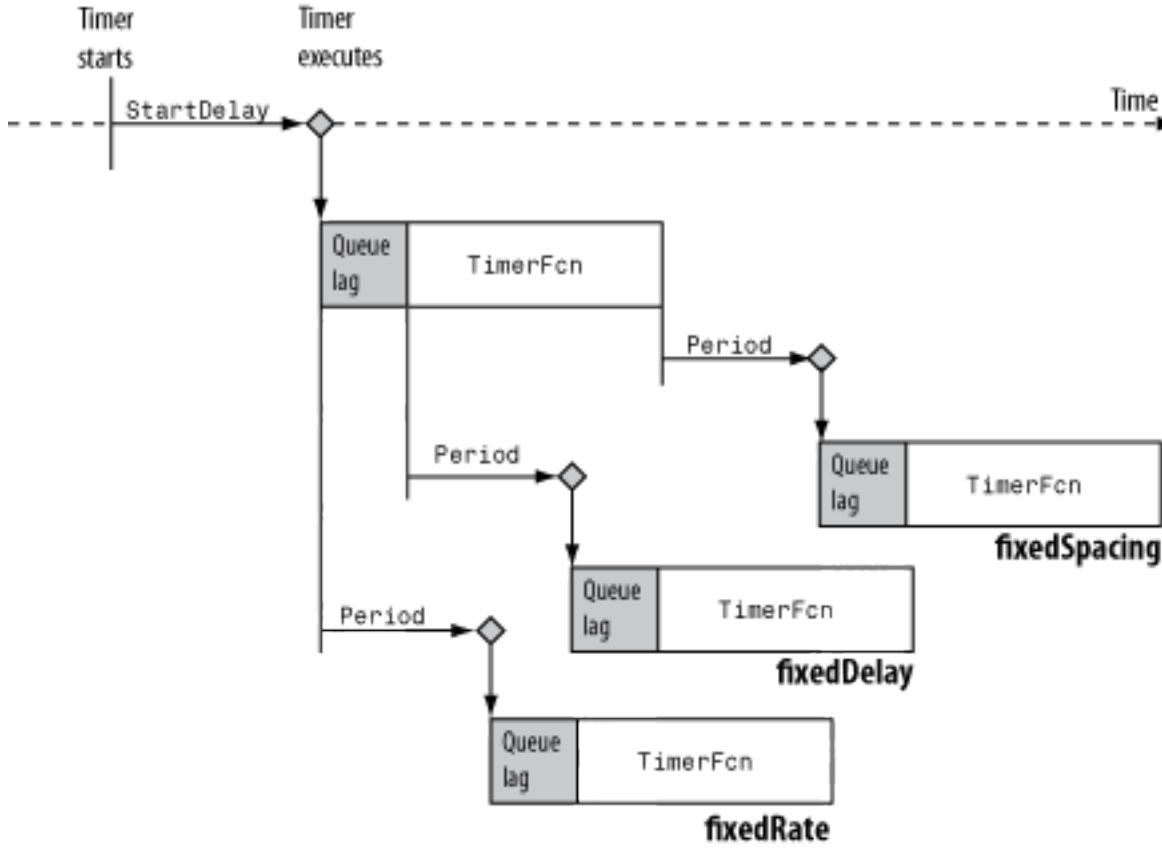
String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time `Period` Start Point
`'singleShot'`	In this mode, the timer callback function is only executed once. Therefore, the `Period` property has no effect. This is the default execution mode.
`'fixedRate'`	Starts immediately after the timer callback function is added to the MATLAB execution queue
`'fixedDelay'`	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
`'fixedSpacing'`	Starts when the timer callback function finishes executing.

- `'singleShot'` is the single execution mode for the `timer` class, and is the default value.



- `'fixedDelay'`, `'fixedRate'`, and `'fixedSpacing'` are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.



Default: `'singleShot'`

`'Name'`

String representing the `timer` name.

Default: `'timer-`*`i`*`'`, where *`i`* is a number indicating the *`i`*th timer object created this session. To reset *`i`* to 1, execute the `clear classes` command.

`'ObjectVisibility'`

String with possible values of `'on'` or `'off'`, that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function

does not return an object whose `ObjectVisibility` property is set to `'off'`. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

Default: `'on'`

`'Period'`

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

Default: 1.0

`'StartDelay'`

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

Default: 0

`'StartFcn'`

String, function handle, or cell array defining the function that executes when the timer starts.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see “Timer Callback Functions”.

`'StopFcn'`

String, function handle, or cell array defining the function that executes when the timer stops.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

`'Tag'`

String that represents a label for the object.

`'TasksToExecute'`

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

Default: `Inf`

`'TimerFcn'`

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

- If you specify this property using a string, when MATLAB executes the callback it evaluates the MATLAB code contained in the string.
- If you specify this property using a function handle, when MATLAB executes the callback it passes the `timer` object and an event structure to the callback function. The event structure contains the type of event in the `Type` field and the time of the event in the `Data` field.
- If your callback function accepts arguments in addition to the `timer` object and event data, specify this property as a cell array containing the function handle and the additional arguments.

For more information, see "Timer Callback Functions".

`'UserData'`

Generic field for data that you want to add to the object.

Read Only Name-Value Pair Arguments

`AveragePeriod`

Average time in seconds between `TimerFcn` executions since the timer started. Value is `NaN` until timer executes two timer callbacks.

`InstantPeriod`

The time in seconds between the last two executions of `TimerFcn`. Value is `NaN` until timer executes two timer callbacks.

`Running`

String defined as `'off'` or `'on'`, indicating whether the timer is currently executing callback functions.

`TasksExecuted`

The number of times the timer called `TimerFcn` since the timer started.

`Type`

String that identifies the object type.

Examples

Find and Delete All Timers From Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers `t2` and `t4` to be invisible.

```
t2.ObjectVisibility = 'off';
t4.ObjectVisibility = 'off';
```

Clear timers `t1` and `t2` from the workspace.

```
clear t1 t2
whos
```

```
  Name      Size            Bytes  Class    Attributes

  t3        1x1               104  timer
  t4        1x1               104  timer
```

Find all visible timers in memory.

```
timerfind
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        1x1 function_handle arraytimer-1
   2       singleShot      1        1x1 function_handle arraytimer-3
```

`timerfind` finds only timers `t1` and `t2`, since they are visible. Timer `t2` is still valid and in memory even though it was cleared from the workspace

Find all timers in memory.

```
timerfindall
```

```
Timer Object Array
```

```
   Index:  ExecutionMode:  Period:  TimerFcn:               Name:
   1       singleShot      1        1x1 function_handle arraytimer-1
   2       singleShot      1        1x1 function_handle arraytimer-2
   3       singleShot      1        1x1 function_handle arraytimer-3
   4       singleShot      1        1x1 function_handle arraytimer-4
```

`timerfindall` finds all four valid timers in memory even though `t2` and `t4` are invisible and `t1` and `t2` were cleared from the workspace.

Delete all timers from memory.

```
delete(timerfindall)
```

Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag', 'broadcastProgress','UserData','Monday');
t2 = timer('Tag', 'displayProgress','UserData','Monday');
timerArr = [timer('Tag', 'broadcastProgress','UserData','Tuesday');
    timer('Tag', 'displayProgress','UserData','Tuesday');
    timer('Tag', 'displayProgress','UserData','Wednesday');];
```

Make timer `t1` and `timerArr(2)` invisible.

```
t1.ObjectVisibility = 'off';
timerArr(2).ObjectVisibility = 'off';
```

Find all the timers in memory using `timerfind`.

```
out1 = timerfind
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:               Name:
   1       singleShot      1        ''                     timer-2
   2       singleShot      1        ''                     timer-3
   3       singleShot      1        ''                     timer-5
```

`timerfind` does not find the hidden timers.

Find all the timers in memory using `timerfindall`.

```
out2 = timerfindall
```

```
Timer Object Array
```

```
   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                    timer-1
   2       singleShot      1        ''                    timer-2
   3       singleShot      1        ''                    timer-3
   4       singleShot      1        ''                    timer-4
   5       singleShot      1        ''                    timer-5
```

`timerfindall` finds all timers, even the invisible ones.

Find only those timers in memory that have the string value, `'displayProgress'`, as the `Tag` property.

```
out3 = timerfindall('Tag','displayProgress')
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                    timer-2
   2       singleShot      1        ''                    timer-4
   3       singleShot      1        ''                    timer-5
```

Limit the search for timers that have the string value, `'displayProgress'`, as the `Tag` property to timer objects in `timerArr`.

```
out4 = timerfindall(timerArr,'Tag','displayProgress')
```

```
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:              Name:
   1       singleShot      1        ''                    timer-4
   2       singleShot      1        ''                    timer-5
```

Define a `struct` containing the `Tag` and `UserData` properties of interest.

```
searchStruct = struct('Tag','broadcastProgress','UserData','Monday')
```

```
searchStruct =

         Tag: 'broadcastProgress'
    UserData: 'Monday'
```

Use the `struct` as the search criteria to find timer objects in memory.

```
out5 = timerfindall(searchStruct)
```

```
   Timer Object: timer-1

   Timer Settings
      ExecutionMode: singleShot
             Period: 1
           BusyMode: drop
            Running: off

   Callbacks
           TimerFcn: ''
           ErrorFcn: ''
           StartFcn: ''
            StopFcn: ''
```

Delete the timer objects.

```
delete(timerfindall)
```

Find Invisible Timers

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers `t2` and `t4` to be invisible, and clear timers `t1` and `t2` from the workspace.

```
t2.ObjectVisibility = 'off';
t4.ObjectVisibility = 'off';
clear t1 t2;
whos
```

```
  Name      Size            Bytes  Class    Attributes

  t3        1x1               104  timer
  t4        1x1               104  timer
```

Find all valid invisible timers.

```
out = timerfindall('ObjectVisibility','off')
```

```
Timer Object Array
```

```
Index:  ExecutionMode:  Period:  TimerFcn:               Name:
1       singleShot      1        1x1 function_handle arraytimer-2
2       singleShot      1        1x1 function_handle arraytimer-4
```

Both valid invisible timers were found by `timerfindall`, regardless of whether they were in the workspace.

Introduced before R2006a

wait

Class: timer

Block command prompt until timer stops running

Syntax

```
wait(t)
```

Description

`wait(t)` blocks the command prompt until timer, `t`, stops running. If `t` is an array of timer objects, `wait` blocks the MATLAB command line until each timer in `t` has stopped running.

To block the command line, the timer object must first start via `start` or `startat` before calling the `wait` method. If the timer is not running, `wait` returns immediately.

Input Arguments

`t`

Array of `timer` objects

Default:

Examples

Block Command Prompt While Timer Runs

Create a timer that waits 10 seconds, and then displays a message. Start the timer and wait for it to finish.

```
T = timer('TimerFcn',@(~,~)disp('Fired.'),'StartDelay',10);
start(T)
```

```
Fired.
```

Notice that after the timer starts, the MATLAB prompt returns.

Start the timer and use the wait method to block anyone from entering commands at the MATLAB command line. You must start the timer before calling the wait command.

```
start(T)
wait(T)
```

```
Fired.
```

Notice that after the timer starts, the MATLAB prompt disappears until the timer stops.

Delete the timer.

```
delete(T)
```

`timer` | `start`

Introduced before R2006a

times, .*

Element-wise multiplication

Syntax

```
C = A.*B
C = times(A,B)
```

Description

`C = A.*B` multiplies arrays `A` and `B` element by element and returns the result in `C`.

`C = times(A,B)` is an alternate way to execute `A.*B`, but is rarely used. It enables operator overloading for classes.

Examples

Multiply Two Vectors

Create two vectors, `A` and `B`, and multiply them element by element.

```
A = [1 0 3];
B = [2 3 7];
C = A.*B
```

```
C =

     2     0    21
```

Multiply Two Arrays

Create two 3-by-3 arrays, `A` and `B`, and multiply them element by element.

```
A = [1 0 3; 5 3 8; 2 4 6];
B = [2 3 7; 9 1 5; 8 8 3];
C = A.*B
```

```
C =
```

```
     2     0    21
    45     3    40
    16    32    18
```

- “Combine Categorical Arrays Using Multiplication”

Input Arguments

A — Left array

scalar | vector | matrix | multidimensional array

Left array, specified as a scalar, vector, matrix, or multidimensional array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `categorical` | `duration` | `calendarDuration`
Complex Number Support: Yes

B — Right array

scalar | vector | matrix | multidimensional array

Right array, specified as a scalar, vector, matrix, or multidimensional array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `categorical` | `duration` | `calendarDuration`
Complex Number Support: Yes

`mtimes`

Introduced before R2006a

title

Add title to current axes

Syntax

```
title(str)
title(str,Name,Value)

title(ax, ___ )

h = title( ___ )
```

Description

`title(str)` adds the title consisting of a string, `str`, at the top and in the center of the current axes. Reissuing the `title` command causes the new title to replace the old title.

`title(str,Name,Value)` additionally specifies the title properties using one or more `Name,Value` pair arguments.

`title(ax, ___ )` adds the title to the axes specified by `ax`. This syntax allows you to specify the axes to which to add a title. `ax` can precede any of the input argument combinations in the previous syntaxes.

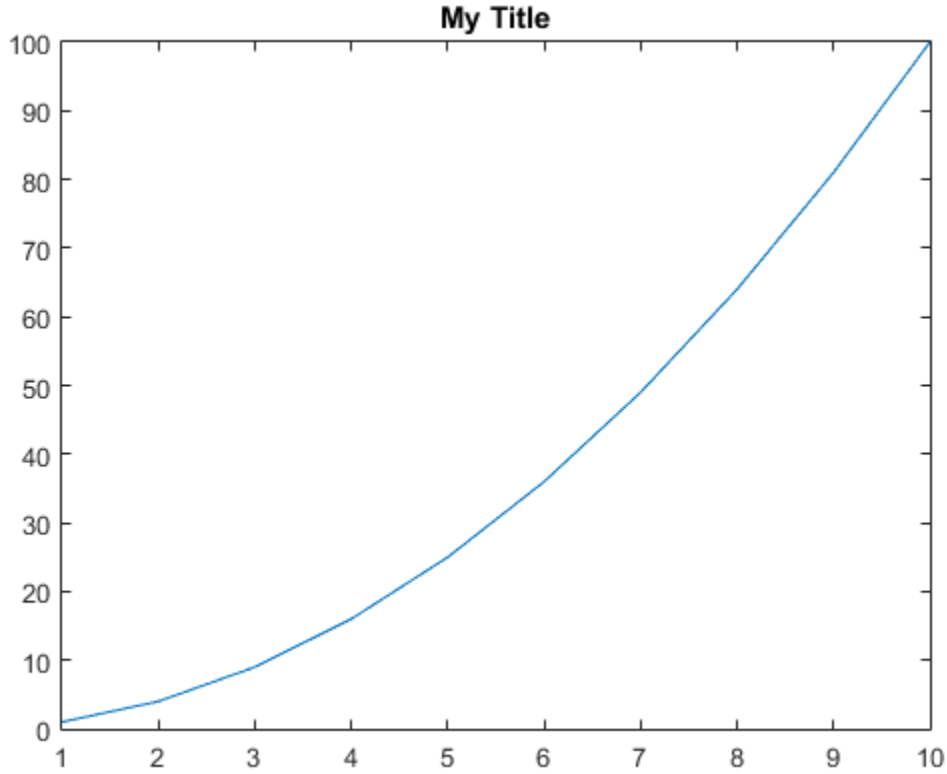
`h = title( ___ )` returns the handle to the text object used as the title. The handle is useful when making future modifications to the title.

Examples

Add Title to Current Figure

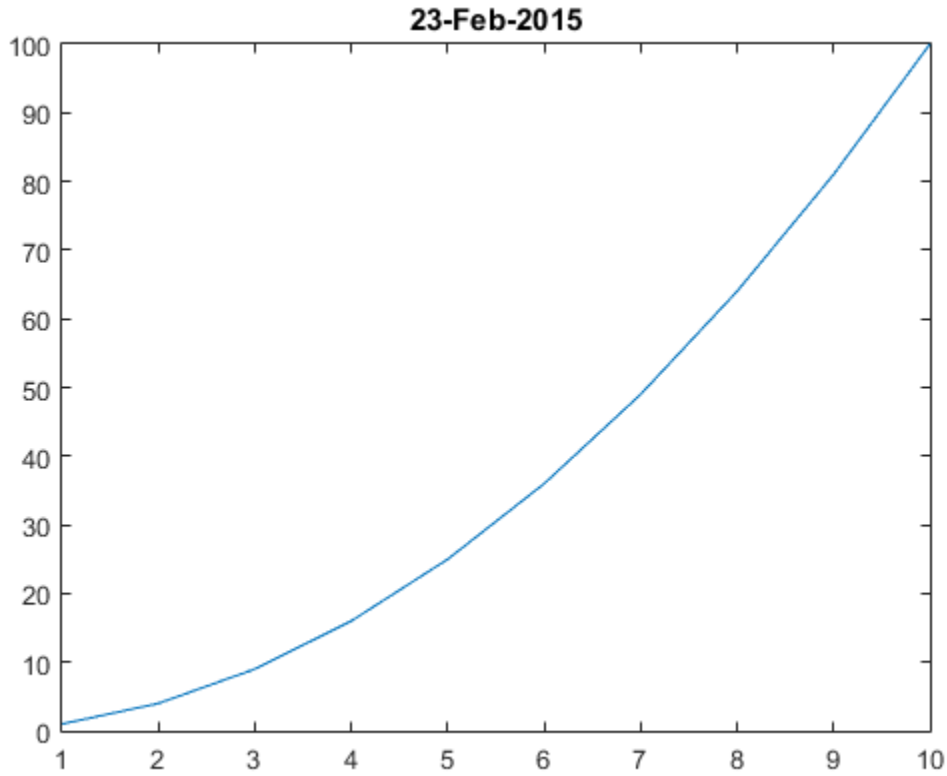
Create a figure and display a title in the current axes.

```
figure
plot((1:10).^2)
title('My Title')
```



You also can call `title` with a function that returns a string. For example, the `date` function returns a string containing today's date.

```
title(date)
```

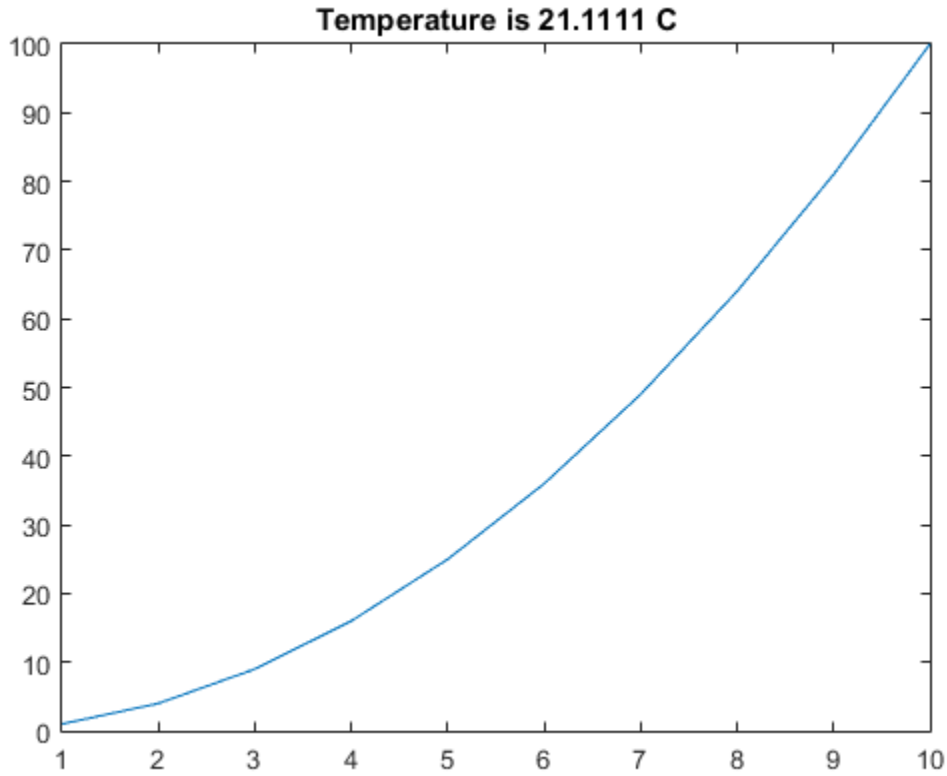


MATLAB® sets the output of `date` as the axes title.

Include Variable's Value in Title

Include the value of variable `c` in a title.

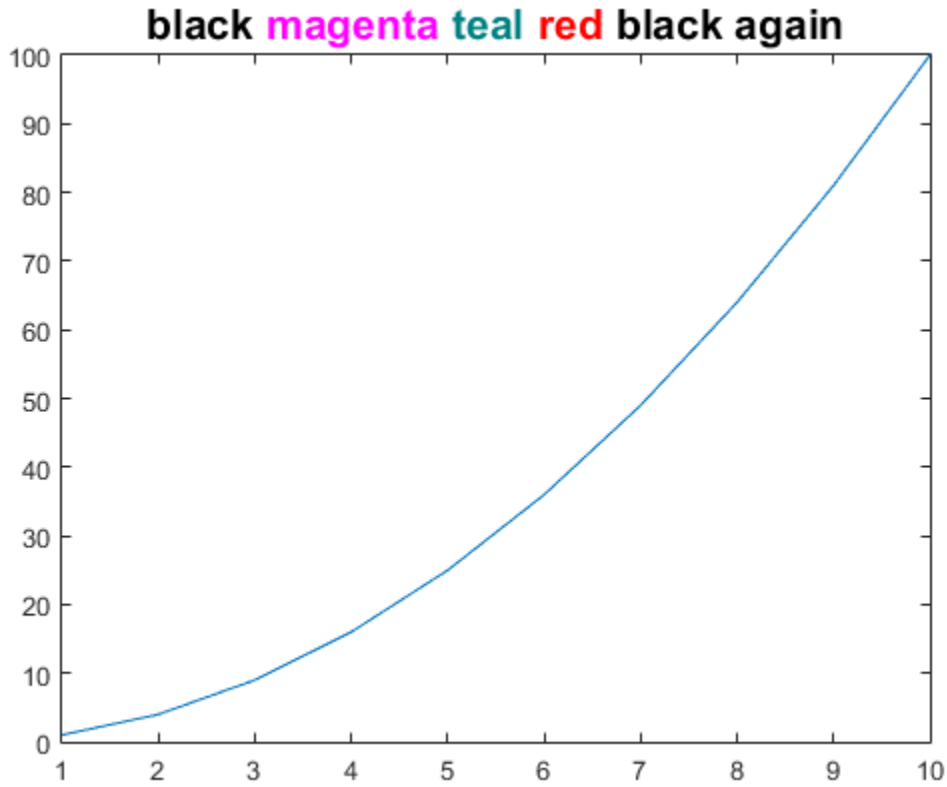
```
figure
plot((1:10).^2)
f = 70;
c = (f-32)/1.8;
title(['Temperature is ',num2str(c),' C'])
```



Create Multicolored Title Using TeX Markup

In a TeX string, use the color modifier `\color` to change the color of characters following it from the previous color.

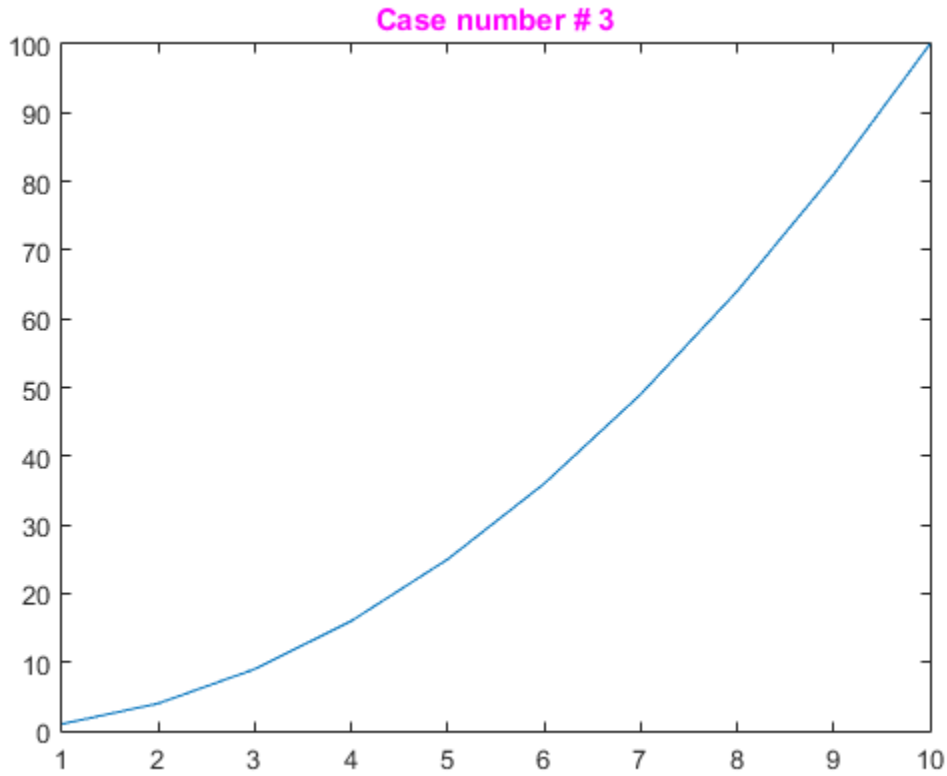
```
figure
plot((1:10).^2)
title(['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0 .5 .5}teal \color{red}red} black again'])
```



Create Colored Title Using Name,Value Pair Argument

Use the `Name,Value` pair `'Color','m'` to set the color of the title to magenta.

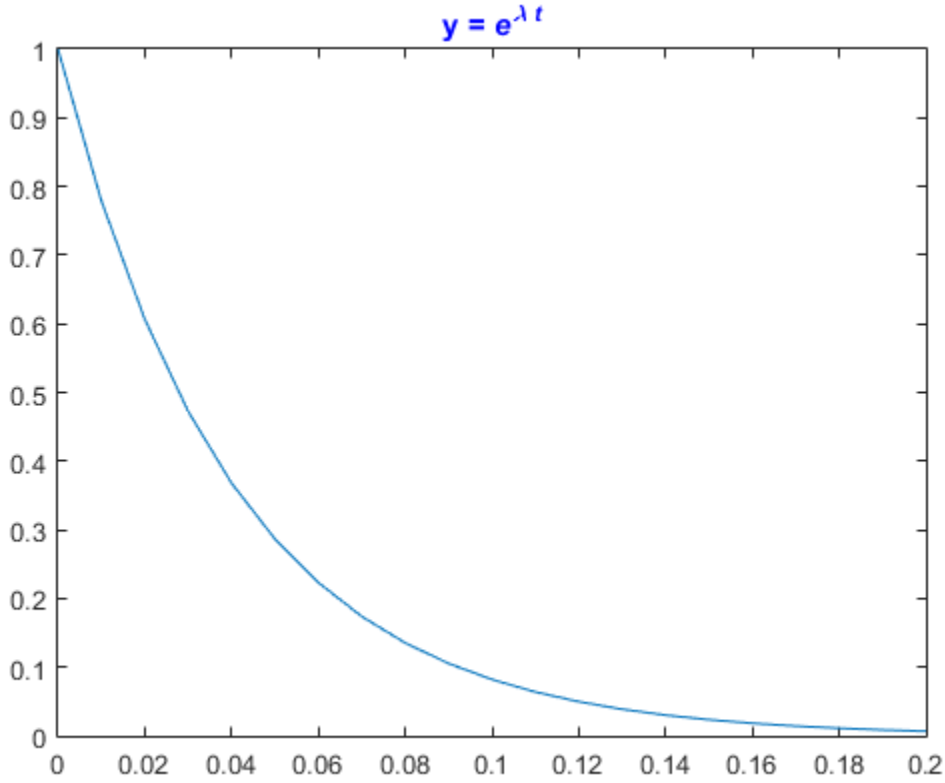
```
figure
plot((1:10).^2)
title('Case number # 3','Color', 'm')
```



Include Greek Symbols in Title

Use a TeX string to include Greek symbols in a title.

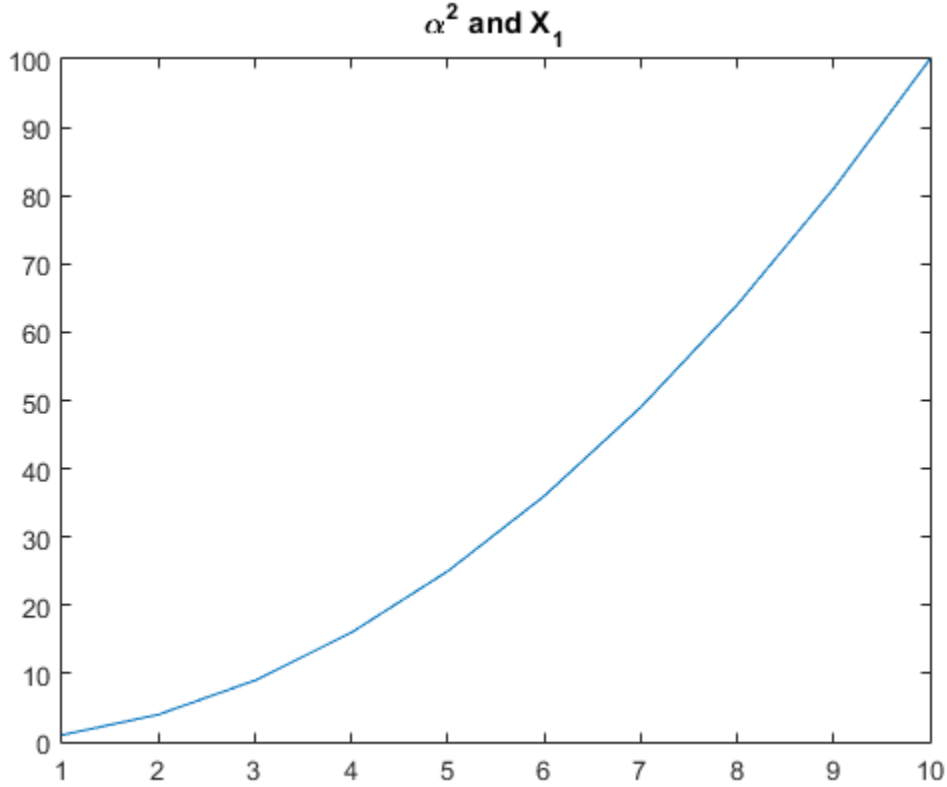
```
t = (0:0.01:0.2);
y = exp(-25*t);
figure
plot(t,y)
title('y = \ite^{\lambda t}','Color','b')
```



The `'Interpreter'` property must be `'tex'` (the default).

Include Superscript or Subscript Character in Title

```
figure
plot((1:10).^2)
title('\alpha^2 and X_1')
```

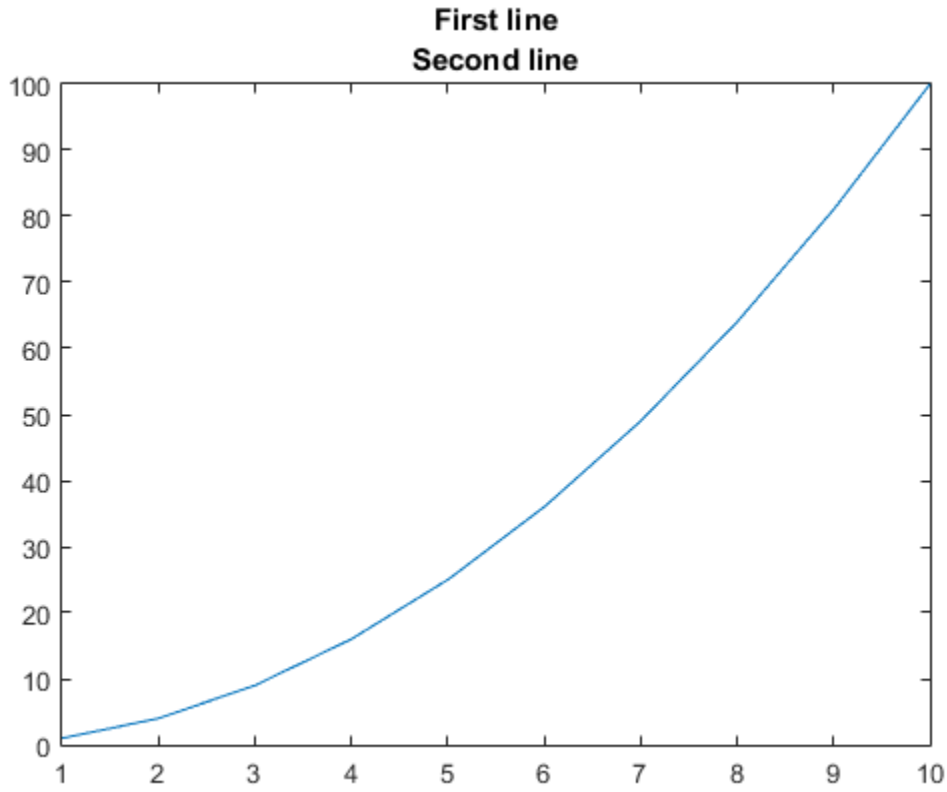


The superscript character, "^", and the subscript character, "_", modify the character or substring defined in braces immediately following.

Create Multiline Title

Create a multiline title using a multiline cell array.

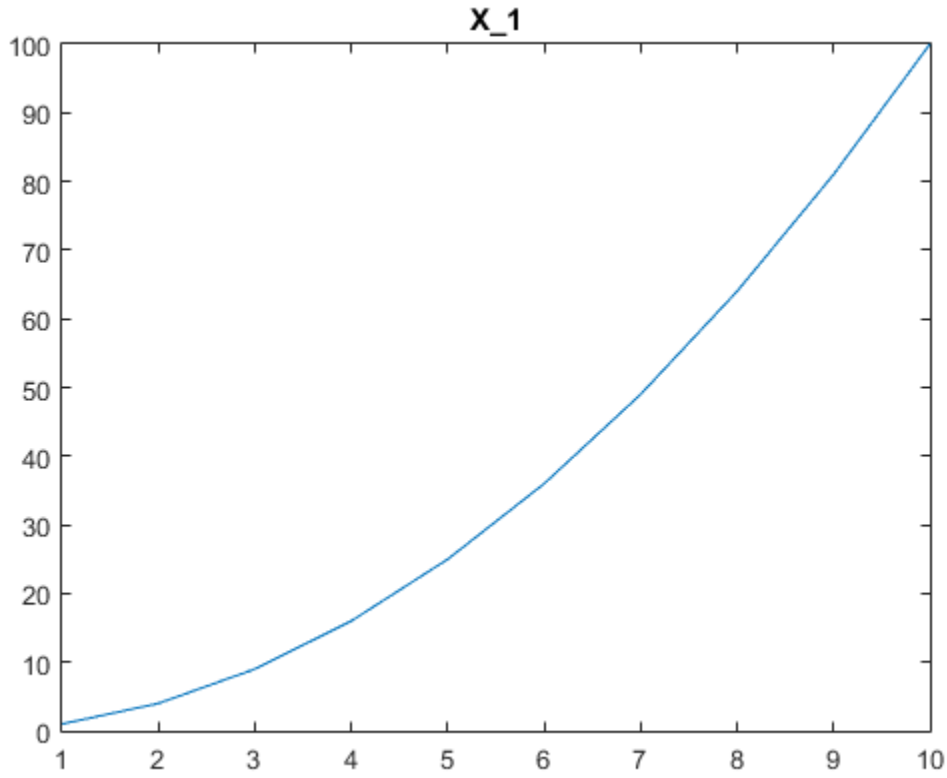
```
figure
plot((1:10).^2)
title({'First line';'Second line'})
```



Display Text As Typed

Set the `Interpreter` property as `'none'` so that the string `X_1` is displayed in the figure as typed, without making `1` a subscript of `X`.

```
figure
plot((1:10).^2)
title('X_1','Interpreter','none')
```

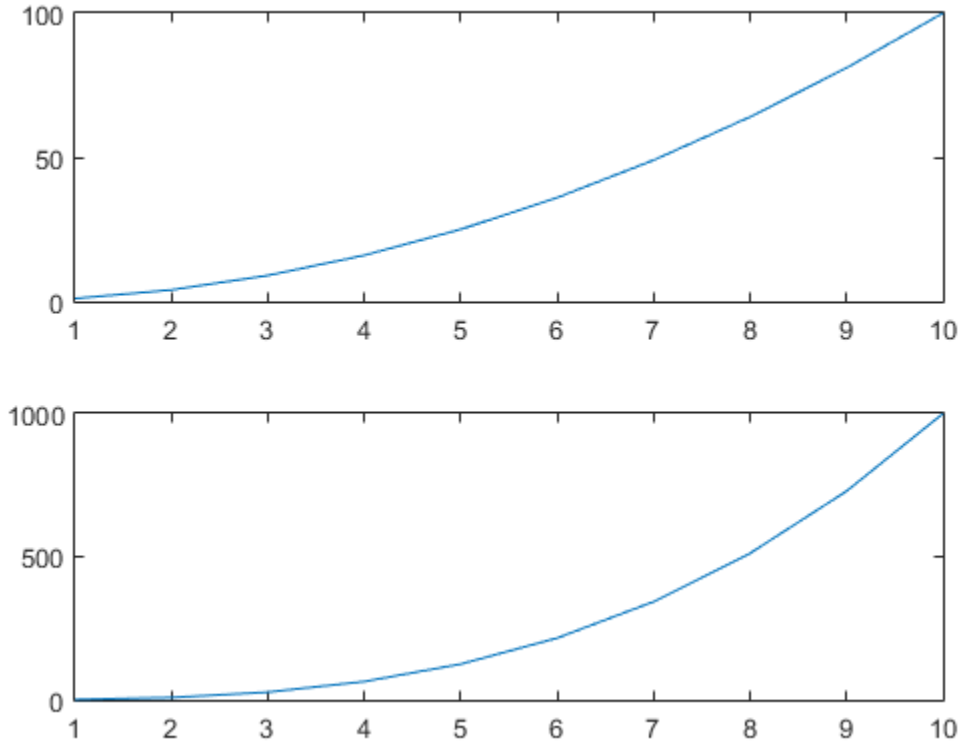


MATLAB® displays the string `X_1` in the title of the figure.

Add Title to Specific Axes

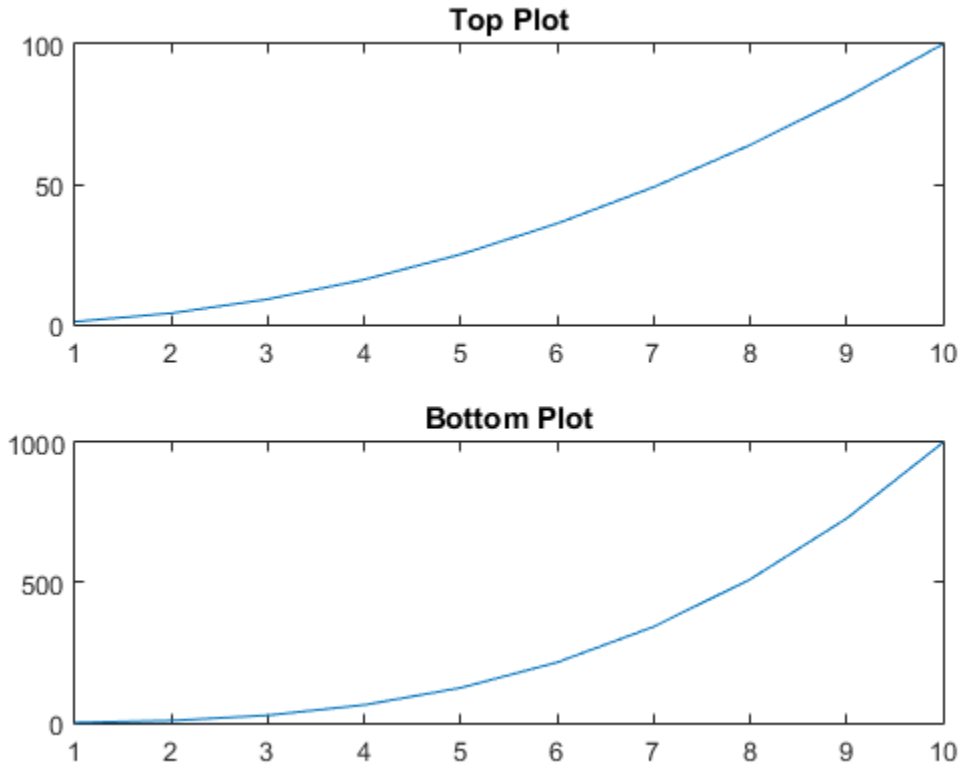
Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```



Add a title to each subplot by referring to its axes handle, `s(1)`, or `s(2)`.

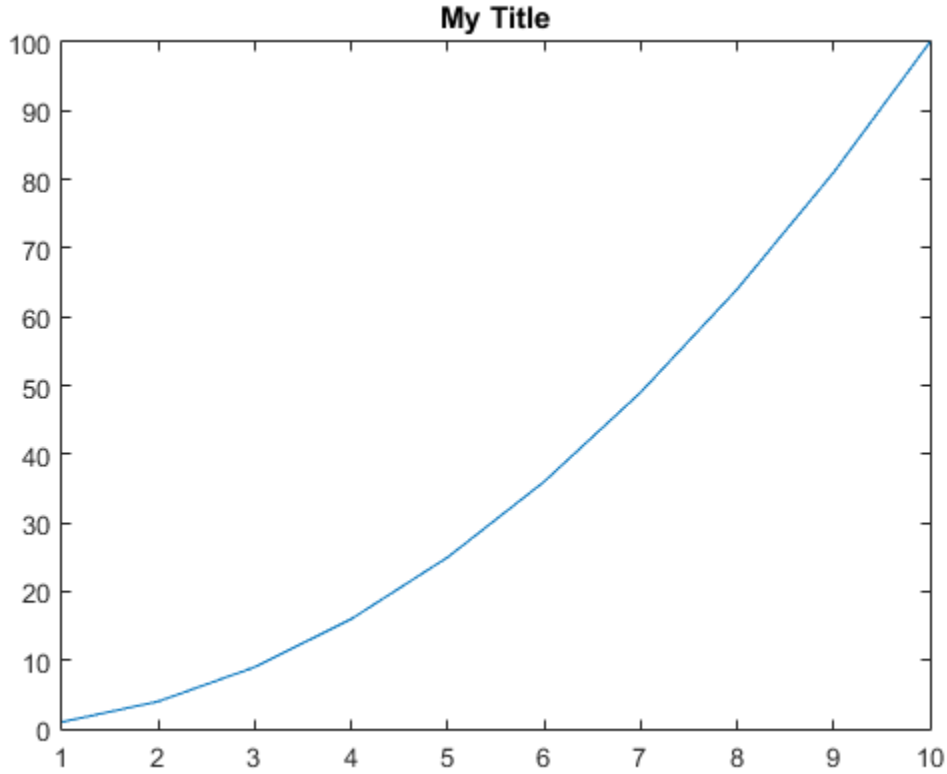
```
title(s(1),'Top Plot')
title(s(2),'Bottom Plot')
```



Add Title and Return Text Handle

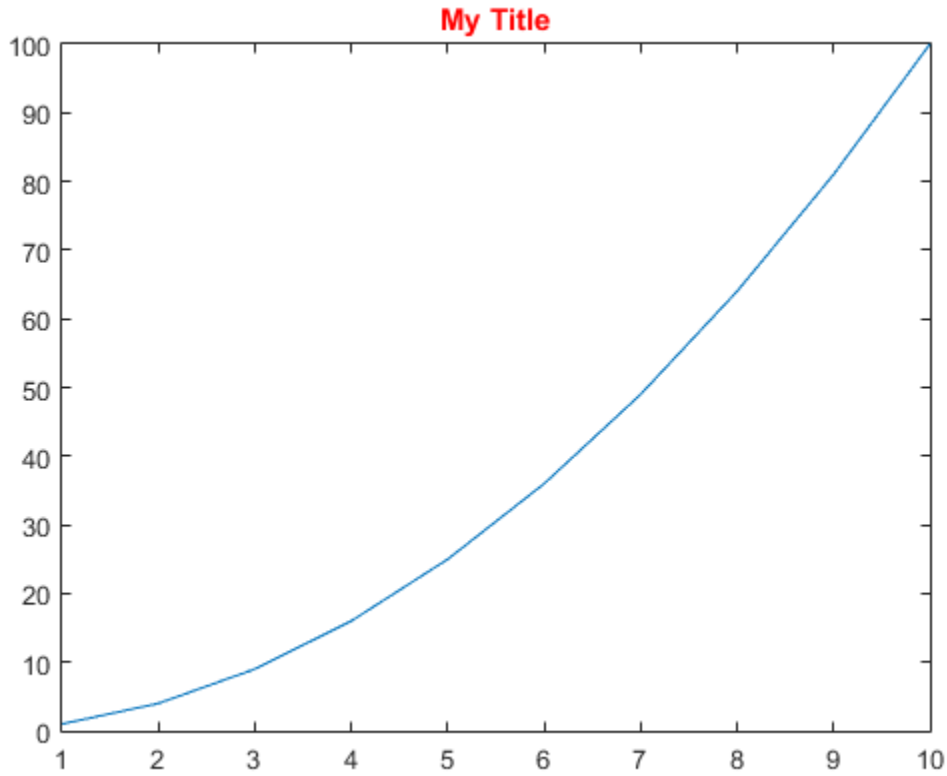
Add a title to a plot and return the text object.

```
plot((1:10).^2)
t = title('My Title');
```



Set the color of the title to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t.Color = 'red';
```



Input Arguments

`str` — Text to display as title

character array | cell array | numeric value

Text to display as title, specified as a character array, cell array, or numeric value.

Example: `'my label'`

Example: `{'first line','second line'}`

Example: `123`

To include numeric variables with text in a title, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the Interpreter property.

To create multiline titles:

- Use a cell array, where each cell contains a line of text, such as `{'first line','second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric titles are converted to text using `sprintf('%g',value)`. For example, `12345678` displays as `1.23457e+07`.

Note: The words `default`, `factory`, and `remove` are reserved words that will not appear in a title when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

ax — Axes object

axes object

Axes object. If you do not specify an axes, then the `title` function uses the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','FontSize',14` adds a title with red, 14-point font.

In addition to the following, you can specify other text object properties using `Name,Value` pair arguments. See Text Properties.

`'FontSize'` — Font size

`11` (default) | scalar value greater than `0`

Font size, specified as a scalar value greater than `0` in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Setting the font size properties for the associated axes also affects the title font size. The title font size updates to equal the axes font size times the title scale factor. The `FontSize` property of the axes contains the axes font size. The `TitleFontSizeMultiplier` property of the axes contains the scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the title font size is 11 points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'FontWeight'` — Thickness of text characters

`'bold'` (default) | `'normal'`

Thickness of the text characters, specified as one of these values:

- `'bold'` — Thicker characters outlines than normal
- `'normal'` — Normal weight as defined by the particular font

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

The `TitleFontWeight` property for the associated axes affects the `FontWeight` value for the title.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

`'FontName'` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`'Color'` — Text color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default color is black with an RGB triplet value of `[0 0 0]`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`'Interpreter'` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`

Modifier	Description	Example of String
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

Output Arguments

h — Text object

text object

Text object used as the title. Use `h` to access and modify properties of the title after its created.

Functions

`num2str` | `text` | `xlabel` | `ylabel` | `zlabel`

Properties

Text Properties

Introduced before R2006a

todatenum

Convert CDF epoch object to MATLAB serial date number

Syntax

```
n = todatenum(obj)
```

Description

`n = todatenum(obj)` converts the CDF epoch object `ep_obj` into a MATLAB serial date number. Note that a CDF epoch is the number of milliseconds since `01-Jan-0000` whereas a MATLAB datenum is the number of days since 00`-Jan-0000`.

Examples

Construct a CDF epoch object from a date string, and then convert the object back into a MATLAB date string:

```
dstr = datestr(today)
dstr =
   08-Oct-2003

obj = cdfepoch(dstr)
obj =
     cdfepoch object:
     08-Oct-2003 00:00:00

dstr2 = datestr(todatenum(obj))
dstr2 =
   08-Oct-2003
```

See Also

`cdfepoch` | `cdfinfo` | `cdfread` | `datenum` | `datetime`

Introduced before R2006a

toeplitz

Toeplitz matrix

Syntax

```
T = toeplitz(c,r)
T = toeplitz(r)
```

Description

A *Toeplitz* matrix is defined by one row and one column. A *symmetric Toeplitz* matrix is defined by just one row. `toeplitz` generates Toeplitz matrices given just the row or row and column description.

`T = toeplitz(c,r)` returns a nonsymmetric Toeplitz matrix `T` having `c` as its first column and `r` as its first row. If the first elements of `c` and `r` are different, a message is printed and the column element is used.

For a real vector `r`, `T = toeplitz(r)` returns the symmetric Toeplitz matrix formed from vector `r`, where `r` defines the first row of the matrix. For a complex vector `r` with a real first element, `T = toeplitz(r)` returns the Hermitian Toeplitz matrix formed from `r`, where `r` defines the first row of the matrix and `r'` defines the first column. When the first element of `r` is not real, the resulting matrix is Hermitian off the main diagonal, i.e., $T_{ij} = \mathrm{conj}(T_{ji})$ for $i \neq j$.

Examples

A Toeplitz matrix with diagonal disagreement is

```
c = [1  2  3  4  5];
r = [1.5  2.5  3.5  4.5  5.5];
toeplitz(c,r)
Column wins diagonal conflict:
ans =
    1.000    2.500    3.500    4.500    5.500
```

```
    2.000    1.000    2.500    3.500    4.500
    3.000    2.000    1.000    2.500    3.500
    4.000    3.000    2.000    1.000    2.500
    5.000    4.000    3.000    2.000    1.000
```

See Also

Introduced before R2006a

toolboxdir

Root folder for specified toolbox

Syntax

```
toolboxdir('tbxFolderName')
s = toolboxdir('tbxFolderName')
s = toolboxdir tbxFolderName
```

Description

`toolboxdir('tbxFolderName')` returns a string that is the absolute path to the specified toolbox, `tbxFolderName`, where `tbxFolderName` is the folder name for the toolbox.

`s = toolboxdir('tbxFolderName')` returns the absolute path to the specified toolbox to the output argument, `s`.

`s = toolboxdir tbxFolderName` is the command form of the syntax.

Examples

Obtain the path for the Control System Toolbox software:

```
s = toolboxdir('control')
```

MATLAB returns:

```
s = C:\Program Files\MATLAB\R2012a\toolbox\control
```

More About

Tips

`toolboxdir` is particularly useful for MATLAB Compiler software. The base folder of all toolboxes installed with MATLAB software is:

matlabroot/**toolbox**/tbxFolderName

However, in deployed mode, the base folders of the toolboxes are different. `toolboxdir` returns the correct root folder, whether running from MATLAB or from an application deployed with the MATLAB Compiler software.

To determine the folder name for a given toolbox, run the following code, substituting the name of a product function for *toolbxfcn*:

```
n = 'toolbxfcn';
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

For example, to determine the product name for Control System Toolbox set `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss'
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+'
regexp(which(n), pat, 'match', 'once')
```

```
control
```

See Also

`fullfile` | `path` | `matlabroot`

trace

Sum of diagonal elements

Syntax

```
b = trace(A)
```

Description

`b = trace(A)` is the sum of the diagonal elements of the matrix `A`.

More About

Algorithms

```
t = sum(diag(A));
```

See Also

`det` | `eig`

Introduced before R2006a

transpose, .'

Transpose

Syntax

```
B = A.'
B = transpose(A)
```

Description

`B = A.'` computes the nonconjugate transpose of `A`.

`B = transpose(A)` is an alternate way to execute `A.'`, but is rarely used. It enables operator overloading for classes.

Examples

Transpose of Real Matrix

Create a 4-by-4 matrix.

```
A = magic(4)
```

```
A =

    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
```

Find the transpose of `A`.

```
B = A.'
```

```
B =

    16     5     9     4
```

```
     2    11     7    14
     3    10     6    15
    13     8    12     1
```

The result, B, has the same elements as A, but the row and column index for each element are interchanged.

Transpose of Complex Matrix

Create a 2-by-4 matrix containing complex elements.

```
A = [1 3 4-1i 2+2i; 0+1i 1-1i 5 6-1i]
```

```
A =

   1.0000 + 0.0000i   3.0000 + 0.0000i   4.0000 - 1.0000i   2.0000 + 2.0000i
   0.0000 + 1.0000i   1.0000 - 1.0000i   5.0000 + 0.0000i   6.0000 - 1.0000i
```

Find the transpose of A.

```
B = A.'
```

```
B =

   1.0000 + 0.0000i   0.0000 + 1.0000i
   3.0000 + 0.0000i   1.0000 - 1.0000i
   4.0000 - 1.0000i   5.0000 + 0.0000i
   2.0000 + 2.0000i   6.0000 - 1.0000i
```

The result, B, is a 4-by-2 matrix. The non-conjugate transpose does not change the sign of the imaginary parts of the complex elements.

Input Arguments

A — Input array

vector | matrix | cell array | categorical array | datetime array | duration array | calendarDuration array | structure field

Input array, specified as a vector or matrix of any numeric, logical, or `char` data type, or as a cell array, categorical array, datetime array, duration array, calendarDuration array, or structure field.

Complex Number Support: Yes

More About

Nonconjugate Transpose

The nonconjugate transpose of a matrix interchanges the row and column index for each element, reflecting the elements across the main diagonal, with the diagonal elements themselves unchanged. This operation does not affect the sign of the imaginary parts of complex elements.

For example, if `B = A.'` and `A(3,2)` is `1+1i`, then the element `B(2,3)` is `1+1i`.

Tips

- The complex conjugate transpose operator, `A'`, also negates the sign of the imaginary portion of the complex elements in `A`.
- "Array vs. Matrix Operations"
- "Operator Precedence"

trapz

Trapezoidal numerical integration

Syntax

```
Q = trapz(Y)
Q = trapz(X,Y)
Q = trapz( ___ ,dim)
```

Description

`Q = trapz(Y)` returns the approximate integral of `Y` via the trapezoidal method with unit spacing. The size of `Y` determines the dimension to integrate along:

- If `Y` is a vector, then `trapz(Y)` is the approximate integral of `Y`.
- If `Y` is a matrix, then `trapz(Y)` integrates over each column and returns a row vector of integration values.
- If `Y` is a multidimensional array, then `trapz(Y)` integrates over the first dimension whose size does not equal 1. The size of this dimension becomes 1, and the sizes of other dimensions remain unchanged.

`Q = trapz(X,Y)` integrates `Y` with spacing increment `X`. By default, `trapz` operates on the first dimension of `Y` whose size does not equal 1. `length(X)` must be equal to the size of this dimension . If `X` is a scalar, then `trapz(X,Y)` is equivalent to `X*trapz(Y)`.

`Q = trapz( ___ ,dim)` integrates along the dimension `dim` using any of the previous syntaxes. You must specify `Y`, and optionally can specify `X`. The length of `X`, if specified, must be the same as `size(Y,dim)`. For example, if `Y` is a matrix, then `trapz(X,Y,2)` integrates each row of `Y`.

Examples

Integrate Vector of Data with Unit Spacing

Create a numeric vector of data.

```
Y = [1 4 9 16 25];
```

Y contains function values for $f(x) = x^2$ in the domain [1,5].

Use trapz to integrate the data points with unit spacing.

```
Q = trapz(Y)
```

```
Q =

    42
```

This approximate integration yields a value of 42. In this case, the exact answer is a little less, $41\frac{1}{3}$. The trapz function overestimates the value of the integral because *f(x)* is concave up.

Integrate Vector of Data with Nonunit Spacing

Create a domain vector, X.

```
X = 0:pi/100:pi;
```

Calculate the sine of X and store the result in Y.

```
Y = sin(X);
```

Integrate the function values contained in Y using trapz.

```
Q = trapz(X,Y)
```

```
Q =

    1.9998
```

When the spacing between points is constant, but not equal to 1, you can multiply by the spacing value, in this case pi/100*trapz(Y). The answer is the same if you pass the value directly to the function with trapz(X,Y).

Integrate Matrix with Nonuniform Spacing

Create a vector of time values, X. Also create a matrix, Y, containing values evaluated at the irregular intervals in X.

```
X = [1 2.5 7 10]';
```

```
Y = [5.2 4.8 4.9 5.1; 7.7 7.0 6.5 6.8; 9.6 10.5 10.5 9.0; 13.2 14.5 13.8 15.2]
```

```
Y =

    5.2000    4.8000    4.9000    5.1000
    7.7000    7.0000    6.5000    6.8000
    9.6000   10.5000   10.5000    9.0000
   13.2000   14.5000   13.8000   15.2000
```

The columns of `Y` represent velocity data, taken at the times contained in `X`, for several different trials.

Use `trapz` to integrate each column independently and find the total distance traveled in each trial. Since the function values are not evaluated at constant intervals, specify `X` to indicate the spacing between the data points.

```
Q = trapz(X,Y)
```

```
Q =

   82.8000   85.7250   83.2500   80.7750
```

The result is a row vector of integration values, one for each column in `Y`. By default, `trapz` integrates along the first dimension of `Y` whose size does not equal 1.

Alternatively, you can integrate the rows of a matrix by specifying `dim = 2`.

In this case, use `trapz` on `Y'`, which contains the velocity data in the rows.

```
dim = 2;
Q1 = trapz(X,Y',dim)
```

```
Q1 =

   82.8000
   85.7250
   83.2500
   80.7750
```

The result is a column vector of integration values, one for each row in `Y'`.

Multiple Numerical Integrations

Created a grid of domain values.

```
x = -3:.1:3;
```

```
y = -5:.1:5;
[X,Y] = meshgrid(x,y);
```

Calculate the function $f(x,y) = x^2 + y^2$ over the grid.

```
F = X.^2 + Y.^2;
```

`trapz` integrates numeric data rather than functional expressions, so in general the expression does not need to be known to use `trapz` on a matrix of data.

Use `trapz` to approximate the double integral

$$I = \int_{-5}^{5} \int_{-3}^{3} \left(x^2 + y^2\right) dx dy .$$

To perform double or triple integrations on an array of numeric data, nest function calls to `trapz`.

```
I = trapz(y,trapz(x,F,2))
```

```
I =

  680.2000
```

`trapz` performs the integration over *x* first, producing a column vector. Then, the integration over *y* reduces the column vector to a single scalar. `trapz` slightly overestimates the exact answer of 680 because *f(x,y)* is concave up.

Input Arguments

`Y` — Numeric data

vector | matrix | multidimensional array

Numeric data, specified as a vector, matrix, or multidimensional array. By default, `trapz` integrates along the first dimension of `Y` whose size does not equal 1.

Data Types: `single` | `double`
Complex Number Support: Yes

`X` — Point spacing

1 (default) | uniform scalar spacing | vector of nonuniform spacings

Point spacing, specified as `1` (default), a uniform scalar spacing, or a vector of nonuniform spacings. If `X` is a vector, then `length(X)` must be the same as the size of the integration dimension in `Y`.

Data Types: `single` | `double`
Complex Number Support: Yes

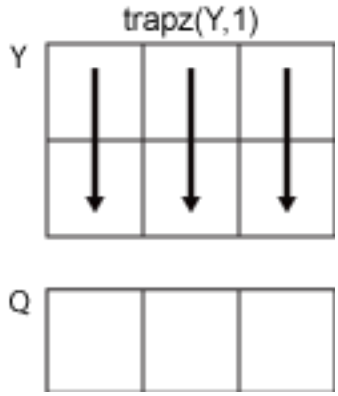
`dim` — Dimension to operate along

positive integer scalar

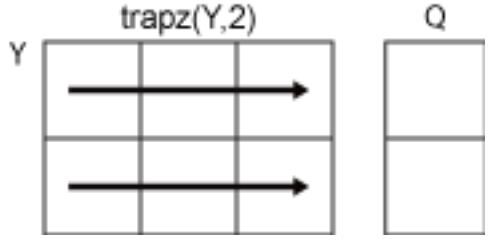
Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `Y`:

- `trapz(Y,1)` works on successive elements in the columns of `Y` and returns a row vector of integration values.



- `trapz(Y,2)` works on successive elements in the rows of `Y` and returns a column vector of integration values.



If `dim` is greater than `ndims(Y)`, then `trapz` returns an array of zeros of the same size as `Y`.

More About

Trapezoidal Method

`trapz` performs numerical integration via the trapezoidal method. This method approximates the integration over an interval by breaking the area down into trapezoids with more easily computable areas.

For an integration with `N+1` evenly spaced points, the approximation is

$$\int_a^b f(x)dx \approx \frac{b-a}{2N}\sum_{n=1}^{N}\left(f(x_n)+f(x_{n+1})\right)$$
$$= \frac{b-a}{2N}\left[f(x_1)+2f(x_2)+\ldots+2f(x_N)+f(x_{N+1})\right],$$

where the spacing between each point is equal to the scalar value $\frac{b-a}{N}$.

If the spacing between the points is not constant, then the formula generalizes to

$$\int_a^b f(x)dx \approx \frac{1}{2}\sum_{n=1}^{N}(x_{n+1}-x_n)\left[f(x_n)+f(x_{n+1})\right],$$

where $(x_{n+1}-x_n)$ is the spacing between each consecutive pair of points.

Tips

- `trapz` reduces the size of the dimension it operates on to 1, and returns only the final integration value. `cumtrapz` also returns the intermediate integration values, preserving the size of the dimension it operates on.
- “Integration of Numeric Data”

Introduced before R2006a

treelayout

Lay out tree or forest

Syntax

```
[x,y] = treelayout(parent,post)
[x,y,h,s] = treelayout(parent,post)
```

Description

`[x,y] = treelayout(parent,post)` lays out a tree or a forest. `parent` is the vector of parent pointers, with `0` for a root. `post` is an optional postorder permutation on the tree nodes. If you omit `post`, `treelayout` computes it. `x` and `y` are vectors of coordinates in the unit square at which to lay out the nodes of the tree to make a nice picture.

`[x,y,h,s] = treelayout(parent,post)` also returns the height of the tree `h` and the number of vertices `s` in the top-level separator.

See Also

`etree` | `treeplot` | `etreeplot` | `symbfact`

Introduced before R2006a

treeplot

Plot picture of tree

Syntax

```
treeplot(p)
treeplot(p,nodeSpec,edgeSpec)
```

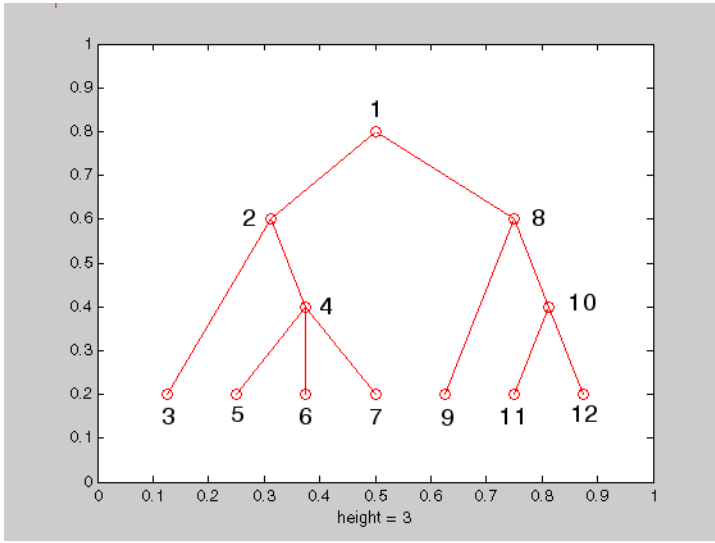
Description

`treeplot(p)` plots a picture of a tree given a vector of parent pointers, with `p(i)` = 0 for a root.

`treeplot(p,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `''` to omit one or both.

Examples

To plot a tree with 12 nodes, call `treeplot` with a 12-element input vector. The index of each element in the vector is shown adjacent to each node in the figure below. (These indices are shown only for the point of illustrating the example; they are not part of the `treeplot` output.)



To generate this plot, set the value of each element in the `nodes` vector to the index of its parent, (setting the parent of the root node to zero).

The node marked `1` in the figure is represented by `nodes(1)` in the input vector, and because this is the root node which has a parent of zero, you set its value to zero:

```
nodes(1) = 0;      % Root node
```

`nodes(2)` and `nodes(8)` are children of `nodes(1)`, so set these elements of the input vector to `1`:

```
nodes(2) = 1;      nodes(8) = 1;
```

`nodes(5:7)` are children of `nodes(4)`, so set these elements to `4`:

```
nodes(5) = 4;      nodes(6) = 4;      nodes(7) = 4;
```

Continue in this manner until each element of the vector identifies its parent. For the plot shown above, the `nodes` vector now looks like this:

```
nodes = [0 1 2 2 4 4 4 1 8 8 10 10];
```

Now call `treeplot` to generate the plot:

```
treeplot(nodes)
```

See Also

`etree` | `etreeplot` | `treelayout`

Introduced before R2006a

tril

Lower triangular part of matrix

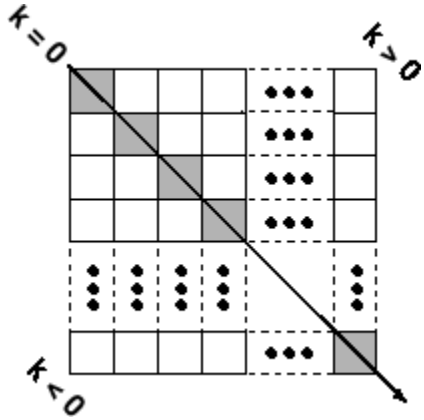
Syntax

```
L = tril(X)
L = tril(X,k)
```

Description

`L = tril(X)` returns the lower triangular part of `X`.

`L = tril(X,k)` returns the elements on and below the kth diagonal of `X`. `k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.



Examples

```
tril(ones(4,4),-1)

ans =
```

```
     0     0     0     0
     1     0     0     0
     1     1     0     0
     1     1     1     0
```

See Also

`diag` | `triu`

Introduced before R2006a

trimesh

Triangular mesh plot

Syntax

```
trimesh(Tri,X,Y,Z,C)
trimesh(Tri,X,Y,Z)
trimesh(Tri,X,Y)
trimesh(TR)
trimesh(...'PropertyName',PropertyValue...)
h = trimesh(...)
```

Description

`trimesh(Tri,X,Y,Z,C)` displays triangles defined in the *m*-by-3 face matrix `Tri` as a mesh. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the `X`, `Y`, and `Z` vertices. The edge color is defined by the vector `C`.

`trimesh(Tri,X,Y,Z)` uses `C = Z` so color is proportional to surface height.

`trimesh(Tri,X,Y)` displays the triangles in a 2-D plot.

`trimesh(TR)` displays the triangles in a triangulation representation.

`trimesh(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

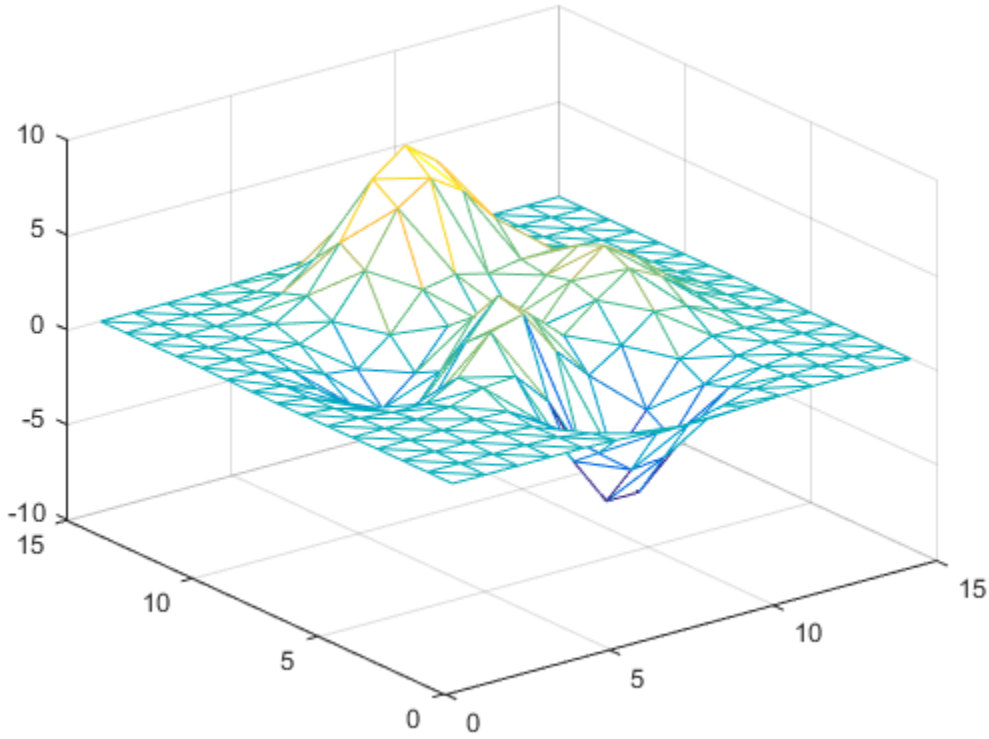
`h = trimesh(...)` returns a handle to the displayed triangles.

Examples

Create Triangular Mesh Plot

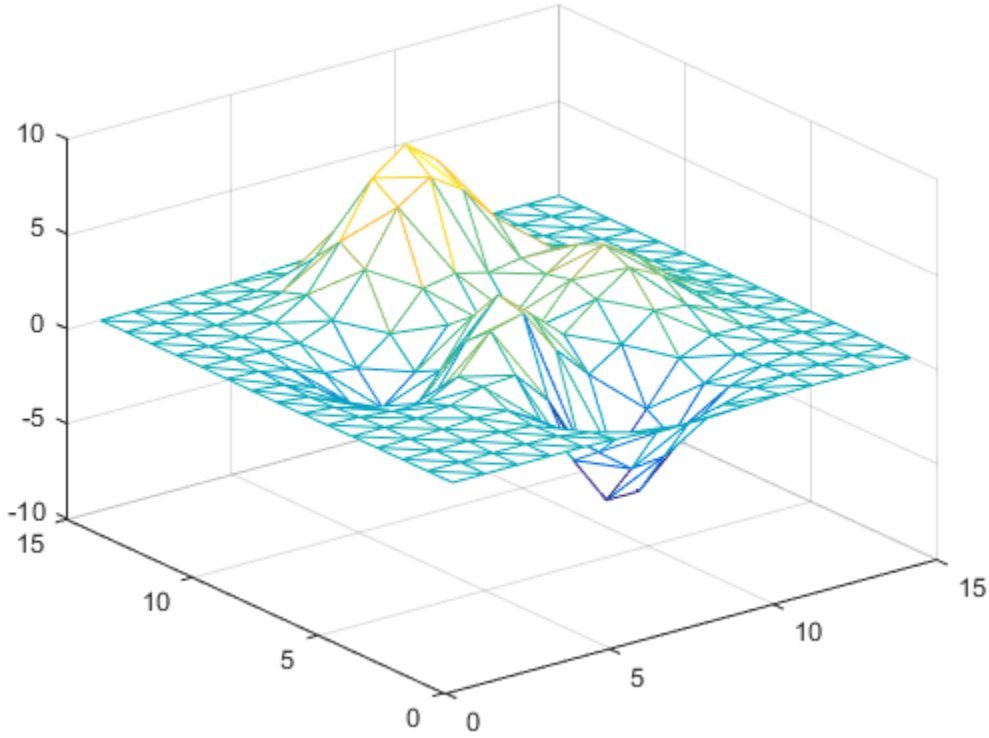
Create vertex vectors and a face matrix, and then create a triangular mesh plot.

```
[x,y] = meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trimesh(tri,x,y,z)
```



If the surface is already a triangulation representation, then you can pass the triangulation to `trimesh`:

```
tr = triangulation(tri,x(:),y(:),z(:));
trimesh(tr)
```



See Also

`patch` | `trisurf` | `triangulation` | `delaunay` | `delaunayTriangulation`

Introduced before R2006a

triplequad

Numerically evaluate triple integral

Compatibility

`triplequad` will be removed in a future release. Use `integral3` instead.

Syntax

```
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)
```

Description

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)` evaluates the triple integral `fun(x,y,z)` over the three dimensional rectangular region `xmin <= x <= xmax`, `ymin <= y <= ymax`, `zmin <= z <= zmax`. The first input, `fun`, is a function handle. `fun(x,y,z)` must accept a vector `x` and scalars `y` and `z`, and return a vector of values of the integrand.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quadl` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quadl`.

Examples

Pass function handle `@integrnd` to `triplequad`:P

```
Q = triplequad(@integrnd,0,pi,0,1,-1,1);
```

where the file `integrnd.m` is

```
function f = integrnd(x,y,z)
f = y*sin(x)+z*cos(x);
```

Pass anonymous function handle `F` to `triplequad`:

```
F = @(x,y,z)y*sin(x)+z*cos(x);
Q = triplequad(F,0,pi,0,1,-1,1);
```

This example integrates `y*sin(x)+z*cos(x)` over the region `0 <= x <= pi`, `0 <= y <= 1`, `-1 <= z <= 1`. Note that the integrand can be evaluated with a vector `x` and scalars `y` and `z`.

triplot

2-D triangular plot

Note: The behavior of `h = triplot(...)` has changed. The new behavior returns a single chart line handle.

Syntax

```
triplot(TRI,x,y)
triplot(TRI,x,y,color)
triplot(TR)
h = triplot(...)
triplot(...,'param','value','param','value'...)
```

Description

`triplot(TRI,x,y)` displays the triangles defined in the `m`-by-3 matrix `TRI`. A row of `TRI` contains indices into the vectors `x` and `y` that define a single triangle. The default line color is blue.

`triplot(TRI,x,y,color)` uses the string `color` as the line color. `color` can also be a line specification. See `ColorSpec` for a list of valid color strings. See `LineSpec` for information about line specifications.

`triplot(TR)` displays the triangles in a triangulation representation.

`h = triplot(...)` returns a single chart line handle to the displayed triangles.

`triplot(...,'param','value','param','value'...)` allows additional line property name/property value pairs to be used when creating the plot. See Chart Line Properties for information about the available properties.

Examples

Plot Delaunay Triangulation

Plot a Delaunay triangulation for 10 randomly generated points.

```
P = gallery('uniformdata',10,2,2);
DT = delaunayTriangulation(P);
triplot(DT)
```

`delaunayTriangulation` | `triangulation` | `delaunay` | `trimesh` | `trisurf`

Introduced before R2006a

TriRep class

(Will be removed) Triangulation representation

Note: `TriRep` will be removed in a future release. Use `triangulation` instead.

Description

`TriRep` provides topological and geometric queries for triangulations in 2-D and 3-D space. For example, for triangular meshes you can query triangles attached to a vertex, triangles that share an edge, neighbor information, circumcenters, or other features. You can create a `TriRep` directly using existing triangulation data. Alternatively, you can create a Delaunay triangulation, via `DelaunayTri`, which provides access to the `TriRep` functionality.

Construction

.TriRep	(Will be removed) Triangulation representation

Methods

baryToCart	(Will be removed) Convert point coordinates from barycentric to Cartesian
cartToBary	(Will be removed) Convert point coordinates from cartesian to barycentric
circumcenters	(Will be removed) Circumcenters of specified simplices

edgeAttachments	(Will be removed) Simplices attached to specified edges
edges	(Will be removed) Triangulation edges
faceNormals	(Will be removed) Unit normals to specified triangles
featureEdges	(Will be removed) Sharp edges of surface triangulation
freeBoundary	(Will be removed) Facets referenced by only one simplex
incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information
size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

Properties

X	Coordinates of the points in the triangulation
Triangulation	Triangulation data structure

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

Indexing

`TriRep` objects support indexing into the triangulation using parentheses (). The syntax is the same as for arrays.

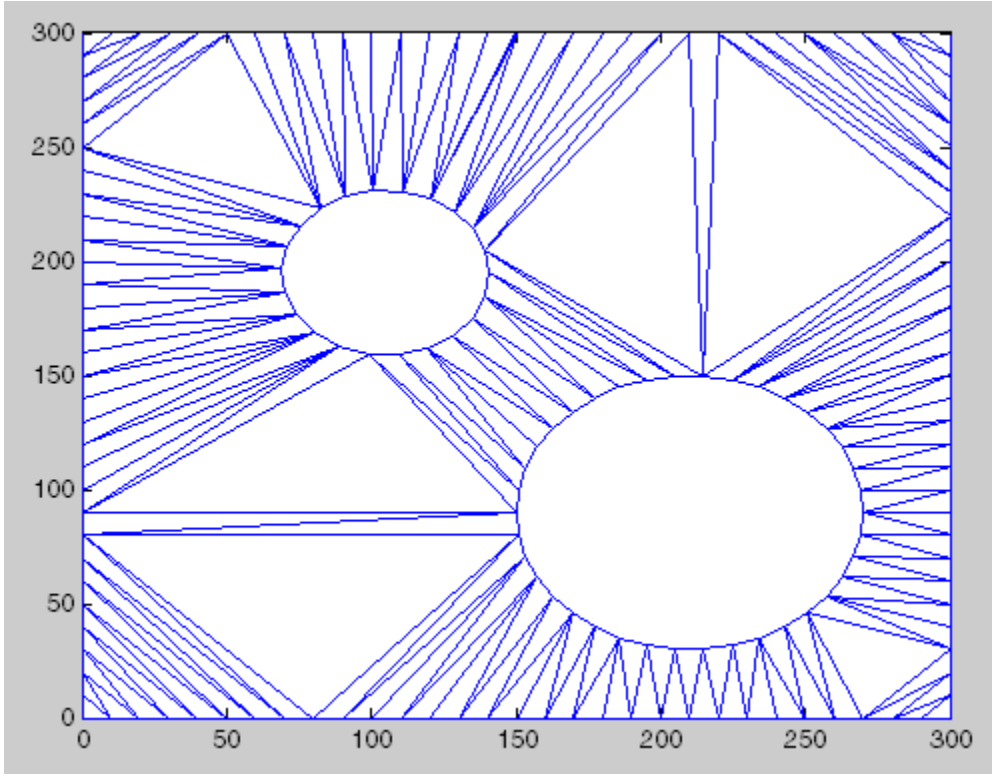
Examples

Load a 2-D triangulation and use the `TriRep` constructor to build an array of the free boundary edges:

```
load trimesh2d
```

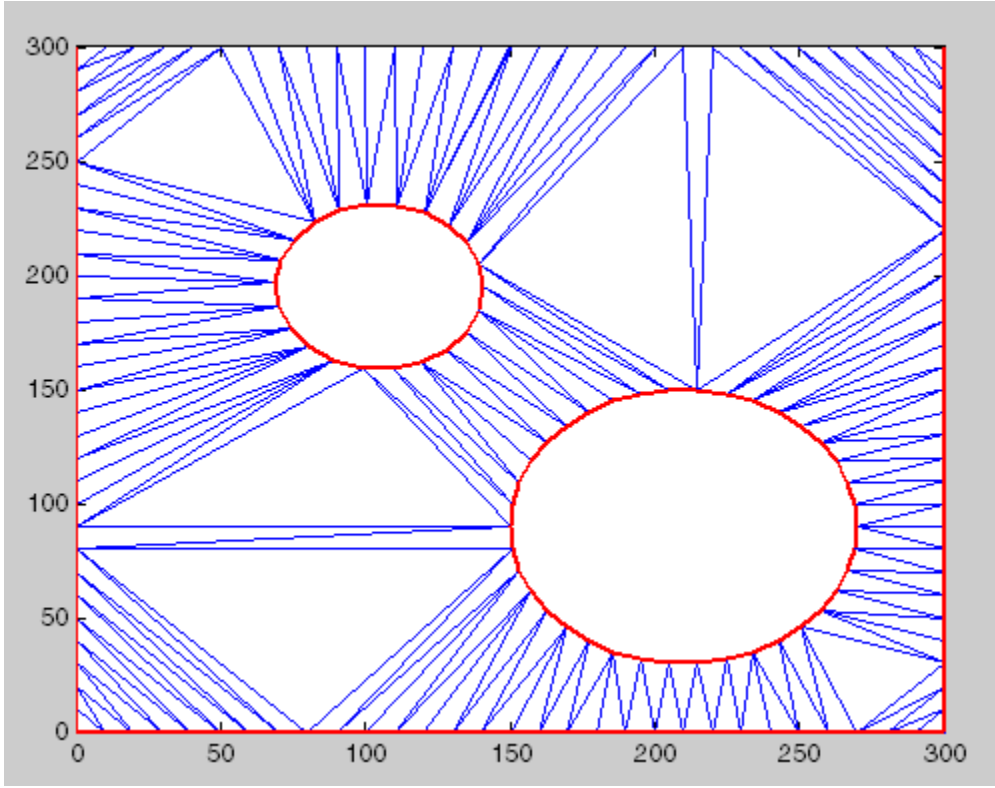
This loads triangulation `tri` and vertex coordinates `x`, `y`:

```
trep = TriRep(tri, x,y);
fe = freeBoundary(trep)';
triplot(trep);
```



You can add the free edges `fe` to the plot:

```
hold on;
plot(x(fe), y(fe), 'r','LineWidth',2);
hold off;
axis([-50 350 -50 350]);
axis equal;
```



See Also

`triangulation` | `delaunayTriangulation` | `scatteredInterpolant`

TriRep

Class: TriRep

(Will be removed) Triangulation representation

Note: `TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
TR = TriRep(TRI, X, Y)
TR = TriRep(TRI, X, Y, Z)
TR = TriRep(TRI, X)
```

Description

`TR = TriRep(TRI, X, Y)` creates a 2-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y)`. `TRI` is an `m`-by-3 matrix that defines the triangulation in face-vertex format, where `m` is the number of triangles. Each row of `TRI` is a triangle defined by indices into the column vector of vertex coordinates `(X, Y)`.

`TR = TriRep(TRI, X, Y, Z)` creates a 3-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y, Z)`. `TRI` is an `m`-by-3 or `m`-by-4 matrix that defines the triangulation in simplex-vertex format, where where m is the number of simplices; triangles or tetrahedra in this case. Each row of `TRI` is a simplex defined by indices into the column vector of vertex coordinates `(X, Y, Z)`.

`TR = TriRep(TRI, X)` creates a triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `X`. `TRI` is an `m`-by-`n` matrix that defines the triangulation in simplex-vertex format, where `m` is the number of simplices and `n` is the number of vertices per simplex. Each row of `TRI` is a simplex defined by indices into the array of vertex coordinates `X`. `X` is an `mpts`-by-`ndim` matrix where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, where $2 \le$ `ndim` ≤ 3.

Examples

Load a 3-D tetrahedral triangulation compute the free boundary. First, load triangulation `tet` and vertex coordinates `X`.

```
load tetmesh
```

Create the triangulation representation and compute the free boundary.

```
trep = TriRep(tet, X);
[tri, Xb] = freeBoundary(trep);
```

See Also

`scatteredInterpolant` | `delaunayTriangulation`

TriScatteredInterp class

(Will be removed) Interpolate scattered data

Note: `TriScatteredInterp` will be removed in a future release. Use `scatteredInterpolant` instead.

Description

`TriScatteredInterp` is used to perform interpolation on a scattered dataset that resides in 2-D or 3-D space. A scattered data set defined by locations `X` and corresponding values `V` can be interpolated using a Delaunay triangulation of `X`. This produces a surface of the form `V = F(X)`. The surface can be evaluated at any query location `QX`, using `QV = F(QX)`, where `QX` lies within the convex hull of `X`. The interpolant `F` always goes through the data points specified by the sample.

Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set. The *convex hull* of a set of points is the smallest convex set containing all points of the original set. These definitions extend naturally to higher dimensions.

Construction

.TriScatteredInterp	(Will be removed) Interpolate scattered data

Properties

`X`	Defines locations of scattered data points in 2-D or 3-D space.	
`V`	Defines value associated with each data point.	
`Method`	Defines method used to interpolate the data .	
	`natural`	Natural neighbor interpolation
	`linear`	Linear interpolation (default)
	`nearest`	Nearest neighbor interpolation

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

Examples

Create a data set:

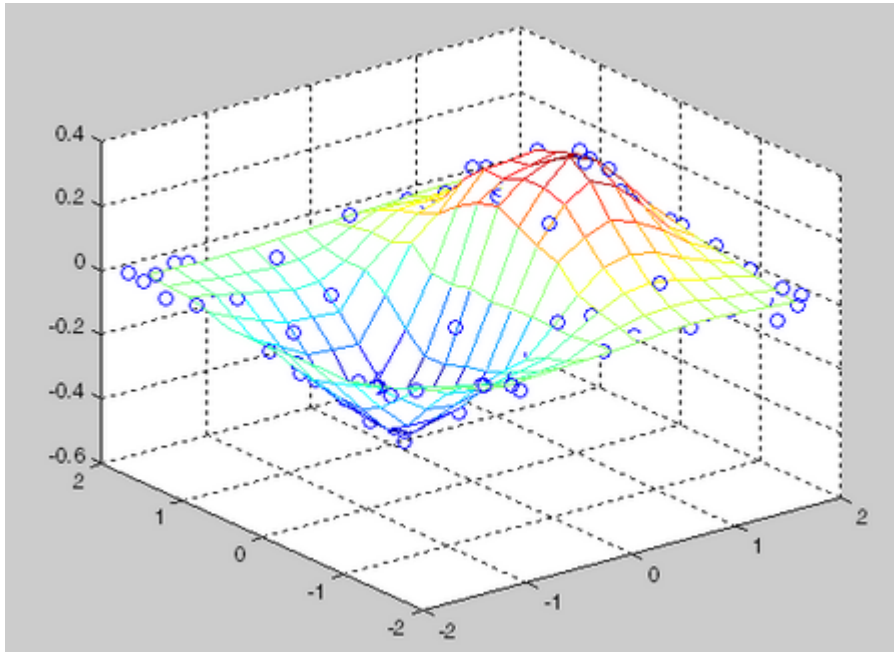
```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations `(qx, qy)`. The corresponding value at these locations is `qz`:

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z,'o');
```



See Also

`delaunayTriangulation` | `interp1` | `interp2` | `interp3` | `meshgrid`

TriScatteredInterp

Class: TriScatteredInterp

(Will be removed) Interpolate scattered data

Note: `TriScatteredInterp` will be removed in a future release. Use `scatteredInterpolant` instead.

Syntax

```
F = TriScatteredInterp()
F = TriScatteredInterp(X, V)
F = TriScatteredInterp(X, Y, V)
F = TriScatteredInterp(X, Y, Z, V)
F = TriScatteredInterp(DT, V)
F = TriScatteredInterp(..., method)
```

Description

`F = TriScatteredInterp()` creates an empty scattered data interpolant. This can subsequently be initialized with sample data points and values (`Xdata`, `Vdata`) via `F.X = Xdata` and `F.V = Vdata`.

`F = TriScatteredInterp(X, V)` creates an interpolant that fits a surface of the form `V = F(X)` to the scattered data in (`X`, `V`). `X` is a matrix of size `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside (`ndim` is 2 or 3). The column vector `V` defines the values at `X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(X, Y, V)` and `F = TriScatteredInterp(X, Y, Z, V)` allow the data point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`F = TriScatteredInterp(DT, V)` uses the specified `DelaunayTri` object `DT` as a basis for computing the interpolant. `DT` is a Delaunay triangulation of the scattered data locations, `DT.X`. The matrix `DT.X` is of size `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, `2 <= ndim <= 3`. `V` is a column vector that defines the values at `DT.X`, where the length of `V` equals `mpts`.

`F = TriScatteredInterp(..., method)` allows selection of the technique `method` used to interpolate the data.

Input Arguments

`X`	Matrix of size `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside. Input may also be specified as column vectors (`X`, `Y`) or (`X`, `Y`, `Z`)	
`V`	Column vector that defines the values at `X`, where the length of `V` equals `mpts`.	
`DT`	Delaunay triangulation of the scattered data locations	
`method`	`natural`	Natural neighbor interpolation
	`linear`	Linear interpolation (default)
	`nearest`	Nearest-neighbor interpolation

Output Arguments

`F`	Creates an interpolant that fits a surface of the form `V = F(X)` to the scattered data.

Evaluation

To evaluate the interpolant, express the statement in Monge's form `Vq = F(Xq)`, `Vq = F(Xq,Yq)`, or `Vq = F(Xq,Yq,Zq)` where `Vq` is the value of the interpolant at the query location and `Xq`, `Yq`, and `Zq` are the vectors of point locations.

Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set.

Examples

Create a data set:

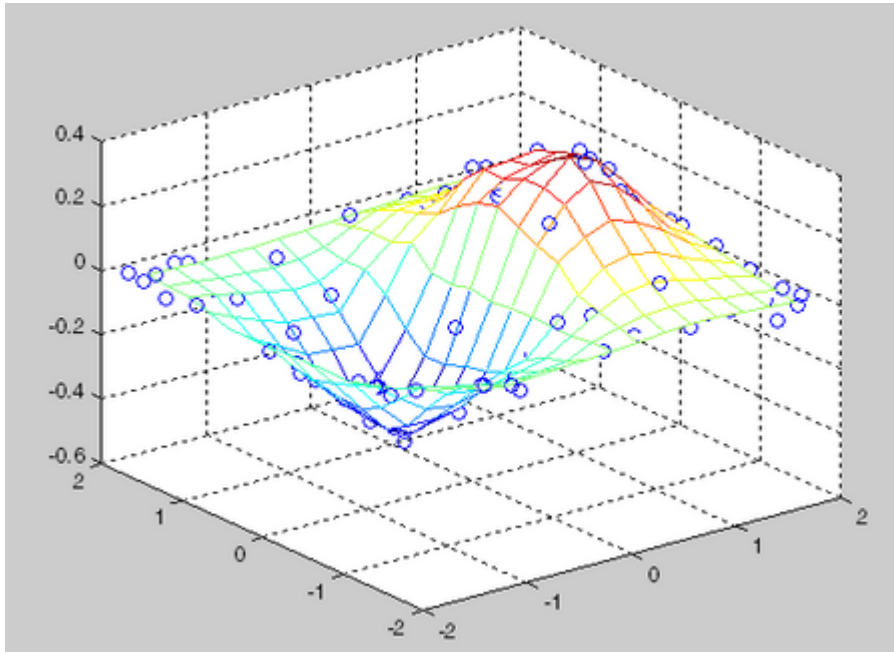
```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations `(qx, qy)`. The corresponding value at these locations is `qz` .

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z,'o');
```



See Also

`delaunayTriangulation` | `interp1` | `interp2` | `interp3` | `meshgrid`

trisurf

Triangular surface plot

Syntax

```
trisurf(Tri,X,Y,Z,C)
trisurf(Tri,X,Y,Z)
trisurf(TR)
trisurf(...'PropertyName',PropertyValue...)
h = trisurf(...)
```

Description

`trisurf(Tri,X,Y,Z,C)` displays triangles defined in the *m*-by-3 face matrix `Tri` as a surface. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the `X`, `Y`, and `Z` vertices. The color is defined by the vector `C`.

`trisurf(Tri,X,Y,Z)` uses `C=Z` so color is proportional to surface height.

`trisurf(TR)` displays the triangles in a triangulation representation. It uses `C = TR.Points(:,3)` to make sure the surface color is proportional to height.

`trisurf(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trisurf(...)` returns a patch handle.

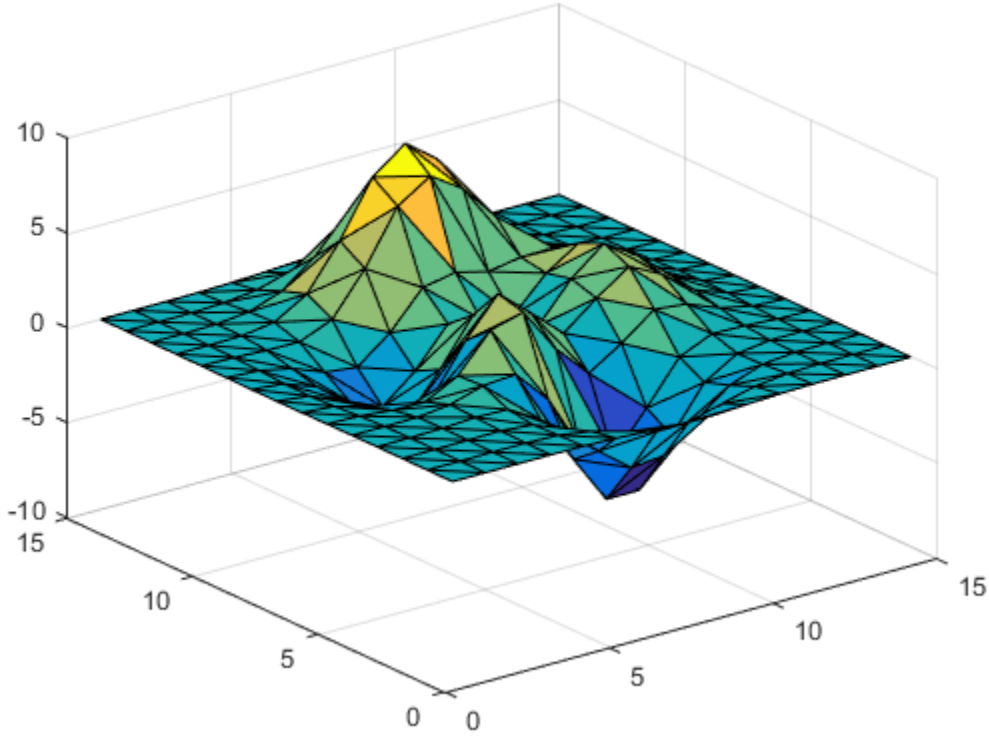
Examples

Create Triangular Surface Plot

Create vertex vectors and a face matrix, then create a triangular surface plot.

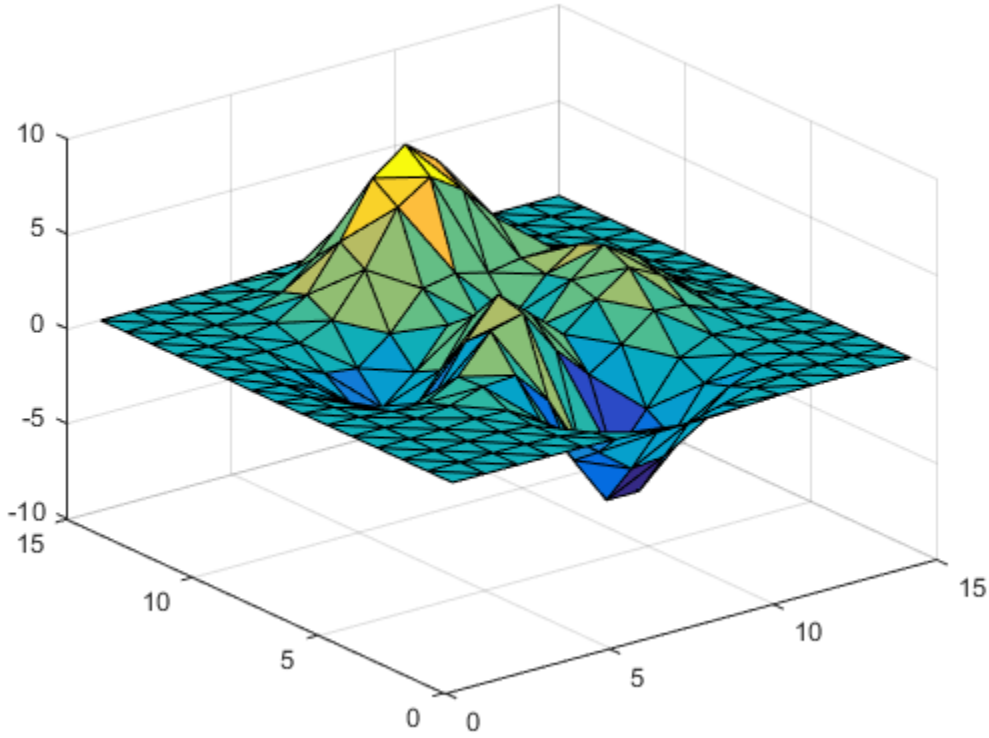
```
[x,y] = meshgrid(1:15,1:15);
```

```
tri = delaunay(x,y);
z = peaks(15);
trisurf(tri,x,y,z)
```



If the surface is in the form of a triangulation representation, you can pass it to `trisurf` alone:

```
tr = triangulation(tri,x(:),y(:),z(:));
trisurf(tr)
```



See Also

Introduced before R2006a

triu

Upper triangular part of matrix

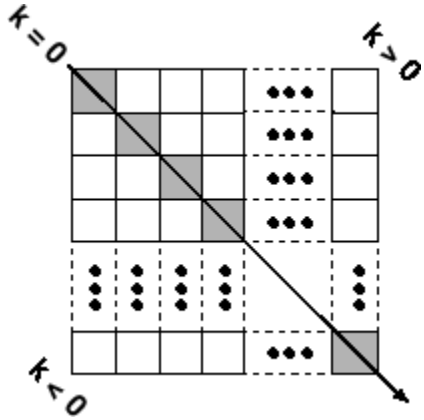
Syntax

```
U = triu(X)
U = triu(X,k)
```

Description

`U = triu(X)` returns the upper triangular part of `X`.

`U = triu(X,k)` returns the element on and above the kth diagonal of `X`. `k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.



Examples

```
triu(ones(4,4),-1)

ans =
```

```
     1     1     1     1
     1     1     1     1
     0     1     1     1
     0     0     1     1
```

See Also

`diag` | `tril`

Introduced before R2006a

true

Logical 1 (true)

Syntax

```
true
T = true(n)
T = true(sz)
T = true(sz1,...,szN)
T = true( ___ ,'like',p)
```

Description

`true` is shorthand for `logical(1)`.

`T = true(n)` is an `n`-by-`n` matrix of logical ones.

`T = true(sz)` is an array of logical ones where the size vector, `sz`, defines `size(T)`. For example, `true([2 3])` returns a 2-by-3 array of logical ones.

`T = true(sz1,...,szN)` is a `sz1`-by-`...`-by-`szN` array of logical ones where `sz1,...,szN` indicates the size of each dimension. For example, `true(2,3)` returns a 2-by-3 array of logical ones.

`T = true( ___ ,'like',p)` returns an array of logical ones of the same sparsity as the logical variable `p` using any of the previous size syntaxes.

Examples

Generate Square Matrix of Logical Ones

Use `true` to generate a 3-by-3 square matrix of logical ones.

```
A = true(3)
class(A)
```

```
A =
     1     1     1
     1     1     1
     1     1     1
ans =
logical
```

The result is of class `logical`.

Generate Array of Logical Ones with Arbitrary Dimensions

Use `true` to generate a 3-by-2-by-2 matrix of logical ones.

```
true(3,2,2)
```

```
ans(:,:,1) =
     1     1
     1     1
     1     1

ans(:,:,2) =
     1     1
     1     1
     1     1
```

Alternatively, you can use a size vector to specify the size of the matrix.

```
true([3,2,2])
```

```
ans(:,:,1) =
     1     1
     1     1
     1     1

ans(:,:,2) =
     1     1
     1     1
     1     1
```

Note that specifying multiple vector inputs returns an error.

Execute Logic Statement

`true` along with `false` can be used to execute logic statements.

Test the logical statement $\sim(A\ and\ B) \equiv (\sim A)\ or\ (\sim B)$ for A = logical true and B = logical false.

```
~(true & false) == (~true) | (~false)
```

```
ans =
     1
```

The result is logical 1 (true), since the logical statements on both sides of the equation are equivalent. This logical statement is an instance of De Morgan's Law.

Generate Logical Array of Selected Sparsity

Generate a logical array of the same sparsity as the selected array.

```
A = logical(sparse(5,3));
whos A
T = true(4,'like',A);
whos T
```

```
Name      Size            Bytes  Class      Attributes
  A         5x3                41  logical    sparse
Name      Size            Bytes  Class      Attributes
  T         4x4               184  logical    sparse
```

The output array T has the same `sparse` attribute and data-type as the specified array A.

Input Arguments

n — Size of square matrix

integer

Size of square matrix, specified as an integer. `n` sets the output array size to `n`-by-`n`. For example, `true(3)` returns a 3-by-3 array of logical ones.

- If n is `0`, then T is an empty matrix.
- If n is negative, then it is treated as `0`.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

sz — Size vector

row vector of integers

Size vector, specified as a row vector of integers. For example, `true([2 3])` returns a 2-by-3 array of logical ones.

- If the size of any dimension is `0`, then T is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- If any trailing dimensions greater than `2` have a size of `1`, then the output, T, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

sz1,...,szN — Size inputs

comma-separated list of integers

Size inputs, specified by a comma-separated list of integers. For example, `true(2,3)` returns a 2-by-3 array of logical ones.

- If the size of any dimension is `0`, then T is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- If any trailing dimensions greater than `2` have a size of `1`, then the output, T, does not include those dimensions.

Data Types: `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

p — Prototype

logical variable

Prototype, specified as a logical variable.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

Output Arguments

T — Output of logical ones

scalar | vector | matrix | N-D array

Output of logical ones, returned as a scalar, vector, matrix, or N-D array.

Data Types: `logical`

More About

Tips

- `true(n)` is much faster and more memory efficient than `logical(true(n))`.
- "Class Support for Array-Creation Functions"

`false` | `logical`

Introduced before R2006a

try, catch

Execute statements and catch resulting errors

Syntax

```
try
   statements
catch exception
   statements
end
```

Description

`try` *`statements`*`, catch` *`statements`* `end` executes the statements in the `try` block and catches resulting errors in the `catch` block. This approach allows you to override the default error behavior for a set of program statements. If any statement in a `try` block generates an error, program control goes immediately to the `catch` block, which contains your error handling statements.

`exception` is an `MException` object that allows you to identify the error. The `catch` block assigns the current exception object to the variable in *`exception`*.

Both `try` and `catch` blocks can contain nested `try/catch` statements.

Examples

Supplement Error Message

Create two matrices that you cannot concatenate vertically.

```
A = rand(3);
B = ones(5);

C = [A; B];
```

```
Error using vertcat
Dimensions of matrices being concatenated are not consistent.
```

Use `try/catch` to display more information about the dimensions.

```
try
   C = [A; B];
catch ME
   if (strcmp(ME.identifier,'MATLAB:catenate:dimensionMismatch'))
      msg = ['Dimension mismatch occurred: First argument has ', ...
            num2str(size(A,2)),' columns while second has ', ...
            num2str(size(B,2)),' columns.'];
        causeException = MException('MATLAB:myCode:dimensions',msg);
        ME = addCause(ME,causeException);
   end
   rethrow(ME)
end
```

```
Error using vertcat
Dimensions of matrices being concatenated are not consistent.

Caused by:
    Dimension mismatch occurred: First argument has 3 columns while second has 5 columr
```

If matrix dimensions do not agree, MATLAB displays more information about the mismatch. Any other errors appear as usual.

Repackage Error as Warning

Catch any exception generated by calling the nonexistent function, `notaFunction`. If there is an exception, issue a warning and assign the output a value of 0.

```
try
    a = notaFunction(5,6);
catch
    warning('Problem using function.  Assigning a value of 0.');
    a = 0;
end
```

```
Warning: Problem using function.  Assigning a value of 0.
```

By itself, the call to `notaFunction` results in an error. If you use `try` and `catch`, this code catches any exception and repackages it as a warning, allowing MATLAB to continue executing subsequent commands.

Handle Different Types of Errors

Use `try/catch` to handle different types of errors in different ways.

- If the function `notaFunction` is undefined, issue a warning instead of an error and assign the output a value of `NaN`.
- If `notaFunction.m` exists, but is a script instead of a function, issue a warning instead of an error, run the script, and assign the output a value of `0`.
- If MATLAB throws an error for any other reason, rethrow the exception.

```
try
    a = notaFunction(5,6);
catch ME
    switch ME.identifier
        case 'MATLAB:UndefinedFunction'
            warning('Function is undefined.  Assigning a value of NaN.');
            a = NaN;
        case 'MATLAB:scriptNotAFunction'
            warning(['Attempting to execute script as function. '...
                'Running script and assigning output a value of 0.']);
            notaFunction;
            a = 0;
        otherwise
            rethrow(ME)
    end
end
```

```
Warning: Function is undefined.  Assigning a value of NaN.
```

More About

Tips

- You cannot use multiple `catch` blocks within a `try` block, but you can nest complete `try/catch` blocks.
- Unlike some other languages, MATLAB does not allow the use of a `finally` block within `try/catch` statements.

`MException` | `assert` | `error`

Introduced before R2006a

tscollection

Create `tscollection` object

Syntax

```
tsc = tscollection(TimeSeries)
tsc = tscollection(Time)
tsc = tscollection(...,'Parameter',Value,...)
```

Description

`tsc = tscollection(TimeSeries)` creates a `tscollection` object `tsc` with one or more `timeseries` objects already in the MATLAB workspace. The argument `TimeSeries` can be a

- Single `timeseries` object
- Cell array of `timeseries` objects

`tsc = tscollection(Time)` creates an empty `tscollection` object with the time vector `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.

`tsc = tscollection(...,'Parameter',Value,...)` creates a `tscollection` object with optional parameter-value pairs you enter after specifying either a time vector or a `timeseries` object. You can specify the following parameter:

- `Name` — String that specifies the name of this `tscollection` object

Examples

The following example shows how to create a `tscollection` object.

1 Import the sample data.

```
load count.dat
```

2 Create three `timeseries` objects to store each set of data:

```
count1 = timeseries(count(:,1),1:24,'name', 'ts1');
count2 = timeseries(count(:,2),1:24,'name', 'ts2');
count3 = timeseries(count(:,3),1:24,'name', 'ts3');
```

3 Create a `tscollection` object named `tsc` and add to it two out of three time series already in the MATLAB workspace, by using the following syntax:

```
tsc = tscollection({count1 count2},'name','tsc')
```

More About

Tips

Definition: Time Series Collection

A time series collection object is a MATLAB variable that groups several time series with a common time vector. The time series that you include in the collection are called members of this collection.

Properties of Time Series Collection Objects

This table lists the properties of the `tscollection` object. You can specify the `Time`, `TimeSeries`, and `Name` properties as input arguments in the constructor.

Property	Description
`Name`	`tscollection` name as a string. This can differ from the `tscollection` name in the MATLAB workspace.
`Time`	When `TimeInfo.StartDate` is empty, values are measured relative to `0` . When `TimeInfo.StartDate` is defined, values represent date strings measured relative to the `StartDate`. The length of `Time` must be the same as the first or the last dimension of `Data` for each collection .

Property	Description
`TimeInfo`	Contains fields for contextual information about `Time`: • `Units` — Time units with any of the following values: `'weeks'`, `'days'`, `'hours'`, `'minutes'`, `'seconds'`, `'milliseconds'`, `'microseconds'`, `'nanoseconds'` • `Start` — Start time • `End` — End time (read only) • `Increment` — Interval between subsequent time values. `NaN` when times are not uniformly sampled. • `Length` — Length of the time vector (read only) • `Format` — String defining the date string display format. See `datestr`. • `StartDate` — Date string defining the reference date. See `setabstime (tscollection)`. • `UserData` — Any additional user-defined information

Introduced before R2006a

tsdata.event

Construct event object for `timeseries` object

Syntax

```
e = tsdata.event(Name,Time)
e = tsdata.event(Name,Time,'Datenum')
```

Description

`e = tsdata.event(Name,Time)` creates an event object with the specified Name that occurs at the time Time. Time can either be a real value or a date string.

`e = tsdata.event(Name,Time,'Datenum')` uses `'Datenum'` to indicate that the `Time` value is a serial date number generated by the `datenum` function. The `Time` value is converted to a date string after the event is created.

More About

Tips

You add events by using the `addevent` method.

Fields of the `tsdata.event` object include the following:

- `EventData` — MATLAB array that stores any user-defined information about the event
- `Name` — String that specifies the name of the event
- `Time` — Time value when this event occurs, specified as a real number
- `Units` — Time units
- `StartDate` — A reference date, specified in MATLAB `datestr` format. `StartDate` is empty when you have a numerical (non-date-string) time vector.

Introduced before R2006a

tsearchn

N-D closest simplex search

Syntax

```
t = tsearchn(X,TRI,XI)
[t,P] = tsearchn(X,TRI,XI)
```

Description

`t = tsearchn(X,TRI,XI)` returns the indices `t` of the enclosing simplex of the Delaunay triangulation `TRI` for each point in `XI`. `X` is an `m`-by-`n` matrix, representing `m` points in N-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in N-dimensional space. `tsearchn` returns `NaN` for all points outside the convex hull of `X`. `tsearchn` requires a triangulation `TRI` of the points `X` obtained from `delaunayn`.

`[t,P] = tsearchn(X,TRI,XI)` also returns the barycentric coordinate `P` of `XI` in the simplex `TRI`. `P` is a `p`-by-`n+1` matrix. Each row of `P` is the barycentric coordinate of the corresponding point in `XI`. It is useful for interpolation.

See Also

`delaunayTriangulation`

Introduced before R2006a

type

Display contents of file

Syntax

```
type('filename')
type filename
```

Description

`type('filename')` displays the contents of the specified file in the MATLAB Command Window. Use the full path for `filename`, or use a MATLAB relative partial path.

If you do not specify a file extension and there is no `filename` file without an extension, the `type` function adds the `.m` extension by default. The `type` function checks the folders specified in the MATLAB search path, which makes it convenient for listing the contents of files on the screen. Use `type` with `more on` to see the listing one screen at a time.

`type filename` is the command form of the syntax.

Examples

`type('foo.bar')` lists the contents of the file `foo.bar`.

`type foo` lists the contents of the file `foo`. If `foo` does not exist, `type foo` lists the contents of the file `foo.m`.

`cd` | `dbtype` | `delete` | `dir` | `more` | `path` | `what` | `who`

Introduced before R2006a

typecast

Convert data types without changing underlying data

Syntax

```
Y = typecast(X, type)
```

Description

`Y = typecast(X, type)` converts a numeric value in `X` to the data type specified by `type`. Input `X` must be a full, noncomplex, numeric scalar or vector. The `type` input is a string set to one of the following: `'uint8'`, `'int8'`, `'uint16'`, `'int16'`, `'uint32'`, `'int32'`, `'uint64'`, `'int64'`, `'single'`, or `'double'`.

`typecast` is different from the MATLAB `cast` function in that it does not alter the input data. `typecast` always returns the same number of bytes in the output `Y` as were in the input `X`. For example, casting the 16-bit integer 1000 to `uint8` with `typecast` returns the full 16 bits in two 8-bit segments (3 and 232) thus keeping its original value (3*256 + 232 = 1000). The `cast` function, on the other hand, truncates the input value to 255.

The output of `typecast` can be formatted differently depending on what system you use it on. Some computer systems store data starting with its most significant byte (an ordering called *big-endian*), while others start with the least significant byte (called *little-endian*).

Note MATLAB issues an error if `X` contains fewer values than are needed to make an output value.

Examples

Example 1

This example converts between data types of the same size:

```
typecast(uint8(255), 'int8')
ans =
   -1

typecast(int16(-1), 'uint16')
ans =
  65535
```

Example 2

Set X to a 1-by-3 vector of 32-bit integers, then cast it to an 8-bit integer type:

```
X = uint32([1 255 256])
X =
           1          255          256
```

Running this on a little-endian system produces the following results. Each 32-bit value is divided up into four 8-bit segments:

```
Y = typecast(X, 'uint8')
Y =
   1   0   0   0  255   0   0   0   0   1   0   0
```

The third element of `X`, 256, exceeds the 8 bits that it is being converted to in `Y`(9) and thus overflows to `Y`(10):

```
Y(9:12)
ans =
    0    1    0    0
```

Note that `length(Y)` is equal to `4.*length(X)`. Also note the difference between the output of `typecast` versus that of `cast`:

```
Z = cast(X, 'uint8')
Z =
    1  255  255
```

Example 3

This example casts a smaller data type (`uint8`) into a larger one (`uint16`). Displaying the numbers in hexadecimal format makes it easier to see just how the data is being rearranged:

```
format hex
```

```
X = uint8([44 55 66 77])
X =
   2c   37   42   4d
```

The first `typecast` is done on a big-endian system. The four 8-bit segments of the input data are combined to produce two 16-bit segments:

```
Y = typecast(X, 'uint16')
Y =
   2c37   424d
```

The second is done on a little-endian system. Note the difference in byte ordering:

```
Y = typecast(X, 'uint16')
Y =
   372c   4d42
```

You can format the little-endian output into big-endian (and vice versa) using the `swapbytes` function:

```
Y = swapbytes(typecast(X, 'uint16'))
Y =
   2c37   424d
```

Example 4

This example attempts to make a 32-bit value from a vector of three 8-bit values. MATLAB issues an error because there are an insufficient number of bytes in the input:

```
format hex
typecast(uint8([120 86 52]), 'uint32')

Error using typecast
Too few input values to make output type.
```

Repeat the example, but with a vector of four 8-bit values, and it returns the expected answer:

```
typecast(uint8([120 86 52 18]), 'uint32')
ans =
   12345678
```

See Also

`cast` | `class` | `swapbytes`

Introduced before R2006a

tzoffset

Time zone offset from UTC

Syntax

```
dt = tzoffset(t)
[dt,dst] = tzoffset(t)
```

Description

`dt = tzoffset(t)` returns an array of durations equal to the time zone offset from UTC of each datetime value in `t`. That is, `dt` is the amount of time that each datetime in `t` differs from UTC. For datetimes that occur during Daylight Saving Time (DST), `dt` includes the time shift for DST. The offset for unzoned datetime values is not defined.

`[dt,dst] = tzoffset(t)` additionally returns the time shift for Daylight Saving Time for each datetime in `t`.

Examples

Find Time Zone Offset

Create a `datetime` array in the time zone for New York City.

```
t1 = datetime('today','TimeZone','America/New_York');
t = dateshift(t1,'end','month',[1:3:9])
```

```
t =

   31-Mar-2015   30-Jun-2015   30-Sep-2015
```

Find the time zone offset from UTC and the time shift for Daylight Saving Time for each datetime value.

```
[dt,dst] = tzoffset(t)
```

```
dt =

   -4:00   -4:00   -4:00

dst =

   01:00   01:00   01:00
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

Output Arguments

`dt` — Time zone offset from UTC

scalar | vector | matrix | multidimensional array

Time zone offset from UTC, returned as a scalar, vector, matrix, or multidimensional `duration` array. `dt` is the same size as `t`.

`dst` — Time shift for Daylight Saving Time

scalar | vector | matrix | multidimensional array

Time shift for Daylight Saving Time, returned as a scalar, vector, matrix, or multidimensional `duration` array. `dt` is the same size as `t`. A value of `01:00` indicates that the corresponding datetime in `t` occurs during Daylight Saving Time in a location that observes it. For locations that do not observe Daylight Saving Time, the elements of the `dst` array are all `00:00`.

`isdst`

Introduced in R2014b

uibuttongroup

Create button group to manage radio buttons and toggle buttons

Syntax

```
b = uibuttongroup
b = uibuttongroup(Name,Value,...)
b = uibuttongroup(parent)
b = uibuttongroup(parent,Name,Value,...)
```

Description

`b = uibuttongroup` creates a uibuttongroup in an existing figure and returns the uibuttongroup object, `b`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`b = uibuttongroup(Name,Value,...)` creates a uibuttongroup and specifies one or more uibuttongroup property names and corresponding values. Use this syntax to override the default uibuttongroup properties.

`b = uibuttongroup(parent)` creates a uibuttongroup and designates a specific parent object. The `parent` argument can be a figure, uipanel, uitab, or another uibuttongroup object.

`b = uibuttongroup(parent,Name,Value,...)` creates a uibuttongroup with a specific parent and one or more uibuttongroup properties.

Uibuttongroups are containers that group UI components together and manage exclusive selection of radio buttons and toggle buttons. These are some of the important characteristics of the uibuttongroups and some recommended best practices:

- Uibuttongroups can contain any UI component type (except anActiveX control), but it only manages the selection of radio buttons and toggle buttons.
- Define a `SelectionChangedFcn` callback function for the uibuttongroup to make your program respond when the user selects a radio button or toggle button that is inside the button group. Do not define callbacks for in the individual buttons.

- Query the `SelectedObject` property of the uibuttongroup to determine which radio button or toggle button is currently selected. You can execute this query anywhere in your code that can access the uibuttongroup object.

Examples

This example creates a uibuttongroup with three radio buttons. It manages the radio buttons with the SelectionChangedFcn callback, `bselection`.

When the user selects a new radio button, the `bselection` function displays the previous and current selection.

Copy and paste this code into the Editor and run it to see how it works.

```
function myui
bg = uibuttongroup('Visible','off',...
                   'Position',[0 0 .2 1],...
                   'SelectionChangedFcn',@bselection);

% Create three radio buttons in the button group.
r1 = uicontrol(bg,'Style',...
                   'radiobutton',...
                   'String','Option 1',...
                   'Position',[10 350 100 30],...
                   'HandleVisibility','off');

r2 = uicontrol(bg,'Style','radiobutton',...
                   'String','Option 2',...
                   'Position',[10 250 100 30],...
                   'HandleVisibility','off');

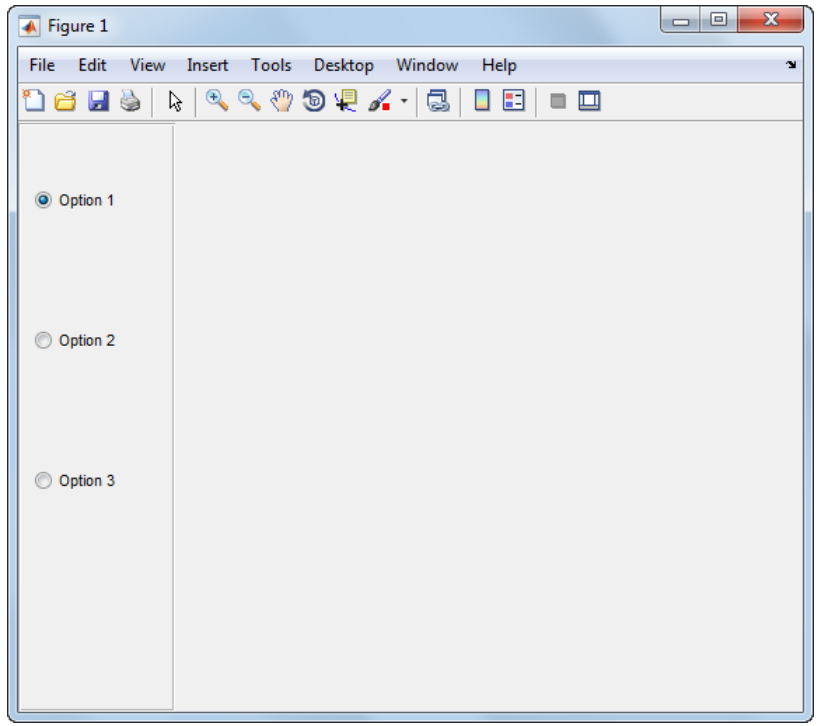
r3 = uicontrol(bg,'Style','radiobutton',...
                   'String','Option 3',...
                   'Position',[10 150 100 30],...
                   'HandleVisibility','off');

% Make the uibuttongroup visible after creating child objects.
bg.Visible = 'on';

    function bselection(source,callbackdata)
       display(['Previous: ' callbackdata.OldValue.String]);
       display(['Current: ' callbackdata.NewValue.String]);
       display('------------------');
    end
end
```

The `bselection` function displays the `OldValue` and `NewValue` properties of the `callbackdata` object. MATLAB passes the `callbackdata` object to this callback function when you specify the SelectionChangedFcn property as a function handle

(or a cell array containing a function handle). See `SelectionChangedFcn` for more information.



More About

Tips

If you set the Visible property of a `uibuttongroup` object to `'off'`, then any child objects it contains (buttons, other button groups, etc.) become invisible along with the parent uibuttongroup. However, the Visible *property value* of each child object remains unaffected.

- "Access Property Values"

Uibuttongroup Properties | `uicontrol` | `uipanel`

Introduced before R2006a

Uibuttongroup Properties

Control appearance and behavior of button group

Uibuttongroups are containers for grouping together and managing the exclusive selection of radio buttons and toggle buttons. The `uibuttongroup` function creates a button group and sets any required properties. By changing uibuttongroup property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
b = uibuttongroup;
bgcolor = b.BackgroundColor;
b.BackgroundColor = [.5 .5 .5];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uibuttongroup visibility

`'on'` (default) | `'off'`

Uibuttongroup visibility, specified as `'on'` or `'off'`. The Visible property determines whether the uibuttongroup displays on the screen. If the Visible property of a uibuttongroup is set to `'off'`, the entire uibuttongroup is invisible, but you can still specify and access its properties.

Changing the size of an invisible uibuttongroup triggers the SizeChangedFcn callback when the uibuttongroup becomes visible.

Note Changing the Visible property of a uibuttongroup does *not* change the Visible property of its child components even though hiding the uibuttongroup prevents its children from displaying.

`BackgroundColor` — Uibuttongroup background color

`[.94 .94 .94]` (default) | RGB triplet | short name | long name

Uibuttongroup background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uibuttongroup.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Note: Some operating systems override the `BackgroundColor` value.

Data Types: `double` | `char`

`ForegroundColor` — Uibuttongroup title color

`[0 0 0]` (default) | RGB triplet | short name | long name

Uibuttongroup title color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

BorderType — Border of the uibuttongroup

'etchedin' (default) | 'etchedout' | 'beveledin' | 'beveledout' | 'line' | 'none'

Border of the uibuttongroup area, specified as 'etchedin', 'none', 'etchedout', 'beveledin', 'beveledout', or 'line'.

- For a 3-D look, use etched or beveled borders.

  Use the HighlightColor and ShadowColor properties to specify the color of 3-D borders.
- For a 2-D look, use a line border.

  Use the ForegroundColor property to specify the line border color.

BorderWidth — Width of uibuttongroup border

1 (default) | positive integer value

Width of the uibuttongroup border, specified as a positive integer value. The unit of measurement is pixels. Etched and beveled borders wider than three pixels might not appear correctly at the corners.

HighlightColor — Uibuttongroup 3-D frame highlight color

RGB triplet | short name | long name

Uibuttongroup 3-D frame highlight color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

ShadowColor — Uibuttongroup border shadow color

RGB triplet | short name | long name

Uibuttongroup border shadow color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

`Clipping` — Clipping of child components to uibuttongroup

`'on'` (default) | `'off'`

Note: The behavior of the Clipping property has changed. It no longer has any effect on uibuttongroups. Child objects are now clipped to the uibuttongroup boundary regardless of the value of this property. This property might be removed in a future release.

Location and Size

`Position` — Location and size of uibuttongroup relative to parent

`[left bottom width height]`

Location and size of the uibuttongroup relative to the parent, specified as the vector, `[left bottom width height]`. This table describes each element in the vector.

Element	Description
`left`	Distance from the inner left edge of the parent container to the outer left edge of the uibuttongroup
`bottom`	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uibuttongroup
`width`	Distance between the right and left outer edges of the uibuttongroup
`height`	Distance between the top and bottom outer edges of the uibuttongroup

All measurements are in units specified by the Units property.

Note: If the parent of the uibuttongroup is a figure, then the Position values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

Example: Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the Position vector. For example, this code sets the width of the Uibuttongroup to `0.5`:

```
b = uibuttongroup;
b.Position(3) = 0.5;
b.Position

ans =

      0   0   0.5000  1.0000
```

Units — Units of measurement

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'pixels'` | `'points'` | `'characters'`

Units of measurement, specified as `'normalized'`, `'inches'`, `'centimeters'`, `'pixels'`, `'points'`, or `'characters'`.

MATLAB uses these units to interpret the location and size values of the Position property:

- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- The size of a uibuttongroup specified in pixel units depends on the system display settings and resolution.
- Characters units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

The order in which you specify the Units and Position properties has these effects:

- If you specify the Units property before the Position property, then MATLAB sets Position using the units you specified.
- If you specify the Units property after the Position property, MATLAB sets the position using the default Units. Then, MATLAB converts the Position values to the equivalent values in the units you specified.

`SizeChangedFcn` — Uibuttongroup resize callback function

`''` (default) | function handle | cell array | string

Uibuttongroup resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uibuttongroup changes.

The SizeChangedFcn callback executes under these circumstances:

- The uibuttongroup becomes visible for the first time.
- The uibuttongroup is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the uibuttongroup.
- The uibuttongroup becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the uibuttongroup is invisible, and then it becomes visible later.

These are some of the important characteristics of the SizeChangedFcn callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the uibuttongroup's SizeChangedFcn uses are defined. This practice can prevent the uibuttongroup's SizeChangedFcn callback from returning an error. To delay the display of the figure, set its Visible property to `'off'`. Then, set the Visible property to `'on'` after you define the variables that your SizeChangedFcn callback uses.
- Use the `gcbo` function in your SizeChangedFcn code to get the uibuttongroup object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcbo`.
- All visible Uibuttongroups that are specified in normalized units resize before the parent figure does. All visible, nested uibuttongroups resize from inside-out.

Tip As an easy alternative to specifying a SizeChangedFcn callback, you can set the Units property of all the objects you put inside the uibuttongroup to `'normalized'`. Doing so makes those components scale proportionally with the uibuttongroup.

See “Managing the Layout in Resizable UIs” for more information on controlling the resize behavior of programmatic UIs.

See Resize Behavior for more information on the resize behavior of GUIDE UIs.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`ResizeFcn` — Uibuttongroup resize callback function

`''` (default) | function handle | cell array | string

Callback function that executes when the uibuttongroup size changes, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Note: Use of the ResizeFcn property is not recommended. It might be removed in a future release. Use SizeChangedFcn instead.

Data Types: `function_handle | cell | char`

Font Style

`FontName` — Font for displaying uibuttongroup title

string

Font for displaying the uibuttongroup title, specified as a string. To display and print properly, the font name must refer to a font that the user’s system supports. The default font is system dependent.

To use a fixed-width font, set the FontName property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root FixedWidthFontName property, which you can set in the `startup.m` file.

See “Startup Options in MATLAB Startup File” for more information about the `startup.m` file.

Example: `'Arial'`

`FontSize` — Font size for uibuttongroup title

positive number

Font size for the uibuttongroup title, specified as a positive number. The FontUnits property specifies the units. The default size is system-dependent.

Example: `12`

Example: `12.5`

Data Types: `double`

`FontUnits` — Units of font size for uibuttongroup title

`'points'` (default) | `'inches'` | `'centimeters'` | `'normalized'` | `'pixels'`

Units of font size for the uibuttongroup title, specified as `'points'`, `'inches'`, `'centimeters'`, `'normalized'`, or `'pixels'`.

If you set this property to `'normalized'`, then MATLAB interprets the font size as a fraction of the uibuttongroup height. When you resize the uibuttongroup, MATLAB scales the displayed font to maintain that fraction.

The other FontUnits options (`pixels`, `inches`, `centimeters`, and `points`) are absolute units. 1 point = 1/72 inch.

`FontWeight` — Font weight for the uibuttongroup title

`'normal'` (default) | `'bold'`

Font weight of uibuttongroup title, specified as a value from the following table.

FontWeight Value	Description
`'normal'`	Normal font weight
`'bold'`	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the `FontWeight` property, the result might appear the same as the default.

Note: The `'light'` and `'demi'` font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

`FontAngle` — Character slant of the uibuttongroup title

`'normal'` (default) | `'italic'`

Character slant of uibuttongroup title, specified as `'normal'` or `'italic'`. MATLAB uses this property to select a font from those available on your system. Setting this property to `'italic'` selects a slanted version of the font, if it is available on your system.

Note: The `'oblique'` value has been removed. Use `'italic'` instead.

Text

`Title` — Uibuttongroup title

string

Uibuttongroup title, specified as a string.

MATLAB does not interpret a vertical slash (`'|'`) character as a line break, it displays as a vertical slash in the uibuttongroup title.

If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as `Multiples of` π.

Example: `'Options'`

Example: `['Multiples of ' char(960)]`

`TitlePosition` — Location of uibuttongroup title

`'lefttop'` (default) | `'centertop'` | `'righttop'` | `'leftbottom'` | `'centerbottom'` | `'righttbottom'`

Location of the uibuttongroup title, specified as `'lefttop'`, `'centertop'`, `'righttop'`, `'leftbottom'`, `'centerbottom'`, or `'righttbottom'`.

Interactive Control

`SelectionChangedFcn` — Callback that executes when user selects a different button

`''` (default) | function handle | cell array | string

Callback that executes when the user selects a different button, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes when the user selects a different button within the uibuttongroup.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in this table. You can access these properties inside the callback function using dot notation.

Property	Description
`OldValue`	Previously selected button, or `[]` if none was selected
`NewValue`	Currently selected button
`Source`	The parent uibuttongroup object
`EventName`	`'SelectionChanged'`

Define a uibuttongroup SelectionChangedFcn callback to make your program respond when the user selects different buttons within the uibuttongroup. Do not code the response in the individual uicontrol Callback functions.

If you want another component to respond to the selection, then that component's callback function can access the selected radio button or toggle button from the uibuttongroup's SelectedObject property.

Example: `@myfun`

Example: `{@myfun,x}`

`ButtonDownFcn` — Button-press callback function

`''` (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The ButtonDownFcn callback is a function that executes when the user clicks a mouse button on the uibuttongroup.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

`UIContextMenu` — Uibuttongroup context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu object

Uibuttongroup context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the uibuttongroup. Create the context menu using the `uicontextmenu` function.

`Selected` — Selection status of uibuttongroup

`'off'` (default) | `'on'`

Note: The behavior of the Selected property changed in R2014b, and it is not recommended. It no longer has any effect on uibuttongroups. This property might be removed in a future release.

`SelectionHighlight` — Ability to highlight selection handles

`'on'` (default) | `'off'`

Note: The behavior of the SelectionHighlight property changed in R2014b, and it is not recommended. It no longer has any effect on uibuttongroups. This property might be removed in a future release.

Callback Execution Control

`Interruptible` — Callback interruption

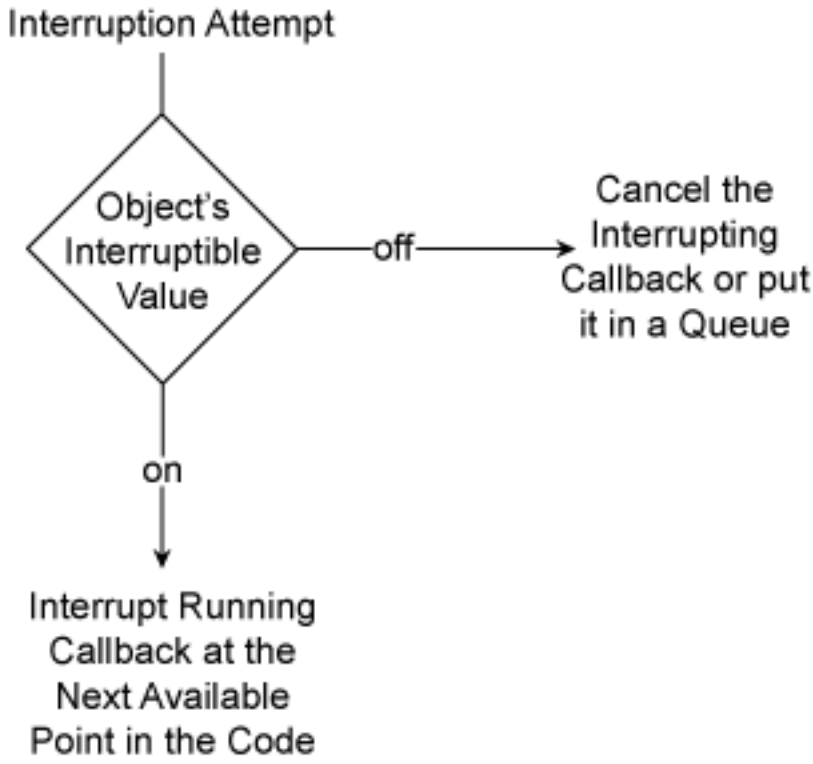
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uibuttongroup callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See "Interrupt Callback Execution" for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See "Interrupt Callback Execution" for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

Ability to become current object, specified as `'on'` or `'off'`:

- Setting the value to `'on'` allows the uibuttongroup to become the current object when the user clicks on it. A value of `'on'` also allows the figure CurrentObject property and the `gco` function to report the uibuttongroup as the current object.
- Setting the value to `'off'` sets the figure CurrentObject property to an empty `GraphicsPlaceholder` array when the user clicks on the uibuttongroup.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uibuttongroup

`'off'` (default) | `'on'`

Deletion status of uibuttongroup, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uibuttongroup begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uibuttongroup no longer exists.

Check the value of the BeingDeleted property to verify that the uibuttongroup is not about to be deleted before querying or modifying it.

`CreateFcn` — Uibuttongroup creation function

function handle | cell array | string

Uibuttongroup creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uibuttongroup. MATLAB initializes all uibuttongroup property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uibuttongroup that is being created.

Setting the CreateFcn property on an existing uibuttongroup has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uibuttongroup object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uibuttongroup deletion function

function handle | cell array | string

Uibuttongroup deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uibuttongroup (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the uibuttongroup. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uibuttongroup that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object

`'uibuttongroup'`

Type of graphics object, returned as `'uibuttongroup'`.

`Tag` — Uibuttongroup identifier

`''` (default) | string

Uibuttongroup identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uibuttongroup. When you need access to the uibuttongroup elsewhere in your code, you can use the `findobj` function to search for the uibuttongroup based on the Tag value.

Example: `'buttongroup1'`

Data Types: `char`

`UserData` — Data to associate with the uibuttongroup object

empty array (default) | array

Data to associate with the uibuttongroup object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

`SelectedObject` — Currently selected radio button or toggle button

uicontrol object | `[]`

Currently selected radio button or toggle button, specified as a uicontrol object.

Use this property to determine the currently selected button within a uibuttongroup. You can also use this property to set a default button selection. If you want no selection, then set this property to `[]`.

The default value of the SelectedObject property is the first uicontrol radio button or toggle button that you add to the uibuttongroup.

Note: The SelectionChangedFcn callback does not execute when you set the SelectedObject property programmatically..

Parent/Child

`Parent` — Uibuttongroup parent

figure | uipanel | uibuttongroup | uitab

Uibuttongroup parent, specified as a figure, uipanel, uibuttongroup, or uitab. You can move a uibuttongroup to a different figure, uipanel, uibuttongroup, or uitab by setting this property to the handle of the target figure, uipanel, uibuttongroup, or uitab.

`Children` — Children of uibuttongroup

empty `GraphicsPlaceholder` array (default) | 1-D array of component objects

Children of uibuttongroup, returned as an empty `GraphicsPlaceholder` or a 1-D array of component objects. Although a uibuttongroup manages only the user selection of radio buttons and toggle buttons, its children can be axes, uipanels, uibuttongroups, and any style of uicontrol.

You cannot add or remove children using the `Children` property of the uibuttongroup. Use this property to view the list of children or to reorder the children. The order of the

children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the uibuttongroup object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of uibuttongroup handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uibuttongroup handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uibuttongroup handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uibuttongroup handle is always visible.
`'callback'`	The uibuttongroup handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uibuttongroup at the command-line, but allows callback functions to access it.
`'off'`	The uibuttongroup handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

Note: Do not try to access radio buttons and toggle buttons that are managed by a `uibuttongroup` outside of the button group. Set the HandleVisibility of those radio buttons and toggle buttons to `'off'` to prevent accidental access.

uicontextmenu

Create context menu

A uicontextmenu is a context menu that appears when the user right-clicks on a graphics object or UI component. The `uicontextmenu` function creates a context menu and sets any required properties.

Syntax

```
c = uicontextmenu
c = uicontextmenu(Name,Value)

c = uicontextmenu(parent)
c = uicontextmenu(parent,Name,Value)
```

Description

`c = uicontextmenu` creates a uicontextmenu in the current figure and returns the uicontextmenu object as c. If no figure is available, then MATLAB creates a new figure to serve as the parent.

`c = uicontextmenu(Name,Value)` specifies one or more uicontextmenu property names and corresponding values. Use this syntax to override the default uicontextmenu property values.

`c = uicontextmenu(parent)` creates a uicontextmenu and specifies the parent figure.

`c = uicontextmenu(parent,Name,Value)` specifies a parent figure and one or more uicontextmenu properties.

Examples

Context Menu Attached to a Plot Line

Specify a value for the line object's UIContextMenu property to attach a uicontextmenu to that line. The context menu becomes visible when the user right-clicks on the line. For

instance, create a program file called `myprogram.m` that creates a plot and attaches a uicontextmenu to the plot line:

```
function myprogram

    f = figure('WindowStyle','normal');
    ax = axes;
    x = 0:100;
    y = x.^2;

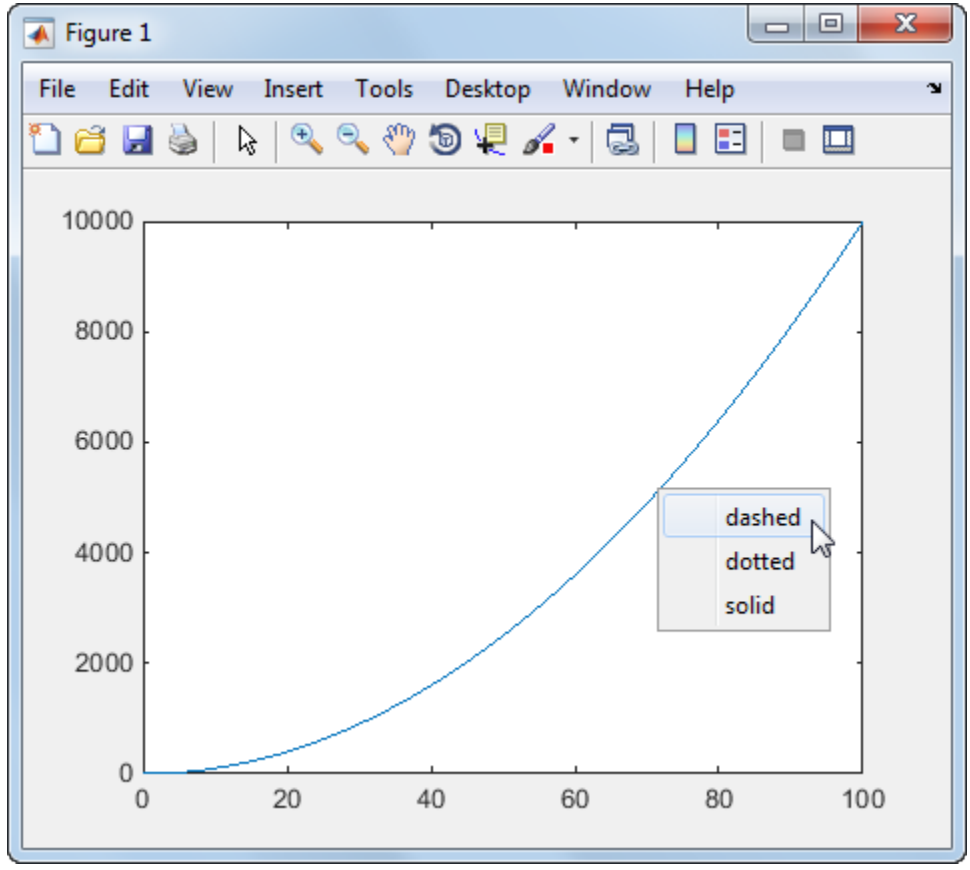
    plotline = plot(x,y);
    c = uicontextmenu;

    % Set c to be the plot line's UIContextMenu
    plotline.UIContextMenu = c;

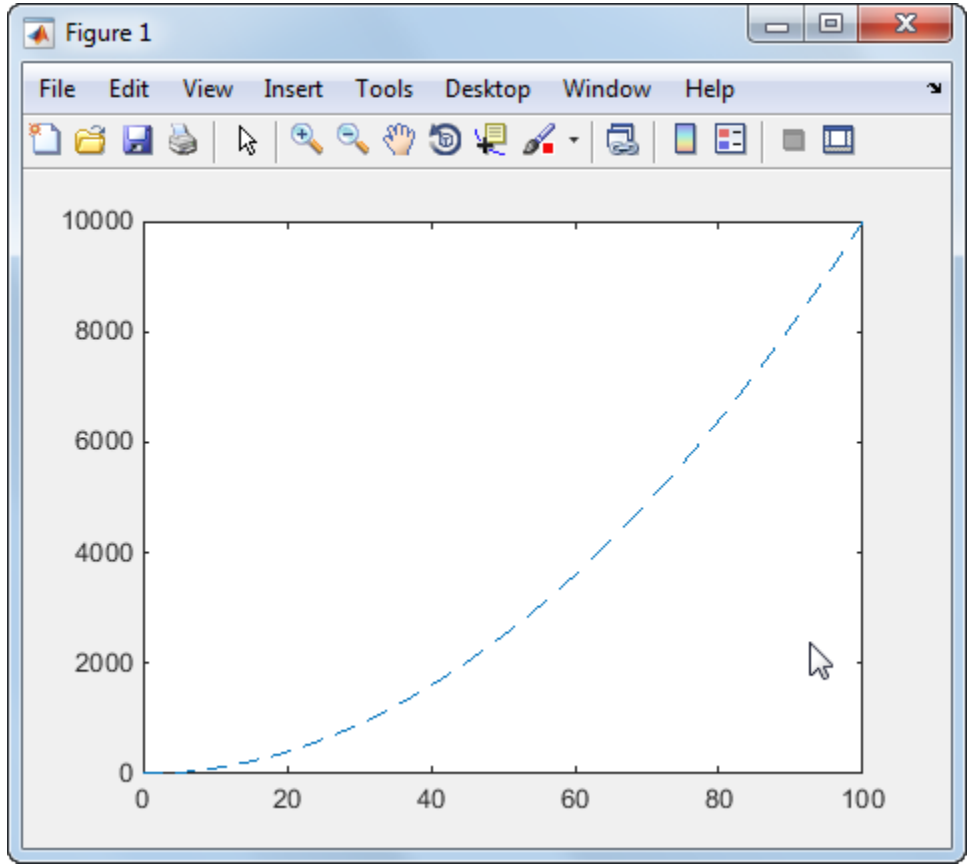
    % Create menu items for the uicontextmenu
    m1 = uimenu(c,'Label','dashed','Callback',@setlinestyle);
    m2 = uimenu(c,'Label','dotted','Callback',@setlinestyle);
    m3 = uimenu(c,'Label','solid','Callback',@setlinestyle);

        function setlinestyle(source,callbackdata)
            switch source.Label
                case 'dashed'
                    plotline.LineStyle = '--';
                case 'dotted'
                    plotline.LineStyle = ':';
                case 'solid'
                    plotline.LineStyle = '-';
            end
        end
end
```

The context menu appears when the user right-clicks the plot line.



Selecting an item from the context menu changes the line style.



Context Menu with Submenus

Specify the Parent property value of any uimenu to make it into a submenu. For instance, create a program file called `myprogram2` that creates a uicontextmenu containing one top-level menu and two submenu items:

```
function myprogram2
    f = figure('WindowStyle','normal');
    c = uicontextmenu(f);

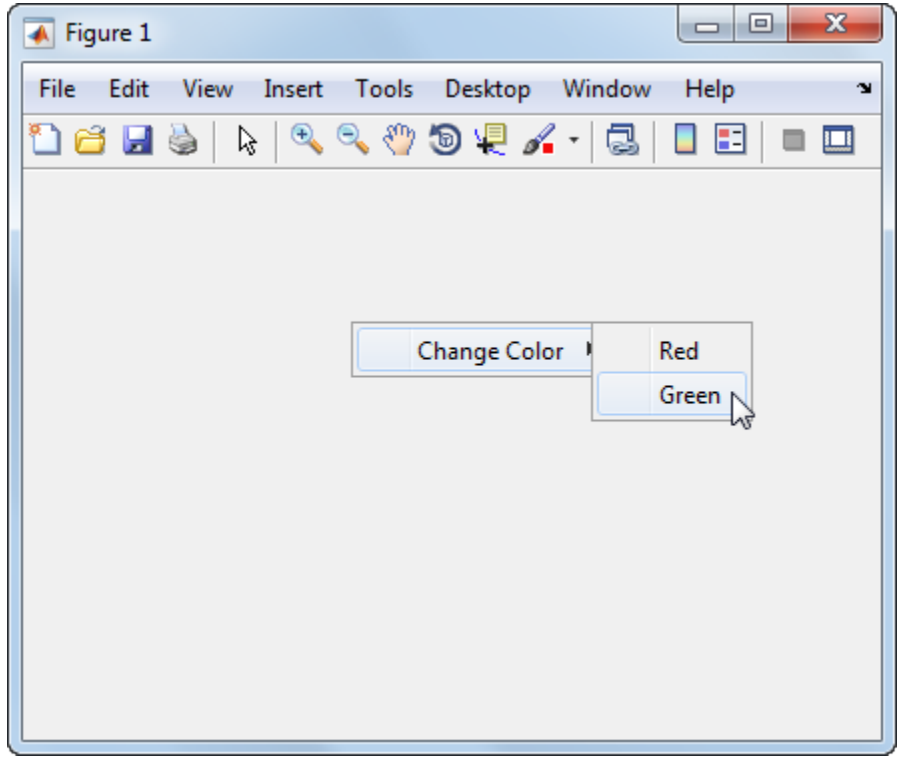
    % Assign the uicontextmenu to the figure
    f.UIContextMenu = c;
```

```
    % Create top-level menu item
    topmenu = uimenu('Parent',c,'Label','Change Color');

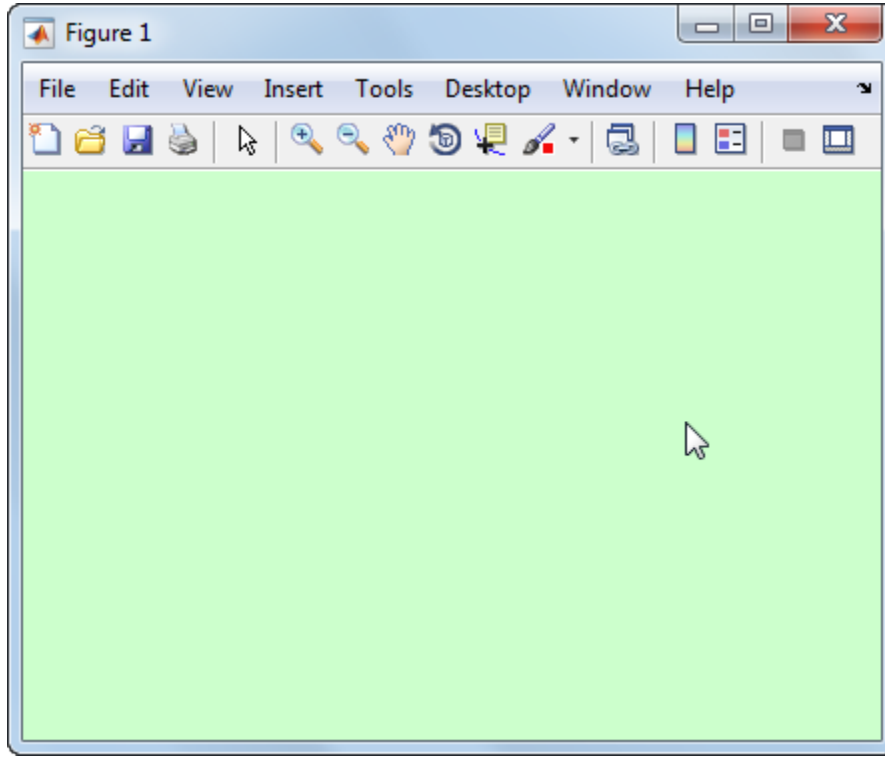
    % Create submenu items
    m1 = uimenu('Parent',topmenu,'Label','Red','Callback',@changecolor);
    m2 = uimenu('Parent',topmenu,'Label','Green','Callback',@changecolor);

    function changecolor(source,callbackdata)
        switch source.Label
            case 'Red'
                f.Color = [1.0 0.80 0.80];
            case 'Green'
                f.Color = [0.80 1.0 0.80];
        end
    end
end
```

The resulting context menu appears when the user right-clicks the mouse inside the figure.



Selecting a color from the context menu changes the color of the window.



Input Arguments

`parent` — Parent figure

figure

Parent figure, specified as a figure object.

Name-Value Pair Arguments

The properties listed here are only a subset, for a complete list see Uicontextmenu Properties.

Example: `'Callback',@myfunction` specifies `myfunction` to be the function that executes when the user interacts with the context menu.

`'Callback'` — Callback function that executes when user selects the uicontextmenu

`''` (default) | function handle | cell array | string

Callback function that executes when user selects the uicontextmenu, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

`'Children'` — Children of uicontextmenu

empty `GraphicsPlaceholder` array (default) | 1-D array of uimenu objects

Children of uicontextmenu, returned as an empty `GraphicsPlaceholder` or a 1-D array of uimenu objects. The children of uicontextmenus are other uimenus that function as submenus.

You cannot add or remove children using the `Children` property of the uicontextmenu. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the displayed menu items.

To add a child to this list, set the `Parent` property of the child component to be the uicontextmenu object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

More About

Tips

The context menu becomes accessible in the UI when both of these requirements are met:

- You create at least one uimenu and set its parent to be the uicontextmenu. Here is an example:

  ```
  c = uicontextmenu;
  m = uimenu('Parent',c,'Label','Disable');
  ```

- You assign the uicontextmenu to be another component's UIContextMenu property value. Here is an example:

  ```
  c = uicontextmenu;
  b = uicontrol('UIContextMenu',c);
  ```

  `b` must be a descendant of the same figure as `c`.

`uibuttongroup` | Uicontextmenu Properties | `uicontrol` | `uimenu` | `uipanel`

Introduced before R2006a

Uicontextmenu Properties

Control appearance and behavior of context menu

A uicontextmenu is a context menu that appears when the user right-clicks on a graphics object or UI component. The `uicontextmenu` function creates a context menu and sets any required properties. By changing uicontextmenu property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
c = uicontextmenu;
pos = c.Position;
c.Position = [20 20];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uicontextmenu visibility

`'off'` (default) | `'on'`

Uicontextmenu visibility, specified as `'on'` or `'off'`. You can use the Visible property in one of two ways:

- Query the value to find out if the context menu is currently posted. The context menu is posted while the Visible property value is set to `'on'`.
- Set the Visible property to `'on'` to make the context menu to appear. Set this property to `'off'` to make the context menu to disappear.

Location and Size

`Position` — Uicontextmenu location

`[left bottom]`

Uicontextmenu location, specified as the vector, `[left bottom]`. This table describes each element in the vector.

Element	Description
`left`	Distance from the inner left edge of the figure to the left edge of the uicontextmenu
`bottom`	Distance from the inner bottom edge of the figure to the top edge of the uicontextmenu

The Position property defines the location of a context menu when its Visible property is set to `'on'`.

Data Types: `double`

Interactive Control

`Callback` — Callback function that executes when user selects the uicontextmenu

`''` (default) | function handle | cell array | string

Callback function that executes when user selects the uicontextmenu, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Callback Execution Control

`Interruptible` — Callback interruption

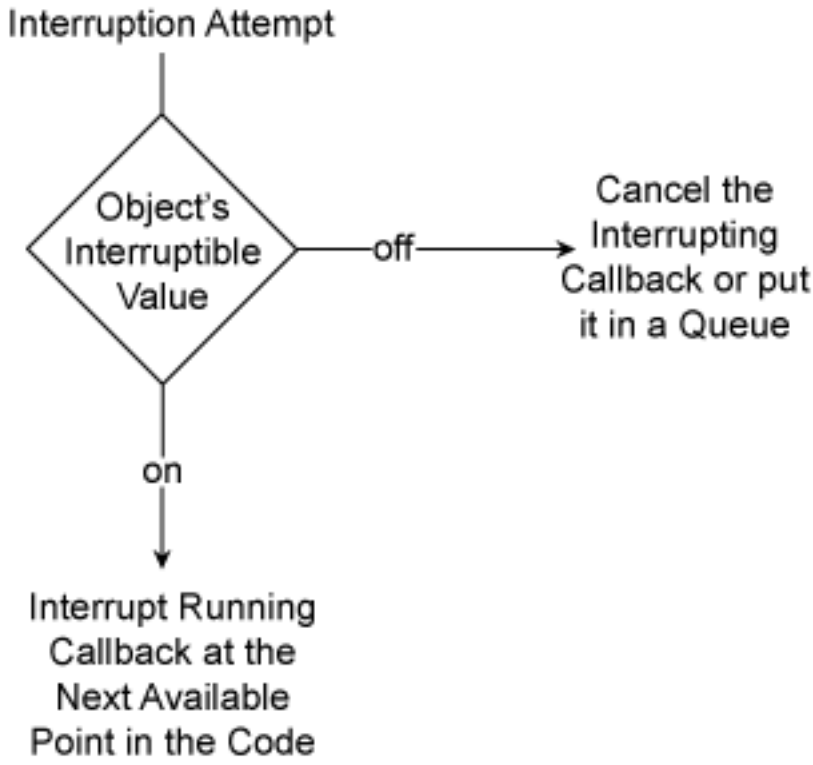
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uicontextmenu callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See “Interrupt Callback Execution” for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uicontextmenu

`'off'` (default) | `'on'`

Deletion status of uicontextmenu, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uicontextmenu begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uicontextmenu no longer exists.

Check the value of the BeingDeleted property to verify that the uicontextmenu is not about to be deleted before querying or modifying it.

`CreateFcn` — Uicontextmenu creation function

function handle | cell array | string

Uicontextmenu creation function, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uicontextmenu. MATLAB initializes all uicontextmenu property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uicontextmenu that is being created.

Setting the CreateFcn property on an existing uicontextmenu has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uicontextmenu object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uicontextmenu deletion function

function handle | cell array | string

Uicontextmenu deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uicontextmenu (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the uicontextmenu. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uicontextmenu that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object

`'uicontextmenu'`

Type of graphics object, returned as `'uicontextmenu'`.

`Tag` — Uicontextmenu identifier

`''` (default) | string

Uicontextmenu identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uicontextmenu. When you need access to the uicontextmenu elsewhere in your code, you can use the `findobj` function to search for the uicontextmenu based on the Tag value.

Example: `'contextmenu1'`

Data Types: `char`

`UserData` — Data to associate with the uicontextmenu object

empty array (default) | array

Data to associate with the uicontextmenu object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uicontextmenu parent

figure

Uicontextmenu parent, specified as a figure. You can move a uicontextmenu to a different figure by setting this property to the handle of the target figure.

`Children` — Children of uicontextmenu

empty `GraphicsPlaceholder` array (default) | 1-D array of uimenu objects

Children of uicontextmenu, returned as an empty `GraphicsPlaceholder` or a 1-D array of uimenu objects. The children of uicontextmenus are other uimenus that function as submenus.

You cannot add or remove children using the `Children` property of the uicontextmenu. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the displayed menu items.

To add a child to this list, set the `Parent` property of the child component to be the uicontextmenu object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of Uicontextmenu handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uicontextmenu handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uicontextmenu handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's

handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uicontextmenu handle is always visible.
`'callback'`	The uicontextmenu handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uicontextmenu at the command-line, but allows callback functions to access it.
`'off'`	The uicontextmenu handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

uicontrol

Create user interface control object

Syntax

```
c = uicontrol
c = uicontrol(Name,Value,...)
c = uicontrol(parent)
c = uicontrol(parent,Name,Value,...)
uicontrol(c)
```

Description

`c = uicontrol` creates a uicontrol (push button) in the current figure and returns the uicontrol object, `c`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`c = uicontrol(Name,Value,...)` creates a uicontrol and specifies one or more uicontrol property names and corresponding values. Use this syntax to override the default uicontrol properties. The default uicontrol style is `'pushbutton'`.

`c = uicontrol(parent)` creates a uicontrol and designates a specific parent object. The `parent` argument can be a figure, uipanel, uibuttongroup, or uitab object.

`c = uicontrol(parent,Name,Value,...)` creates a uicontrol with a specific parent and one or more uicontrol properties.

`uicontrol(c)` gives focus to a specific uicontrol object, `c`.

Specifying the Uicontrol Style

When selected, most uicontrol objects perform a predefined action. To create a specific type of uicontrol, set the `Style` property as one of the strings that follow. You can specify a partial string if it is unique among all the styles. For example, instead of `'radiobutton'`, you can specify `'radio'`.

- `'checkbox'` – A check box generates an action when you select it. Use check boxes to provide a number of independent choices. To activate a check box, click the mouse button on the object. The check box updates its appearance when its state changes.
- `'edit'` – Editable text fields enable you to enter or modify text values. Use editable text when you want free text as input. To enable multiple lines of text, set `Max-Min>1`. Multiline edit boxes provide a vertical scroll bar for scrolling. The arrow keys also provide a way to scroll. Obtain the current text by getting the `String` property. The `String` property does not update as you type in an edit box. To execute the callback routine for an edit text control, type in the desired text and then do one of the following:
  - Click another component, the menu bar, or elsewhere on the window.
  - For a single line editable text box, press **Enter**.
  - For a multiline editable text box, press **Ctl+Enter**.
- `'frame'`

  Note MathWorks recommends you use `uipanel` or `uibuttongroup` instead of frames.

  GUIDE continues to support frames in UIs that contain them, but the frame component does not appear in the GUIDE Layout Editor component palette.
- `'listbox'` – List boxes display a list of items, from which you can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked. The `Min` and `Max` properties control the selection mode:
  - To enable multiple selection of items, set `Max-Min > 1`.
  - To enable selection of only one item at a time, set `Max-Min <= 1`

  The `Value` property stores the row indexes of currently selected list box items, and is a vector value when you select multiple items. After any mouse button up event that changes the `Value` property, MATLAB evaluates the list box's callback routine. To delay action when multiple items can be selected, you can associate a "Done" push button with the list box. Use the callback for that button to evaluate the list box `Value` property.

  List boxes with the `Enable` property set to `on` differentiate between single and double left clicks. MATLAB sets the figure `SelectionType` property to `normal` or `open` accordingly before evaluating the list box `Callback` property. For enabled list boxes,

Ctrl-left click and **Shift**-left click also set the figure `SelectionType` property to `normal` or `open`, respectively indicating a single or double click.

- `'popupmenu'` – Pop-up menus (also known as drop-down menus) display a list of choices when you open them with a button-press. When closed, a pop-up menu indicates the current choice. Pop-up menus are useful when you want to provide a number of mutually exclusive choices, but do not want to take up the amount of space that a group of radio buttons requires.
- `'pushbutton'` – Push buttons generate an action when activated. Left-click a push button to activate it. The button appears to depress until you release the mouse button. The callback activates when you release the mouse button while still pointing within the push button.
- `'radiobutton'` – Radio buttons are similar to check boxes, but are intended to be mutually exclusive within a group of related radio buttons. When used this way, you can only select one radio button at any given time). To activate a radio button, click and release the mouse button over it. The easiest way to implement mutually exclusive behavior for a set of radio buttons is to place them within a `uibuttongroup`.
- `'slider'` – Sliders accept numeric input within a specific range when you move the "thumb" button along a bar. The location of the thumb indicates a numeric value, assigned to the `Value` property when you release the mouse button. You can set the minimum, maximum, and current values, and step sizes of a slider.

  Move the thumb by doing any one of the following:

  - Press the mouse button on the thumb, and drag it along the bar.
  - Click in the bar or on arrow buttons located at both ends of the bar.
  - Click the keyboard arrow keys when the slider is in focus.
- `'text'` – Static text boxes display lines of text. You typically use static text to label other controls, provide information to the user, or indicate values associated with a slider. If you assign the Callback property of a static text object to a function (or a string of commands), the static text will not respond when users try to interact with the text. However, you can code the `ButtonDownFcn` callback to respond to mouse clicks on the static text. See "Tips" on page 1-8439 for more information.
- `'togglebutton'` – Toggle buttons are similar in appearance to push buttons, but they visually indicate their state, either `'on'` (depressed) or `'off'` (up). Clicking a toggle button changes its state, and switches its `Value` property between the toggle button's `Min` and `Max` values.

Examples

Create uicontrols to allow users to adjust the appearance of a plot. For instance, create a program file called `myui.m` that contains the following code.

```
function myui
   % Create a figure and axes
   f = figure('Visible','off');
   ax = axes('Units','pixels');
   surf(peaks)

   % Create pop-up menu
   popup = uicontrol('Style', 'popup',...
          'String', {'parula','jet','hsv','hot','cool','gray'},...
          'Position', [20 340 100 50],...
          'Callback', @setmap);

  % Create push button
   btn = uicontrol('Style', 'pushbutton', 'String', 'Clear',...
       'Position', [20 20 50 20],...
       'Callback', 'cla');

  % Create slider
   sld = uicontrol('Style', 'slider',...
       'Min',1,'Max',50,'Value',41,...
       'Position', [400 20 120 20],...
       'Callback', @surfzlim);

   % Add a text uicontrol to label the slider.
   txt = uicontrol('Style','text',...
       'Position',[400 45 120 20],...
       'String','Vertical Exaggeration');

   % Make figure visble after adding all components
   f.Visible = 'on';
   % This code uses dot notation to set properties.
   % Dot notation runs in R2014b and later.
   % For R2014a and earlier: set(f,'Visible','on');

   function setmap(source,callbackdata)
       val = source.Value;
       maps = source.String;
       % For R2014a and earlier:
       % val = get(source,'Value');
```

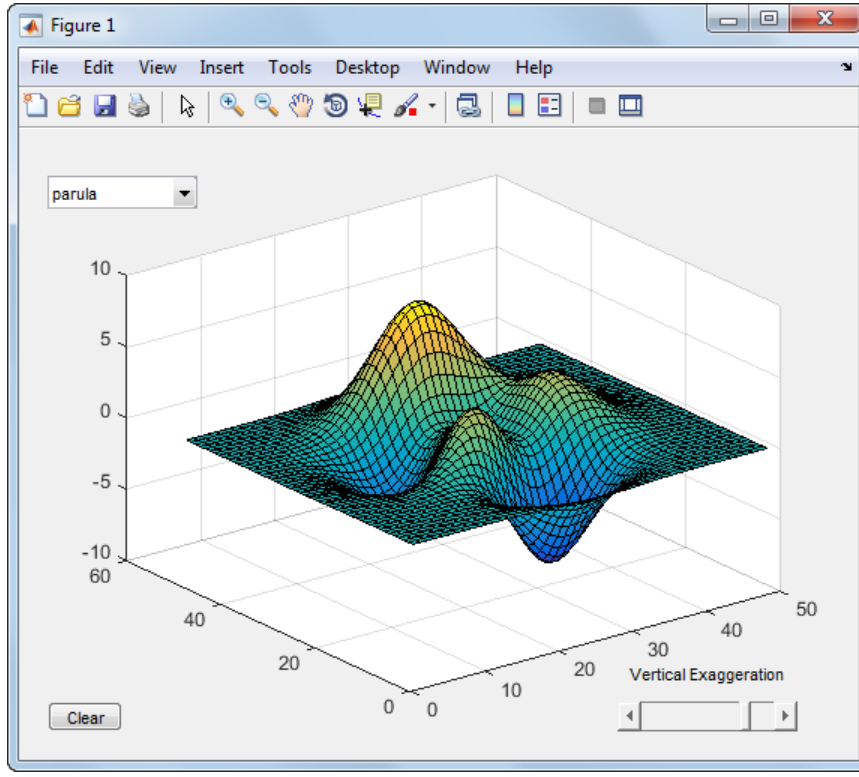
```
        % maps = get(source,'String');

        newmap = maps{val};
        colormap(newmap);
    end

    function surfzlim(source,callbackdata)
        val = 51 - source.Value;
        % For R2014a and earlier:
        % val = 51 - get(source,'Value');

        zlim(ax,[-val val]);
    end
end
```

The resulting UI displays a plot. Users can adjust the color map, change the vertical scaling, or clear the axes.



More About

Tips

- To make static text respond to mouse clicks, set the text object's `Enable` property to `'Inactive'`. Then, define a `ButtonDownFcn` callback that responds when the user clicks on the text. For example, the following code displays `'Text was clicked'` in the Command Window when the user clicks on the text in the UI.

  ```
  mytxt = uicontrol('Style','text','String','Click Me!');
  mytxt.Enable = 'Inactive';
  mytxt.ButtonDownFcn = 'disp(''Text was clicked'')';
  ```

  Note that this code uses dot notation to set properties. Dot notation runs in R2014b and later. If you are using an earlier release, use the `set` function instead.

`figure` | `uibuttongroup` | Uicontrol Properties

Introduced before R2006a

Uicontrol Properties

Control appearance and behavior of user interface control

Uicontrols are interface components, such as buttons and sliders, that users can interact with. The `uicontrol` function creates an interface component and sets any required properties before displaying it. By changing uicontrol property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
b = uicontrol('Style','pushbutton');
pos = b.Position;
b.Position = [100 100 50 20];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uicontrol visibility

`'on'` (default) | `'off'`

Uicontrol visibility, specified as `'on'` or `'off'`. When Visible is `'off'`, the uicontrol is not visible, but you can query and set its properties.

To make your program start faster, set the Visible property of all uicontrols that are not initially displayed to `'off'`.

`BackgroundColor` — Uicontrol background color

`[.94 .94 .94]` (default) | RGB triplet | short name | long name

Uicontrol background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uicontrol.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Note: Some operating systems override the `BackgroundColor` value.

Data Types: `double` | `char`

`ForegroundColor` — Uicontrol text color

`[0 0 0]` (default) | RGB triplet | short name | long name

Uicontrol text color, specified as an RGB triplet, short name, or long name from the table below.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]

Long Name	Short Name	RGB Triplet
'black	'k'	[0 0 0]

Note: If you change the value of `ForegroundColor` for a listbox, then MATLAB uses that color for all listbox items, except for the currently selected listbox item. For selected items, MATLAB uses a color that ensures good contrast between the text of selected items and the selection color.

Example: `[0 0 1]`

Example: `'b'`

Example: `'blue'`

Data Types: `double | char`

`CData` — Optional image to display on uicontrol

3-D array of truecolor RGB values

Optional image to display on the uicontrol, specified as a 3-D array of truecolor RGB values. The values in the array can be:

- Double-precision values between `0.0` and `1.0`
- `uint8` values between `0` and `255`

Push buttons and toggle buttons are the only uicontrols that fully support CData. If you specify the CData property for a radio button or check box, the image might overlap with the text string. Also, specifying an image for radio button or check box disables the ability to show when they are selected or deselected.

Example: `zeros(16,16,3)`

Example: `uint8(zeros(16,16,3))`

Data Types: `double | uint8`

Location and Size

`Position` — Location and size of uicontrol

`[left bottom width height]`

Location and size of the uicontrol relative to the parent, specified as the vector, `[left bottom width height]`. This table describes each element in the vector.

Element	Description
`left`	Distance from the inner left edge of the parent container to the outer left edge of the uicontrol
`bottom`	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uicontrol
`width`	Distance between the right and left outer edges of the uicontrol
`height`	Distance between the top and bottom outer edges of the uicontrol

All measurements are in units specified by the Units property.

Note: If the parent of the uicontrol is a figure, then the Position values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the Position vector. For example, this code changes the width of the uicontrol to `52`:

```
b = uicontrol;
b.Position(3) = 52;
b.Position
```

```
ans =

    20    20    52    20
```

Data Types: `double`

`Units` — Units of measurement

`'pixels'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'points'` | `'characters'`

Units of measurement, specified as `'pixels'`, `'normalized'`, `'inches'`, `'centimeters'`, `'points'`, or `'characters'`.

MATLAB uses these units to interpret the location and size values of the Position property:

- The size of a uicontrol specified in pixel units depends on the system display settings and resolution.
- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- Character units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

The order in which you specify the Units and Position properties has these effects:

- If you specify the Units before the Position property, then MATLAB sets Position using the units you specify.
- If you specify the Units property after the Position property, MATLAB sets the position using the default Units. Then, MATLAB converts the Position value to the equivalent value in units you specify.

`Extent` — Size of uicontrol rectangle

four-element row vector

Size of uicontrol rectangle, returned as a four-element row vector. The first two elements of the vector are always zero. The third and fourth elements are the width and height of the rectangle containing the uicontrol, respectively. All measurements are in units specified by the Units property.

MATLAB determines the size of the rectangle based on the size of the String property value and the font characteristics. To adjust the width and height of the uicontrol to accommodate the size of the String value, set the Position width and height values to be slightly larger than the Extent width and height values.

For single line strings, the height element of the Extent property indicates the height of a single line. The width element indicates the width of the longest line, even if the

string wraps when displayed on the control. For multiline strings, the Extent rectangle encompasses all lines of text. Editable text fields are considered multiline if Max – Min > 1.

When the uicontrol Units property is `'normalized'`, the Extent values are measured relative to the figure, regardless of whether the uicontrol is contained in (parented to) a uipanel.

Font Style

`FontName` — Font for displaying uicontrol text

`'Helvetica'` (default) | string

Font for displaying the uicontrol text, specified as a string. This property specifies the name of the font to use to display the text specified in the uicontrol 'String' property.

To use a fixed-width font, set the FontName property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root FixedWidthFontName property, which you can set in the `startup.m` file.

Ror more information about the `startup.m` file, see"Startup Options in MATLAB Startup File".

Example: `'Arial'`

`FontSize` — Font size for uicontrol text

positive number

Font size for the uicontrol text, specified as a positive number. The FontUnits property specifies the units. The default size is system-dependent.

Example: `12`

Example: `12.5`

Data Types: `double`

`FontUnits` — Units of font size for uicontrol text

`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Units of font size for the uicontrol text, specified as `'points'`, `'normalized'`, `'inches'`, `'centimeters'`, or `'pixels'`.

If you set this property to `'normalized'`, then MATLAB interprets the font size as a fraction of the uicontrol height. When you resize the uicontrol, MATLAB scales the displayed font to maintain that fraction.

The other FontUnits options (`pixels`, `inches`, `centimeters`, and `points`) are absolute units. 1 point = 1/72 inch.

`FontWeight` — Font weight for uicontrol text

`'normal'` (default) | `'bold'`

Font weight for the uicontrol text, specified as a value from the table below.

FontWeight Value	Description
`'normal'`	Normal font weight
`'bold'`	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the `FontWeight` property, the result might appear the same as the default.

Note: The `'light'` and `'demi'` font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

`FontAngle` — Character slant of uicontrol text

`'normal'` (default) | `'italic'`

Character slant of uicontrol text, specified as `'normal'` or `'italic'`. MATLAB uses this property to select a font from those available on your system. Setting this property to `'italic'` selects a slanted version of the font, if it is available on your system.

Note: The `'oblique'` value has been removed. Use `'italic'` instead.

Text

`String` — Text to display

string | cell array of `char` values | pipe-delimited row vector | padded column matrix

Text to display, specified as a string, cell array, a pipe-delimited row vector, or a padded column matrix. The uicontrol `Style` property value determines the array format you can use.

Style Property Value	Supported Array Formats	Examples
`'checkbox'`	• String • Cell array of char values	`'Item 1'` `{'Item 1'}`
`'edit'`	• String • Cell array of char values	`'Default text'` `{'Default text'}`
`'pushbutton'`	• String • Cell array of char values	`'Evaluate'` `{'Evaluate'}`
`'radiobutton'`	• String • Cell array of char values	`'Round to nearest integer'` `{'Round to nearest integer'}`
`'text'`	• String • Cell array of char values	`'Enter values'` `{'Enter values'}`
`'togglebutton'`	• String • Cell array of char values	`'Activate'` `{'Activate'}`

`'listbox'`	• String
	• Cell array of char values
	• Pipe-delimited row vector
	• Padded column matrix
		`'Red'`
		`{'Red','Blue','Orange'}`
		`'Red|Blue|Orange'`
		`['Red   ';'Blue  ';'Orange']`

`'popupmenu'`	• String	`'Red'`
		`{'Red','Blue','Orange'}`
		`'Red|Blue|Orange'`

Style Property Value	Supported Array Formats	Examples
	• Cell array of char values • Pipe-delimited row vector • Padded column matrix	`['Red   ';'Blue  ';'Orange']`

Note: Some important characteristics of the String property:

- If you specify a cell array for a check box, push button, radio button, or toggle button, then MATLAB displays only the first element in the cell array.
- If you programmatically replace the string of an `'edit'` style of uicontrol, the cursor moves to the beginning of the text.
- If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as Multiples of π.

Data Types: `char`

`HorizontalAlignment` — Alignment of uicontrol text

`'center'` (default) | `'left'` | `'right'`

Alignment of the uicontrol text, specified as `'center'`, `'left'`, or `'right'`. This property determines the justification of the String property text.

Interactive Control

`Callback` — Callback function that executes when user interacts with uicontrol

`''` (default) | function handle | cell array | string

Uicontrol action, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This is a function that makes the uicontrol respond to user inputs, such as push button clicks, slider movements, or check box selections.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`ButtonDownFcn` — Button-press callback function

`''` (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The ButtonDownFcn callback is a function that executes when the user clicks a mouse button on the uicontrol. The callback executes in the following situations:

- The user right-clicks the uicontrol, and the uicontrol Enable property is set to `'on'`.
- The end user right-clicks or left-clicks the Uicontrol, and the uicontrol Enable property is set to `'off'` or `'inactive'`.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

KeyPressFcn — Key press callback function

'' (default) | function handle | cell array | string

Key press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes when the uicontrol object has focus and the user presses a key. If you do not define a function for this property, MATLAB passes key presses to the parent figure. Repeated key presses retain the focus of the uicontrol, and the function executes with each key press. If the user presses multiple keys at approximately the same time, MATLAB detects the key press for the last key pressed.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
Character	The character that displays as a result of pressing a key or keys. The character can be empty or unprintable.	'a'	'='	''	'A'
Modifier	A cell array containing the names of one or more modifier keys that are being pressed (such as, **Ctrl**, **Alt**, **Shift**).	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.	'a'	'equal'	'shift'	'a'

Property	Description	Examples:			
		a	=	Shift	Shift-a
`Source`	The object that has focus when the user presses the key.	uicontrol object	uicontrol object	uicontrol object	uicontrol object
`EventName`	The action that caused the callback function to execute.	`'KeyPre`	`'KeyPre`	`'KeyPress`	`'KeyPress'`

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the `Character` property, but do not change the `Key` property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the `Character` property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate `Character` property data.

You also can query the CurrentCharacter property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`KeyReleaseFcn` — Key-release callback function

`''` (default) | function handle | cell array | string

Key-release callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the uicontrol object has focus and the user releases a key.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
`Character`	Character interpretation of the key that was released.	`'a'`	`'='`	`''`	`'A'`
`Modifier`	Current modifier, such as `'control'`. This value is always an empty cell array for aseFcn callbacks.	`{1x0 cell}`	`{1x0 cell}`	`{1x0 cell}`	`{1x0 cell}`
`Key`	Name of the key that was released, identified by the lowercase label on the key, or a descriptive string.	`'a'`	`'equal'`	`'shift'`	`'a'`
`Source`	The object that has focus when the user presses the key.	uicontrol object	uicontrol object	uicontrol object	uicontrol object
`EventName`	The action that caused the callback function to execute.	`'ase'`	`'ase'`	`'ase'`	`'ase'`

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the `Character` property, but do not change the `Key` property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the `Character` property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate `Character` property data.

You also can query the CurrentCharacter property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`Enable` — Operational state of uicontrol

`'on'` (default) | `'off'` | `'inactive'`

Operational state of the uicontrol, specified as `'on'`, `'off'`, or `'inactive'`. The `Enable` property controls whether the uicontrol responds to button clicks. These are the possible values:

- `'on'` – The uicontrol is operational.
- `'off'` – The uicontrol is not operational and appears grayed-out.
- `'inactive'` – The uicontrol is not operational, but it has the same appearance as when `Enable` is set to `'on'`.

The value of the `Enable` property and the type of button click determine the response.

Enable Value	Response to Left-Click	Response to Right-Click
`'on'`	The uicontrol's `Callback` function executes.	**1** The figure's `WindowButtonDownFcn` callback executes. **2** The uicontrol's `ButtonDownFcn` callback executes.
`'off'` or `'inactive'`	**1** The figure's `WindowButtonDownFcn` callback executes. **2** The uicontrol's `ButtonDownFcn` callback executes.	**1** The figure's `WindowButtonDownFcn` callback executes. **2** The uicontrol's `ButtonDownFcn` callback executes.

`TooltipString` — Tooltip text

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the uicontrol and leaves it there, the tooltip displays. If you want to create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the TooltipString to that string.

Specify TooltipString Containing Two Lines

```
b = uicontrol;
s = sprintf('Tooltip line 1\nTooltip line 2');
b.TooltipString = s;
```

`UIContextMenu` — Uicontrol context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu object

Uicontrol context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the uicontrol. Create the context menu using the `uicontextmenu` function.

`Selected` — Selection status of uicontrol

`'off'` (default) | `'on'`

Note: The behavior of the Selected property changed in R2014b, and it is not recommended. It no longer has any effect on uicontrols. This property might be removed in a future release.

`SelectionHighlight` — Ability to highlight selection handles

`'on'` (default) | `'off'`

Note: The behavior of the SelectionHighlight property changed in R2014b, and it is not recommended. It no longer has any effect on uicontrols. This property might be removed in a future release.

Callback Execution Control

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

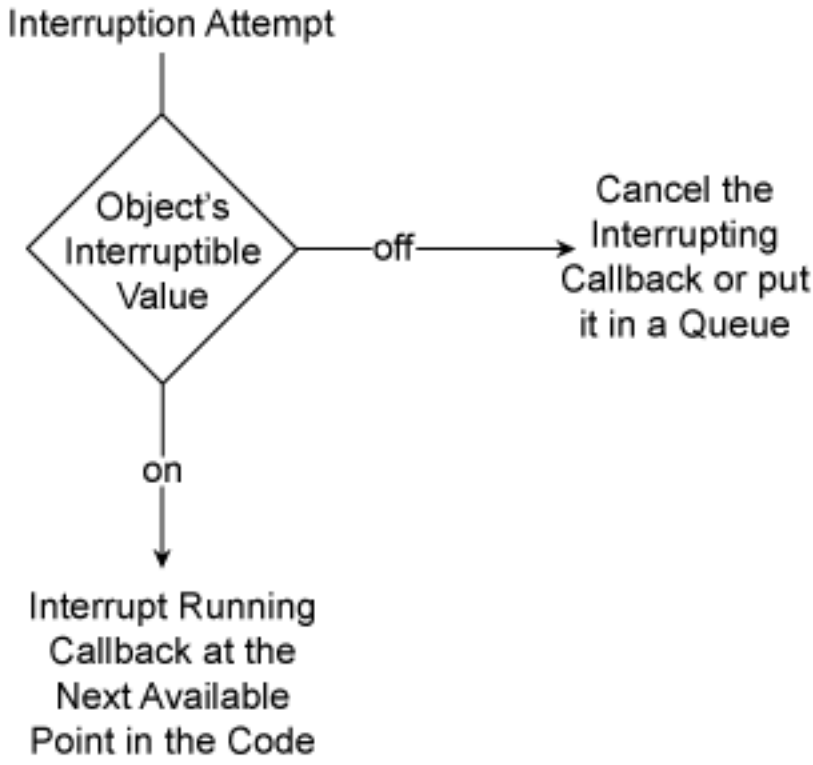
Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction

property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uicontrol callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback.

MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.

- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See "Interrupt Callback Execution" for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

This property has no effect on the uicontrol.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uicontrol

`'off'` (default) | `'on'`

Deletion status of uicontrol, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uicontrol begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uicontrol no longer exists.

Check the value of the BeingDeleted property to verify that the uicontrol is not about to be deleted before querying or modifying it.

`CreateFcn` — Uicontrol creation function

function handle | cell array | string

Uicontrol creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uicontrol. MATLAB initializes all uicontrol property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uicontrol that is being created.

Setting the CreateFcn property on an existing uicontrol has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uicontrol object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uicontrol deletion function

function handle | cell array | string

Uicontrol deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uicontrol (for example, when the end user deletes the figure). MATLAB executes the

DeleteFcn callback before destroying the properties of the uicontrol. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uicontrol that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object
`'uicontrol'`

Type of graphics object, returned as `'uicontrol'`.

`Tag` — Uicontrol identifier
`''` (default) | string

Uicontrol identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uicontrol. When you need access to the uicontrol elsewhere in your code, you can use the `findobj` function to search for the uicontrol based on the Tag value.

Example: `'pushbutton1'`

Data Types: `char`

`UserData` — Data to associate with the uicontrol object
empty array (default) | array

Data to associate with the uicontrol object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uicontrol parent

figure | uipanel | uibuttongroup | uitab

Uicontrol parent, specified as a figure, uipanel, uibuttongroup, or uitab. You can move a uicontrol to a different figure, uipanel, uibuttongroup, or uitab by setting this property to the handle of the target figure, uipanel, uibuttongroup, or uitab.

`Children` — Children of uicontrol

empty array

Children of uicontrol, returned as an empty array. Uicontrol objects have no children. Setting this property has no effect.

`HandleVisibility` — Visibility of uicontrol handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uicontrol handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uicontrol handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uicontrol handle is always visible.
`'callback'`	The uicontrol handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uicontrol at the command-line, but allows callback functions to access it.

HandleVisibility Value	Description
`'off'`	The uicontrol handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

Note: Do not try to access radio buttons and toggle buttons that are managed by a `uibuttongroup` outside of the button group. Set the HandleVisibility of those radio buttons and toggle buttons to `'off'` to prevent accidental access.

Type of Control

`Style` — Style of uicontrol

`'pushbutton'` (default) | string

Style of uicontrol, specified as a string from the following table. See "Specifying the Uicontrol Style" on page 1-8434 for more details about each style.

Style Value	Description
`'pushbutton'`	Button that appears to depress until you release the mouse button.
`'togglebutton'`	Button that can have two states: up or depressed. The state of the toggle button changes every time you click it.
`'checkbox'`	Check box that can have two states: checked or unchecked. The state changes when the user clicks and releases the mouse button over it.
`'radiobutton'`	Button that can have two states: selected or deselected. Radio buttons are intended to be mutually exclusive within a group of related radio buttons.
`'edit'`	Editable text field.

Style Value	Description
`'text'`	Static text field.
`'slider'`	Button that the user pushes along a horizontal or vertical bar. The position of the button indicates a value within a specified range.
`'listbox'`	List of items from which the user can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked.
`'popupmenu'`	Isolated menu that expands to display a list of choices when you click it. When it is collapsed, the menu shows the current choice.

`Value` — Current value of uicontrol

number

Current value of uicontrol, specified as a number. The Value property is useful in querying or modifying the status of certain uicontrols:

Style of uicontrol	Description of Value Property
`'togglebutton'`	• **Raised:** Value property equals the value of the Min property. • **Depressed:** Value property equals the value of the Max property.
`'checkbox'`	• **Unchecked:** Value property changes to the value of the Min property. • **Checked:** Value property changes to the value of the Max property.
`'radiobutton'`	• **Deselected:** Value property changes to the value of the Min property. • **Selected:** Value property changes to the value of the Max property.
`'slider'`	Value property equals the corresponding slider value.
`'listbox'`	Value property equals an array index corresponding to the selected item in the list box. A value of `1` corresponds to the first item in the list.

Style of uicontrol	Description of Value Property
`'popupmenu'`	Value property equals an array index corresponding to the selected item in the pop-up menu. A value of `1` corresponds to the first item in the pop-up menu.

`Max` — Maximum value of uicontrol

`1` (default) | number

Maximum value of uicontrol, specified as a number. The Max property affects the presentation of certain uicontrols:

Style of uicontrol	Description of Value Property
`'togglebutton'`	When the toggle button is depressed, the Value property changes to the value of the Max property.
`'checkbox'`	When the check box is checked, the Value property changes to the value of the Max property.
`'radiobutton'`	When the radio button is selected, the Value property changes to the value of the Max property.
`'edit'`	The edit text box accepts multiple lines of input when `Max – Min > 1`. Otherwise, the edit text box accepts a single line of input. The absolute values of `Max` and `Min` have no effect on the number of possible lines. As long as the difference is greater than `1`, the edit box can contain any number of lines.
`'slider'`	The Max property value is the maximum slider value, which must be greater than the Min property value.
`'listbox'`	The Max property value helps determine whether the user can select multiple items in the list box simultaneously. If Max – Min > 1, then the user can select multiple items simultaneously. Otherwise, the user cannot select multiple items simultaneously. If you set the Max and Min properties to allow multiple selections, then the Value property value can be a vector of indices.

`Min` — Minimum value of uicontrol

`0` (default) | number

Minimim value of uicontrol, specified as a number. The Min property affects the presentation of certain uicontrols:

Style of uicontrol	Description of Value Property
`'togglebutton'`	When the toggle button is raised, the Value property changes to the value of the Min property.
`'checkbox'`	When the check box is unchecked, the Value property changes to the value of the Min property.
`'radiobutton'`	When the radio button is deselected, the Value property changes to the value of the Min property.
`'edit'`	The edit text box accepts multiple lines of input when `Max – Min > 1`. Otherwise, the edit text box accepts a single line of input. The absolute values of `Max` and `Min` have no effect on the number of possible lines. As long as the difference is greater than `1`, the edit box can contain any number of lines.
`'slider'`	The Min property value is the minimum slider value, which must be less than the Max property value.
`'listbox'`	The Max property value helps determine whether the user can select multiple items in the list box simultaneously. If Max – Min > 1, then the user can select multiple items simultaneously. Otherwise, the user cannot select multiple items simultaneously. If you set the Max and Min properties to allow multiple selections, then the Value property value can be a vector of indices.

`SliderStep` — Slider step size

`[0.01 0.10]` (default) | `[minorstep majorstep]`

Slider step size, specified as the array, `[minorstep majorstep]`. This property controls the magnitude of the slider value change when the user clicks the arrow keys or the slider trough (slider channel):

- The slider Value property increases or decreases by the value of `minorstep` when the user presses an arrow key.

- The slider Value property increases or decreases by the value of `majorstep` when the user clicks the slider trough.

Both `minorstep` and `majorstep` must be greater than `1e-6`, and `minorstep` must be less than or equal to `majorstep`.

The actual step size depends on the SliderStep value and the slider range (Max – Min). For example, a slider having SliderStep value of `[0.01 0.10]`, Max value of `1`, and Min of `0` provides a 1% change when the user presses an arrow key and a 10% change when the user clicks in the trough.

As `majorstep` increases, the slider thumb indicator grows longer. When `majorstep` is equal to `1`, the thumb indicator is half as long as the trough. The size is larger for `majorstep` values greater than `1`.

Example: `[.5 1]`

`ListboxTop` — Index of top item in list box

1 (default) | integer value

Index of top item in list box, specified as an integer value. This property applies only to the listbox style of uicontrol. This property specifies which string appears in the top-most position in a list box that is not large enough to display all list entries. The ListboxTop value is an index into the array of strings you specify as the String property value. The ListboxTop value must be between `1` and the number of strings in the array. Noninteger values are fixed to the next lowest integer.

Note: The String and Value properties might override the value of the ListboxTop property regardless of the ListboxTop value you specify. The ListboxTop value can change depending on the value of other uicontrol properties. For example, explicitly setting the Value property scrolls the list to that value.

For the most reliable results, query or modify the ListboxTop property after MATLAB finishes drawing the uicontrol on the screen.

Example: `3`

Data Types: `double`

More About

- "Access Property Values"
- "Default Property Values"

uigetdir

Open folder selection dialog box

Syntax

```
folder_name = uigetdir
folder_name = uigetdir(start_path)
folder_name = uigetdir(start_path,dialog_title)
```

Description

`folder_name = uigetdir` displays a modal dialog box showing the folders that are inside the current working directory. This dialog allows you to navigate to a folder and select it (or type the name of a folder). If the folder you specify exists, `uigetdir` returns the selected path when you click **OK**. If you click **Cancel** (or the window's close box), `uigetdir` returns `0`.

`folder_name = uigetdir(start_path)` shows the folders that are inside the folder, `start_path`. If `start_path` is an empty string (`''`) or is not a valid path, the dialog box opens in the current working directory.

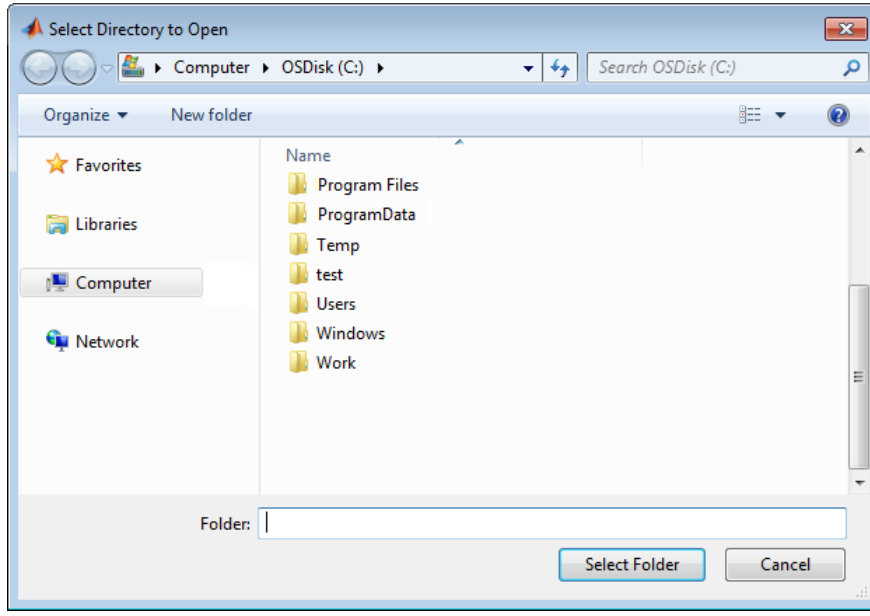
`folder_name = uigetdir(start_path,dialog_title)` opens a dialog box with the title, `dialog_title`. The default `dialog_title` is **Select folder to Open**.

Note: The visual characteristics of the dialog box depend on the operating system that is running MATLAB.

Examples

The following statement displays directories on the `C:` drive.

```
dname = uigetdir('C:\');
```



This statement uses `matlabroot` to display the MATLAB root folder in the dialog box:

```
uigetdir(matlabroot,'MATLAB Root Directory')
```

See Also

`uigetfile` | `uiputfile`

Introduced before R2006a

uigetfile

Open file selection dialog box

Syntax

```
filename = uigetfile
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle)
[FileName,PathName,FilterIndex] =
uigetfile(FilterSpec,DialogTitle,DefaultName)
[FileName,PathName,FilterIndex] =
uigetfile(...,'MultiSelect',selectmode)
```

Description

`filename = uigetfile` displays a modal dialog box that lists files in the current folder and enables you to select or enter the name of a file. If the file name is valid (and the file exists), `uigetfile` returns the file name as a string when you click **Open**. If you click **Cancel** (or the window's close box), `uigetfile` returns `0`.

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uigetfile` also displays in gray the files that do not match `FilterSpec`. `FilterSpec` can be a string or a cell array of strings, and can include the `*` wildcard.

- If `FilterSpec` is a file name, that file name displays, selected in the **File name** field. The extension of the file is the default filter.
- `FilterSpec` can include a path. That path can contain `'.'`,`'..'`, \, `'/'`, or `'~'`. For example, `'../*.m'` lists all code files in the folder above the current folder.
- If `FilterSpec` is a folder name, `uigetfile` displays the contents of that folder, the **File name** field is empty, and no filter applies. To specify a folder name, make the last character of `FilterSpec` either `'\'` or `'/'`.
- If `FilterSpec` is a cell array of strings, it can include two columns. The first column contains a list of file extensions. The optional second column contains a corresponding

list of descriptions. These descriptions replace standard descriptions in the **Files of type** field. A description cannot be an empty string. The second and third examples illustrate use of a cell array as `FilterSpec`.

If `FilterSpec` is missing or empty, `uigetfile` uses the default list of file types (for example, all MATLAB files).

After you click **Open** and if the file name exists,`uigetfile` returns the name of the file in `FileName` and its path in `PathName`. If you click **Cancel** or the window's close box, the function sets `FileName` and `PathName` to `0`.

`FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click **Cancel** or the window's close box, the function sets `FilterIndex` to `0`.

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle)` displays a dialog box that has the title `DialogTitle`. To use the default file types and specify a dialog title, enter

```
uigetfile('',DialogTitle)
```

`[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle,DefaultName)` displays a dialog box in which the file name specified by `DefaultName` appears in the **File name** field. `DefaultName` can also be a path or a path/filename. In this case, `uigetfile` opens the dialog box in the folder specified by the `path`. You can use `'.'`,`'..'`, `\`, or `'/'` in the `DefaultName` argument. To specify a folder name, make the last character of `DefaultName` either `'\'` or `'/'`. If the specified path does not exist, `uigetfile` opens the dialog box in the current folder.

`[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',`*`selectmode`*`)` opens the dialog box in *multiselect* mode. Valid values for *`selectmode`* are `'on'` and `'off'` (the default, which allows single selection only). If `'MultiSelect'` is `'on'` and you select more than one file in the dialog box, then `FileName` is a cell array of strings. Each array element contains the name of a selected file. File names in the cell array are sorted in the order your platform uses. If you select multiple files, they must be in the same folder, otherwise MATLAB displays a warning dialog box. Be aware that Microsoft Windows libraries can span multiple folders. `PathName` is a string identifying the folder containing the files.

If you include either of the wildcard characters, `'*'` or `'?'`, in a file name, `uigetfile` does not respond to clicking **Open**. The dialog box remains open until you cancel it or

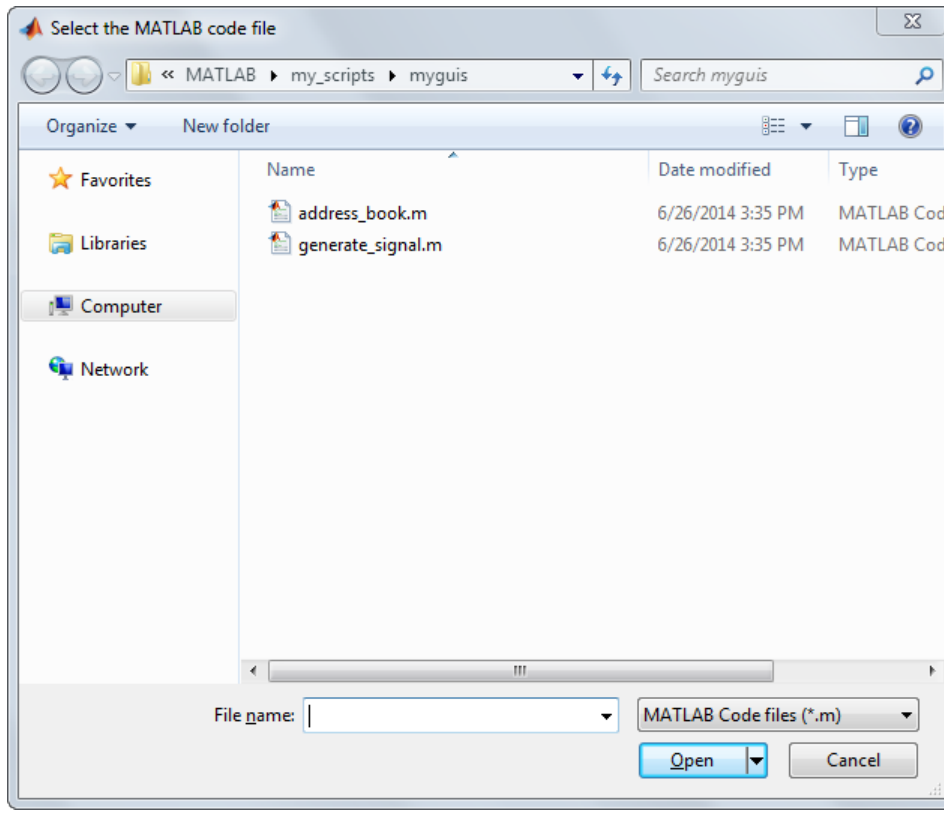
remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

Note: The visual characteristics of the dialog box depend on the operating system that is running MATLAB.

Examples

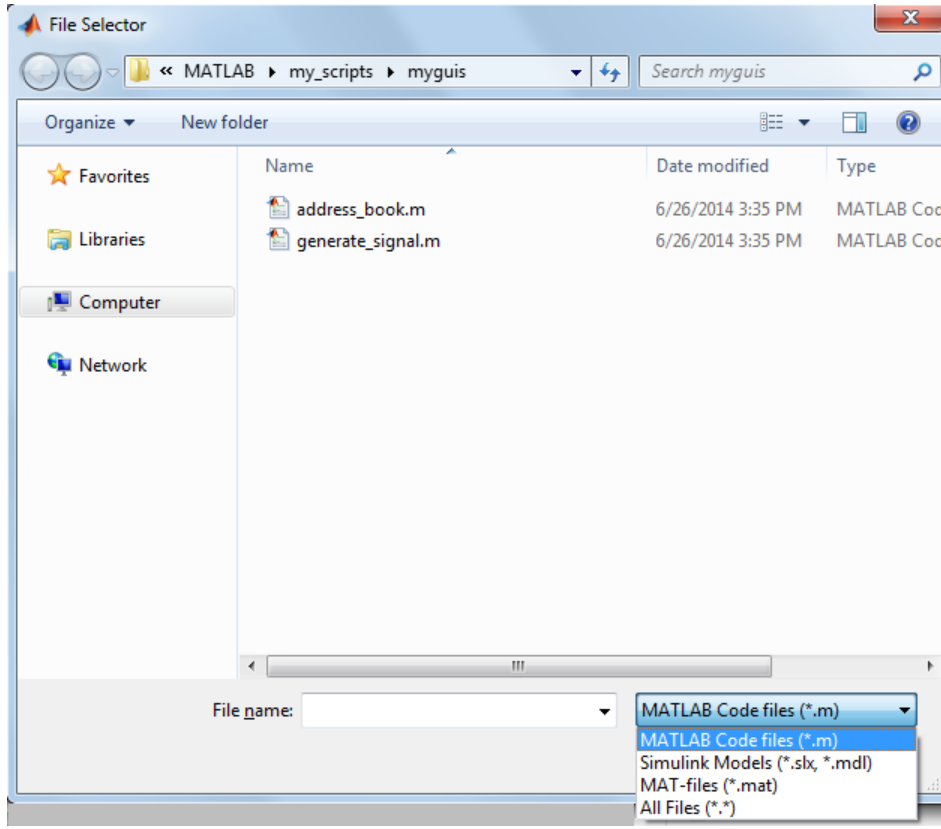
This dialog box lists all MATLAB code files in the current directory. `uigetfile` returns the name and path to the file you select.

```
[FileName,PathName] = uigetfile('*.m','Select the MATLAB code file');
```



To create a list of file types that appears in the file type drop-down list, separate the file extensions with semicolons, as in the following code. `uigetfile` displays a default description for each known file type.

```
[filename, pathname] = ...
     uigetfile({'*.m';'*.slx';'*.mat';'*.*'},'File Selector');
```

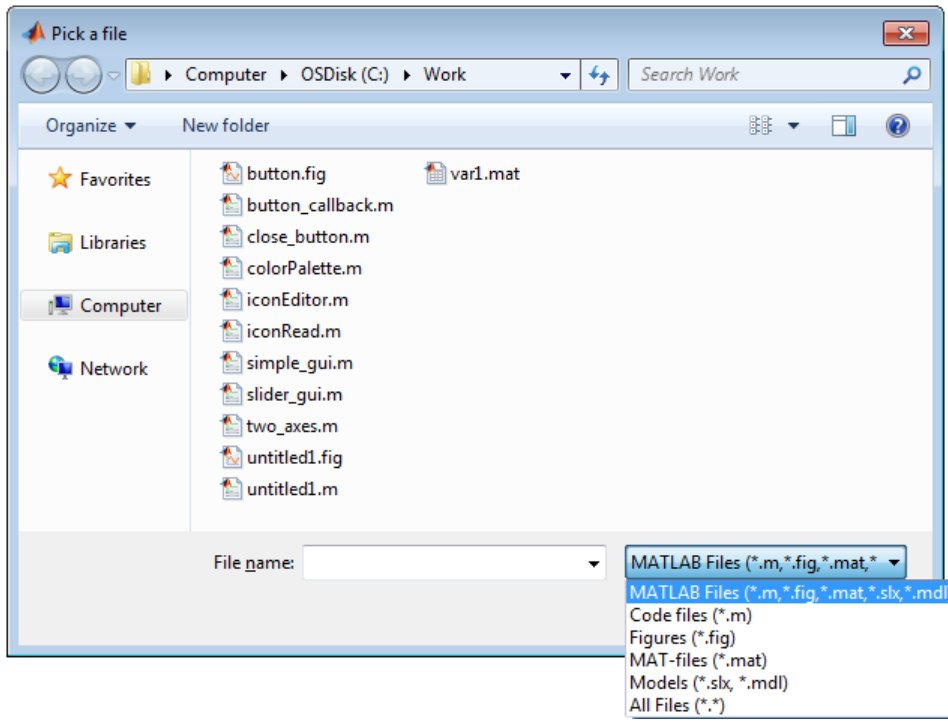


If you want to create a list of file types and give them descriptions that are different from the defaults, use a cell array, as in the following code. This example also associates multiple file types with the `'MATLAB Files'` and `'Models'` descriptions.

```
[filename, pathname] = uigetfile( ...
{'*.m;*.fig;*.mat;*.slx;*.mdl',...
 'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
   '*.m',  'Code files (*.m)'; ...
   '*.fig','Figures (*.fig)'; ...
```

```
'*.mat','MAT-files (*.mat)'; ...
'*.mdl;*.slx','Models (*.slx, *.mdl)'; ...
'*.*',  'All Files (*.*)'}, ...
'Pick a file');
```

The first column of the cell array contains the file extensions, while the second contains your descriptions of the file types. In this example, the first entry of column one contains several extensions, separated by semicolons, which are all associated with the description `'MATLAB Files (*.m,*.fig,*.mat,*.mdl)'`. The code produces the dialog box shown in the following figure.



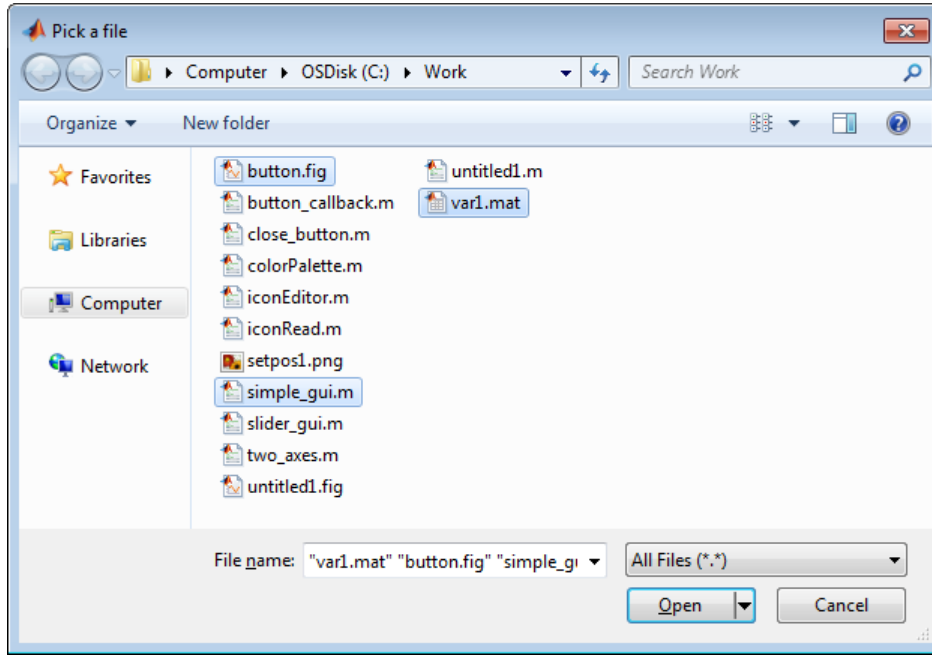
The following code lets you select a file, and then displays a message in the Command Window that summarizes the result.

```
[filename, pathname] = uigetfile('*.m', 'Select a MATLAB code file');
if isequal(filename,0)
   disp('User selected Cancel')
else
   disp(['User selected ', fullfile(pathname, filename)])
```

```
end
```

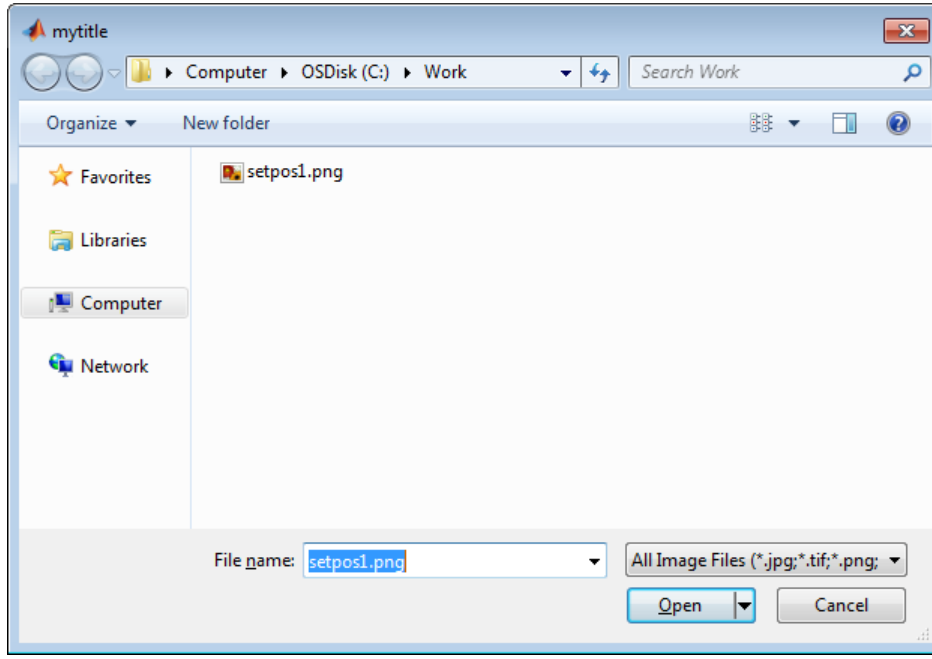
This code creates a list of file types and gives them descriptions that are different from the defaults. It also enables multiple-file selection. Select multiple files by holding down the **Shift** or **Ctrl** key and clicking on additional file names.

```
[filename, pathname, filterindex] = uigetfile( ...
{  '*.mat','MAT-files (*.mat)'; ...
   '*.slx;*.mdl','Models (*.slx, *.mdl)'; ...
   '*.*',  'All Files (*.*)'}, ...
   'Pick a file', ...
   'MultiSelect', 'on');
```



You can use the `DefaultName` argument to specify a start path and a default file name for the dialog box.

```
uigetfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
          '*.*','All Files' },'mytitle',...
          'C:\myfiles\my_examples\gbtools\setpos1.png')
```



Alternatives

Use the `dir` function to return a filtered or unfiltered list of files in your current folder or a folder you specify. `dir` also can return file attributes.

`uigetdir` | `uiopen` | `uiputfile`

Introduced before R2006a

uigetpref

Conditionally open dialog box according to user preference

Syntax

```
pref_value = uigetpref(group,pref,title,question,pref_choices)
[pref_value,dlgshown] = uigetpref(...)
[...] = uigetpref(... 'Name',value)
```

Description

`pref_value = uigetpref(group,pref,title,question,pref_choices)` returns one of the strings in `pref_choices` in either of two ways:

- Displays a multiple-choice dialog box that prompts you to answer a question. The dialog box includes a check box with the label **Do not show this dialog again**.
- Retrieves a previous answer from the preferences data base and returns it without displaying a dialog. No dialog is displayed if you previously selected the check box **Do not show this dialog again**.

`[pref_value,dlgshown] = uigetpref(...)` also returns in `dlgshown` whether or not the dialog displayed.

`[...] = uigetpref(... 'Name',value)` specify optional name-value pairs to control how dialogs display.

Input Arguments

`group`

String specifying the name of the preference group that preference `pref` belongs to. If the group does not already exist, `uigetpref` creates it.

Default: None

`pref`

String specifying the name of the preference that controls whether the dialog displays. If the preference does not already exist, `uigetpref` creates it.

Default: None

`title`

String to display in the dialog box title bar

Default:

`question`

String or cell array of strings specifying a descriptive paragraph for the dialog to display. Use `question` to define what you are asking the user to decide. Clearly state the alternatives and the consequences of choosing among them. The dialog box that `uigetpref` generates inserts line breaks between rows of the string array, between elements of the cell array of strings, and between `'|'` or newline characters within a string vector.

Default: None

`pref_choices`

String, cell array of strings, or `'|'`-separated strings specifying the labels for the dialog box push buttons. The string on the selected push button is returned.

If the internal preference values are different from the strings displayed on the push buttons, provide a 2-by-n cell array of strings. The first row contains the preference strings, and the second row contains the associated push button strings. When `pref_choices` is not a 2-by-n cell array, MATLAB constructs lowercase versions of the button labels and returns them in `pref_value`. If your code tests returned values, make sure it compares them against the appropriate strings.

Default: None

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CheckboxState'`

State of check box when dialog box opens:

- `false` or `0`: Check box is not initially selected.
- `true` or `1`: Check box is initially selected.

Default: `0`

`'CheckboxString'`

String specifying the label for the check box.

Default: `'Do not show this dialog again'`

`'HelpString'`

String specifying the label for **Help** button.

Default: No **Help** button displays.

`'HelpFcn'`

String or function handle specifying the callback that executes when you click the **Help** button. Also, to have a button to trigger the callback, you must specify the `HelpString` option.

Default: `doc('uigetpref')`

`'ExtraOptions'`

String or cell array of strings specifying extra buttons. The additional buttons are not mapped to any preference settings. If you click any of these buttons, the dialog closes and `uigetpref` returns the string in `value`.

Default: `{}`

`'DefaultButton'`

String specifying the value that `uigetpref` returns if you close the dialog without clicking a button. This string does not have to correspond to any preference or `ExtraOption`.

Default: The first button specified in pref_choices

Output Arguments

`pref_value`

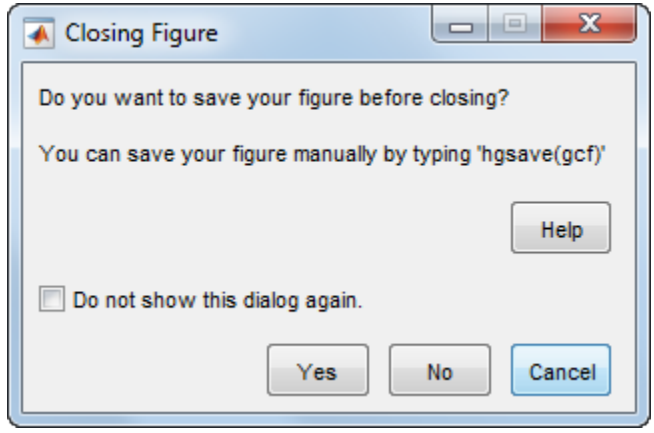
String containing the preference corresponding to the button you press. If you cancel the dialog by clicking its close box, `uigetpref` returns the label of the first button specified in pref_choices or the value for `DefaultButton`, if specified. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same group and pref arguments. Instead, it returns the last choice you made (your registered preference) in pref_value immediately.

`dlgshown`

Logical value that indicates whether or not the dialog displayed. The value is `1` when the dialog displays. The value is `0` when the dialog does not display. If the user selects the **Do not show this dialog again** check box, then the dialog does not display the next time your code calls the `uigetpref` function with the same group and pref arguments.

Examples

Create a preference dialog for the `'savefigurebeforeclosing'` preference in the `'mygraphics'` group of preferences.



This function, `save_figure_perhaps`, displays a dialog that asks the user to save current figure. The function responds appropriately, depending on the value returned by `uigetpref`.

```
function save_figure_perhaps
% Closes figure conditionally, asking whether to save it first.
% User can suppress the dialog from UIGETPREF permanently by selecting
% "Do not show this dialog again".

fig = gcf;
[selectedButton dlgshown] = uigetpref(...
    'mygraphics',...                        % Group
    'savefigurebeforeclosing',...           % Preference
    'Closing Figure',...                    % Window title
    {'Do you want to save your figure before closing?'
     ''
     'You can save your figure manually by typing ''hgsave(gcf)'''},...
    {'always','never';'Yes','No'},...        % Values and button strings
     'ExtraOptions','Cancel',...             % Additional button
     'DefaultButton','Cancel',...            % Default choice
     'HelpString','Help',...                 % String for Help button
     'HelpFcn','doc(''closereq'');');        % Callback for Help button
switch selectedButton
    case 'always'  % Open a Save dialog (without testing if saved before)
    [fileName,pathName,filterIndex] = uiputfile('fig', ...
                                    'Save current figure', ...
                                    'untitled.fig');
       if filterIndex == 0     % User cancelled save or named no file
           delete(fig);
       else                    % Use filename returned from UIPUTFILE
           saveas(fig,[pathName fileName])
           delete(fig);
       end
   case 'never'                % Close the figure without saving it
       delete(fig);
   case 'cancel'               % Do not close the figure
       return
 end
```

To run this example, copy and paste the code into a new program file. Name the file `save_figure_perhaps.m` and save it on your search path. To use the function as a `CloseRequestFcn` callback, create a figure as follows:

```
figure('CloseRequestFcn','save_figure_perhaps');
```

Clicking the figure's close box displays the dialog box until you select **Do not show this dialog again**.

More About

Preferences

Preferences provide the ability to specify how applications behave and how users interact with them. For example, you can set a preference for which products display their

documentation in the Help browser, or which messages the Code Analyzer displays. In MathWorks software products, preferences persist across sessions and are stored in a preference data base, the location of which is system-dependent. Use the **Preferences** option on the **File** menu to access all built-in preferences.

`uigetpref` uses the same preference data base as `addpref`, `getpref`, `ispref`, `rmpref`, and `setpref`. However, `uigetpref` registers the preferences it sets as a separate list, so that it and `uisetpref` can manage those preferences.

To modify preferences registered with `uigetpref`, you can use `setpref` and `uisetpref` to explicitly change preference values to `'ask'`. If you specify a preference that does not already exist in the preference data base, `uigetpref` creates it.

Tips

- You must supply all input arguments up to and including pref_choices.
- `uigetpref` creates specified groups and preferences, if they do not currently exist. To delete a preference group you no longer need, use `rmpref`.
- The string returned in pref_value is a preference name (as specified in pref), not its button label (as specified in pref_choices).
- After you select the check box **Do not show this dialog again** and close the dialog box, the dialog box does not display again for the same preference. To reenable dialogs that are being suppressed by preferences, use the command:

  ```
  uisetpref('clearall')
  ```

  Executing `uisetpref` with this command re-enables *all* preference dialogs you have defined with `uigetpref`, not just the most recent one.

Introduced before R2006a

uiimport

Import data interactively

Syntax

```
uiimport
uiimport(filename)
uiimport('-file')
uiimport('-pastespecial')
S = uiimport( ___ )
```

Description

`uiimport` opens a dialog to interactively load data from a file or the clipboard. MATLAB displays a preview of the data in the file.

`uiimport(filename)` opens the file specified in `filename`.

`uiimport('-file')` presents the file selection dialog first.

`uiimport('-pastespecial')` presents the clipboard contents first.

`S = uiimport( ___ )` stores the resulting variables as fields in the struct `S`.

`load` | `importdata` | `clipboard`

Introduced before R2006a

uimenu

Create menus and menu items on figure windows

Syntax

```
m = uimenu
m = uimenu(Name,Value,...)
m = uimenu(parent)
m = uimenu(parent,Name,Value,...)
```

Description

`m = uimenu` creates a uimenu in an existing figure's menu bar and returns the uimenu object, `m`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`m = uimenu(Name,Value,...)` creates a uimenu and specifies one or more uimenu property names and corresponding values. Use this syntax to override the default uimenu properties.

`m = uimenu(parent)` creates a uimenu and designates a specific parent object. The `parent` argument can be a figure, uicontextmenu, or another uimenu object. Setting the parent to a uicontextmenu or another uimenu makes `m` a submenu of the parent menu.

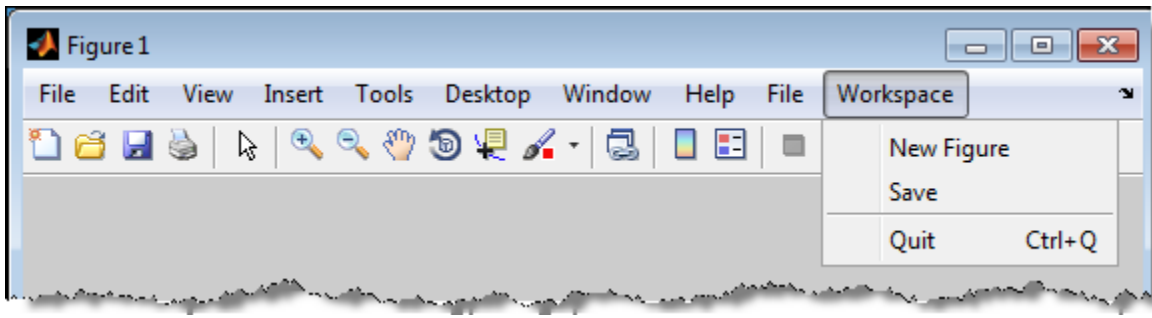
`m = uimenu(parent,Name,Value,...)` creates a uimenu with a specific parent and one or more uimenu properties.

Examples

This example creates a menu labeled **Workspace** with menu options for creating a new figure window, saving workspace variables, and exiting MATLAB. In addition, it defines an accelerator key for the Quit option.

```
f = uimenu('Label','Workspace');
    uimenu(f,'Label','New Figure','Callback','disp(''figure'')');
```

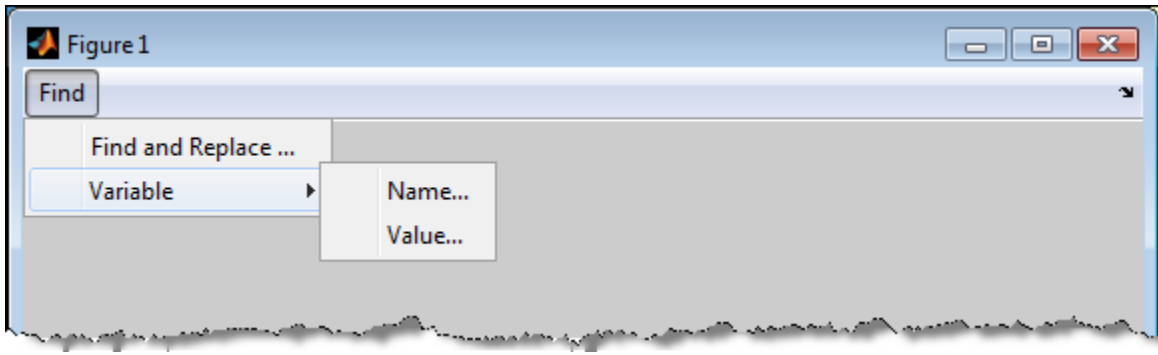
```
uimenu(f,'Label','Save','Callback','disp(''save'')');
uimenu(f,'Label','Quit','Callback','disp(''exit'')',...
       'Separator','on','Accelerator','Q');
```



This example creates a new figure with a menu bar that excludes the built-in menus. It creates a **Find** menu with options **Find & Replace**, and **Variable**. For the Variable option, it creates a submenu with options of **Name** and **Value**.

```
f = figure('MenuBar','None');
mh = uimenu(f,'Label','Find');
frh = uimenu(mh,'Label','Find and Replace ...',...
            'Callback','disp(''goto'')');
frh = uimenu(mh,'Label','Variable');
uimenu(frh,'Label','Name...', ...
          'Callback','disp(''variable'')');

uimenu(frh,'Label','Value...', ...
          'Callback','disp(''value'')');
```

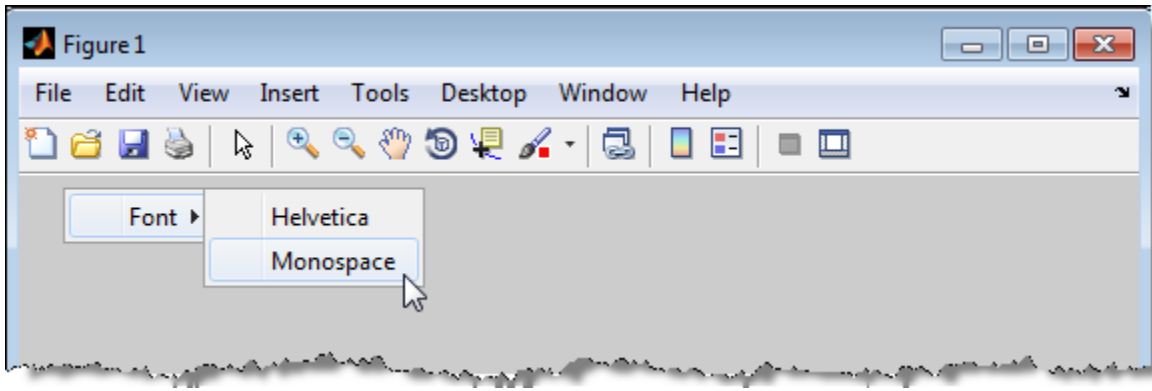


This example creates a context menu, **Font**, on a figure with menu options **Helvetica** and **Monospace**. When you run the code and then right-click anywhere within the figure window, the context menu displays.

```
f = figure;
% Create the UICONTEXTMENU
cmenu = uicontextmenu;

% Create the parent menu
fontmenu = uimenu(cmenu,'label','Font');

% Create the submenus
font1 = uimenu(fontmenu,'label','Helvetica',...
                'Callback','disp(''HelvFont'')');
font2 = uimenu(fontmenu,'label',...
                'Monospace','Callback','disp(''MonoFont'')');
f.UIContextMenu = cmenu;
```



More About

Tips

If you want the uimenu to respond when the user activates the uimenu, set its `Callback` property to be a function handle (or a string of MATLAB commands). Uimenus respond to different actions, depending on their location:

- Top level (in the menu bar) — Responds to a single mouse click

- Submenu that contains other submenus — Responds to hovering the mouse
- Terminating submenu — Responds to a single mouse click

The value of the figure's `MenuBar` property determines the content in the menu bar. When the MenuBar property is set to `'figure'`, a default set of menus appear alongside the uimenus defined in your code. When the MenuBar property is set to `'none'`, the default menus do not appear, but the uimenus you create appear in the menu bar.

Uimenus do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing uimenu children is changed to `'Modal'`, the uimenu children still exist in the `Children` property of the figure. However, the uimenus do not display while WindowStyle is set to `'Modal'`.

`figure` | `uicontextmenu` | Uimenu Properties

Introduced before R2006a

Uimenu Properties

Control appearance and behavior of menu

A uimenu is a menu in a figure's menu bar. The `uimenu` function adds a menu to a figure or adds a submenu to an existing menu and sets any required properties. By changing uimenu property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
m = uimenu;
color = m.ForegroundColor;
m.ForegroundColor = [0 0 1];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uimenu visibility

`'on'` (default) | `'off'`

Uimenu visibility, specified as `'on'` or `'off'`. When the Visible property is set to `'off'`, the uimenu is not visible, but you can query and set its properties.

`Label` — Menu label

string

Menu label, specified as a string. This property specifies the text that appears on the menu (or menu item).

You can specify a mnemonic for the label using the ampersand (&) character. The character that follows the ampersand appears underlined in the menu. The user can select the menu item by pressing the **Alt** key followed by the underlined character.

In order for the mnemonic system to work, you must specify a mnemonic for all menu items you define in the UI.

If you want to display an ampersand in the menu label, specify two consecutive ampersands in the string.

Here are some examples:

String	Resulting Menu Label
`'&Open Selection'`	**Open Selection** (pressing **Alt** underlines O)
`'O&pen Selection'`	**Open Selection** (pressing **Alt** underlines p)
`'&Save && Go'`	**Save & Go** (pressing **Alt** underlines S)
`'Save& Go'`	**Save& Go** (space cannot be a mnemonic character)

Note: Avoid using these case-sensitive reserved words: “default”, “remove”, and “factory”. If you must use a reserved word, then escape that word by preceding it with a back-slash character. For instance, `'\default'` escapes “default”.

Example: `'Open Selection'`

Example: `'&Open Selection'`

Data Types: `char`

`Checked` — Menu check indicator

`'off'` (default) | `'on'`

Menu check indicator, specified as `'off'` or `'on'`. Setting this property to `'on'` places a check mark next to the corresponding menu item. Setting it to `'off'` removes the check mark. You can use this feature to show the state of menu items that enable or disable functionality in your application.

`Separator` — Separator line mode

`'off'` (default) | `'on'`

Separator line mode, specified as `'off'` or `'on'`. Setting this property to `'on'` draws a dividing line above the uimenu.

`ForegroundColor` — Uimenu text color

`[0 0 0]` (default) | RGB triplet | short name | long name

Uimenu text color, specified as an RGB triplet, short name, or long name from the table below.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0 0 1]`

Example: `'b'`

Example: `'blue'`

Data Types: `double` | `char`

Location and Size

`Position` — Relative menu position

scalar integer value

Relative menu position, specified as a scalar integer value. The value of Position property indicates placement on the menu bar or within a menu. Top-level menus appear from left to right on the menu bar according to the value of their Position property, with 1 representing the left-most position. The individual items within a given menu appear from top to bottom according to the value of their Position property, with 1 representing the top-most position.

Data Types: `double`

Interactive Control

`Callback` — Callback function that executes when user selects the uimenu

`''` (default) | function handle | cell array | string

Callback function that executes when user selects the uimenu, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Note: Do not use a uimenu callback to dynamically change menu items. Deleting, adding, and replacing menu items in a callback can result in a blank menu on some platforms. You can hide, show, and disable menu items in a callback to achieve the same effect. To fully repopulate menu items, delete and create them outside the callback.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell`

`Enable` — Operational state of uimenu

`'on'` (default) | `'off'`

Operational state of uimenu, specified as `'on'` or `'off'`. This property controls whether the user can select a menu item. When the value is `'off'`, the menu label appears dimmed, indicating that the user cannot select it.

`Accelerator` — Keyboard equivalent

character

Keyboard equivalent, specified as a character. This property defines a keyboard equivalent character for selecting the menu item. Specifying an Accelerator value

allows users to select the menu item by pressing a character and another key, instead of selecting the menu item with the mouse. The key sequence is platform specific:

- For Windows, the sequence is **Ctrl**+Accelerator. Windows reserves these keys for default menu items: `a`, `c`, `v`, and `x`
- For Macintosh systems, the sequence is **Command**+Accelerator. Apple reserves these keys for default menu items: `a`, `c`, `v`, and `x`.
- For Linux systems, the sequence is **Ctrl**+Accelerator. Linux systems reserve these keys for default menu items: `o`, `p`, `s`, and `w`. Like the other platforms, many Linux applications also use `a`, `c`, `v`, and `x`.

Accelerated menu items do not have to be displayed for the accelerator key to work. However, some restrictions apply:

- You can define the Accelerator property for only menu items that do not have submenus menus.
- Accelerators work only for menu items that execute a callback function.
- The figure must be in focus when entering the accelerator key sequence.

To remove an Accelerator value, set the Accelerator property to an empty string, `''`.

Example: `'f'`

Callback Execution Control

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

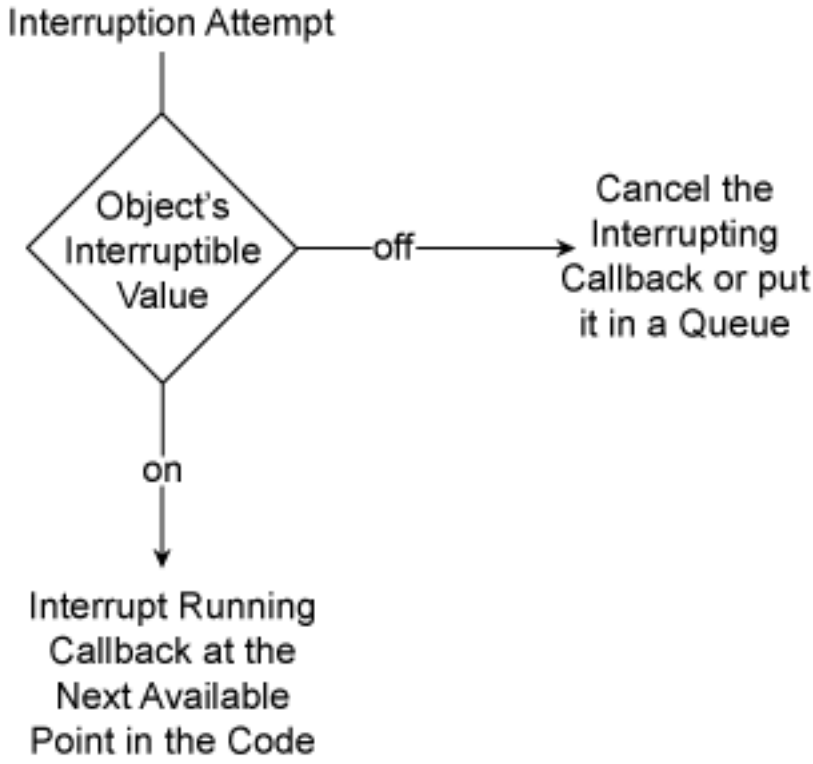
Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback

determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uimenu callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback.

MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.

- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See “Interrupt Callback Execution” for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

This property has no effect on the uimenu.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uimenu

`'off'` (default) | `'on'`

Deletion status of uimenu, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uimenu begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uimenu no longer exists.

Check the value of the BeingDeleted property to verify that the uimenu is not about to be deleted before querying or modifying it.

`CreateFcn` — Uimenu creation function

function handle | cell array | string

Uimenu creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uimenu. MATLAB initializes all uimenu property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uimenu that is being created.

Setting the CreateFcn property on an existing uimenu has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uimenu object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uimenu deletion function

function handle | cell array | string

Uimenu deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uimenu (for example, when the end user deletes the figure). MATLAB executes the

DeleteFcn callback before destroying the properties of the uimenu. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uimenu that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object

`'uimenu'`

Type of graphics object, returned as `'uimenu'`.

`Tag` — Uimenu identifier

`''` (default) | string

Uimenu identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uimenu. When you need access to the uimenu elsewhere in your code, you can use the `findobj` function to search for the uimenu based on the Tag value.

Example: `'menu1'`

Data Types: `char`

`UserData` — Data to associate with the uimenu object

empty array (default) | array

Data to associate with the uimenu object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uimenu parent

figure | uicontextmenu | uimenu

Uimenu parent, specified as a figure, uicontextmenu, or another uimenu object. You can move a uimenu to a different figure, or move it under a different uimenu by setting this property to the target figure, uicontextmenu, or uimenu object.

`Children` — Children of uimenu

empty `GraphicsPlaceholder` array (default) | 1-D array of uimenu objects

Children of uimenu, returned as an empty `GraphicsPlaceholder` or a 1-D array of uimenu objects. The children of uimenus are other uimenus that function as submenus.

You cannot add or remove children using the `Children` property of the uimenu. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the displayed menu items.

To add a child to this list, set the `Parent` property of the child component to be the uimenu object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of Uimenu handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uimenu handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uimenu handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uimenu handle is always visible.

HandleVisibility Value	Description
`'callback'`	The uimenu handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uimenu at the command-line, but allows callback functions to access it.
`'off'`	The uimenu handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

`uimenu`

More About

- "Default Property Values"

uint8

Convert to 8-bit unsigned integer

Syntax

```
intArray = uint8(array)
```

Description

`intArray = uint8(array)` converts the elements of an array into unsigned 8-bit (1-byte) integers of class `uint8`.

Input Arguments

`array`

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint8`, the `uint8` function has no effect.

Output Arguments

`intArray`

Array of class `uint8`. Values range from 0 to $2^8 - 1$.

The `uint8` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint8(2^8)   %  2^8 = 256
```

returns

```
ans =
    255
```

Examples

Convert a `double` array to `uint8`:

```
mydata = uint8(magic(10));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint8(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint8');   % Preferred
```

See Also

Introduced before R2006a

uint16

Convert to 16-bit unsigned integer

Syntax

```
intArray = uint16(array)
```

Description

`intArray = uint16(array)` converts the elements of an array into unsigned 16-bit (2-byte) integers of class `uint16`.

Input Arguments

`array`

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint16`, the `uint16` function has no effect.

Output Arguments

`intArray`

Array of class `uint16`. Values range from 0 to $2^{16} - 1$.

The `uint16` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint16(2^16)   %  2^16 = 65536
```

returns

```
ans =
    65535
```

Examples

Convert a `double` array to `uint16`:

```
mydata = uint16(magic(100));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint16(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint16');   % Preferred
```

See Also

`double` | `single` | `uint8` | `uint32` | `uint64` | `int8` | `int16` | `int32` | `int64` | `intmax` | `intmin`

uint32

Convert to 32-bit unsigned integer

Syntax

```
intArray = uint32(array)
```

Description

`intArray = uint32(array)` converts the elements of an array into unsigned 32-bit (4-byte) integers of class `uint32`.

Input Arguments

`array`

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint32`, the `uint32` function has no effect.

Output Arguments

`intArray`

Array of class `uint32`. Values range from 0 to $2^{32} - 1$.

The `uint32` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint32(2^32)    % 2^32 = 4294967296
```

returns

```
ans =
    4294967295
```

Examples

Convert a `double` array to `uint32`:

```
mydata = uint32(magic(1000));
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint32(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint32');   % Preferred
```

Introduced before R2006a

uint64

Convert to 64-bit unsigned integer

Syntax

```
intArray = uint64(array)
```

Description

`intArray = uint64(array)` converts the elements of an array into unsigned 64-bit (8-byte) integers of class `uint64`.

Input Arguments

`array`

Array of any numeric class, such as `single` or `double`. If `array` is already of class `uint64`, the `uint64` function has no effect.

Output Arguments

`intArray`

Array of class `uint64`. Values range from 0 to $2^{64} - 1$.

The `uint64` function maps any values in `array` that are outside the limit to the nearest endpoint. For example,

```
uint64(2^64)    % 2^64 = 18446744073709551616
```

returns

```
ans =
    18446744073709551615
```

Examples

Convert a literal value to `uint64`:

```
x = uint64(9007199254740993);
```

Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint64(zeros(100));     % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint64');   % Preferred
```

More About

Tips

Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, `double` values cannot represent all integers greater than 2^{53} correctly. Before performing arithmetic operations on values larger than 2^{53} in magnitude, convert the values to 64-bit integers. For example,

```
x = uint64(2^53+1);    % Floating-point arithmetic, loses precision
```

is not as accurate as the 64-bit integer arithmetic operation:

```
x = uint64(2^53) + 1;  % Preferred
```

uiopen

Open dialog box for selecting file to load into workspace

Syntax

```
uiopen
uiopen(type)
uiopen(filename)
uiopen(filename, TF)
```

Description

`uiopen` displays the dialog box with the file filter set to all MATLAB files (with file extensions `*.m`, `*.mat`, `*.fig`, `*.mdl`, and `*.slx`).

`uiopen(type)` sets the file filter according to the `type`.

`uiopen(filename)` displays `filename` as the default value for **File name** in the dialog box and lists only files having the same extension.

`uiopen(filename, TF)` directly opens file `filename` without displaying a dialog box if `TF` is true, and displays the dialog box if `TF` is false.

Input Arguments

`type`

String that specifies the kind of file to show in the dialog box (the file filter). Acceptable values for type are the following.

Type string	Files Displayed
`matlab`	All MATLAB files (with file extensions `*.m`, `*.mat`, `*.fig`, `*.mdl`, and `*.slx`.)

Type string	Files Displayed
`load`	All MAT-files (`*.mat`)
`figure`	All figure files (`*.fig`)
`simulink`	All Simulink model files (`*.mdl` and `*.slx`)
`editor`	All MATLAB files except for `.mat`, `.fig`, and `.slx` files.

Default:

`filename`

A string, including the file extension, naming a file to open. The filename can be a wildcard character plus extension. For example, `*.txt` displays a list of all files with the file extension `.txt`.

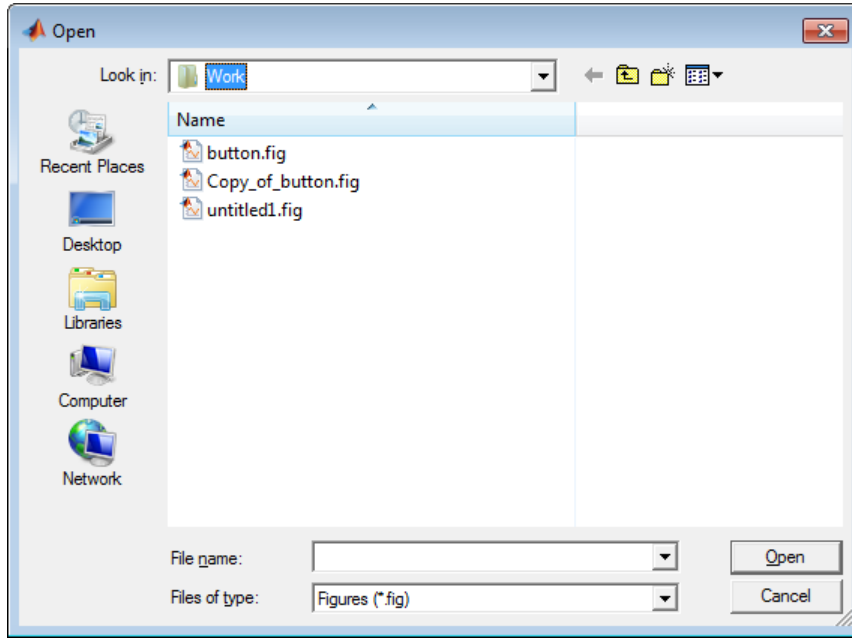
`TF`

A MATLAB expression that evaluates to `true` or `false`. If `true`, filename opens directly, without displaying the dialog.

Examples

Filter to display only FIG-files by setting the **Files of type** field to `Figures (*.fig)`:

```
uiopen('figure')
```



Alternatives

In MATLAB code or in a command:

- To open a file appropriately based on its file extension, use the `open` function.
- To open a file in the Editor, use the `edit` function.
- To open a MAT-file and load its contents into the workspace, use the `load` function.
- To open a FIG-file, use the `openfig` function.
- To open a file in an application in Microsoft Windows, use the `winopen` function.

More About

Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

Tips

When you select a file and click **open**, `uiopen` does the following:

- Gets the file using `uigetfile`.
- Opens the file using the `open` command.
  - Files with a file extension of `.m` open in the Editor.
  - Variables stored in files with a file extension of `.mat` appear in the caller's workspace.
  - Files with a file extension of `.fig` open as figure windows.
  - Files with a file extension of `.mdl` or `.slx` open as models in Simulink.
- `uiopen('load')` is the only the form of `uiopen` that you can compile into a standalone application. You can create a file selection dialog box that you can compile using `uigetfile`.
- The `uiopen` dialog box is modal. A modal dialog box prevents you from interacting with other windows until you respond to the modal one.
- `uiopen` displays the same dialog box that opens when you use the MATLAB desktop toolstrip to open a file. (On the **Home** tab, in the **File** section, click **Open**  .)

Introduced before R2006a

uipanel

Create panel container object

Syntax

```
p = uipanel
p = uipanel(Name,Value,...)
p = uipanel(parent)
p = uipanel(parent,Name,Value,...)
```

Description

`p = uipanel` creates a uipanel in an existing figure and returns the uipanel object, `p`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`p = uipanel(Name,Value,...)` creates a uipanel and specifies one or more uipanel property names and corresponding values. Use this syntax to override the default uipanel properties.

`p = uipanel(parent)` creates a uipanel and designates a specific parent object. The `parent` argument can be a figure, uitab, uibuttongroup or another uipanel object.

`p = uipanel(parent,Name,Value,...)` creates a uipanel with a specific parent and one or more uipanel properties.

Uipanels are containers that group UI components together. Uipanels can contain uicontrols, axes, uitables, uitabs, uibuttongroups, and other uipanels. Uipanels cannot contain ActiveX controls.

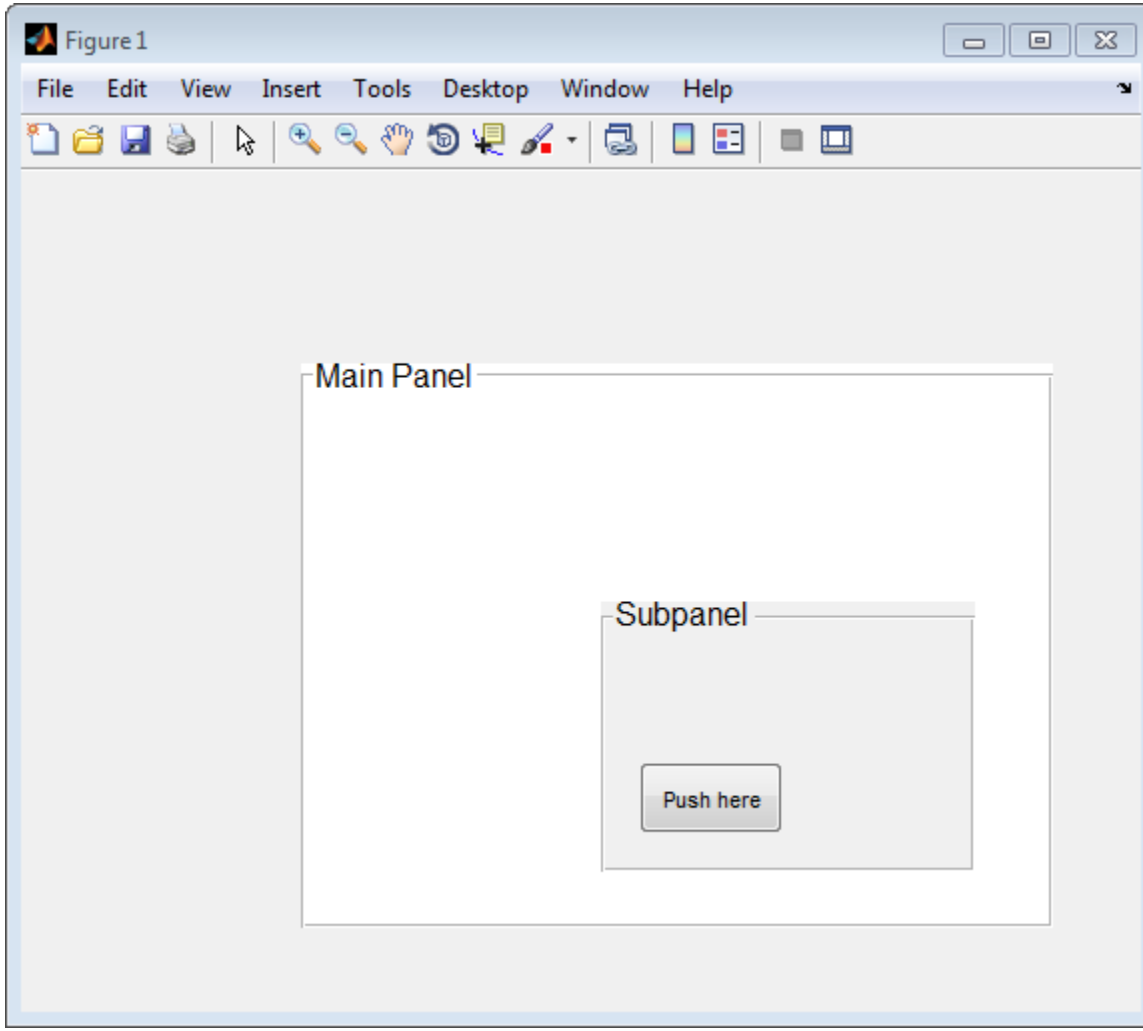
Examples

Create uipanel With Children

Create a figure containing two panels and a push button. The panels use the default Units property value, `'normalized'`. The default units for the `uicontrol` is `'pixels'`.

```
h = figure;
hp = uipanel('Title','Main Panel','FontSize',12,...
```

```
                'BackgroundColor','white',...
                'Position',[.25 .1 .67 .67]);
hsp = uipanel('Parent',hp,'Title','Subpanel','FontSize',12,...
                'Position',[.4 .1 .5 .5]);
hbsp = uicontrol('Parent',hsp,'String','Push here',...
                'Position',[18 18 72 36]);
```



Uipanel That Always Matches Figure Window Width

Create a uipanel that always matches the width of the figure, but maintains a constant height. Use the SizeChangedFcn callback to keep the panel's width equal to the width of the figure's drawable area.

To see how this code works, copy and paste this code into the Editor and run it.

```
function myui
f = figure('Visible','off','SizeChangedFcn',@match_width);
u = uipanel('Units','Pixels', 'Tag','StatusBar',...
            'BackgroundColor','blue');
f.Visible= 'on';
    function match_width(hObject,eventdata)
       fig = gcbo;
       u = findobj(fig,'Tag','StatusBar');

       % change panel units to pixels and adjust position
       panelunits = u.Units;
       u.Units = 'pixels';
       figpos = fig.Position;
       upos = [1, figpos(4) - 20, figpos(3), 20];
       u.Position = upos;

       % restore original panel units
       u.Units = panelunits;

    end
end
```

More About

Tips

If you set the Visible property of a `uipanel` object to `'off'`, then any child objects it contains (buttons, button groups, axes, etc.) become invisible along with the parent uipanel. However, the Visible *property value* of each child object remains unaffected.

- "Access Property Values"

Introduced before R2006a

Uipanel Properties

Control appearance and behavior of panel

Uipanels are containers for grouping together graphics objects or UI components. The `uipanel` function creates a panel in a figure and sets any required properties before displaying it. By changing the uipanel property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
p = uipanel;
pos = p.Position;
p.Position = [.1 .1 .7 .8];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uipanel visibility

`'on'` (default) | `'off'`

Uipanel visibility, specified as `'on'` or `'off'`. The Visible property determines whether the uipanel displays on the screen. If the Visible property of a uipanel is set to `'off'`, the entire uipanel is invisible, but you can still specify and access its properties.

Changing the size of an invisible uipanel triggers the SizeChangedFcn callback when the uipanel becomes visible.

Note Changing the Visible property of a uipanel does *not* change the Visible property of its child components even though hiding the uipanel prevents its children from displaying.

`BackgroundColor` — Uipanel background color

`[.94 .94 .94]` (default) | RGB triplet | short name | long name

Uipanel background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uipanel.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Note: Some operating systems override the `BackgroundColor` value.

Data Types: `double` | `char`

`ForegroundColor` — Uipanel title color

`[0 0 0]` (default) | RGB triplet | short name | long name

Uipanel title color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

BorderType — Border of the uipanel

'etchedin' (default) | 'etchedout' | 'beveledin' | 'beveledout' | 'line' | 'none'

Border of the uipanel area, specified as 'etchedin', 'none', 'etchedout', 'beveledin', 'beveledout', or 'line'.

- For a 3-D look, use etched or beveled borders.

  Use the HighlightColor and ShadowColor properties to specify the color of 3-D borders.
- For a 2-D look, use a line border.

  Use the ForegroundColor property to specify the line border color.

BorderWidth — Width of uipanel border

1 (default) | positive integer value

Width of the uipanel border, specified as a positive integer value. The unit of measurement is pixels. Etched and beveled borders wider than three pixels might not appear correctly at the corners.

HighlightColor — Uipanel 3-D frame highlight color

RGB triplet | short name | long name

Uipanel 3-D frame highlight color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

ShadowColor — Uipanel border shadow color

RGB triplet | short name | long name

Uipanel border shadow color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Clipping — Clipping of child components to uipanel

'on' (default) | 'off'

Note: The behavior of the Clipping property has changed. It no longer has any effect on uipanels. Child objects are now clipped to the uipanel boundary regardless of the value of this property. This property might be removed in a future release.

Location and Size

`Position` — Location and size of uipanel relative to parent

`[left bottom width height]`

Location and size of the uipanel relative to the parent, specified as the vector, `[left bottom width height]`. This table describes each element in the vector.

Element	Description
`left`	Distance from the inner left edge of the parent container to the outer left edge of the uipanel
`bottom`	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uipanel
`width`	Distance between the right and left outer edges of the uipanel
`height`	Distance between the top and bottom outer edges of the uipanel

All measurements are in units specified by the Units property.

Note: If the parent of the uipanel is a figure, then the Position values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

Example: Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the Position vector. For example, this code changes the width of the uipanel to `0.5`:

```
p = uipanel;
p.Position(3) = 0.5;
p.Position
```

```
ans =
```

```
      0    0    0.5000   1.0000
```

Data Types: `double`

`Units` — Units of measurement

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'pixels'` | `'points'` | `'characters'`

Units of measurement, specified as `'normalized'`, `'inches'`, `'centimeters'`, `'pixels'`, `'points'`, or `'characters'`.

MATLAB uses these units to interpret the location and size values of the Position property:

- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- The size of a uipanel specified in pixel units depends on the system display settings and resolution.
- Characters units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

The order in which you specify the Units and Position properties has these effects:

- If you specify the Units property before the Position property, then MATLAB sets Position using the units you specified.
- If you specify the Units property after the Position property, MATLAB sets the position using the default Units. Then, MATLAB converts the Position values to the equivalent values in the units you specified.

`SizeChangedFcn` — Uipanel resize callback function

`''` (default) | function handle | cell array | string

Uipanel resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uipanel changes.

The SizeChangedFcn callback executes under these circumstances:

- The uipanel becomes visible for the first time.
- The uipanel is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the uipanel.
- The uipanel becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the uipanel is invisible, and then it becomes visible later.

These are some of the important characteristics of the SizeChangedFcn callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the uipanel's SizeChangedFcn uses are defined. This practice can prevent the uipanel's SizeChangedFcn callback from returning an error. To delay the display of the figure, set its Visible property to `'off'`. Then, set the Visible property to `'on'` after you define the variables that your SizeChangedFcn callback uses.
- Use the `gcbo` function in your SizeChangedFcn code to get the uipanel object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcbo`.
- All visible Uipanels that are specified in normalized units resize before the parent figure does. All visible, nested uipanels resize from inside-out.

Tip As an easy alternative to specifying a SizeChangedFcn callback, you can set the Units property of all the objects you put inside the uipanel to `'normalized'`. Doing so makes those components scale proportionally with the uipanel.

See "Managing the Layout in Resizable UIs" for more information on controlling the resize behavior of programmatic UIs.

See Resize Behavior for more information on the resize behavior of GUIDE UIs.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`ResizeFcn` — Uipanel resize callback function

`''` (default) | function handle | cell array | string

Callback function that executes when the uipanel size changes, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Note: Use of the ResizeFcn property is not recommended. It might be removed in a future release. Use SizeChangedFcn instead.

Data Types: `function_handle | cell | char`

Font Style

`FontName` — Font for displaying uipanel title

string

Font for displaying the uipanel title, specified as a string. To display and print properly, the font name must refer to a font that the user's system supports. The default font is system dependent.

To use a fixed-width font, set the FontName property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root FixedWidthFontName property, which you can set in the `startup.m` file.

See "Startup Options in MATLAB Startup File" for more information about the `startup.m` file.

Example: `'Arial'`

`FontSize` — Font size for uipanel title

positive number

Font size for the uipanel title, specified as a positive number. The FontUnits property specifies the units. The default size is system-dependent.

Example: `12`

Example: `12.5`

Data Types: `double`

`FontUnits` — Units of font size for uipanel title

`'points'` (default) | `'inches'` | `'centimeters'` | `'normalized'` | `'pixels'`

Units of font size for the uipanel title, specified as `'points'`, `'inches'`, `'centimeters'`, `'normalized'`, or `'pixels'`.

If you set this property to `'normalized'`, then MATLAB interprets the font size as a fraction of the uipanel height. When you resize the uipanel, MATLAB scales the displayed font to maintain that fraction.

The other FontUnits options (`pixels`, `inches`, `centimeters`, and `points`) are absolute units. 1 point = 1/72 inch.

`FontWeight` — Font weight for the uipanel title

`'normal'` (default) | `'bold'`

Font weight of uipanel title, specified as a value from the following table.

FontWeight Value	Description
`'normal'`	Normal font weight
`'bold'`	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the `FontWeight` property, the result might appear the same as the default.

Note: The `'light'` and `'demi'` font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

FontAngle — Character slant of the uipanel title

'normal' (default) | 'italic'

Character slant of uipanel title, specified as 'normal' or 'italic'. MATLAB uses this property to select a font from those available on your system. Setting this property to 'italic' selects a slanted version of the font, if it is available on your system.

Note: The 'oblique' value has been removed. Use 'italic' instead.

Text

Title — Uipanel title

string

Uipanel title, specified as a string.

MATLAB does not interpret a vertical slash ('|') character as a line break, it displays as a vertical slash in the uipanel title.

If you want to specify a Unicode character, pass the Unicode decimal code to the char function. For example, ['Multiples of ' char(960)] displays as Multiples of π.

Example: 'Options'

Example: ['Multiples of ' char(960)]

TitlePosition — Location of uipanel title

'lefttop' (default) | 'centertop' | 'righttop' | 'leftbottom' | 'centerbottom' | 'righttbottom'

Location of the uipanel title, specified as 'lefttop', 'centertop', 'righttop', 'leftbottom', 'centerbottom', or 'righttbottom'.

Interactive Control

ButtonDownFcn — Button-press callback function

'' (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The ButtonDownFcn callback is a function that executes when the user clicks a mouse button on the uipanel.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`UIContextMenu` — Uipanel context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu object

Uipanel context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the uipanel. Create the context menu using the `uicontextmenu` function.

`Selected` — Selection status of uipanel

`'off'` (default) | `'on'`

Note: The behavior of the Selected property changed in R2014b, and it is not recommended. It no longer has any effect on uipanels. This property might be removed in a future release.

`SelectionHighlight` — Ability to highlight selection handles

`'on'` (default) | `'off'`

Note: The behavior of the SelectionHighlight property changed in R2014b, and it is not recommended. It no longer has any effect on uipanels. This property might be removed in a future release.

Callback Execution Control

`Interruptible` — Callback interruption

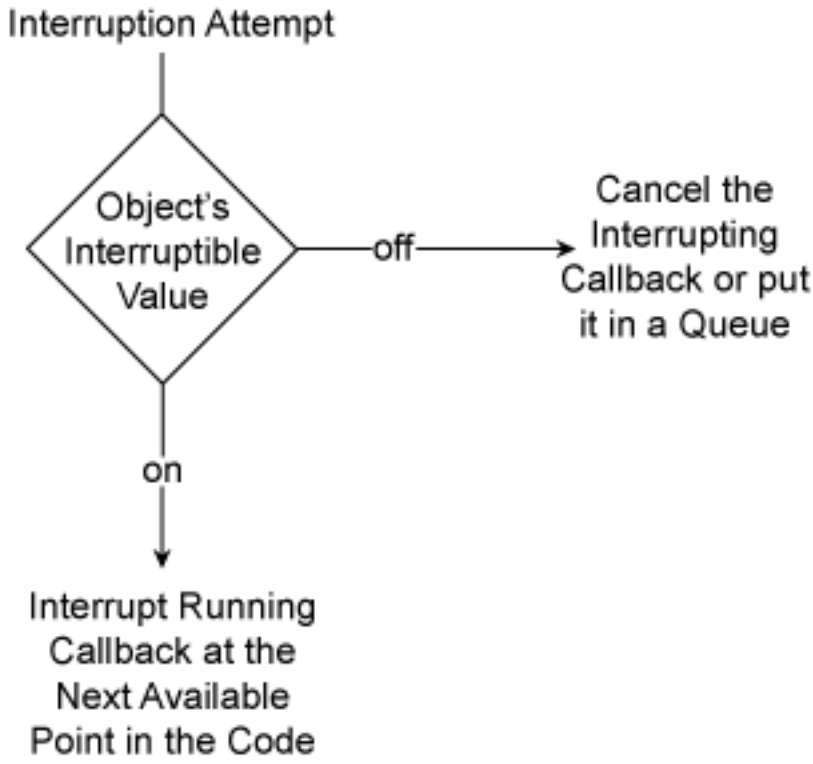
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uipanel callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See "Interrupt Callback Execution" for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See "Interrupt Callback Execution" for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

Ability to become current object, specified as `'on'` or `'off'`:

- Setting the value to `'on'` allows the uipanel to become the current object when the user clicks on it. A value of `'on'` also allows the figure CurrentObject property and the `gco` function to report the uipanel as the current object.
- Setting the value to `'off'` sets the figure CurrentObject property to an empty `GraphicsPlaceholder` array when the user clicks on the uipanel.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uipanel

`'off'` (default) | `'on'`

Deletion status of uipanel, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uipanel begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uipanel no longer exists.

Check the value of the BeingDeleted property to verify that the uipanel is not about to be deleted before querying or modifying it.

`CreateFcn` — Uipanel creation function

function handle | cell array | string

Uipanel creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uipanel. MATLAB initializes all uipanel property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uipanel that is being created.

Setting the CreateFcn property on an existing uipanel has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uipanel object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uipanel deletion function

function handle | cell array | string

Uipanel deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uipanel (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the uipanel. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uipanel that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object
`'uipanel'`

Type of graphics object, returned as `'uipanel'`.

`Tag` — Uipanel identifier
`''` (default) | string

Uipanel identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uipanel. When you need access to the uipanel elsewhere in your code, you can use the `findobj` function to search for the uipanel based on the Tag value.

Example: `'panel1'`

Data Types: `char`

`UserData` — Data to associate with the uipanel object
empty array (default) | array

Data to associate with the uipanel object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uipanel parent

figure | uipanel | uibuttongroup | uitab

Uipanel parent, specified as a figure, uipanel, uibuttongroup, or uitab. You can move a uipanel to a different figure, uipanel, uibuttongroup, or uitab by setting this property to the handle of the target figure, uipanel, uibuttongroup, or uitab.

`Children` — Children of uipanel

empty `GraphicsPlaceholder` array (default) | 1-D array of component objects

Children of uipanel, returned as an empty `GraphicsPlaceholder` or a 1-D array of component objects. The children of uipanel can be axes, uipanels, uibuttongroups, and uicontrols.

You cannot add or remove children using the `Children` property of the uipanel. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the uipanel object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of Uipanel handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uipanel handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uipanel handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not

visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uipanel handle is always visible.
`'callback'`	The uipanel handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uipanel at the command-line, but allows callback functions to access it.
`'off'`	The uipanel handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

uipushtool

Create push button on toolbar

Syntax

```
p = uipushtool
p = uipushtool(Name,Value,...)
p = uipushtool(parent)
p = uipushtool(parent,Name,Value,...)
```

Description

`p = uipushtool` creates a uipushtool in the current figure's uitoolbar and returns the uipushtool object, `p`. If there is no uitoolbar available, then MATLAB creates a new uitoolbar in the current figure to serve as the parent. Similarly, if there no figure is available, then MATLAB creates a new figure with a uitoolbar.

`p = uipushtool(Name,Value,...)` creates a uipushtool and specifies one or more uipushtool property names and corresponding values. Use this syntax to override the default uipushtool properties.

`p = uipushtool(parent)` creates a uipushtool and designates a specific parent object. The `parent` argument must be a uitoolbar object.

`p = uipushtool(parent,Name,Value,...)` creates a uipushtool with a specific parent and one or more uipushtool properties.

A uipushtool is a push button that appears in the figure's tool bar. The button has no icon, but its borders highlight when the user hovers over it with the mouse. You can create a button icon by setting the uipushtool's `CData` property.

Examples

Create uipushtool With Icon and Tool Tip

```
f  = figure('ToolBar','none');
```

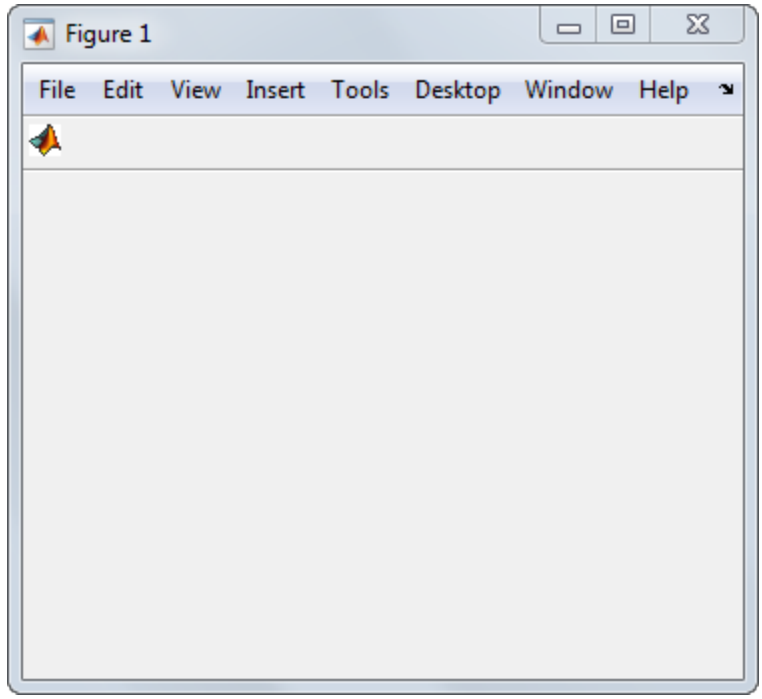
```
t = uitoolbar(f);

% Read an image
[img,map] = imread(fullfile(matlabroot,...
            'toolbox','matlab','icons','matlabicon.gif'));

% Convert image from indexed to truecolor
icon = ind2rgb(img,map);

% Create a uipushtool in the toolbar
p = uipushtool(t,'TooltipString','Toolbar push button',...
                 'ClickedCallback',...
                 'disp(''Clicked uipushtool.'')');

% Set the button icon
p.CData = icon;
```



More About

Tips

- Uitoolbars (and their child uipushtools) do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing a uitoolbar is changed to `'Modal'`, the uitoolbar still exists in the `Children` property of the figure. However, the uitoolbar does not display while WindowStyle is set to `'Modal'`.
- Unlike uicontrol push buttons, uipushtools do not set the figure's `SelectionType` property to `'open'` on the second click.

Uipushtool Properties | `uitoggletool` | `uitoolbar`

Introduced before R2006a

Uipushtool Properties

Control appearance and behavior of uipushtool

Uipushtools are push buttons that appear on the tool bar at the top of the a figure. The `uipushtool` function creates a push button on a tool bar and sets any required properties before displaying it. By changing uipushtool property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
p = uipushtool;
sep = p.Separator;
p.Separator = 'on';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uipushtool visibility

`'on'` (default) | `'off'`

Uipushtool visibility, specified as `'on'` or `'off'`. When the Visible property is set to `'off'`, the uipushtool is not visible, but you can query and set its properties.

`Separator` — Separator line mode

`'off'` (default) | `'on'`

Separator line mode, specified as `'off'` or `'on'`. Setting this property to `'on'` draws a dividing line to left of the uipushtool.

`CData` — Optional image to display on uipushtool

3-D array of truecolor RGB values

Optional image to display on the uipushtool, specified as a 3-D array of truecolor RGB values. The values in the array can be:

- Double-precision values between `0.0` and `1.0`
- `uint8` values between `0` and `255`

The length of the array's first and second dimensions must be less than or equal to 16. Otherwise, it might be clipped or distorted when it displays.

Data Types: `double` | `uint8`

Interactive Control

`ClickedCallback` — Callback function that executes when user clicks uipushtool

`''` (default) | function handle | cell array | string

Callback function that executes when a user clicks the uipushtool, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying callback functions as function handles, cell arrays, or strings, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

`Enable` — Operational state of uipushtool

`'on'` (default) | `'off'`

Operational state of uipushtool, specified as `'on'` or `'off'`. The `Enable` property controls whether the uipushtool responds to button clicks. The are two possible values:

- `'on'` – The uipushtool is operational.
- `'off'` – The uipushtool is not operational and appears grayed out.

The value of the `Enable` property and the type of button click determine the response.

Enable Value	Response to Left-Click	Response to Right-Click
`'on'`	The uipushtool's `ClickedCallback` function executes.	The uipushtool is not operational. No callback executes.

Enable Value	Response to Left-Click	Response to Right-Click
`'off'`	The uipushtool is not operational. No callback executes.	The uipushtool is not operational. No callback executes.

`TooltipString` — Tooltip text

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the uipushtool and leaves it there, the tooltip appears.

Example: `'Some string'`

`UIContextMenu` — Context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu handle

This property has no effect on uipushtools.

Callback Execution Control

`Interruptible` — Callback interruption

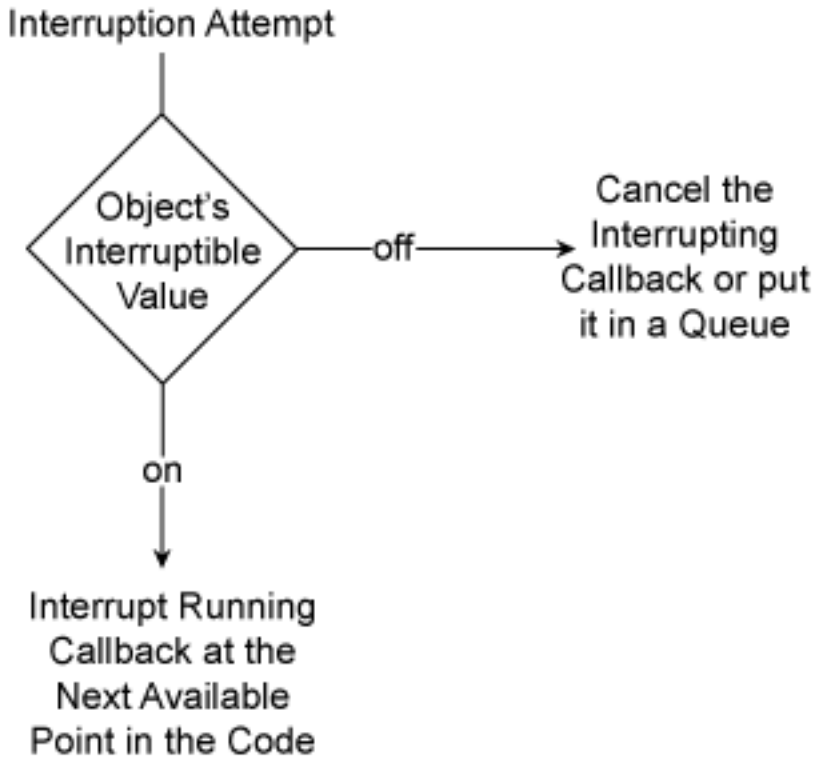
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uipushtool callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See “Interrupt Callback Execution” for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

This property has no effect on the uipushtool.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uipushtool

`'off'` (default) | `'on'`

Deletion status of uipushtool, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uipushtool begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uipushtool no longer exists.

Check the value of the BeingDeleted property to verify that the uipushtool is not about to be deleted before querying or modifying it.

`CreateFcn` — Uipushtool creation function

function handle | cell array | string

Uipushtool creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uipushtool. MATLAB initializes all uipushtool property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uipushtool that is being created.

Setting the CreateFcn property on an existing uipushtool has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uipushtool object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uipushtool deletion function

function handle | cell array | string

Uipushtool deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uipushtool (for example, when the end user deletes the figure). MATLAB executes

the DeleteFcn callback before destroying the properties of the uipushtool. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uipushtool that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object

`'uipushtool'`

Type of graphics object, returned as `'uipushtool'`.

`Tag` — Uipushtool identifier

`''` (default) | string

Uipushtool identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uipushtool. When you need access to the uipushtool elsewhere in your code, you can use the `findobj` function to search for the uipushtool based on the Tag value.

Example: `'pushtool1'`

Data Types: `char`

`UserData` — Data to associate with the uipushtool object

empty array (default) | array

Data to associate with the uipushtool object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uipushtool parent

uitoolbar

Uipushtool parent, specified as a uitoolbar. You can move a uipushtool to a different uitoolbar by setting this property to the handle of the target uitoolbar.

`HandleVisibility` — Visibility of Uipushtool handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uipushtool handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uipushtool handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uipushtool handle is always visible.
`'callback'`	The uipushtool handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uipushtool at the command-line, but allows callback functions to access it.
`'off'`	The uipushtool handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

uiputfile

Open dialog box for saving files

Syntax

```
FileName = uiputfile
[FileName,PathName] = uiputfile
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle)
[FileName,PathName,FilterIndex] =
uiputfile(FilterSpec,DialogTitle,DefaultName)
```

Description

Note: Successful execution of `uiputfile` does not create a file; it only returns the name of a new or existing file that you designate.

`FileName = uiputfile` displays a modal dialog box for selecting or specifying a file you want to create or save. The dialog box lists the files and folders in the current folder. If the selected or specified file name is valid, `uiputfile` returns that name in `FileName`.

`[FileName,PathName] = uiputfile` also returns the path to `FileName` in `PathName`, or if you cancel the dialog, returns `0` for both arguments. If you do not provide any output arguments, the file name alone is returned in `ans`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uiputfile` also displays in gray any files that do not match `FilterSpec`. The `uiputfile` function appends `'All Files'` to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the `*` and `?` wildcard characters. For example, `'*.m'` lists all MATLAB program files in a folder.

`FilterSpec` can be a string that contains a file name. `uiputfile` displays the file name selected in the **File name** field and uses the file extension as the default filter.

The `FilterSpec` string can include a path, or consist of a path only. To specify a folder only, make the last character in `DefaultName` `'\'` or `'/'`. A path can contain special path characters, such as `'.'`, `'..'`, `'/'`, `'\'`, or `'~'`. For example, `'../*.m'` lists all program files in the folder above the current folder. If `FilterSpec` is a cell array of strings, the first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace the default descriptions in the **Save as type** pop-up menu. A description cannot be an empty string. See the "Examples" on page 1-8549 for illustration of using cell arrays as `FilterSpec`. If you do not specify `FilterSpec`, `uiputfile` uses the default list of file types (all MATLAB files). `FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click the **Cancel** button, the window's close box, or if the file does not exist, `uiputfile` returns `FilterIndex` as `0`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle)` displays a dialog box that has the title `DialogTitle`. To use the default file types and to specify a dialog title, enter `uiputfile('','DialogTitle')`

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle,DefaultName)` displays a dialog box in which the file name specified by `DefaultName` appears in the **File name** field. `DefaultName` can also be a path or a path+filename. To specify a folder only, make the last character in `DefaultName` `'\'` or `'/'`. In this case, `uiputfile` opens the dialog box in the folder specified by the path. If you specify a path in `DefaultName` that does not exist, `uiputfile` opens the dialog box in the current folder. You can use `'.'`,`'..'`, `'\'`, `'/'`, or ~ in the `DefaultName` argument.

When typing into the dialog box, if you include either of the wildcard characters `'*'` or `'?'` in a file name, `uiputfile` does not respond to clicking **Save**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

If you select or specify an existing file name, a warning dialog box opens stating that the file already exists and asks if you want to replace it.

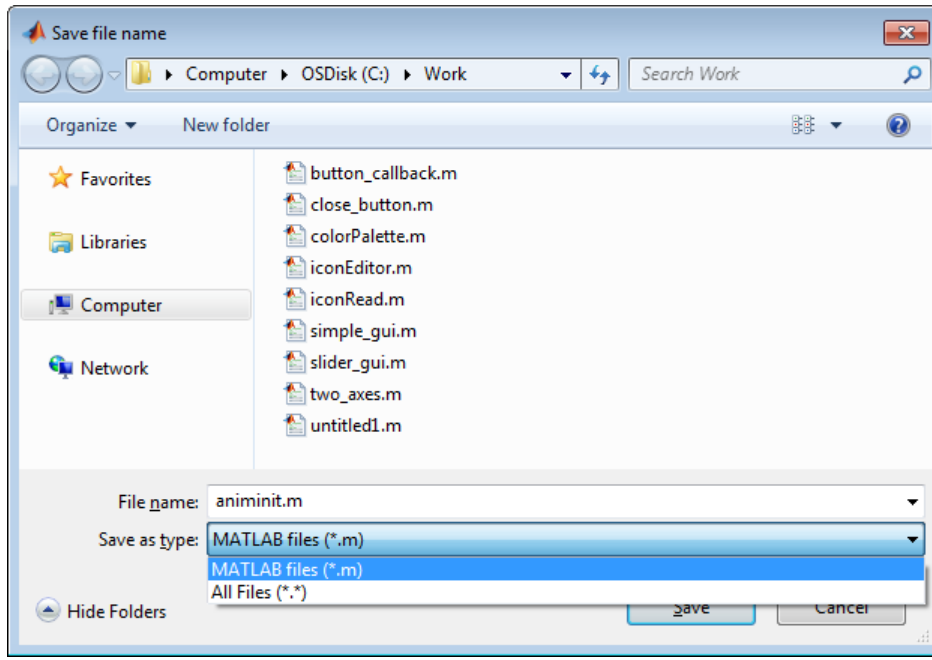
Select **Yes** to replace the existing file or **No** to return to the dialog to select another file name. Selecting **Yes** returns the name of the file. Selecting **No** returns `0`.

The visual characteristics of the dialog box depend on the operating system that is running MATLAB.

Examples

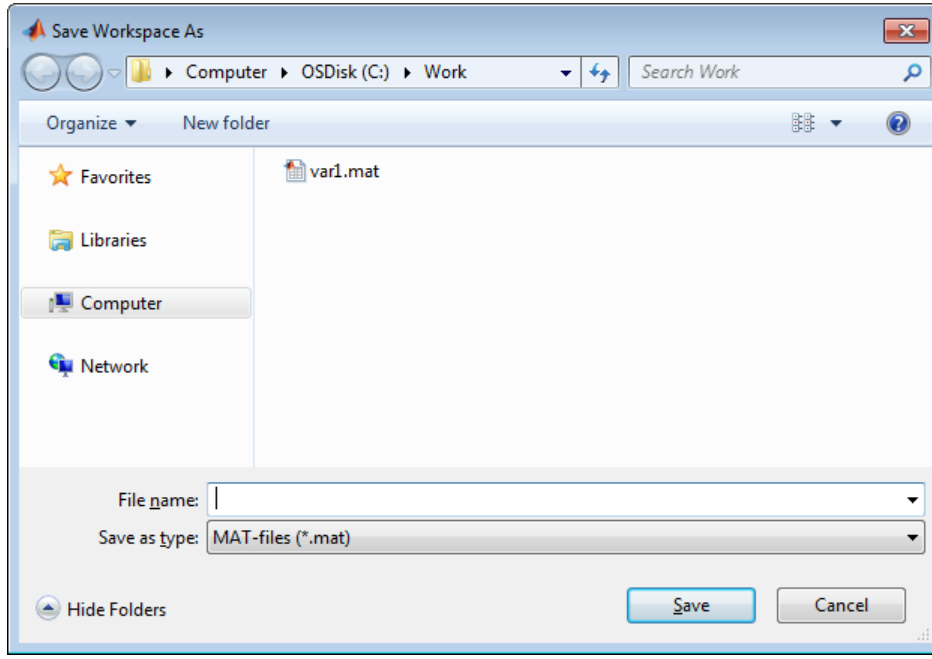
The following statement displays a dialog box entitled `'Save file name'`. This command also sets the **File name** field to `aminimit.m`, and it sets the filter to `program files (*.m)`.

```
[file,path] = uiputfile('aminimit.m','Save file name');
```



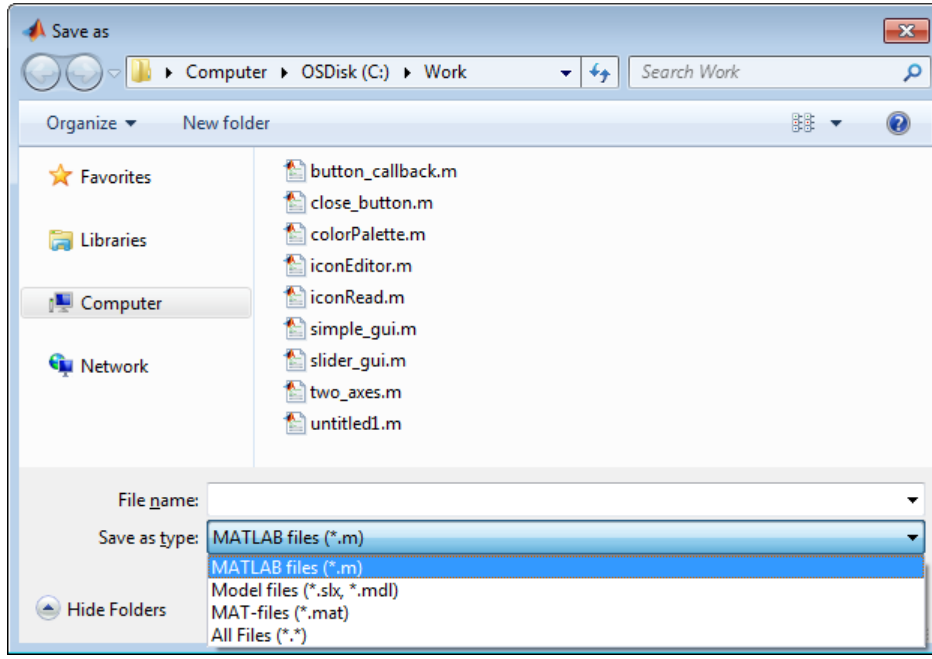
The following statement displays a dialog box entitled `'Save Workspace As'` with the filter set to MAT-files.

```
[file,path] = uiputfile('*.mat','Save Workspace As');
```



To display several file types in the **Save as type** list box, separate each file extension with a semicolon, as in the following code. `uiputfile` displays a default description for each known file type, such as "Model files" for Simulink `.mdl` and `.slx` files.

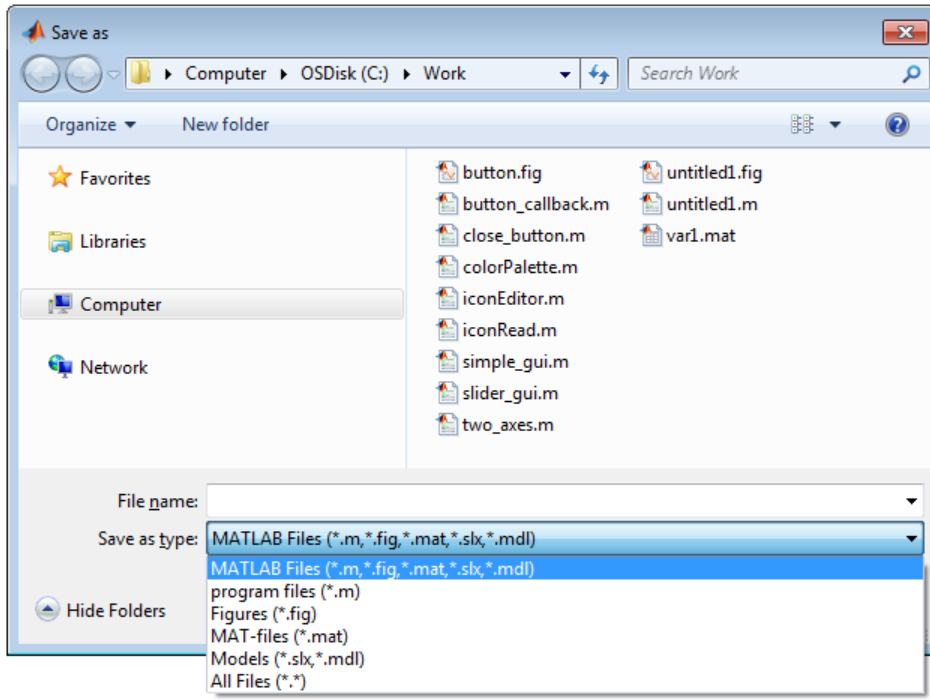
```
[filename, pathname] = uiputfile(...
 {'*.m';'*.slx';'*.mat';'*.*'},...
 'Save as');
```



To create a list of file types and give them descriptions that are different from the defaults, use a cell array. This example also associates multiple file types with the `'MATLAB Files'` and `'Models'` descriptions.

```
[filename, pathname, filterindex] = uiputfile( ...
{'*.m;*.fig;*.mat;*.slx;*.mdl',...
 'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
 '*.m', 'program files (*.m)';...
 '*.fig','Figures (*.fig)';...
 '*.mat','MAT-files (*.mat)';...
 '*.slx;*.mdl','Models (*.slx,*.mdl)';...
 '*.*',  'All Files (*.*)'},...
 'Save as');
```

The first column of the cell array contains the file extensions, while the second contains the descriptions you want to provide for the file types. The first entry of column one contains several extensions separated by semicolons. These file types all associate with the description `'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)'`. The code produces the dialog box shown in the following figure.



The following code checks for the existence of the file and displays a message about the result of the file selection operation.

```
[filename, pathname] = uiputfile('*.m',...
                       'Pick a MATLAB program file');
if isequal(filename,0) || isequal(pathname,0)
   disp('User selected Cancel')
else
   disp(['User selected ',fullfile(pathname,filename)])
end
```

Select or enter a file name for saving a figure as an image in one of four formats, described in a cell array.

```
uiputfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
          '*.*','All Files' },'Save Image',...
          'C:\Work\newfile.jpg')
```

`save` | `uigetdir` | `uisave` | `uigetfile`

Introduced before R2006a

uiresume

Resume execution of blocked program

Syntax

```
uiresume(h)
```

Description

`uiresume(h)` resumes the program execution that `uiwait` suspended.

Examples

This example code creates a window containing a push button. The `uiwait` function blocks MATLAB execution until the user clicks the push button.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
              'Callback','uiresume(gcbf)');
disp('This will print immediately');
uiwait(gcf);
disp('This will print after you click Continue');
close(f);
```

The `gcbf` function returns the current figure.

More About

Tips

The `uiwait` and `uiresume` functions block and resume MATLAB program execution. When creating a dialog box, you should have a uicontrol component with a callback that calls `uiresume` or a callback that destroys the dialog box. These are the only methods that resume program execution after the `uiwait` function blocks execution.

When used in conjunction with a modal dialog box, `uiresume` can resume the execution of the program that `uiwait` suspended while presenting a dialog box.

Introduced before R2006a

uisave

Open dialog box for saving variables to MAT-file

Syntax

```
uisave
uisave(variables)
uisave(variables,filename)
```

Description

`uisave`, with no arguments, prompts you for a file name, and then saves all variables from your workspace to that file.

`uisave(variables)` saves one or more workspace variables listed in variables. The variables argument is a string or a cell array of strings.

`uisave(variables,filename)` uses the specified filename as the default **File name** in the Save Workspace Variables dialog box, instead of the default `matlab.mat`.

Input Arguments

`variable`

String containing the name of a variable in the current workspace or cell array of strings when specifying more than one variable.

Default: All variables in the current workspace are saved to a MAT-file.

`filename`

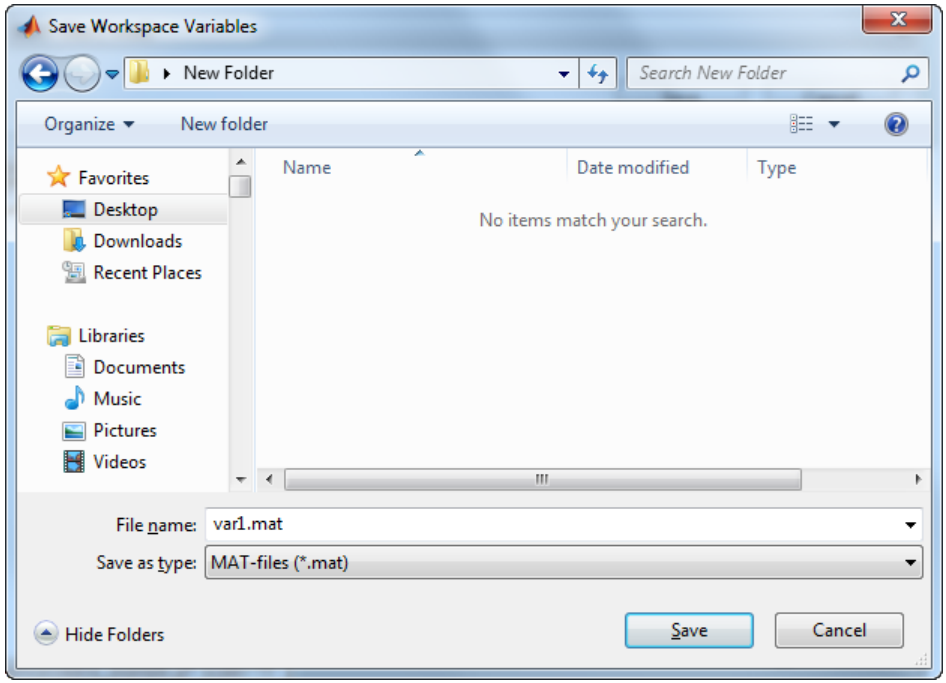
String naming a file to appear in the dialog **File name** field when the dialog opens. You can omit a file extension, or specify the file extension as `.mat`.

Default: `matlab.mat`

Examples

Create workspace variables `h` and `g`, and then display the Save Workspace Variables dialog box in the current folder with the default **File name** set to `var1`.

```
h = 365;
g = 52;
uisave({'h','g'},'var1');
```



Clicking **Save** stores the workspace variables `h` and `g` in the file `var1.mat` in the displayed folder.

More About

Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in Figure Properties.

Tips

- If you type a name in the **File name** field, such as `my_vars`, and click **Save**, the dialog saves all workspace variables to the file `my_vars.mat`. The default filename is `matlab.mat`.
- `uisave` calls `uiputfile` to choose a filename.
- If the filename you specify exists in that folder, `uisave` informs you and gives you a chance to cancel the operation.
- The `uisave` dialog box is modal.
- The `uisave` dialog is modal. A modal dialog box prevents you from interacting with other windows until you respond to it.
- "Save, Load, and Delete Workspace Variables"

uisetcolor

Open color selection dialog box

Syntax

```
c = uisetcolor
c = uisetcolor([r g b])
c = uisetcolor(h)
c = uisetcolor(...,'dialogTitle')
```

Description

`c = uisetcolor` displays a modal color selection dialog appropriate to the platform, and returns the color selected by the user. The dialog box is initialized to `white`.

`c = uisetcolor([r g b])` displays a dialog box initialized to the specified color, and returns the color selected by the user. `r`, `g`, and `b` must be values between 0 and 1.

`c = uisetcolor(h)` displays a dialog box initialized to the color of the object specified by handle `h`, returns the color selected by the user, and applies it to the object. `h` must be the handle to an object containing a color property.

`c = uisetcolor(...,'dialogTitle')` displays a dialog box with the specified title.

If the user presses **Cancel** from the dialog box, or if any error occurs, the output value is set to the input RGB triple, if provided; otherwise, it is set to 0.

More About

Modal Dialog

A window that blocks interaction with other windows until the user closes the blocking window. For more information, see the figure `WindowStyle` property description.

Introduced before R2006a

uisetfont

Open font selection dialog box

Syntax

```
uisetfont
uisetfont(h)
uisetfont(S)
uisetfont(...,'DialogTitle')
S = uisetfont(...)
```

Description

`uisetfont` enables you to change font properties (`FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle`) for a `text`, `axes`, or `uicontrol` object. The function returns a structure consisting of font properties and values. You can specify an alternate title for the dialog box.

`uisetfont` displays a modal dialog box and returns the selected font properties.

Note A modal dialog box prevents the user from interacting with other windows before responding. For more information, see WindowStyle in Figure Properties.

`uisetfont(h)` displays a modal dialog box, initializing the font property values with the values of those properties for the object whose handle is `h`. Selected font property values are applied to the current object. If a second argument is supplied, it specifies a name for the dialog box.

`uisetfont(S)` displays a modal dialog box, initializing the font property values with the values defined for the specified structure (`S`). `S` must define legal values for one or more of these properties: `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` and the field names must match the property names exactly. If other properties are defined, they are ignored. If a second argument is supplied, it specifies a name for the dialog box.

`uisetfont(...,'DialogTitle')` displays a modal dialog box with the title `DialogTitle` and returns the values of the font properties selected in the dialog box.

`S = uisetfont(...)` returns the properties `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` as fields in a structure. If the user presses **Cancel** from the dialog box or if an error occurs, the output value is set to 0.

Examples

These statements create a text object, then display a dialog box (labeled Update Font) that enables you to change the font characteristics:

```
h = text(.5,.5,'Figure Annotation');
uisetfont(h,'Update Font')
```

These statements create two push buttons, then set the font properties of one based on the values set for the other:

```
% Create push button with string ABC
c1 = uicontrol('Style', 'pushbutton', ...
     'Position', [10 10 100 20], 'String', 'ABC');
% Create push button with string XYZ
c2 = uicontrol('Style', 'pushbutton', ...
     'Position', [10 50 100 20], 'String', 'XYZ');
% Display set font dialog box for c1, make selections,
& and save to d
d = uisetfont(c1);
% Apply those settings to c2
set(c2, d)
```

See Also

`axes` | `text` | `uicontrol`

Introduced before R2006a

uisetpref

Manage preferences used in `uigetpref`

Syntax

```
uisetpref('clearall')
```

Description

`uisetpref('clearall')` resets the value of all preferences registered through `uigetpref` to `'ask'`. This causes the dialog box to display when you call `uigetpref`.

Note Use `setpref` to set the value of a particular preference to `'ask'`.

`setpref` | `uigetpref`

Introduced before R2006a

uistack

Reorder visual stacking order of objects

Note: The `uistack` function might return different results, starting in R2014b. For more information about how the stacking behavior of UI components has changed, see "Why Are Some Components Missing or Partially Obscured?".

Syntax

```
uistack(h)
uistack(h,stackopt)
uistack(h,stackopt,step)
```

Description

`uistack(h)` shifts object `h` up one level within the visual stacking order of UI objects. You can also specify `h` to be a vector of UI objects. When `h` is a vector, the objects stack according to their order in the vector. All items in the stack must share the same parent.

`uistack(h,stackopt)` moves the object `h` to another place in the stack according to `stackopt`:

- `'up'` – moves `h` up one position in the stacking order
- `'down'` – moves `h` down one position in the stacking order
- `'top'` – moves `h` to the top of the current stack
- `'bottom'` – moves `h` to the bottom of the current stack

`uistack(h,stackopt,step)` moves object `h` up or down the number of levels specified by `step`. For example, `uistack(h,'up',2)` moves `h` up two levels in the stack.

Examples

Change Stacking Order of Two Plots in a Figure

Create a figure containing a uipanel and a child axes. Then, plot a sine function in the axes.

```
f = figure;
p1 = uipanel(f,'Position',[.10 .10 .80 .80],...
             'Tag','Panel with Sine Plot');
ax1 = axes('Parent',p1,'Position',[.1 .1 .8 .8]);

theta = -3*pi:pi/64:3*pi;
y1 = sin(theta);
plot(ax1,theta,y1);
```

In the same figure, create a second uipanel with a child axes. Then, create a surface plot in this axes.

```
p2 = uipanel(f,'Position',[.10 .10 .80 .80],...
             'Tag','Panel with Surface Plot');
ax2 = axes('Parent',p2,'Position',[.1 .1 .8 .8]);
Z  = peaks(25);
surf(ax2,Z);
```

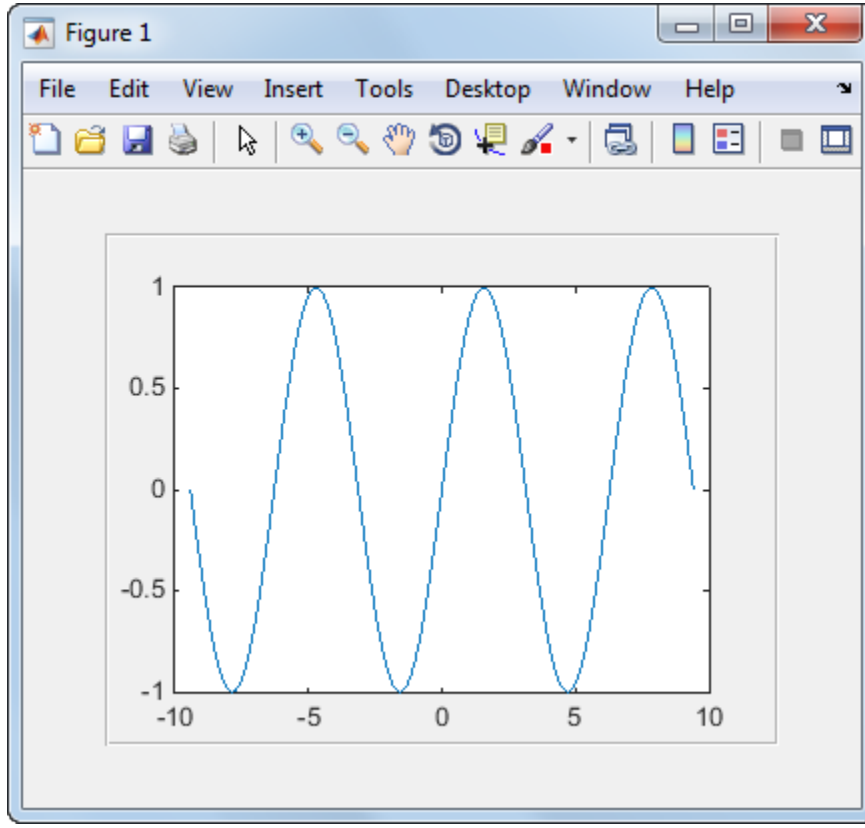
Next, move the uipanel containing the sine function to the top.

```
uistack(p1,'top');
f.Children

ans =

  2x1 Panel array:

  Panel    (Panel with Sine Plot)
  Panel    (Panel with Surface Plot)
```



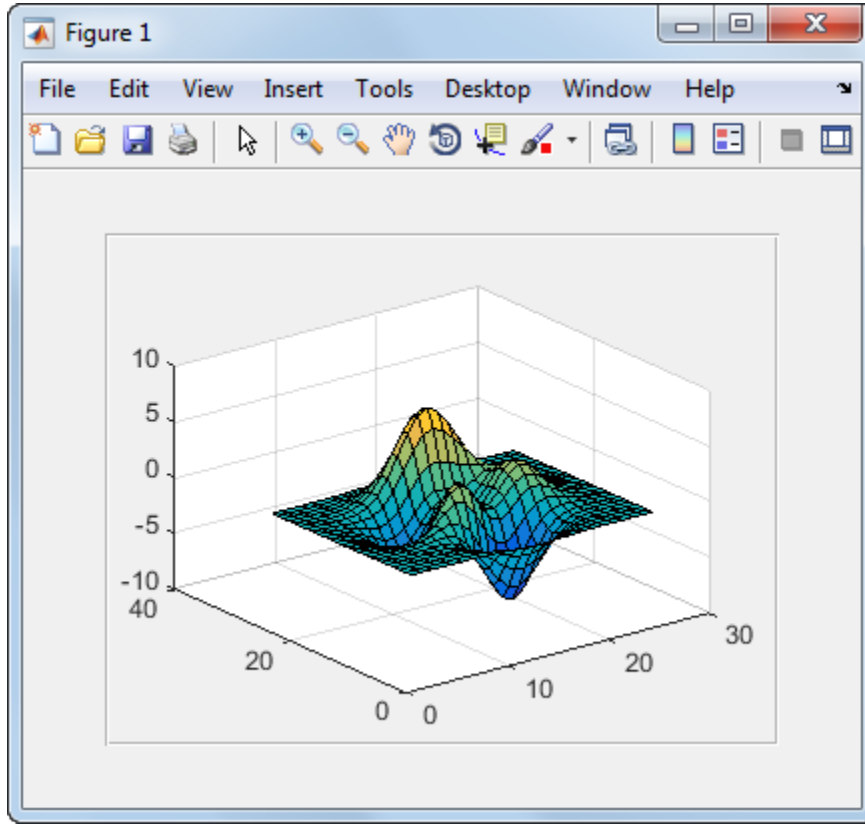
Now, move the other uipanel to the top.

```
uistack(p2,'top');
f.Children
```

```
ans =

  2x1 Panel array:

  Panel    (Panel with Surface Plot)
  Panel    (Panel with Sine Plot)
```



More About

Visual Stacking Order

The order of overlapping components in a UI window. Components on top of the stack appear in front of components that are lower in the stack.

- "Manage the Stacking Order of Grouped Components"

`figure` | `uibuttongroup` | `uipanel` | `uitab`

Introduced before R2006a

uitab

Create tabbed panel

Uitabs are tabbed panels for grouping UI components together. The `uitab` function creates a uitab in a figure and sets any required properties before displaying it.

Syntax

```
t = uitab
t = uitab(Name,Value)

t = uitab(parent)
t = uitab(parent,Name,Value)
```

Description

`t = uitab` creates a uitab in an existing uitabgroup and returns the uitab object in the variable, t. If there is no uitabgroup available, then MATLAB creates a new uitabgroup in a figure to serve as the parent.

`t = uitab(Name,Value)` creates a uitab and specifies one or more uitab property names and corresponding values. Use this syntax to override the default uitab property values.

`t = uitab(parent)` creates a uitab and specifies the parent uitabgroup object for the uitab.

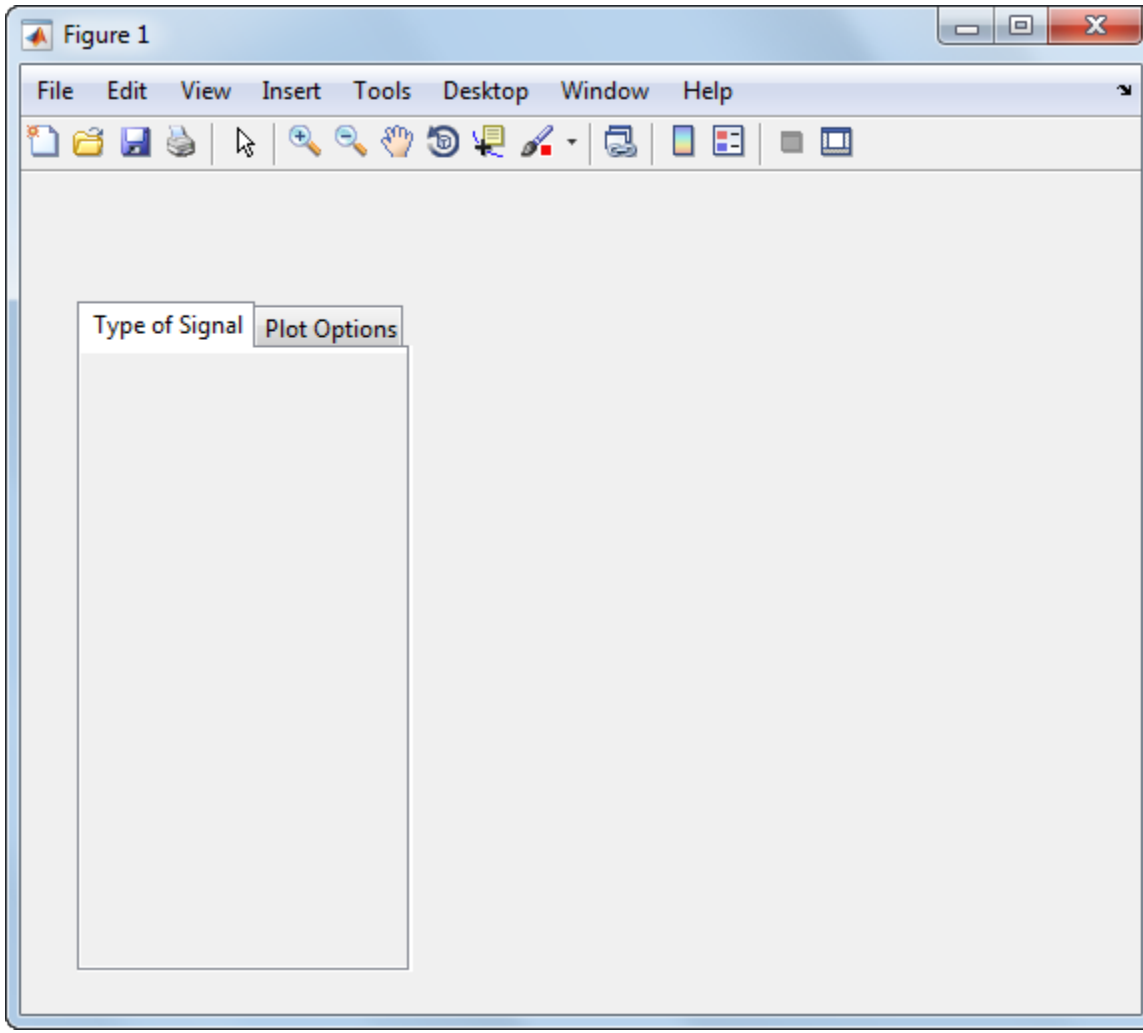
`t = uitab(parent,Name,Value)` creates a uitab with a specific parent and one or more uitab properties.

Examples

Create Two Tabs in a Figure

Create a figure containing a uitabgroup and two uitabs.

```
f = figure;
tabgp = uitabgroup(f,'Position',[.05 .05 .3 .8]);
tab1 = uitab(tabgp,'Title','Type of Signal');
tab2 = uitab(tabgp,'Title','Plot Options');
```



Get the title of the first uitab.

```
tab1.Title
```

```
ans =

Type of Signal
```

Input Arguments

`parent` — Uitab parent

uitabgroup

Uitab parent, specified as a uitabgroup object. You can move a uitab to a different uitabgroup by setting this value to the target uitabgroup object.

Name-Value Pair Arguments

The properties listed here are only a subset, for a complete list see Uitab Properties.

Example: `'Title','Plot Options'`

`'Title'` — uitab title

string

uitab title, specified as a string.

MATLAB does not interpret a vertical slash (`'|'`) character as a line break, it displays as a vertical slash in the uitab title.

If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as Multiples of π.

Example: `'Options'`

Example: `['Multiples of ' char(960)]`

`'BackgroundColor'` — uitab background color

`[.94 .94 .94]` (default) | RGB triplet | short name | long name

uitab background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uitab.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

[0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Note: Some operating systems override the BackgroundColor value.

Data Types: double | char

'Position' — Location and size of uitab relative to parent

[left bottom width height]

Location and size of uitab relative to parent, returned as the vector, [left bottom width height]. The left value is the distance from the inner left edge of the parent container to the outer left edge of the uitab. The bottom value is the distance from the inner bottom edge of the parent container to the outer bottom edge of the uitab. The width value specifies the distance between the right and left outer edges of the uitab. The height value specifies the distance between the top and bottom outer edges of the uitab. All measurements are in units specified by the Units property.

'Units' — Units of measurement

'normalized' (default) | 'inches' | 'centimeters' | 'pixels' | 'points' | 'characters'

Units of measurement, specified as 'normalized', 'inches', 'centimeters', 'pixels', 'points', or 'characters'.

MATLAB uses these units to display the location and size values in the Position property:

- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- The size of a uitab specified in pixel units depends on the system display settings and resolution.
- Characters units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

Uitab Properties | Uitabgroup Properties | `uitabgroup`

Introduced in R2014b

Uitab Properties

Control appearance and behavior of tabbed panel

Uitabs are tabbed panels for grouping UI components together. The `uitab` function creates a uitab in a figure and sets any required properties before displaying it. By changing uitab property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitab;
bgcolor = t.BackgroundColor;
t.BackgroundColor = [.5 .5 .5];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`BackgroundColor` — Uitab background color

`[.94 .94 .94]` (default) | RGB triplet | short name | long name

Uitab background color, specified as an RGB triplet, short name, or long name. The color you specify fills the area bounded by the uitab.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Note: Some operating systems override the `BackgroundColor` value.

Data Types: `double` | `char`

`ForegroundColor` — Uitab title color

`[0 0 0]` (default) | RGB triplet | short name | long name

Uitab title color, specified as an RGB triplet, short name, or long name.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `[0 0 1]`

Example: `'b'`

Example: `'blue'`

Location and Size

`Position` — Location and size of uitab relative to parent
`[left bottom width height]`

Location and size of uitab relative to parent, returned as the vector, `[left bottom width height]`. The `left` value is the distance from the inner left edge of the parent container to the outer left edge of the uitab. The `bottom` value is the distance from the inner bottom edge of the parent container to the outer bottom edge of the uitab. The `width` value specifies the distance between the right and left outer edges of the uitab. The `height` value specifies the distance between the top and bottom outer edges of the uitab. All measurements are in units specified by the Units property.

`Units` — Units of measurement
`'normalized'` (default) | `'inches'` | `'centimeters'` | `'pixels'` | `'points'` | `'characters'`

Units of measurement, specified as `'normalized'`, `'inches'`, `'centimeters'`, `'pixels'`, `'points'`, or `'characters'`.

MATLAB uses these units to display the location and size values in the Position property:

- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- The size of a uitab specified in pixel units depends on the system display settings and resolution.
- Characters units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

`SizeChangedFcn` — Uitab resize callback function
`''` (default) | function handle | cell array | string

Uitab resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uitab changes.

The SizeChangedFcn callback executes in these circumstances:

- The uitab becomes visible for the first time.
- The uitab is visible while its drawable area changes. The drawable area is the area inside the outer bounds of the uitab.
- The uitab becomes visible for the first time after its drawable area changes. This situation occurs when the drawable area changes while the uitab is invisible, and then it becomes visible later.

These are some of the important characteristics of the SizeChangedFcn callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the uitab's SizeChangedFcn uses are defined. This practice can prevent the uitab's SizeChangedFcn callback from returning an error. To delay the display of the figure, set its Visible property to `'off'`. Then, set the Visible property to `'on'` after you define the variables that your SizeChangedFcn callback uses.
- Use the `gcbo` function in your SizeChangedFcn code to get the uitab object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcbo`.
- All visible Uitabs that are specified in normalized units resize before the parent figure does. All visible, nested uitabs resize from inside-out.

Tip As an easy alternative to specifying a SizeChangedFcn callback, you can set the Units property of all the objects you put inside the uitab to `'normalized'`. Doing so makes those components scale proportionally with the uitab.

See"Managing the Layout in Resizable UIs" for more information on controlling the resize behavior of a programmatic UIs.

Example: `@myfun`

Example: `{@myfun,x}`

Text

`Title` — Uitab title

string

Uitab title, specified as a string.

MATLAB does not interpret a vertical slash (`'|'`) character as a line break, it displays as a vertical slash in the uitab title.

If you want to specify a Unicode character, pass the Unicode decimal code to the `char` function. For example, `['Multiples of ' char(960)]` displays as Multiples of π.

Example: `'Options'`

Example: `['Multiples of ' char(960)]`

Interactive Control

`ButtonDownFcn` — Button-press callback function

`''` (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The ButtonDownFcn callback is a function that executes when the user clicks a mouse button on the uitab.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

`UIContextMenu` — Uitab context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu object

Uitab context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the uitab. Create the context menu using the `uicontextmenu` function.

`TooltipString` — Tooltip text

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the uitab and leaves it there, the tooltip displays.

Example: `'Some string'`

Callback Execution Control

`Interruptible` — Callback interruption

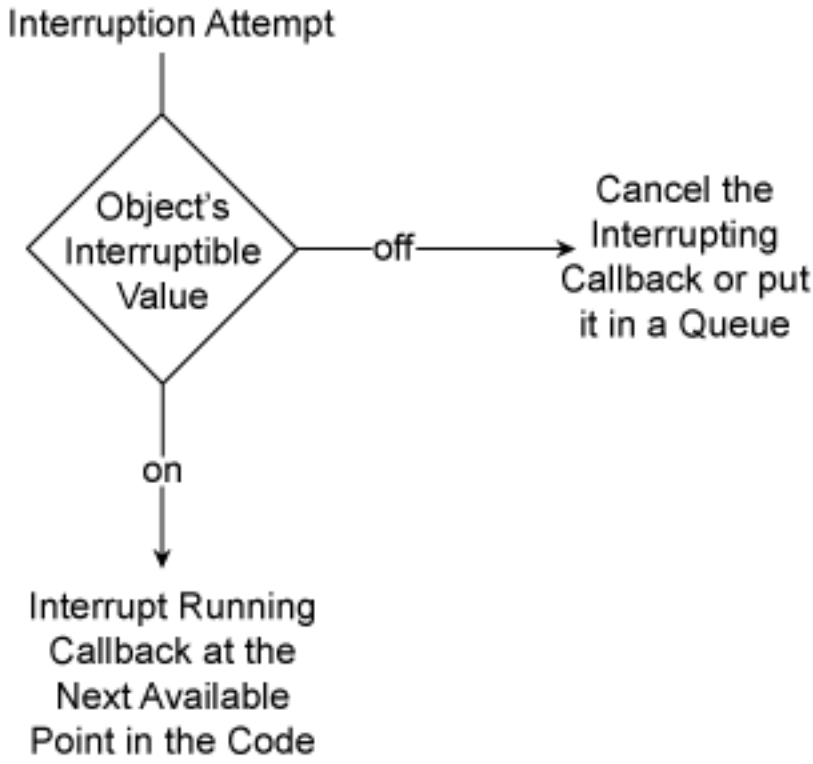
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uitab callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See "Interrupt Callback Execution" for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uitab

`'off'` (default) | `'on'`

Deletion status of uitab, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uitab begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uitab no longer exists.

Check the value of the BeingDeleted property to verify that the uitab is not about to be deleted before querying or modifying it.

`CreateFcn` — Uitab creation function

function handle | cell array | string

Uitab creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uitab. MATLAB initializes all uitab property values before executing the CreateFcn callback.

If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uitab that is being created.

Setting the CreateFcn property on an existing uitab has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uitab object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uitab deletion function

function handle | cell array | string

Uitab deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uitab (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the uitab. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uitab that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

Identifiers

`Type` — Type of graphics object
`'uitab'`

Type of graphics object, returned as `'uitab'`.

`Tag` — Uitab identifier
`''` (default) | string

Uitab identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uitab. When you need access to the uitab elsewhere in your code, you can use the `findobj` function to search for the uitab based on the Tag value.

Example: `'tab1'`

Data Types: `char`

`UserData` — Data to associate with the uitab object
empty array (default) | array

Data to associate with the uitab object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uitab parent
uitabgroup

Uitab parent, specified as a uitabgroup. You can move a uitab to a different uitabgroup by setting this property to the handle of the target uitabgroup.

`Children` — Children of uitab

empty `GraphicsPlaceholder` array (default) | 1-D array of component objects

Children of uitab, returned as an empty `GraphicsPlaceholder` or a 1-D array of UI component objects. The children of uitab can be axes, uipanels, uibuttongroups, and uicontrols.

You cannot add or remove children using the `Children` property of the uitab. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the front-to-back order (stacking order) of the components on the screen.

To add a child to this list, set the `Parent` property of the child component to be the uitab object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of Uitab handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uitab handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uitab handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uitab handle is always visible.
`'callback'`	The uitab handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitab at the command-line, but allows callback functions to access it.

HandleVisibility Value	Description
`'off'`	The uitab handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

More About

- “Access Property Values”
- “Default Property Values”

uitabgroup

Create container for tabbed panels

Uitabgroups are uitab containers. They allow you to group uitabs together, identify the currently selected uitab, and detect when the user selects a different uitab.

Syntax

```
g = uitabgroup
g = uitabgroup(Name,Value)

g = uitabgroup(parent)
g = uitabgroup(parent,Name,Value)
```

Description

`g = uitabgroup` creates a uitabgroup in the current figure and returns the uitabgroup object in the variable, g. If no figure exists, then MATLAB creates a new figure and places the uitabgroup in it.

`g = uitabgroup(Name,Value)` creates a uitabgroup and specifies one or more uitabgroup property names and corresponding values. Use this syntax to override the default uitabgroup property values.

`g = uitabgroup(parent)` creates a uitabgroup and specifies the parent object for the uitabgroup (a figure, uipanel, or uibuttongroup).

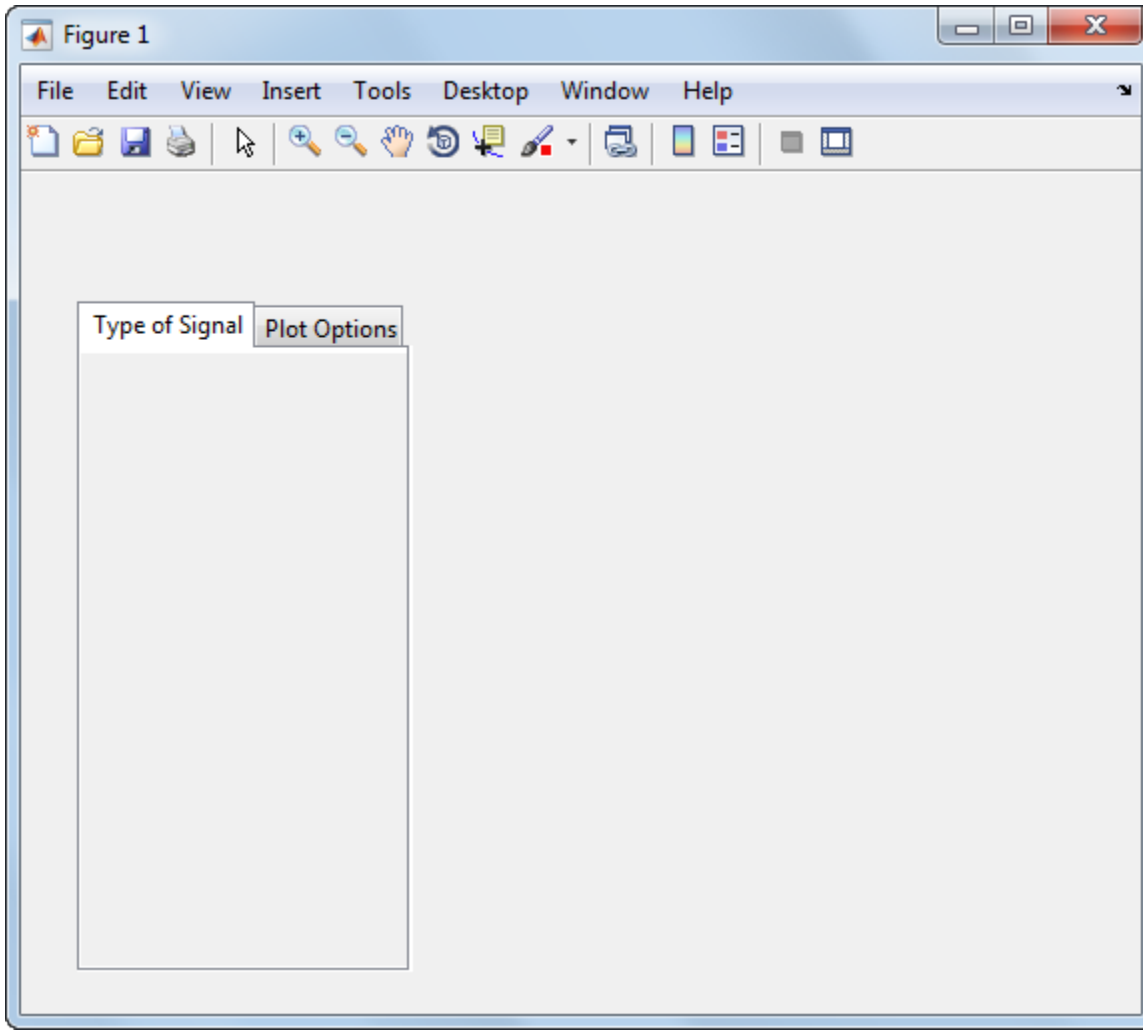
`g = uitabgroup(parent,Name,Value)` creates a uitabgroup with a specific parent and one or more uitabgroup properties.

Examples

Create Two Tabs in a Figure

Create a figure containing a uitabgroup and two uitabs.

```
f = figure;
tabgp = uitabgroup(f,'Position',[.05 .05 .3 .8]);
tab1 = uitab(tabgp,'Title','Type of Signal');
tab2 = uitab(tabgp,'Title','Plot Options');
```



Get the currently selected uitab.

```
currenttab = tabgp.SelectedTab
```

```
currenttab =

  Tab (Type of Signal) with properties:

              Title: 'Type of Signal'
    BackgroundColor: [0.9400 0.9400 0.9400]
           Position: [0.0119 0.0089 0.9702 0.9107]
              Units: 'normalized'
```

Input Arguments

`parent` — Uitabgroup parent

figure | uipanel | uitab

Uitabgroup parent, specified as a figure, uipanel, or uitab object. You can move a uitabgroup to a different figure, uipanel, or uitab by setting this value to the target parent object.

Name-Value Pair Arguments

The properties listed here are only a subset, for a complete list see Uitabgroup Properties.

Example: `'TabLocation','left'`

`'SelectedTab'` — Currently selected tab

uitab object

Currently selected tab, specified as a uitab object.

Use this property to determine the currently selected uitab within a uitabgroup. You can also use this property to set the default uitab selection.

The default value of the SelectedTab property is the first uitab that you add to the uitabgroup.

`'SelectionChangedFcn'` — Uitab selection callback

`''` (default) | function handle | cell array | string

Uitab selection callback, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This callback function executes when the user selects a different tab within the uitabgroup.

If you set the SelectionChangedFcn property to a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Callbackdata Field	Description
`OldValue`	Previously selected uitab, or `[]` if none was selected
`NewValue`	Currently selected uitab
`Source`	The parent uitabgroup object
`EventName`	`'SelectionChange'`

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

`'TabLocation'` — Tab label location

`'top'` (default) | `'bottom'` | `'left'` | `'right'`

Tab label location, specified as `'top'`, `'bottom'`, `'left'`, or `'right'`. This property specifies the location of the tab labels with respect to the uitabgroup.

`'Position'` — Location and size of uitabgroup relative to parent

`[left bottom width height]`

Location and size of the uitabgroup relative to the parent, specified as the vector, `[left bottom width height]`. This table describes each element in the vector.

Element	Description
`left`	Distance from the inner left edge of the parent container to the outer left edge of the uitabgroup
`bottom`	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uitabgroup
`width`	Distance between the right and left outer edges of the uitabgroup
`height`	Distance between the top and bottom outer edges of the uitabgroup

All measurements are in units specified by the Units property.

Note: If the parent of the uitabgroup is a figure, then the Position values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

Example: Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the Position vector. For example, this code sets the width of the uitabgroup to `.5` without changing any of the other Position values:

```
tg = uitabgroup;
tg.Position(3) = .5;
```

`'Units'` — Units of measurement
`'normalized'` (default) | `'inches'` | `'centimeters'` | `'pixels'` | `'points'` | `'characters'`

Units of measurement, specified as `'normalized'`, `'inches'`, `'centimeters'`, `'pixels'`, `'points'`, or `'characters'`.

MATLAB uses these units to interpret the location and size values of the Position property:

- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.

- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- The size of a uitabgroup specified in pixel units depends on the system display settings and resolution.
- Characters units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

The order in which you specify the Units and Position properties has these effects:

- If you specify the Units property before the Position property, then MATLAB sets Position using the units you specified.
- If you specify the Units property after the Position property, MATLAB sets the position using the default Units. Then, MATLAB converts the Position values to the equivalent values in the units you specified.

See Also

Uitab Properties | `uitab` | Uitabgroup Properties

Introduced in R2014b

Uitabgroup Properties

Control appearance and behavior of tabbed panel container

Uitabgroups are uitab containers that allow to you identify the currently selected uitab and detect when the user selects a different uitab. By changing uitabgroup property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
g = uitabgroup;
pos = g.Position;
g.Position = [.1 .1 .8 .8];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uitabgroup visibility

`'on'` (default) | `'off'`

Uitabgroup handle visibility, specified as `'on'` or `'off'`. The Visible property determines whether the uitabgroup displays on the screen. If the Visible property of a uitabgroup is set to `'off'`, the entire uitabgroup is invisible, but you can still specify and access its properties.

Changing the size of an invisible uitabgroup triggers the SizeChangedFcn callback if and when the uitabgroup becomes visible.

Note Changing the Visible property of a uitabgroup does *not* change the settings of the Visible property of its child components even though hiding the uitabgroup causes them to be hidden.

Location and Size

`TabLocation` — Tab label location

`'top'` (default) | `'bottom'` | `'left'` | `'right'`

Tab label location, specified as `'top'`, `'bottom'`, `'left'`, or `'right'`. This property specifies the location of the tab labels with respect to the uitabgroup.

`Position` — Location and size of uitabgroup relative to parent

`[left bottom width height]`

Location and size of the uitabgroup relative to the parent, specified as the vector, `[left bottom width height]`. This table describes each element in the vector.

Element	Description
`left`	Distance from the inner left edge of the parent container to the outer left edge of the uitabgroup
`bottom`	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uitabgroup
`width`	Distance between the right and left outer edges of the uitabgroup
`height`	Distance between the top and bottom outer edges of the uitabgroup

All measurements are in units specified by the Units property.

Note: If the parent of the uitabgroup is a figure, then the Position values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

Example: Modify One Value in the Position Vector

You can combine dot notation and array indexing when you want to change one value in the Position vector. For example, this code sets the width of the Uitabgroup to `.5` without changing any of the other Position values:

```
tg = uitabgroup;
tg.Position(3) = .5;
```

`Units` — Units of measurement

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'pixels'` | `'points'` | `'characters'`

Units of measurement, specified as `'normalized'`, `'inches'`, `'centimeters'`, `'pixels'`, `'points'`, or `'characters'`.

MATLAB uses these units to interpret the location and size values of the Position property:

- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- The size of a uitabgroup specified in pixel units depends on the system display settings and resolution.
- Characters units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

The order in which you specify the Units and Position properties has these effects:

- If you specify the Units property before the Position property, then MATLAB sets Position using the units you specified.
- If you specify the Units property after the Position property, MATLAB sets the position using the default Units. Then, MATLAB converts the Position values to the equivalent values in the units you specified.

`SizeChangedFcn` — Uitabgroup resize callback function

`''` (default) | function handle | cell array | string

Uitabgroup resize callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

Define this callback function to control the UI layout when the size of the uitabgroup changes.

The SizeChangedFcn callback executes in these circumstances:

- The uitabgroup becomes visible for the first time.
- The uitabgroup is visible while its size changes.
- The uitabgroup becomes visible for the first time after its size changes. This situation occurs when the size changes while the uitabgroup is invisible, and then it becomes visible later.

These are some of the important characteristics of the SizeChangedFcn callback and some recommended best practices:

- Consider delaying the display of the figure until after all the variables that the uitabgroup SizeChangedFcn uses are defined. This practice can prevent the uitabgroup SizeChangedFcn callback from returning an error. To delay the display of the figure, set its Visible property to `'off'`. Then, set the Visible property to `'on'` after you define all the variables that your SizeChangedFcn callback uses.
- Use the `gcbo` function in your SizeChangedFcn code to get the uitabgroup object that the user is resizing. See the description of the figure `SizeChangedFcn` for an example that uses `gcbo`.
- All visible Uitabgroups that are specified in normalized units resize before the parent figure does. All visible, nested uitabgroups resize from inside-out.

Tip As an easy alternative to specifying a SizeChangedFcn callback, you can set the Units property of all the objects you put inside the uitabgroup to `'normalized'`. Doing so makes those components scale proportionally with the uitabgroup.

See “Managing the Layout in Resizable UIs” for more information.

Example: `@myfun`

Example: `{@myfun,x}`

Interactive Control

`SelectionChangedFcn` — Uitab selection callback

`''` (default) | function handle | cell array | string

Uitab selection callback, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This callback function executes when the user selects a different tab within the uitabgroup.

If you set the SelectionChangedFcn property to a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Callbackdata Field	Description
`OldValue`	Previously selected uitab, or `[]` if none was selected
`NewValue`	Currently selected uitab
`Source`	The parent uitabgroup object
`EventName`	`'SelectionChange'`

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

Example: `@myfun`

Example: `{@myfun,x}`

`ButtonDownFcn` — Button-press callback function

`''` (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The ButtonDownFcn callback is a function that executes when the user clicks a mouse button on the uitabgroup.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`UIContextMenu` — Uitabgroup context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu object

Uitabgroup context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the uitabgroup. Create the context menu using the `uicontextmenu` function.

Callback Execution Control

`Interruptible` — Callback interruption

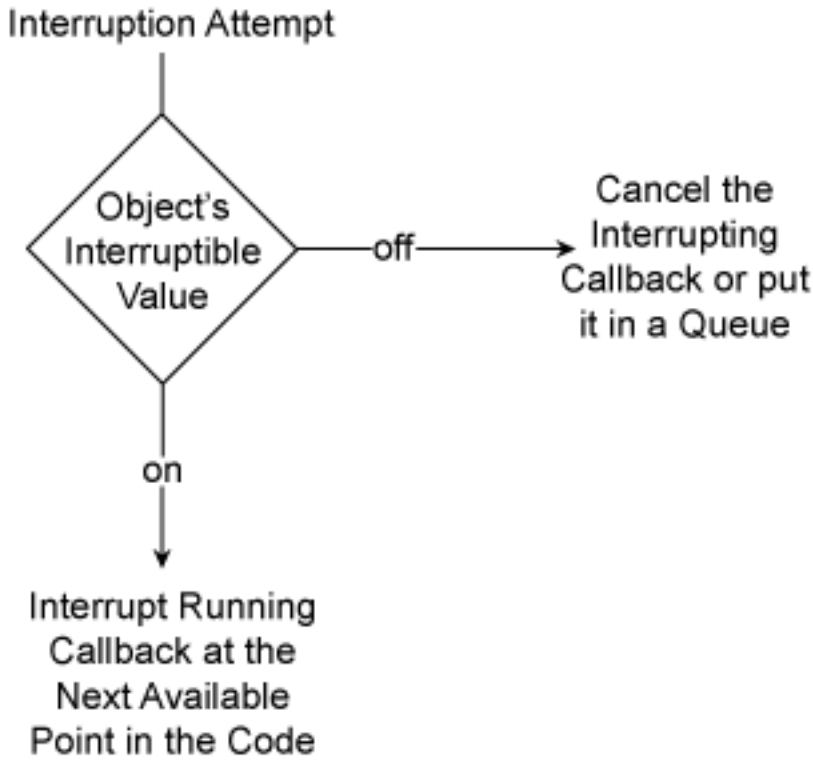
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uitabgroup callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.

  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.

  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See "Interrupt Callback Execution" for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uitabgroup

`'off'` (default) | `'on'`

Deletion status of uitabgroup, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uitabgroup begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uitabgroup no longer exists.

Check the value of the BeingDeleted property to verify that the uitabgroup is not about to be deleted before querying or modifying it.

`CreateFcn` — Uitabgroup creation function

function handle | cell array | string

Uitabgroup creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This property specifies a callback function to execute when MATLAB creates the uitabgroup. MATLAB initializes all uitabgroup property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uitabgroup that is being created.

Setting the CreateFcn property on an existing uitabgroup has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uitabgroup object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uitabgroup deletion function

function handle | cell array | string

Uitabgroup deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uitabgroup (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the uitabgroup. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uitabgroup that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`SelectedTab` — Currently selected tab

uitab object

Currently selected tab, specified as a uitab object.

Use this property to determine the currently selected uitab within a uitabgroup. You can also use this property to set the default uitab selection.

The default value of the SelectedTab property is the first uitab that you add to the uitabgroup.

`Type` — Type of graphics object

`'uitabgroup'`

Type of graphics object, returned as `'uitabgroup'`.

`Tag` — Uitabgroup identifier

`''` (default) | string

Uitabgroup identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uitabgroup. When you need access to the uitabgroup elsewhere in your code, you can use the `findobj` function to search for the uitabgroup based on the Tag value.

Example: `'tabgroup1'`

Data Types: `char`

`UserData` — Data to associate with the uitabgroup object

empty array (default) | array

Data to associate with the uitabgroup object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uitabgroup parent

figure | uipanel | uitab

Uitabgroup parent, specified as a figure, uipanel, or uitab. You can move a uitabgroup to a different figure, uipanel, or uitab by setting this property to the handle of the target figure, uipanel, or uitab.

`Children` — Children of uitabgroup

empty `GraphicsPlaceholder` array (default) | 1-D array of component objects

Children of the uitabgroup, returned as an empty `GraphicsPlaceholder` or a 1-D array of component objects. The children of uitabgroup are uitabs.

You cannot add or remove children using the `Children` property of the uitabgroup. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the tabs displayed on the screen.

To add a child to this list, set the `Parent` property of the child component to be the uitabgroup object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of Uitabgroup handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uitabgroup handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uitabgroup handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`,

and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uitabgroup handle is always visible.
`'callback'`	The uitabgroup handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitabgroup at the command-line, but allows callback functions to access it.
`'off'`	The uitabgroup handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

uitable

Create table UI component

Syntax

```
t = uitable
t = uitable(Name,Value,...)
t = uitable(parent)
t = uitable(parent,Name,Value,...)
```

Description

`t = uitable` creates a uitable in an existing figure and returns the uitable object, `t`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`t = uitable(Name,Value,...)` creates a uitable and specifies one or more uitable property names and corresponding values. Use this syntax to override the default uitable properties.

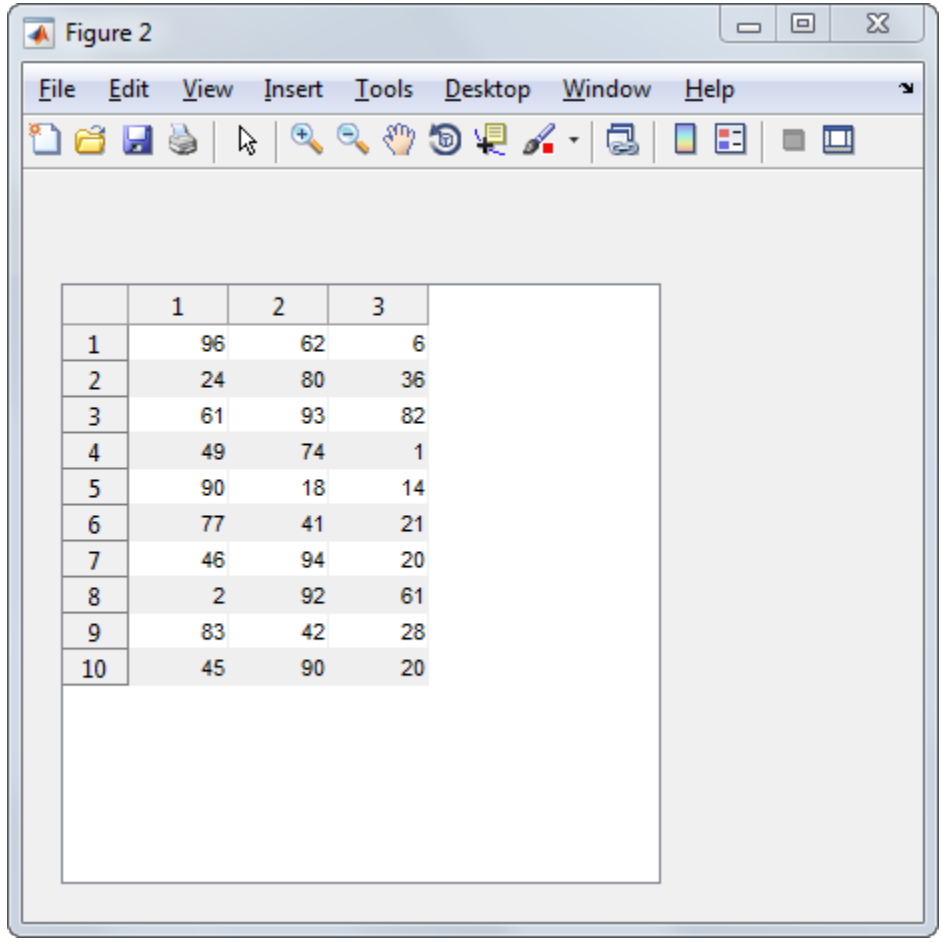
`t = uitable(parent)` creates a uitable and designates a specific parent object. The `parent` argument can be a figure, uipanel, uibuttongroup, or uitab object.

`t = uitable(parent,Name,Value,...)` creates a uitable with a specific parent and one or more uitable properties.

Examples

This example creates a uitable containing three columns of random numbers. The columns in this uitable are 50 pixels wide.

```
f = figure;
d = gallery('integerdata',100,[10 3],0);
t = uitable(f,'Data',d,'ColumnWidth',{50});
```



Next, set the width and height of the uitable to match the size of the enclosing rectangle:

```
t.Position(3) = t.Extent(3);
t.Position(4) = t.Extent(4);
```

	1	2	3
1	96	62	6
2	24	80	36
3	61	93	82
4	49	74	1
5	90	18	14
6	77	41	21
7	46	94	20
8	2	92	61
9	83	42	28
10	45	90	20

This example creates a uitable with specific column names and row names:

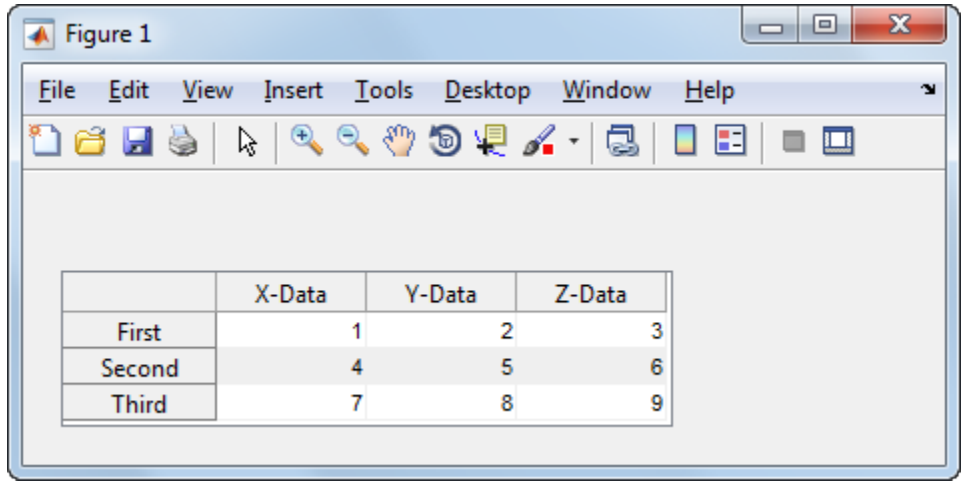
```
f = figure('Position',[440 500 461 146]);

% create the data
d = [1 2 3; 4 5 6; 7 8 9];

% Create the column and row names in cell arrays
cnames = {'X-Data','Y-Data','Z-Data'};
rnames = {'First','Second','Third'};
```

```
% Create the uitable
t = uitable(f,'Data',d,...
            'ColumnName',cnames,...
            'RowName',rnames);

% Set width and height
t.Position(3) = t.Extent(3);
t.Position(4) = t.Extent(4);
```



This example creates a table containing different types of data:

- First two columns are numeric. The first column displays values with up to four decimal places. The second column displays values in currency format.
- Third column contains check boxes (specified as `logical` values in the Data array).
- Fourth column contains pop-up menus, each having two choices: `Fixed` and `Adjustable`.

```
f = figure('Position',[100 100 400 150]);

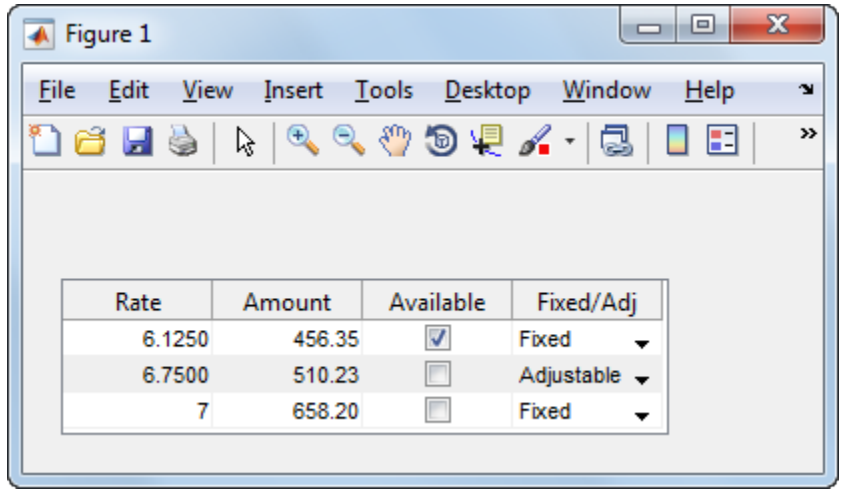
% Column names and column format
columnname = {'Rate','Amount','Available','Fixed/Adj'};
columnformat = {'numeric','bank','logical',{'Fixed' 'Adjustable'}};

% Define the data
d =    {6.125678  456.3457  true   'Fixed';...
        6.75   510.2342  false  'Adjustable';...
```

```
        7      658.2     false   'Fixed';};

% Create the uitable
t = uitable('Data', d,...
            'ColumnName', columnname,...
            'ColumnFormat', columnformat,...
            'ColumnEditable', [false false true true],...
            'RowName',[]);

% Set width and height
t.Position(3) = t.Extent(3);
t.Position(4) = t.Extent(4);
```



More About

Tips

If the `ColumnEditable` property is set to `true` for specific columns, the user can edit values in that column. By default, this property is set to `false` for all columns. If a noneditable column contains pop-up choices, then only the current choice is visible in the table.

The CellEditCallback function executes after the user edits a value and perform any of these actions:

- Press the **Enter** key.
- Click anywhere else within the table.
- Click anywhere else within the same figure window, or in another figure window.

The CellSelectionCallback function executes when the user selects one or more table cells or modifies the current selection.

You cannot select table cells programmatically. Directly clicking cells is the only method of selection.

`figure` | `format` | Uitable Properties

Introduced in R2008a

Uitable Properties

Control appearance and behavior of table

Uitables are tables that list data in a figure. The `uitable` function creates a table and sets any required properties before displaying it. By changing uitable property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitable;
fgcolor = t.ForegroundColor;
t.ForegroundColor = [0 0 1];
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uitable visibility

`'on'` (default) | `'off'`

Uitable visibility, specified as `'on'` or `'off'`. When Visible is `'off'`, the uitable is not visible, but you can query and set its properties.

To make your program start faster, set the Visible property of all uitables that are not initially displayed to `'off'`.

`BackgroundColor` — Uitable cell background color

RGB triplet | 2-by-3 matrix of RGB triplets

Uitable cell background color, specified as an RGB triplet or a 2-by-3 matrix of RGB triplets. An RGB triplet is a row vector that specifies the intensities of the red, green, and blue components of the color. The intensities must be in the range, `[0,1]`. If you specify a 2-by-3 matrix, then each row of the matrix must be an RGB triplet. Color names are not valid.

If you specify the background color as a 2-by-3 matrix, then MATLAB uses the second row of the matrix when the RowStriping property is `'on'`. The table background is not striped unless both RowStriping is `'on'` and the background color is a 2-by-3 matrix.

The following table lists the RGB triplets for commonly used colors.

Color	RGB Triplet
Yellow	`[1 1 0]`
Magenta	`[1 0 1]`
Cyan	`[0 1 1]`
Red	`[1 0 0]`
Green	`[0, 1 0]`
Blue	`[0 0 1]`
White	`[1 1 1]`
Black	`[0 0 0]`

Example: `[1 1 1]`

Example: `[1 1 1; .9 .9 .9]`

`ForegroundColor` — Cell text color

`[0 0 0]` (default) | RGB triplet | short name | long name

Cell text color, specified as an RGB triplet, short name, or long name. The color you specify sets the text color for all cells.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

Location and Size

Position — Location and size of uitable

[left bottom width height]

Location and size of the uitable relative to the parent, specified as the vector, [left bottom width height]. This table describes each element in the vector.

Element	Description
left	Distance from the inner left edge of the parent container to the outer left edge of the uitable
bottom	Distance from the inner bottom edge of the parent container to the outer bottom edge of the uitable
width	Distance between the right and left outer edges of the uitable
height	Distance between the top and bottom outer edges of the uitable

All measurements are in units specified by the Units property.

Note: If the parent of the uitable is a figure, then the Position values are relative to the figure's *drawable area*. The drawable area of a figure is the area inside the window borders, excluding the menu bar and tool bar.

Use the Extent property to determine proper sizing for a uitable with respect to the table data. Set the `width` and `height` of Position property to the width and height of the Extent property. Be aware that if the table has large extents, doing this can cause the table to extend beyond the right or top edge of its parent container.

Example: `[0 0 300 300]`

Example: Set Width and Height to Accommodate Data Size

You can combine dot notation and array indexing when you want to change one or two consecutive values in the Position vector. For example, this code sets the width and height of the uitable to match the Extent of the table:

```
t = uitable('Data',rand(10,3));
t.Position(3:4) = t.Extent(3:4);
```

`Units` — Units of measurement

`'pixels'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'points'` | `'characters'`

Units of measurement, specified as `'pixels'`, `'normalized'`, `'inches'`, `'centimeters'`, `'points'`, or `'characters'`.

MATLAB uses these units to interpret the location and size values of the Position property:

- The size of a uitable specified in pixel units depends on the system display settings and resolution.
- Normalized units map the lower left corner of the parent container to `(0,0)` and the upper right corner to `(1.0,1.0)`.
- Inches, centimeters, and points are absolute units. 1 point = 1/72 inch.
- Character units are determined by the default system font. Each character unit is the width of the letter x. The height of each character unit is the distance between the baselines of two lines of text.

MATLAB measures all units from the lower left corner of the parent object.

If you change the value of the Units property, it is good practice to return it to its default value after completing your computation to avoid affecting other functions that assume the Units property is set to the default value.

The order in which you specify the Units and Position properties has these effects:

- If you specify the Units before the Position property, then MATLAB sets Position using the units you specify.
- If you specify the Units property after the Position property, MATLAB sets the position using the default Units. Then, MATLAB converts the Position value to the equivalent value in units you specify.

`Extent` — Size of uitable rectangle

four-element row vector

Size of the uitable rectangle, returned as a four-element row vector. The first two elements of the vector are always zero. The third and fourth elements are the width and height of the rectangle containing the uitable, respectively. All measurements are in units specified by the Units property.

MATLAB determines the size of the rectangle based on the current Data, RowName and ColumnName property values. MATLAB estimates the width and height values using the column and row widths. The estimated extent can be larger than the figure.

When the uitable Units property is set to `'normalized'`, the Extent values are measured relative to the figure, regardless of whether the uitable is contained in (parented to) a uipanel.

Consider using the Extent property value when specifying the width and height values of the uitable Position property.

Font Style

`FontName` — Font for displaying cell content

string

Font for displaying the cell content, specified as a string. To display and print properly, this must be a font that your system supports. To display and print properly, the font name must refer to a font that the user's system supports. The default font is system dependent.

To use a fixed-width font, set the FontName property to the string, `'FixedWidth'`. This setting instructs MATLAB to use the value of the root FixedWidthFontName property, which you can set in the `startup.m` file.

For more information about the `startup.m` file, see "Startup Options in MATLAB Startup File"

Example: `'Arial'`

`FontSize` — Font size for uitable cell content

positive number

Font size for the uitable cell content, specified as a positive number. MATLAB uses the units specified by FontUnits. The default size is system-dependent. If you set FontUnits to `'normalized'`, then the FontSize value is a number between 0 and 1.

Example: `12`

Example: `12.5`

Data Types: `double`

`FontUnits` — Units of font size for uitable cell contents

`'points'` (default) | `'normalized'` | `'inches'` | `'centimeters'` | `'pixels'`

Units of font size for the uitable cell contents, specified as `'points'`, `'normalized'`, `'inches'`, `'centimeters'`, or `'pixels'`.

If you set this property to `'normalized'`, then MATLAB interprets the font size as a fraction of the uitable height. When you resize the uitable, MATLAB scales the displayed font to maintain that fraction.

The other FontUnits options (`pixels`, `inches`, `centimeters`, and `points`) are absolute units. 1 point = 1/72 inch.

`FontWeight` — Font weight for uitable cell contents

`'normal'` (default) | `'bold'`

Font weight for the uitable cell contents, specified as a value from the following table.

FontWeight Value	Description
`'normal'`	Normal font weight
`'bold'`	Heavy font weight

Not all fonts support all font weights. Therefore, if you specify an unsupported value for the `FontWeight` property, the result might appear the same as the default.

Note: The `'light'` and `'demi'` font weight values have been removed in R2014b. If you specify either of these values, the result is a normal font weight.

`FontAngle` — Character slant of uitable cell contents

`'normal'` (default) | `'italic'`

Character slant of the uitable cell contents, specified as `'normal'` or `'italic'`. MATLAB uses this property to select a font from those available on your system. Setting this property to `'italic'` selects a slanted version of the font, if it is available on your system.

Note: The `'oblique'` value has been removed. Use `'italic'` instead.

Interactive Control

`CellEditCallback` — Cell edit callback function

function handle | cell array | string

Cell edit callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This function makes the uitable respond when the user changes the contents of a table cell. You can use this callback function to perform calculations or validate user input.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description
`Indices`	1-by-2 array containing the row and column indices of the cell the user edited.
`PreviousData`	Previous cell data. The default is an empty matrix, `[]`.
`EditData`	User-entered string.
`NewData`	Value that MATLAB wrote to the Data property array. It is either the same as EditData or a converted value. The `NewData` property is empty if MATLAB detects an error in the user-entered data.
`Error`	Error message returned if MATLAB detects an error in the user-entered data. The `Error` property is empty when MATLAB successfully writes the value to the Data property. If the `Error` property is not empty, then the CellEditCallback can display the string, or it can attempt to fix the problem.

When the user edits a cell, MATLAB attempts to store the user-entered value in the Data property, converting the value if necessary. Next, MATLAB calls the CellEditCallback function and passes the callback data. If there is no CellEditCallback function, and the user-entered data results in an error, then the contents of the cell reverts to its previous value and no error displays.

Example: Evaluate User Input

This example shows how to create a callback function that evaluates a user-entered data in a numeric table cell. Paste this code into an editor and run it to see how it works.

```
function myui
    f = figure;
    myData = { 'A '  31; 'B'  41; 'C'  5; 'D' 2.6};
    t = uitable('Parent',f,...
                'Position', [25 25 700 200], ...
                'Data',myData,...
                'ColumnEditable', [false true], ...
                'CellEditCallback',@converttonum);
        function converttonum(hObject,callbackdata)
             numval = eval(callbackdata.EditData);
```

```
            r = callbackdata.Indices(1)
            c = callbackdata.Indices(2)
            hObject.Data{r,c} = numval;
        end
end
```

When you run `myui`, you can change a value in the second column of the table. In response, the `converttonum` callback function executes. The `converttonum` function uses the `eval` function to evaluate your input. Then, it sets the cell data to the value of `numval`. For example, if you enter `pi` or`1+1`, the `converttonum` function sets the table cell value to a numeric representation of the input. Because there is no error checking in the `converttonum` function, invalid expressions return an error and the new value of the table cell becomes `NaN`.

`CellSelectionCallback` — Cell selection callback function

function handle | cell array | string

Cell selection callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the user performs one of the following actions:

- Highlights a data cell (not a row or column header cell) by clicking it or navigating to it with an arrow key
- Adds a new cell to their selection by **Shift**-clicking it
- Deselects a cell by **Ctrl**-clicking it

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains one property, `Indices`. The `Indices` property is an n-by-2 array containing the row index and column index of the selected cells.

Example: `@myfun`

Example: `{@myfun,x}`

`ColumnEditable` — Ability to edit column cells

empty matrix ([ ]) (default) | logical 1-by-n array | scalar logical value

Ability to edit column cells, specified as:

- An empty matrix ([ ]) — No columns are editable.
- A logical 1-by-n array — Specify which columns are editable. The value of n is equal to the number of columns in the table. Each value in the array corresponds to a table column. A value of `true` in the array makes the cells in that column editable. A value of `false` makes the cells in that column uneditable.
- A scalar logical value — Make the entire table editable or uneditable.

Table columns that contain check boxes or pop-up menus must be editable so the user can interact with these controls.

Example: `[ ]`

Example: `[false true true]`

Example: `false`

`RearrangeableColumns` — Ability to rearrange table columns

`'off'` (default) | `'on'`

Ability to rearrange table columns, specified as `'off'` or `'on'`. This property provides a way to let users reorder the table columns (but not the labels) by clicking and dragging the column headers.

Note: Rearranging table columns in the UI does not affect the columns in the Data property array.

`ButtonDownFcn` — Button-press callback function

`''` (default) | function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

The ButtonDownFcn callback is a function that executes when the user clicks a mouse button on the uitable. The callback executes in the following situations:

- The user right-clicks the uitable, and the uitable Enable property is set to `'on'`.
- The end user right-clicks or left-clicks the Uitable, and the uitable Enable property is set to `'off'` or `'inactive'`.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`KeyPressFcn` — Key press callback function

`''` (default) | function handle | cell array | string

Key press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

This callback function executes when the uitable object has focus and the user presses a key. If you do not define a function for this property, MATLAB passes key presses to the parent figure. Repeated key presses retain the focus of the uitable, and the function executes with each key press. If the user presses multiple keys at approximately the same time, MATLAB detects the key press for the last key pressed.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
`Character`	The character that displays as a result of pressing a key or keys. The character can be empty or unprintable.	`'a'`	`'='`	`''`	`'A'`
`Modifier`	A cell array containing the names of one or more modifier keys that are being pressed (such as, **Ctrl**, **Alt**, **Shift**).	`{1x0 cell}`	`{1x0 cell}`	`{'shift'}`	`{'shift'}`
`Key`	The key being pressed, identified by the (lowercase) label on the key, or a descriptive string.	`'a'`	`'equal'`	`'shift'`	`'a'`
`Source`	The object that has focus when the user presses the key.	uitable object	uitable object	uitable object	uitable object
`EventName`	The action that caused the callback function to execute.	`'KeyPres`	`'KeyPre`	`'KeyPress`	`'KeyPress'`

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the `Character` property, but do not change the `Key` property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the `Character` property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate `Character` property data.

You also can query the CurrentCharacter property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`KeyReleaseFcn` — Key-release callback function

`''` (default) | function handle | cell array | string

Key-release callback function, specified as one of these values:

- Function handle

- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This callback function executes when the uitable object has focus and the user releases a key.

If you specify this property as a function handle (or cell array containing a function handle), MATLAB passes an object containing callback data as the second argument to the callback function. This object contains the properties described in the following table. You can access these properties inside the callback function using dot notation.

Property	Description	Examples:			
		a	=	Shift	Shift-a
`Character`	Character interpretation of the key that was released.	`'a'`	`'='`	`''`	`'A'`
`Modifier`	Current modifier, such as `'control'`. This value is always an empty cell array for aseFcn callbacks.	`{1x0 cell}`	`{1x0 cell}`	`{1x0 cell}`	`{1x0 cell}`
`Key`	Name of the key that was released, identified by the lowercase label on the key, or a descriptive string.	`'a'`	`'equal'`	`'shift'`	`'a'`
`Source`	The object that has focus when the user presses the key.	uitable object	uitable object	uitable object	uitable object
`EventName`	The action that caused the callback function to execute.	`'ase'`	`'ase'`	`'ase'`	`'ase'`

Pressing modifier keys affects the callback data in the following ways:

- Modifier keys can affect the `Character` property, but do not change the `Key` property.
- Certain keys, and keys modified with **Ctrl**, put unprintable characters in the `Character` property.
- **Ctrl**, **Alt**, **Shift**, and several other keys, do not generate `Character` property data.

You also can query the CurrentCharacter property of the figure to determine which character the user pressed.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`Enable` — Operational state of uitable

`'on'` (default) | `'inactive'` | `'off'`

Operational state of uitable, specified as `'on'`, `'off'`, or `'inactive'`. The Enable property controls whether the uitable responds to button clicks. The are three possible values:

- `'on'` – The uitable is operational.
- `'off'` – The uitable is not operational and appears grayed-out.
- `'inactive'` – The uitable is not operational, but it has the same appearance as when Enable is `'on'`.

The value of the Enable property and the type of button click determine how the UI responds.

Enable Value	Response to Left-Click	Response to Right-Click
`'on'`	The uitable's CellSelectionCallback function executes (only for table cells, not header cells). The `Indices` property updates in the callback data object that MATLAB passes to the callback function.	**1** The figure's `WindowButtonDownFcn` callback executes. **2** The uitable `ButtonDownFcn` callback executes.
`'off'` or `'inactive'`	**1** The figure's `WindowButtonDownFcn` callback executes. **2** The uitable's `ButtonDownFcn` callback executes.	**1** The figure's `WindowButtonDownFcn` callback executes. **2** The uitable's `ButtonDownFcn` callback executes.

`TooltipString` — Tooltip text

string

Tooltip text, specified as a string. When the user hovers the mouse pointer over the uitable and leaves it there, the tooltip displays. If you want to create a tooltip that has

more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the TooltipString to that string.

Example: `'Some string'`

Example: Specify TooltipString Containing Two Lines

```
t = uitable;
s = sprintf('UITable tooltip line 1\nUITable tooltip line 2');
t.TooltipString = s;
```

Data Types: `char`

`UIContextMenu` — Uitable context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu object

Uitable context menu, specified as a uicontextmenu object. Use this property to display a context menu when the user right-clicks on the uitable. Create the context menu using the `uicontextmenu` function.

`Selected` — Selection status of uitable

`'off'` (default) | `'on'`

Note: The behavior of the Selected property changed in R2014b, and it is not recommended. It no longer has any effect on uitables. This property might be removed in a future release.

`SelectionHighlight` — Ability to highlight selection handles

`'on'` (default) | `'off'`

Note: The behavior of the SelectionHighlight property changed in R2014b, and it is not recommended. It no longer has any effect on uitables. This property might be removed in a future release.

Callback Execution Control

`Interruptible` — Callback interruption

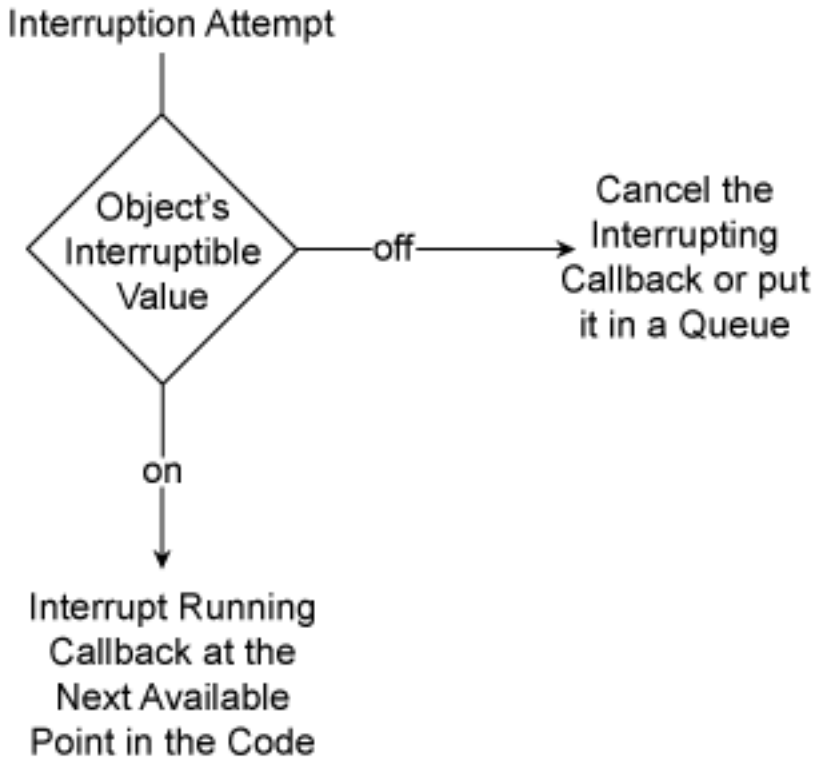
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uitable callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See “Interrupt Callback Execution” for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

Ability to become current object, specified as `'on'` or `'off'`:

- Setting the value to `'on'` allows the uitable to become the current object when the user clicks on it. A value of `'on'` also allows the figure CurrentObject property and the `gco` function to report the uitable as the current object.
- Setting the value to `'off'` sets the figure CurrentObject property to an empty `GraphicsPlaceholder` array when the user clicks on the uitable.

Note: Use the Enable property to enable or disable a uitable.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uitable

`'off'` (default) | `'on'`

Deletion status of uitable, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uitable begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uitable no longer exists.

Check the value of the BeingDeleted property to verify that the uitable is not about to be deleted before querying or modifying it.

`CreateFcn` — Uitable creation function

function handle | cell array | string

Uitable creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uitable. MATLAB initializes all uitable property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uitable that is being created.

Setting the CreateFcn property on an existing uitable has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uitable object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uitable deletion function

function handle | cell array | string

Uitable deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uitable (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the uitable. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uitable that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object

`'uitable'`

Type of graphics object, returned as `'uitable'`.

`Tag` — Uitable identifier

`''` (default) | string

Uitable identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uitable. When you need access to the uitable elsewhere in your code, you can use the `findobj` function to search for the uitable based on the Tag value.

Example: `'table1'`

Data Types: `char`

`UserData` — Data to associate with the uitable object

empty array (default) | array

Data to associate with the uitable object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uitable parent

figure | uipanel | uibuttongroup | uitab

Uitable parent, specified as a figure, uipanel, uibuttongroup, or uitab. You can move a uitable to a different figure, uipanel, uibuttongroup, or uitab by setting this property to the handle of the target figure, uipanel, uibuttongroup, or uitab.

`Children` — Children of uitable

empty array

Children of uitable, returned as an empty array. Uitable objects have no children. Setting this property has no effect.

`HandleVisibility` — Visibility of Uitable handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uitable handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uitable handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions

that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uitable handle is always visible.
`'callback'`	The uitable handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitable at the command-line, but allows callback functions to access it.
`'off'`	The uitable handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

Table Data

`Data` — Table content

numeric array | cell array

Table content, specified as a numeric array or cell array. The table data can be any numeric type, `logical`, or `char`. Use a cell array to specify a mixture of different data types.

The ColumnFormat property specifies the format for displaying the table contents. Therefore, if there is a mismatch between the data type of the Data property array and the ColumnFormat property, MATLAB converts the data value or displays a warning. See the ColumnFormat property description for more information.

To prevent warnings that might occur when users enter invalid data, write a CellEditCallback function to convert the data to the appropriate type.

If the number of rows in the Data property array does not match the number of elements in the RowName array, then the number of rows in the resulting table is the larger of the two values. The same is true when the ColumnName property does not match the number of columns in the Data property array.

Example: `rand(10,3)`

Example: `{'blue' 5 true; 'orange' 25 false}`

Table Layout

`RowName` — Row heading names

`'numbered'` (default) | n-by-1 cell array of strings | empty cell array (`{}`) | empty matrix (`[]`)

Row heading names, specified as one of these values:

- `'numbered'` — The row headings are sequential numbers that start at `1`.
- Cell array — Each element of the cell array becomes the name of a row. Row names are restricted to one line of text. If you specify a 1-by-n cell array, MATLAB stores and returns the value as a n-by-1 cell array.
- Empty cell array (`{}`) — The resulting table has no row headings.
- Empty matrix (`[]`) — The resulting table has no row headings

If the number of rows in the Data property array does not match the number of elements in the RowName array, then the number of rows in the resulting table is the larger of the two values.

Example: `{'Name';'Telephone Number'}`

Example: `{'Name';[]}`

`ColumnName` — Column heading names

`'numbered'` (default) | n-by-1 cell array of strings | empty cell array (`{}`) | empty matrix (`[]`)

Column heading names, specified as one of these values:

- `'numbered'` — The column headings are sequential numbers that start at `1`.
- Cell array — Each element of the cell array becomes the name of a column. If you specify a 1-by-n cell array, MATLAB stores and returns the value as a n-by-1 cell array. Specify a multiline column name as a string vector separated by vertical slash (`|`) characters. For example, the value, `'Telephone|Number'`, produces a column heading with a newline character between the words, "Telephone" and "Number".
- Empty cell array (`{}`) — The resulting table has no column headings.
- Empty matrix (`[]`) — The resulting table has no column headings

If the number of columns in the Data property array does not match the number of elements in the ColumnName array, then the number of columns in the resulting table is the larger of the two values.

Example: `{'Name'; 'Telephone Number'}`

Example: `{'Name'; []}`

Example: `{'Name'; 'Telephone|Number'}`

`ColumnWidth` — Width of table columns

`'auto'` (default) | 1-by-n cell array

Width of table columns, specified as a 1-by-n cell array or `'auto'`.

Each column in the cell array corresponds to a column in the table. The values are in pixel units. If you specify `'auto'`, then MATLAB calculates the width of the column automatically using several factors, one of which is the ColumnName property value.

You can combine fixed column widths and `'auto'` column widths in a cell array, or you can specify a single value of `'auto'` to make all column widths automatic.

Selecting **Auto Width** in the Table Property Editor has the same effect as setting the ColumnWidth property to `'auto'`.

Example: `'auto'`

Example: `{64 60 40}`

Example: `{64 'auto' 40}`

`ColumnFormat` — Cell display format

empty cell array ({}) (default) | 1-by-n cell array of strings

Cell display format, specified as an empty cell array or a cell array of strings.

This property determines how the data in each column displays and the constraints for editing that data in the UI. The length of the cell array must equal the number of columns in the table, and the elements of the cell array correspond to columns in the Data property array. If you do not want to specify a display format for a particular column, specify `[]` for that column. If you do not specify a format for a column, MATLAB determines the default display by the data type of the data in the cell.

Elements of the cell array must be one of the strings described in the following table.

Cell Format	Description
`'char'`	Display a left-justified string. To edit a cell, the user types a string that replaces the existing string.
`'logical'`	Display a check box. To edit a cell, the user selects or clears the check box. Then, MATLAB sets the corresponding Data value to `true` or `false` accordingly. The ColumnEditable property value must be `true` to allow users to select or deselect the check boxes. Initially, a check box is selected when the corresponding Data value is `true`. The corresponding values in the Data property array must be of type `logical` to ensure the data displays correctly in the table.
`'numeric'`	Display a right-justified string equivalent to the Command Window display for numeric data. If an element in the Data property array is logical, then `1` or `0` appears in the table. If an element in the Data property array is not numeric and not logical, then `NaN` appears in the table. To edit a cell, the user can enter any string. If a user enters a string representing a constant, such as `pi`, you can code the CellEditCallback function to convert the value to the numeric equivalent. In this case,

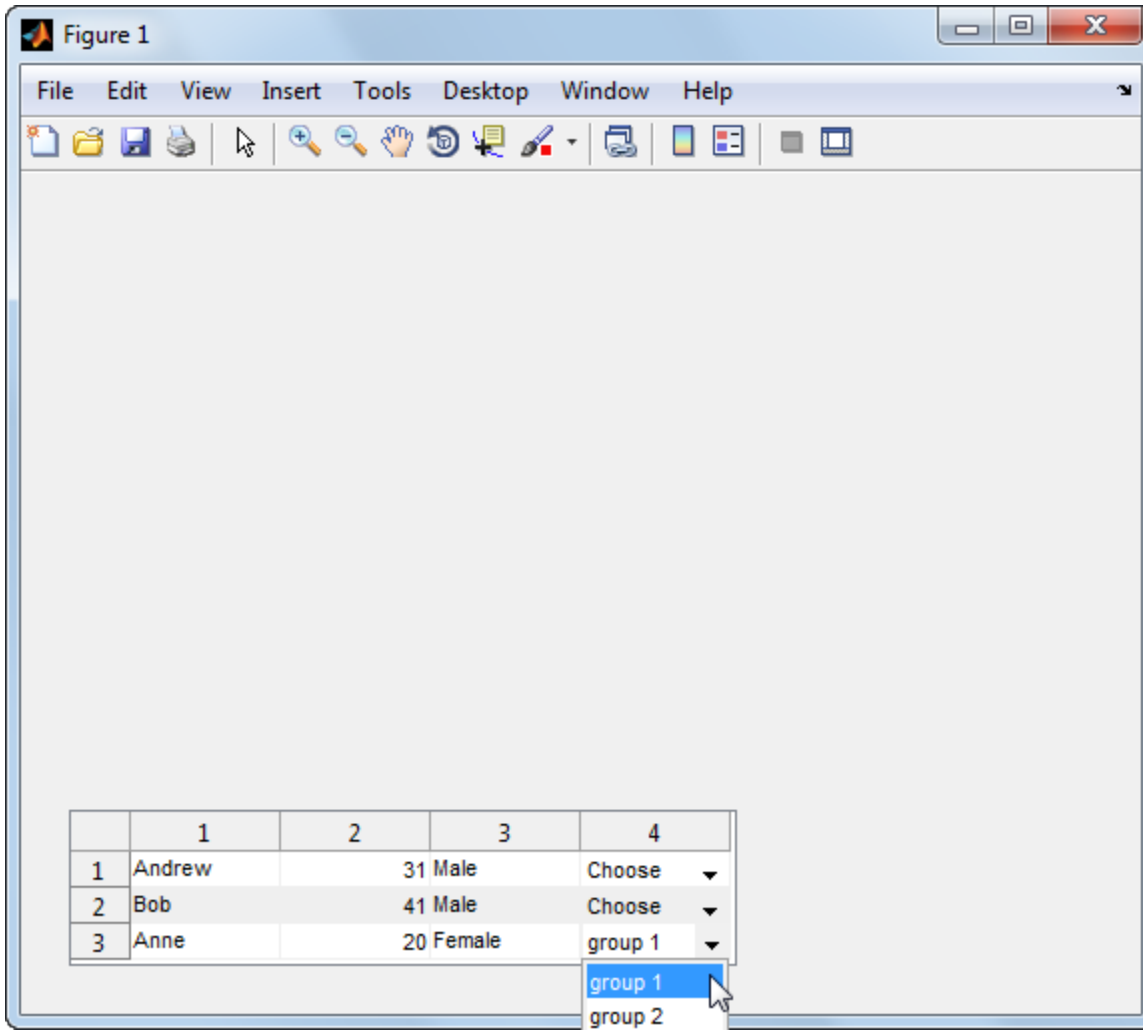
Cell Format	Description
	MATLAB attempts to convert the user-entered string to a numeric value and stores it in the Data property. Then, the CellEditCallback function executes. See the CellEditCallback description for an example.
A 1-by-n cell array of strings. For example, `{'one' 'two' 'three'}`	Display a pop-up menu. To edit a cell, the user selects an item from the pop-up menu. MATLAB sets the corresponding Data property array value to the selected menu item. The ColumnEditable property value must be `true` to allow users to select items in the pop-up menu.
A string accepted by the `format` function, such as: `'short'`, `'bank'`, `'long'`	Display the Data property values using the specified format.

Effect of Pop-Up Menu ColumnFormat and Various Data Types

The initial Data values do not have to be items in the pop-up menu. If the ColumnFormat value defines a pop-up menu, that pop-up menu displays the corresponding value in Data property until the user makes a selection.

For instance, suppose the Data property value for a given column is the string, `'Choose'` in all the rows, and the ColumnFormat value specifies a pop-up menu with the choices of `'group 1'` and `'group 2'`. When MATLAB creates the table, those table cells display `'Choose'` until the user selects an item in the pop-up menu:

```
f = figure;
myData = {'Andrew' 31 'Male' 'Choose'; ...
          'Bob' 41 'Male' 'Choose';  ...
          'Anne' 20 'Female' 'Choose';};
t = uitable('Parent', f,...
            'Position', [25 25 334 78],...
            'ColumnFormat',({[] [] [] {'group 1' 'group 2'}}),...
            'ColumnEditable', true,...
            'Data', myData);
```



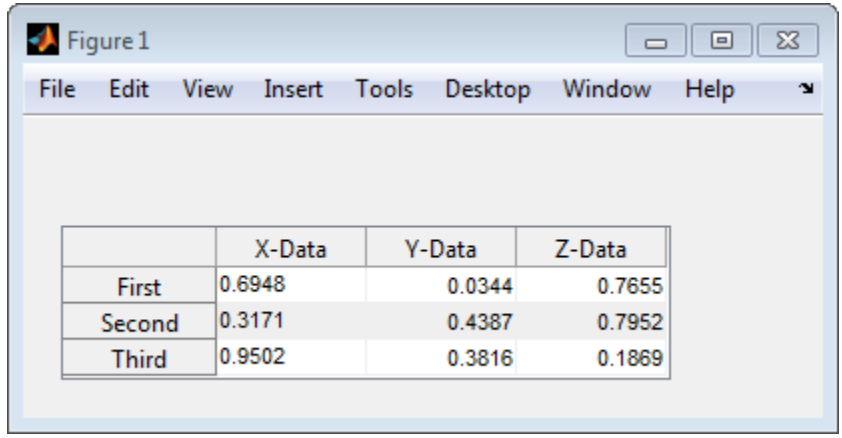
Data Display of Editable Columns

This table describes how various data types display with specific ColumnFormat values.

	ColumnFormat

		'numeric'	'char'	'logical'
Data Type of Data Array Value	Any numeric type	Table displays number as-is.	MATLAB converts the value to a text string and displays it left-justified in the table.	Not recommended. MATLAB might return a warning when the user edits the cell, unless you define a CellEditCallback function.
	`char`	MATLAB converts the text string to a `double` value. If MATLAB cannot convert the string, then**NaN** displays. See `str2double` for more information.	Table displays the string as is.	Not recommended. MATLAB might return a warning when the user edits the cell, unless you define a CellEditCallback function.
	`logical`	Table displays logical values as numbers. MATLAB might return a warning when the user edits the cell, unless you define a CellEditCallback function.	Table displays `'true'` or `'false'`. MATLAB might return a warning when the user edits the cell, unless you define a CellEditCallback function.	Table displays logical values as check boxes.

For example, in the following table, the first column (X-Data) is left justified because the ColumnFormat value for that column is `'char'`.



`RowStriping` — Alternate row shading
`'on'` (default) | `'off'`

Alternate row shading, specified as `'on'` or `'off'`. This property controls the shading pattern of the table rows.

When the RowStriping value is set to `'on'`, the BackgroundColor matrix specifies the background color of consecutive rows . The first color matrix row defines the shading for odd-numbered rows in the table. The second color matrix row defines the shading for even-numbered rows. If the BackgroundColor matrix has only one row, then the shading is the same in all table rows.

When RowStriping is set to `'off'`, then the first color in the BackgroundColor property defines the shading for all rows in the table.

uitoggletool

Create toggle button on toolbar

Syntax

```
t = uitoggletool
t = uitoggletool(Name,Value,...)
t = uitoggletool(parent)
t = uitoggletool(parent,Name,Value,...)
```

Description

`t = uitoggletool` creates a uitoggletool in the current figure's uitoolbar and returns the uitoggletool object, `t`. If there is no uitoolbar available, then MATLAB creates a new uitoolbar in the current figure to serve as the parent. Similarly, if there no figure is available, then MATLAB creates a new figure with a uitoolbar.

`t = uitoggletool(Name,Value,...)` creates a uitoggletool and specifies one or more uitoggletool property names and corresponding values. Use this syntax to override the default uitoggletool properties.

`t = uitoggletool(parent)` creates a uitoggletool and designates a specific parent object. The `parent` argument must be a uitoolbar object.

`t = uitoggletool(parent,Name,Value,...)` creates a uitoggletool with a specific parent and one or more uitoggletool properties.

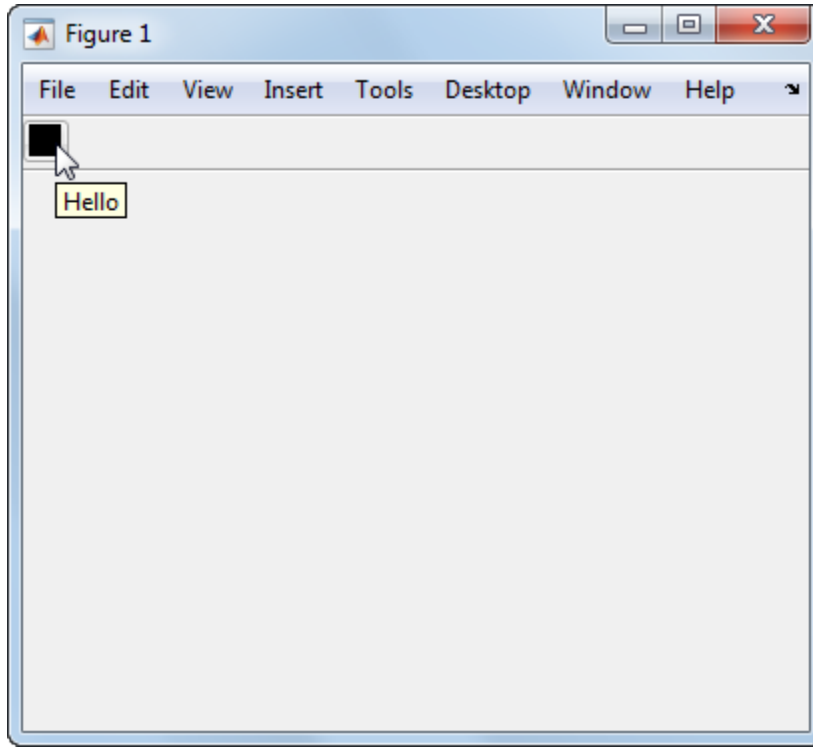
A uitoggletool is a toggle button that appears in the figure's tool bar. The button has no icon, but its borders highlight when the user hovers over it with the mouse. You can create a button icon by setting the uitoggletool's `CData` property.

Examples

This example creates a `uitoolbar` and places a `uitoggletool` inside it.

```
f = figure('ToolBar','none');
tb = uitoolbar(f);
img = zeros(16,16,3);
```

```
t = uitoggletool(tb,'CData',img,'TooltipString','Hello');
```



The `CData` property is set to a 16-by-16-by-3 array in which all elements are `0`. The zero values make the uitoggletool appear black.

Alternatives

You can create toolbars with toggle tools using GUIDE.

More About

Tips

- Uitoolbars (and their child uitoggletools) do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing a uitoolbar is

changed to `'Modal'`, the uitoolbar still exists in the `Children` property of the figure. However, the uitoolbar does not display while WindowStyle is set to `'Modal'`.

`uipushtool` | Uitoggletool Properties | `uitoolbar`

Introduced before R2006a

Uitoggletool Properties

Control appearance and behavior of uitoggletool

Uitoggletools are toggle buttons that appear on the tool bar at the top of the a figure. The `uitoggletool` function creates a toggle button on a tool bar and sets any required properties before displaying it. By changing uitoggletool property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitoggletool;
sep = t.Separator;
t.Separator = 'on';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uitoggletool visibility

`'on'` (default) | `'off'`

Uitoggletool visibility, specified as `'on'` or `'off'`. When the Visible property is set to `'off'`, the uitoggletool is not visible, but you can query and set its properties.

`Separator` — Separator line mode

`'off'` (default) | `'on'`

Separator line mode, specified as `'off'` or `'on'`. Setting this property to `'on'` draws a dividing line to left of the uitoggletool.

`CData` — Optional image to display on uitoggletool

3-D array of truecolor RGB values

Optional image to display on the uitoggletool, specified as a 3-D array of truecolor RGB values. The values in the array can be:

- Double-precision values between `0.0` and `1.0`
- `uint8` values between `0` and `255`

The length of the array's first and second dimensions must be less than or equal to 16. Otherwise, it might be clipped or distorted when it displays.

Data Types: `double` | `uint8`

Interactive Control

`State` — Toggle button state

`'off'` (default) | `'on'`

Toggle button state, specified as `'off'` or `'on'`. When this property value is `'on'`, the toggle button appears in the down (depressed) position. When this property value is `'off'`, the toggle button appears in the up position. Changing the state causes the appropriate OnCallback or OffCallback function to execute.

`ClickedCallback` — Callback function that executes when user clicks uitoggletool

`''` (default) | function handle | cell array | string

Callback function that executes when a user clicks the uitoggletool, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

This callback function executes after the OnCallback function or OffCallback function executes (depending on the state of the button).

For more information about specifying callback functions as function handles, cell arrays, or strings, see “How to Specify Callback Property Values”.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle` | `cell` | `char`

`OnCallback` — Callback to execute when user turns on toggle button

`''` (default) | function handle | cell array | string

Callback to execute when user turns on the toggle button, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying callback functions as function handles, cell arrays, or strings, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`OffCallback` — Callback to execute when user turns off the toggle button

`''` (default) | function handle | cell array | string

Callback to execute when user turns off toggle button, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying callback functions as function handles, cell arrays, or strings, see "How to Specify Callback Property Values".

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`Enable` — Operational state of uitoggletool

`'on'` (default) | `'off'`

Operational state of uitoggletool, specified as `'on'` or `'off'`. The `Enable` property controls whether the uitoggletool responds to button clicks. The are two possible values:

- `'on'` – The uitoggletool is operational.
- `'off'` – The uitoggletool is not operational and appears grayed-out.

The value of the `Enable` property and the type of button click determine the response.

Enable Value	Response to Left-Click	Response to Right-Click
`'on'`	**1** The OnCallback or OffCallback function execute, depending on the current state of the uitoggletool. **2** The uitoggletool's `ClickedCallback` function executes.	The uitoggletool is not operational. No callback executes.
`'off'`	The uitoggletool is not operational. No callback executes.	The uitoggletool is not operational. No callback executes.

`TooltipString` — Tooltip text

string

Content of uitoggletool tooltip, specified as a string. When the user moves the mouse pointer over the uitoggletool and leaves it there, the tooltip displays.

Example: `'Some string'`

`UIContextMenu` — Context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu handle

This property has no effect on uitoggletools.

Callback Execution Control

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

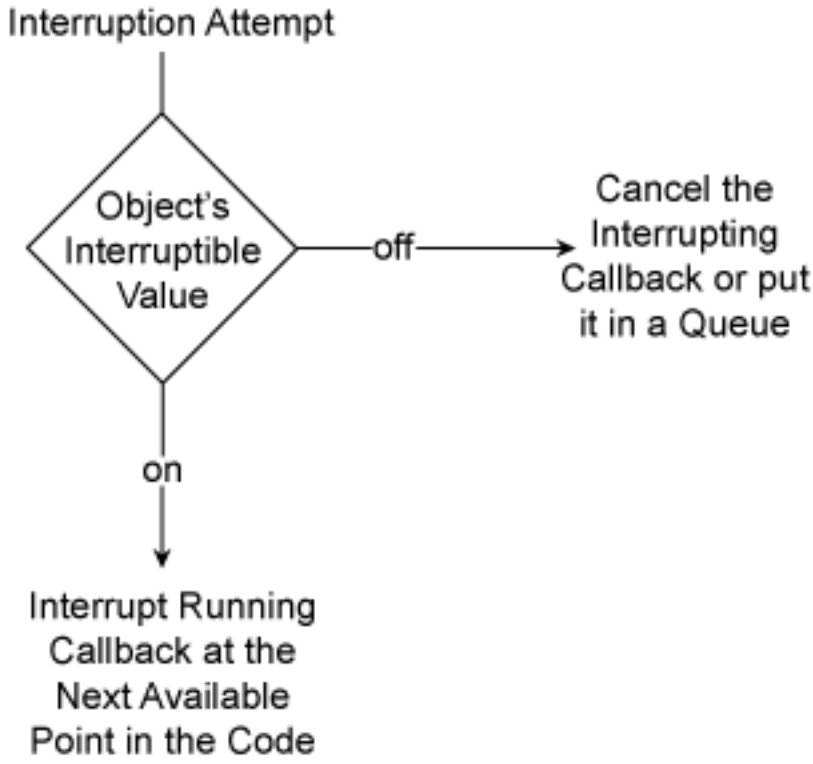
Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback

determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uitoggletool callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback.

MATLAB resumes executing the running callback when the interrupting callback completes.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.

- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See “Interrupt Callback Execution” for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

This property has no effect on the uitoggletool.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uitoggletool

`'off'` (default) | `'on'`

Deletion status of uitoggletool, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uitoggletool begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uitoggletool no longer exists.

Check the value of the BeingDeleted property to verify that the uitoggletool is not about to be deleted before querying or modifying it.

`CreateFcn` — Uitoggletool creation function

function handle | cell array | string

Uitoggletool creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uitoggletool. MATLAB initializes all uitoggletool property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uitoggletool that is being created.

Setting the CreateFcn property on an existing uitoggletool has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uitoggletool object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uitoggletool deletion function

function handle | cell array | string

Uitoggletool deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uitoggletool (for example, when the end user deletes the figure). MATLAB executes

the DeleteFcn callback before destroying the properties of the uitoggletool. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uitoggletool that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object

`'uitoggletool'`

Type of graphics object, returned as `'uitoggletool'`.

`Tag` — Uitoggletool identifier

`''` (default) | string

Uitoggletool identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uitoggletool. When you need access to the uitoggletool elsewhere in your code, you can use the `findobj` function to search for the uitoggletool based on the Tag value.

Example: `'toggletool1'`

Data Types: `char`

`UserData` — Data to associate with the uitoggletool object

empty array (default) | array

Data to associate with the uitoggletool object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uitoggletool parent

uitoolbar

Uitoggletool parent, specified as a uitoolbar. You can move a uitoggletool to a different uitoolbar by setting this property to the handle of the target uitoolbar.

`HandleVisibility` — Visibility of Uitoggletool handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uitoggletool handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uitoggletool handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uitoggletool handle is always visible.
`'callback'`	The uitoggletool handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitoggletool at the command-line, but allows callback functions to access it.
`'off'`	The uitoggletool handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

uitoolbar

Create toolbar on figure

Syntax

```
t = uitoolbar
t = uitoolbar(Name,Value,...)
t = uitoolbar(parent)
t = uitoolbar(parent,Name,Value,...)
```

Description

`t = uitoolbar` creates a uitoolbar in an existing figure and returns the uitoolbar object, `t`. If there is no figure available, then MATLAB creates a new figure to serve as the parent.

`t = uitoolbar(Name,Value,...)` creates a uitoolbar and specifies one or more uitoolbar property names and corresponding values. Use this syntax to override the default uitoolbar properties.

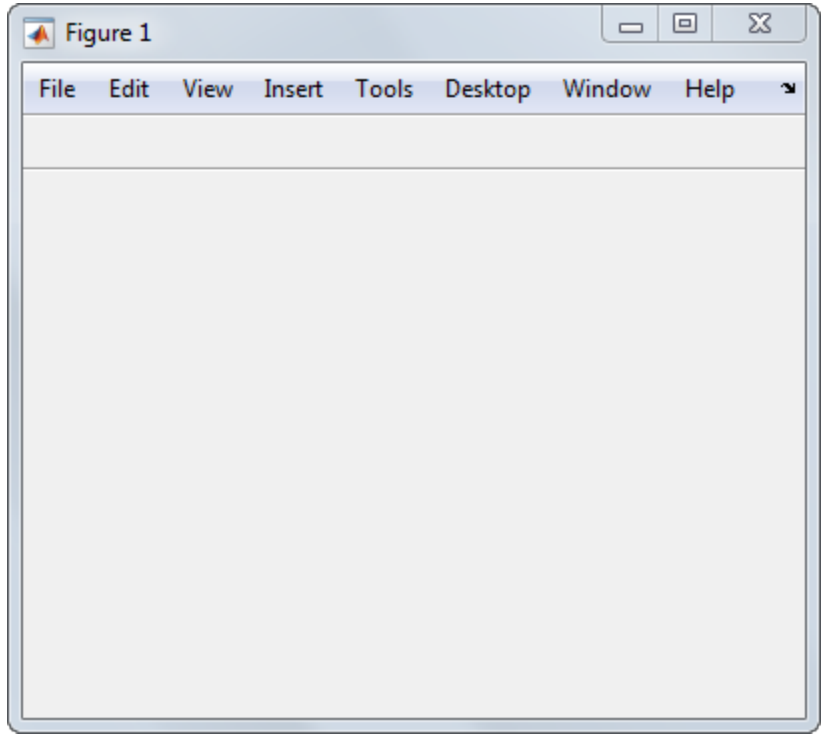
`t = uitoolbar(parent)` creates a uitoolbar in a specific parent figure. The `parent` input argument is the parent figure object.

`t = uitoolbar(parent,Name,Value,...)` creates a uitoolbar with a specific parent and one or more uitoolbar properties.

Examples

This example creates a figure containing an empty uitoolbar.

```
f = figure('ToolBar','none')
t = uitoolbar(f)
```



More About

Tips

Uitoolbars do not appear in figures whose `WindowStyle` property is set to `'Modal'`. If a figure containing a uitoolbar child is changed to `'Modal'`, the uitoolbar child still exist in the `Children` property of the figure. However, the uitoolbar does not display while WindowStyle is set to `'Modal'`.

`figure` | `uipushtool` | `uitoggletool` | Uitoolbar Properties

Introduced before R2006a

Uitoolbar Properties

Control appearance and behavior tool bar

A uitoolbar is a tool bar containing buttons at the top of a figure window. The `uitoolbar` function creates a tool bar in a figure and sets any required properties before displaying it. By changing uitoolbar property values, you can modify certain aspects of its appearance and behavior.

Starting in R2014b, you can use dot notation to query and set properties.

```
t = uitoolbar;
isvisible = t.Visible;
t.Visible = 'off';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Visible` — Uitoolbar visibility

`'on'` (default) | `'off'`

Uitoolbar visibility, specified as `'on'` or `'off'`. When the Visible property is set to `'off'`, the uitoolbar is not visible, but you can query and set its properties.

Interactive Control

`UIContextMenu` — Context menu

empty `GraphicsPlaceholder` array (default) | uicontextmenu handle

This property has no effect on uitoolbars.

Callback Execution Control

`Interruptible` — Callback interruption

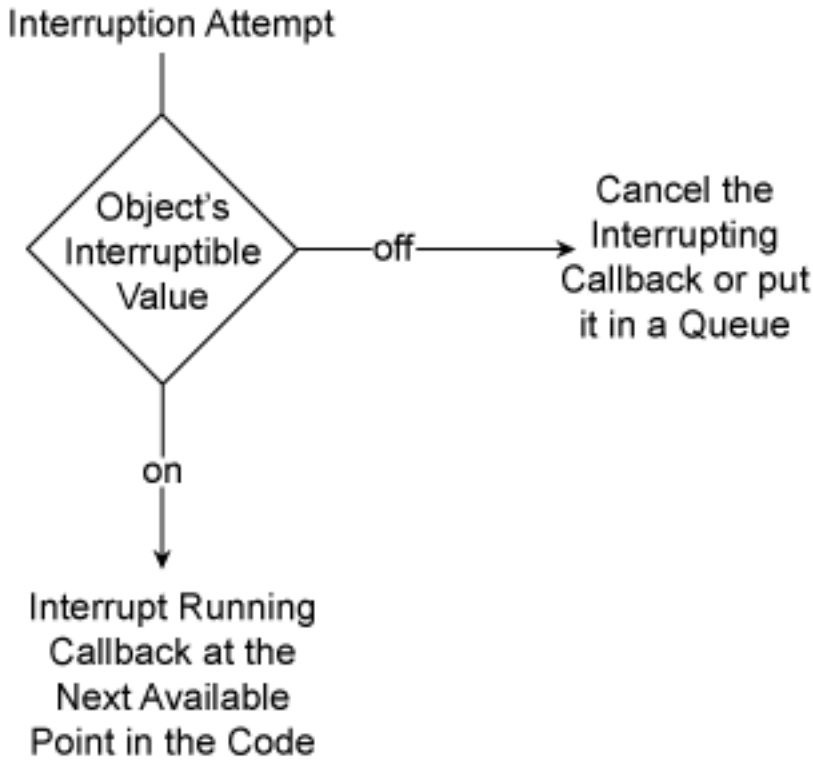
`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The Interruptible property determines if a running callback can be interrupted.

There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt the running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the BusyAction property of the object owning the interrupting callback determines if it is discarded or put into a queue.



If a uitoolbar callback is the running callback, then the Interruptible property determines if it can be interrupted by another callback. The Interruptible property has two possible values:

- `'on'` — A callback can interrupt the running callback. The interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause`.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — A callback cannot interrupt the running callback. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.

Note: Callback interruption and execution behave differently in these situations:

- If the interrupting callback is a DeleteFcn, CloseRequestFcn, or SizeChangedFcn callback, then the interruption occurs regardless of the Interruptible property value.
- If the running callback is currently executing the `waitfor` function, then the interruption occurs regardless of the Interruptible property value.
- MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command might change when another callback executes.

See “Interrupt Callback Execution” for an example that shows how the Interruptible and BusyAction properties affect the behavior of a program.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` (default) or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks. There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

The `BusyAction` property of the source of the interrupting callback determines how MATLAB handles its execution. The `BusyAction` property has these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution.
- `'cancel'` — Do not execute the interrupting callback.

Whenever MATLAB invokes a callback, that callback always attempts to interrupt an executing callback. The Interruptible property of the object whose callback is running determines if interruption is allowed. If Interruptible is set to:

- `on` — Interruption occurs at the next point where MATLAB processes the queue. This is the default.
- `off` — The BusyAction property (of the object owning the interrupting callback) determines if MATLAB enqueues or ignores the interrupting callback.

See “Interrupt Callback Execution” for an example that shows how the BusyAction and Interruptible properties affect the behavior of a program.

`HitTest` — Ability to become current object

`'on'` (default) | `'off'`

This property has no effect on the uitoolbar.

Creation and Deletion Control

`BeingDeleted` — Deletion status of uitoolbar

`'off'` (default) | `'on'`

Deletion status of uitoolbar, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the uitoolbar begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the uitoolbar no longer exists.

Check the value of the BeingDeleted property to verify that the uitoolbar is not about to be deleted before querying or modifying it.

`CreateFcn` — Uitoolbar creation function

function handle | cell array | string

Uitoolbar creation function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

This property specifies a callback function to execute when MATLAB creates the uitoolbar. MATLAB initializes all uitoolbar property values before executing the CreateFcn callback. If you do not specify the CreateFcn property, then MATLAB executes a default creation function.

Use the `gcbo` function in your CreateFcn code to get the handle to the uitoolbar that is being created.

Setting the CreateFcn property on an existing uitoolbar has no effect.

Note: Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a CreateFcn. Copying the uitoolbar object causes the CreateFcn callback to execute repeatedly.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

`DeleteFcn` — Uitoolbar deletion function

function handle | cell array | string

Uitoolbar deletion function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.

- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

For more information about specifying a callback property value as a function handle, cell array, or string, see "How to Specify Callback Property Values".

The DeleteFcn property specifies a callback function to execute when MATLAB deletes the uitoolbar (for example, when the end user deletes the figure). MATLAB executes the DeleteFcn callback before destroying the properties of the uitoolbar. If you do not specify the DeleteFcn property, then MATLAB executes a default deletion function.

Use the `gcbo` function in your DeleteFcn code to get the handle to the uitoolbar that is being deleted.

Example: `@myfun`

Example: `{@myfun,x}`

Data Types: `function_handle | cell | char`

Identifiers

`Type` — Type of graphics object
`'uitoolbar'`

Type of graphics object, returned as `'uitoolbar'`.

`Tag` — Uitoolbar identifier
`''` (default) | string

Uitoolbar identifier, specified as a string. You can specify a unique Tag value to serve as an identifier for the uitoolbar. When you need access to the uitoolbar elsewhere in your code, you can use the `findobj` function to search for the uitoolbar based on the Tag value.

Example: `'toolbar1'`

Data Types: `char`

`UserData` — Data to associate with the uitoolbar object
empty array (default) | array

Data to associate with the uitoolbar object, specified as any array. Specifying UserData can be useful for sharing data values within and across UIs. See “Share Data Among Callbacks” for more information.

Example: `[1 2 3]`

Example: `'April 21'`

Example: `struct('value1',[1 2 3],'value2','April 21')`

Example: `{[1 2 3],'April 21'}`

Parent/Child

`Parent` — Uitoolbar parent

figure

Uitoolbar parent, specified as a figure. You can move a uitoolbar to a different figure by setting this property to the handle of the target figure.

`Children` — Children of uitoolbar

empty `GraphicsPlaceholder` array (default) | 1-D array of component objects

Children of uitoolbar, returned as an empty `GraphicsPlaceholder` or a 1-D array of component objects. The children of uitoolbars are uipushtools and uitoggletools.

You cannot add or remove children using the `Children` property of the uitoolbar. Use this property to view the list of children or to reorder the children. The order of the children in this array reflects the order of the components displayed in the Uitoolbar.

To add a child to this list, set the `Parent` property of the child component to be the uitoolbar object.

Objects with the HandleVisibility property set to `'off'` do not list in the Children property. For more information, see the HandleVisibility property description.

`HandleVisibility` — Visibility of Uitoolbar handle

`'on'` (default) | `'callback'` | `'off'`

Visibility of Uitoolbar handle, specified as `'on'`, `'callback'`, or `'off'`.

This property controls the visibility of the uitoolbar handle in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions

that obtain handles by searching the object hierarchy or querying handle properties. These functions include `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. The HandleVisibility property also controls the visibility of the object's handle in the parent figure's CurrentObject property. Handles are still valid even if they are not visible. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HandleVisibility Value	Description
`'on'`	The uitoolbar handle is always visible.
`'callback'`	The uitoolbar handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the uitoolbar at the command-line, but allows callback functions to access it.
`'off'`	The uitoolbar handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

Set the graphics root ShowHiddenHandles property to `'on'` to make all handles visible, regardless of their HandleVisibility value. This setting has no effect on their HandleVisibility values.

- "Default Property Values"

uiwait

Block program execution and wait to resume

Syntax

```
uiwait
uiwait(h)
uiwait(h,timeout)
```

Description

`uiwait` blocks execution until `uiresume` is called or the current figure is deleted. This syntax is the same as `uiwait(gcf)`.

`uiwait(h)` blocks execution until `uiresume` is called or the figure `h` is deleted.

`uiwait(h,timeout)` blocks execution until `uiresume` is called, the figure `h` is deleted, or `timeout` seconds elapse. The minimum value of `timeout` is 1. If `uiwait` receives a smaller value, it issues a warning and uses a 1 second `timeout`.

Examples

This example creates a UI with a **Continue** push button. The example calls `uiwait` to block MATLAB execution until `uiresume` is called. This happens when the user clicks the **Continue** push button because the push button's `Callback`, which responds to the click, calls `uiresume`.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
              'Callback','uiresume(gcbf)');
disp('This will print immediately');
uiwait(gcf);
disp('This will print after you click Continue');
close(f);
```

`gcbf` is the handle of the figure that contains the object whose callback is executing.

More About

Tips

The `uiwait` and `uiresume` functions block and resume MATLAB and Simulink program execution. `uiwait` also blocks the execution of Simulink models. The functions `pause` (with no argument) and `waitfor` also block execution in this manner. `uiwait` is a convenient way to use the `waitfor` command. You typically use it in conjunction with a dialog box. It provides a way to block the execution of the MATLAB program that created the dialog, until the user responds to the dialog box. When used in conjunction with a modal dialog, `uiwait` can block the execution of the program file *and* restrict user interaction to the dialog only.

Introduced before R2006a

uminus, -

Unary minus

Syntax

```
C = -A
C = uminus(A)
```

Description

`C = -A` negates the elements of `A` and stores the result in `C`.

`C = uminus(A)` is an alternative way to execute `-A`, but is rarely used. It enables operator overloading for classes.

Examples

Negate Elements of Matrix

Create a 2-by-2 matrix, `A`.

```
A = [1 -3; -2 4]
```

```
A =

     1    -3
    -2     4
```

Negate the elements of `A`.

```
C = -A
```

```
C =

    -1     3
```

```
     2    -4
```

Input Arguments

A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. A can be a numeric array, logical array, character array, duration array, or calendar duration array.
Complex Number Support: Yes

More About

- "Array vs. Matrix Operations"
- "Operator Precedence"

See Also

`minus` | `uplus`

undocheckout

(To be removed) Undo previous checkout from source control system (UNIX platforms)

Note: `undocheckout` will be removed in a future release.

Syntax

```
undocheckout('filename')
undocheckout({'filename1','filename2', ...,'filenamen'})
```

Description

`undocheckout('filename')` makes the file `filename` available for checkout, where `filename` does not reflect any of the changes you made after you last checked it out. Use the full path for `filename` and include the file extension.

`undocheckout({'filename1','filename2', ...,'filenamen'})` makes `filename1` through `filenamen` available for checkout, where the files do not reflect any of the changes you made after you last checked them out. Use the full paths for the file names and include the file extensions.

Examples

Undo the checkouts of `/myserver/myfiles/clock.m` and `/myserver/myfiles/calendar.m` from the source control system:

```
undocheckout({'/myserver/myfiles/clock.m', ...
'/myserver/myfiles/calendar.m'})
```

Introduced before R2006a

unicode2native

Convert Unicode character representation to numeric bytes

Syntax

```
bytes = unicode2native(unicodestr)
bytes = unicode2native(unicodestr,encoding)
```

Description

`bytes = unicode2native(unicodestr)` converts a `char` vector of Unicode character representations, `unicodestr`, to the user default encoding, and returns the bytes as a `uint8` vector, `bytes`. Output vector `bytes` has the same general array shape as the `unicodestr` input. You can save the output of `unicode2native` to a file using the `fwrite` function.

`bytes = unicode2native(unicodestr,encoding)` converts `unicodestr` to the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string (`''`) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. If `encoding` is unspecified or is the empty string (`''`), the default encoding scheme is used.

Examples

This example begins with two strings containing Unicode character representations. It assumes that string `str1` contains text in a Western European language and string `str2` contains Japanese text. The example writes both strings into the same file, using the ISO-8859-1 character encoding scheme for the first string and the Shift-JIS encoding scheme for the second string. The example uses `unicode2native` to convert the two strings to the appropriate encoding schemes.

```
fid = fopen('mixed.txt', 'w');
bytes1 = unicode2native(str1, 'ISO-8859-1');
fwrite(fid, bytes1, 'uint8');
bytes2 = unicode2native(str2, 'Shift_JIS');
```

```
fwrite(fid, bytes2, 'uint8');
fclose(fid);
```

See Also

native2unicode

Introduced before R2006a

union

Set union of two arrays

Syntax

```
C = union(A,B)
C = union(A,B,'rows')
[C,ia,ib] = union(A,B)
[C,ia,ib] = union(A,B,'rows')

[C,ia,ib] = union( ___ ,setOrder)

[C,ia,ib] = union(A,B,'legacy')
[C,ia,ib] = union(A,B,'rows','legacy')
```

Description

`C = union(A,B)` returns the combined data from `A` and `B` with no repetitions.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then `union` returns the combined values from `A` and `B`. The values of `C` are in sorted order.
- If `A` and `B` are tables, then `union` returns the combined set of rows from both tables. The rows of table `C` are in sorted order.

`C = union(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the combined rows from `A` and `B` with no repetitions. The rows of `C` are in sorted order.

The `'rows'` option does not support cell arrays, unless one of the inputs is either a categorical array or a datetime array.

`[C,ia,ib] = union(A,B)` also returns index vectors `ia` and `ib`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, or cell arrays of strings, then the values in `C` are a sorted combination of the values of `A(ia)` and `B(ib)`.

- If A and B are tables, then C is a sorted combination of the rows of A(ia,:) and B(ib,:).

[C,ia,ib] = union(A,B,'rows') also returns index vectors ia and ib, such that the rows of C are a sorted combination of the rows of A(ia,:) and B(ib,:).

[C,ia,ib] = union(___ ,setOrder) returns C in a specific order using any of the input arguments in the previous syntaxes. setOrder='sorted' returns the values (or rows) of C in sorted order. setOrder='stable' returns the values (or rows) of C in the same order as A, and then B. If no value is specified, the default is 'sorted'.

[C,ia,ib] = union(A,B,'legacy') and [C,ia,ib] = union(A,B,'rows','legacy') preserve the behavior of the union function from R2012b and prior releases.

The 'legacy' option does not support categorical arrays, tables, datetime arrays, or duration arrays.

Examples

Union of Two Vectors

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors A and B.

```
C = union(A,B)
```

```
C =

     1     3     5     7
```

Union of Two Tables

Define two tables with rows in common.

```
A = table([1:5]',['A';'B';'C';'D';'E'],logical([0;1;0;1;0]))
B = table([1:2:10]',['A';'C';'E';'G';'I'],logical(zeros(5,1)))
```

```
A =
```

```
    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    2       B       true
    3       C       false
    4       D       true
    5       E       false

B =

    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    3       C       false
    5       E       false
    7       G       false
    9       I       false
```

Find the union of tables `A` and `B`.

```
C = union(A,B)
```

```
C =

    Var1    Var2    Var3
    ----    ----    -----
    1       A       false
    2       B       true
    3       C       false
    4       D       true
    5       E       false
    7       G       false
    9       I       false
```

Union of Two Vectors and Their Indices

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors `A` and `B`, as well as the index vectors, `ia` and `ib`.

```
[C,ia,ib] = union(A,B)
```

```
C =

     1     3     5     7

ia =

     3
     1
     2

ib =

     1
```

The values in `C` are the combined values of `A(ia)` and `B(ib)`.

Union of Two Tables and Their Indices

Define a table, `A`, of gender, age, and height for three people.

```
A = table(['M';'M';'F'],[27;52;31],[74;68;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty'})
```

```
A =

              Gender    Age    Height
              ------    ---    ------
    Ted       M         27     74
    Fred      M         52     68
    Betty     F         31     64
```

Define a table, `B` with the same variables as `A`.

```
B = table(['F';'M'],[64;68],[31;47],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe'})
```

```
B =

            Gender    Height    Age
            ------    ------    ---
    Meg     F         64        31
```

```
    Joe    M         68        47
```

Find the union of tables `A` and `B`, as well as the index vectors, `ia` and `ib`.

```
[C,ia,ib] = union(A,B)
```

```
C =

            Gender    Age    Height
            ------    ---    ------
    Betty   F         31     64
    Ted     M         27     74
    Joe     M         47     68
    Fred    M         52     68

ia =

     3
     1
     2

ib =

     2
```

The data for `Meg` and `Betty` are the same. `union` only returns the index from `A`, which corresponds to `Betty`.

Union of Rows in Two Matrices

Define two matrices with a row in common.

```
A = [2 2 2; 0 0 1];
B = [1 2 3; 2 2 2; 2 2 2];
```

Find the combined rows of `A` and `B`, with no repetition, as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = union(A,B,'rows')
```

```
C =

     0     0     1
```

```
     1     2     3
     2     2     2

ia =

     2
     1

ib =

     1
```

The rows of `C` are the combined rows of `A(ia,:)` and `B(ib,:)`.

Union of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` if you want the values in `C` to have the same order as in `A` and `B`.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'stable')
```

```
C =

     5     7     1     3

ia =

     1
     2
     3

ib =

     1
```

Alternatively, you can specify `'sorted'` order.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'sorted')
```

```
C =

     1     3     5     7

ia =

     3
     1
     2

ib =

     1
```

Union of Vectors Containing NaNs

Define two vectors containing `NaN`.

```
A = [5 NaN 1]; B = [4 NaN NaN];
```

Find the union of vectors `A` and `B`.

```
C = union(A,B)
```

```
C =

     1     4     5   NaN   NaN   NaN
```

`union` treats `NaN` values as distinct.

Cell Array of Strings with Trailing White Space

Create a cell array of strings, `A`.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, `B`, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Combine the elements of `A` and `B`.

```
[C,ia,ib] = union(A,B)
```

```
C =

    'cat'    'dog'    'dog '    'fish'    'fish '    'horse'

ia =

     2
     1
     3
     4

ib =

     1
     3
```

`union` treats trailing white space in cell arrays of strings as distinct characters.

Union of Vectors of Different Classes and Shapes

Create a column vector character array.

```
A = ['A';'B';'C'], class(A)
```

```
A =

A
B
C

ans =

char
```

Create a row vector containing elements of numeric type `double`.

```
B = [68 69 70], class(B)
```

```
B =
```

```
    68    69    70

ans =

double
```

The `union` of `A` and `B` returns a column vector character array.

```
C = union(A,B), class(C)

C =

A
B
C
D
E
F

ans =

char
```

Union of Char and Cell Array of Strings

Create a character array containing the letters `a` , `b`, and `c`.

```
A = ['a';'b';'c'];
class(A)

ans =

char
```

Create a cell array of strings containing the letters `c`, `d`, and `e`.

```
B = {'c','d','e'};
class(B)

ans =

cell
```

Combine the elements of A and B.

```
C = union(A,B)
```

```
C =

    'a'
    'b'
    'c'
    'd'
    'e'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =

cell
```

Preserve Legacy Behavior of union

Use the `'legacy'` flag to preserve the behavior of `union` from R2012b and prior releases in your code.

Find the union of A and B with the current behavior.

```
A = [5 7 1]; B = [3 1 1];
[C1,ia1,ib1] = union(A,B)
```

```
C1 =

     1     3     5     7

ia1 =

     3
     1
     2

ib1 =

     1
```

Find the union of A and B, and preserve the legacy behavior.

```
A = [5 7 1]; B = [3 1 1];
[C2,ia2,ib2] = union(A,B,'legacy')
```

```
C2 =

     1     3     5     7

ia2 =

     1     2

ib2 =

     3     1
```

Input Arguments

A,B — Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays | datetime arrays | duration arrays | cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, datetime arrays, duration arrays, cell arrays of strings, or tables.

A and B must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.
- Datetime arrays can combine with cell arrays of date strings or single date strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

If `A` and `B` are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

If `A` and `B` are datetime arrays, they must be consistent with each other in whether they specify a time zone.

Furthermore, `A` and `B` can be objects with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

`setOrder` — Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in `C`.

Order Flag	Meaning
`'sorted'`	The values (or rows) in `C` return in sorted order. For example: `C = union([5 5 3],[1 2],'sorted')` returns `C = [1 2 3 5]`.
`'stable'`	The values (or rows) in `C` return in the same order as they appear in `A` and `B`. For example: `C = union([5 5 3],[1 2],'stable')` returns `C = [5 3 1 2]`.

Output Arguments

`C` — Combined data of `A` and `B`

vector | matrix | table

Combined data of `A` and `B`, returned as a vector, matrix, or table. If the inputs `A` and `B` are tables, the order of the variables in the resulting table, `C`, is the same as the order of the variables in `A`.

The following describes the shape of `C` when the inputs are vector or matrices and when the `'legacy'` flag is not specified:

- If the `'rows'` flag is not specified, then `C` is a column vector unless both `A` and `B` are row vectors.
- If the `'rows'` flag is not specified and both `A` and `B` are row vectors, then `C` is a row vector.
- If the `'rows'` flag is specified, then `C` is a matrix containing the combined rows of `A` and `B`.

The class of the inputs `A` and `B` determines the class of `C`:

- If the class of `A` and `B` are the same, then `C` is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then `C` is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then `C` is `double`.
- If you combine a cell array of strings with `char`, then `C` is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then `C` is a categorical array.
- If you combine a datetime array with a cell array of date strings or single date string, then `C` is a datetime array.

`ia` — Index to `A`

column vector

Index to `A`, returned as a column vector when the `'legacy'` flag is not specified. `ia` indicates the values (or rows) in `A` that contribute to the union. If a value (or row) appears multiple times in `A`, then `ia` contains the index to the first occurrence of the value (or row). If a value appears in both `A` and `B`, then `ia` contains the index to the first occurrence in `A`.

`ib` — Index to `B`

column vector

Index to `B`, returned as a column vector when the `'legacy'` flag is not specified. `ib` indicates the values (or rows) in `B` that contribute to the union. If there is a repeated value (or row) appearing exclusively in `B`, then `ib` contains the index to the first occurrence of the value. If a value (or row) appears in both `A` and `B`, then `ib` does not contain an index to the value (or row).

More About

Tips

- To find the union with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `union(A(:,vars),B(:,vars))`, where *`vars`* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.
- "Combine Categorical Arrays"

See Also

`intersect` | `ismember` | `issorted` | `setdiff` | `setxor` | `sort` | `unique`

Introduced before R2006a

unique

Unique values in array

Syntax

```
C = unique(A)
C = unique(A,'rows')
[C,ia,ic] = unique(A)
[C,ia,ic] = unique(A,'rows')

[C,ia,ic] = unique(A,setOrder)
[C,ia,ic] = unique(A,'rows',setOrder)

[C,ia,ic] = unique(A,'legacy')
[C,ia,ic] = unique(A,'rows','legacy')
[C,ia,ic] = unique(A,occurrence,'legacy')
[C,ia,ic] = unique(A,'rows',occurrence,'legacy')
```

Description

`C = unique(A)` returns the same data as in `A`, but with no repetitions.

- If A is a numeric array, logical array, character array, categorical array, datetime array, duration array, or a cell array of strings, then `unique` returns the unique values in A. The values of C are in sorted order.
- If A is a table, then `unique` returns the unique rows in A. The rows of table C are in sorted order.

`C = unique(A,'rows')` treats each row of A as a single entity and returns the unique rows of A. The rows of the array C are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ic] = unique(A)` also returns index vectors ia and ic.

- If A is a vector, then `C = A(ia)` and `A = C(ic)`.
- If `A` is a matrix or array, then `C = A(ia)` and `A(:) = C(ic)`.

- If A is a table, then `C = A(ia,:)` and `A = C(ic,:)`.

`[C,ia,ic] = unique(A,'rows')` also returns index vectors ia and ic, such that `C = A(ia,:)` and `A = C(ic,:)`.

`[C,ia,ic] = unique(A,setOrder)` and `[C,ia,ic] = unique(A,'rows', setOrder)` return C in a specific order. `setOrder='sorted'` returns the values (or rows) of C in sorted order. `setOrder='stable'` returns the values (or rows) of C in the same order as A. If no value is specified, the default is `'sorted'`.

`[C,ia,ic] = unique(A,'legacy')`, `[C,ia,ic] = unique(A,'rows','legacy')`, `[C,ia,ic] = unique(A,occurrence,'legacy')`,and `[C,ia,ic] = unique( A,'rows',occurrence,'legacy')` preserve the behavior of the `unique` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

Examples

Unique Values in Vector

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of A.

```
C = unique(A)
```

```
C =

     2     5     9
```

Unique Rows in Table

Define a table with repeated data.

```
Name = {'Fred';'Betty';'Bob';'George';'Jane'};
Age = [38;43;38;40;38];
Height = [71;69;64;67;64];
Weight = [176;163;131;185;131];

A = table(Age,Height,Weight,'RowNames',Name)
```

```
A =

              Age    Height    Weight
              ---    ------    ------
    Fred      38     71        176
    Betty     43     69        163
    Bob       38     64        131
    George    40     67        185
    Jane      38     64        131
```

Find the unique rows of `A`.

```
C = unique(A)
```

```
C =

              Age    Height    Weight
              ---    ------    ------
    Bob       38     64        131
    Fred      38     71        176
    George    40     67        185
    Betty     43     69        163
```

`unique` returns the rows of `A` in sorted order by the first variable, `Age` and then by the second variable, `Height`.

Unique Values and Their Indices

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of `A` and the index vectors `ia` and `ic`, such that `C = A(ia)` and `A = C(ic)`.

```
[C, ia, ic] = unique(A)
```

```
C =

     2     5     9

ia =

     2
     4
```

```
     1

ic =

     3
     1
     3
     2
```

Unique Rows in Matrix

Define a matrix with a repeated row.

```
A = [9 2 9 5; 9 2 9 0; 9 2 9 5];
```

Find the unique rows of `A` and the index vectors `ia` and `ic`, such that `C = A(ia,:)` and `A = C(ic,:)`.

```
[C, ia, ic] = unique(A,'rows')
```

```
C =

     9     2     9     0
     9     2     9     5

ia =

     2
     1

ic =

     2
     1
     2
```

Notice that the second row in `A` is identified as unique even though the elements `9`, `2`, and `9` are repeated in the other rows.

Unique Values in Vector with Specified Order

Use the `setOrder` argument to specify the ordering of the values in `C`.

Specify `'stable'` if you want the values in `C` to have the same order as in `A`.

```
A = [9 2 9 5];
[C, ia, ic] = unique(A,'stable')
```

```
C =

     9     2     5

ia =

     1
     2
     4

ic =

     1
     2
     1
     3
```

Alternatively, you can specify `'sorted'` order.

```
[C, ia, ic] = unique(A,'sorted')
```

```
C =

     2     5     9

ia =

     2
     4
     1

ic =

     3
     1
     3
```

```
     2
```

Unique Values in Array Containing NaNs

Define a vector containing `NaN`.

```
A = [5 5 NaN NaN];
```

Find the unique values of `A`.

```
C = unique(A)
```

```
C =

     5   NaN   NaN
```

`unique` treats `NaN` values as distinct.

Unique Entries in Cell Array of Strings

Define a cell array of strings.

```
A = {'one','two','twenty-two','One','two'};
```

Find the unique strings contained in `A`.

```
C = unique(A)
```

```
C =

    'One'    'one'    'twenty-two'    'two'
```

Cell Array of Strings with Trailing White Space

Define a cell array of strings, `A`, where some of the strings have trailing white space.

```
A = {'dog','cat','fish','horse','dog ','fish '};
```

Find the unique strings contained in `A`.

```
C = unique(A)
```

```
C =

    'cat'    'dog'    'dog '    'fish'    'fish '    'horse'
```

`unique` treats trailing white space in cell arrays of strings as distinct characters.

Preserve Legacy Behavior of unique

Use the `'legacy'` flag to preserve the behavior of `unique` from R2012b and prior releases in your code.

Find the unique elements of `A` with the current behavior.

```
A = [9 2 9 5];
[C1, ia1, ic1] = unique(A)
```

```
C1 =

     2     5     9

ia1 =

     2
     4
     1

ic1 =

     3
     1
     3
     2
```

Find the unique elements of `A`, and preserve the legacy behavior.

```
[C2, ia2, ic2] = unique(A, 'legacy')
```

```
C2 =

     2     5     9

ia2 =

     2     4     3
```

```
ic2 =

     3     1     3     2
```

Input Arguments

A — Input array

numeric array | logical array | character array | categorical array | datetime arrays | duration arrays | cell array of strings | table

Input array, specified as a numeric array, logical array, character array, categorical array, datetime array, duration array, cell array of strings, or table.

If A is a table, `unique` does not take row names into account. Two rows that have the same values, but different names, are considered equal.

Furthermore, A can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

`setOrder` — Order flag

`'sorted'` (default) | `'stable'`

Order flag, specified as `'sorted'` or `'stable'`, indicates the order of the values (or rows) in C.

Order Flag	Meaning
`'sorted'`	The values (or rows) in C return in sorted order. For example: `C = unique([5 5 3 4],'sorted')` returns `C = [3 4 5]`.
`'stable'`	The values (or rows) in C return in the same order as in A. For example: `C = unique([5 5 3 4],'stable')` returns `C = [5 3 4]`.

`occurrence` — Occurrence flag for legacy behavior

`'last'` (default) | `'first'`

Occurrence flag for legacy behavior, specified as `'first'` or `'last'`, indicates whether ia should contain the first or last indices to repeated values found in A.

Occurrence Flag	Meaning
`'last'`	If there are repeated values (or rows) in A, then ia contains the index to the last occurrence of the repeated value. For example: `[C,ia,ic] = unique([9 9 9],'last','legacy')` returns `ia = 3`.
`'first'`	If there are repeated values (or rows) in A, then ia contains the index to the first occurrence of the repeated value. For example: `[C,ia,ic] = unique([9 9 9],'first','legacy')` returns `ia = 1`.

Output Arguments

`C` — Unique data of `A`

vector | matrix | table

Unique data of A, returned as a vector, matrix, or table. The following describes the shape of C when the input, A, is a vector or a matrix:

- If the `'rows'` flag is not specified and A is a row vector, then C is a row vector.
- If the `'rows'` flag is not specified and A is not a row vector, then C is a column vector.
- If the `'rows'` flag is specified, then C is a matrix containing the unique rows of A.

The class of C is the same as the class of the input A.

`ia` — Index to `A`

column vector

Index to A, returned as a column vector of indices to the *first* occurrence of repeated elements. When the `'legacy'` flag is specified, ia is a row vector that contains indices to the *last* occurrence of repeated elements.

The indices generally satisfy `C = A(ia)`. If `A` is a table, or if the `'rows'` option is specified, then `C = A(ia,:)`.

`ic` — Index to `C`

column vector

Index to C, returned as a column vector when the `'legacy'` flag is not specified. ic contains indices that satisfy the following properties.

- If `A` is a vector, then `A = C(ic)`.
- If `A` is a matrix or array, then `A(:) = C(ic)`.
- If `A` is a table, or if the `'rows'` option is specified, then `A = C(ic,:)`.

More About

Tips

- To find unique rows in table `A` with respect to a subset of variables, you can use column subscripting. For example, you can use `unique(A(:,vars))`, where *`vars`* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

See Also

`intersect` | `ismember` | `issorted` | `setdiff` | `setxor` | `sort` | `union` | `uniquetol`

Introduced before R2006a

uniquetol

Set unique within a tolerance

`uniquetol` is similar to `unique`. Whereas `unique` performs exact comparisons, `uniquetol` performs comparisons using a tolerance.

Syntax

```
C = uniquetol(A,tol)
C = uniquetol(A)
[C,IA,IC] = uniquetol( ___ )
[ ___ ] = uniquetol( ___ ,Name,Value)
```

Description

`C = uniquetol(A,tol)` returns the unique elements in `A` using tolerance `tol`. Two values, `u` and `v`, are within tolerance if

```
abs(u-v) <= tol*max(abs(A(:)))
```

That is, `uniquetol` scales the `tol` input based on the magnitude of the data.

`C = uniquetol(A)` uses a default tolerance of `1e-6` for single-precision inputs and `1e-12` for double-precision inputs.

`[C,IA,IC] = uniquetol( ___ )` returns index vectors `IA` and `IC`, such that `C = A(IA)` and `A~C(IC)` (or `A(:)~C(IC)` if `A` is a matrix), where ~ means the values are within tolerance of each other. You can use any of the input arguments in previous syntaxes.

`[ ___ ] = uniquetol( ___ ,Name,Value)` uses additional options specified by one or more Name-Value pair arguments using any of the input or output argument combinations in previous syntaxes. For example, `uniquetol(A,'ByRows',true)` determines the unique rows in `A`.

Examples

Unique Elements in Presence of Numerical Error

Create a vector, `x`. Obtain a second vector, `y`, by transforming and untransforming `x`. This transformation introduces round-off differences to `y`.

```
x = (1:6)'*pi;
y = 10.^log10(x);
```

Verify that `x` and `y` are not identical by taking the difference.

```
x-y
```

```
ans =

   1.0e-14 *

    0.0444
         0
         0
         0
         0
   -0.3553
```

Use `unique` to find the unique elements in the concatenated vector `[x;y]`. The `unique` function performs exact comparisons and determines that some values in `x` are not exactly equal to values in `y`. These are the same elements that have a nonzero difference in `x-y`. Thus, `c` contains values that *appear* to be duplicates.

```
c = unique([x;y])
```

```
c =

    3.1416
    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
```

```
   18.8496
   18.8496
```

Use `uniquetol` to perform the comparison using a small tolerance. `uniquetol` treats elements that are within tolerance as equal.

```
C = uniquetol([x;y])
```

```
C =

    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
   18.8496
```

Determine Unique Rows

By default, `uniquetol` looks for unique *elements* that are within tolerance, but it also can find unique *rows* of a matrix that are within tolerance.

Create a numeric matrix, `A`. Obtain a second matrix, `B`, by transforming and untransforming `A`. This transformation introduces round-off differences to `B`.

```
A = [0.05 0.11 0.18; 0.18 0.21 0.29; 0.34 0.36 0.41; 0.46 0.52 0.76];
B = log10(10.^A);
```

Use `unique` to find the unique rows in `A` and `B`. The `unique` function performs exact comparisons and determines that all of the rows in the concatenated matrix `[A;B]` are unique, even though some of the rows differ by only a small amount.

```
unique([A;B],'rows')
```

```
ans =

    0.0500    0.1100    0.1800
    0.0500    0.1100    0.1800
    0.1800    0.2100    0.2900
```

```
    0.1800    0.2100    0.2900
    0.3400    0.3600    0.4100
    0.3400    0.3600    0.4100
    0.4600    0.5200    0.7600
    0.4600    0.5200    0.7600
```

Use `uniquetol` to find the unique rows. `uniquetol` treats rows that are within tolerance as equal.

```
uniquetol([A;B],'ByRows',true)
```

```
ans =

    0.0500    0.1100    0.1800
    0.1800    0.2100    0.2900
    0.3400    0.3600    0.4100
    0.4600    0.5200    0.7600
```

Prepare Vectors for Exact Comparison

Create a vector, `x`. Obtain a second vector, `y`, by transforming and untransforming `x`. This transformation introduces round-off differences to some elements in `y`.

```
x = (1:6)'*pi;
y = 10.^log10(x);
```

Combine `x` and `y` into a single tall vector, `A`. Use `uniquetol` to reconstruct `A`, treating the values that are within tolerance as equal.

```
A = [x;y]
[C,IA,IC] = uniquetol(A);
newA = C(IC)
```

```
A =

    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
```

```
   18.8496
    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
   18.8496

newA =

    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
   18.8496
    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
   18.8496
```

You can use `newA` with `==` or functions that use exact equality like `isequal` or `unique` in subsequent code.

```
D1 = unique(A)
D2 = unique(newA)

D1 =

    3.1416
    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
   18.8496
   18.8496

D2 =
```

```
    3.1416
    6.2832
    9.4248
   12.5664
   15.7080
   18.8496
```

Subset Data Using Large Tolerance

Create a cloud of 2-D sample points constrained to be inside a circle of radius `0.5` centered at the point $(\frac{1}{2}, \frac{1}{2})$.

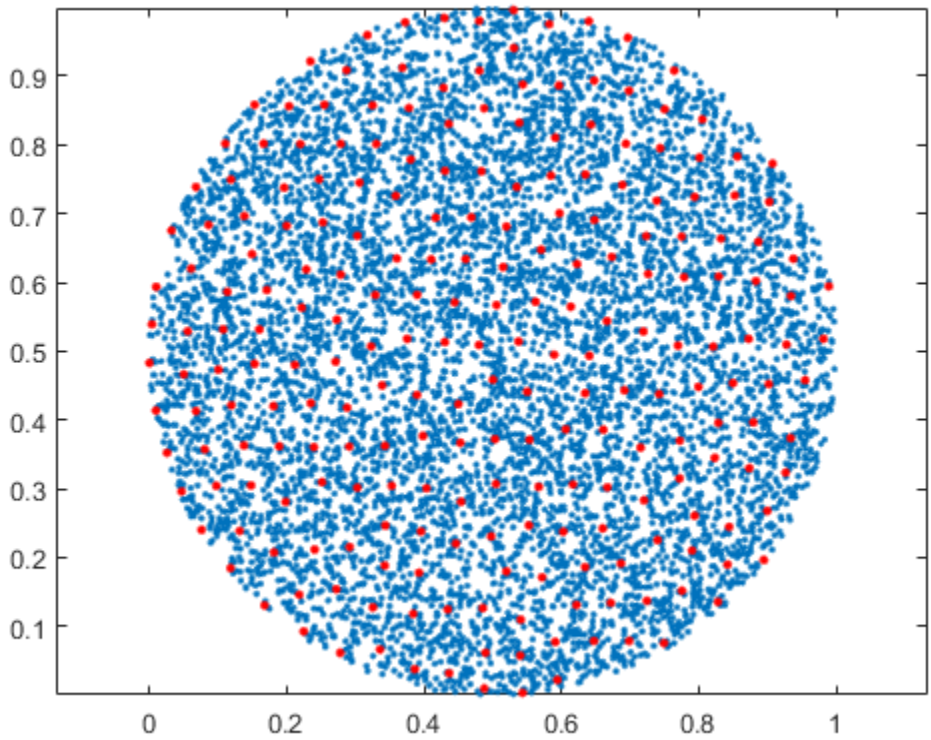
```
x = rand(10000,2);
insideCircle = sqrt((x(:,1)-.5).^2+(x(:,2)-.5).^2)<0.5;
y = x(insideCircle,:);
```

Find a reduced set of points, such that each point of the original dataset is within tolerance of a point.

```
tol = 0.05;
C = uniquetol(y,tol,'ByRows',true);
```

Plot the reduced set of points as red dots on top of the original data set. The red dots are all members of the original data set. All the red dots are at least a distance `tol` apart.

```
plot(y(:,1),y(:,2),'.')
hold on
axis equal
plot(C(:,1), C(:,2), '.r', 'MarkerSize', 10)
```



Average Similar Values in Vector

Create a vector of random numbers and determine the unique elements using a tolerance. Specify `OutputAllIndices` as `true` to return all of the indices for the elements that are within tolerance of the unique values.

```
A = rand(100,1);
[C,IA] = uniquetol(A,1e-2,'OutputAllIndices',true);
```

Find the average value of the elements that are within tolerance of the value `C(2)`.

```
C(2)
allA = A(IA{2})
aveA = mean(allA)
```

```
ans =

    0.0318

allA =

    0.0357
    0.0318
    0.0344

aveA =

    0.0340
```

Specify Absolute Tolerance

By default, `uniquetol` uses a tolerance test of the form `abs(u-v) <= tol*DS`, where `DS` automatically *scales* based on the magnitude of the input data. You can specify a different `DS` value to use with the `DataScale` option. However, absolute tolerances (where `DS` is a scalar) do not scale based on the magnitude of the input data.

First, compare two small values that are a distance `eps` apart. Specify `tol` and `DS` to make the within tolerance equation: `abs(u-v) <= 10^-6`.

```
x = 0.1;
uniquetol([x, exp(log(x))], 10^-6, 'DataScale', 1)
```

```
ans =

    0.1000
```

Next, increase the magnitude of the values. The round-off error in the calculation `exp(log(x))` is proportional to the magnitude of the values, specifically to `eps(x)`. Even though the two large values are a distance `eps` from one another, `eps(x)` is now much larger. Therefore, `10^-6` is no longer a suitable tolerance.

```
x = 10^10;
uniquetol([x, exp(log(x))], 10^-6, 'DataScale', 1)
```

```
ans =

   1.0e+10 *

    1.0000    1.0000
```

Correct this issue by using the default (scaled) value of `DS`.

```
format long
Y = [0.1 10^10];
uniquetol([Y, exp(log(Y))])
```

```
ans =

   1.0e+10 *

   0.000000000010000   1.000000000000000
```

Specify DataScale by Column

Create a set of random 2-D points, then use `uniquetol` to group the points into vertical bands that have a similar (within tolerance) x-coordinate. Use these options with `uniquetol`:

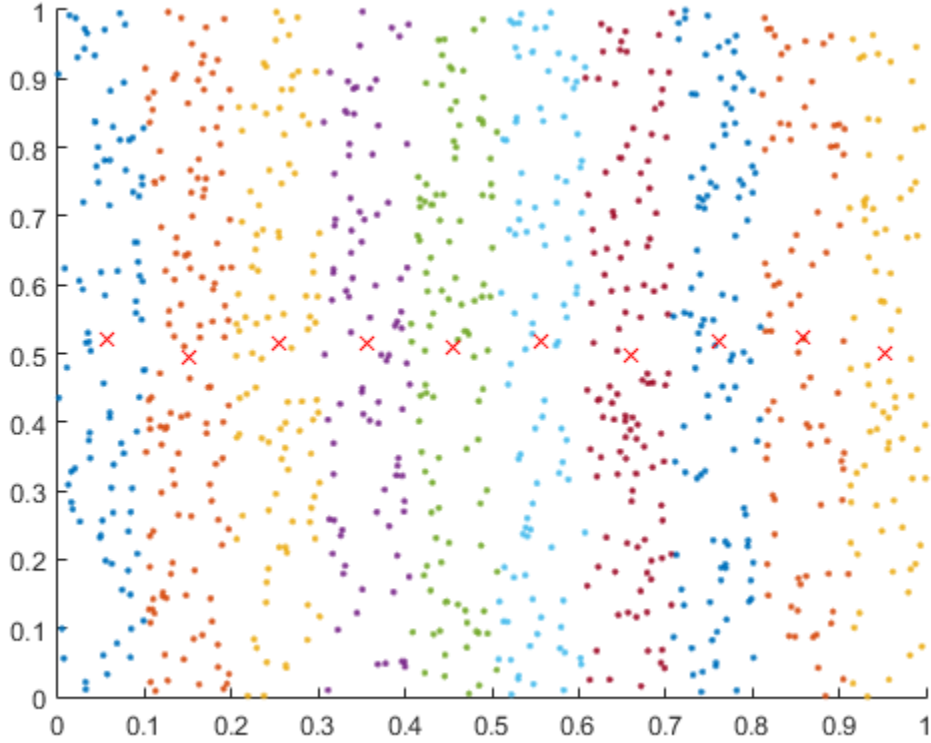
- Specify `ByRows` as `true` since the point coordinates are in the rows of `A`.
- Specify `OutputAllIndices` as `true` to return the indices for all points that have an x-coordinate within tolerance of each other.
- Specify `DataScale` as `[1 Inf]` to use an absolute tolerance for the `x`-coordinate while ignoring the `y`-coordinate.

```
A = rand(1000,2);
DS = [1 Inf];
[C,IA] = uniquetol(A, 0.1, 'ByRows', true, ...
    'OutputAllIndices', true, 'DataScale', DS);
```

Plot the points and average value for each band.

```
hold on
for k = 1:length(IA)
    plot(A(IA{k},1), A(IA{k},2), '.')
```

```
    meanAi = mean(A(IA{k},:));
    plot(meanAi(1), meanAi(2), 'xr')
end
```



- “Average Similar Data Points Using a Tolerance”

Input Arguments

A — Query array

scalar | vector | matrix

Query array, specified as a scalar, vector, or matrix. A must be full.

Data Types: `single | double`

`tol` — Comparison tolerance

positive, real scalar

Comparison tolerance, specified as a positive, real scalar. `uniquetol` scales the `tol` input using the maximum absolute value in input array `A`. Then `uniquetol` uses the resulting scaled comparison tolerance to determine which elements in `A` are unique. If two elements in `A` are within tolerance of each other, then `uniquetol` considers them to be equal.

Two values, `u` and `v`, are within tolerance if `abs(u-v) <= tol*max(abs(A))`.

To specify an absolute tolerance, specify both `tol` and the `'DataScale'` Name-Value pair.

Example: `tol = 0.05`

Example: `tol = 1e-8`

Example: `tol = eps`

Data Types: `single | double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `C = uniquetol(A,'ByRows',true)`

`'OutputAllIndices'` — Output index type

`false` (default) | `true` | `0` | `1`

Output index type, specified as the comma-separated pair consisting of `'OutputAllIndices'` and either `false` (default), `true`, `0`, or `1`. `uniquetol` interprets numeric `0` as `false` and numeric `1` as `true`.

When `OutputAllIndices` is `true`, the `uniquetol` function returns the second output, `IA`, as a cell array. The cell array contains the indices for *all* elements in `A` that are within tolerance of a value in `C`. That is, each cell in `IA` corresponds to a value in `C`, and the values in each cell correspond to locations in `A`.

Example: `[C,IA] = uniquetol(A,tol,'OutputAllIndices',true)`

`'ByRows'` — Row comparison toggle
`false` (default) | `true` | `0` | `1`

Row comparison toggle, specified as the comma-separated pair consisting of `'ByRows'` and either `false` (default), `true`, `0`, or `1`. `uniquetol` interprets numeric `0` as `false` and numeric `1` as `true`. Use this option to find rows in `A` that are unique, within tolerance.

When `ByRows` is `true`:

- `uniquetol` compares the rows of `A` by considering each column separately. For two rows to be within tolerance of one another, each column has to be in tolerance.
- Each row in `A` is within tolerance of a row in `C`. However, no two rows in `C` are within tolerance of each other.

Two rows, `u` and `v`, are within tolerance if `abs(u-v) <= tol*max(abs(A),[],1)`.

Example: `C = uniquetol(A,tol,'ByRows',true)`

`'DataScale'` — Scale of data
scalar | vector

Scale of data, specified as the comma-separated pair consisting of `'DataScale'` and either a scalar or vector. Specify `DataScale` as a numeric scalar, `DS`, to change the tolerance test to be `abs(u-v) <= tol*DS`.

When used together with the `ByRows` option, the `DataScale` value also can be a vector. In this case, each element of the vector specifies `DS` for a corresponding column in `A`. If a value in the `DataScale` vector is `Inf`, then `uniquetol` ignores the corresponding column in `A`.

Example: `C = uniquetol(A,'DataScale',1)`

Example: `[C,IA,IC] = uniquetol(A,'ByRows',true,'DataScale',[eps(1) eps(10) eps(100)])`

Data Types: `single` | `double`

Output Arguments

`C` — Unique elements in `A`
vector | matrix

Unique elements in `A` (within tolerance), returned as a vector or matrix. If `A` is a row vector, then `C` is also a row vector. Otherwise, `C` is a column vector. The elements in `C` are sorted in ascending order. Each element in `A` is within tolerance of an element in `C`, but no two elements in `C` are within tolerance of each other.

If the `ByRows` option is `true`, then `C` is a matrix containing the unique rows in `A`. In this case, the rows in `C` are sorted in ascending order by the first column. Each row in `A` is within tolerance of a row in `C`, but no two rows in `C` are within tolerance of each other.

`IA` — Index to `A`

column vector | cell array

Index to `A`, returned as a column vector of indices to the first occurrence of repeated elements, or as a cell array. `IA` generally satisfies `C = A(IA)`, with the following exceptions:

- If the `ByRows` option is `true`, then `C = A(IA,:)`.
- If the `OutputAllIndices` option is `true`, then `IA` is a cell array and `C(i)~A(IA{i})` where ~ means the values are within tolerance of each other.

`IC` — Index to `C`

column vector

Index to `C`, returned as a column vector of indices. `IC` satisfies the following properties, where ~ means the values are within tolerance of each other.

- If `A` is a vector, then `A~C(IC)`.
- If `A` is a matrix, then `A(:)~C(IC)`.
- If the `ByRows` option is `true`, then `A~C(IC,:)`.

More About

Tips

- There can be multiple valid `C` outputs that satisfy the condition, *no two elements in `C` are within tolerance of each other*. The `uniquetol` function just returns one of the valid outputs.

  `uniquetol` sorts the input lexicographically, and then starts at the lowest value to find unique values within tolerance. As a result, changing the sorting of the input

could change the output. For example, `uniquetol(-A)` might not give the same results as `-uniquetol(A)`.

Introduced in R2015a

matlab.unittest

Summary of packages and classes in MATLAB Unit Test Framework

Description

The `matlab.unittest` package consists of the following classes and packages:

matlab.unittest.constraints	Summary of classes in MATLAB Constraints Interface
matlab.unittest.diagnostics	Summary of classes in MATLAB Diagnostics Interface
matlab.unittest.fixtures	Summary of classes in MATLAB Fixtures Interface
matlab.unittest.FunctionTestCase	TestCase used for function-based tests
matlab.unittest.parameters	Summary of classes associated with MATLAB Unit Test parameters
matlab.unittest.plugins	Summary of classes in MATLAB Plugins Interface
matlab.unittest.plugins.plugindata	Summary of classes in MATLAB Plugin Data Interface
matlab.unittest.qualifications	Summary of classes in MATLAB Qualifications Interface
matlab.unittest.selectors	Summary of classes in MATLAB Selectors Interface
matlab.unittest.Test	Specification of a single test method

matlab.unittest.TestCase	Superclass of all `matlab.unittest` test classes
matlab.unittest.TestResult	Result of running test suite
matlab.unittest.TestRunner	Class for running tests in `matlab.unittest` framework
matlab.unittest.TestSuite	Class for grouping tests to run
matlab.unittest.Verbosity	Verbosity level enumeration class

unix

Execute UNIX command and return output

Syntax

```
status = unix(command)
[status,cmdout] = unix(command)
[status,cmdout] = unix(command,'-echo')
```

Description

`status = unix(command)` calls the UNIX operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = unix(command)` additionally returns the standard output of the command to `cmdout`. This syntax is most useful for commands that do not require user input.

`[status,cmdout] = unix(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

Examples

Save UNIX Command Exit Status and Output

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = unix(command);
status
```

```
status =
```

```
     0
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

Input Arguments

`command` — UNIX command

string

UNIX command, specified as a string. The `command` executes in a UNIX shell, which might not be the shell from which you launched MATLAB.

Example: `'ls'`

Output Arguments

`status` — Command exit status

0 | nonzero integer

Command exit status, returned as either `0` or a nonzero integer. When the command is successful, `status` is `0`. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (`&`), then `status` is the exit status upon command launch.
- If `command` does not include the ampersand character (`&`), then `status` is the exit status upon command completion.

`cmdout` — Output of operating system command

string

Output of the operating system command, returned as a string.

More About

Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the `command` argument (for example, `'emacs &'`). The exit status

is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

Note: If `command` includes the trailing `&` character, `cmdout` is empty.

- The `unix` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while the `unix` function executes. This can lead to corrupted output when `unix` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

Algorithms

MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

Introduced before R2006a

unloadlibrary

Unload shared library from memory

Syntax

```
unloadlibrary libname
```

Description

`unloadlibrary libname` unloads library `libname` from memory.

Examples

Unload Library

Add path to examples folder.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

Load the library, if it is not already loaded.

```
if ~libisloaded('shrlibsample')
   loadlibrary('shrlibsample')
end
```

Clean up.

```
unloadlibrary shrlibsample
```

Input Arguments

`libname` — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: `char`

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

More About

Tips

- To unload a MEX-file, use the `clear` function.

See Also

`clear` | `libisloaded` | `loadlibrary`

Introduced before R2006a

unmesh

Convert edge matrix to coordinate and Laplacian matrices

Syntax

```
[L,XY] = unmesh(E)
```

Description

`[L,XY] = unmesh(E)` returns the Laplacian matrix `L` and mesh vertex coordinate matrix `XY` for the `M`-by-4 edge matrix `E`. Each row of the edge matrix must contain the coordinates `[x1 y1 x2 y2]` of the edge endpoints.

Input Arguments

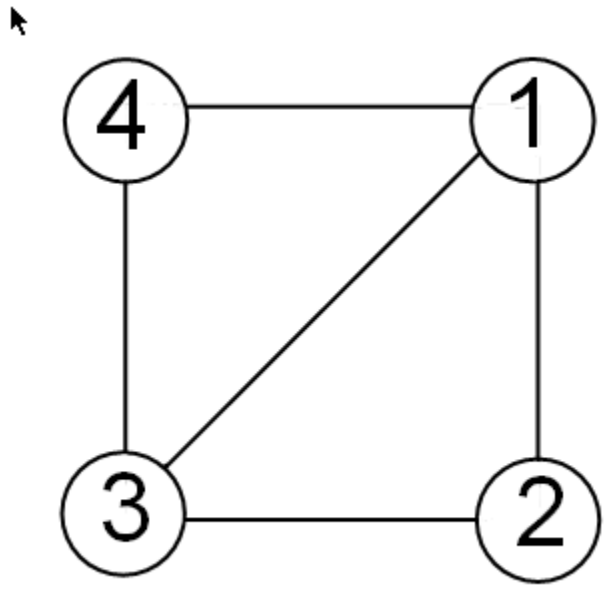
`E`	M-by-4 edge matrix `E`.

Output Arguments

`L`	Laplacian matrix representation of the graph.
`XY`	Mesh vertex coordinate matrix.

Examples

Take a simple example of a square with vertices at (1,1), (1,–1),(–1,–1), and (–1,1), where the connections between vertices are the four perpendicular edges of the square plus one diagonal connection between (–1, –1) and (1,1).



The edge matrix `E` for this graph is:

```
E=[1 1 1 -1;  % edge from 1 to 2
1 -1 -1 -1;   % edge from 2 to 3
-1 -1 -1 1;   % edge from 3 to 4
-1 -1 1 1;    % edge from 4 to 1
-1 1 1 1]     % edge from 3 to 1
```

Use `unmesh` to create the output matrices,

```
[A,XY]=unmesh(E);
4 vertices:
4/4
```

The Laplacian matrix is defined as

$$L_{ij} = \begin{cases} \deg(v_i) & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and } v_i \text{ is adjacent to } v_j \\ 0 & \text{otherwise} \end{cases}$$

`unmesh` returns the Laplacian matrix `L` in sparse notation.

```
L
```

```
L =

   (1,1)         3
   (2,1)        -1
   (3,1)        -1
   (4,1)        -1
   (1,2)        -1
   (2,2)         2
   (4,2)        -1
   (1,3)        -1
   (3,3)         2
   (4,3)        -1
   (1,4)        -1
   (2,4)        -1
   (3,4)        -1
```

To see `L` in regular matrix notation, use the `full` command.

```
full(L)
```

```
ans =

     3    -1    -1    -1
    -1     2     0    -1
    -1     0     2    -1
    -1    -1    -1     3
```

The mesh coordinate matrix `XY` returns the coordinates of the corners of the square.

```
XY
```

```
XY =

    -1    -1
    -1     1
     1    -1
     1     1
```

`gplot` | `treeplot`

unmkpp

Piecewise polynomial details

Syntax

```
[breaks,coefs,l,k,d] = unmkpp(pp)
```

Description

`[breaks,coefs,l,k,d] = unmkpp(pp)` extracts, from the piecewise polynomial `pp`, its breaks `breaks`, coefficients `coefs`, number of pieces `l`, order `k`, and dimension `d` of its target. Create `pp` using `spline` or the spline utility `mkpp`.

Examples

This example creates a description of the quadratic polynomial

$$\frac{-x^2}{4} + x$$

as a piecewise polynomial `pp`, then extracts the details of that description.

```
pp = mkpp([-8 -4],[-1/4 1 0]);
[breaks,coefs,l,k,d] = unmkpp(pp)

breaks =
    -8    -4

coefs =
   -0.2500    1.0000         0

l =
     1

k =
     3
```

```
d =
     1
```

See Also

`mkpp` | `ppval` | `spline`

Introduced before R2006a

unregisterallevents

Unregister all event handlers associated with COM object events at run time

Syntax

```
unregisterallevents(h)
```

Description

`unregisterallevents(h)` unregisters all events previously registered with COM object `h`. After calling `unregisterallevents`, the object no longer responds to any events until you register them again using the `registerevent` function.

COM functions are available on Microsoft Windows systems only.

Examples

Register and unregister events for an instance of the `mwsamp` control, using the `eventlisteners` function to see the event handler associated with each event:

1. Register three events and their respective handler routines.

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', ...
    [0 0 200 200],f, ...
    {'Click' 'myclick'; 'DblClick' 'my2click'; ...
    'MouseDown' 'mymoused'});
eventlisteners(h)

ans =
    'click'         'myclick'
    'dblclick'      'my2click'
    'mousedown'     'mymoused'
```

2. Unregister all events simultaneously with `unregisterallevents`. `eventlisteners` returns an empty cell array, indicating that there are no longer any events registered with the control:

```
unregisterallevents(h);
eventlisteners(h)

ans =
     {}
```

See Also

events (COM) | eventlisteners | registerevent | unregisterevent | isevent

Introduced before R2006a

unregisterevent

Unregister event handler associated with COM object event at run time

Syntax

```
unregisterevent(h,eventhandler)
```

Description

`unregisterevent(h,eventhandler)` unregisters specific event handler routines from their corresponding events. Once you unregister an event, the object no longer responds to the event.

You can unregister events at any time after creating a control. The `eventhandler` argument, which is a cell array, specifies both events and event handlers.

```
unregisterevent(h,{'event_name',@event_handler});
```

Specify events in the `eventhandler` argument using the names of the events. Strings used in the `eventhandler` argument are not case-sensitive. `unregisterevent` does not accept numeric event identifiers.

COM functions are available on Microsoft Windows systems only.

Examples

Unregister events for a control:

1. Create an `mwsamp` control and register all events with the same handler routine, `sampev`. Use `eventlisteners` to see the event handler used by each event. In this case, each event, when fired, calls `sampev.m`:

   ```
   f = figure('position',[100 200 200 200]);
   h = actxcontrol('mwsamp.mwsampctrl.2',...
       [0 0 200 200],f,'sampev');
   eventlisteners(h)
   ```

```
ans =
    'Click'          'sampev'
    'DblClick'       'sampev'
    'MouseDown'      'sampev'
    'Event_Args'     'sampev'
```

2. Unregister just the `dblclick` event. Now, when you list the registered events using `eventlisteners`, `dblclick` is no longer registered and the control does not respond when you double-click the mouse over it:

```
unregisterevent(h,{'dblclick' 'sampev'});
eventlisteners(h)
```

```
ans =
    'Click'          'sampev'
    'MouseDown'      'sampev'
    'Event_Args'     'sampev'
```

3. Now, register the `click` and `dblclick` events with a different event handler for `myclick` and `my2click`, respectively:

```
unregisterallevents(h);
registerevent(h,{'click' 'myclick';'dblclick' 'my2click'});
eventlisteners(h)
```

```
ans =
    'click'        'myclick'
    'dblclick'     'my2click'
```

4. Unregister these same events by specifying event names and their handler routines in a cell array. `eventlisteners` now returns an empty cell array, meaning that no events are registered for the `mwsamp` control:

```
unregisterevent(h,{'click' 'myclick'; 'dblclick' 'my2click'});
eventlisteners(h)
```

```
ans =
     {}
```

Unregister Microsoft Excel workbook events:

1. Create a `Workbook` object and register two events with the event handler routines, `EvtActivateHndlr` and `EvtDeactivateHndlr`:

```
myApp = actxserver('Excel.Application');
wbs = myApp.Workbooks;
```

```
wb = Add(wbs);
registerevent(wb,{'Activate' 'EvtActivateHndlr';...
    'Deactivate' 'EvtDeactivateHndlr'})
eventlisteners(wb)

ans =
    'Activate'      'EvtActivateHndlr'
    'Deactivate'    'EvtDeactivateHndlr'
```

MATLAB shows the events with the corresponding event handlers.

2 Next, unregister the `Deactivate` event handler:

```
unregisterevent(wb,{'Deactivate' 'EvtDeactivateHndlr'})
eventlisteners(wb)

ans =
    'Activate'    'EvtActivateHndlr'
```

MATLAB shows the remaining registered event (`Activate`) with its corresponding event handler.

Introduced before R2006a

unstack

Unstack data from single variable into multiple variables

Syntax

```
W = unstack(T,vars,ivar)
W = unstack(T,vars,ivar,Name,Value)
[W,it] = unstack( ___ )
```

Description

`W = unstack(T,vars,ivar)` converts the tall table, `T`, to an equivalent table, `W`, that is in wide format. `unstack` unstacks a single variable in `T`, specified by `vars`, into multiple variables in `W`. In general, `W` contains more variables, but fewer rows, than `T`.

An indicator variable in `T`, specified by `ivar`, determines which variable in `W` contains each value in `var` after it is unstacked. `unstack` treats the remaining variables in `T` as grouping variables. Each unique combination of values in the grouping variables identifies a group of rows in `T` that will be unstacked into a single row of `W`.

`W = unstack(T,vars,ivar,Name,Value)` converts the table `T` to wide format with additional options specified by one or more Name,Value pair arguments.

For example, you can specify how `unstack` converts variables from `T` to variables in `W`.

`[W,it] = unstack( ___ )` also returns an index vector, it, indicating the correspondence between rows in `W` and rows in `T`. You can use any of the previous input arguments.

Examples

Separate One Variable into Three Variables

Create a table indicating the amount of snowfall in various towns for various storms.

```
Storm = [3;3;1;3;1;1;4;2;4;2;4;2];
Town = {'T1';'T3';'T1';'T2';'T2';'T3';...
    'T2';'T1';'T3';'T3';'T1';'T2'};
Snowfall = [0;3;5;5;9;10;12;13;15;16;17;21];

T = table(Storm,Town,Snowfall)

T =

    Storm    Town    Snowfall
    _____    ____    ________

    3        'T1'     0
    3        'T3'     3
    1        'T1'     5
    3        'T2'     5
    1        'T2'     9
    1        'T3'    10
    4        'T2'    12
    2        'T1'    13
    4        'T3'    15
    2        'T3'    16
    4        'T1'    17
    2        'T2'    21
```

`T` contains three snowfall entries for each storm, one for each town.

Separate the variable `Snowfall` into three variables, one for each town specified in the variable, `Town`.

```
W = unstack(T,'Snowfall','Town')

W =

    Storm    T1    T2    T3
    _____    __    __    __

    3         0     5     3
    1         5     9    10
    4        17    12    15
    2        13    21    16
```

Each row in W contains data from rows in T that have the same value in the grouping variable, Storm. The order of the unique values in Storm determines the order of the data in W.

Apply Aggregation Function to Each Group

Unstack data and apply an aggregation function to multiple rows in the same group that have the same values in the indicator variable.

Create a table containing data on the price of two stocks over 2 days.

```
Date = [repmat({'4/12/2008'},6,1);...
    repmat({'4/13/2008'},5,1)];
Stock = {'Stock1';'Stock2';'Stock1';'Stock2';...
    'Stock2';'Stock2';'Stock1';'Stock2';...
    'Stock2';'Stock1';'Stock2'};
Price = [60.35;27.68;64.19;25.47;28.11;27.98;...
    63.85;27.55;26.43;65.73;25.94];

T = table(Date,Stock,Price)
```

```
T =

       Date          Stock      Price
    ____________    ________    _____

    '4/12/2008'     'Stock1'    60.35
    '4/12/2008'     'Stock2'    27.68
    '4/12/2008'     'Stock1'    64.19
    '4/12/2008'     'Stock2'    25.47
    '4/12/2008'     'Stock2'    28.11
    '4/12/2008'     'Stock2'    27.98
    '4/13/2008'     'Stock1'    63.85
    '4/13/2008'     'Stock2'    27.55
    '4/13/2008'     'Stock2'    26.43
    '4/13/2008'     'Stock1'    65.73
    '4/13/2008'     'Stock2'    25.94
```

T contains two prices for STOCK1 during the first day and four prices for STOCK2 during the first day.

Create a table containing separate variables for each stock and one row for each day. Use Date as the grouping variable and apply the aggregation function, @mean, to the numeric values from the variable, Price, for each group.

```
[W,it] = unstack(T,'Price','Stock',...
    'AggregationFunction',@mean)
```

```
W =

       Date         Stock1    Stock2
    ____________    ______    ______

    '4/12/2008'     62.27     27.31
    '4/13/2008'     64.79     26.64

it =

     1
     7
```

`W` contains the average price for each stock grouped by date.

`it` identifies the index of the first value for each group of rows in `T`. The first value for the group `'4/13/2008'` is in the seventh row of `T`.

Input Arguments

`T` — Tall table

table

Tall table, specified as a table. `T` must contain data variables to unstack, `vars`, and an indicator variable, `ivars`. The remaining variables in `T` are either grouping variables or constant variables.

`vars` — Variables in `T` to unstack

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in `T` to unstack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

`ivar` — Indicator variable in `T`

positive integer | variable name

Indicator variable in `T`, specified as a positive integer or a variable name. The variable specified by `ivar` indicates which variable in `W` each value in `var` is unstacked into.

`ivar` can be a numeric vector, logical vector, character array, cell array of strings, or categorical vector.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'AggregationFunction',@mean` applies the aggregation function `@mean` to the values in `vars`.

`'GroupingVariables'` — Grouping variables in `T` that define groups of rows
positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Grouping variables in `T` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. Each group of rows in `T` becomes one row in `W`.

The default is all the variables in `T` not listed in vars or ivar.

`'ConstantVariables'` — Variables constant within a group
positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables constant within a group, specified as the comma-separated pair consisting of `'ConstantVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. The default is no variables.

The values for these variables in `W` are taken from the first row in each group in `T`.

`'NewDataVariableNames'` — Names for new data variables in `W`
cell array of strings

Names for new data variables in `W`, specified as the comma-separated pair consisting of `'NewDataVariableNames'` and a cell array of strings. The default is strings based on the values of the grouping variable specified in ivar.

`'AggregationFunction'` — Aggregation function from values in `vars` to single value
function handle

Aggregation function from values in `vars` to single value, specified as the comma-separated pair consisting of `'AggregationFunction'` and a function handle. `unstack` applies this function to rows from the same group that have the same value in ivar. The function must aggregate the data values into a single value.

For a numeric data variable, the default is `@sum`. For nonnumeric variables, there is no default function, and you must specify the `'AggregationFunction'` name-value pair argument if multiple rows in the same group have the same value in ivar.

Output Arguments

`W` — Wide table

table

Wide table, returned as a table. `W` contains the unstacked data variables, the grouping variables, and the first value of each group from any constant variables.

The order of the data in `W` is based on the order of the unique values in the grouping variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see `Table Properties`.

`it` — Index to `T`

column vector

Index to `T`, returned as a column vector. For each row in `W`, the index vector, `it`, identifies the index of the first value in the corresponding group of rows in `T`.

More About

Grouping Variables

Grouping variables are utility variables used to group, or categorize, data. Grouping variables are useful for summarizing or visualizing data by group. You can define groups in your table by specifying one or more grouping variables.

A grouping variable can be any of the following:

- Categorical vector
- Cell array of strings
- Character array
- Numeric vector, typically containing positive integers
- Logical vector

Rows that have the same grouping variable value belong to the same group. If you use multiple grouping variables, rows that have the same combination of grouping variable values belong to the same group.

Tips

- You can specify more than one data variable in `T`, and each variable becomes a set of unstacked data variables in `W`. Use a vector of positive integers, a cell array containing multiple variable names, or a logical vector to specify `vars`. The one indicator variable, specified by the input argument, `ivar`, applies to all data variables specifies by `vars`.

`join` | `stack`

untar

Extract contents of tar file

Syntax

```
untar(tarfilename)
untar(tarfilename,outputdir)
untar(url, ___ )
filenames = untar( ___ )
```

Description

`untar(tarfilename)` extracts the archived contents of `tarfilename` into the current directory and sets the files' attributes. It overwrites any existing files with the same names as those in the archive if the existing files' attributes and ownerships permit it. For example, if you rerun `untar` on the same `tarfilename`, MATLAB software does not overwrite files with a read-only attribute; instead, `untar` displays a warning for such files. On Microsoft Windows platforms, the hidden, system, and archive attributes are not set.

`tarfilename` is a string specifying the name of the tar file. `tarfilename` is gunzipped to a temporary directory and deleted if its extension ends in `.tgz` or `.gz`. If an extension is omitted, `untar` searches for `tarfilename` appended with `.tgz`, `.tar.gz`, or `.tar`. `tarfilename` can include the directory name; otherwise, the file must be in the current directory or in a directory on the MATLAB path.

`untar(tarfilename,outputdir)` uncompresses the archive `tarfilename` into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`untar(url, ___ )` extracts the tar archive from an Internet URL. The URL must include the protocol type (for example, `'http://'` or `'ftp://'`). MATLAB downloads the URL to a temporary directory, and then deletes it.

`filenames = untar( ___ )` extracts the tar archive and returns the names of the extracted files in the string cell array `filenames`. If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

Examples

Using tar and untar to Copy Files

Copy all `.m` files in the current directory to the directory `backup`.

```
tar('mymfiles.tar.gz','*.m');
untar('mymfiles','backup');
```

Using untar with URL

Run `untar` to list Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`.

```
url ='http://www.mathworks.com/moler/ncm.tar.gz';
ncmFiles = untar(url,'ncm')
```

See Also

`gzip` | `gunzip` | `tar` | `unzip` | `zip`

Introduced before R2006a

unwrap

Correct phase angles to produce smoother phase plots

Syntax

```
Q = unwrap(P)
Q = unwrap(P,tol)
Q = unwrap(P,[],dim)
Q = unwrap(P,tol,dim)
```

Description

`Q = unwrap(P)` corrects the radian phase angles in a vector `P` by adding multiples of $\pm 2\pi$ when absolute jumps between consecutive elements of `P` are greater than or equal to the default jump tolerance of π radians. If `P` is a matrix, `unwrap` operates columnwise. If `P` is a multidimensional array, `unwrap` operates on the first nonsingleton dimension.

`Q = unwrap(P,tol)` uses a jump tolerance `tol` instead of the default value, π.

`Q = unwrap(P,[],dim)` unwraps along `dim` using the default tolerance.

`Q = unwrap(P,tol,dim)` uses a jump tolerance of `tol`.

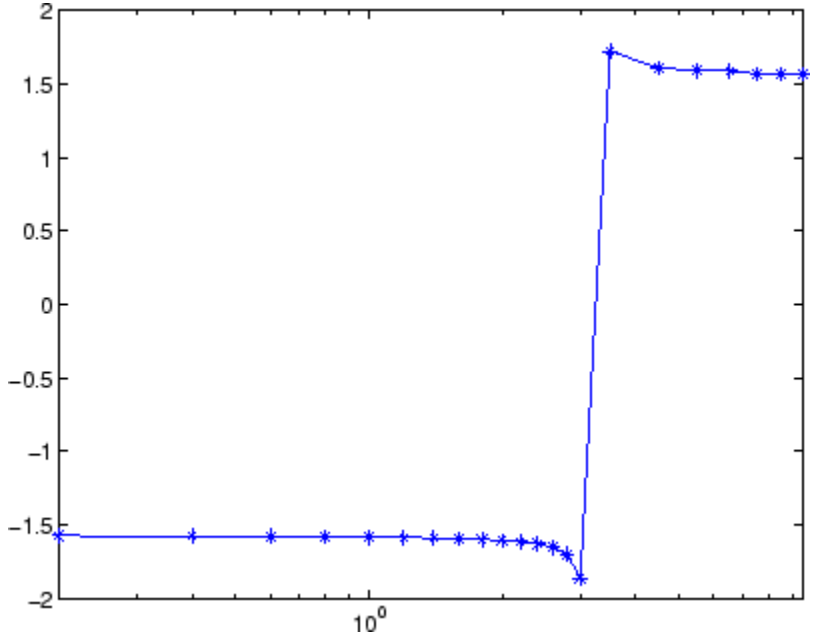
Note A jump tolerance less than π has the same effect as a tolerance of π. For a tolerance less than π, if a jump is greater than the tolerance but less than π, adding $\pm 2\pi$ would result in a jump larger than the existing one, so `unwrap` chooses the current point. If you want to eliminate jumps that are less than π, try using a finer grid in the domain.

Examples

Example 1

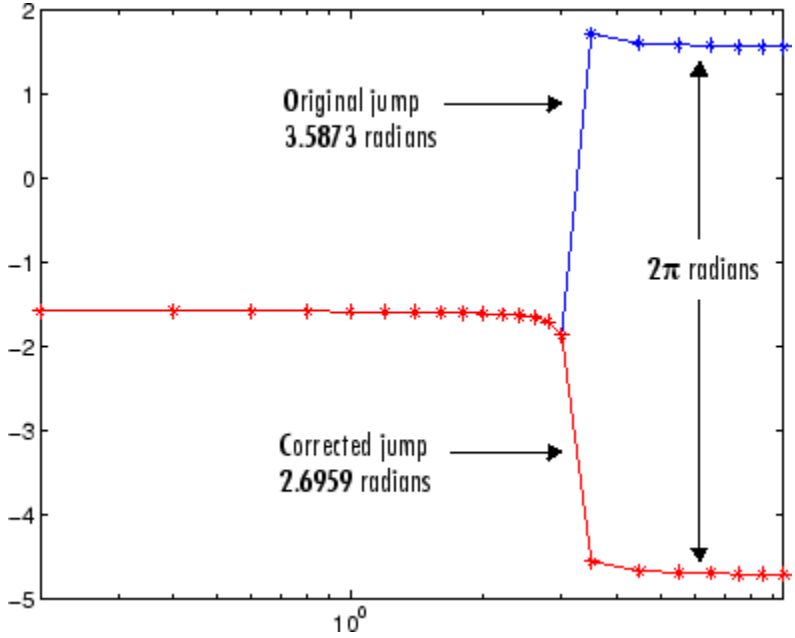
The following phase data comes from the frequency response of a third-order transfer function. The phase curve jumps `3.5873` radians between `w = 3.0` and `w = 3.5`, from `-1.8621` to `1.7252`.

```
w = [0:.2:3,3.5:1:10];
p = [    0
     -1.5728
     -1.5747
     -1.5772
     -1.5790
     -1.5816
     -1.5852
     -1.5877
     -1.5922
     -1.5976
     -1.6044
     -1.6129
     -1.6269
     -1.6512
     -1.6998
     -1.8621
      1.7252
      1.6124
      1.5930
      1.5916
      1.5708
      1.5708
      1.5708 ];
semilogx(w,p,'b*-'), hold
```



Using `unwrap` to correct the phase angle, the resulting jump is `2.6959`, which is less than the default jump tolerance π. This figure plots the new curve over the original curve.

```
semilogx(w,unwrap(p),'r*-')
```



Example 2

Array `P` features smoothly increasing phase angles except for discontinuities at elements `(3,1)` and `(1,2)`.

```
P = [      0    7.0686    1.5708    2.3562
      0.1963    0.9817    1.7671    2.5525
      6.6759    1.1781    1.9635    2.7489
      0.5890    1.3744    2.1598    2.9452 ]
```

The function `Q = unwrap(P)` eliminates these discontinuities.

```
Q =
            0    7.0686    1.5708    2.3562
      0.1963    7.2649    1.7671    2.5525
      0.3927    7.4613    1.9635    2.7489
      0.5890    7.6576    2.1598    2.9452
```

See Also

`abs` | `angle`

Introduced before R2006a

unzip

Extract contents of zip file

Syntax

```
unzip(zipfilename)
unzip(zipfilename,outputdir)
filenames = unzip(zipfilename,outputdir)
```

Description

`unzip(zipfilename)` extracts the archived contents of `zipfilename` into the current folder, preserving the files' attributes and timestamps. The `unzip` function can extract files from your local system or files from an Internet URL.

`unzip(zipfilename,outputdir)` extracts the contents of `zipfilename` into the folder `outputdir`.

`filenames = unzip(zipfilename,outputdir)` returns the names of the extracted files in the string cell array `filenames`. Specifying `outputdir` is optional.

Input Arguments

`zipfilename`

String that specifies the name of the zip file.

If `zipfilename` does not include the full path, `unzip` searches for the file in the current folder and along the MATLAB path. If you do not specify the file extension, `unzip` appends `.zip`.

If you are downloading a URL, `zipfilename` must include the protocol type (for example, `http://`). The `unzip` function downloads the URL to the temporary folder on your system, and deletes the URL on cleanup.

`outputdir`

String that specifies the target folder for the extracted files.

Default: current folder (`'.'`)

Output Arguments

`entrynames`

Cell array of strings that contain the paths of the extracted files.

If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

Examples

Copy the example MAT-files to the folder `archive`:

```
% Zip the example MAT-files to examples.zip
zip('examples.zip','*.mat',...
    fullfile(matlabroot,'toolbox','matlab','demos'))

% Unzip examples.zip to the folder 'archive'
unzip('examples','archive')
```

Download Cleve Moler's "Numerical Computing with MATLAB" examples to the output folder `ncm`:

```
url ='http://www.mathworks.com/moler/ncm.zip';
ncmFiles = unzip(url,'ncm')
```

Alternatives

To extract files from a zip file using the Current Folder browser, select the zip file, right-click to open the context menu, and then select **Extract**.

More About

Tips

- `unzip` does not support password-protected or encrypted zip archives.

- If any files in the target folder have the same name as files in the zip file, and you have write permission to the files, `unzip` overwrites the existing files with the archived versions. If you do not have write permission, `unzip` issues a warning.
- Extract files that contain non-7-bit ASCII characters on a machine that has the appropriate language/encoding settings.

`gzip` | `gunzip` | `tar` | `untar` | `zip` | `fileattrib`

Introduced before R2006a

uplus, +

Unary plus

Syntax

```
C = +A
C = uplus(A)
```

Description

`C = +A` returns array `A` and stores it in `C`.

`C = uplus(A)` is an alternate way to execute `+A`, but is rarely used. It enables operator overloading for classes.

Examples

Unary Plus of Matrix

Create a 2-by-2 matrix, `A`.

```
A = [1 -3; -2 4]
```

```
A =

     1    -3
    -2     4
```

Use unary plus on `A`.

```
C = +A
```

```
C =

     1    -3
    -2     4
```

`C` and `A` are the same.

Input Arguments

`A` — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

More About

- "Array vs. Matrix Operations"
- "Operator Precedence"

See Also

`plus` | `uminus`

upper

Convert string to uppercase

Syntax

```
t = upper('str')
B = upper(A)
```

Description

`t = upper('str')` converts any lowercase characters in the string `str` to the corresponding uppercase characters and leaves all other characters unchanged.

`B = upper(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `upper` to each string within `A`.

Examples

`upper('attention!')` is `ATTENTION!`.

More About

Tips

Character sets supported:

- PC: Windows Latin-1
- Other: ISO Latin-1 (ISO 8859-1)

`lower`

Introduced before R2006a

urlread

Download URL content to MATLAB string (not recommended)

Compatibility

`urlread` is not recommended. Use `webread` or `webwrite` instead.

Syntax

```
str = urlread(URL)
str = urlread(URL,Name,Value)
[str,status] = urlread( ___ )
```

Description

`str = urlread(URL)` downloads the HTML web content from the specified `URL` into the string `str`. `urlread` does not retrieve hyperlink targets and images.

`str = urlread(URL,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[str,status] = urlread( ___ )` suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is `1`. Otherwise, `status` is `0`

Examples

Download Web Content by Specifying Complete URL

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
```

```
    '?term=urlread'];
str = urlread(fullURL);
```

`urlread` reads from the specified URL and downloads the HTML content to the string `str`.

Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
str = urlread(URL,'Get',{'term','urlread'});
```

`urlread` reads from http://www.mathworks.com/matlabcentral/fileexchange/?term=urlread and downloads the HTML content to the string `str`.

Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
    '?term=urlread'];
str = urlread(fullURL,'Timeout',5);
```

Input Arguments

`URL` — Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

Example: `'http://www.mathworks.com/matlabcentral'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

`'Get'` — Data to send to the web form using the GET method

cell array

Parameters of the data to send to the web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

Example: `'Get',{'term','urlread'}`

`'Post'` — Data to send to the web form using the POST method

cell array

Parameters of the data to send to the web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

`'Charset'` — Character encoding

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, `Charset` defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

Example: `'Charset','ISO-8859-1'`

`'Timeout'` — Timeout duration

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of `'Timeout'` and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

Example: `'Timeout',10`

`'UserAgent'` — Client user agent identification
string

Client user agent identification, specified as the comma-separated pair consisting of `'UserAgent'` and a string.

Example: `'UserAgent','MATLAB R2012b'`

`'Authentication'` — HTTP authentication mechanism
`'Basic'`

HTTP authentication mechanism, specified as the comma-separated pair consisting of `'Authentication'` and a string. Currently, only the value `'Basic'` is supported. `'Authentication','Basic'` specifies basic authentication.

If you include the `Authentication` argument, you must also include the `Username` and `Password` arguments.

`'Username'` — User identifier
string

User identifier, specified as the comma-separated pair consisting of `'Username'` and a string. If you include the `Username` argument, you must also include the `Password` and `Authentication` arguments.

Example: `'Username','myName'`

`'Password'` — User authentication password
string

User authentication password, specified as the comma-separated pair consisting of `'Password'` and a string. If you include the `Password` argument, you must also include the `Username` and `Authentication` arguments.

Example: `'Password','myPassword123'`

Output Arguments

`str` — Contents of the file at the specified URL
string

Contents of the file at the specified URL, returned as a string. For example, if the URL corresponds to an HTML page, `str` contains the text and markup in the HTML file. If the URL corresponds to a binary file, `str` is not readable.

`status` — Download status

`1 | 0`

Download status, returned as either `1` or `0`. When the download is successful, `status` is `1`. Otherwise, `status` is `0`.

More About

Tips

- `urlread` saves web content to a string. To save content to a file, use `urlwrite`.
- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.
- "Specify Proxy Server Settings for Connecting to the Internet"

See Also

`ftp | mget | urlwrite | web`

Introduced before R2006a

urlwrite

Download URL content and save to file (not recommended)

Compatibility

`urlwrite` is not recommended. Use `websave` instead.

Syntax

```
urlwrite(URL,filename)
urlwrite(URL,filename,Name,Value)

[filestr,status] = urlwrite( ___ )
```

Description

`urlwrite(URL,filename)` reads web content at the specified `URL` and saves it to the file specified by `filename`.

`urlwrite(URL,filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[filestr,status] = urlwrite( ___ )` stores the file path in variable `filestr`, and suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is `1`. Otherwise, `status` is `0`.

Examples

Download Web Content by Specifying Complete URL

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current folder.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
           '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename);
```

View the file.

```
web(filename)
```

Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current folder.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
filename = 'samples.html';
urlwrite(URL,filename,'get',{'term','urlwrite'});
```

`urlwrite` downloads the HTML content from http://www.mathworks.com/matlabcentral/fileexchange/?term=urlwrite and writes it to `samples.html`.

Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
    '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename,'Timeout',5);
```

Input Arguments

`URL` — Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

Example: `'http://www.mathworks.com/matlabcentral'`

`filename` — Name of file to store web content

string

Name of the file to store the web content, specified as a string. If you do not specify the path for `filename`, `urlwrite` saves the file in the current folder.

Example: `'myfile.html'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

`'Get'` — Data to send to the web form using the GET method

cell array

Parameters of the data to send to the web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

Example: `'Get',{'term','urlread'}`

`'Post'` — Data to send to the web form using the POST method

cell array

Parameters of the data to send to the web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

`'Charset'` — Character encoding

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, `Charset` defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

Example: `'Charset','ISO-8859-1'`

`'Timeout'` — Timeout duration
scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of `'Timeout'` and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

Example: `'Timeout',10`

`'UserAgent'` — Client user agent identification
string

Client user agent identification, specified as the comma-separated pair consisting of `'UserAgent'` and a string.

Example: `'UserAgent','MATLAB R2012b'`

`'Authentication'` — HTTP authentication mechanism
`'Basic'`

HTTP authentication mechanism, specified as the comma-separated pair consisting of `'Authentication'` and a string. Currently, only the value `'Basic'` is supported. `'Authentication','Basic'` specifies basic authentication.

If you include the `Authentication` argument, you must also include the `Username` and `Password` arguments.

`'Username'` — User identifier
string

User identifier, specified as the comma-separated pair consisting of `'Username'` and a string. If you include the `Username` argument, you must also include the `Password` and `Authentication` arguments.

Example: `'Username','myName'`

`'Password'` — User authentication password
string

User authentication password, specified as the comma-separated pair consisting of `'Password'` and a string. If you include the `Password` argument, you must also include the `Username` and `Authentication` arguments.

Example: `'Password','myPassword123'`

Output Arguments

`filestr` — Path of the file

string

Path of the file specified by `filename`, returned as a string.

`status` — Download status

`1` | `0`

Download status, returned as either `1` or `0`. When the download is successful, `status` is `1`. Otherwise, `status` is `0`.

More About

Tips

- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

Introduced before R2006a

usejava

Determine if Java feature is available

Syntax

```
tf = usejava(feature)
```

Description

`tf = usejava(feature)` returns logical `1` (`true`) if the specified feature is supported. Otherwise, it returns logical `0` (`false`). Use for error handling if Java feature is unavailable.

Examples

Display Error Message

Use the following code snippet to test that the AWT GUI components are available before attempting to display a Java Frame.

```
if usejava('awt')
   myFrame = java.awt.Frame;
else
   disp('Unable to open a Java Frame');
end
```

If the AWT is not available on your system, MATLAB displays the message.

Call error Function

Use the following code snippet to terminate a script if MATLAB does not have access to JVM software.

The variable, `filename`, is a function that contains Java code.

```
if ~usejava('jvm')
   error([filename ' requires Java to run.']);
```

```
end
```

Input Arguments

`feature` — Java feature

`'awt' | 'desktop' | 'jvm' | 'swing'`

Java feature, specified as one of these values:

`'awt'`	UI components in the Java Abstract Window Toolkit (AWT) are available.
`'desktop'`	MATLAB interactive desktop is running.
`'jvm'`	Java Virtual Machine software (JVM) is running.
`'swing'`	Swing components (Java lightweight UI components in the Java Foundation Classes) are available.

Introduced before R2006a

userpath

View or change user portion of search path

Syntax

```
userpath

userpath(newpath)
userpath('reset')
userpath('clear')
```

Description

`userpath` returns a string specifying the first folder on the search path. MATLAB adds the *`userpath`* to the search path upon startup.

`userpath(newpath)` sets the primary *`userpath`* folder to `newpath`. The `newpath` folder appears at the top of the search path immediately and at startup in future sessions. MATLAB removes the folder previously specified by *`userpath`* from the search path.

`userpath('reset')` sets the primary *`userpath`* folder to the default for that platform, creating the `Documents/MATLAB` (or `My Documents/MATLAB`) folder, if it does not exist. MATLAB immediately adds the default folder to the top of the search path, and also adds it to the search path at startup in future sessions. On Linux, the `MATLAB` directory is not created if the `Documents` directory does not exist.

`userpath('clear')` clears the value for the primary *`userpath`* immediately, and for future MATLAB sessions. MATLAB removes the folder previously specified by *`userpath`* from the search path.

Examples

View userpath Folder

This example assumes `userpath` is set to the default value on the Windows XP platform, `My Documents\MATLAB`. Start MATLAB and display the current folder:

```
pwd
```

```
H:\My Documents\MATLAB
```

In this example, `H` is the drive at which `My Documents` is located.

Confirm that the current folder is the *`userpath`*.

```
userpath
```

```
H:\My Documents\MATLAB;
```

Display the search path.

```
path
```

```
MATLABPATH

 H:\My Documents\MATLAB
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB returns the search path. The *`userpath`* portion is at the top.

Set New Value for userpath

Assume *`userpath`* is set to the default value on the Windows XP platform, `My Documents\MATLAB`. Change the value from the default for *`userpath`* to `C:\Research_Project`.

```
newpath = 'C:\Research_Project';
userpath(newpath)
```

View the effect of the change on the search path.

```
path
```

```
MATLABPATH

 C:\Research_Project
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
 C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB displays the search path, with the new value for *userpath* portion at the top. Note that MATLAB automatically removed the previous value of *userpath*, `H:\My Documents\MATLAB`, from the search path when you assigned a new value to *userpath*.

Clear the Value for userpath

Assume `userpath` is set to the default value and you do not want any folders to be added to the search path upon startup. Confirm the default is currently set.

```
userpath
```

```
H:\My Documents\MATLAB;
```

Verify that the `userpath` folder is at the top of the search path.

```
path
```

```
MATLABPATH

H:\My Documents\MATLAB
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

Clear the value.

```
userpath('clear')
```

Verify the result.

```
userpath
```

```
ans =
     ''
```

Confirm the *userpath* folder was removed from the search path.

```
path
```

```
MATLABPATH

C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

Note: If you clear the value for *userpath*, the startup folder will not necessarily be on the search path. Removing the *userpath* folder from the search path *and* saving the changes to the path has the same effect.

Input Arguments

newpath — New userpath value

string

New userpath value, specified as a string. `newpath` must be an absolute path.

Example: `'C:\myFolder'`

More About

Tips

- By default, the startup folder is the *userpath* folder when you start MATLAB by double-clicking the shortcut on Windows platforms, or by double-clicking the application on Mac platforms. If you clear the value for *userpath*, the startup folder will not necessarily be on the search path. Removing the *userpath* folder from the search path *and* saving the changes to the path has the same effect.

  To specify the current folder, set the **Initial working folder** preference, described in "General Preferences".
- On Mac and Linux platforms, you can automatically add subfolders to the top of the search path upon startup by specifying the path for the subfolders via the `MATLABPATH` environment variable.

- "What Is the MATLAB Search Path?"
- "MATLAB Startup Folder"

Using ValueIterator Objects

An iterator over intermediate values for use with mapreduce

The `mapreduce` function automatically creates a `ValueIterator` object during execution and uses it to store the values associated with each unique intermediate key added by the map function. Although you never need to explicitly create a `ValueIterator` object to use `mapreduce`, you do need to interact with this object in the reduce function. Use the `hasnext` and `getnext` object functions to retrieve the values associated with each unique key in the intermediate `KeyValueStore` object.

Examples

Get Values from ValueIterator in Reduce Function

Use the `hasnext` and `getnext` functions in a `while` loop within the reduce function to iteratively get values from the `ValueIterator`. For example,

```
function MeanDistReduceFun(sumLenKey, sumLenIter, outKVStore)
    sumLen = [0, 0];
    while hasnext(sumLenIter)
        sumLen = sumLen + getnext(sumLenIter);
    end
    add(outKVStore, 'Mean', sumLen(1)/sumLen(2));
end
```

Always call `hasnext` before `getnext` to confirm availability of a value. `mapreduce` returns an error if you call `getnext` with no remaining values in the `ValueIterator`.

Properties

`Key` — Intermediate key

numeric scalar | string

Intermediate key, specified as a numeric scalar or string. `Key` is one of the unique keys added by a map function. All the values in the `ValueIterator` object are associated with this key.

Object Functions

`hasnext` `getnext`

Create Object

The `mapreduce` function automatically creates `ValueIterator` objects during execution.

- “Getting Started with MapReduce”
- Using KeyValueStore Objects

validateattributes

Check validity of array

Syntax

```
validateattributes(A,classes,attributes)
validateattributes(A,classes,attributes,argIndex)
validateattributes(A,classes,attributes,funcName)
validateattributes(A,classes,attributes,funcName,varName)
validateattributes(A,classes,attributes,funcName,varName,argIndex)
```

Description

`validateattributes(A,classes,attributes)` validates that array `A` belongs to at least one of the specified classes (or its subclass) and has all of the specified attributes. If `A` does not meet the criteria, MATLAB throws an error and displays a formatted error message. Otherwise, `validateattributes` completes without displaying any output.

`validateattributes(A,classes,attributes,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validateattributes(A,classes,attributes,funcName)` includes the specified function name in generated error identifiers.

`validateattributes(A,classes,attributes,funcName,varName)` includes the specified variable name in generated error messages.

`validateattributes(A,classes,attributes,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

Examples

Validate the Size of an Array

```
classes = {'numeric'};
attributes = {'size',[4,6,2]};
```

```
A = rand(3,5,2);
validateattributes(A,classes,attributes)
```

```
Expected input to be of size 4x6x2 when it is actually size 3x5x2.
```

Because A did not match the specified attributes, MATLAB throws an error message.

Validate Array Monotonicity

Determine if an array is increasing or nondecreasing.

```
A = [1 5 8 2;
     9 6 9 4]
validateattributes(A, {'double'},{'nondecreasing'})
validateattributes(A, {'double'},{'increasing'})
```

```
A =

     1     5     8     2
     9     6     9     4
```

Since `A` is both increasing and nondecreasing, `validateattributes` does not throw an error for either attribute check.

Setting `A(2,3)` equal to `A(1,3)` results in a column that is no longer strictly increasing, so `validateattributes` throws an error.

```
A(2,3) = 8
validateattributes(A, {'double'},{'increasing'})
```

```
A =

     1     5     8     2
     9     6     8     4

Expected input to be increasing valued.
```

However, the columns remain nondecreasing since each column element is equal to or greater than the next. The following code does not throw an error.

```
validateattributes(A, {'double'},{'nondecreasing'})
```

Check the Attributes of a Complex Number

Assuming that `a` is to be the second input argument to a function, check that it is nonnegative.

```
a = complex(1,1);
validateattributes(a,{'numeric'},{'nonnegative'},2)

Expected input number 2 to be nonnegative.
```

Because complex numbers lack a well-defined ordering in the complex plane, `validateattributes` does not recognize them as positive or negative.

Ensure Array Values Are Within a Specified Range

Check that the values in an array are 8-bit integers between 0 and 10.

Assume that this code occurs in a function called `Rankings`.

```
classes = {'uint8','int8'};
attributes = {'>',0,'<',10};
funcName = 'Rankings';
A = int8(magic(4));

validateattributes(A,classes,attributes,funcName)

Error using Rankings
Expected input to be an array with all of the values < 10.
```

Validate Function Input Parameters Using `inputParser`

Create a custom function that checks input parameters with `inputParser`, and use `validateattributes` as the validating function for the `addRequired` and `addOptional` methods.

Define the function.

```
function a = findArea(shape,dim1,varargin)
   p = inputParser;
   charchk = {'char'};
   numchk = {'numeric'};
   nempty = {'nonempty'};

   addRequired(p,'shape',@(x)validateattributes(x,charchk,nempty))
   addRequired(p,'dim1',@(x)validateattributes(x,numchk,nempty))
   addOptional(p,'dim2',1,@(x)validateattributes(x,numchk,nempty))
   parse(p,shape,dim1,varargin{:})

   switch shape
```

```
      case 'circle'
         a = pi * dim1.^2;
      case 'rectangle'
         a = dim1 .* p.Results.dim2;
   end
end
```

Call the function with a nonnumeric third input.

```
myarea = findArea('rectangle',3,'x')
```

```
Error using findArea (line 10)
Argument 'dim2' failed validation with error:
Expected input to be one of these types:

double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64

Instead its type was char.
```

Validate Arguments of a Function

Check the inputs of a function and include information about the input name and position in generated error.

Define the function.

```
function v = findVolume(shape,ht,wd,ln)
   validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
   validateattributes(ht,{'numeric'},{'nonempty'},mfilename,'Height',2)
   validateattributes(wd,{'numeric'},{'nonempty'},mfilename,'Width',3)
   validateattributes(ln,{'numeric'},{'nonempty'},mfilename,'Length',4)
```

Call the function without the `shape` input string.

```
vol = findVolume(10,7,4)
```

```
Error using findVolume
Expected input number 1, Shape, to be one of these types:

char

Instead its type was double.

Error in findVolume (line 2)
validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
```

The function name becomes part of the error identifier.

```
MException.last.identifier
```

```
ans =

MATLAB:findVolume:invalidType
```

Input Arguments

A — Input

any type of array

Input, specified as any type of array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell` | `function_handle`
Complex Number Support: Yes

`classes` — Valid data types

cell array of strings

Valid data types, specified as a cell array of strings. Each string can be the name of any built-in or custom class, including:

`'single'`	Single-precision number
`'double'`	Double-precision number
`'int8'`	Signed 8-bit integer
`'int16'`	Signed 16-bit integer
`'int32'`	Signed 32-bit integer
`'int64'`	Signed 64-bit integer
`'uint8'`	Unsigned 8-bit integer
`'uint16'`	Unsigned 16-bit integer
`'uint32'`	Unsigned 32-bit integer
`'uint64'`	Unsigned 64-bit integer
`'logical'`	Logical `true` or `false`
`'char'`	Character or string

`'struct'`	Structure array
`'cell'`	Cell array
`'function_handle'`	function handle
`'numeric'`	Any data type for which the `isa(A,'numeric')` function returns true, including `int8`, `int16`, `int32`, `int64`, `uint8`, `uint16`, `uint32`, `uint64`, `single`, or `double`
`'<class_name>'`	Any other class name

Data Types: `cell`

`attributes` — Valid attributes

cell array of strings

Valid attributes, specified as a cell array of strings.

Some attributes also require numeric values, such as attributes that specify the size or number of elements of A. For these attributes, the numeric value or vector must immediately follow the attribute name string in the cell array.

Attributes that describe the size and shape of array A:

`'2d'`	Two-dimensional array, including scalars, vectors, matrices, and empty arrays
`'3d'`	Array with three or fewer dimensions
`'column'`	Column vector, `N`-by-1
`'row'`	Row vector, 1-by-`N`
`'scalar'`	Scalar value, 1-by-1
`'vector'`	Row or column vector, or a scalar value
`'size', [d1,...,dN]`	Array with dimensions `d1`-by-...-by-`dN`. To skip checking a particular dimension, specify `NaN` for that dimension, such as `[3,4,NaN,2]`.
`'numel', N`	Array with `N` elements
`'ncols', N`	Array with `N` columns
`'nrows', N`	Array with `N` rows
`'ndims', N`	`N`-dimensional array

`'square'`	Square matrix; in other words, a two-dimensional array with equal number of rows and columns
`'diag'`	Diagonal matrix
`'nonempty'`	No dimensions that equal zero
`'nonsparse'`	Array that is not sparse

Attributes that specify valid ranges for values in A:

`'>', N`	All values greater than `N`
`'>=', N`	All values greater than or equal to `N`
`'<', N`	All values less than `N`
`'<=', N`	All values less than or equal to `N`

Attributes that check types of values in a numeric or logical array, `A`:

`'binary'`	Array of ones and zeros
`'even'`	Array of even integers (includes zero)
`'odd'`	Array of odd integers
`'integer'`	Array of integer values
`'real'`	Array of real values
`'finite'`	Array of finite values
`'nonnan'`	No NaN (Not a Number) elements
`'nonnegative'`	No elements less than zero
`'nonzero'`	No elements equal to zero
`'positive'`	No elements less than or equal to zero
`'decreasing'`	Each element of a column is less than the previous element and no element is `NaN`
`'increasing'`	Each element of a column is greater than the previous element and no element is `NaN`
`'nondecreasing'`	Each element of a column is greater than or equal to the previous element and no element is `NaN`
`'nonincreasing'`	Each element of a column is less than or equal to the previous element and no element is `NaN`

Data Types: `cell`

`funcName` — Name of function whose input you are validating

string

Name of function whose input you are validating, specified as a string. If you specify an empty string, `''`, the `validateattribute` function ignores the `funcName` input.

Data Types: `char`

`varName` — Name of input variable

string

Name of input variable, specified as a string. If you specify an empty string, `''`, the `validateattribute` function ignores the `varName` input.

Data Types: `char`

`argIndex` — Position of input argument

positive integer

Position of input argument, specified as a positive integer.

Data Types: `double`

See Also

`inputParser` | `is*` | `isa` | `isnumeric` | `validatestring`

validatestring

Check validity of text string

Syntax

```
validStr = validatestring(str,validStrings)
validStr = validatestring(str,validStrings,argIndex)
validStr = validatestring(str,validStrings,funcName)
validStr = validatestring(str,validStrings,funcName,varName)
validStr = validatestring(str,validStrings,funcName,varName,
argIndex)
```

Description

`validStr = validatestring(str,validStrings)` checks the validity of text string `str`. If `str` is an unambiguous, case-insensitive match to a string in cell array `validStrings`, the `validatestring` function returns the matching string in `validstr`. Otherwise, MATLAB throws an error and issues a formatted error message.

`validStr = validatestring(str,validStrings,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validStr = validatestring(str,validStrings,funcName)` includes the specified function name in generated error identifiers.

`validStr = validatestring(str,validStrings,funcName,varName)` includes the specified variable name in generated error messages.

`validStr = validatestring(str,validStrings,funcName,varName, argIndex)` includes the specified information in generated error messages or identifiers.

Input Arguments

`str`

String to validate, of type `char`.

`validStrings`

Cell array of allowed strings.

`funcName`

String that specifies the name of the function whose input you are validating. If you specify an empty string, `''`, the `validatestring` function ignores the `funcname` input.

`varName`

String that specifies the name of the input variable. If you specify an empty string, `''`, the `validatstring` function ignores the `varName` input.

`argIndex`

Positive integer that specifies the position of the input argument.

Output Arguments

`validStr`

String that contains the element of `validStrings` that is an unambiguous, case-insensitive match to `str`.

Example — Match `'ball'` with . . .	Return Value	Type of Match
`ball`, `barn`, `bell`	`ball`	Exact match
`balloon`, `barn`	`balloon`	Partial match (leading characters)
`ballo`, `balloo`, `balloon`	`ballo` (shortest match)	Multiple partial matches where each string is a subset of another
`balloon`, `ballet`	Error	Multiple partial matches to unique strings
`barn`, `bell`	Error	No match

Examples

Check whether a string is in a set of valid values.

```
str = 'won';
validStrings = {'wind','wonder','when'};

validStr = validatestring(str,validStrings)
```

Because `str` is a partial match to a unique string, this code returns

```
validStr =
     wonder
```

However, if `str` is a partial match to multiple strings, and the strings are not subsets of each other, `validatestring` throws an error and displays a formatted message.

```
str = 'won';
validStrings = {'wonder','wondrous','wonderful'};

validStr = validatestring(str,validStrings)
```

The error message is

```
Expected argument to match one of these strings:

  wonder, wondrous, wonderful

The input, 'won', matched more than one valid string.
```

Check inputs to a custom function, and include information about the input name and position in generated errors.

```
function a = findArea(shape,ht,wd,units)
   a = 0;
   expectedShapes = {'square','rectangle','triangle'};
   expectedUnits = {'cm','m','in','ft','yds'};

   shapeName = validatestring(shape,expectedShapes,mfilename,'Shape',1)
   unitAbbrev = validatestring(units,expectedUnits,mfilename,'Units',4)
```

When you call the function with valid input strings,

```
myarea = findArea('rect',10,3,'cm')
```

the function stores the inputs in local variables `shapeName` and `unitAbbrev`:

```
shapeName =
     rectangle
```

```
unitAbbrev =
     cm
```

However, if the inputs are not valid, such as

```
myarea = findArea('circle',10,3,'cm')
```

MATLAB displays

```
Error using findArea
Expected argument 1, Shape, to match one of these strings:

  square, rectangle, triangle

The input, 'circle', did not match any of the valid strings.
```

The function name is part of the error identifier, so

```
MException.last.identifier
```

returns

```
MATLAB:findArea:unrecognizedStringChoice
```

values

Class: containers.Map
Package: containers

Identify values in `containers.Map` object

Syntax

```
valueSet = values(mapObj)
valueSet = values(mapObj,keySet)
```

Description

`valueSet = values(mapObj)` returns all of the values in `mapObj`.

`valueSet = values(mapObj,keySet)` returns values that correspond to the specified keys.

Input Arguments

`mapObj`

Object of class `containers.Map`.

`keySet`

Cell array that specifies keys in `mapObj`.

Output Arguments

`valueSet`

Cell array containing values from `mapObj`. If you specify `keySet`, the `valueSet` array has the same size and dimensions as `keySet`.

Examples

Get All Values in a Map

Create a map, and view all values in the map:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
mapObj = containers.Map(myKeys,myValues);

valueSet = values(mapObj)
```

This code returns 1-by-3 cell array `valueSet`:

```
valueSet =
    [1]    [2]    [3]
```

Get Selected Values in a Map

View the values corresponding to keys `a` and `c` in `mapObj`, created in the previous example:

```
keySet = {'a','c'};
valueSet = values(mapObj,keySet)
```

This code returns 1-by-2 cell array `valueSet`:

```
valueSet =
    [1]    [3]
```

`keys` | `isKey` | `containers.Map`

vander

Vandermonde matrix

Syntax

```
A = vander(v)
```

Description

`A = vander(v)` returns the "Vandermonde Matrix" on page 1-8781 such that its columns are powers of the vector v.

Examples

Find the Vandermonde Matrix for Vector Input

Use the colon operator to create vector `v`. Find the Vandermonde matrix for `v`.

```
v = 1:.5:3
A = vander(v)
```

```
v =
    1.0000    1.5000    2.0000    2.5000    3.0000

A =
    1.0000    1.0000    1.0000    1.0000    1.0000
    5.0625    3.3750    2.2500    1.5000    1.0000
   16.0000    8.0000    4.0000    2.0000    1.0000
   39.0625   15.6250    6.2500    2.5000    1.0000
   81.0000   27.0000    9.0000    3.0000    1.0000
```

Find the alternate form of the Vandermonde matrix using `fliplr`.

```
A = fliplr(vander(v))
```

```
A =
    1.0000    1.0000    1.0000    1.0000    1.0000
    1.0000    1.5000    2.2500    3.3750    5.0625
    1.0000    2.0000    4.0000    8.0000   16.0000
```

```
    1.0000    2.5000    6.2500   15.6250   39.0625
    1.0000    3.0000    9.0000   27.0000   81.0000
```

Input Arguments

v — Input

numeric vector

Input, specified as a numeric vector.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Vandermonde Matrix

For input vector $v = \begin{bmatrix} v_1 & v_2 & \dots & v_N \end{bmatrix}$, the Vandermonde matrix is

$$\begin{bmatrix} v_1^{N-1} & \cdots & v_1^1 & v_1^0 \\ v_2^{N-1} & \cdots & v_2^1 & v_2^0 \\ & \iddots & \vdots & \vdots \\ v_N^{N-1} & & v_N^1 & v_N^0 \end{bmatrix}$$

The matrix is described by the formula $A(i,j) = v(i)^{(N-j)}$ such that its columns are powers of the vector v.

An alternate form of the Vandermonde matrix flips the matrix along the vertical axis, as shown. Use `fliplr(vander(v))` to return this form.

$$\begin{bmatrix} v_1^0 & v_1^1 & \cdots & v_1^{N-1} \\ v_2^0 & v_2^1 & \cdots & v_2^{N-1} \\ \vdots & \vdots & \ddots & \\ v_N^0 & v_N^1 & & v_N^{N-1} \end{bmatrix}$$

var

Variance

Syntax

```
V = var(A)
V = var( ___ ,w)
V = var( ___ ,dim)
V = var( ___ ,nanflag)
```

Description

`V = var(A)` returns the variance of the elements of `A`along the first array dimension whose size does not equal 1.

- If `A` is a vector of observations, the variance is a scalar.
- If `A` is a matrix whose columns are random variables and whose rows are observations, `V` is a row vector containing the variances corresponding to each column.
- If `A` is a multidimensional array, then `var(A)` treats the values along the first array dimension whose size does not equal 1 as vectors. The size of this dimension becomes `1` while the sizes of all other dimensions remain the same.
- The variance is normalized by the number of observations`-1` by default.
- If `A` is a scalar, `var(A)` returns `0`. If `A` is a `0`-by-`0` empty array, `var(A)` returns `NaN`.

`V = var( ___ ,w)` specifies a weighting scheme for any of the previous syntaxes. When `w = 0` (default), `V` is normalized by the number of observations`-1`. When `w = 1`, it is normalized by the number of observations. `w` can also be a weight vector containing nonnegative elements. In this case, the length of `w` must equal the length of the dimension over which `var` is operating.

`V = var( ___ ,dim)` returns the variance along the dimension `dim` for any of the previous syntaxes. To maintain the default normalization while specifying the dimension of operation, set `w = 0` in the second argument.

`V = var( ___ ,nanflag)` specifies whether to include or omit `NaN` values from the calculation for any of the previous syntaxes. For example, `var(A,'includenan')` includes all `NaN` values in `A` while `var(A,'omitnan')` ignores them.

Examples

Variance of Matrix

Create a matrix and compute its variance.

```
A = [4 -7 3; 1 4 -2; 10 7 9];
var(A)
```

```
ans =

   21.0000   54.3333   30.3333
```

Variance of Array

Create a 3-D array and compute its variance.

```
A(:,:,1) = [1 3; 8 4];
A(:,:,2) = [3 -4; 1 2];
var(A)
```

```
ans(:,:,1) =

   24.5000    0.5000

ans(:,:,2) =

     2    18
```

Specify Variance Weight Vector

Create a matrix and compute its variance according to a weight vector `w`.

```
A = [5 -4 6; 2 3 9; -1 1 2];
w = [0.5 0.25 0.25];
var(A,w)
```

```
ans =
```

```
    6.1875    9.5000    6.1875
```

Specify Dimension for Variance

Create a matrix and compute its variance along the first dimension.

```
A = [4 -2 1; 9 5 7];
var(A,0,1)
```

```
ans =

   12.5000   24.5000   18.0000
```

Compute the variance of `A` along the second dimension.

```
var(A,0,2)
```

```
ans =

     9
     4
```

Variance Excluding `NaN`

Create a vector and compute its variance, excluding `NaN` values.

```
A = [1.77 -0.005 3.98 -2.95 NaN 0.34 NaN 0.19];
V = var(A,'omitnan')
```

```
V =

    5.1970
```

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

`w` — Weight

`0` (default) | `1` | vector

Weight, specified as one of:

- `0` — normalizes by the number of observations-`1`. If there is only one observation, the weight is 1.
- `1` — normalizes by the number of observations.
- a vector made up of nonnegative scalar weights corresponding to the dimension of `A` along which the variance is calculated.

Data Types: `single` | `double`

`dim` — Dimension to operate along

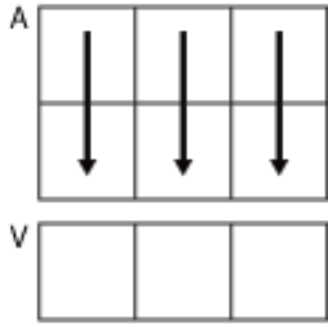
positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to `1`. The `size(V,dim)` is `1`, while the sizes of all other dimensions remain the same.

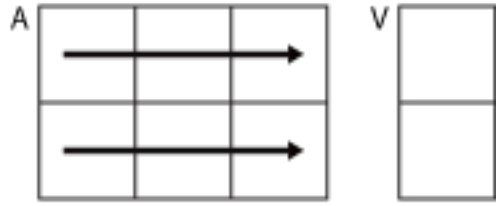
Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `var(A,0,1)` returns a row vector containing the variance of the elements in each column.



var(A,0,1)

- If `dim = 2`, then `var(A,0,2)` returns a column vector containing the variance of the elements in each row.



var(A,0,2)

`var` returns an array of zeros the same size as `A` when `dim` is greater than `ndims(A)`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`nanflag` — `NaN` condition
'`includenan`' (default) | '`omitnan`'

`NaN` condition, specified as one of these values:

- '`includenan`' — the variance of input containing `NaN` values is also `NaN`.
- '`omitnan`' — all `NaN` values appearing in either the input array or weight vector are ignored.

Data Types: `char`

More About

Variance

For a random variable vector A made up of N scalar observations, the variance is defined as

$$V = \frac{1}{N-1}\sum_{i=1}^{N} |A_i - \mu|^2$$

where μ is the mean of A,

$$\mu = \frac{1}{N}\sum_{i=1}^{N} A_i.$$

Some definitions of variance use a normalization factor of N instead of $N-1$, which can be specified by setting `w` to `1`. In either case, the mean is assumed to have the usual normalization factor N.

varargin

Variable-length input argument list

Syntax

```
varargin
```

Description

`varargin` is an input variable in a function definition statement that allows the function to accept any number of input arguments. Specify `varargin` using lowercase characters, and include it as the last input argument after any explicitly declared inputs. When the function executes, `varargin` is a 1-by-*N* cell array, where *N* is the number of inputs that the function receives after the explicitly declared inputs.

Examples

Variable Number of Function Inputs

Define a function in a file named `varlist.m` that accepts a variable number of inputs and displays the values of each input.

```
function varlist(varargin)
   fprintf('Number of arguments: %d\n',nargin)
   celldisp(varargin)
```

Call `varlist` with several inputs.

```
varlist(ones(3),'some text',pi)
```

```
Number of arguments: 3

varargin{1} =
     1     1     1
     1     1     1
     1     1     1
```

```
varargin{2} =
some text

varargin{3} =
    3.1416
```

varargin and Declared Inputs

Define a function in a file named `varlist2.m` that expects inputs `X` and `Y`, and accepts a variable number of additional inputs.

```
function varlist2(X,Y,varargin)
   fprintf('Total number of inputs = %d\n',nargin);

   nVarargs = length(varargin);
   fprintf('Inputs in varargin(%d):\n',nVarargs)
   for k = 1:nVarargs
      fprintf('   %d\n', varargin{k})
   end
```

Call `varlist2` with more than two inputs.

```
varlist2(10,20,30,40,50)
```

```
Total number of inputs = 5
Inputs in varargin(3):
   30
   40
   50
```

`inputname` | `nargin` | `narginchk` | `nargout` | `nargoutchk` | `varargout`

Introduced before R2006a

varargout

Variable-length output argument list

Syntax

```
varargout
```

Description

`varargout` is an output variable in a function definition statement that allows the function to return any number of output arguments. Specify `varargout` using lowercase characters, and include it as the last output argument after any explicitly declared outputs. When the function executes, `varargout` is a 1-by-*N* cell array, where *N* is the number of outputs requested after the explicitly declared outputs.

Examples

Variable Number of Function Outputs

Define a function in a file named `sizeout.m` that returns an output size vector `s` and a variable number of additional scalar values.

```
function [s,varargout] = sizeout(x)
nout = max(nargout,1) - 1;
s = size(x);
for k = 1:nout
   varargout{k} = s(k);
end
```

Output `s` contains the dimensions of the input array `x`. Additional outputs correspond to the individual dimensions within `s`.

Call `sizeout` on a three-dimensional array and request three outputs.

```
[s,rows,cols] = sizeout(rand(4,5,2))
```

```
s =
```

```
     4     5     2

rows =
     4

cols =
     5
```

See Also

varargin | nargin | nargout | nargoutchk | narginchk | inputname

Introduced before R2006a

varfun

Apply function to table variables

Syntax

```
B = varfun(func,A)
B = varfun(func,A,Name,Value)
```

Description

`B = varfun(func,A)` applies the function func separately to each variable of the table `A` and returns the results in the table `B`.

The function `func` must take one input argument and return arrays with the same number of rows each time it is called. The `i`th variable in the output table, `B{:,i}`, is equal to `func(A{:,i})`.

`B = varfun(func,A,Name,Value)` applies the function `func` separately to each variable of the table `A` with additional options specified by one or more Name,Value pair arguments.

For example, you can specify which variables to pass to the function.

Examples

Apply Element-wise Function

Define and apply an element-wise function to the variables of a table to square all the elements.

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =
```

```
    Var1     Var2
    _____    _____

     0.71     0.23
    -2.05     0.12
    -0.35    -0.18
    -0.82     0.23
     1.57     0.41
```

Define the anonymous function to find the square of an input.

```
func = @(x) x.^2;
```

Apply the function to all the variables of table A.

```
B = varfun(func,A)
```

```
B =

    Fun_Var1    Fun_Var2
    ________    ________

    0.5041      0.0529
    4.2025      0.0144
    0.1225      0.0324
    0.6724      0.0529
    2.4649      0.1681
```

The variables of B have names based on the function and the variable names from A.

Apply Function that Returns Scalar From Vector

Compute the mean of each variable in a 5-by-2 table.

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =

    Var1     Var2
    _____    _____

     0.71     0.23
```

```
    -2.05     0.12
    -0.35    -0.18
    -0.82     0.23
     1.57     0.41
```

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

`func` uses an existing MATLAB function to define the operation.

Apply the function to all the variables of table `A`.

```
B = varfun(func,A)
```

```
B =

    mean_Var1    mean_Var2
    _________    _________

    -0.188        0.162
```

`B` is a table containing the average value from each variable. To return a numeric vector instead of a table, you can use `B = varfun(func,A,'OutputFormat','uniform')`.

Apply Function to Groups Within Variables

Compute the group-wise means of variables in a table, `A`, and return them as rows in a table, `B`.

Create a table where one variable defines groups.

```
A = table({'test2';'test1';'test2';'test3';'test1'},...
    [0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =

     Var1       Var2      Var3
    _______    ______    _____

    'test2'     0.71      0.23
    'test1'    -2.05      0.12
    'test2'    -0.35     -0.18
    'test3'    -0.82      0.23
    'test1'     1.57      0.41
```

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

`func` uses an existing MATLAB function to define the operation.

Apply the function to each group of data defined by `Var1`.

```
B = varfun(func,A,'GroupingVariables','Var1')
```

```
B =

              Var1       GroupCount    mean_Var2    mean_Var3
             _______    __________    _________    _________

    test1    'test1'    2              -0.24        0.265
    test2    'test2'    2               0.18        0.025
    test3    'test3'    1              -0.82         0.23
```

`B` contains row names based on the grouping variables and a variable called `GroupCount` to indicate the number of entries from table `A` in that group.

Input Arguments

`func` — Function

function handle

Function, specified as a function handle. You can define the function in a file or as an anonymous function. If `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

Use the `'OutputFormat','cell'` name-value pair argument, if the function `func` take one input argument and returns arrays with a different numbers of rows each time it is called. Otherwise, `func` must return arrays with the same number of rows.

Example: `func = @(x) x.^2;` conputes the square of each element of an input.

`A` — Input table

table

Input table, specified as a table.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'InputVariables',2` uses only the second variable in `A` as an input to `func`.

`'InputVariables'` — Variables of `A` to pass to `func`

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `varfun` only passes the variables in `A` where the specified function returns `1` (`true`).

`'GroupingVariables'` — One or more variables in `A` that define groups of rows

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in `A` that have the same grouping variable values belong to the same group. `varfun` applies `func` to each group of rows within each of the variables of `A`, rather than to each entire variable.

The output, `B`, has one row for each group when you specify `'OutputFormat','uniform'` or `'OutputFormat','cell'`. When you specify `'OutputFormat','table'`, the sizes of the outputs from `func` determine how many rows of `B` correspond to each group. When multiple rows of `B` correspond to a group, `varfun` appends a unique identifier to the row names.

`'OutputFormat'` — Format of `B`

`'table'` (default) | `'uniform'` | `'cell'`

Format of B, specified as the comma-separated pair consisting of 'OutputFormat' and either the string 'uniform', 'table', or 'cell'.

'table'	varfun returns a table with one variable for each variable in A (or each variable specified with 'InputVariables'). For grouped computation, B, also contains the grouping variables. 'table' allows you to use a function that returns values of different sizes or data types for the different variables in A. However, for ungrouped computation, func must return arrays with the same number of rows each time it is called. For grouped computation, func must return values with the same number of rows each time it is called for a given group. This is the default output format.
'uniform'	varfun concatenates the values into a vector. func must return a scalar with the same data type each time it is called.
'cell'	varfun returns B as a cell array. 'cell' allows you to use a function that returns values of different sizes or data types.

'ErrorHandler' — Function to call if func fails

function handle

Function to call if func fails, specified as the comma-separated pair consisting of 'ErrorHandler' and a function handle. Define this function so that it rethrows the error or returns valid outputs for function func.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

identifier	Error identifier.
message	Error message text.
index	Index of the variable for which the error occurred.
name	Name of the variable for which the error occurred.

- The set of input arguments to function func at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
```

```
warning(S.identifier, S.message)
A = NaN; B = NaN;
```

Output Arguments

B — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

- "Anonymous Functions"

See Also

`arrayfun` | `cellfun` | `rowfun` | `structfun`

vectorize

Vectorize expression

Syntax

```
vectorize(s)
vectorize(f)
```

Description

`vectorize(s)` where `s` is a string expression, inserts a `.` before any `^`, `*` or `/` in `s`. The result is a character string.

Note: `vectorize` will not accept inline function objects (`f`) in a future release.

`vectorize(f)` where `f` is an inline function object, vectorizes the formula for `f`. The result is the vectorized version of the function.

`inline` | `cd` | `dbtype` | `delete` | `dir` | `path` | `what` | `who`

Introduced before R2006a

ver

Version information for MathWorks products

Syntax

```
ver
ver product

product_info = ver(product)
```

Description

`ver` displays:

- A header containing the current MATLAB product family version number, license number, operating system, and version of Java software for the MATLAB product.
- The version numbers for MATLAB and all other installed MathWorks products.

`ver product` displays, in addition to the header information:

- The current version number for product, where product is the name of the folder that contains the `Contents.m` file for the product you are inquiring about.

`product_info = ver(product)` returns product information to the structure array, product_info.

Examples

Version for All Installed Products

Display version information for all installed products. The output shown here is representative. Your results might differ.

```
ver
```

```
-----------------------------------------------------------------------------------------------------
MATLAB Version: 8.2.0.29 (R2013b)
MATLAB License Number: 234567
```

```
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service Pack 1)
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Server VM mixed mode
------------------------------------------------------------------------------------------------------
MATLAB                                                Version 8.2       (R2013b)
Simulink                                              Version 8.2       (R2013b)
Control System Toolbox                                Version 9.6       (R2013b)
```

Version for a Particular Product

Display version information for MATLAB and the Control System Toolbox product. The output shown here is representative. Your results might differ.

1. Determine the product name for Control System Toolbox by setting `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss';
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

```
ans=
control
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
ver control
```

```
------------------------------------------------------------------------------------------------------
MATLAB Version: 8.2.0.29 (R2013b)
MATLAB License Number: 234567
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service Pack 1)
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Server VM mixed mode
------------------------------------------------------------------------------------------------------
Control System Toolbox                                Version 9.6       (R2013b)
```

Structure Containing Version for the MATLAB family of products

Create a structure containing version information, and then display the structure values. The output shown here is representative. Your results might differ.

```
v = ver;
for k = 1:length(v)
  fprintf('%s\n', v(k).Name);
  fprintf('  Version: %s\n', v(k).Version);
end
```

```
MATLAB
 Version: 8.2

MATLAB Compiler
```

```
 Version: 5.0

My Custom Toolbox
 Version: 1.0
```

Structure Containing Version for a Particular Product

Create a structure containing version information for just the Symbolic Math Toolbox product. The output shown here is representative. Your results might differ.

1. Determine the product name for Symbolic Math Toolbox by setting `n` to the name of a function unique to Symbolic Math Toolbox, such as `sym`:

```
n = 'sym';
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

```
ans =

symbolic
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
v = ver('symbolic')
```

```
v =

        Name: 'Symbolic Math Toolbox'
     Version: '5.11'
     Release: '(R2013b)'
        Date: '19-May-2013'
```

Input Arguments

`product` — product-specific information

string

The product or toolbox for which you want to view version information, specified as a string.

To determine the string to use, run the following code, substituting the name of a product function for *toolbxfcn*:

```
n = 'toolbxfcn';
```

```
pat = '(?<=^.+[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

Output Arguments

`product_info` — product name, version, release, and date
structure array

Product name, version, release, and date, returned as a structure array with these fields: `Name`, `Version`, `Release`, and `Date`. If a license is a trial version, the value in the `Version` field is preceded by the letter `T`

matlab.unittest.Verbosity class

Package: matlab.unittest

Verbosity level enumeration class

Description

The `matlab.unittest.Verbosity` enumeration class provides a means to specify the level of detail related to running tests. A higher value results in a higher level of detail. The enumeration class contains the following members.

Numeric Representation	Enumeration Member Name	Verbosity Description
1	`Terse`	Minimal amount of information
2	`Concise`	Typical amount of information
3	`Detailed`	Supplemental amount of information
4	`Verbose`	Surplus of information

Construction

`matlab.unittest.Verbosity.`*`MemberName`* creates an instance of the verbosity level enumeration class.

Examples

Create Instance of Enumeration Class

```
n = matlab.unittest.Verbosity.Detailed
```

```
n =

    Detailed
```

Display information about the variables.

```
whos n
```

```
  Name      Size            Bytes  Class                          Attributes

  n         1x1               112  matlab.unittest.Verbosity
```

- “Working with Enumerations”

Introduced in R2014b

verctrl

(To be removed) Source control actions (Windows platforms)

Note: `verctrl` will be removed in a future release. Access source control actions through the context menu instead.

Syntax

```
verctrl('action',{'filename1','filename2',....},0)
result=verctrl('action',{'filename1','filename2',....},0)
verctrl('action','filename',0)
result=verctrl('isdiff','filename',0)
list = verctrl('all_systems')
```

Description

`verctrl('action',{'filename1','filename2',....},0)` performs the source control operation specified by `'action'` for a single file or multiple files. Enter one file as a string; specify multiple files using a cell array of strings. Use the full paths for each file name and include the extensions. Specify `0` as the last argument. Complete the resulting dialog box to execute the operation. Available values for `'action'` are as follows:

action Argument	Purpose
`'add'`	Adds files to the source control system. Files can be open in the Editor or closed when added.
`'checkin'`	Checks files into the source control system, storing the changes and creating a new version.
`'checkout'`	Retrieves files for editing.
`'get'`	Retrieves files for viewing and compiling, but not editing. When you open the files, they are labeled as read-only.

action Argument	Purpose
`'history'`	Displays the history of files.
`'remove'`	Removes files from the source control system. It does not delete the files from disk, but only from the source control system.
`'runscc'`	Starts the source control system. The file name can be an empty string.
`'uncheckout'`	Cancels a previous checkout operation and restores the contents of the selected files to the precheckout version. All changes made to the files since the checkout are lost.

`result=verctrl('action',{'filename1','filename2',....},0)` performs the source control operation specified by `'action'` on a single file or multiple files. The action can be any one of: `'add'`, `'checkin'`, `'checkout'`, `'get'`, `'history'`, or `'undocheckout'`. `result` is a logical `1` (true) when you complete the operation by clicking **OK** in the resulting dialog box, and is a logical `0` (false) when you abort the operation by clicking **Cancel** in the resulting dialog box.

`verctrl('action','filename',0)` performs the source control operation specified by `'action'` for a single file. Use the absolute path for `'filename'`. Specify `0` as the last argument. Complete any resulting dialog boxes to execute the operation. Available values for `'action'` are as follows:

action Argument	Purpose
`'showdiff'`	Displays the differences between a file and the latest checked in version of the file in the source control system.
`'properties'`	Displays the properties of a file.

`result=verctrl('isdiff','filename',0)` compares `filename` with the latest checked in version of the file in the source control system. `result` is a logical `1` (true) when the files are different, and is a logical `0` (false) when the files are identical. Use the full path for `'filename'`. Specify `0` as the last argument.

`list = verctrl('all_systems')` displays in the Command Window a list of all source control systems installed on your computer.

Examples

Check In a File

Check in `D:\file1.ext` to the source control system:

```
result = verctrl('checkin','D:\file1.ext', 0)
```

This opens the Check in file(s) dialog box. Click **OK** to complete the check in. MATLAB displays

```
 result = 1
```

indicating the checkin was successful.

Add Files to the Source Control System

Add `D:\file1.ext` and `D:\file2.ext` to the source control system.

```
verctrl('add',{'D:\file1.ext','D:\file2.ext'}, 0)
```

This opens the Add to source control dialog box. Click **OK** to complete the operation.

Display the Properties of a File

Display the properties of `D:\file1.ext`.

```
verctrl('properties','D:\file1.ext', 0)
```

This opens the source control properties dialog box for your source control system. The function is complete when you close the properties dialog box.

Show Differences for a File

To show the differences between the version of `file1.ext` that you just edited and saved, with the last version in source control, run

```
verctrl('showdiff','D:\file1.ext',0)
```

MATLAB displays differences dialog boxes and results specific to your source control system. After checking in the file, if you run this statement again, MATLAB displays

```
??? The file is identical to latest version under source control.
```

List All Installed Source Control Systems

To view all of the source control systems installed on your computer, type

```
list = verctrl ('all_systems')
```

MATLAB displays all the source control systems currently installed on your computer. For example:

```
list =
'Microsoft Visual SourceSafe'
'ComponentSoftware RCS'
```

More About

- "MSSCCI Source Control Interface"

Introduced before R2006a

verLessThan

Compare toolbox version to specified version string

Syntax

```
verLessThan(toolbox, version)
```

Description

`verLessThan(toolbox, version)` returns logical 1 (`true`) if the version of the toolbox specified by the string `toolbox` is older than the version specified by the string `version`, and logical 0 (`false`) otherwise. Use this function when you want to write code that can run across multiple versions of the MATLAB software, when there are differences in the behavior of the code in the different versions.

The `toolbox` argument is a string enclosed within single quotation marks that contains the name of a MATLAB toolbox folder. The `version` argument is a string enclosed within single quotation marks that contains the version to compare against. This argument must be in the form `major[.minor[.revision]]`, such as `7`, `7.1`, or `7.0.1`. If `toolbox` does not exist, MATLAB generates an error.

To specify `toolbox`, find the folder that holds the `Contents.m` file for the toolbox and use that folder name. To see a list of all toolbox folder names, enter the following statement in the MATLAB Command Window:

```
dir([matlabroot '/toolbox'])
```

Examples

These examples illustrate usage of the `verLessThan` function.

Example 1 – Checking For the Minimum Required Version

```
if verLessThan('simulink', '4.0')
```

```
    error('Simulink 4.0 or higher is required.');
end
```

Example 2 – Choosing Which Code to Run

```
if verLessThan('matlab', '7.0.1')
% -- Put code to run under MATLAB 7.0.0 and earlier here --
else
% -- Put code to run under MATLAB 7.0.1 and later here --
end
```

Example 3 – Looking Up the Folder Name

Find the name of the Data Acquisition Toolbox folder:

```
dir([matlabroot '/toolbox/d*'])

   daq        database   des      distcomp   dotnetbuilder
   dastudio   datafeed   dials    dml        dspblks
```

Use the toolbox folder name, `daq`, to compare the Data Acquisition Toolbox software version that MATLAB is currently running against version number `3`:

```
verLessThan('daq', '3')
ans =
     1
```

See Also

`ver` | `version` | `license` | `ispc` | `isunix` | `ismac` | `dir`

version

Version number for MATLAB and libraries

Syntax

```
version
version -date
version -description
version -release
version -java
v = version('-versionOption')
[v d] = version
```

Description

`version` returns in `ans` the version and release number for the MATLAB software currently running.

`version -date` returns in `ans` the release date for the MATLAB software.

`version -description` returns in `ans` a description of the version. Usually, the description is for special versions, such as beta versions.

`version -release` returns in `ans` the release number for the MATLAB software currently running.

`version -java` returns in `ans` the version of the Oracle JVM software that MATLAB is using.

`v = version('-versionOption')`, where *`versionOption`* is one of the above option strings, is an alternate form of the syntax.

`[v d] = version` returns the version and release number in string `v` and the release date in string `d`. No input arguments are allowed in this syntax.

Examples

Display MATLAB Version

```
version
```

```
ans =

8.2.0.29 (R2013b)
```

Display MATLAB Release

Display the release, prefaced by a descriptor.

```
['Release R' version('-release')]
```

```
ans =

Release R2013b
```

Get Release Version and Date as Separate Strings

```
[v d] = version
```

```
v =

8.2.0.29 (R2013b)

d =

May 19, 2013
```

Display Java Version

```
version -java
```

```
ans =

Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Server VM mixed mode
```

`computer` | `ver` | `verlessthan`

Introduced before R2006a

vertcat

Concatenate arrays vertically

Syntax

```
C = vertcat(A1,...,AN)
```

Description

`C = vertcat(A1,...,AN)` vertically concatenates arrays `A1,...,AN`. All arrays in the argument list must have the same number of columns.

- If the inputs are multidimensional arrays, `vertcat` concatenates N-dimensional arrays along the first dimension. The remaining dimensions must match.
- If the inputs are tables, `vertcat` concatenates by matching variable names. Variable names for all tables must be identical, except for order. Row names, when present, must be unique across tables.

  `vertcat` fills in default row names when some of the inputs have names and some do not. `vertcat` assigns values for each table property (except for `RowNames`) using the first nonempty value for the corresponding property in the tables `A1,...,AN`.

`vertcat` also concatenates character strings. Each string being concatenated must have the same number of characters.

MATLAB calls `C = vertcat(A1, A2, ...)` for the syntax `C = [A1; A2; ...]` when any of the inputs are an object.

Tips

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

You can concatenate datetime arrays with cell arrays of strings.

You can concatenate duration arrays and calendar duration arrays. The result is a calendar duration array.

You can concatenate duration or calendar duration arrays with numeric arrays. Prior to concatenation, MATLAB converts the numeric array to an array of equivalent days using the `days` function.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see "Valid Combinations of Unlike Classes".

Examples

Vertically Concatenate Two Matrices

Create a 5-by-3 matrix, `A`.

```
A = magic(5);
A(:, 4:5) = []
```

```
A =

    17    24     1
    23     5     7
     4     6    13
    10    12    19
    11    18    25
```

Create a 3-by-3 matrix, `B`.

```
B = magic(3)*100
```

```
B =

   800   100   600
   300   500   700
   400   900   200
```

Vertically concatenate `A` and `B`.

```
C = vertcat(A,B)
```

```
C =

    17    24     1
    23     5     7
     4     6    13
    10    12    19
    11    18    25
   800   100   600
   300   500   700
   400   900   200
```

Vertically Concatenate Two Tables

Create a table, A, with three rows and five variables.

```
A = table([5;6;5],['M';'M';'M'],[45;41;40],[45;32;34],{'NY';'CA';'MA'},...
    'VariableNames',{'Age' 'Gender' 'Height' 'Weight' 'Birthplace'},...
    'RowNames',{'Thomas' 'Gordon' 'Percy'})
```

```
A =

              Age    Gender    Height    Weight    Birthplace
              ---    ------    ------    ------    ----------
    Thomas    5      M         45        45        'NY'
    Gordon    6      M         41        32        'CA'
    Percy     5      M         40        34        'MA'
```

Create a table, B, with the same variables as A except for order.

```
B = table(['F';'M';'F'],[6;6;5],{'AZ';'NH';'CO'},[31;42;33],[39;43;40],...
    'VariableNames',{'Gender' 'Age' 'Birthplace' 'Weight' 'Height'})
```

```
B =

    Gender    Age    Birthplace    Weight    Height
    ------    ---    ----------    ------    ------
    F         6      'AZ'          31        39
    M         6      'NH'          42        43
    F         5      'CO'          33        40
```

Vertically concatenate tables A and B.

```
C = vertcat(A,B)
```

```
C =
```

```
           Age    Gender    Height    Weight    Birthplace
           ---    ------    ------    ------    ----------
Thomas     5      M         45        45        'NY'
Gordon     6      M         41        32        'CA'
Percy      5      M         40        34        'MA'
Row4       6      F         39        31        'AZ'
Row5       6      M         43        42        'NH'
Row6       5      F         40        33        'CO'
```

The variables of `C` are in the same order as the variables of `A` and default row names are used for the rows from `B`.

- "Concatenation Methods"

See Also

`horzcat` | `cat`

Introduced before R2006a

vertcat (tscollection)

Vertical concatenation for `tscollection` objects

Syntax

```
tsc = vertcat(tsc1,tsc2,...)
```

Description

`tsc = vertcat(tsc1,tsc2,...)` performs

```
tsc = [tsc1;tsc2;...]
```

This operation appends `tscollection` objects. The time vectors must not overlap. The last time in tsc1 must be earlier than the first time in tsc2. All `tscollection` objects to be concatenated must have the same `timeseries` members.

See Also

`horzcat (tscollection)` | `tscollection`

Introduced before R2006a

vertexAttachments

Class: TriRep

(Will be removed) Return simplices attached to specified vertices

---

Note: `vertexAttachments(TriRep)` will be removed in a future release. Use `vertexAttachments(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
SI = vertexAttachments(TR, VI)
```

Description

`SI = vertexAttachments(TR, VI)` returns the vertex-to-simplex information for the specified vertices `VI`. For 2-D triangulations in MATLAB, the triangles `SI` are arranged in counter-clockwise order around the attached vertex `VI`.

Input Arguments

`TR`	Triangulation representation
`VI`	`VI` is a column vector of indices into the array of points representing the vertex coordinates, `TR.X`. The simplices associated with vertex `i` are the `i`'th entry in the cell array. If `VI` is not specified the vertex-simplex information for the entire triangulation is returned.

Output Arguments

`SI`	Cell array of indices of the simplices attached to a vertex. A cell array is used to store the information because the number of simplices

associated with each vertex can vary. The simplices associated with vertex `i` are in the `i`'th entry in the cell array `SI`.

Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

Examples

Example 1

Load a 2-D triangulation and use `TriRep` to compute the vertex-to-triangle relations.

```
load trimesh2d
trep = TriRep(tri, x, y);
```

Find the indices of the tetrahedra attached to the first vertex:

```
Tv = vertexAttachments(trep, 1)
Tv{:}
```

Example 2

Perform a direct query of a 2-D triangulation created using `DelaunayTri`.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
```

Find the triangles attached to vertex 5:

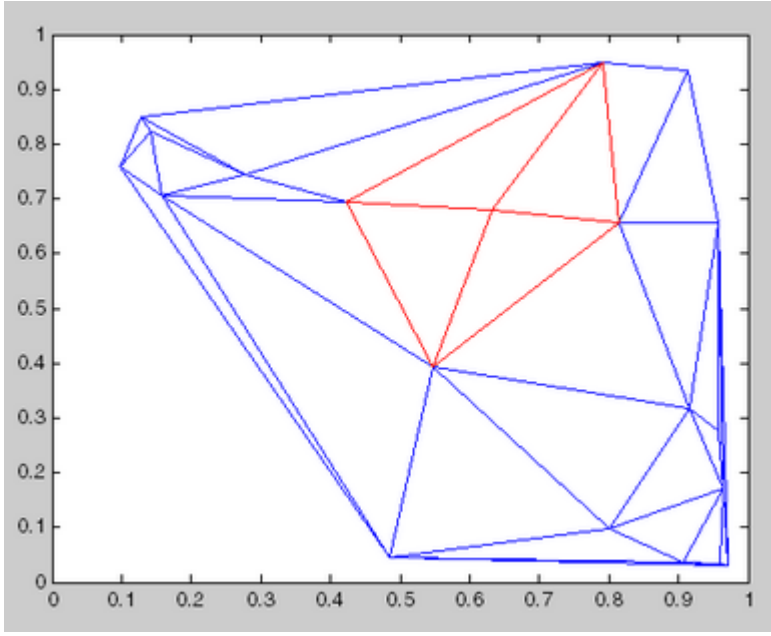
```
t = vertexAttachments(dt,5);
```

Plot the triangulation:

```
triplot(dt);
hold on;
```

Plot the triangles attached to vertex 5 (in red):

```
triplot(dt(t{:},:),x,y,'Color','r');
hold off;
```



See Also

`triangulation` | `delaunayTriangulation`

VideoReader class

Read video files

Description

Use the `VideoReader` function with the `read` method to read video data from a file into the MATLAB workspace.

The file formats that `VideoReader` supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	AVI, including uncompressed, indexed, grayscale, and Motion JPEG-encoded video (`.avi`) Motion JPEG 2000 (`.mj2`)
All Windows	MPEG-1 (`.mpg`) Windows Media Video (`.wmv`, `.asf`, `.asx`) Any format supported by Microsoft DirectShow®
Windows 7 or later	MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Apple QuickTime Movie (`.mov`) Any format supported by Microsoft Media Foundation
Macintosh	Most formats supported by QuickTime Player, including: MPEG-1 (`.mpg`) MPEG-4, including H.264 encoded video (`.mp4`, `.m4v`) Apple QuickTime Movie (`.mov`) 3GPP 3GPP2 AVCHD DV
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on http://gstreamer.freedesktop.org/documentation/plugins.html, including Ogg Theora (`.ogg`).

Construction

`obj = VideoReader(filename)` constructs obj to read video data from the file named filename. If it cannot construct the object for any reason, `VideoReader` generates an error.

`obj = VideoReader(filename,Name,Value)` constructs the object with additional options specified by one or more Name,Value pair arguments. `Name` is `'Tag'` or `'UserData'` and `Value` is the corresponding value. You can specify two name and value pair arguments in any order as `Name1,Value1,Name2,Value2`.

Input Arguments

`filename`

String in single quotation marks that specifies the video file to read. The `VideoReader` constructor searches for the file on the MATLAB path.

Name-Value Pair Arguments

Optional comma-separated pairs of Name,Value arguments, where `Name` is `'Tag'` or `'UserData'` and `Value` is the corresponding value. You can specify two name and value pair arguments in any order as `Name1,Value1,Name2,Value2`.

`'Tag'`

String that identifies the object.

Default: `''`

`'UserData'`

Generic field for data of any class that you want to add to the object.

Default: `[]`

Properties

All properties are read-only except `CurrentTime`, `Tag` and `UserData`.

`BitsPerPixel`

Bits per pixel of the video data.

CurrentTime

Timestamp of the video frame to read, specified in seconds from the start of the video file. `CurrentTime` can be a `double` value between zero and the duration of the video.

Duration

Total length of the file in seconds.

FrameRate

Frame rate of the video in frames per second.

Height

Height of the video frame in pixels.

Name

Name of the file associated with the object.

NumberOfFrames

Note: `NumberOfFrames` will be removed in a future release.

Total number of frames in the video stream.

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `VideoReader` cannot determine the number of frames until you read the last frame. When you construct the object, `VideoReader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = VideoReader('varFrameRateFile.wmv');
lastFrame = read(vidObj, inf);
numFrames = vidObj.NumberOfFrames;
```

Path

String containing the full path to the file associated with the reader.

Tag

String that identifies the object.

Default: `''`

Type

Class name of the object: `'VideoReader'`.

UserData

Generic field for data of any class that you want to add to the object.

Default: `[]`

VideoFormat

String indicating the MATLAB representation of the video format.

Video Format	Value of `VideoFormat`
AVI or MPEG-4 files with RGB24 video	`'RGB24'`
AVI files with indexed video	`'Indexed'`
AVI files with grayscale video	`'Grayscale'`

For Motion JPEG 2000 files, `VideoFormat` is one of the following.

Format of Image Data	Value of `VideoFormat`
Single-band `uint8`	`'Mono8'`
Single-band `int8`	`'Mono8 Signed'`
Single-band `uint16`	`'Mono16'`
Single-band `int16`	`'Mono16 Signed'`
Three-banded `uint8`	`'RGB24'`
Three-banded `int8`	`'RGB24 Signed'`
Three-banded `uint16`	`'RGB48'`
Three-banded `int16`	`'RGB48 Signed'`

`Width`

Width of the video frame in pixels.

Methods

get	Query property values for video reader object
getFileFormats	File formats that `VideoReader` supports
hasFrame	Determine if frame available to read
read	Read video frame data from file
readFrame	Read video frame from video file
set	Set property values for video reader object

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Construct `VideoReader` Object

Construct a `VideoReader` object for the example movie file `xylophone.mp4` and view its properties.

```
xyloObj = VideoReader('xylophone.mp4');
get(xyloObj)
```

```
obj =
```

```
  VideoReader with properties:

   General Properties:
           Name: 'xylophone.mp4'
           Path: 'matlabroot\toolbox\matlab\audiovideo'
       Duration: 4.7000
    CurrentTime: 0
            Tag: ''
       UserData: []

   Video Properties:
          Width: 320
         Height: 240
       FrameRate: 30
    BitsPerPixel: 24
     VideoFormat: 'RGB24'
```

Read and Play Back Movie File

Read and play back the sample movie file, `xylophone.mp4`.

Construct a `VideoReader` object to read data from the sample file. Then, determine the width and height of the video.

```
xyloObj = VideoReader('xylophone.mp4');

vidWidth = xyloObj.Width;
vidHeight = xyloObj.Height;
```

Create a movie structure array, `mov`.

```
mov = struct('cdata',zeros(vidHeight,vidWidth,3,'uint8'),...
    'colormap',[]);
```

Read one frame at a time until the end of the video is reached.

```
k = 1;
while hasFrame(xyloObj)
    mov(k).cdata = readFrame(xyloObj);
    k = k+1;
end
```

Size a figure based on the video's width and height. Then, play back the movie once at the video's frame rate.

```
hf = figure;
set(hf,'position',[150 150 vidWidth vidHeight]);

movie(hf,mov,1,xyloObj.FrameRate);
```

`mmfileinfo` | `VideoWriter`

How To

- “Read Video Files”

VideoWriter class

Write video files

Description

Use the `VideoWriter` object with the `open`, `writeVideo`, and `close` methods to create video files from figures, still images, or MATLAB movies. `VideoWriter` can create uncompressed AVI and Motion JPEG 2000 compressed AVI files on all platforms, and MPEG-4 files on Windows 7 or later and Mac OS X 10.7 and higher. `VideoWriter` supports files larger than 2 GB, which is the limit for `avifile`.

To set video properties, `VideoWriter` includes predefined *profiles* such as `'Uncompressed AVI'` or `'MPEG-4'`.

Construction

`writerObj = VideoWriter(filename)` constructs a `VideoWriter` object to write video data to an AVI file with Motion JPEG compression.

`writerObj = VideoWriter(filename,profile)` applies a set of properties tailored to a specific file format (such as `'MPEG-4'` or `'Uncompressed AVI'`) to a `VideoWriter` object.

Input Arguments

`filename`

String enclosed in single quotation marks that specifies the name of the file to create.

`VideoWriter` supports these file extensions:

`.avi`	AVI file
`.mj2`	Motion JPEG 2000 file
`.mp4` or `.m4v`	MPEG-4 file (systems with Windows 7 or later, or Mac OS X 10.7 and later)

If you do not specify a valid file extension, `VideoWriter` appends the extension `.avi`, `.mj2` or `.mp4`, depending on the `profile`. If you do not specify a value for `profile`, then `VideoWriter` creates a Motion JPEG compressed AVI file with the extension `.avi`.

`profile`

String enclosed in single quotation marks that describes the type of file to create. Specifying a profile sets default values for video properties such as `VideoCompressionMethod`. Possible values:

`'Archival'`	Motion JPEG 2000 file with lossless compression
`'Motion JPEG AVI'`	Compressed AVI file using Motion JPEG codec
`'Motion JPEG 2000'`	Compressed Motion JPEG 2000 file
`'MPEG-4'`	Compressed MPEG-4 file with H.264 encoding (systems with Windows 7 or later, or Mac OS X 10.7 and later)
`'Uncompressed AVI'`	Uncompressed AVI file with `RGB24` video
`'Indexed AVI'`	Uncompressed AVI file with indexed video
`'Grayscale AVI'`	Uncompressed AVI file with grayscale video

Default: `'Motion JPEG AVI'`

Properties

`ColorChannels`

Number of color channels in each output video frame. (Read-only)

AVI and MPEG-4 files with RGB24 data have three color channels. Indexed and Grayscale AVI files have one color channel. The number of channels for Motion JPEG 2000 files depends on the input data to the `writeVideo` method: one for monochrome image data, three for color data.

`Colormap`

`P`-by-3 numeric matrix that contains color information about the video file. The colormap can have a maximum of 256 entries of type `uint8` or `double`. The entries of the colormap must be integers. Each row of `Colormap` specifies the red, green, and blue

components of a single color. The colormap can be set explicitly before the call to `open`, or using the `colormap` field of a movie frame structure at the time of writing the first frame.

Only applies to objects associated with Indexed AVI files.

After you call `open`, you cannot change the `Colormap` value.

Default: none

`CompressionRatio`

Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. The data is compressed as much as possible, up to the specified target.

Only available for objects associated with Motion JPEG 2000 files. After you call `open`, you cannot change the `CompressionRatio` value. If you previously set `LosslessCompression` to `true`, setting `CompressionRatio` generates an error.

Default: `10`

`Duration`

Scalar value specifying the duration of the file in seconds. (Read-only)

`FileFormat`

String specifying the type of file to write: `'avi'`, `'mp4'`, or `'mj2'`. (Read-only)

`Filename`

String specifying the name of the file. (Read-only)

`FrameCount`

Number of frames written to the video file. (Read-only)

`FrameRate`

Rate of playback for the video in frames per second. After you call `open`, you cannot change the `FrameRate` value.

Default: 30

`Height`

Height of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame height for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a row of black pixels at the bottom.

`LosslessCompression`

Boolean value (logical `true` or `false`) only available for objects associated with Motion JPEG 2000 files. If `true`:

- The `writeVideo` method uses reversible mode so that the decompressed data is identical to the input data.
- `VideoWriter` ignores any specified value for `CompressionRatio`.

After you call `open`, you cannot change the `LosslessCompression` value.

Default: `false` for the `'Motion JPEG 2000'` profile, `true` for the `'Archival'` profile

`MJ2BitDepth`

Number of least significant bits in the input image data, from 1 to 16.

Only available for objects associated with Motion JPEG 2000 files. If you do not specify a value before calling the `open` method, `VideoWriter` sets the bit depth based on the input data type. For example, if the input data to `writeVideo` is an array of `uint8` or `int8` values, `MJ2BitDepth` is `8`.

`Path`

String specifying the fully qualified path. (Read-only)

`Quality`

Integer from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.

Only available for objects associated with the `MPEG-4` or `Motion JPEG AVI` profile. After you call `open`, you cannot change the `Quality` value.

Default: 75

`VideoBitsPerPixel`

Number of bits per pixel in each output video frame. (Read-only)

AVI files with truecolor video and MPEG-4 files have 24 bits per pixel (8 bits for each of three color bands).

For Motion JPEG 2000 files, the number of bits per pixel depends on the value of `MJ2BitDepth` and the number of bands of image data. For example, if the input data to `writeVideo` is a three-dimensional array of `uint16` or `int16` values, the default value of `MJ2BitDepth` is `16`, and `VideoBitsPerPixel` is `48` (three times the bit depth).

`VideoCompressionMethod`

String indicating the type of video compression: `'None'`, `'H.264'`, `'Motion JPEG'`, or `'Motion JPEG 2000'`. (Read-only)

`VideoFormat`

String indicating the MATLAB representation of the video format. (Read-only)

Video Format	Value of `VideoFormat`
AVI or MPEG-4 files with RGB24 video	`'RGB24'`
AVI files with indexed video	`'Indexed'`
AVI files with grayscale video	`'Grayscale'`

For Motion JPEG 2000 files, `VideoFormat` depends on the value of `MJ2BitDepth` and the format of the input image data to the `writeVideo` method. For example, if you do not specify the `MJ2BitDepth` property, `VideoWriter` sets the format as shown in this table.

Format of Image Data	Value of `VideoFormat`
Single-band `uint8`	`'Mono8'`
Single-band `int8`	`'Mono8 Signed'`

Format of Image Data	Value of `VideoFormat`
Single-band `uint16`	`'Mono16'`
Single-band `int16`	`'Mono16 Signed'`
Three-banded `uint8`	`'RGB24'`
Three-banded `int8`	`'RGB24 Signed'`
Three-banded `uint16`	`'RGB48'`
Three-banded `int16`	`'RGB48 Signed'`

`Width`

Width of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame width for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a column of black pixels along the right side.

Methods

close	Close file after writing video data
getProfiles	List profiles and file formats supported by `VideoWriter`
open	Open file for writing video data
writeVideo	Write video data to file

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

View and Set Object Properties

Construct a `VideoWriter` object and view its properties.

```
writerObj = VideoWriter('newfile.avi')
```

Set the frame rate to 60 frames per second, using the `FrameRate` property.

```
writerObj.FrameRate = 60;
```

AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
axis tight
set(gca,'nextplot','replacechildren');
set(gcf,'Renderer','zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
   surf(sin(2*pi*k/20)*Z,Z)
   frame = getframe;
   writeVideo(writerObj,frame);
end

close(writerObj);
```

`VideoReader` | `mmfileinfo`

view

Viewpoint specification

Syntax

```
view(az,el)
view([az,el])
view([x,y,z])
view(2)
view(3)
view(ax,...)
[az,el] = view
```

Description

The position of the viewer (the viewpoint) determines the orientation of the axes. You specify the viewpoint in terms of azimuth and elevation, or by a point in three-dimensional space.

`view(az,el)` and `view([az,el])` set the viewing angle for a three-dimensional plot. The azimuth, `az`, is the horizontal rotation about the *z*-axis as measured in degrees from the negative *y*-axis. Positive values indicate counterclockwise rotation of the viewpoint. `el` is the vertical elevation of the viewpoint in degrees. Positive values of elevation correspond to moving above the object; negative values correspond to moving below the object.

`view([x,y,z])` sets the view direction to the Cartesian coordinates `x`, `y`, and `z`. The magnitude of `(x,y,z)` is ignored.

`view(2)` sets the default two-dimensional view, `az = 0`, `el = 90`.

`view(3)` sets the default three-dimensional view, `az = –37.5`, `el = 30`.

`view(ax,...)` uses axes `ax` instead of the current axes.

`[az,el] = view` returns the current azimuth and elevation.

Examples

View the object from directly overhead.

```
az = 0;
el = 90;
view(az, el);
```

Set the view along the *y*-axis, with the *x*-axis extending horizontally and the *z*-axis extending vertically in the figure.

```
view([0 0]);
```

Rotate the view about the *z*-axis by 180°.

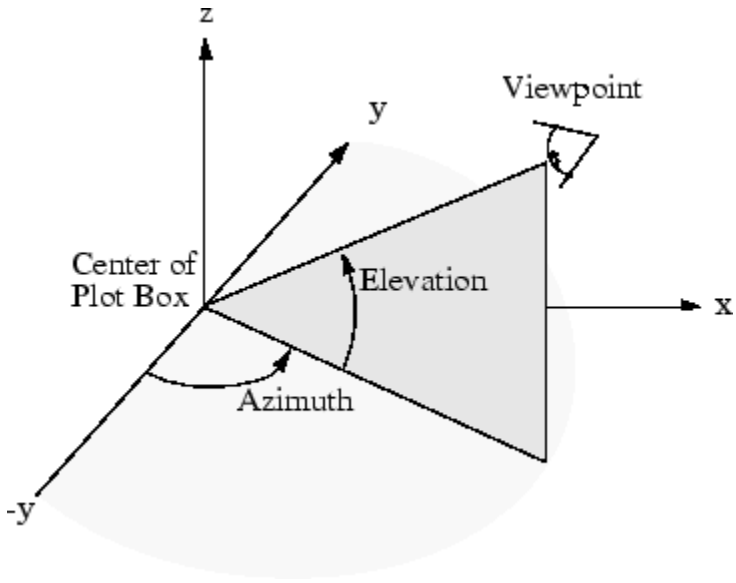
```
az = 180;
el = 90;
view(az, el);
```

More About

Tips

Azimuth is a polar angle in the *x*-*y* plane, with positive angles indicating counterclockwise rotation of the viewpoint. Elevation is the angle above (positive angle) or below (negative angle) the *x*-*y* plane.

This diagram illustrates the coordinate system. The arrows indicate positive directions.



For more information, see `CameraPosition`, `CameraTarget`, `CameraViewAngle`, and `Projection`.

- "View Overview"

`hgtransform` | `rotate3d`

Introduced before R2006a

viewmtx

View transformation matrices

Syntax

```
viewmtx
T = viewmtx(az,el)
T = viewmtx(az,el,phi)
T = viewmtx(az,el,phi,xc)
```

Description

`viewmtx` computes a 4-by-4 orthographic or perspective transformation matrix that projects four-dimensional homogeneous vectors onto a two-dimensional view surface (e.g., your computer screen).

`T = viewmtx(az,el)` returns an *orthographic* transformation matrix corresponding to azimuth `az` and elevation `el`. `az` is the azimuth (i.e., horizontal rotation) of the viewpoint in degrees. `el` is the elevation of the viewpoint in degrees. This returns the same matrix as the commands

```
view(az,el)
T = view
```

but does not change the current view.

`T = viewmtx(az,el,phi)` returns a *perspective* transformation matrix. `phi` is the perspective viewing angle in degrees. `phi` is the subtended view angle of the normalized plot cube (in degrees) and controls the amount of perspective distortion.

Phi	Description
0 degrees	Orthographic projection
10 degrees	Similar to telephoto lens
25 degrees	Similar to normal lens
60 degrees	Similar to wide-angle lens

`T = viewmtx(az,el,phi,xc)` returns the perspective transformation matrix using `xc` as the target point within the normalized plot cube (i.e., the camera is looking at the point `xc`). `xc` is the target point that is the center of the view. You specify the point as a three-element vector, `xc = [xc,yc,zc]`, in the interval [0,1]. The default value is `xc = [0,0,0]`.

A four-dimensional homogenous vector is formed by appending a 1 to the corresponding three-dimensional vector. For example, `[x,y,z,1]` is the four-dimensional vector corresponding to the three-dimensional point `[x,y,z]`.

Examples

Determine the projected two-dimensional vector corresponding to the three-dimensional point (0.5,0.0,-3.0) using the default view direction. Note that the point is a column vector.

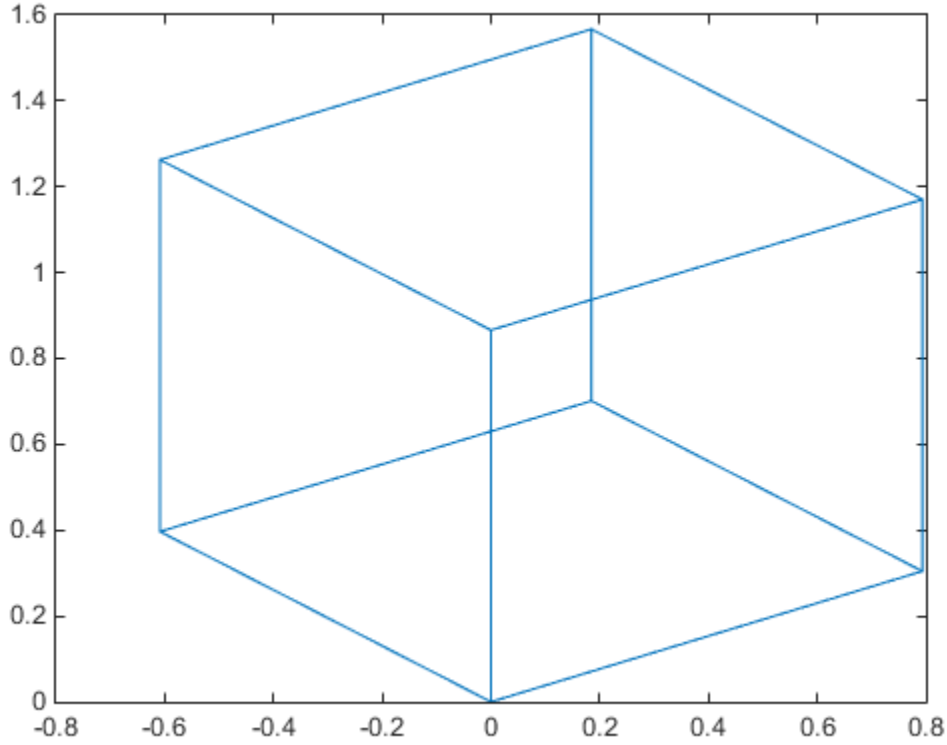
```
A = viewmtx(-37.5,30);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)
x2d =
   0.3967
   -2.4459
```

These vectors trace the edges of a unit cube:

```
x = [0  1  1  0  0  0  1  1  0  0  1  1  1  1  0  0];
y = [0  0  1  1  0  0  0  1  1  0  0  0  1  1  1  1];
z = [0  0  0  0  0  1  1  1  1  1  1  0  0  1  1  0];
```

Transform the points in these vectors to the screen, then plot the object.

```
A = viewmtx(-37.5,30);
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:);
y2(:) = x2d(2,:);
figure
plot(x2,y2)
```



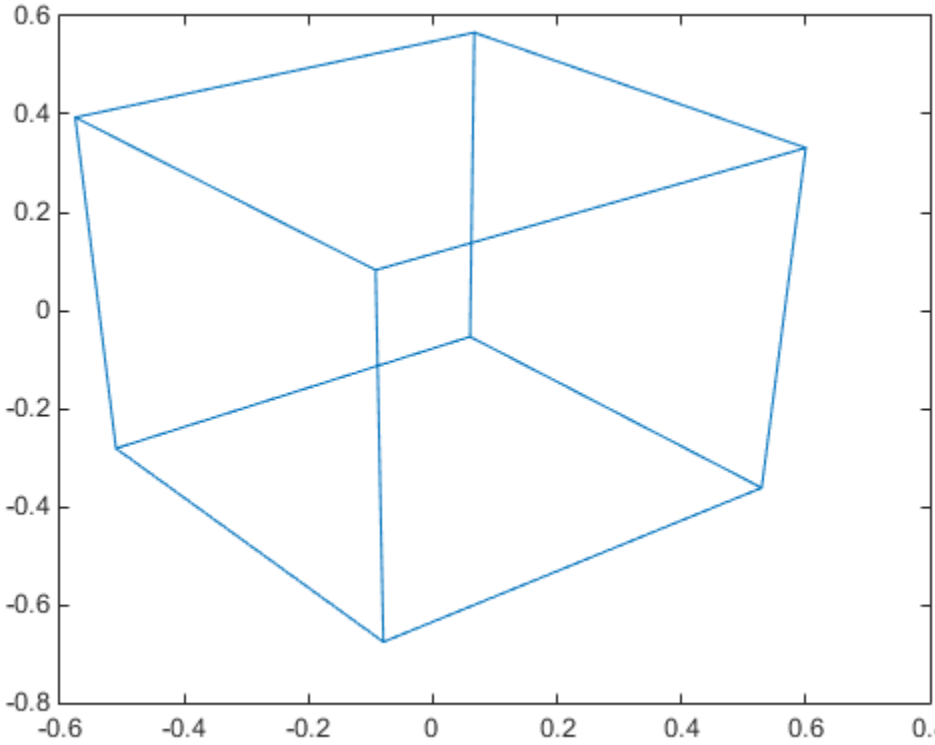
Use a perspective transformation with a 25 degree viewing angle:

```
A = viewmtx(-37.5,30,25);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)/x2d(4)
x2d =
   0.1777
   -1.8858
```

Transform the cube vectors to the screen and plot the object:

```
A = viewmtx(-37.5,30,25);
[m,n] = size(x);
```

```
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:)./x2d(4,:);
y2(:) = x2d(2,:)./x2d(4,:);
figure
plot(x2,y2)
```



See Also

`view` | `hgtransform`

Introduced before R2006a

visdiff

Compare two text files, MAT-Files, binary files, Zip files, or folders

Syntax

```
visdiff('filename1', 'filename2')
visdiff('filename1', 'filename2', 'type')
```

Description

`visdiff('filename1', 'filename2')` opens the Comparison Tool and presents the differences between the two files or folders. Either ensure that the two files or folders appear on the MATLAB path, or provide the full path for each file or folder. You can compare files or any combination of folders, zip files, Simulink manifests or models.

If you have Simulink Report Generator™ software, you can select a pair of Simulink models to compare XML text files generated from them. For information, see "Model Comparison".

`visdiff('filename1', 'filename2', 'type')` opens the Comparison Tool and presents the differences between the two files using the specified comparison type. *`type`* can be `'text'` or `'binary'`. If you do not specify `type`, `visdiff` creates the default comparison type for your selected files. The *`type`* option does not apply when comparing folders.

If there are multiple comparison types available for your selections (e.g., text, binary, file list, or XML comparison), you can create a new comparison and choose a different comparison type.

1. In the Comparison Tool, click the New comparison button.

   The dialog box Select Files or Folders for Comparison opens and shows your previous comparison selections in the drop-down lists.

2. Change the comparison type and click **Compare**.

Examples

Specifying Files or Folders to Compare

The `visdiff` function accepts fully qualified file names, relative file names, or names of files on the MATLAB path.

If the files you want to compare appear on the MATLAB path or in the current folder, you can specify the file names without the full path, for example:

```
visdiff('lengthofline.m','lengthofline2.m')
```
or

```
visdiff('lengthofline','lengthofline2')
```

If the files you want to compare are not on the path, either specify the full path to each file, or add the folders to the path.

For example, to specify the fully qualified file names to compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

Specify the full path to files as follows:

```
visdiff('C:\Work\comp\lengthofline.m', 'C:\Work\comp\lengthofline2.m')
```

You can specify paths to files relative to the current folder. For the preceding example, if the current folder is `Work`, then the relative paths are:

```
visdiff('comp\lengthofline.m', 'comp\lengthofline2.m')
```

Compare Two Text Files

To view a comparison of the two example files, `lengthofline.m` and `lengthofline2.m`:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline.m'), fullfile(matlabroot,'help',...
'techdoc','matlab_env','examples','lengthofline2.m'))
```

For information about using the report features, see “Comparing Text Files”.

Note: If the text files you compare are XML files, you see different results if you have MATLAB Report Generator installed. For details, see “Comparing Files and Folders”.

Compare Two MAT-Files

To compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

For information about the report features, see “Comparing MAT-Files”.

Compare Two Binary Files

The following example code adds a folder containing two MEX-files to the MATLAB path, and then compares the files:

```
addpath([matlabroot '\extern\examples\shrlib'])
visdiff('shrlibsample.mexw32', 'yprime.mexw32')
```

The Comparison Tool opens and indicates that the files are different, but does not provide details about the differences.

For more information on binary comparisons, see “Comparing Binary Files”.

Compare Two Folders or Zip Files

You can perform file list comparisons for any combinations of folders and zip files. To view an example folder comparison and instructions for using the report features, see “Comparing Folders and Zip Files”.

Compare Files and Specify Type

To compare two example text files and specify comparison type as binary:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline.m'), fullfile(matlabroot,'help',...
'techdoc','matlab_env','examples','lengthofline2.m'), 'binary')
```

If you do not specify type, `visdiff` creates the default comparison type for your selected files, in this case, text comparison. By changing to the binary comparison type you could examine differences such as end-of-line characters.

Similarly, when you compare XML files without specifying type, you get a hierarchical XML comparison report. If instead you want a text or binary comparison, you can specify "text" or "binary" comparison types to see more details. When you compare zip files, the default comparison type is a file list comparison, and you might want to specify a binary comparison instead.

Alternatives

As an alternative to the `visdiff` function, compare files and folders using any of these interactive methods:

- From the Current Folder browser:
  - Select a file or folder. Right-click the file or folder, and select **Compare Against**.
  - For two files or subfolders in the same folder, select the files or folders. Then, right-click, and select **Compare Selected Files/Folders**.
- From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare** and then select the files or folders to compare.
- If you have a file open in the Editor, on the **Editor** tab, in the **File** section, click **Compare**. Alternatively, under **Compare**, you can choose a file to compare against, or compare with the autosave version or the version on disk. See “Comparing Files with Autosave Version or Version on Disk”.

More About

- “Comparing Files and Folders”
- “Model Comparison”

volumebounds

Coordinate and color limits for volume data

Syntax

```
lims = volumebounds(X,Y,Z,V)
lims = volumebounds(X,Y,Z,U,V,W)
lims = volumebounds(V)
lims = volumebounds(U,V,W)
```

Description

`lims = volumebounds(X,Y,Z,V)` returns the x, y, z, and color limits of the current axes for scalar volume data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax cmin cmax]
```

You can pass this vector to the `axis` command.

`lims = volumebounds(X,Y,Z,U,V,W)` returns the x, y, and z limits of the current axes for vector volume data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax]
```

`lims = volumebounds(V)` and `lims = volumebounds(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(V)`.

Examples

This example uses `volumebounds` to set the axis and color limits for an `isosurface` generated by the `flow` function.

```
[x y z v] = flow;
```

```
p = patch(isosurface(x,y,z,v,-3));
isonormals(x,y,z,v,p)
daspect([1 1 1])
isocolors(x,y,z,fliplr(v),p)
shading interp
axis(volumebounds(x,y,z,v))
```

See Also

`isosurface` | `streamslice`

Introduced before R2006a

voronoi

Voronoi diagram

Note: Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `voronoi`.

Note: The behavior of `h = voronoi(...)` has changed. The new behavior returns a vector of two chart line handles; one representing the points and the other representing the voronoi edges.

Syntax

```
voronoi(x,y)
voronoi(x,y,TRI)
voronoi(dt)
voronoi(AX,...)
voronoi(...,'LineSpec')
h = voronoi(...)
[vx,vy] = voronoi(...)
```

Description

`voronoi(x,y)` plots the bounded cells of the Voronoi diagram for the points `x`,`y`. Lines-to-infinity are approximated with an arbitrarily distant endpoint.

`voronoi(x,y,TRI)` uses the triangulation `TRI` instead of computing internally.

`voronoi(dt)` uses the Delaunay triangulation `dt` instead of computing it.

`voronoi(AX,...)` plots into `AX` instead of `gca`.

`voronoi(...,'LineSpec')` plots the diagram with color and line style specified.

`h = voronoi(...)` returns `h`, which is a vector of two chart line handles. One represents the points and the other represents the voronoi edges.

`[vx,vy] = voronoi(...)` returns the finite vertices of the Voronoi edges in `vx` and `vy`.

Note For the topology of the Voronoi diagram, i.e., the vertices for each Voronoi cell, use `voronoin`.

```
[v,c] = voronoin([x(:) y(:)])
```

Definitions

Consider a set of coplanar points *P*. For each point P_x in the set *P*, you can draw a boundary enclosing all the intermediate points lying closer to P_x than to other points in the set *P*. Such a boundary is called a *Voronoi polygon*, and the set of all Voronoi polygons for a given point set is called a *Voronoi diagram*.

Visualization

Use one of these methods to plot a Voronoi diagram:

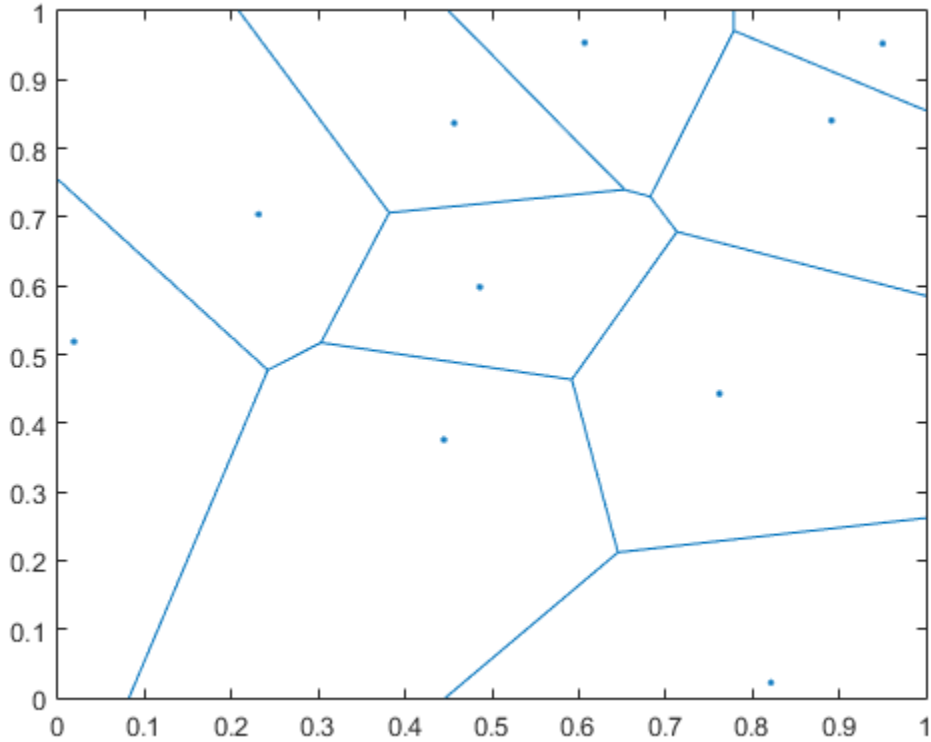
- If you provide no output argument, `voronoi` plots the diagram.
- To gain more control over color, line style, and other figure properties, use the syntax `[vx,vy] = voronoi(...)`. This syntax returns the vertices of the finite Voronoi edges, which you can then plot with the `plot` function.
- To fill the cells with color, use `voronoin` with `n = 2` to get the indices of each cell, and then use `patch` and other plot functions to generate the figure. Note that `patch` does not fill unbounded cells with color.

Examples

Voronoi Diagram Based on Points

This code uses the `voronoi` function to plot the Voronoi diagram for 10 randomly generated points.

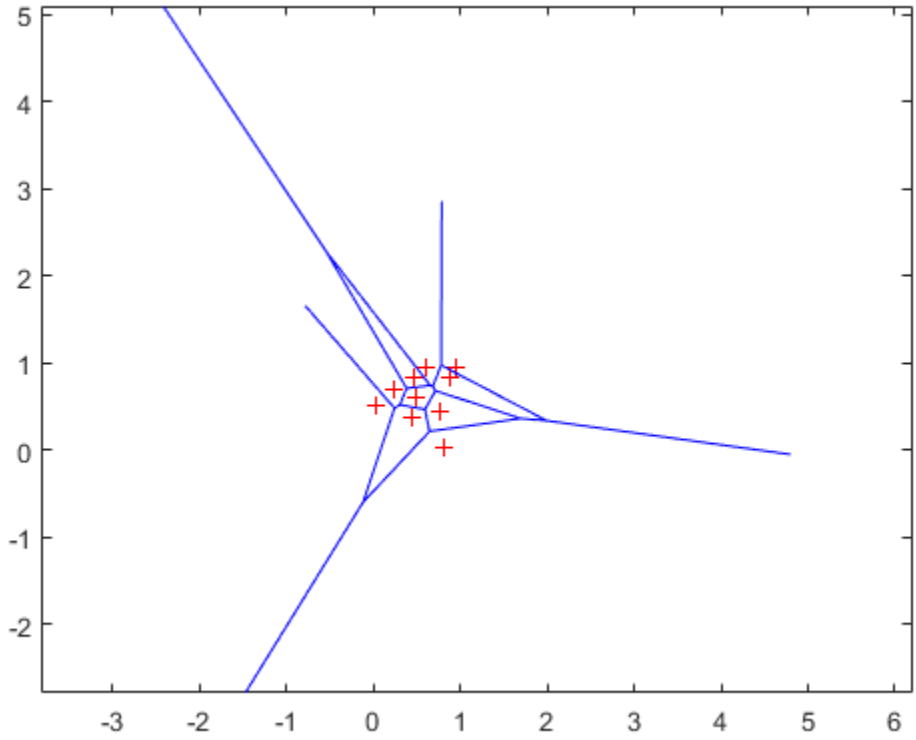
```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
voronoi(x,y)
```



Voronoi Diagram Based on Vertices of Voronoi Edges

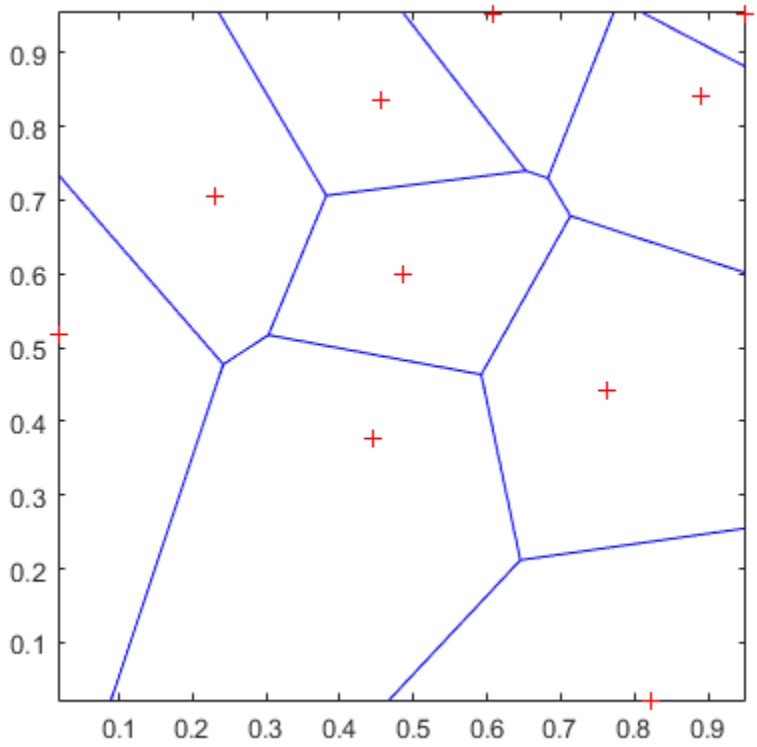
This code uses the vertices of the finite Voronoi edges to plot the Voronoi diagram for the same 10 points used in the previous example.

```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
[vx,vy] = voronoi(x,y);
plot(x,y,'r+',vx,vy,'b-')
axis equal
```



Note that you can add the following code to get the figure shown in the previous example.

```
xlim([min(x) max(x)])
ylim([min(y) max(y)])
```



Voronoi Diagram with Color

This code uses `voronoin` and `patch` to fill the bounded cells of the same Voronoi diagram with color.

```
x = gallery('uniformdata',[10 2],5);
[v,c] = voronoin(x);
for i = 1:length(c)
if all(c{i}~=1)   % If at least one of the indices is 1,
                  % then it is an open region and we can't
                  % patch that.
patch(v(c{i},1),v(c{i},2),i); % use color i.
end
end
```

Introduced before R2006a

voronoiDiagram

Class: DelaunayTri

(Will be removed) Voronoi diagram

Note: `voronoiDiagram(DelaunayTri)` will be removed in a future release. Use `voronoiDiagram(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
[V, R] = voronoiDiagram(DT)
```

Description

`[V, R] = voronoiDiagram(DT)` returns the vertices `V` and regions `R` of the Voronoi diagram of the points `DT.X`. The region `R{i}` is a cell array of indices into `V` that represents the Voronoi vertices bounding the region. The Voronoi region associated with the `i`'th point, `DT.X(i)` is `R{i}`. For 2-D, vertices in `R{i}` are listed in adjacent order, i.e. connecting them will generate a closed polygon (Voronoi diagram). For 3-D the vertices in `R{i}` are listed in ascending order.

The Voronoi regions associated with points that lie on the convex hull of `DT.X` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

Input Arguments

`DT`	Delaunay triangulation.

Output Arguments

`V`	`numv`-by-`ndim` matrix representing the coordinates of the Voronoi vertices, where `numv` is the number of vertices and `ndim` is the dimension of the space where the points reside.
`R`	Vector cell array of `length(DR.X)`, representing the Voronoi cell associated with each point.

Definitions

The *Voronoi diagram* of a discrete set of points `X` decomposes the space around each point `X(i)` into a region of influence `R{i}`. Locations within the region are closer to point `i` than any other point. The region of influence is called the Voronoi region. The collection of all the Voronoi regions is the Voronoi diagram.

The *convex hull* of a set of points `X` is the smallest convex polygon (or polyhedron in higher dimensions) containing all of the points of `X`.

Examples

Compute the Voronoi Diagram of a set of points:

```
X = [ 0.5    0
      0      0.5
     -0.5   -0.5
     -0.2   -0.1
     -0.1    0.1
      0.1   -0.1
      0.1    0.1 ]
dt = DelaunayTri(X)
[V,R] = voronoiDiagram(dt)
```

See Also

`voronoi` | `delaunayTriangulation` | `voronoin` | `triangulation`

voronoin

N-D Voronoi diagram

Syntax

```
[V,C] = voronoin(X)
[V,C] = voronoin(X,options)
```

Description

`[V,C] = voronoin(X)` returns Voronoi vertices `V` and the Voronoi cells `C` of the Voronoi diagram of `X`. `V` is a `numv`-by-`n` array of the `numv` Voronoi vertices in n-dimensional space, each row corresponds to a Voronoi vertex. `C` is a vector cell array where each element contains the indices into `V` of the vertices of the corresponding Voronoi cell. `X` is an `m`-by-`n` array, representing `m` n-dimensional points, where `n > 1` and `m >= n+1`.

The first row of `V` is a point at infinity. If any index in a cell of the cell array is `1`, then the corresponding Voronoi cell contains the first point in `V`, a point at infinity. This means the Voronoi cell is unbounded.

`voronoin` uses Qhull.

`[V,C] = voronoin(X,options)` specifies a cell array of strings `options` to be used in Qhull. The default options are

- `{'Qbb'}` for 2- and 3-dimensional input
- `{'Qbb','Qx'}` for 4 and higher-dimensional input

If `options` is `[]`, the default options are used. If `code` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see http://www.qhull.org.

Visualization

You can plot individual bounded cells of an n-dimensional Voronoi diagram. To do this, use `convhulln` to compute the vertices of the facets that make up the Voronoi cell. Then use `patch` and other plot functions to generate the figure.

Examples

Example 1

Let

```
x = [ 0.5    0
      0      0.5
     -0.5   -0.5
     -0.2   -0.1
     -0.1    0.1
      0.1   -0.1
      0.1    0.1 ]
```

then

```
[V,C] = voronoin(x)
```

```
V =
       Inf       Inf
       0.3833    0.3833
       0.7000   -1.6500
       0.2875    0.0000
      -0.0000    0.2875
      -0.0000   -0.0000
      -0.0500   -0.5250
      -0.0500   -0.0500
      -1.7500    0.7500
      -1.4500    0.6500
C =

    [1x4 double]
    [1x5 double]
    [1x4 double]
    [1x4 double]
    [1x4 double]
    [1x5 double]
    [1x4 double]
```

Use a `for` loop to see the contents of the cell array `C`.

```
for i=1:length(C), disp(C{i}), end
```

```
     4     2     1     3
    10     5     2     1     9
     9     1     3     7
    10     8     7     9
    10     5     6     8
     8     6     4     3     7
     6     4     2     5
```

In particular, the fifth Voronoi cell consists of 4 points: `V(10,:)`, `V(5,:)`, `V(6,:)`, `V(8,:)`.

Example 2

The following example illustrates the `options` input to `voronoin`. The commands

```
X = [-1 -1; 1 -1; 1 1; -1 1];
[V,C] = voronoin(X)
```

return an error message.

```
? qhull input error: can not scale last coordinate. Input is
cocircular
   or cospherical. Use option 'Qz' to add a point at infinity.
```

The error message indicates that you should add the option `'Qz'`. The following command passes the option `'Qz'`, along with the default `'Qbb'`, to `voronoin`.

```
[V,C] = voronoin(X,{'Qbb','Qz'})
V =

   Inf   Inf
     0     0

C =

    [1x2 double]
    [1x2 double]
    [1x2 double]
    [1x2 double]
```

More About

Algorithms

`voronoin` is based on Qhull [1]. For information about Qhull, see http://www.qhull.org/.

Introduced before R2006a

waitbar

Open or update wait bar dialog box

Syntax

```
h = waitbar(x,'message')
waitbar(x,'message','CreateCancelBtn','button_callback')
waitbar(x,'message',property_name,property_value,...)
waitbar(x)
waitbar(x,h)
waitbar(x,h,'updated message')
```

Description

A wait bar is a figure that displays what percentage of a calculation is complete as the calculation proceeds by progressively filling a bar with red from left to right.

`h = waitbar(x,'message')` displays a wait bar of fractional length `x`. The wait bar figure displays until the code that controls it closes it or the use clicks its Close Window button. Its (figure) handle is returned in `h`. The argument `x` must be between `0` and `1`.

Note Wait bars are not modal figures (their WindowStyle is `'normal'`). They often appear to be modal because the computational loops within which they are called prevent interaction with the Command Window until they terminate. For more information, see WindowStyle in Figure Properties.

`waitbar(x,'message','CreateCancelBtn','button_callback')` specifying `CreateCancelBtn` adds a **Cancel** button to the figure that executes the MATLAB commands specified in `button_callback` when the user clicks the **Cancel** button or the **Close Figure** button. `waitbar` sets both the **Cancel** button callback and the figure CloseRequestFcn to the string specified in `button_callback`.

`waitbar(x,'message',property_name,property_value,...)` optional arguments `property_name` and `property_value` enable you to set Figure Properties for the `waitbar`.

`waitbar(x)` subsequent calls to `waitbar(x)` extend the length of the bar to the new position `x`. Successive values of `x` normally increase. If they decrease, the wait bar runs in reverse.

`waitbar(x,h)` extends the length of the bar in the wait bar `h` to the new position `x`.

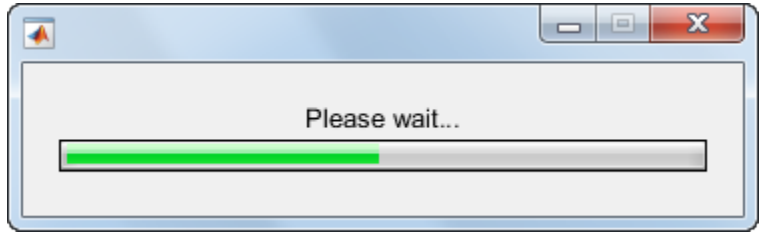
`waitbar(x,h,'updated message')` updates the message text in the `waitbar` figure, in addition to setting the fractional length to `x`.

Examples

Example 1 — Basic Wait Bar

Typically, you call `waitbar` repeatedly inside a `for` loop that performs a lengthy computation. For example:

```
h = waitbar(0,'Please wait...');
steps = 1000;
for step = 1:steps
    % computations take place here
    waitbar(step / steps)
end
close(h)
```



Example 2 — Wait Bar with Dynamic Text and Cancel Button

Adding a **Cancel** button allows user to abort the computation. Clicking it sets a logical flag in the figure's application data (appdata). The function tests for that value within the main loop and exits the loop as soon as the flag has been set. The example iteratively approximates the value of π. At each step, the current value is encoded as a string and

displayed in the wait bar's message field. When the function finishes, it destroys the wait bar and returns the current estimate of π and the number of steps it ran.

Copy the following function to a code file and save it as `approxpi.m`. Execute it as follows, allowing it to run for 10,000 iterations.

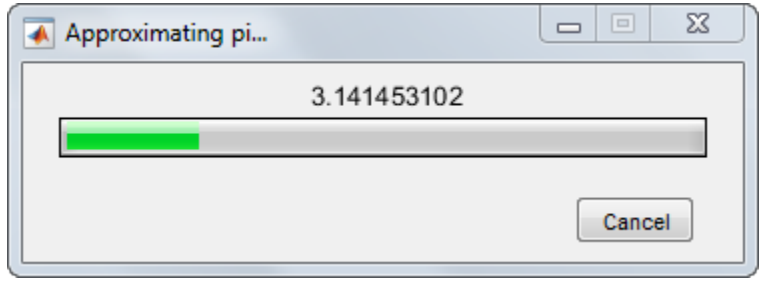
```
[estimated_pi steps] = approxpi(10000)
```

You can click **Cancel** or close the window to abort the computation and return the current estimate of π.

```
function [valueofpi step] = approxpi(steps)
% Converge on pi in steps iterations, displaying waitbar.
% User can click Cancel or close button to exit the loop.
% Ten thousand steps yields error of about 0.001 percent.

h = waitbar(0,'1','Name','Approximating pi...',...
            'CreateCancelBtn',...
            'setappdata(gcbf,''canceling'',1)');
setappdata(h,'canceling',0)
% Approximate as pi^2/8 = 1 + 1/9 + 1/25 + 1/49 + ...
pisqover8 = 1;
denom = 3;
valueofpi = sqrt(8 * pisqover8);
for step = 1:steps
    % Check for Cancel button press
    if getappdata(h,'canceling')
        break
    end
    % Report current estimate in the waitbar's message field
    waitbar(step/steps,h,sprintf('%12.9f',valueofpi))
    % Update the estimate
    pisqover8 = pisqover8 + 1 / (denom * denom);
    denom = denom + 2;
    valueofpi = sqrt(8 * pisqover8);
end
delete(h)       % DELETE the waitbar; don't try to CLOSE it.
```

The function sets the figure Name property to describe what is being computed. In the `for` loop, calling `waitbar` sets the fractional progress indicator and displays intermediate results. the code `waitbar(i/steps,h,sprintf('%12.9f',valueofpi))` sets the wait bar's `message` variable to a string representation of the current estimate of *pi*. Naturally, the extra computation involved makes iterations last longer than they need to, but such feedback can be helpful to users.



Note: You should call `delete` to remove a wait bar when you give it a CloseRequestFcn, as in the preceding code; calling `close` does not close it, and makes its Cancel and Close Window buttons unresponsive. This happens because the figure's CloseRequestFcn callback recursively calls itself. In such a situation you must forcibly remove the wait bar, for example like this:

```
set(groot,'ShowHiddenHandles','on')
delete(get(groot,'Children'))
```

However, as issuing these commands will delete all open figures—not just the wait bar—it is best never to use `close` in a CloseRequestFcn to close a window.

Introduced before R2006a

waitfor

Block execution and wait for condition

Syntax

```
waitfor(h)
waitfor(h,PropertyName)
waitfor(h,PropertyName,PropertyValue)
```

Description

`waitfor(h)` blocks the caller from executing statements until the graphics object identified by `h` closes (is deleted). When object `h` no longer exists, `waitfor` returns, enabling execution to resume. If the object does not exist, `waitfor` returns immediately without processing any events.

`waitfor(h,PropertyName)` blocks the caller from executing until the value of `PropertyName` (any property of the graphics object `h`) changes or `h` closes (is deleted). If `PropertyName` is not a valid property for the object, MATLAB returns an error.

`waitfor(h,PropertyName,PropertyValue)` blocks the caller from executing until the value of `PropertyName` for the graphics object `h` changes to the specific value `PropertyValue` or `h` closes (is deleted). If the value of `PropertyName` is already `PropertyValue`, `waitfor` returns immediately without processing any events.

Here are some important characteristics of the `waitfor` function:

- The `waitfor` function prevents its caller from continuing, but callbacks that respond to various user actions (for example, pressing a mouse button) can still run.
- The `waitfor` function also blocks Simulink models from executing, but callbacks do still execute.
- The `waitfor` function can block nested function calls. For example, a callback that executes while the `waitfor` function is running can call `waitfor`.
- If a callback function of a UI component is currently executing the `waitfor` function, then that callback can be interrupted regardless of that component's Interruptible property value.

- If you type **Ctrl+C** in the Command Window while the `waitfor` function is executing, the executing program terminates. To avoid terminating, the program can call the `waitfor` function within a `try/catch` block that handles the exception that typing **Ctrl+C** generates.

Examples

Create a plot and pause execution of the rest of the statements until you close the figure window:

```
f = warndlg('This is a warning.', 'A Warning Dialog');
disp('This prints immediately');
drawnow     % Necessary to print the message
waitfor(f);
disp('This prints after you close the warning dialog');
```

Suspend execution until name of figure changes:

```
f = figure('Name', datestr(now));
h = uicontrol('String','Change Name',...
              'Position',[20 20 100 30],...
'Callback', 'set(gcbf, ''Name'', datestr(now))');
disp('This prints immediately');
drawnow     % Necessary to print the message
waitfor(f, 'Name');
disp('This prints after clicking the push button');
```

Display text object and wait for user to edit it:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately.');
drawnow
waitfor(textH,'Editing','off');
set(textH,'BackgroundColor',[1 1 0]);
disp('This prints after text editing is complete.');
```

If you close the figure while `waitfor` is executing, an error occurs because the code attempts to access handles of objects that no longer exist. You can handle the error by enclosing code starting with the call to `waitfor` in a try/catch block, as follows:

```
figure;
```

```
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately.');
drawnow
% Use try/catch block to handle errors,
% such as deleting figure
try
    waitfor(textH,'Editing','off');
    set(textH,'BackgroundColor',[1 1 0]);
    disp('This prints after text editing is complete.');
catch ME
    disp('This prints if figure is deleted:')
    disp(ME.message)
  % You can place other code to respond to the error here
end
```

The `ME` variable is a MATLAB Exception object that you can use to determine the type of error that occurred. For more information, see " Respond to an Exception".

`drawnow` | `pause` | `keyboard` | `uiresume` | `uiwait` | `waitforbuttonpress`

Introduced before R2006a

waitforbuttonpress

Wait for key press or mouse-button click

Note: The behavior of the `waitforbuttonpress` function changed in R2014b. The figure that is current when you call the `waitforbuttonpress` function is the only area in which users can press a key or click a mouse button to resume program execution.

Syntax

```
k = waitforbuttonpress
```

Description

`k = waitforbuttonpress` blocks the caller's execution stream until the function detects that the user has clicked a mouse button or pressed a key while the figure window is active. The figure that is current when you call the `waitforbuttonpress` function is the only area in which users can press a key or click a mouse button to resume program execution. The return argument, `k`, can have these values:

- `0` if it detects a mouse button click
- `1` if it detects a key press

If a `WindowButtonDownFcn` callback is defined for the figure, its callback is executed before `waitforbuttonpress` returns a value.

Only keys that generate characters cause the function to return. Pressing any of the following keys by itself does nothing: **Ctrl**, **Shift**, **Alt**, **Caps_lock**, **Num_lock**, **Scroll_lock**.

These figure properties provide additional information about the user's interaction with the window: `CurrentCharacter`, `SelectionType`, and `CurrentPoint`.

You can interrupt the `waitforbuttonpress` function by typing **Ctrl**+C, but it returns an error unless your code calls it from within a `try/catch` block. The

`waitforbuttonpress` function errors if the user closes the figure by clicking the **X** (close box) unless your code calls the `waitforbuttonpress` function within a `try/catch` block.

Examples

These statements display text in the Command Window when the user either clicks a mouse button or types a key in the figure window:

```
f = figure;
w = waitforbuttonpress;
if w == 0
    disp('Button click')
else
    disp('Key press')
end
```

See Also

`dragrect` | `ginput` | `rbbox` | `waitfor`

Introduced before R2006a

warndlg

Create warning dialog box

Syntax

```
h = warndlg
h = warndlg(warningstring)
h = warndlg(warningstring,dlgname)
h = warndlg(warningstring,dlgname,createmode)
```

Description

`h = warndlg` displays a dialog box named `Warning Dialog` containing the string, `This is the default warning string`. The `warndlg` function returns the handle of the dialog box in `h`. The warning dialog box disappears after the user clicks **OK**.

`h = warndlg(warningstring)` displays a dialog box with the title `Warning Dialog` containing the string specified by `warningstring`. The `warningstring` argument can be any valid string format – cell arrays are preferred.

To use multiple lines in your warning, define `warningstring` using either of the following:

- `sprintf` with `newline` characters separating the lines

  ```
  warndlg(sprintf('Message line 1 \n Message line 2'))
  ```

- Cell arrays of strings

  ```
  warndlg({'Message line 1';'Message line 2'})
  ```

`h = warndlg(warningstring,dlgname)` displays a dialog box with title `dlgname`.

`h = warndlg(warningstring,dlgname,createmode)` specifies whether the warning dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `warningstring` and `dlgname`. The *`createmode`* argument can be a string or a structure.

If *createmode* is a string, it must be one of the values shown in the following table.

createmode Value	Description
`modal`	Replaces the warning dialog box having the specified `Title`, that was last created or clicked on, with a modal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
`nonmodal` (default)	Creates a new nonmodal warning dialog box with the specified parameters. Existing warning dialog boxes with the same title are not deleted.
`replace`	Replaces the warning dialog box having the specified `Title`, that was last created or clicked on, with a nonmodal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

Note: A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

Modal dialogs (created using `errordlg`, `msgbox`, or `warndlg`) replace any existing dialogs created with these functions that also have the same name.

For more information about modal dialog boxes, see WindowStyle in Figure Properties.

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings `'tex'` or `'none'`. The default value for `Interpreter` is `'none'`.

Examples

The statement

```
warndlg('Pressing OK will clear memory','!! Warning !!')
```

displays this dialog box:

`dialog` | `errordlg` | `helpdlg` | `inputdlg` | `listdlg` | `msgbox` | `questdlg` | `figure` | `uiwait` | `uiresume` | `warning`

Introduced before R2006a

warning

Display warning message

Syntax

```
warning(msg)
warning(msg,A1,...,An)
warning(msgID, ___ )

warning(state)
warning(state,msgID)
warning

warnStruct = warning
warning(warnStruct)

warning(state,mode)
warnStruct = warning(state,mode)
```

Description

`warning(msg)` displays the warning message and sets the warning state for the`lastwarn` function. If `msg` is an empty string (`''`), `warning` resets the warning state for `lastwarn`, but does not display any text.

`warning(msg,A1,...,An)` displays a message string that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `msg` is converted to one of the values `A1,...,An`.

`warning(msgID, ___ )` attaches a warning identifier to the warning message. You can include any of the input arguments in the previous syntaxes. The identifier enables you to distinguish warnings and to control what happens when MATLAB encounters the warnings.

`warning(state)` enables, disables, or displays the state of all warnings.

`warning(state,msgID)` acts on the state of a specified warning.

`warning` displays the state of all of the warnings. It is equivalent to `warning('query')`.

`warnStruct = warning` returns a structure or array of structures that contains information about which warnings are enabled and disabled. `warnStruct` includes an `identifier` field with a `msgID` or `'all'`, and a `state` field that indicates the state of the corresponding warning.

`warning(warnStruct)` sets the current warning settings as indicated in the structure array, `warnStruct`.

`warning(state,mode)` controls whether MATLAB displays the stack trace or additional information about the warning.

`warnStruct = warning(state,mode)` returns a structure with an `identifier` field containing the `mode` and a `state` field containing the current state of `mode`. If you pass the output structure, `warnStruct`, into the `warning` function, you set the state of the `mode`, not which warnings are enabled or disabled.

Examples

Issue Warning Message

Generate a warning that displays a message.

```
n = 7;
if ~ischar(n)
   warning('Input must be a string')
end
```

```
Warning: Input must be a string
```

Include information about `n` in the warning message.

```
if ~ischar(n)
   warning('Input must be a string, not a %s',class(n))
end
```

```
Warning: Input must be a string, not a double
```

Attach a message identifier to the warning message.

```
if ~ischar(n)
```

```
   warning('MyComponent:incorrectType',...
       'Input must be a string, not a %s',class(n))
end
```

```
Warning: Input must be a string, not a double
```

Set and Query Warning State

Disable all warnings.

```
warning('off')
```

Query the warnings.

```
warning
```

```
All warnings have the state 'off'.
```

Enable all warnings, disable the singular matrix warning, and query all warnings.

```
warning('on')
warning('off','MATLAB:singularMatrix')
warning
```

```
The default warning state is 'on'. Warnings not set to the default are

State  Warning Identifier

    off  MATLAB:singularMatrix
```

Re-enable the singular matrix warning.

```
warning('on','MATLAB:singularMatrix')
```

Save and Restore Warning Settings

Enable all warnings, and then disable the singular matrix warning.

```
warning('on')
warning('off','MATLAB:singularMatrix')
```

Save the current warning settings.

```
s = warning
```

```
s =
```

```
2x1 struct array with fields:

    identifier
    state
```

Examine the two structures.

```
s(1)
```

```
ans =

    identifier: 'all'
         state: 'on'
```

```
s(2)
```

```
ans =

    identifier: 'MATLAB:singularMatrix'
         state: 'off'
```

All warnings are enabled except for `'MATLAB:singularMatrix'`.

Disable and query all warnings.

```
warning('off')
warning('query')
```

```
All warnings have the state 'off'.
```

Restore the saved warning state structure, and query the state.

```
warning(s)
warning('query')
```

```
The default warning state is 'on'. Warnings not set to the default are

State  Warning Identifier

    off  MATLAB:singularMatrix
```

Control Warning Verbosity

Ensure `verbose` and `backtrace` settings are the default values.

```
warning('off','verbose')
warning('on','backtrace')
```

Turn on all warnings, and remove a folder that does not exist on the MATLAB path.

```
warning('on')
rmpath('nosuchfolder')
```

```
Warning: "nosuchfolder" not found in path.
> In rmpath at 57
```

Enable verbosity to display an extended warning message.

```
warning('on','verbose')
rmpath('nosuchfolder')
```

```
Warning: "nosuchfolder" not found in path.
(Type "warning off MATLAB:rmpath:DirNotFound" to suppress this warning.)

> In rmpath at 57
```

Disable display of the stack trace.

```
warning('off','backtrace')
rmpath('nosuchfolder')
```

```
Warning: "nosuchfolder" not found in path.
(Type "warning off MATLAB:rmpath:DirNotFound" to suppress this warning.)
```

Temporarily Disable Warning

Compute a singular matrix.

```
A = eye(2);
B = [3 6; 4 8];
C = B\A;
```

```
Warning: Matrix is singular to working precision.
```

Find the warning ID, save the current warning state, and disable the specific warning

```
[msgStr,msgId] = lastwarn;
warnStruct = warning('off',msgId);
C = B\A;
```

Restore previous warning state.

```
warning(warnStruct);
C = B\A;
```

```
Warning: Matrix is singular to working precision.
```

- “Issue Warnings and Errors”
- “Suppress Warnings”
- “Restore Warnings”
- “Change How Warnings Display”

Input Arguments

`msg` — Information about cause of warning

`string`

Information about the cause of the warning and how you might correct it, specified as a string. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1,...,An` input arguments. For more information, see “Formatting Strings”.

Note: You must specify more than one input argument with `warning` if you want MATLAB to convert special characters (such as `\t`, `\n`, `%s`, and `%d`) in the warning message string.

Example: `'Input must be a string.'`

`A1,...,An` — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msg`.

`msgID` — Identifier for warning

string | `'all'` | `'last'`

Identifier for the warning, specified as a string, `'all'`, or `'last'`. Use the warning identifier to help identify the source of the warning or to control a selected subset of the warnings in your program.

The message identifier includes a `component` and `mneumonic`. The identifier must always contain a colon and follows this simple format: `component:mnemonic`. The `component` and `mneumonic` fields must each begin with a letter. The remaining characters can be alphanumerics (A–Z, a–z, 0–9) and underscores. No whitespace characters can appear anywhere in msgID. For more information, see "Message Identifiers".

When you set the state of a warning, the `msgID` can have a value of `'all'` or `'last'`. Use `'all'` to set the state of all warnings, and use `'last'` to set the state of the last issued warning.

Example: `'MATLAB:singularMatrix'`

Example: `'MATLAB:narginchk:notEnoughInputs'`

`state` — Warning control indicator

`'on' | 'off' | 'query'`

Warning control indicator specified as `'on'`, `'off'`, or `'query'`. Use `'on'` or `'off'` to control whether MATLAB issues a warning. Use `'query'` to query the current state of the warning.

`warnStruct` — Warning settings

structure | array of structures

Warning settings, specified as a structure or array of structures that contains information about which warnings are enabled and which are disabled. `warnStruct` includes an `identifier` field with a `msgID` or `'all'`, and `state` field indicating the state of the corresponding warning.

`mode` — Verbosity and sack trace display settings

`'backtrace' | 'verbose'`

Verbosity and the stack trace display of settings, specified by `'backtrace'` or `'verbose'`. By default, the state of verbosity is set to `'off'` and the state of stack trace display is set to `'on'`.

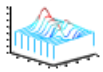
Introduced before R2006a

waterfall

Waterfall plot



Syntax

```
waterfall(Z)
waterfall(X,Y,Z)
waterfall(...,C)
waterfall(axes_handles,...)
h = waterfall(...)
```

Description

The `waterfall` function draws a mesh similar to the `meshz` function, but it does not generate lines from the columns of the matrices. This produces a “waterfall” effect.

`waterfall(Z)` creates a waterfall plot using `x = 1:size(Z,2)` and `y = 1:size(Z,1)`. `Z` determines the color, so color is proportional to surface height.

`waterfall(X,Y,Z)` creates a waterfall plot using the values specified in `X`, `Y`, and `Z`. `Z` also determines the color, so color is proportional to the surface height. If `X` and `Y` are vectors, `X` corresponds to the columns of `Z`, and `Y` corresponds to the rows, where `length(x) = n`, `length(y) = m`, and `[m,n] = size(Z)`. `X` and `Y` are vectors or matrices that define the *x*- and *y*-coordinates of the plot. `Z` is a matrix that defines the *z*-coordinates of the plot (i.e., height above a plane). If `C` is omitted, color is proportional to `Z`.

`waterfall(...,C)` uses scaled color values to obtain colors from the current colormap. Color scaling is determined by the range of `C`, which must be the same size as `Z`.

MATLAB performs a linear transformation on `C` to obtain colors from the current colormap.

`waterfall(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

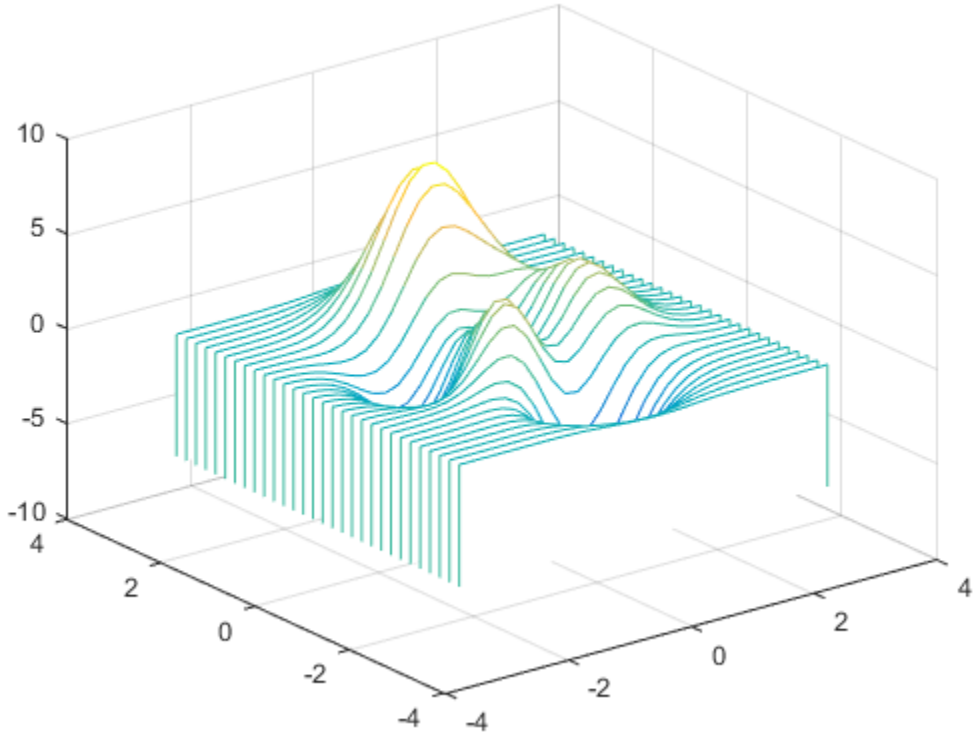
`h = waterfall(...)` returns the handle of the patch graphics object used to draw the plot.

Examples

Create Waterfall Plot

Create a waterfall plot of the peaks function.

```
figure
[X,Y,Z] = peaks(30);
waterfall(X,Y,Z)
```



More About

Tips

For column-oriented data analysis, use `waterfall(Z')` or `waterfall(X',Y',Z')`.

Algorithms

The range of `X`, `Y`, and `Z`, or the current setting of the axes `XLim`, `YLim`, and `ZLim` properties, determines the range of the axes (also set by `axis`). The range of `C`, or the current setting of the axes `CLim` property, determines the color scaling (also set by `caxis`).

The `CData` property for the patch graphics objects specifies the color at every point along the edge of the patch, which determines the color of the lines.

The waterfall plot looks like a mesh surface; however, it is a patch graphics object. To create a surface plot similar to `waterfall`, use the `meshz` function and set the `MeshStyle` property of the surface to `'Row'`. For a discussion of parametric surfaces and related color properties, see `surf`.

`axis` | `caxis` | `meshz` | `ribbon` | `surf`

Introduced before R2006a

wavfinfo

Information about WAVE (`.wav`) sound file

Note: `wavfinfo` will be removed in a future release. Use `audioinfo` instead.

Syntax

```
[m d] = wavfinfo(filename)
```

Description

`[m d] = wavfinfo(filename)` returns information about the contents of the WAVE sound file specified by the string *`filename`*. Enclose the *`filename`* input in single quotes.

`m` is the string `'Sound (WAV) file'`, if *`filename`* is a WAVE file. Otherwise, it contains an empty string (`''`).

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If *`filename`* is not a WAVE file, it contains the string `'Not a WAVE file'`.

See Also

`audioplayer` | `audiorecorder` | `audioread` | `audiowrite`

Introduced before R2006a

wavplay

Play recorded sound on PC-based audio output device

Note: `wavplay` has been removed. Use `audioplayer` instead.

Syntax

```
wavplay(y,Fs)
wavplay(y,Fs,mode)
```

Description

`wavplay(y,Fs)` plays the audio signal stored in the vector `y` on a PC-based audio output device. `Fs` is the integer sample rate in Hz (samples per second). The default value for `Fs` is 11025 Hz. `wavplay` supports only 1- or 2-channel (mono or stereo) audio signals. To play in stereo, `y` must be a two-column matrix.

`wavplay(y,Fs,mode)` specifies how `wavplay` interacts with the command line. The string `mode` is one of the following:

- `'sync'` (default): You do not have access to the command line until the sound has finished playing (a blocking device call).
- `'async'`: You have immediate access to the command line as soon as the sound begins to play on the audio output device (a nonblocking device call). If you call `wavplay` again in `async` mode while the audio is playing, `wavplay` blocks access to the command line until the original playback completes.

The audio signal `y` can be one of four data types. The number of bits used to quantize and play back each sample depends on the data type.

Data Types for wavplay

Data Type	Quantization
Double-precision (default value)	16 bits/sample

Data Type	Quantization
Single-precision	16 bits/sample
16-bit signed integer	16 bits/sample
8-bit unsigned integer	8 bits/sample

Examples

The MAT-files `gong.mat` and `chirp.mat` both contain an audio signal `y` and a sampling frequency `Fs`. Load and play the gong and the chirp audio signals. Change the names of these signals in between `load` commands and play them sequentially using the `'sync'` option for `wavplay`.

```
load chirp;
y1 = y; Fs1 = Fs;
load gong;
wavplay(y1,Fs1,'sync') % The chirp signal finishes before the
wavplay(y,Fs)          % gong signal begins playing.
```

More About

Tips

The `wavplay` function is for use only with 32-bit Microsoft Windows operating systems. To play audio data on other platforms, use `audioplayer`.

See Also

`audioplayer` | `audioinfo` | `audioread` | `audiowrite`

Introduced before R2006a

wavread

Read WAVE (`.wav`) sound file

Note: `wavread` will be removed in a future release. Use `audioread` instead.

Syntax

```
y = wavread(filename)
[y, Fs] = wavread(filename)
[y, Fs, nbits] = wavread(filename)
[y, Fs, nbits, opts] = wavread(filename)
[ ___ ] = wavread(filename, N)
[ ___ ] = wavread(filename, [N1 N2])
[ ___ ] = wavread( ___ , fmt)
siz = wavread(filename,'size')
```

Description

`y = wavread(filename)` loads a WAVE file specified by the string *`filename`*, returning the sampled data in *`y`*. If *`filename`* does not include an extension, `wavread` appends `.wav`.

`[y, Fs] = wavread(filename)` returns the sample rate (*`Fs`*) in Hertz used to encode the data in the file.

`[y, Fs, nbits] = wavread(filename)` returns the number of bits per sample (*`nbits`*).

`[y, Fs, nbits, opts] = wavread(filename)` returns a structure *`opts`* of additional information contained in the WAV file. The content of this structure differs from file to file. Typical structure fields include *`opts`*`.fmt` (audio format information) and *`opts`*`.info` (text that describes the title, author, etc.).

`[ ___ ] = wavread(filename, N)` returns only the first *`N`* samples from each channel in the file.

`[ ___ ] = wavread(filename, [N1 N2])` returns only samples *N1* through *N2* from each channel in the file.

`[ ___ ] = wavread( ___ , fmt)` specifies the data format of *y* used to represent samples read from the file. *fmt* can be either of the following values, or a partial match (case-insensitive):

`'double'`	Double-precision normalized samples (default).
`'native'`	Samples in the native data type found in the file.

siz `= wavread(`*filename*`,'size')` returns the size of the audio data contained in *filename* instead of the actual audio data, returning the vector *siz* `= [`*samples channels*`]`.

Output Scaling

The range of values in *y* depends on the data format *fmt* specified. Some examples of output scaling based on typical bit-widths found in a WAV file are given below for both `'double'` and `'native'` formats.

Native Formats

Number of Bits	MATLAB Data Type	Data Range
8	`uint8` (unsigned integer)	0 <= *y* <= 255
16	`int16` (signed integer)	-32768 <= *y* <= +32767
24	`int32` (signed integer)	-2^23 <= *y* <= 2^23-1
32	`single` (floating point)	-1.0 <= *y* < +1.0

Double Formats

Number of Bits	MATLAB Data Type	Data Range
N<32	`double`	-1.0 <= *y* < +1.0
N=32	`double`	-1.0 <= *y* <= +1.0 Note: Values in *y* might exceed -1.0 or +1.0 for the case of N=32 bit data samples stored in the WAV file.

`wavread` supports multi-channel data, with up to 32 bits per sample.

`wavread` supports Pulse-code Modulation (PCM) data format only.

Examples

Create a WAV file from the example file `handel.mat`, and read portions of the file back into MATLAB.

```
% Create WAV file in current folder.
load handel.mat

hfile = 'handel.wav';
wavwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits, readinfo] = wavread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = wavread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = wavread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = wavread(hfile, [startpos endpos]);
sound(y3, Fs);
```

`mmfileinfo` | `audioinfo` | `audiowrite` | `audioread` | `audioplayer` | `audiorecorder` | `sound`

Introduced before R2006a

wavrecord

Record sound using PC-based audio input device

Note: `wavrecord` has been removed. Use `audiorecorder` instead.

Syntax

```
y = wavrecord(n,Fs)
y = wavrecord(___,ch)
y = wavrecord(___,'dtype')
```

Description

`y = wavrecord(n,Fs)` records `n` samples of an audio signal, sampled at a rate of `Fs` Hz (samples per second). The default value for `Fs` is 11025 Hz.

`y = wavrecord(___,ch)` uses `ch` number of input channels from the audio device. `ch` can be either 1 or 2, for mono or stereo, respectively. The default value for `ch` is 1.

`y = wavrecord(___,'dtype')` uses the data type specified by the string `'dtype'` to record the sound. The following table lists the string values for `'dtype'` along with the corresponding bits per sample and acceptable data range for `y`.

dtype	Bits/sample	y Data Range
`'double'`	16	–1.0 <= y < +1.0
`'single'`	16	–1.0 <= y < +1.0
`'int16'`	16	–32768 <= y <= +32767
`'uint8'`	8	0 <= y <= 255

Examples

Record 5 seconds of 16-bit audio sampled at 11025 Hz. Play back the recorded sound using `wavplay`. Speak into your audio device (or produce your audio signal) while the `wavrecord` command runs.

```
Fs = 11025;
y = wavrecord(5*Fs,Fs,'int16');
wavplay(y,Fs);
```

More About

Tips

Standard sampling rates for PC-based audio hardware are 8000, 11025, 22050, and 44100 samples per second. Stereo signals are returned as two-column matrices. The first column of a stereo audio matrix corresponds to the left input channel, while the second column corresponds to the right input channel.

The `wavrecord` function is for use only with 32-bit Microsoft Windows operating systems. To record audio data from audio input devices on other platforms, use `audiorecorder`.

See Also

`audiorecorder` | `audioinfo` | `audioread` | `audiowrite`

Introduced before R2006a

wavwrite

Write WAVE (`.wav`) sound file

Note: `wavwrite` will be removed in a future release. Use `audiowrite` instead.

Syntax

```
wavwrite(y,filename)
wavwrite(y,Fs,filename)
wavwrite(y,Fs,N,filename)
```

Description

`wavwrite(y,filename)` writes the data stored in the variable *y* to a WAVE file called *filename*. The *filename* input is a string enclosed in single quotes. The data has a sample rate of 8000 Hz and is assumed to be 16-bit. Each column of the data represents a separate channel. Therefore, stereo data should be specified as a matrix with two columns.

`wavwrite(y,Fs,filename)` writes the data stored in the variable *y* to a WAVE file called *filename*. The data has a sample rate of *Fs* Hz and is assumed to be 16-bit.

`wavwrite(y,Fs,N,filename)` writes the data stored in the variable *y* to a WAVE file called *filename*. The data has a sample rate of *Fs* Hz and is *N*-bit, where *N* is 8, 16, 24, or 32.

Input Data Ranges

The range of values in *y* depends on the number of bits specified by *N* and the data type of *y*. The following tables list the valid input ranges based on the value of *N* and the data type of *y*.

If *y* contains integer data:

N Bits	y Data Type	y Data Range	Output Format
8	`uint8`	0 <= *y* <= 255	`uint8`
16	`int16`	–32768 <= *y* <= +32767	`int16`
24	`int32`	–2^23 <= *y* <= 2^23 – 1	`int32`

If `y` contains floating-point data:

N Bits	y Data Type	y Data Range	Output Format
8	`single` or `double`	–1.0 <= *y* < +1.0	`uint8`
16	`single` or `double`	–1.0 <= *y* < +1.0	`int16`
24	`single` or `double`	–1.0 <= *y* < +1.0	`int32`
32	`single` or `double`	–1.0 <= *y* <= +1.0	`single`

For floating point data where *N* < 32, amplitude values are clipped to the range –1.0 <= *y* < +1.0.

Note 8-, 16-, and 24-bit files are type 1 integer pulse code modulation (PCM). 32-bit files are written as type 3 normalized floating point.

Introduced before R2006a

web

Open Web page or file in browser

Syntax

```
web
web(url)
web(url,opt)
web(url,opt1,...,optN)

stat = web( ___ )
[stat,h] = web( ___ )
[stat,h,url] = web( ___ )
```

Description

`web` opens an empty MATLAB Web browser.

`web(url)` opens the page specified by `url` in the MATLAB Web browser. If multiple browsers are open, the page displays in the one that was most recently used.

`web(url,opt)` opens the page using the specified browser option, such as `'-new'` to create a new browser instance or `'-browser'` to use the system browser.

`web(url,opt1,...,optN)` opens the page using one or more browser options.

`stat = web( ___ )` returns the status of the operation: `0` if successful, `1` or `2` if unsuccessful. You can include any of the input arguments in previous syntaxes.

`[stat,h] = web( ___ )` returns a handle to a MATLAB Web browser that allows you to close it using the command `close(h)`. If you do not specify any inputs to the `web` function, such as `[stat,h] = web`, then the handle corresponds to the most recently used MATLAB Web browser.

`[stat,h,url] = web( ___ )` returns the URL of the current page in the MATLAB Web browser.

Examples

Web Page in MATLAB Web Browser

Open the MathWorks Web site home page.

```
url = 'http://www.mathworks.com';
web(url)
```

Open the page in a new instance of the browser that does not include a toolbar.

```
web(url,'-new','-notoolbar')
```

File in MATLAB Web Browser

View an HTML file that resides on your system.

Create an HTML file by publishing an example program file. Copy the program file to the current folder so that the code can run during the publishing process.

```
program = fullfile(matlabroot,'help','techdoc',...
          'matlab_env','examples','fourier_demo2.m');
copyfile(program);
htmlFile = publish('fourier_demo2.m');
```

View a file by specifying the file name.

```
web(htmlFile)
```

Alternatively, you can use the `file:///` URL scheme, as long as you include the full path. The `publish` function returns the path in the `htmlFile` output.

```
url = ['file:///',htmlFile];
web(url)
```

Web Page in System Browser

Open the MathWorks Web site home page in the system browser.

```
url = 'http://www.mathworks.com';
web(url,'-browser')
```

Email from System Browser

Send email from your system browser's default mail application using the `mailto:` URL scheme.

To run this example, replace the value for `email` with a valid email address.

```
email = 'myaddress@provider.ext';
url = ['mailto:',email];
web(url)
```

Handle to MATLAB Web Browser

Open the MathWorks Web site home page, and then close the browser using its handle.

```
url = 'http://www.mathworks.com';
[stat,h] = web(url);
```

Close the browser window.

```
close(h)
```

Text Displayed in MATLAB Web Browser

View formatted text using the `text://` URL scheme.

```
web('text://<html><h1>Hello World</h1></html>')
```

Input Arguments

`url` — Web page address or file location

string

Web page address or file location, specified as a string. File locations can include an absolute or relative path.

If `url` corresponds to a file in the installed product documentation, then the page displays in the MATLAB Help browser instead of the Web browser.

Example: `'http:\\www.mathworks.com'`

Example: `'myfolder/myfile.html'`

`opt` — Browser option

`'-browser' | '-new' | '-noaddressbox' | '-notoolbar'`

Browser option, specified as one of the following strings. Options can appear in any order.

`'-browser'`	Opens the page in a system browser window instead of the MATLAB Web browser. On Microsoft Windows and Apple Macintosh platforms, the operating system determines the system Web browser. On other systems, the default is the Mozilla® Firefox® browser, but you can change the default using MATLAB Web preferences.
`'-new'`	Opens the page in a new MATLAB Web browser window. Does not apply to the system browser.
`'-noaddressbox'`	Opens the page in a browser that does not display the address box. Only applies to new instances of the MATLAB Web browser.
`'-notoolbar'`	Opens the page in a browser that does not display a toolbar or address box. Only applies to new instances of the MATLAB Web browser.

Example: `'-new','-noaddressbox'`

Output Arguments

`stat` — Browser status

`0 | 1 | 2`

Browser status, returned as an integer with one of these values:

`0`	Found and launched system browser.
`1`	Could not find system browser.
`2`	Found, but could not launch system browser.

`h` — Handle to most recent MATLAB Web browser

scalar

Handle to the most recent MATLAB Web browser, returned as a scalar instance of the associated Java class.

If you do not request the handle when you open the page, be aware that this handle might not correspond to your most recent use of the `web` function. Other MATLAB functionality also uses the `web` function, such as links to external sites from the Help browser.

`url` — Current page address

string

Current page address in the most recent MATLAB Web browser, returned as a string.

More About

Tips

- If you plan to deploy an application that calls the `web` function using the MATLAB Compiler product, then use the `'-browser'` option.
- If you are displaying Japanese streaming text in the MATLAB Web browser, specify a header that includes the `charset` attribute. For example:

```
web(['text://<html><head><meta http-equiv="content-type" ' ...
     'content="text/html;charset=utf-8"></head><body>TEXT</body></html>'])
```

- "Web Browsers and MATLAB"
- "Specify Proxy Server Settings for Connecting to the Internet"
- "Specify the System Browser for Linux Platforms"

`urlread` | `urlwrite`

Introduced before R2006a

weboptions

Specify parameters for RESTful web service

Syntax

```
options = weboptions
options = weboptions(Name,Value)
```

Description

`options = weboptions` creates a default `weboptions` object to specify parameters for a request to a web service. A `weboptions` object can be an optional input argument to the `webread`, `websave`, and `webwrite` functions.

`options = weboptions(Name,Value)` creates a `weboptions` object with the named parameters set to the specified values.

Examples

Default `weboptions` Object

Create a default `weboptions` object and display the default values for its properties.

```
options = weboptions
```

```
options =

  weboptions with properties:

    CharacterEncoding: 'auto'
            UserAgent: 'MATLAB 8.5.0.184244 (R2015a)'
              Timeout: 5
             Username: ''
             Password: ''
              KeyName: ''
             KeyValue: ''
          ContentType: 'auto'
        ContentReader: []
```

```
           MediaType: 'application/x-www-form-urlencoded'
       RequestMethod: 'auto'
```

User Name and Password in `weboptions` Object

Set a user name and password in a `weboptions` object. When given this `weboptions` object, `webread` can provide the user name and password to a web service that requires authentication.

```
options = weboptions('Username','jdoe','Password','mypassword')
```

```
options =

  weboptions with properties:

    CharacterEncoding: 'auto'
            UserAgent: 'MATLAB 8.5.0.184244 (R2015a)'
              Timeout: 5
             Username: 'jdoe'
             Password: '**********'
              KeyName: ''
             KeyValue: ''
          ContentType: 'auto'
        ContentReader: []
            MediaType: 'application/x-www-form-urlencoded'
        RequestMethod: 'auto'
```

The password is obscured when you display the `weboptions` object. However, the object stores the password as plain text. You can retrieve the password from the `weboptions.Password` property.

```
options.Password
```

```
ans =

mypassword
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `weboptions('Timeout',60)` creates a `weboptions` object that sets the timeout connection duration to 60 seconds.

`'CharacterEncoding'` — Character encoding
`'auto'` (default) | string

Character encoding, specified as a string. Common encodings include `'US-ASCII'`, `'UTF-8'`, `'latin1'`, `'Shift_JS'`, and `'ISO-8859-1'`.

`'UserAgent'` — User agent identification
`['MATLAB ' version]` (default) | string

User agent identification, specified as a string indicating the client user agent.

`'Timeout'` — Timeout connection duration
5 (default) | positive numeric scalar

Timeout connection duration in seconds, specified as a positive numeric scalar. Set to `Inf` to disable timeouts.

`'Username'` — User identifier
`''` (default) | string

User identifier, specified as a string for basic HTTP authentication (no encryption).

`'Password'` — User authentication password
`''` (default) | string

User authentication password, specified as a string for basic HTTP authentication (no encryption). If you display a `weboptions` object with the `Password` property set, the value is displayed as a string containing '*'. However, the object stores the value of the `Password` property as plain text.

`'KeyName'` — Name of key
`''` (default) | string

Name of a key, specified as a string. `KeyName` is an additional name to add to the HTTP request header. For example, `KeyName` can be a web service API key name.

Example: `weboptions('KeyName','duration','KeyValue',7)` creates a `weboptions` object that contains a key name, `duration`, defined by a web service.

`'KeyValue'` — Value of key

`''` (default) | string | numeric | logical

Value of a key, specified as a string, numeric, or logical value to add to the HTTP request header. `KeyValue` is the value of a key specified by `KeyName`.

Example: `weboptions('KeyName','duration','KeyValue',7)` creates a `weboptions` object that contains a key value, `7`, paired with a key name, `duration`.

`'ContentType'` — Content type

`'auto'` (default) | string

Content type, specified as a string. You can define the `ContentType` property of a `weboptions` object, and pass the object as an input argument to `webread`. Then `webread` returns data as that type of content. The table lists the valid content types.

`'auto'`	Output type automatically determined based on content type (default).

`'text'`	String for content types:
	
	`text/plain`
	`text/html`
	`text/xml`
	`application/xml`
	`application/javascript`
	`application/x-javascript`
	`application/x-www-form-urlencoded`
	
	If a web service returns a MATLAB file with a `.m` extension, the function returns its content as a string.

`'image'`	Numeric or logical matrix for `image/format` content. If the first output argument is an indexed image, the second output argument is the colormap, and the third output argument is the alpha channel.
`'audio'`	Numeric matrix for `audio/format` content with numeric scalar sampling rate as a second output argument.
`'binary'`	`uint8` column vector for binary content (that is, content not to be treated as type `char`).
`'table'`	Scalar table object for spreadsheet and CSV (`text/csv`) content.

`'json'`	`char`, numeric, logical, structure, or cell array, for `application/json` content.
`'xmldom'`	Java Document Object Model (DOM) node for `text/xml` or `application/xml` content. If not specified, the function returns XML content as a string.
`'raw'`	`char` column vector for `'text'`, `'xmldom'`, and `'json'` content. The function returns any other content type as a `uint8` column vector.

Example: `weboptions('ContentType','text')` creates a `weboptions` object that instructs `webread` to return text, JSON, or XML content as a character vector.

`'ContentReader'` — Content reader

`[ ]` (default) | function handle

Content reader, specified as a function handle. You can create a `weboptions` object with `ContentReader` specified, and pass the object as an input argument to `webread`. Then `webread` downloads data from a web service and reads the data with the function specified by the function handle. `webread` ignores `ContentType` when `ContentReader` is specified.

Example: `weboptions('ContentReader',@readtable)` creates a `weboptions` object that instructs `webread` to use `readtable` to read content as a table.

`'MediaType'` — Media type

`'application/x-www-form-urlencoded'` (default) | string

Media type, specified as a string. See Internet Media Types for a complete list of media types.

Example: `weboptions('MediaType','application/json')` creates a `weboptions` object that instructs `webwrite` to encode string data as JSON to post it to a web service.

`'RequestMethod'` — HTTP request method

`'auto'` (default) | `'get'` | `'post'`

HTTP request method, specified as `'auto'`, `'get'`, or `'post'`. `RequestMethod` can be set to `'get'` to indicate the HTTP GET method, `'post'` to indicate the HTTP POST method, or `'auto'`.

- `webread` and `websave` use the HTTP GET method when the `RequestMethod` property of an input `weboptions` object is set to `'auto'`.

- `webwrite` uses the HTTP POST method when the `RequestMethod` property of an input `weboptions` object is set to `'auto'`.

Example: `weboptions('RequestMethod','post')` creates a `weboptions` object that instructs `webread`, `websave`, or `webwrite` to use the HTTP POST method of a web service.

`webread` | `websave` | `webwrite`

Introduced in R2014b

webread

Read content from RESTful web service

Syntax

```
data = webread(url)
data = webread(url,QueryName,QueryValue)
data = webread( ___ ,options)

[data,colormap,alpha] = webread( ___ )

[data,Fs] = webread( ___ )
```

Description

`data = webread(url)` reads content from the web service specified by `url` and returns the content in `data`.

The web service provides a "RESTful API" on page 1-8916 that returns data in an internet media type format such as JSON, XML, image, or text.

`data = webread(url,QueryName,QueryValue)` appends additional web service query parameters to `url`, as specified by one or more pairs of `Name,Value` arguments.

`data = webread( ___ ,options)` adds other HTTP request options, specified by the `weboptions` object `options`. You can use this syntax with any of the input arguments of the previous syntaxes.

To read content with a function, specify the `ContentReader` property of `options` as a handle to the function. `webread` downloads data from a web service and reads the data with the specified function:

- If you specify a handle to a function that returns multiple output arguments, `webread` returns all output arguments.
- If you specify a handle to a function that returns no output argument (such as `@implay` for video files), `webread` returns no output argument.

`webread` supports HTTP GET and POST methods. To send an HTTP POST request, specify the `RequestMethod` property of `options` as `'post'`. Many web services provide both GET and POST methods to request data.

`[data,colormap,alpha] = webread( ___ )` reads an image from the web service specified by `url` and returns the image in `data`. You can use the previous syntaxes to return the image only. Use this syntax to return the colormap and alpha channels associated with the image.

`[data,Fs] = webread( ___ )` reads audio data from the web service specified by `url` and returns the audio data in `data`. You can use the previous syntaxes to return the audio data only. Use this syntax to return the sample rate of the audio data in hertz.

Examples

Read Image from Website

Read an image of Jupiter from the Hubble Heritage website.

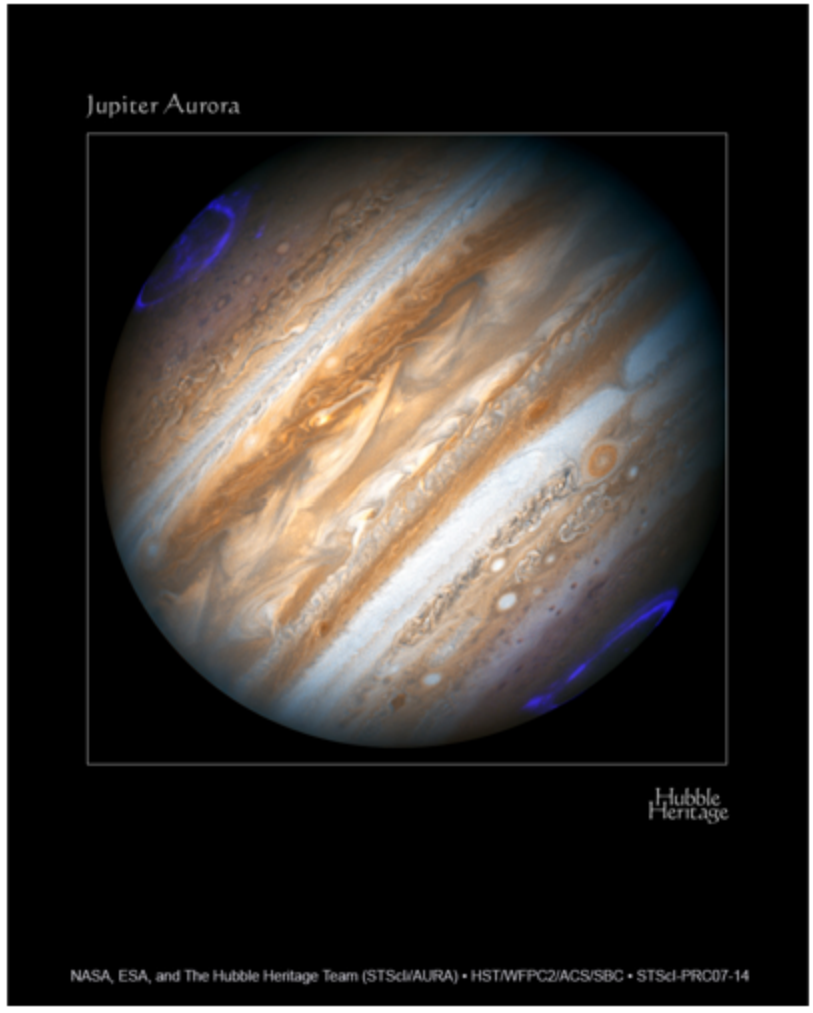
```
url = 'http://heritage.stsci.edu/2007/14/images/p0714aa.jpg';
rgb = webread(url);
whos rgb
```

```
  Name          Size                 Bytes  Class    Attributes

  rgb        1000x800x3            2400000  uint8
```

Resize and display the image.

```
rgb = imresize(rgb,0.6);
imshow(rgb)
```



Jupiter Aurora
Hubble Heritage
NASA, ESA, and The Hubble Heritage Team (STScI/AURA) • HST/WFPC2/ACS/SBC • STScI-PRC07-14

Jupiter image courtesy of NASA, ESA, and the Hubble Heritage Team (STScI/AURA). (See Hubble Heritage Information Center for terms of use.)

Read Data from Web Service API

Read data from the World Bank Climate Data API. This API returns data in JSON format.

```
api = 'http://climatedataapi.worldbank.org/climateweb/rest/v1/';
url = [api 'country/cru/tas/year/USA'];
S = webread(url)
```

```
S =

112x1 struct array with fields:

    year
    data
```

This API returns data as a JSON object. `webread` converts the JSON object to a structure array. Each structure contains the year and the average temperature in the USA for that year, in degrees Celsius.

Display the temperature for the first year.

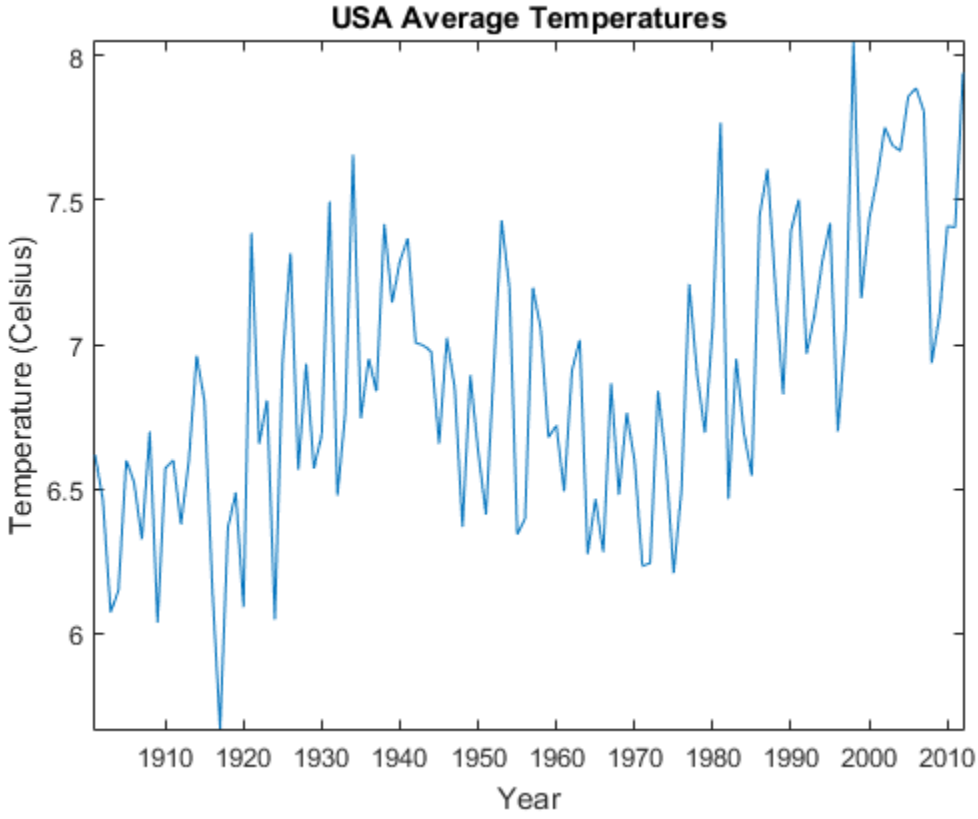
```
S(1)
```

```
ans =

    year: 1901
    data: 6.6187
```

Plot the average temperatures. Concatenate `S.year` and `S.data` into arrays and plot them.

```
year = [S.year];
data = [S.data];
plot(year,data)
xlabel('Year');
ylabel('Temperature (Celsius)');
title('USA Average Temperatures')
axis tight
```



API and data courtesy of the World Bank: Climate Data API. (See World Bank: Climate Data API for more information about the API, and World Bank: Terms of Use for terms of use.)

Specify Web Service Query Parameters

Specify web service query parameters with `webread`. Search the File Exchange for files uploaded within the past 7 days that contain the word *Simulink*. Use `QueryName,QueryValue` pairs to specify the `term` and `duration` query parameters. The File Exchange web service defines the `term` and `duration` query parameters, not the `webread` function. `webread` appends web service query parameters to the URL.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
data = webread(url,'term','simulink','duration',7);
```

`webread` returns the HTML for the search result page as a character array.

Specify Additional Query Parameters

Specify additional web service query parameters with a `weboptions` object. Read data from the World Bank Climate Data API, but do not convert the JSON object to a structure array. Create a `weboptions` object and set its `ContentType` to `'text'`. The `webread` function converts the JSON object to a character array. Display the beginning of the character array.

```
api = 'http://climatedataapi.worldbank.org/climateweb/rest/v1/';
url = [api 'country/cru/tas/year/USA'];
options = weboptions('ContentType','text');
data = webread(url,options);
data(1:62)
```

```
ans =

[{"year":1901,"data":6.6187487},{"year":1902,"data":6.4643273}
```

API and data courtesy of the World Bank: Climate Data API. (See World Bank: Climate Data API for more information about the API, and World Bank: Terms of Use for terms of use.)

Read Data with POST Request

Send an HTTP POST request to search File Exchange for files uploaded within the past 7 days that contain the word *Simulink*.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
options = weboptions('RequestMethod','post');
data = webread(url,'term','simulink','duration',7,options);
```

Many web services provide a POST method for requesting data in addition to GET.

- “Download Data from Web Service”
- “Convert Data from Web Service”

Input Arguments

`url` — URL to web service

string

URL to a web service, specified as a string. The web service implements a RESTful interface. See “RESTful API” on page 1-8916 for more information.

Example: `webread('http://www.mathworks.com/matlabcentral')` reads the web page and returns its HTML as a string.

`QueryName,QueryValue` — Web service query parameters

`Name,Value` pairs

Web service query parameters, specified as pairs of `Name,Value` arguments. `QueryName` must be a string that specifies the name of a query parameter. `QueryValue` must be a string, numeric, or logical value that specifies the value of the query parameter. Numeric and logical values can be in arrays. The web service defines these `Name,Value` pairs.

Example: `webread('http://www.mathworks.com/matlabcentral/fileexchange/','term','webread','duration',7)` retrieves a list of files uploaded to the File Exchange within the past 7 days that contain the word `webread`. The File Exchange web service defines the `term` and `duration` query parameters.

`options` — Additional HTTP request options

`weboptions` object

Additional HTTP request options, specified as a `weboptions` object. See `weboptions` for all request options that are `weboptions` properties.

Output Arguments

`data` — Content from web service

scalar | array | structure | table

Content read from a web service, returned as a scalar, array, structure, or table.

You can define the `ContentType` property of a `weboptions` object, and pass the object as an input argument to `webread`. Then `webread` returns `data` as that type of content. The table lists the valid content types you can specify in a `weboptions` object.

`'auto'`	Output type automatically determined based on content type (default).
`'text'`	String for content types:

	`text/plain`
	`text/html`
	`text/xml`
	`application/xml`
		`application/javascript`
		`application/x-javascript`
		`application/x-www-form-urlencoded`

If a web service returns a MATLAB file with a `.m` extension, the function returns its content as a string.

`'image'`	Numeric or logical matrix for `image/format` content. If the first output argument is an indexed image, the second output argument is the colormap, and the third output argument is the alpha channel.
`'audio'`	Numeric matrix for `audio/format` content with numeric scalar sampling rate as a second output argument.
`'binary'`	`uint8` column vector for binary content (that is, content not to be treated as type `char`).
`'table'`	Scalar table object for spreadsheet and CSV (`text/csv`) content.
`'json'`	`char`, numeric, logical, structure, or cell array, for `application/json` content.
`'xmldom'`	Java Document Object Model (DOM) node for `text/xml` or `application/xml` content. If not specified, the function returns XML content as a string.
`'raw'`	`char` column vector for `'text'`, `'xmldom'`, and `'json'` content. The function returns any other content type as a `uint8` column vector.

`colormap` — Colormap associated with indexed image

numeric array

Colormap associated with an indexed image, returned as a numeric array.

`alpha` — Alpha channels associated with indexed image

numeric array

Alpha channels associated with an indexed image, returned as a numeric array.

`Fs` — Sample rate of audio data in hertz

positive numeric scalar

Sample rate of audio data in hertz, returned as a positive numeric scalar.

More About

RESTful API

REST means *representational state transfer*, a common architectural style for web services. RESTful APIs or interfaces provide standard HTTP methods such as GET, PUT, POST, or DELETE.

Tips

- This function supports only nonauthenticated and basic authentication types for use with your proxy server. To enable proxy support, run MATLAB with the Java JVM. To specify proxy server settings, see "Specify Proxy Server Settings for Connecting to the Internet".
- For HTTPS connections, this function verifies that the certificate domain matches the host name of the web service. This function does not verify the certificate chain.
- For HTTP POST requests, this function supports only the `application/x-www-form-urlencoded` media type. To send a POST request with content of any other internet media type, use `webwrite`.

Algorithms

JSON supports fewer data types than MATLAB. `webread` converts JSON data types to the MATLAB data types shown in the table.

JSON Data Type	MATLAB Data Type
Number	`double`
String	`char` array
Boolean	`logical`
Array, when all elements are of the same data type	Array
Array, when elements are of different data types	Cell array
Object. (In JSON, *object* means an unordered set of name-value pairs.)	Scalar structure
Array of objects, when all objects have the same set of field names	Structure array

JSON Data Type	MATLAB Data Type
Array of objects, when objects have different field names	Cell array of scalar structures

`webread` converts JSON object field names to MATLAB structure field names.

- Representational State Transfer
- JavaScript Object Notation (JSON)

`weboptions` | `websave` | `webwrite`

Introduced in R2014b

websave

Save content from RESTful web service to file

Syntax

```
outfilename = websave(filename,url)
outfilename = websave(filename,url,QueryName,QueryValue)
outfilename = websave( ___ ,options)
```

Description

`outfilename = websave(filename,url)` saves content from the web service specified by `url` to the file, `filename`. The full path to `filename` is returned as `outfilename`.

The web service provides a "RESTful API" on page 1-8921 that returns data in an internet media type format such as JSON, XML, image, or text.

`outfilename = websave(filename,url,QueryName,QueryValue)` appends additional web service query parameters to `url`, as specified by one or more pairs of `Name,Value` arguments.

`outfilename = websave( ___ ,options)` adds other HTTP request options, specified by the `weboptions` object `options`. You can use this syntax with any of the input arguments of the previous syntaxes.

`websave` supports HTTP GET and POST methods. To send an HTTP POST request, specify the `RequestMethod` property of `options` as `'post'`. Many web services provide both GET and POST methods to request data.

Examples

Save Image from Website

Save an image of Jupiter from the Hubble Heritage website.

```
url = 'http://heritage.stsci.edu/2007/14/images/p0714aa.jpg';
filename = 'jupiter_aurora.jpg';
outfilename = websave(filename,url)

outfilename =

C:\Libraries\Documents\jupiter_aurora.jpg
```

`websave` saves the image as a JPEG file, as specified by the Hubble web service, even when you give `filename` a different extension. (Jupiter image courtesy of NASA, ESA, and the Hubble Heritage Team (STScI/AURA). See Hubble Heritage Information Center for terms of use.)

Save Search Results to File

Save the results of a search of the File Exchange to an HTML file. Search File Exchange for files uploaded within the past 7 days that contain the word *Simulink*.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
filename = 'simulink_search.html';
outfilename = websave(filename,url,'term','simulink','duration',7)

outfilename =

C:\Libraries\Documents\simulink_search.html
```

The File Exchange web service defines the `term` and `duration` query parameters, not `websave`.

Display the HTML file in a web browser.

```
web(outfilename)
```

Save Data to File

Save sunspot data from the National Geophysical Data Center (NGDC) to an ASCII file. Use a `weboptions` object to set the timeout value to `Inf` so that the connection does not time out.

```
api = 'http://www.ngdc.noaa.gov/stp/space-weather/';
url = [api 'solar-data/solar-indices/sunspot-numbers/' ...
       'american/lists/list_aavso-arssn_yearly.txt'];
filename = 'sunspots_annual.txt';
options = weboptions('Timeout',Inf);
```

```
outfilename = websave(filename,url,options)

outfilename =

C:\Libraries\Documents\sunspots_annual.txt
```

Aggregated data and web service courtesy of the NGDC. Sunspot data courtesy of the American Association of Variable Star Observers (AAVSO), originally published in AAVSO Sunspot Counts: 1943-2013, AAVSO Solar Section (R. Howe, Chair). (See NGDC Privacy Policy, Disclaimer, and Copyright for NGDC terms of use, and AAVSO Solar Section for AAVSO terms of use.)

Save Data with POST Request

Send an HTTP POST request to search File Exchange for files uploaded within the past 7 days that contain the word *Simulink*. Save the results of the search to an HTML file.

```
url = 'http://www.mathworks.com/matlabcentral/fileexchange/';
filename = 'simulink_search.html';
options = weboptions('RequestMethod','post');
outfilename = websave(filename,url,'term','simulink','duration',7,options);
```

Many web services provide a POST method for requesting data in addition to GET.

Input Arguments

`filename` — Name of file to save content to

string

Name of file to save content to, specified as a string. `websave` saves the content as is. `websave` ignores `options.ContentType` and `options.ContentReader` even if these properties are set.

Example: `websave('matlabcentral.html','http://www.mathworks.com/matlabcentral')` reads the web page and saves its HTML to the file `matlabcentral.html`.

`url` — URL to web service

string

URL to a web service, specified as a string. The web service implements a RESTful interface. See “RESTful API” on page 1-8921 for more information.

`QueryName,QueryValue` — Web service query parameters

`Name,Value` pairs

Web service query parameters, specified as pairs of `Name,Value` arguments. `QueryName` must be a string that specifies the name of a query parameter. `QueryValue` must be a string, numeric, or logical value that specifies the value of the query parameter. Numeric and logical values can be in arrays. The web service defines these `Name,Value` pairs.

Example: `websave('webread_search.html','http://www.mathworks.com/matlabcentral/fileexchange/','term','simulink','duration',7)` retrieves a list of files uploaded to the File Exchange within the past 7 days that contain the word *`simulink`* and saves the HTML to file.

`options` — Additional HTTP request options

`weboptions` object

Additional HTTP request options, specified as a `weboptions` object. See `weboptions` for all request options that are `weboptions` properties.

More About

RESTful API

REST means *representational state transfer*, a common architectural style for web services. RESTful APIs or interfaces provide standard HTTP methods such as GET, PUT, POST, or DELETE.

Tips

- This function supports only nonauthenticated and basic authentication types for use with your proxy server. To enable proxy support, run MATLAB with the Java JVM. To specify proxy server settings, see “Specify Proxy Server Settings for Connecting to the Internet”.
- For HTTPS connections, this function verifies that the certificate domain matches the host name of the web service. This function does not verify the certificate chain.
- For HTTP POST requests, this function supports only the `application/x-www-form-urlencoded` media type. To send a POST request with content of any other internet media type, use `webwrite`.
- Representational State Transfer

- JavaScript Object Notation (JSON)

See Also

`weboptions` | `webread` | `webwrite`

Introduced in R2014b

webwrite

Write data to RESTful web service

Syntax

```
response = webwrite(url,PostName,PostValue)
response = webwrite(url,data)
response = webwrite( ___ ,options)
```

Description

`response = webwrite(url,PostName,PostValue)` writes content to the web service specified by `url` and returns the response in `response`. The input arguments `PostName,PostValue` specify the content as one or more pairs of `Name,Value` arguments. `webwrite` form-encodes `PostName,PostValue` in the body of an HTTP POST request to the web service. The web service defines `response`.

The web service provides a "RESTful API" on page 1-8927 that returns data in an internet media type format such as JSON, XML, image, or text.

`response = webwrite(url,data)` writes content to the web service specified by `url` and returns the response in `response`. The input argument `data` specifies the content as a form-encoded string. `webwrite` puts `data` in the body of an HTTP POST request to the web service. The web service defines `response`.

`response = webwrite( ___ ,options)` adds other HTTP request options, specified by the `weboptions` object `options`. You can use this syntax with any of the input arguments of the previous syntaxes.

To write content as an internet media type other than a form-encoded string (`'application/x-www-form-urlencoded'`), specify the `MediaType` property of `options`.

To request data with an HTTP POST request and read the response with a function, specify the `ContentReader` property of `options` as a handle to the function. If you specify a handle to a function that returns multiple output arguments, `webwrite` returns all output arguments.

Examples

Write Data to Web Service

Write a number to the ThingSpeak server. (To run this code, create a ThingSpeak account. Use the Write API key and Channel ID from your ThingSpeak account. The default field name is `'field1'`.)

```
thingSpeakURL = 'http://api.thingspeak.com/';
thingSpeakWriteURL = [thingSpeakURL 'update'];
writeApiKey = 'Your Write API Key';
fieldName = 'field1';
fieldValue = 42;
response = webwrite(thingSpeakWriteURL,'api_key',writeApiKey,fieldName,fieldValue)
```

`response` is `1` if this call to `webwrite` is the first update to your ThingSpeak channel.

Read back the number you wrote to your channel. ThingSpeak provides a different URL to get the last entry to your channel. Your Channel ID is part of the URL.

```
channelID = num2str(Your Channel ID);
thingSpeakReadURL = [thingSpeakURL 'channels/' channelID '/fields/' fieldName '/last'];
data = webread(thingSpeakReadURL,'api_key',writeApiKey)
```

```
data =

42
```

Write Form-Encoded String

Write a number to the ThingSpeak server. Encode your Write API Key and the number as a form-encoded string. (To run this code, create a ThingSpeak account. Use the Write API key and Channel ID from your ThingSpeak account. The default field name is `'field1'`.)

```
thingSpeakURL = 'http://api.thingspeak.com/';
thingSpeakWriteURL = [thingSpeakURL 'update'];
writeApiKey = 'Your Write API Key';
data = 42;
data = num2str(data);
data = ['api_key=',writeApiKey,'&field1=',data];
response = webwrite(thingSpeakWriteURL,data)
```

`response` is `1` if this call to `webwrite` is the first update to your ThingSpeak channel.

Read back the number you wrote to your channel. ThingSpeak provides a different URL to get the last entry to your channel. Your Channel ID is part of the URL.

```
channelID = num2str(Your Channel ID);
thingSpeakReadURL = [thingSpeakURL 'channels/' channelID '/fields/field1/last'];
data = webread(thingSpeakReadURL,'api_key',writeApiKey)
```

```
data =

42
```

Write JSON Object

Write a number to the ThingSpeak server. Create a structure whose fields are your Write API Key and the number. `webwrite` converts a structure to a JSON object when you use a `weboptions` object to specify the media type as `'application/json'`. (To run this code, create a ThingSpeak account. Use the Write API key and Channel ID from your ThingSpeak account. The default field name is `'field1'`.)

```
thingSpeakURL = 'http://api.thingspeak.com/update.json';
writeApiKey = 'Your Write API Key';
data = 42;
data = struct('api_key',writeApiKey,'field1',data);
options = weboptions('MediaType','application/json');
response = webwrite(thingSpeakURL,data,options)
```

```
response =

    channel_id: Your Channel ID
        field1: 42
        field2: []
        field3: []
        field4: []
        field5: []
        field6: []
        field7: []
        field8: []
    created_at: '2014-11-14T20:08:14Z'
      entry_id: 1
        status: []
      latitude: []
     longitude: []
     elevation: []
      location: []
```

As a response `webwrite` receives a JSON object that contains the number you wrote to your ThingSpeak channel. `webwrite` converts the JSON object and returns it as a structure in `response`.

Input Arguments

`url` — URL to web service

string

URL to a web service, specified as a string. The web service implements a RESTful interface. See "RESTful API" on page 1-8927 for more information.

`PostName,PostValue` — Web service post parameters

`Name,Value` pairs

Web service post parameters, specified as pairs of `Name,Value` arguments. `PostName` must be a string that specifies the name of a post parameter. `PostValue` must be a string, numeric, or logical value that specifies the value of the post parameter. Numeric and logical values can be in arrays. The web service defines these `Name,Value` pairs. `webwrite` encodes the `Name,Value` pairs as a form-encoded string in the body of an HTTP POST request and sets the content type to `application/x-www-form-urlencoded` by default.

Example: `webwrite('http://www.mathworks.com/matlabcentral/fileexchange/','term','webwrite','duration',7)` retrieves a list of files uploaded to the File Exchange within the past 7 days that contain the word `webwrite`. The File Exchange web service defines the `term` and `duration` parameters.

`data` — Data to write to web service

string

Data to write to a web service, specified as a form-encoded string. The web service implements a RESTful interface. `webwrite` puts `data` in the body of an HTTP POST request and sets the media type to `application/x-www-form-urlencoded` by default.

If `data` is not form-encoded, set the `MediaType` property of the `options` input argument to a different media type. See Internet Media Types for a complete list of media types.

Example: `webwrite('http://www.mathworks.com/matlabcentral/fileexchange/','term=webwrite&duration=7')` retrieves a list of files uploaded

to the File Exchange within the past 7 days that contain the word `webwrite`. The File Exchange web service defines the `term` and `duration` parameters.

`options` — Additional HTTP request options

`weboptions` object

Additional HTTP request options, specified as a `weboptions` object. See `weboptions` for all request options that are `weboptions` properties.

Output Arguments

`response` — Response from web service

scalar | array | structure | table

Response from a web service, returned as a scalar, array, structure, or table.

More About

RESTful API

REST means *representational state transfer*, a common architectural style for web services. RESTful APIs or interfaces provide standard HTTP methods such as GET, PUT, POST, or DELETE.

Tips

- `webwrite` writes `PostName,PostValue` input arguments as form-encoded strings. If you also specify the `options` input argument, then its `MediaType` property must be `'application/x-www-form-urlencoded'`.
- This function supports only nonauthenticated and basic authentication types for use with your proxy server. To enable proxy support, run MATLAB with the Java JVM. To specify proxy server settings, see “Specify Proxy Server Settings for Connecting to the Internet”.
- For HTTPS connections, this function verifies that the certificate domain matches the host name of the web service. This function does not verify the certificate chain.

- Representational State Transfer
- JavaScript Object Notation (JSON)

`weboptions` | `webread` | `websave`

Introduced in R2015a

week

Week number

Syntax

```
w = week(t)
w = week(t,weekType)
```

Description

`w = week(t)` returns the week-of-year numbers of the datetime values in `t`. The `m` output is a `double` array the same size as `t` and contains integer values from 1 to 53.

`w = week(t,weekType)` returns the type of week number specified by `weekType`.

Examples

Find Week of Year Numbers of Dates

```
t = datetime(2013,05,31):calmonths(3):datetime(2014,06,15)
```

```
t =

   31-May-2013    31-Aug-2013    30-Nov-2013    28-Feb-2014    31-May-2014
```

```
w = week(t)
```

```
w =

    22    35    48     9    22
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`weekType` — Type of week values

`'weekofyear'` (default) | `'weekofmonth'`

Type of week values, specified as either `'weekofyear'` or `'weekofmonth'`.

- If `weekType` is `'weekofyear'`, then `month` returns the week-of-year number. Week 1 is the week in which January 1 falls, even if fewer than 4 days of that week fall in the same year.
- If `weekType` is `'weekofmonth'`, then `month` returns the week-of-month number. Week 1 in a month is defined as the week in which the first day of the month falls, even if fewer than 4 days of that week fall in the same month.

See Also

`day` | `month` | `quarter` | `year`

Introduced in R2014b

weekday

Day of week

Syntax

```
DayNumber = weekday(D)
[DayNumber,DayName] = weekday(D)
[DayNumber,DayName] = weekday(D,DayForm)
[DayNumber,DayName] = weekday(D,language)
[DayNumber,DayName] = weekday(D,DayForm,language)
```

Description

`DayNumber = weekday(D)` returns a number representing the day of the week for each element in `D`.

`[DayNumber,DayName] = weekday(D)` additionally returns abbreviated English names for the day of the week, in `DayName`.

`[DayNumber,DayName] = weekday(D,DayForm)` returns the name for the day of the week in the format specified by `DayForm`, in US English.

`[DayNumber,DayName] = weekday(D,language)` returns the abbreviated name for the day of the week in the language of the locale specified in `language`.

`[DayNumber,DayName] = weekday(D,DayForm,language)` returns the name for the day of the week in the specified format and in the language of the specified locale. You can specify `DayForm` and `language` in either order.

Examples

Return Day of Week of a Date String

Determine the day of the week of December 21, 2012.

```
D = '21-Dec-2012';
[DayNumber,DayName] = weekday(D)
```

```
DayNumber =

     6

DayName =

Fri
```

December 21, 2012 falls on a Friday.

Return Full Day Names of Multiple Date Numbers

Return the full name of the day of the week for a vector of serial date numbers.

```
D = [734999;735015];
DayForm = 'long';
[DayNumber,DayName] = weekday(D,DayForm)
```

```
DayNumber =

     5
     7

DayName =

Thursday
Saturday
```

Return Full Day Names in Local Language

Return day names in U.S. English using the `language` input argument.

```
D = 728647;
DayForm = 'long';
language = 'en_US';
[DayNumber, DayName] = weekday(D,DayForm,language)
```

```
DayNumber =

     2

DayName =
```

```
Monday
```

In U.S. English, the name of the day of the week is `Monday`.

Return day names in the language of the current locale.

```
language = 'local';
[DayNumber, DayName] = weekday(D,DayForm,language)
```

```
DayNumber =

     2

DayName =

Lundi
```

In a French locale, the name of the day of the week is `Lundi`.

Return Day of Week of a Date String in Custom Format

Determine the day of the week for a date specified in the format `mmm.dd.yyyy`. Call `datenum` inside of `weekday` to specify the format of the input date string.

```
[DayNumber,DayName] = weekday(datenum('Dec.21.2012','mmmm.dd.yyyy'))
```

```
DayNumber =

     6

DayName =

Fri
```

Input Arguments

`D` — Serial date numbers or date strings

vector | matrix | string | cell array of strings | character array

Serial date numbers or date strings. Date numbers can be specified as a vector or matrix. Date strings can be specified as a single string, a cell array of strings, or a character array. If `D` is a cell array of strings, it must be 1-by-`n` or `n`-by-1.

If D is a single date string, a cell array of date strings, or a character array of date strings, the date strings can be in one of the following formats.

Date String Format	Example
dd-mmm-yyyy	01-Mar-2000
mm/dd/yyyy	03/01/2000
yyyy-mm-dd	2000-03-01

For date strings in other formats, first convert them to serial date numbers using the datenum function, before passing them to weekday.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | cell

DayForm — Format of output day names

'short' (default) | 'long'

Format of the output day names, specified as one of the following strings.

DayForm	Format of DayName Names	Example
'short'	Abbreviated name	Mon
'long'	Full name	Monday

language — Output language of day names

'en_US' (default) | 'local'

Output language of day names in DayName, specified as one of the following strings.

language	Description
'en_US'	US English
'local'	Language of the current locale

Output Arguments

DayNumber — Value representing day of week

array of integers in the range [1,7]

Value representing the day of the week, returned as an array of integers in the range `[1,7]`, where `1` represents Sunday, and `7` represents Saturday.

- If input `D` is a numeric array, then the size of `DayNumber` is equivalent to the size of `D`.
- If input `D` is a cell array of strings, then `DayNumber` is an `m`-by-1 vector, where `m` is equivalent to the length of `D`.

`DayName` — Name of day of week

character array

Name of the day of the week, returned as a character array. The content of `DayName` depends on `DayForm`.

- If `DayForm` is `'short'`, then `DayName` contains an abbreviated name (for example, `Tues`).
- If `DayForm` is `'long'`, then `DayName` contains the full name of the weekday (for example, `Tuesday`).

`DayName` is `m`-by-`n`, where `m` is the number of serial date numbers or date strings in `D`.

See Also

`datenum` | `datevec` | `eomday`

Introduced before R2006a

what

List MATLAB files in folder

Syntax

```
what
what folderName
what className
what packageName
s = what('folderName')
```

Description

`what` lists the path for the current folder, and lists all files and folders relevant to MATLAB found in the current folder. Files listed are M, MAT, MEX, MDL, SLX, and P-files. Folders listed are all class and package folders.

`what folderName` lists path, file, and folder information for *`folderName`*.

`what className` lists path, file, and folder information for method folder `@`*`className`*. For example, `what cfit` lists the MATLAB files and folders in `toolbox/curvefit/curvefit/@cfit`.

`what packageName` lists path, file, and folder information for package folder `+`*`packageName`*. For example, `what commsrc` lists the MATLAB files and folders in `toolbox/comm/comm/+commsrc`.

`s = what('folderName')` returns the results in a structure array with the fields shown in the following table.

Field	Description
`path`	Path to folder
`m`	Cell array of MATLAB program file names
`mat`	Cell array of MAT-file names

Field	Description
`mex`	Cell array of MEX-file names
`mdl`	Cell array of MDL-file names
`slx`	Cell array of SLX-file names
`p`	Cell array of P-file names
`classes`	Cell array of class folders
`packages`	Cell array of package folders

Examples

List the MATLAB files and folders in `C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo`, where *`Rnnnn`* represents the folder for the MATLAB release, for example, R2012b:

```
what audiovideo

MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo

FileFormatInfo

Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo

internal  writer

MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

Contents            aufinfo             mmcompinfo          wavplay
audiodevinfo        auread              mmfileinfo          wavread
audioinfo           auwrite             movie2avi           wavrecord
audioplayerreg      avgate              mu2lin              wavwrite
audioread           avifinfo            prefspanel
audiorecorderreg    aviinfo             sound
audiouniquename     aviread             soundsc
audiowrite          lin2mu              wavfinfo

MAT-files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

chirp         handel          splat
gong          laughter        train

Classes in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

VideoReader    audioplayer    avifile
VideoWriter    audiorecorder  mmreader

Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

audiovideo
```

Obtain a structure array containing the file and folder names in `toolbox/matlab/codetools` that are relevant to MATLAB, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012a:

```
s = what('codetools')

s =

        path: 'C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\codetools'
           m: {77x1 cell}
         mat: {0x1 cell}
         mex: {0x1 cell}
         mdl: {0x1 cell}
         slx: {0x1 cell}
           p: {0x1 cell}
     classes: {2x1 cell}
    packages: {3x1 cell}
```

Find the supporting files for one of the packages in the Communications System Toolbox™ product:

```
p1 = what('comm');
p1.packages
ans =

    'gpu'
    'internal'

ans =

    'internal'.
.
.
p2 = what('commsrc');
p2.m
ans =
    'abstractJitter.m'
    'abstractPulse.m'
    'combinedjitter.m'
    'diracjitter.m'
    'periodicjitter.m'
    'randomjitter.m'
```

See Also

`dir` | `exist` | `lookfor` | `ls` | `which` | `who`

Introduced before R2006a

whatsnew

Release Notes

Note: `whatsnew` will be removed in a future release.

Syntax

```
whatsnew
```

Description

`whatsnew` displays the MATLAB Release Notes in the Help browser, presenting information about new features, problems from previous releases that have been fixed in the current release, and compatibility issues.

See Also

`help` | `version`

Introduced before R2006a

which

Locate functions and files

Syntax

```
which item
which fun1 in fun2

which ___ -all

str = which(item)
str = which(fun1,'in',fun2)

str = which( ___ ,'-all')
```

Description

`which item` displays the full path for `item`.

- If `item` is a MATLAB function in an M or P file, or a Simulink model in an SLX or MDL file, then `which` displays the full path for the corresponding file. `item` must be on the MATLAB path.
- If `item` is a method in a loaded Java class, then `which` displays the package, class, and method name for that method.
- If `item` is a workspace variable, then `which` displays a message identifying `item` as a variable.
- If `item` is a file name including the extension, and it is in the current working folder or on the MATLAB path. then `which` displays the full path of `item`.

If `item` is an overloaded function or method, then `which item` returns only the path of the first function or method found.

`which fun1 in fun2` displays the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`which ___ -all` displays the paths to all items on the MATLAB path with the requested name. Such items include methods of instantiated classes. You can use `-all` with the input arguments of any of the previous syntaxes.

`str = which(item)` returns the full path for `item` in the string, `str`.

`str = which(fun1,'in',fun2)` returns the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`str = which(___,'-all')` returns the results of `which` in the string or cell array of strings, `str`. You can use this syntax with any of the input arguments in the previous syntax group.

Examples

Locate MATLAB Function

Locate the `pinv` function.

```
which pinv
```

```
matlabroot\toolbox\matlab\matfun\pinv.m
```

`pinv` is in the `matfun` folder of MATLAB.

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('pinv');
```

Locate Method in a Loaded Java Class

Create an instance of the Java class. This loads the class into MATLAB.

```
myDate = java.util.Date;
```

Locate the `setMonth` method.

```
which setMonth
```

```
setMonth is a Java method  % java.util.Date method
```

Locate Private Function

Find the `orthog` function in a private folder.

```
which private/orthog
```

```
matlabroot\toolbox\matlab\elmat\private\orthog.m  % Private to elmat
```

MATLAB displays the path for `orthog.m` in the `/private` subfolder of `toolbox/matlab/elmat`.

Determine if Local Function is Called

Determine which `parseargs` function is called by `area.m`.

```
which parseargs in area
```

```
matlabroot\toolbox\matlab\specgraph\area.m (parseargs)  % Subfunction of area
```

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('parseargs','in','area');
```

Locate Function Invoked with Given Input Arguments

Suppose you have a `matlab.io.MatFile` object that corresponds to the example MAT-file `'topography.mat'`:

```
matObj = matfile('topography.mat');
```

Display the path of the implementation of `who` that is invoked when called with the input argument `(matObj)`.

```
which who(matObj)
```

```
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m  % matlab.io.MatFile method
```

Store the result to a string.

```
str = which('who(matObj)')
```

```
str =
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
```

If you do not specify the input argument `(matObj)`, then `which` returns only the path of the first function or method found.

```
which who
```

```
built-in (matlabroot\\toolbox\matlab\general\who)
```

Locate All Items with Given Name

Display the paths to all items on the MATLAB path with the name `fopen`.

```
which fopen -all
```

```
built-in (matlabroot\toolbox\matlab\iofun\fopen)
matlabroot\toolbox\matlab\iofun\@serial\fopen.m            % serial method
matlabroot\toolbox\shared\instrument\@icinterface\fopen.m  % icinterface method
matlabroot\toolbox\instrument\instrument\@i2c\fopen.m      % i2c method
```

Return Path Names as Strings

Return the results of `which` in the string `str`.

You must use the function form of `which`, enclosing all arguments in parentheses and single quotes.

```
str = which('private/stradd','-all');
whos str
```

```
  Name      Size            Bytes  Class    Attributes

  str       2x1               650  cell
```

Input Arguments

`item` — Function or file to locate

string

Function or file to locate, specified as a string. When using the function form of `which`, enclose all input strings in single quotes. `item` can be in one of the following forms.

Form of the `item` Input	Path to Display
`fun`	Display full path for `fun`, which can be a MATLAB function, Simulink model, workspace variable, method

Form of the `item` Input	Path to Display
	in a loaded Java class, or file name that includes the file extension. To display the path for a file that has no file extension, type `which file.` (The period following the filename is required). Use `exist` to check for the existence of files anywhere else.
`private/fun`	Limit the search to private functions named `fun`. For example, `which private/orthog` or `which('private/orthog')` displays the path for `orthog.m` in the `/private` subfolder of the parent folder.
`fun(a1,...,an)`	Display the path to the implementation of function `fun` which would be invoked if called with the input arguments `a1,...,an`. Use this syntax to query overloaded functions. See the Example, "Locate Function Invoked with Given Input Arguments" on page 1-8943.

`fun1` — Function to locate

string

Function to locate, specified as a string. `fun1` can be the name of a function, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see "Locate Function Invoked with Given Input Arguments" on page 1-8943.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

`fun2` — Calling file

string

Calling file, specified as a string. `fun2` can be the name of a file, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see "Locate Function Invoked with Given Input Arguments" on page 1-8943.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

Output Arguments

`str` — Function or file location

string | cell array of strings

Function or file location, returned as a string, or returned as a cell array of strings if you use `'-all'`.

- If `item` is a workspace variable, then `str` is the string `'variable'`.
- If `str` is a cell array of strings, then each row of `str` identifies a function. The functions are in order of precedence, unless they are shadowed. Among shadowed functions, you should not rely on the order of the functions in `str`. To determine if a function is shadowed, call `which` using command syntax. For example, `which test -all` displays the paths to all functions with the name `test`. Shadowed functions are indicated by the comment, `% Shadowed`.

Limitations

- When the class is not loaded, `which` only finds methods if they are defined in separate files in an @-folder and are not in any packages.

More About

Tips

- For more information about how MATLAB uses scope and precedence when calling a function, see “Function Precedence Order”.

Introduced before R2006a

while

Repeat execution of statements while condition is true

Syntax

```
while expression
    statements
end
```

Description

`while` *`expression`*`,` *`statements`*`, end` evaluates an expression, and repeats the execution of a group of statements in a loop while the expression is true. An expression is true when its result is nonempty and contains only nonzero elements (logical or real numeric). Otherwise, the expression is false.

Examples

Repeat Statements Until Expression Is False

Use a `while` loop to calculate `factorial(10)`.

```
n = 10;
f = n;
while n > 1
    n = n-1;
    f = f*n;
end
disp(['n! = ' num2str(f)])
```

```
n! = 3628800
```

Skip to Next Loop Iteration

Count the number of lines of code in the file `magic.m`. Skip blank lines and comments using a `continue` statement. `continue` skips the remaining instructions in the `while` loop and begins the next iteration.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) || strncmp(line,'%',1) || ~ischar(line)
        continue
    end
    count = count + 1;
end
count
fclose(fid);
```

```
count =

    31
```

Exit Loop Before Expression Is False

Sum a sequence of random numbers until the next random number is greater than an upper limit. Then, exit the loop using a `break` statement.

```
limit = 0.8;
s = 0;

while 1
    tmp = rand;
    if tmp > limit
        break
    end
    s = s + tmp;
end
```

More About

Expression

An expression can include relational operators (such as < or ==) and logical operators (such as &&, ||, or ~). Use the logical operators `and` and `or` to create compound expressions. MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

Within the conditional expression of a `while...end` block, logical operators `&` and `|` behave as short-circuit operators. This behavior is the same as `&&` and `||`, respectively. Since `&&` and `||` consistently short-circuit in conditional expressions and statements, it is good practice to use `&&` and `||` instead of `&` and `|` within the expression. For example,

```
x = 42;
while exist('myfunction.m','file') && (myfunction(x) >= pi)
    disp('Expressions are true')
    break
end
```

The first part of the expression evaluates to false. Therefore, MATLAB does not need to evaluate the second part of the expression, which would result in an undefined function error.

Tips

- If you inadvertently create an infinite loop (that is, a loop that never ends on its own), stop execution of the loop by pressing **Ctrl+C**.
- If the conditional expression evaluates to a matrix, MATLAB evaluates the statements only if all elements in the matrix are true (nonzero). To execute statements if any element is true, wrap the expression in the `any` function.
- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- When nesting a number of `while` statements, each `while` statement requires an `end` keyword.
- “Relational Operators”

whitebg

Change axes background color

Syntax

```
whitebg
whitebg(fig)
whitebg(ColorSpec)
whitebg(fig, ColorSpec)
whitebg(fig, ColorSpec)
whitebg(fig)
```

Description

`whitebg` complements the colors in the current figure.

`whitebg(fig)` complements colors in all figures specified in the vector `fig`.

`whitebg(ColorSpec)` and `whitebg(fig, ColorSpec)` change the color of the axes, which are children of the figure, to the color specified by `ColorSpec`. Without a figure specification, `whitebg` or `whitebg(ColorSpec)` affects the current figure and the root's default properties so subsequent plots and new figures use the new colors.

`whitebg(fig, ColorSpec)` sets the default axes background color of the figures in the vector `fig` to the color specified by `ColorSpec`. Other axes properties and the figure background color can change as well so that graphs maintain adequate contrast. `ColorSpec` can be a 1-by-3 RGB color or a color string such as `'white'` or `'w'`.

`whitebg(fig)` complements the colors of the objects in the specified figures. This syntax is typically used to toggle between black and white axes background colors, and is where `whitebg` gets its name. Include the root window handle `(0)` in `fig` to affect the default properties for new windows or for `clf reset`.

Examples

Set the background color to blue-gray.

```
whitebg([0 .5 .6])
```

Set the background color to blue.

```
whitebg('blue')
```

More About

Tips

`whitebg` works best in cases where all the axes in the figure have the same background color.

`whitebg` changes the colors of the figure's children, with the exception of shaded surfaces. This ensures that all objects are visible against the new background color. `whitebg` sets the default properties on the root such that all subsequent figures use the new background color.

`ColorSpec` | `colordef`

Introduced before R2006a

who

List variables in workspace

Syntax

```
who
who(variables)
who(location)
who(variables,location)
c = who(variables,location)
```

Description

`who` lists in alphabetical order all variables in the currently active workspace.

`who(variables)` lists only the specified variables.

`who(location)` lists variables in the specified location: `'global'` for the global workspace, or `'-file'` for a MAT-file. For MAT-files, you must also include the file name as an input.

`who(variables,location)` lists the specified variables in the specified location. The `location` input can appear before or after `variables`.

`c = who(variables,location)` stores the names of the variables in cell array `c`. Specifying `variables` and `location` is optional.

Input Arguments

`variables`

Strings that specify the variables to list. Use one of these forms:

`var1, var2, ...`	List the specified variables. Use the `'*'` wildcard to match patterns. For example, `who('A*')` lists all variables that start with `A`.

`'-regexp', expressions`	List variables whose names match the specified regular expressions.

Default: `'*'` (all variables)

`location`

String that indicates whether to list variables from the global workspace or from a file:

`'global'`	Global workspace.
`'-file', filename`	MAT-file. The *`filename`* input can include the full, relative, or partial path.

Default: `''` (current workspace)

Output Arguments

`c`

Cell array of strings that correspond to each variable name.

Examples

Display information about variables in the current workspace whose names start with the letter `a`:

```
who a*
```

Show variables stored in MAT-file `durer.mat`:

```
who -file durer
```

This code returns:

```
Your variables are:

X        caption  map
```

Store the variable names from `durer.mat` in cell array `durerInfo`:

```
durerInfo = who('-file', 'durer');
```

Display the contents of cell array `durerInfo`:

```
for k=1:length(durerInfo)
   disp(durerInfo{k})
end
```

This code returns:

```
  X
  caption
  map
```

Suppose that a file `mydata.mat` contains variables with names that start with `java` and end with `Array`. Display information about those variables:

```
 whos -file mydata -regexp \<java.*Array\>
```

Call `who` within a nested function (`get_date`):

```
function who_demo
date_time = datestr(now);

[str pos] = textscan(date_time, '%s%s%s', ...
                     1, 'delimiter', '- :');
get_date(str);

   function get_date(d)
      day = d{1};
      mon = d{2};
      year = d{3};
      who
   end

end
```

When you run `who_demo`, the `who` function displays the variables by function workspace (although the name of the function does not appear in the output):

```
Your variables are:

d          mon        ans        pos
day        year       date_time  str
```

Alternatives

To view the variables in the workspace, use the Workspace browser. To view the contents of MAT-files, use the Details Panel of the Current Folder browser..

More About

Tips

- The `who` function displays the variable list unless you specify an output argument.
- When used within a nested function, the `who` function lists the variables in the workspaces of that function and all functions containing that function, grouped by workspace. This applies whether you call `who` from your function code or from the MATLAB debugger.

See Also

`assignin` | `clear` | `dir` | `evalin` | `exist` | `inmem` | `load` | `save` | `what` | `whos` | `workspace`

Introduced before R2006a

who

Class: matlab.io.MatFile
Package: matlab.io

Names of variables in MAT-file

Syntax

```
varlist = who(matObj)
varlist = who(matObj,variables)
```

Description

`varlist = who(matObj)` lists alphabetically all variables in the MAT-file associated with `matObj`. Optionally, returns the list in cell array `varlist`.

`varlist = who(matObj,variables)` lists the specified variables.

Input Arguments

`matObj`

Object created by the `matfile` function.

`variables`

Names of variables in the MAT-file corresponding to `matObj`. Use one of these forms:

`var1,...,varN`	Comma-separated list of variable name strings. Optionally, match patterns with the `'*'` wildcard, such as `who(matobj,'A*')`.
`'-regexp',expressions`	Regular expression strings that describe variable names.

Output Arguments

`varlist`

Cell array of strings that correspond to each variable name.

Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');
who(matObj)
```

This code returns:

```
Your variables are:

topo        topolegend  topomap1    topomap2
```

See Also

`whos` | `matfile`

whos

List variables in workspace, with sizes and types

Syntax

```
whos
whos(variables)
whos(location)
whos(variables,location)

S = whos( ___ )
```

Description

`whos` displays in alphabetical order all variables in the currently active workspace, with information about their sizes and types.

`whos(variables)` displays only the specified variables.

`whos(location)` displays variables in the specified location.

`whos(variables,location)` displays the specified variables in the specified location. The `location` and `variables` inputs can appear in either order.

`S = whos( ___ )` stores information about the variables in structure array, `S`, using no input arguments, or any of the input arguments from the previous syntaxes.

Examples

Display Information About Workspace Variables

Display information about variables in the current workspace whose names start with the letter `a`.

```
whos('a*')
```

Display Variables Stored in a MAT-File

Display all variables stored in the sample MAT-file, `durer.mat`.

```
whos('-file','durer.mat')
```

```
  Name           Size                Bytes  Class     Attributes

  X            648x509            2638656  double
  caption        2x28                 112  char
  map          128x3                 3072  double
```

Show only variables in the MAT-file with names that end with `ion`.

```
whos('-file','durer.mat','-regexp','ion$')
```

```
  Name          Size             Bytes  Class    Attributes

  caption       2x28               112  char
```

Store Variable Information in a Structure Array

Store information about the variables in `durer.mat` in structure array `S`.

```
S = whos('-file','durer.mat');
```

Display the contents of `S`.

```
for k = 1:length(S)
   disp(['  ' S(k).name ...
         '  ' mat2str(S(k).size) ...
         '  ' S(k).class]);
end
```

```
  X  [648 509]  double
  caption  [2 28]  char
  map  [128 3]  double
```

Create Function to Display Variable Attribute Information

In the Editor, create a function that creates variables with various persistent, global, sparse, and complex attributes, and then displays information about them.

```
function show_attributes
persistent p;
global g;
p = 1;
```

```
g = 2;
s = sparse(eye(5));
c = [4+5i 9-3i 7+6i];
whos
```

When you call the function, `show_attributes` displays the attributes.

```
show_attributes
```

```
Name      Size            Bytes  Class     Attributes

c         1x3                48  double    complex
g         1x1                 8  double    global
p         1x1                 8  double    persistent
s         5x5               128  double    sparse
```

Call whos Within a Nested or Anonymous Function

Create a function, `whos_demo`, that contains a nested function, `get_date`. Call `whos` within the nested function.

```
function whos_demo
date_time = datestr(now);

C = strsplit(date_time,{'-',''});
get_date(C);

   function get_date(d)
      day = d{1};
      mon = d{2};
      year = d{3};
      whos
   end

end
```

When you run the `whos_demo` function, `whos` displays the variables of the nested `get_date` function, and all functions that contain it, grouped by function workspace. This grouping applies whether you call `whos` from your function code or from the MATLAB debugger.

```
whos_demo
```

```
  Name           Size            Bytes  Class           Attributes
```

```
---- get_date ------------------------------------------------
d               1x3               372  cell
day             1x2                 4  char
mon             1x3                 6  char
year            1x13               26  char

---- whos_demo -----------------------------------------------
C               1x3               372  cell
ans             0x0                 0  (unassigned)
date_time       1x20               40  char
```

When called within an anonymous function, variables in the anonymous function also display in a group, titled with the function signature

Input Arguments

`variables` — Variables to display

strings

Variables to display, specified as one or more strings in one of the following forms.

Form of `Variables` Input	Variable Names
`var1 ... varN`	List the named variables, specified as individual strings. Use the `'*'` wildcard to match patterns. For example, `whos('A*')` lists all variables in the workspace that start with `A`.
`'-regexp',`*`expr1 ... exprN`*	List only the variables that match the regular expressions, specified as strings. For example, `whos('-regexp','^Mon','^Tues')` lists only the variables in the workspace that begin with `Mon` or `Tues`.

`location` — Location of variables

`'global' | '-file',`*`filename`*

Location of variables, specified as one of the following strings.

Value of `location`	Location of Variables
`'global'`	Global workspace.
`'-file',filename`	MAT-file. The *`filename`* input can include the full, relative, or partial path. For example, `whos('-file','myFile.mat')` lists all variables in the MAT-file named `myFile.mat`. `whos('-file',filename)` does not return the sizes of any MATLAB objects in file *`filename`*.

Output Arguments

S — Information about variables

nested structure array

Information about variables, returned as a nested structure array that contains a scalar `struct` for each variable. Each scalar `struct` contains these fields.

Field	Description
`name`	Name of the variable.
`size`	Dimensions of the variable array.
`bytes`	Number of bytes allocated for the variable array.
`class`	Class of the variable. If the variable has no value, class is `'(unassigned)'`.
`global`	True if the variable is global; otherwise, false.
`sparse`	True if the variable is sparse; otherwise, false.
`complex`	True if the variable is complex; otherwise, false.
`nesting`	Structure with these fields: • `function` — Name of the nested or outer function that defines the variable. • `level` — Nesting level of that function.
`persistent`	True if the variable is persistent; otherwise, false.

More About

Tips

- You also can view the contents of MAT-files using the Details Panel of the Current Folder browser.

Algorithms

`whos` returns the number of bytes each variable occupies in the workspace, not in a MAT-file. Version 7 MAT-files and later are compressed, so the number of bytes in the file is typically fewer than the number of bytes required in the workspace.

- "What Is the MATLAB Workspace?"

See Also

`clear` | `exist` | `what` | `who`

Introduced before R2006a

whos

Class: matlab.io.MatFile
Package: matlab.io

Names, sizes, and types of variables in MAT-file

Syntax

```
details = whos(matObj)
details = whos(matObj,variables)
```

Description

`details = whos(matObj)` returns information about all variables in the MAT-file associated with `matObj`.

`details = whos(matObj,variables)` returns information about the specified variables.

Input Arguments

`matObj`

Object created by the `matfile` function.

`variables`

Names of variables in the MAT-file corresponding to `matObj`. Use one of these forms:

`var1,...,varN`	Comma-separated list of variable name strings. Optionally, match patterns with the `'*'` wildcard, such as `whos(matobj,'A*')`.
`'-regexp',expressions`	Regular expression strings that describe variable names.

Output Arguments

`details`

Structure array with these fields (identical to the structure returned by the `whos` function):

`name`	Variable name
`size`	Dimensions of the variable
`bytes`	Number of bytes allocated for the array when you load the entire variable
`class`	Class (data type) of the variable
`global`	Whether the variable is global (`true` or `false`)
`sparse`	Whether the variable is sparse
`complex`	Whether the variable is complex
`nesting`	Structure with these fields: • `function` — Name of the nested or outer function that defines the variable • `level` — Nesting level
`persistent`	Whether the variable is persistent

Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');
whos(matObj)
```

This code returns:

```
  Name              Size              Bytes  Class     Attributes

  topo            180x360             518400  double
  topolegend        1x3                   24  double
  topomap1         64x3                 1536  double
  topomap2        128x3                 3072  double
```

Without loading any data, find the size and number of dimensions of the variable `topo` in `topography.mat`:

```
matObj = matfile('topography.mat');
info = whos(matObj,'topo');
sizeX = info.size
nDimsX = length(sizeX)
```

This code returns:

```
sizeX =
   180   360

nDimsX =
     2
```

See Also

`size` | `matfile`

width

Number of table variables

Syntax

```
W = width(T)
```

Description

`W = width(T)` returns the number of variables in table `T`.

`width(T)` is equivalent to `size(T,2)`.

Examples

Number of Variables in Table

Create a table, `T`.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

T = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
T =

                Age    Height    Weight    BloodPressure
                ___    ______    ______    _____________

    Smith       38     71        176       124          93
    Johnson     43     69        163       109          77
    Williams    38     64        131       125          83
    Jones       40     67        133       117          75
    Brown       49     64        119       122          80
```

Find the number of variables in table `T`.

```
W = width(T)
```

```
W =

     4
```

`T` contains `4` variables; `width` does not count the row names.

The variable `BloodPressure` counts as one variable even though it contains two columns.

Input Arguments

`T` — Input table

table

Input table, specified as a table.

Variables in a table can have multiple columns, but `width(T)` only counts the number of variables.

See Also

`height` | `numel` | `size`

wilkinson

Wilkinson's eigenvalue test matrix

Syntax

```
W = wilkinson(n)
```

Description

`W = wilkinson(n)` returns one of J. H. Wilkinson's eigenvalue test matrices. It is a symmetric, tridiagonal matrix with pairs of nearly, but not exactly, equal eigenvalues.

Examples

```
wilkinson(7)

ans =

    3    1    0    0    0    0    0
    1    2    1    0    0    0    0
    0    1    1    1    0    0    0
    0    0    1    0    1    0    0
    0    0    0    1    1    1    0
    0    0    0    0    1    2    1
    0    0    0    0    0    1    3
```

The most frequently used case is `wilkinson(21)`. Its two largest eigenvalues are both about 10.746; they agree to 14, but not to 15, decimal places.

See Also

`eig` | `gallery` | `pascal`

Introduced before R2006a

winopen

Open file in appropriate application (Windows)

Syntax

```
winopen(fileName)
```

Description

`winopen(fileName)` opens `fileName` in the associated Microsoft Windows application. The application is associated with the extension in `fileName` in the Windows operating system. `filename` is a string enclosed in single quotes. `winopen` uses a Windows shell command, and performs the same action as double-clicking the file in the Windows Explorer program. That is, `winopen` calls the application associated the file extension to open the file. Use an absolute or relative path for `fileName`.

Examples

Open the file `thesis.doc`, located in the current folder, in the Microsoft Word program:

```
winopen('thesis.doc')
```

Open `myresults.html` in the system Web browser:

```
winopen('D:/myfiles/myresults.html')
```

On Microsoft Windows platforms, open the current folder in the Windows Explorer tool:

```
winopen(cd)
```

To open a file on the MATLAB path, use `winopen` with `which`. For example, to open the `meshgrid` function in the Editor, use:

```
winopen(which('meshgrid'))
```

See Also

`dos` | `open` | `web`

Introduced before R2006a

winqueryreg

Item from Windows registry

Syntax

```
valnames = winqueryreg('name', 'rootkey', 'subkey')
value = winqueryreg('rootkey', 'subkey', 'valname')
value = winqueryreg('rootkey', 'subkey')
```

Description

`valnames = winqueryreg('name', 'rootkey', 'subkey')` returns all value names in `rootkey\subkey` of Microsoft Windows operating system registry to a cell array of strings. The first argument is the literal quoted string, `'name'`.

`value = winqueryreg('rootkey', 'subkey', 'valname')` returns the value for value name `valname` in `rootkey\subkey`.

If the value retrieved from the registry is a string, `winqueryreg` returns a string. If the value is a 32-bit integer, `winqueryreg` returns the value as an integer of the MATLAB software type `int32`.

`value = winqueryreg('rootkey', 'subkey')` returns a value in `rootkey\subkey` that has no value name property.

Note The literal **`name`** argument and the `rootkey` argument are case-sensitive. The `subkey` and `valname` arguments are not.

Examples

Example 1

Get the value of `CLSID` for the MATLAB sample Microsoft COM control `mwsampctrl.2`:

```
winqueryreg 'HKEY_CLASSES_ROOT' 'mwsamp.mwsampctrl.2\clsid'

ans =
   {5771A80A-2294-4CAC-A75B-157DCDDD3653}
```

Example 2

Get a list in variable `mousechar` for registry subkey `Mouse`, which is under subkey `Control Panel`, which is under root key `HKEY_CURRENT_USER`.

```
mousechar = winqueryreg('name', 'HKEY_CURRENT_USER', ...
   'control panel\mouse');
```

For each name in the `mousechar` list, get its value from the registry and then display the name and its value:

```
for k=1:length(mousechar)
   setting = winqueryreg('HKEY_CURRENT_USER', ...
      'control panel\mouse', mousechar{k});
   str = sprintf('%s = %s', mousechar{k}, num2str(setting));
   disp(str)
   end

ActiveWindowTracking = 0
DoubleClickHeight = 4
DoubleClickSpeed = 830
DoubleClickWidth = 4
MouseSpeed = 1
MouseThreshold1 = 6
MouseThreshold2 = 10
SnapToDefaultButton = 0
SwapMouseButtons = 0
```

More About

Tips

This function works only for the following registry value types:

- strings (REG_SZ)
- expanded strings (REG_EXPAND_SZ)
- 32-bit integer (REG_DWORD)

Introduced before R2006a

workspace

Open Workspace browser to manage workspace

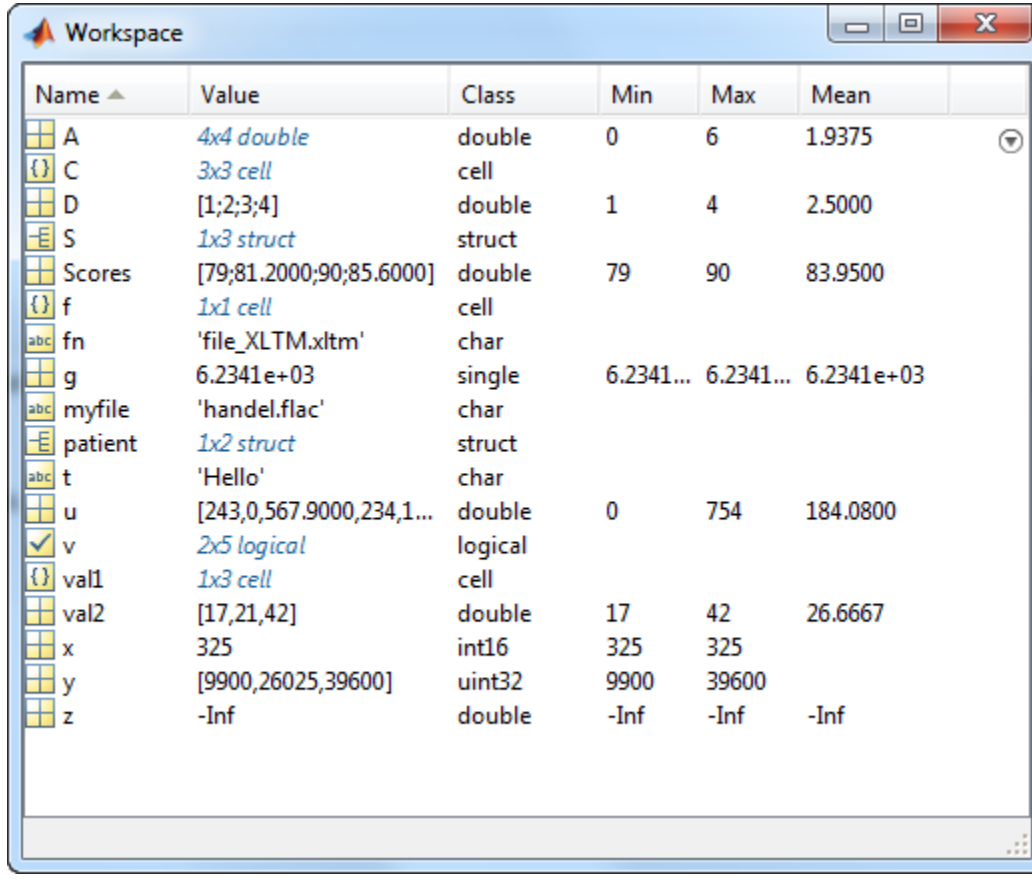
Syntax

```
workspace
```

Description

`workspace` displays the Workspace browser, a graphical user interface that allows you to view and manage the contents of the workspace in MATLAB. It provides a graphical representation of the `whos` display, and allows you to perform the equivalent of the `clear`, `load`, `open`, and `save` functions.

The Workspace browser also displays and automatically updates statistical calculations for each variable, which you can choose to show or hide.



You can edit a value directly in the Workspace browser for small numeric and character arrays. To see and edit a graphical representation of larger variables and for other classes, double-click the variable in the Workspace browser. The variable displays in the Variables editor, where you can view the full contents and make changes.

More About

- "What Is the MATLAB Workspace?"

See Also

`openvar` | `who`

Introduced before R2006a

write

Write data to remote host over TCP/IP interface

Syntax

```
write(t,data)
```

Description

`write(t,data)` sends the N-dimensional matrix of data from `tcpclient` object `t` connected to the remote host. The function waits until the specified values are written to the remote host.

Examples

Read and Write uint8 Data

Create a TCP/IP object called `t`, connecting to a TCP/IP echo server, with Port of `7`. This requires you to have an `echotcpip` server running on Port 7.

```
t = tcpclient('localhost', 7)
```

```
t =

   tcpclient with properties:

          Address: 'local host'
             Port: 7
          Timeout: 10
   BytesAvailable: 0
```

The `write` function synchronously writes data to the remote host connected to the `tcpclient` object. First specify the data, then write the data. The function waits until the specified number of values is written to the remote host.

Assign 10 bytes of `uint8` data to the variable `data`.

```
data = uint8(1:10)
```

```
data =

  1    2    3    4    5    6    7    8    9    10
```

Check the data.

```
whos data
```

```
Name      Size      Bytes      Class      Attributes

data      1x10         10      uint8
```

Write data to the echo server.

```
write(t, data)
```

Check that the data was written using the `BytesAvailable` property.

```
t.BytesAvailable
```

```
ans =

    10
```

Read the data from the server.

```
read(t)
```

```
ans =

  1    2    3    4    5    6    7    8    9    10
```

Close the connection between the TCP/IP client object and the remote host by clearing the object.

```
clear t
```

Input Arguments

`data` — Data to write to the remote host

1xN matrix of numeric data

Data to write to the remote host, specified as a 1xN matrix of numeric data.

Example: `write(t, data)`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

writetable

Write table to file

Syntax

```
writetable(T)
writetable(T,filename)
writetable( ___ ,Name,Value)
```

Description

`writetable(T)` writes the table, `T`, to a comma delimited text file. The file name is the workspace variable name of the table, appended with the extension `.txt`. If `writetable` cannot construct the file name from the input table name, then it writes to the file `table.txt`.

Each column of each variable in `T` becomes a column in the output file. The variable names of `T` become column headings in the first line of the file.

`writetable(T,filename)` writes table `T` to a file with the name and extension specified by `filename`.

`writetable` determines the file format based on the specified extension. The extension must be one of the following:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

`writetable( ___ ,Name,Value)` writes the table to a file with additional options specified by one or more Name,Value pair arguments and can include any of the input arguments in previous syntaxes.

For example, you can specify whether to write the variable names as column headings in the output file.

Examples

Write Table to Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
    {'NY';'CA';'MA'},[true;false;false])
```

```
T =

    Var1      Var2      Var3    Var4
    ____    _________    ____    _____

    M       45    45     'NY'    true
    F       41    32     'CA'    false
    M       40    34     'MA'    false
```

Write the table, `T`, to a comma delimited text file.

```
writetable(T)
```

`writetable` outputs a text file named `T.txt`.

Display the contents of the file.

```
type 'T.txt'
```

```
Var1,Var2_1,Var2_2,Var3,Var4
M,45,45,NY,1
F,41,32,CA,0
M,40,34,MA,0
```

`writetable` appends a unique suffix to the variable name, `Var2`, above the two columns of corresponding data.

Write Table to Space Delimited Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
```

```
    {'NY';'CA';'MA'},[true;false;false])
```

```
T =

    Var1      Var2      Var3    Var4
    ____    _________    ____    _____

    M       45    45     'NY'    true
    F       41    32     'CA'    false
    M       40    34     'MA'    false
```

Write the table to a space delimited text file named `myData.txt`.

```
writetable(T,'myData.txt','Delimiter',' ')
```

Display the contents of the file.

```
type 'myData.txt'
```

```
Var1 Var2_1 Var2_2 Var3 Var4
M 45 45 NY 1
F 41 32 CA 0
M 40 34 MA 0
```

`writetable` appends a unique suffix to the variable name, `Var2`, above the two columns of corresponding data.

Write Table to Text File Including Row Names

Create a table.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

T = table(Age,Height,Weight,BloodPressure,...
    'RowNames',LastName)
```

```
T =
```

```
              Age    Height    Weight    BloodPressure
              ___    ______    ______    _____________

    Smith     38     71        176       124      93
    Johnson   43     69        163       109      77
    Williams  38     64        131       125      83
    Jones     40     67        133       117      75
    Brown     49     64        119       122      80
```

Write the table, `T`, to a comma delimited text file, called `myPatientData.dat`.

```
writetable(T,'myPatientData.dat','WriteRowNames',true)
```

Display the contents of the file.

```
type 'myPatientData.dat'
```

```
Row,Age,Height,Weight,BloodPressure_1,BloodPressure_2
Smith,38,71,176,124,93
Johnson,43,69,163,109,77
Williams,38,64,131,125,83
Jones,40,67,133,117,75
Brown,49,64,119,122,80
```

The first column, which contains the row names, has the column heading, `Row`. This is the first dimension name for the table from the property `T.Properties.DimensionNames`.

Write Quoted Strings to CSV File

Create a table.

```
T = table(['M';'F';'M'],[45;41;36],...
    {'New York, NY';'San Diego, CA';'Boston, MA'},[true;false;false])
```

```
T =

    Var1    Var2         Var3          Var4
    ____    ____    _______________    _____

    M       45      'New York, NY'     true
    F       41      'San Diego, CA'    false
    M       36      'Boston, MA'       false
```

Write the table to a comma-separated text file named `myData.csv`. Enclose strings in double quotation marks using the `'QuoteStrings'` name-value pair argument, to ensure that the commas in the third column are not treated as delimiters.

```
writetable(T,'myData.csv','Delimiter',',','QuoteStrings',true)
```

View the contents of the file.

```
type 'myData.csv'
```

```
Var1,Var2,Var3,Var4
"M",45,"New York, NY",1
"F",41,"San Diego, CA",0
"M",36,"Boston, MA",0
```

Write Table to Specific Sheet and Range in Spreadsheet

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
    {'NY';'CA';'MA'},[true;false;false])
```

```
T =

    Var1          Var2          Var3    Var4
    ____    ________________    ____    _____

    M       45          45      'NY'    true
    F       41          32      'CA'    false
    M       40          34      'MA'    false
```

Write the table to a spreadsheet named `myData.xls`. Include the data on the second sheet in the 5-by-5 region with corners at `B2` and `F6`.

```
writetable(T,'myData.xls','Sheet',2,'Range','B2:F6')
```

Excel fills the row of the spreadsheet from `B6` to `F6` with `#N/A` since the range specified is larger than the size of the input table `T`.

Input Arguments

T — Input table

table

Input table, specified as a table.

`filename` — File name
string

File name, specified as a string. To write to a specific folder, specify the full path name. Otherwise, `writetable` writes to a file in the current folder. If `filename` includes the file's extension, then `writetable` determines the file format from the extension. Otherwise, `writetable` creates a comma separated text file and appends the extension `.txt`. Alternatively, you can specify `filename` without the file's extension, and then include the `'FileType'` name-value pair arguments to indicate the type of file.

If `filename` does not exist, then `writetable` creates the file. If `filename` is the name of an existing text file, then `writetable` overwrites the file. If `filename` is the name of an existing spreadsheet file, then `writetable` writes a table to the specified location, but does not overwrite any values outside that range.

Example: `'myData.xls'`

Example: `'C:\test\myData.txt'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'WriteVariableNames',false` indicates that the variable names should not be included as the first row of the output file.

`'FileType'` — Type of file
`'text'` | `'spreadsheet'`

Type of file, specified as the comma-separated pair consisting of `'FileType'` and the string `'text'` or `'spreadsheet'`.

The `'FileType'` name-value pair must be used with the `filename` input argument. You do not need to specify the `'FileType'` name-value pair argument if the file type can be determined from an extension in the filename input argument.

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

Example: `writetable(T,'mySpreadsheet','FileType','spreadsheet')`

`'WriteVariableNames'` — Indicator for writing variable names as column headings

`true` (default) | `false` | `1` | `0`

Indicator for writing variable names as column headings, specified as the comma-separated pair consisting of `'WriteVariableNames'` and either `true`, `false`, `1`, or `0`.

`true`	`writetable` includes variable names as the column headings of the output. This is the default behavior. If both the `'WriteVariablesNames'` and `'WriteRowNames'` logical indicators are `true`, then `writetable` uses the first dimension name from the property `T.Properties.DimensionNames` as the column heading for the first column of the output.
`false`	`writetable` does not include variable names in the output.

`'WriteRowNames'` — Indicator for writing row names in first column

`false` (default) | `true` | `0` | `1`

Indicator for writing row names in first column, specified as the comma-separated pair consisting of `'WriteRowNames'` and either `false`, `true`, `0`, or `1`.

`true`	`writetable` includes the row names from `T` as the first column of the output. If both the `'WriteVariablesNames'` and `'WriteRowNames'` logical indicators are `true`, then `writetable` uses the first dimension name from the property `T.Properties.DimensionNames` as the column heading for the first column of the output.
`false`	`writetable` does not include the row names from `T` in the output. This is the default behavior.

`'Delimiter'` — Field delimiter character

string

Field delimiter character, specified as the comma-separated pair consisting of `'Delimiter'` and one of the following strings:

`','`	Comma. This is the default behavior.
`'comma'`	
`' '`	Space
`'space'`	
`'\t'`	Tab
`'tab'`	
`';'`	Semicolon
`'semi'`	
`'|'`	Vertical bar
`'bar'`	

You can use the `'Delimiter'` name-value pair only for delimited text files.

Example: `'Delimiter','space'`

`'QuoteStrings'` — Indicator for writing quoted strings

`false` (default) | `true` | `0` | `1`

Indicator for writing quoted strings, specified as the comma-separated pair consisting of `'QuoteStrings'` and either `false`, `true`, `0`, or `1`. If `'QuoteStrings'` is `true`, then `writetable` encloses strings in double quotation marks, and replaces any double-quote characters that appear as part of a string with two double-quote characters. For an example, see "Write Quoted Strings to CSV File" on page 1-8984.

You can use the `'QuoteStrings'` name-value pair only with delimited text files.

`'Sheet'` — Worksheet to write to

string containing worksheet name | positive integer indicating worksheet index

Worksheet to write to, specified as the comma-separated pair consisting of `'Sheet'` and a string containing the worksheet name or a positive integer indicating the worksheet index. The worksheet name string cannot contain a colon (`:`). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsfinfo(filename)`.

If the sheet does not exist, then `writetable` adds a new sheet at the end of the worksheet collection. If the sheet is an index larger than the number of worksheets, then

`writetable` appends empty sheets until the number of worksheets in the workbook equals the sheet index. In either case, `writetable` generates a warning indicating that it has added a new worksheet.

You can use the `'Sheet'` name-value pair only with spreadsheet files.

Example: `'Sheet',2`

`'Range'` — Rectangular portion of worksheet to write to

string

Rectangular portion of worksheet to write to, specified as the comma-separated pair consisting of `'Range'` and a string in one of the following forms.

Form of the Value of `Range`	Description
`'Corner1'`	*`Corner1`* specifies the first cell of the region to write. `writetable` writes table `T` beginning at this cell. **Example:** `'Range','D2'`
`'Corner1:Corner2'`	*`Corner1`* and *`Corner2`* are two opposing corners that define the region to write. For example, `'D2:H4'` represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `'Range'` name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help). If the range you specify is larger than the size of the input table `T`, Excel software fills the remainder of the region with `#N/A`. If the range specified is smaller than the size of the input table `T`, then `writetable` writes only the subset that fits into the range. **Example:** `'Range','D2:H4'`

The `'Range'` name-value pair can only be used with Excel files.

Limitations

- On Linux systems, `writetable` writes only to text files and does not write to spreadsheet files.

More About

Tips

- In the cases below, `writetable` creates a file that does not represent T exactly. Then, if you use `readtable` to read that file and create a new table, the result might not have the same format or contents as the original table. Save `T` as a MAT-file if you need to import it again as a table with the same data and organization.
  - `writetable` outputs numeric variables using `long g` format, and categorical or character variables as unquoted strings in text files.
  - For variables that have more than one column, `writetable` appends a unique identifier to the variable name to use as the column headings.
  - For output variables that have more than two dimensions, `writetable` outputs these variables as two dimensional where the trailing dimensions are collapsed. For example, `writetable` outputs a 4-by-3-by-2 variable as if its size were 4-by-6.
  - For variables with a `cell` data type, `writetable` outputs the contents of each cell as a single row, in multiple fields. If the contents are other than numeric, logical, character, or categorical, then `writetable` outputs a single empty field.

Algorithms

Excel converts `Inf` values to `65535`. MATLAB converts `NaN` values to empty cells.

`readtable` | `table`

Introduced in R2013b

write

Class: Tiff

Write entire image

Syntax

```
write(tiffobj,imageData)
write(tiffobj,Y,Cb,Cr)
```

Description

`write(tiffobj,imageData)` writes `imageData` to TIFF file associated with the Tiff object, `tiffobj`. The `write` method breaks the data into strips or tiles, depending on the value of the `RowsPerStrip` tag, or the `TileLength` and `TileWidth` tags.

`write(tiffobj,Y,Cb,Cr)` writes the YCbCr component data to the TIFF file. Use this syntax only for images with a YCbCr photometric interpretation.

Examples

Write Image Data

Write tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a `Tiff` object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');
t = Tiff('myfile.tif','w');
```

Set tag values.

```
setTag(t,'ImageLength',size(imdata,1))
setTag(t,'ImageWidth',size(imdata,2))
setTag(t,'Photometric',Tiff.Photometric.RGB)
```

```
setTag(t,'BitsPerSample',8)
setTag(t,'SamplesPerPixel',size(imdata,3))
setTag(t,'TileWidth',128)
setTag(t,'TileLength',128)
setTag(t,'Compression',Tiff.Compression.JPEG)
setTag(t,'PlanarConfiguration',Tiff.PlanarConfiguration.Chunky)
setTag(t,'Software','MATLAB')
```

Write the image data to the TIFF file.

```
write(t,imdata)
close(t)
```

See Also

`Tiff.writeDirectory`

writeDirectory

Class: Tiff

Create new IFD and make it current IFD

Syntax

```
writeDirectory(tiffobj)
```

Description

`writeDirectory(tiffobj)` create a new image file directory (IFD) and makes it the current IFD. `Tiff` object methods operate on the current IFD. If you are creating a TIFF file that only contains one image, you do not need to use this method. With single-image TIFF files, just close the `Tiff` object to write data to the file.

Examples

Open a TIFF file for modification and create a new IFD in the file. `writeDirectory` makes the newly created IFD the current IFD. Replace the name `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');
dnum = currentDirectory(t);
writeDirectory(t);
dnum = currentDirectory(t);
```

References

This method corresponds to the `TIFFWriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

See Also

`Tiff.write` | `Tiff.close`

writeEncodedStrip

Class: Tiff

Write data to specified strip

Syntax

```
writeEncodedStrip(tiffobj,stripNumber,imageData)
writeEncodedStrip(tiffobj,stripNumber,Y,Cb,Cr)
```

Description

`writeEncodedStrip(tiffobj,stripNumber,imageData)` writes the data in `imageData` to the strip specified by `stripNumber`. Strip identification numbers are one-based. If `imageData` has fewer bytes than fit into a strip, `writeEncodedStrip` silently pads the strip. If `imageData` has more bytes than fit into a strip, `writeEncodedStrip` issues a warning and truncates the data. To determine the size of a strip, view the value of the `RowsPerStrip` tag.

`writeEncodedStrip(tiffobj,stripNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tag.

Examples

Write Image Data to Strips

Open a `Tiff` object for writing and set tag values.

```
t = Tiff('myfile.tif','w');
setTag(t,'ImageLength',32)
setTag(t,'ImageWidth',32)
setTag(t,'Photometric',Tiff.Photometric.MinIsBlack)
setTag(t,'BitsPerSample',8)
setTag(t,'SamplesPerPixel',1)
setTag(t,'RowsPerStrip',16)
setTag(t,'PlanarConfiguration',Tiff.PlanarConfiguration.Chunky)
```

Write data to the first and second strips.

```
writeEncodedStrip(t,1,ones(16,32,'uint8'))
writeEncodedStrip(t,2,2*ones(16,32,'uint8'))
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

References

This method corresponds to the `TIFFWriteEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

`Tiff.writeEncodedTile`

writeEncodedTile

Class: Tiff

Write data to specified tile

Syntax

```
writeEncodedTile(tiffobj,tileNumber,imageData)
writeEncodedTile(tiffobj,tileNumber,Y,Cb,Cr)
```

Description

`writeEncodedTile(tiffobj,tileNumber,imageData)` writes the data in `imageData` to the tile specified by `tileNumber`. Tile identification numbers are one-based. If `imageData` has fewer bytes than fit into a tile, `writeEncodedTile` silently pads the tile. If `imageData` has more bytes than fit into a tile, `writeEncodedTile` issues a warning and truncates the data. To determine the size of a tile, view the value of the `tileLength` and `tileWidth` tags.

`writeEncodedTile(tiffobj,tileNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tags.

Examples

Write Image Data to Tiles

Open a `Tiff` object for writing and set tag values.

```
t = Tiff('myfile.tif','w');
setTag(t,'ImageLength',32)
setTag(t,'ImageWidth',32)
setTag(t,'Photometric',Tiff.Photometric.MinIsBlack)
setTag(t,'BitsPerSample',8)
setTag(t,'SamplesPerPixel',1)
setTag(t,'TileWidth',16)
setTag(t,'TileLength',16)
```

```
setTag(t,'PlanarConfiguration',Tiff.PlanarConfiguration.Chunky)
```

Write data to four tiles.

```
writeEncodedTile(t,1,ones(16,16,'uint8'))
writeEncodedTile(t,2,2*ones(16,16,'uint8'))
writeEncodedTile(t,3,3*ones(16,16,'uint8'))
writeEncodedTile(t,4,4*ones(16,16,'uint8'))
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

References

This method corresponds to the `TIFFWriteEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTIFF - TIFF Library and Utilities.

`Tiff.writeEncodedStrip`

writeVideo

Class: VideoWriter

Write video data to file

Syntax

```
writeVideo(writerObj,img)
writeVideo(writerObj,images)
writeVideo(writerObj,frame)
writeVideo(writerObj,mov)
```

Description

`writeVideo(writerObj,img)` writes data from an image to a video file.

`writeVideo(writerObj,images)` writes a sequence of color images to a video file.

`writeVideo(writerObj,frame)` writes a frame to the video file associated with writerObj.

`writeVideo(writerObj,mov)` writes a MATLAB movie to a video file. mov is an array of frame structures.

You must call `open(writerObj)` before calling `writeVideo`.

Input Arguments

`writerObj`

`VideoWriter` object created by the `VideoWriter` function.

`img`

When creating AVI or MPEG-4 files, `img` is an array of `single`, `double`, or `uint8` values representing a grayscale or RGB color image, which `writeVideo` writes as an

RGB video frame. Data of type `single` or `double` must be in the range `[0,1]`, except when writing Indexed AVI files.

When creating Motion JPEG 2000 files, `img` is an array of `uint8`, `int8`, `uint16`, or `int16` values representing a monochrome or RGB color image.

For grayscale, monochrome, or indexed data, img must be two-dimensional: height-by-width. For color data that is not indexed, img is three-dimensional: height-by-width-by-3. The height and width must be consistent for all frames within a file. For more information, see "Image Types".

`images`

Four-dimensional array of grayscale (height-by-width-by-1-by-frames) or RGB (height-by-width-by-3-by-frames) images.

`frame`

Structure typically returned by the `getframe` function that contains two fields: `cdata` and `colormap`. If the `colormap` is not empty, `writeVideo` expects a two-dimensional (height-by-width) array `cdata`. The height and width must be consistent for all frames within a file. `colormap` can contain a maximum of 256 entries.

The `profile` of `writerObj` and the size of `cdata` determine how the `writeVideo` method uses `frame`.

`profile` of `VideoWriter` object	Size of `cdata`	Behavior of `writeVideo`
`'Indexed AVI'` or `'Grayscale AVI'`	2-dimensional (height-by-width)	Use frame as provided. For `'Grayscale AVI'`, `colormap` should be empty.
	3-dimensional (height-by-width-by-3)	Error
All other profiles	2-dimensional (height-by-width)	Construct RGB image frames using the `colormap` field
	3-dimensional (height-by-width-by-3)	`Colormap` field ignored. Construct RGB image frames using the `cdata` field

mov

1-by-F array of frame structures, where F is the number of images. Each frame structure contains fields `cdata` and `colormap`.

Examples

AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
axis tight
set(gca,'nextplot','replacechildren');
set(gcf,'Renderer','zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
   surf(sin(2*pi*k/20)*Z,Z)
   frame = getframe;
   writeVideo(writerObj,frame);
end

close(writerObj);
```

MPG to AVI Conversion

Convert an example file, `xylophone.mp4`, to an uncompressed AVI file:

Create objects to read and write the video, and open the AVI file for writing.

```
readerObj = VideoReader('xylophone.mp4');
```

```
writerObj = VideoWriter('transcoded_xylophone.avi', ...
                        'Uncompressed AVI');

open(writerObj);
```

Read and write each frame.

```
for k = 1:readerObj.NumberOfFrames
   img = read(readerObj,k);
   writeVideo(writerObj,img);
end

close(writerObj);
```

See Also

open | close | getframe | VideoReader | VideoWriter

xlabel

Label x-axis

Syntax

```
xlabel(str)
xlabel(str,Name,Value)

xlabel(ax, ___ )

t = xlabel( ___ )
```

Description

`xlabel(str)` labels the *x*-axis of the current axes with the text specified by `str`. Reissuing the `xlabel` command replaces the old label with the new label.

`xlabel(str,Name,Value)` specifies text properties for the label using one or more `Name,Value` pair arguments. For example, `'Color','blue'` creates a blue label.

`xlabel(ax, ___ )` adds the label to the axes specified by `ax`, instead of the current axes. The option `ax` can precede any of the input argument combinations in the previous syntaxes.

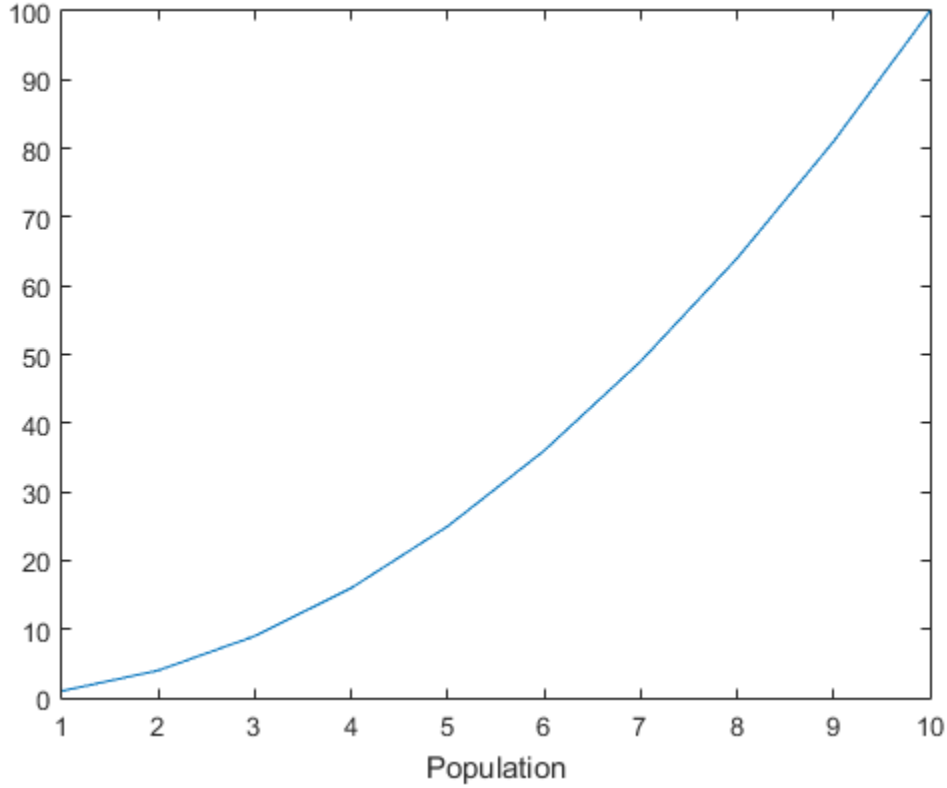
`t = xlabel( ___ )` returns the text object used as the *x*-axis label. Use `t` to make future modifications to the label after it is created.

Examples

Label x-Axis

Display `Population` beneath the *x*-axis.

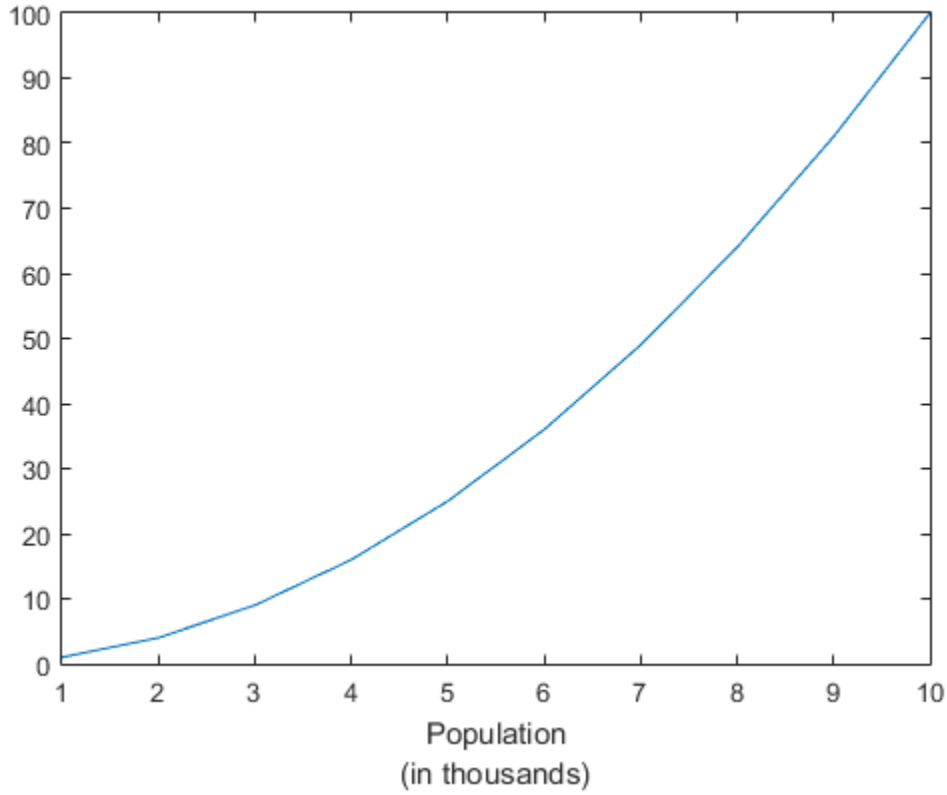
```
plot((1:10).^2)
xlabel('Population')
```



Create Multiline x-Axis Label

Create a multiline label using a cell array of strings.

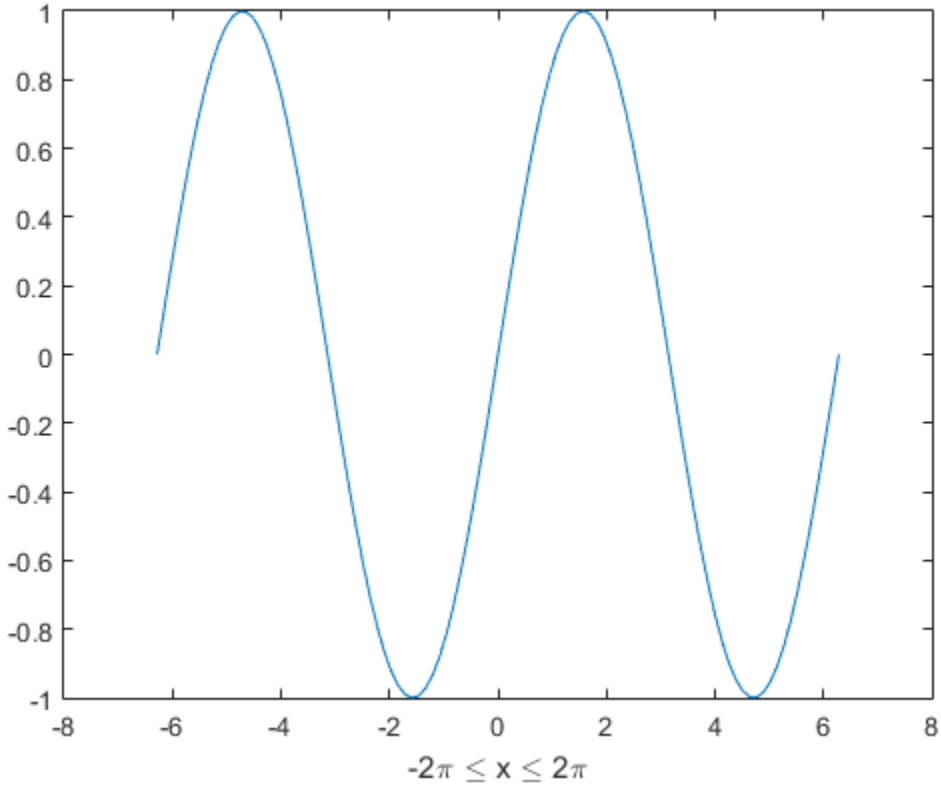
```
plot((1:10).^2)
xlabel({'Population','(in thousands)'})
```



Include Greek Letters in x-Axis Label

Include Greek letters and other special characters in the label using TeX markup.

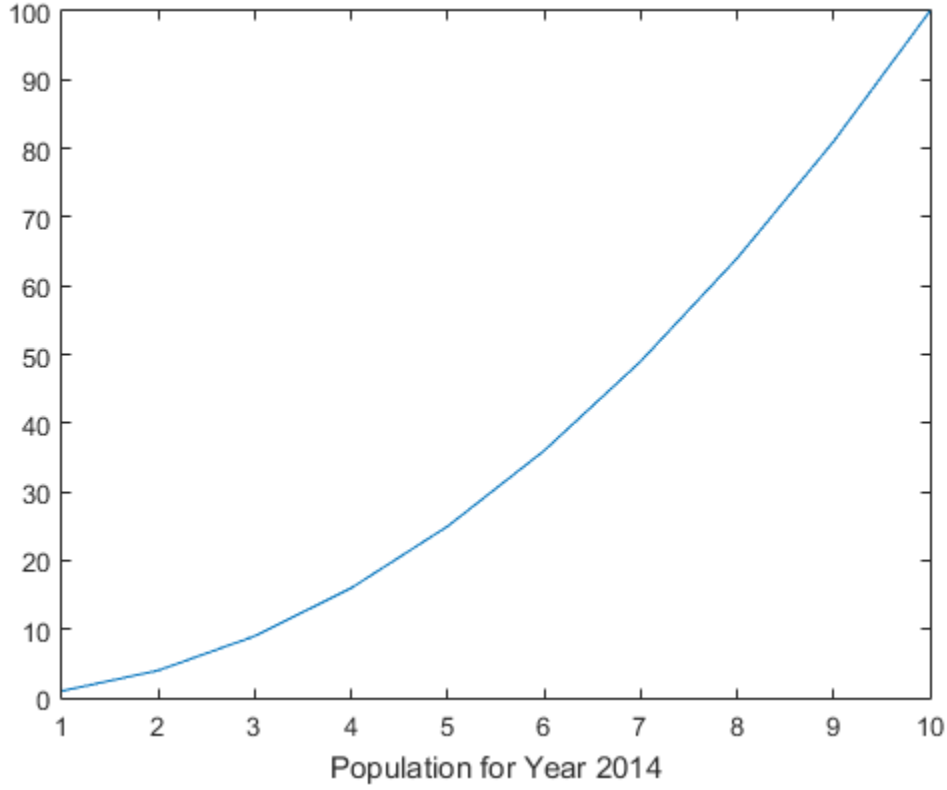
```
x = linspace(-2*pi,2*pi);
y = sin(x);
plot(x,y)
xlabel('-2\pi \leq x \leq 2\pi')
```



Include Variable Value in x-Axis Label

Add a label with text and a variable value. Use the `num2str` function to convert the variable value to a string.

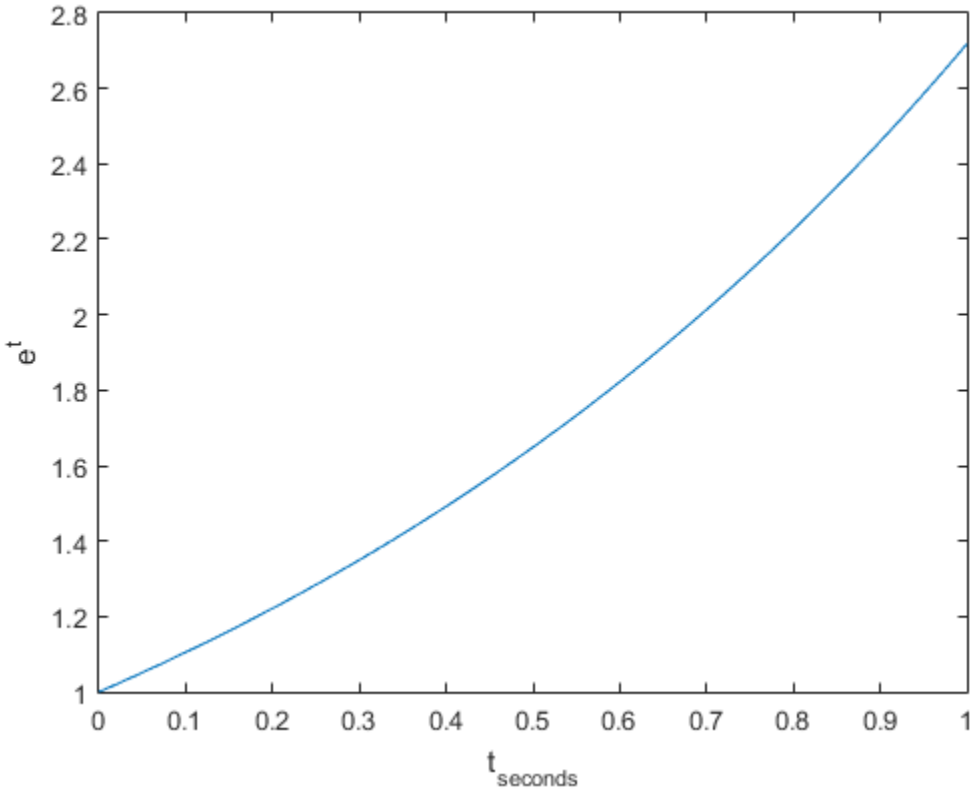
```
plot((1:10).^2)
year = 2014;
xlabel(['Population for Year ',num2str(year)])
```



Include Superscript and Subscript in Axis Labels

Use the `'^'` and `'_'` characters to include superscripts and subscripts in the axis labels. Use curly braces `{}` to modify more than one character.

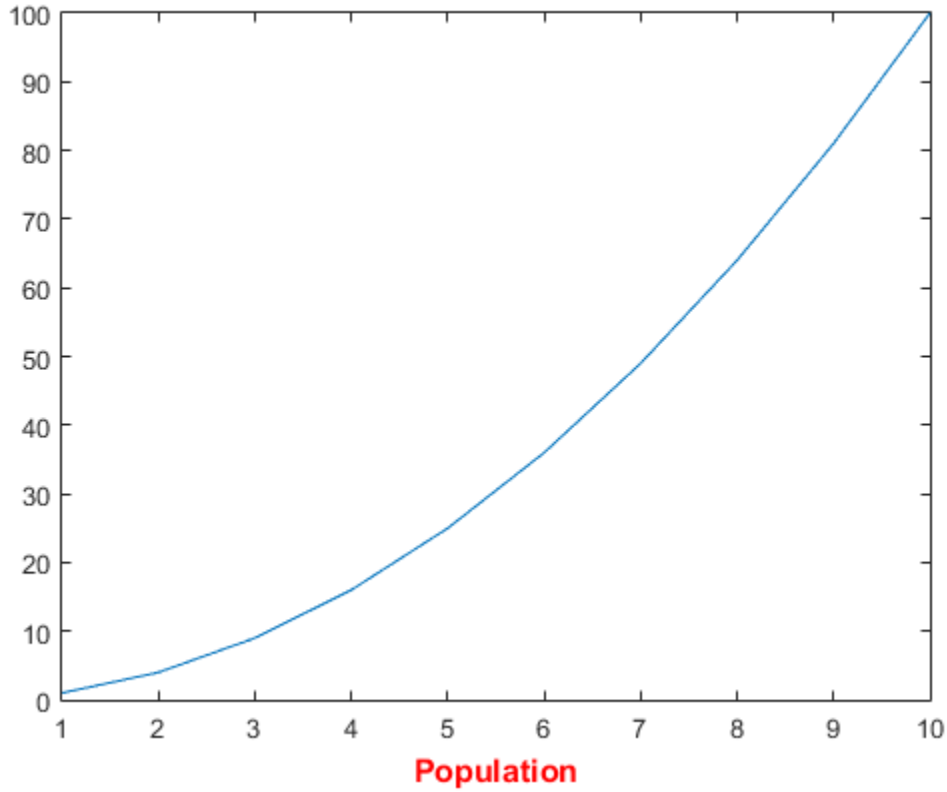
```
t = linspace(0,1);
y = exp(t);
plot(t,y)
xlabel('t_{seconds}')
ylabel('e^t')
```



Change x-Axis Label Font Size and Color

Use `Name,Value` pair arguments to set the font size, font weight, and text color properties of the *x*-axis label.

```
plot((1:10).^2)
xlabel('Population','FontSize',12,'FontWeight','bold','Color','r')
```

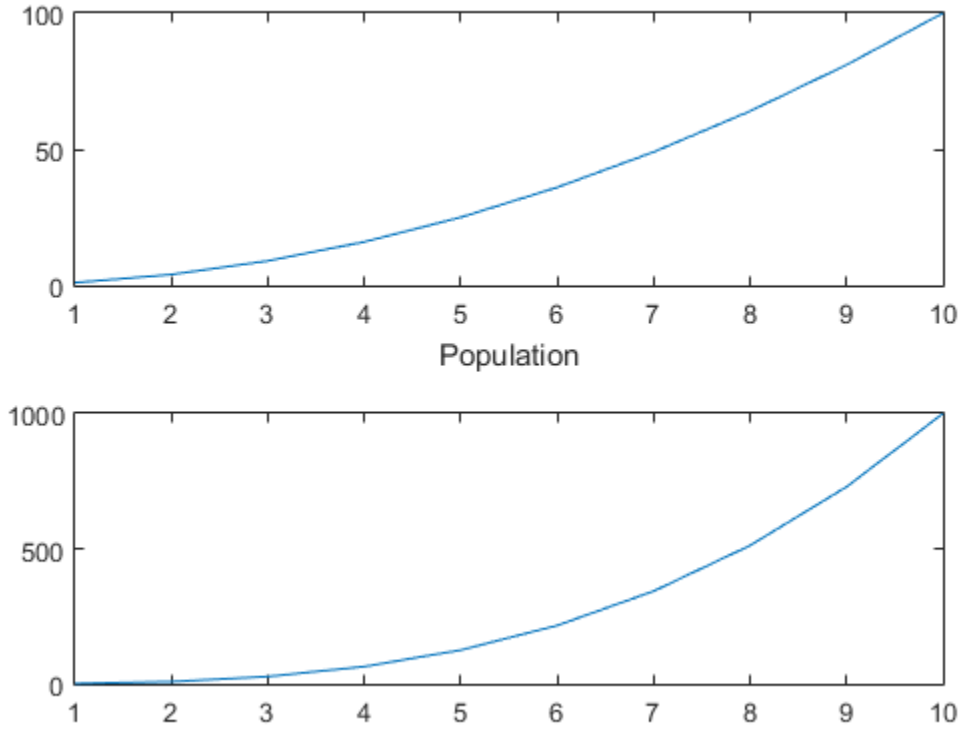


Label x-Axis of Specific Subplot

Create a figure with two subplots. Label the *x*-axis of the top subplot.

```
ax1 = subplot(2,1,1);
plot((1:10).^2)
xlabel(ax1,'Population')

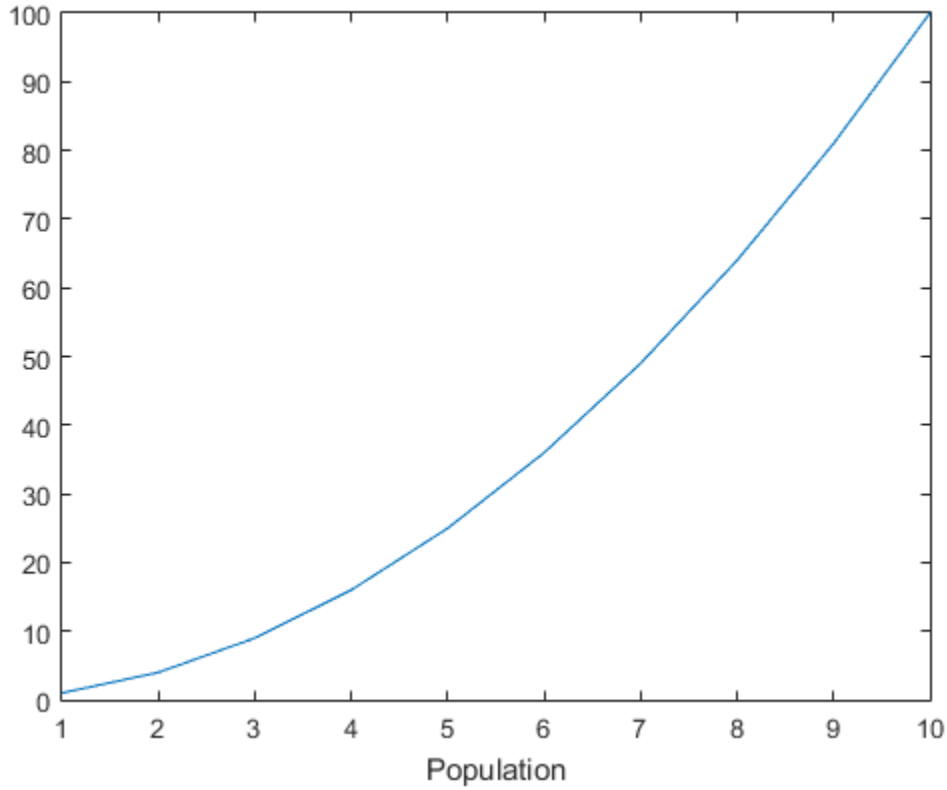
ax2 = subplot(2,1,2);
plot((1:10).^3)
```



Modify x-Axis Label After Creation

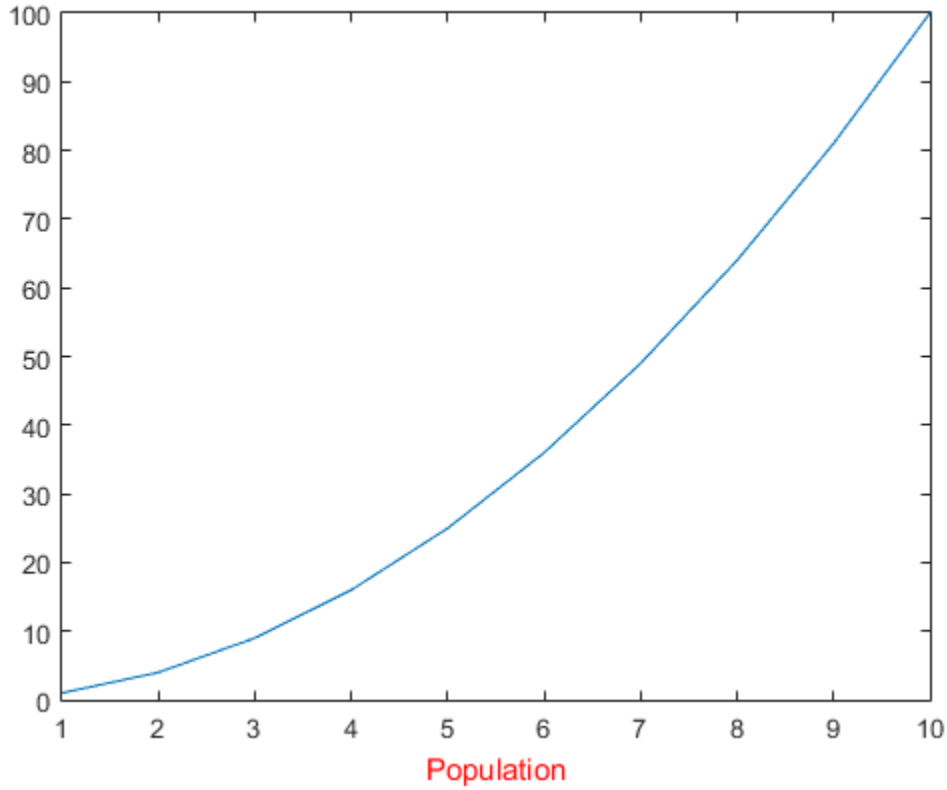
Label the *x*-axis and return the text object used as the label.

```
plot((1:10).^2)
t = xlabel('Population');
```



Use `t` to set text properties of the label after it has been created. For example, set the color of the label to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t.Color = 'red';
```



- “Add Text to Graph Interactively”

Input Arguments

`str` — Axis label

character array | cell array | numeric value

Axis label, specified as a character array, cell array, or numeric value.

Example: `'my label'`

Example: `{'first line','second line'}`

Example: 123

To include numeric variables with text in a label, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the Interpreter property.

To create multiline labels:

- Use a cell array, where each cell contains a line of text, such as `{'first line','second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric labels are converted to text using `sprintf('%g',value)`. For example, `12345678` displays as `1.23457e+07`.

Note: The words `default`, `factory`, and `remove` are reserved words that will not appear in a label when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

ax — Axes object

axes object

Axes object. If you do not specify an axes, then the `xlabel` function adds the label to the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','FontSize',12` specifies red, 12-point font.

The text properties listed here are only a subset. For a complete list, see Text Properties.

`'FontSize'` — Font size

`11` (default) | scalar value greater than `0`

Font size, specified as a scalar value greater than `0` in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Setting the font size properties for the associated axes also affects the label font size. The label font size updates to equal the axes font size times the label scale factor. The `FontSize` property of the axes contains the axes font size. The `LabelFontSizeMultiplier` property of the axes contains the label scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the *x*-axis label font size is 11 points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'FontWeight'` — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

`'FontName'` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`'Color'` — Text color

`[0.15 0.15 0.15]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`'Interpreter'` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`

Modifier	Description	Example of String
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
`\alpha`	α	`\upsilon`	υ	`\sim`	~
`\angle`	∠	`\phi`	Φ	`\leq`	≤
`\ast`	*	`\chi`	χ	`\infty`	∞

\wedge	∧	\varpi	ϖ	\0	∅
\rceil	⌉	\rangle	〉	\mid	|
\vee	∨	\langle	〈	\copyright	©

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

Output Arguments

`t` — Text object

text object

Text object used as the *x*-axis label. Use `t` to access and modify properties of the label after it has been created.

Properties

Text Properties

Introduced before R2006a

matlab.wsdl.createWSDLClient

Create interface to SOAP-based Web service

Syntax

```
matlab.wsdl.createWSDLClient(wsdlURL)
matlab.wsdl.createWSDLClient(wsdlURL,folder)
matlab.wsdl.createWSDLClient(wsdlURL,folder,'silent')

classname = matlab.wsdl.createWSDLClient( ___ )
```

Description

`matlab.wsdl.createWSDLClient(wsdlURL)` creates an interface to a service based on a Web Services Description Language (WSDL) document specified by wsdlURL. This function creates a MATLAB class file for each Simple Object Access Protocol (SOAP) binding in the WSDL and, if required, additional support files in the current folder. You can package and distribute these files to other users.

You must install the WSDL tools, Java JDK™ and Apache™ CXF software, then set the tool paths using the `matlab.wsdl.setWSDLToolPath` function.

You must have write permission for the current folder.

`matlab.wsdl.createWSDLClient(wsdlURL,folder)` creates the interface files in folder, which must be on the MATLAB path.

`matlab.wsdl.createWSDLClient(wsdlURL,folder,'silent')` suppresses display of generated files and folders.

`classname = matlab.wsdl.createWSDLClient( ___ )` returns a handle to the created class. The function returns a cell array of handles if multiple classes were created. You can use this syntax with any of the input arguments of the previous syntaxes.

To get information on using the class, call the MATLAB `help` function on the class name.

Examples

Get Map Name from USGSImageryOnly_MapServer Web Service

You must install the WSDL tools and set the tool paths to run this example. `jdk` and `cxf` are the paths to these tools on your system.

```
matlab.wsdl.setWSDLToolPath('JDK',jdk,'CXF',cxf)
```

Create the class files.

```
url = ...
'http://basemap.nationalmap.gov/arcgis/services/USGSImageryOnly/MapServer?wsdl';
matlab.wsdl.createWSDLClient(url);
```

```
Created USGSImageryOnly_MapServer.
  .\USGSImageryOnly_MapServer.m
  .\+wsdl

In order to use USGSImageryOnly_MapServer, you must run javaaddpath('.\+wsdl\mapserver
```

Add the jar files to the Java path.

```
javaaddpath('.\+wsdl\mapserver.jar')
```

Create the service.

```
wsdl = USGSImageryOnly_MapServer;
```

Read help for the service and its functions.

```
help USGSImageryOnly_MapServer
```

```
USGSImageryOnly_MapServer   A client to connect to the USGSImageryOnly_MapServer servic
     SERVICE = USGSImageryOnly_MapServer  connects to http://basemap.nationalmap.gov/ar

     To communicate with the service, call a function on the SERVICE:

        [...] = FUNCTION(SERVICE,arg,...)

     See doc USGSImageryOnly_MapServer for a list of functions.
```

Call one of the methods, for example `GetDefaultMapName` that returns the map name.

```
GetDefaultMapName(wsdl)
```

```
ans =

Layers
```

- “Set Up WSDL Tools”

Input Arguments

`wsdlURL` — WSDL URL or file path

string

WSDL URL or file path, specified as a string, that defines service methods, arguments, and transactions.

`wsdlURL` can be an `http` or `https` URL or a local path. `wsdlURL` cannot be a `file://` URL. On Microsoft Windows, UNC paths are not supported.

Example: `'http://www.mywebservice.com/servicename?WSDL'`

`folder` — Folder for generated files

string

Folder for generated files, specified as a string. If omitted or empty (`''`), `matlab.wsdl.createWSDLClient` uses the current folder. You must have write permission for the folder. The function overwrites existing files with the same names as the generated files.

Example: `'c:\work'`

Limitations

RPC-encoded WSDL documents are not supported. For these documents, use `createClassFromWsdl`.

The following WSDL documents are not supported:

- Some documents with messages containing multiple parts.
- Some documents with schemas containing anonymous complex types.
- Documents that the Apache CXF program cannot compile into complete code.

More About

Tips

- If you create WSDL files in multiple locations on your computer, avoid confusion by deleting the class files from duplicate locations, and then call `clear java`.

See Also

`clear` | `createClassFromWsdl` | `matlab.wsdl.setWSDLToolPath` | `webread`

Introduced in R2014b

matlab.wsdl.setWSDLToolPath

Location of WSDL tools

Syntax

```
matlab.wsdl.setWSDLToolPath(Name,Value)

paths = matlab.wsdl.setWSDLToolPath
```

Description

`matlab.wsdl.setWSDLToolPath(Name,Value)` sets the paths to Java JDK and Apache CXF software. You must download these tools to use the `matlab.wsdl.createWSDLClient` interface.

Values for the `Name` arguments, `'JDK'` and `'CXF'`, are saved across sessions in your user preferences, so you only need to specify them once. You must specify both values before calling `matlab.wsdl.createWSDLClient`.

`paths = matlab.wsdl.setWSDLToolPath` displays paths to the JDK and CXF software.

Examples

Set Path to Tools

Set `jdk` and `cxf` to valid paths on your system. For example,

```
jdk = 'E:/Program Files/win64/jdk';
cxf = 'c:\apache-cxf-2.7.10'
matlab.wsdl.setWSDLToolPath('JDK',jdk,'CXF',cxf)
```

Check if Tool Paths are Set

```
p = matlab.wsdl.setWSDLToolPath;
if (isempty(p.JDK) || isempty(p.CXF))
    disp('Install the Java Development Kit (JDK) and Apache CXF programs.')
    disp('See the Set Up WSDL Tools example link at the end of this page.')
```

```
else
    disp('Paths set to:')
    matlab.wsdl.setWSDLToolPath
end
```

- "Set Up WSDL Tools"

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'CXF','C:\apache-cxf-2.7.10'`

`'JDK'` — Path to Java JDK software

string

Path to Java Development Kit (JDK) software, specified as a string. Download the software from `http://www.oracle.com/technetwork/java/javase/downloads` and choose the latest release of 7.

Example: `'E:/Program Files/win64/jdk'`

`'CXF'` — Path to Apache CXF software

string

Path to Apache CXF software, specified as a string. CXF is an open-source services framework. Download the software from `http://cxf.apache.org/download` and choose the latest release of 2.7.

Example: `'C:\apache-cxf-2.7.10'`

Output Arguments

`paths` — Tool paths

structure

Tool paths, returned as a structure with the fields:

JDK — Path to Java JDK software
string

Path to Java JDK software, specified as a string. If the value of `JDK` is empty, you cannot call `matlab.wsdl.createWSDLClient`.

CXF — Path to Apache CXF software
string

Path to Apache CXF software, specified as a string. If the value of `CXF` is empty, you cannot call `matlab.wsdl.createWSDLClient`.

- http://www.oracle.com/technetwork/java/javase/downloads
- http://cxf.apache.org/download

See Also

`matlab.wsdl.createWSDLClient`

Introduced in R2014b

year

Year number

Syntax

```
y = year(t)
y = year(t,yearType)
```

Description

`y = year(t)` returns the ISO year numbers for the datetime values in `t`. ISO year numbers include a year zero and represent years BCE using negative values. The `y` output is a `double` array the same size as `t`.

`y = year(t,yearType)` returns the type of year number specified by `yearType`.

The `year` function returns the year numbers of datetime values. To assign ISO year values to a datetime array, `t`, use `t.Year` and modify the `Year` property.

Examples

Extract Year Number from Dates

Extract the year numbers from an array of dates.

```
t = datetime(2010,05,31):calyears(1):datetime(2015,02,28)
```

```
t =

   31-May-2010    31-May-2011    31-May-2012    31-May-2013    31-May-2014
```

```
y = year(t)
```

```
y =
```

2010 2011 2012 2013 2014

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`yearType` — Type of year values

`'iso'` (default) | `'gregorian'`

Type of year values, specified as either `'iso'` or `'gregorian'`.

- If `yearType` is `'iso'`, then `year` returns the ISO year number, which includes a year zero and represents years BCE using negative values.
- If `yearType` is `'gregorian'`, then `year` returns the Gregorian year number, which is an unsigned integer. For example, the Gregorian year number for 5 CE and 5 BCE is 5 in both cases. Gregorian year numbers do not have a year zero.

See Also

datetime Properties | `day` | `month` | `quarter` | `week` | `ymd`

Introduced in R2014b

years

Duration in years

Syntax

```
Y = years(X)
```

Description

`Y = years(X)` returns an array of years equivalent to the values in `X`.

- If `X` is a numeric array, then `Y` is a `duration` array in units of fixed-length years. A fixed-length year is equal to 365.2425 days.
- If `X` is a `duration` array, then `Y` is a `double` array with each element equal to the number of fixed-length years in the corresponding element of X.

The `years` function converts between `duration` and `double` values. To display a duration in units of years, set its `Format` property to `'y'`.

Examples

Create Duration Array of Fixed-Length Years

```
X = [1 3 5; 10 12 15]
```

```
X =

     1     3     5
    10    12    15
```

```
Y = years(X)
```

```
Y =
```

```
   1 yr    3 yrs    5 yrs
  10 yrs   12 yrs   15 yrs
```

Convert Durations to Numeric Array of Years

Find the difference between two arrays of dates. The output is a `duration` array.

```
t1 = datetime(2007:2010,10,1);
t2 = datetime(2014,05,1);
dt = t2 - t1
```

```
dt =

   57696:00:00   48912:00:00   40152:00:00   31392:00:00
```

Convert each duration in `dt` to a number of fixed-length years.

```
Y = years(dt)
```

```
Y =

    6.5819    5.5799    4.5805    3.5812
```

Input Arguments

X — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

More About

Tips

- `years` creates fixed-length years. To create an array of calendar years that account for leap days when used in calendar calculations, use the `calyears` function.

See Also

`calyears`

Introduced in R2014b

ylabel

Label y-axis

Syntax

```
ylabel(str)
ylabel(str,Name,Value)

ylabel(ax, ___ )

h = ylabel( ___ )
```

Description

`ylabel(str)` labels the *y*-axis of the current axes with the string, `str`. Reissuing the `ylabel` command causes the new label to replace the old label. Labels appear beside the axis in a two-dimensional view and to the side or in front of the axis in a three-dimensional view.

`ylabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`ylabel(ax, ___ )` adds the label to the axes specified by `ax`. This syntax allows you to specify the axes to which to add a label. `ax` can precede any of the input argument combinations in the previous syntaxes.

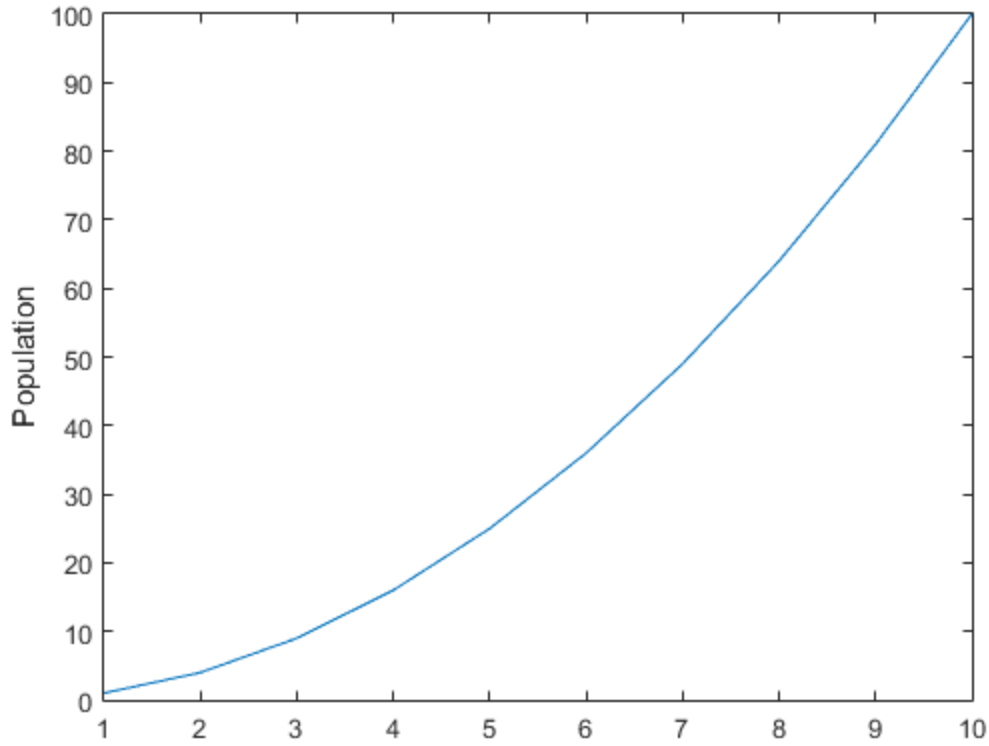
`h = ylabel( ___ )` returns the handle to the text object used as the *y*-axis label. The handle is useful when making future modifications to the label.

Examples

Label y-Axis with String

```
figure
```

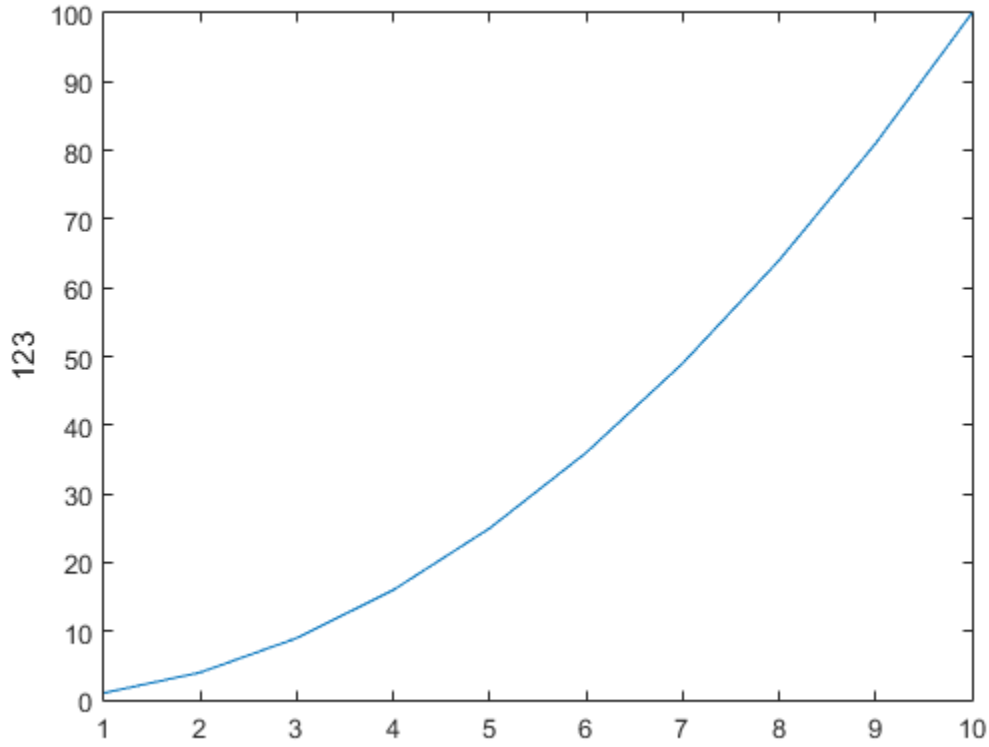
```
plot((1:10).^2)
ylabel('Population')
```



MATLAB® displays `Population` beside the *y*-axis.

Label y-Axis with Numeric Input

```
figure
plot((1:10).^2)
ylabel(123)
```

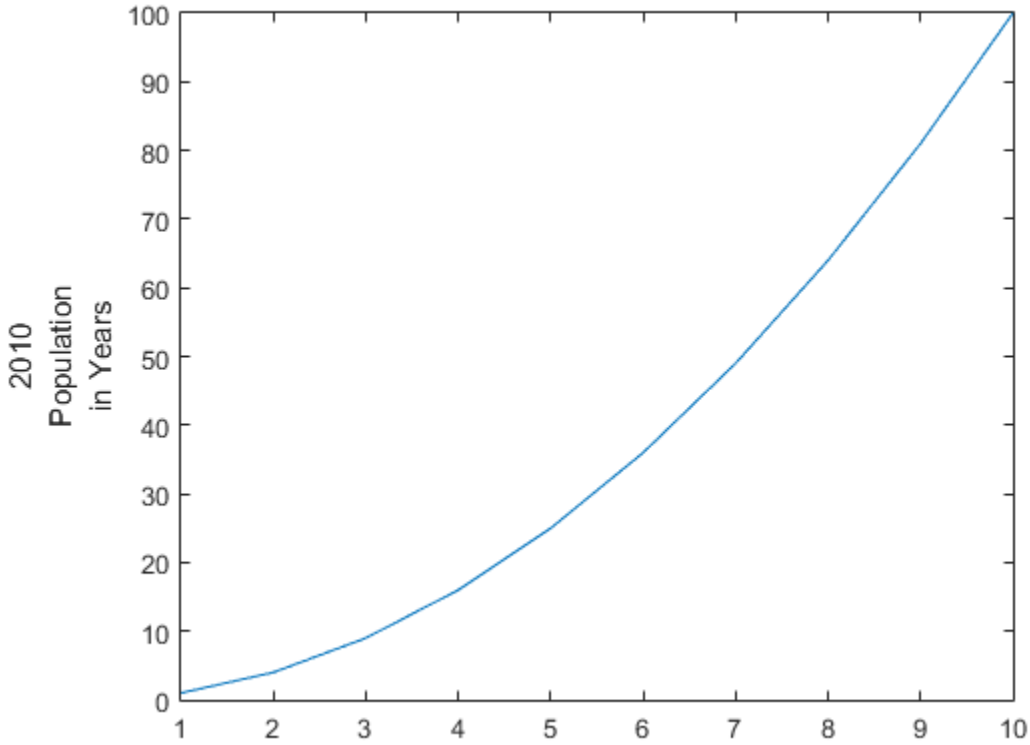


MATLAB® displays `123` beside the *y*-axis.

Create Multiline Label

Create a multiline label using a multiline cell array.

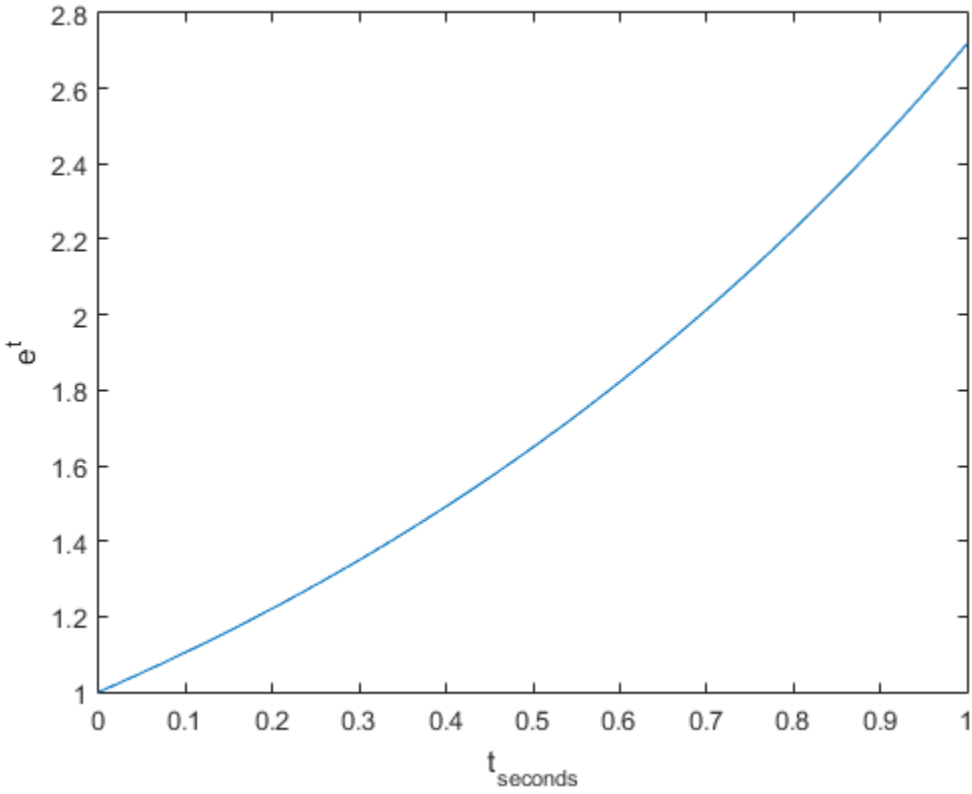
```
figure
plot((1:10).^2)
ylabel({2010;'Population';'in Years'})
```



Include Superscript and Subscript in Axis Labels

Use the `'^'` and `'_'` characters to include superscripts and subscripts in the axis labels. Use curly braces `{}` to modify more than one character.

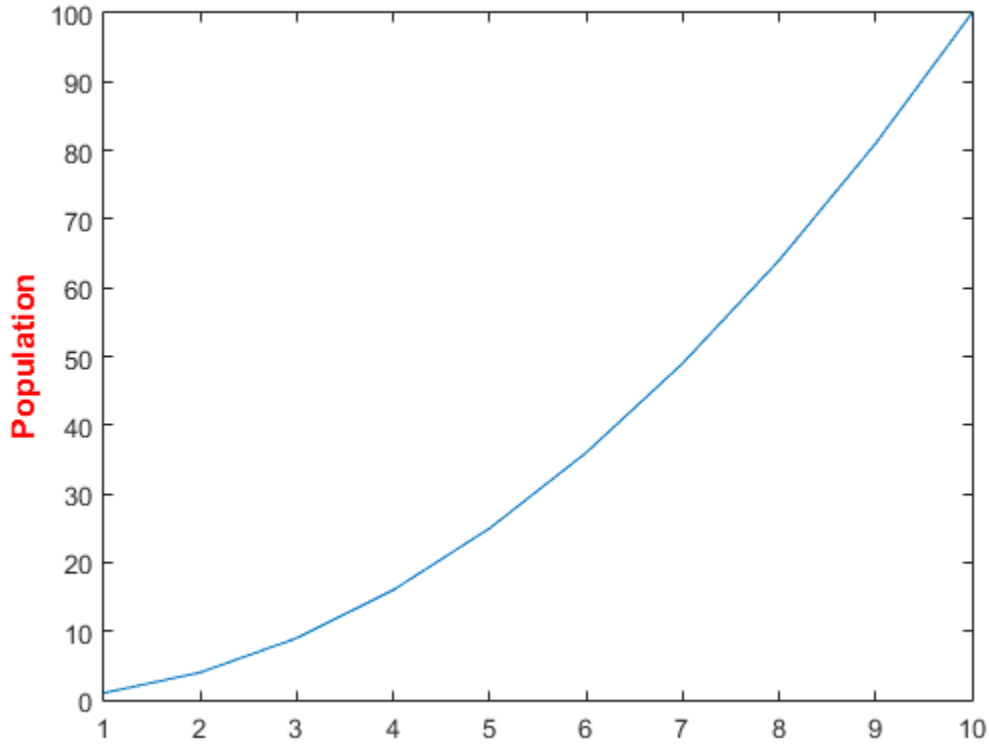
```
t = linspace(0,1);
y = exp(t);
plot(t,y)
xlabel('t_{seconds}')
ylabel('e^t')
```



Create y-Axis Label and Set Font Properties

Use `Name,Value` pairs to set the font size, font weight, and text color properties of the *y*-axis label.

```
figure
plot((1:10).^2)
ylabel('Population','FontSize',12,...
       'FontWeight','bold','Color','r')
```

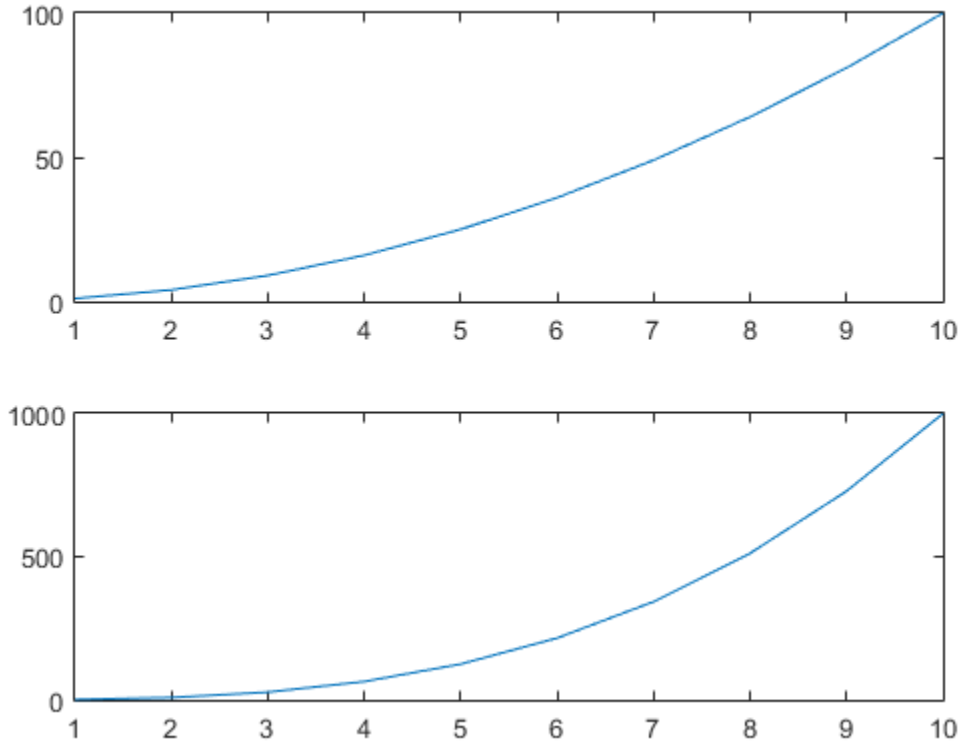


`'FontSize',12` displays the label text in 12-point font. `'FontWeight','bold'` makes the text bold. `'Color','r'` sets the text color to red.

Label y-Axis of Specific Axes

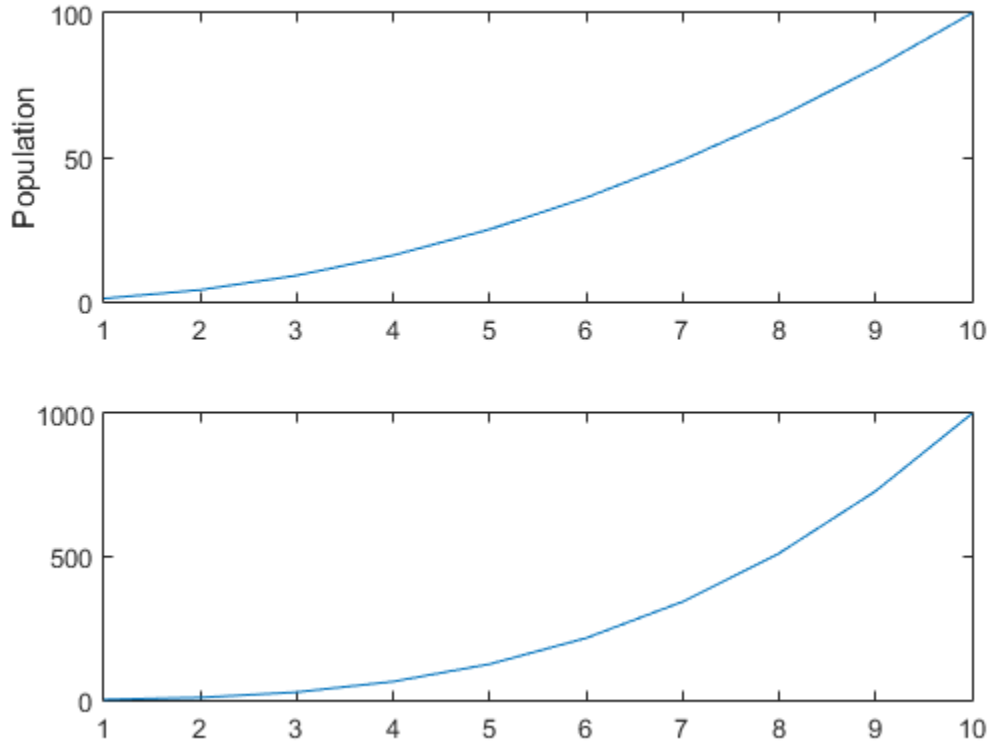
Create two subplots and return the axes handles, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```



Label the *y*-axis of the top plot by referring to its axes handle, `s(1)`.

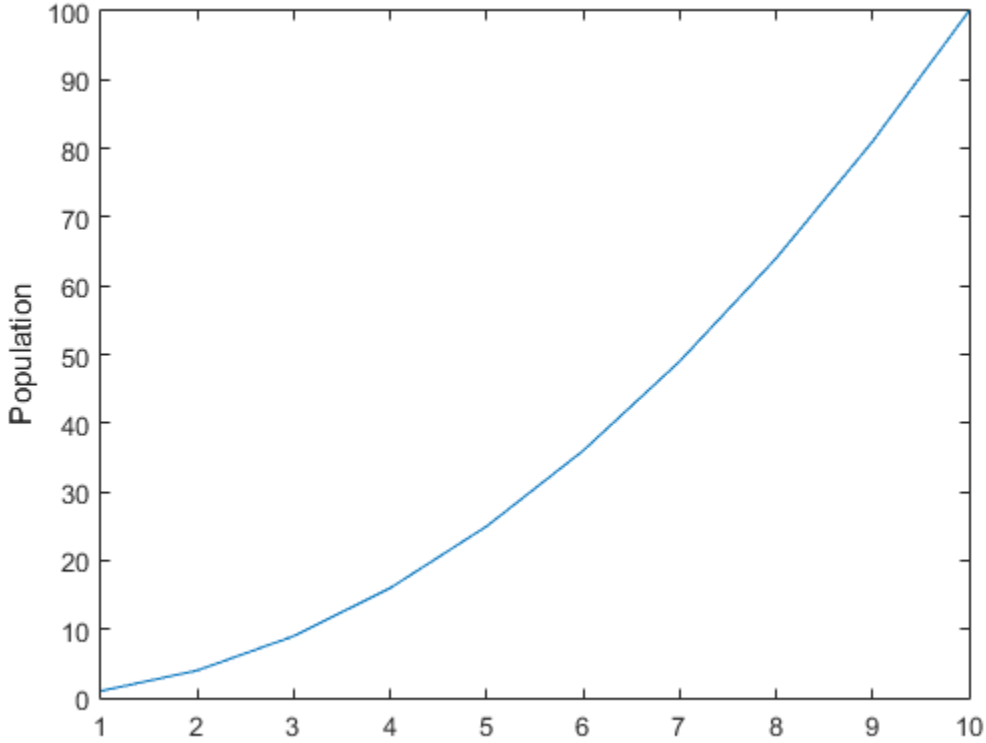
```
ylabel(s(1),'Population')
```



Label y-Axis and Return Object Handle

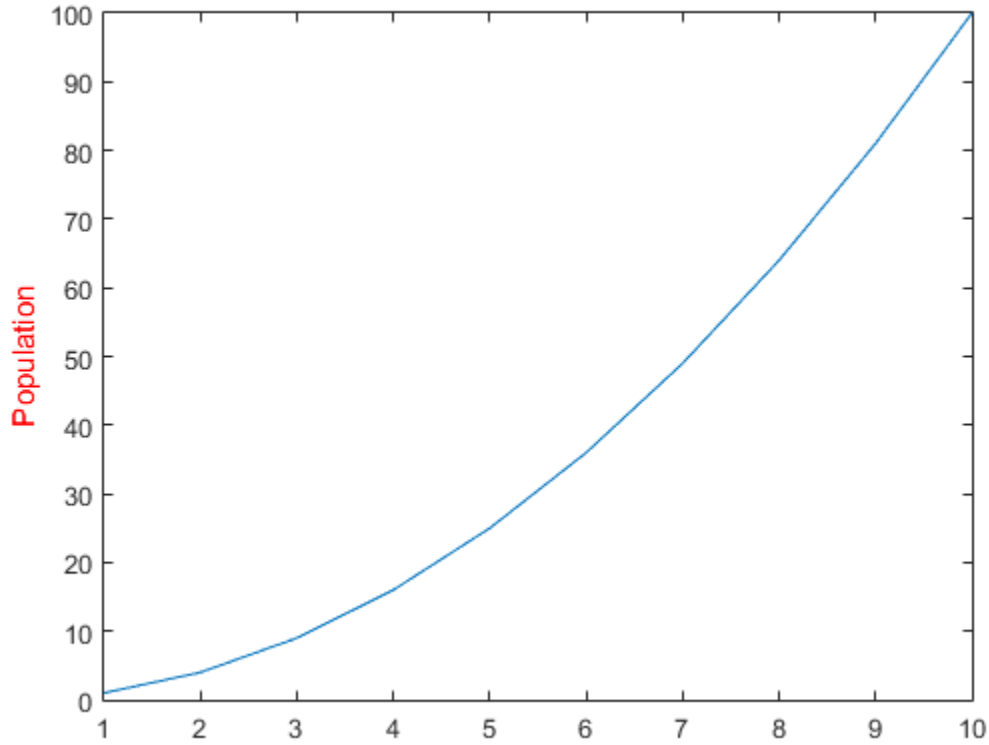
Label the *y*-axis and return the handle to the text object used as the label.

```
plot((1:10).^2)
t = ylabel('Population');
```



Set the color of the label to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t.Color = 'red';
```



- “Add Text to Graph Interactively”

Input Arguments

`str` — Axis label

character array | cell array | numeric value

Axis label, specified as a character array, cell array, or numeric value.

Example: `'my label'`

Example: `{'first line','second line'}`

Example: 123

To include numeric variables with text in a label, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the Interpreter property.

To create multiline labels:

- Use a cell array, where each cell contains a line of text, such as `{'first line','second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric labels are converted to text using `sprintf('%g',value)`. For example, `12345678` displays as `1.23457e+07`.

Note: The words `default`, `factory`, and `remove` are reserved words that will not appear in a label when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

ax — Axes object

axes object

Axes object. If you do not specify an axes, then the `ylabel` function uses the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','FontSize',12` specifies red, 12-point font.

In addition to the following, you can specify other text object properties using `Name,Value` pair arguments. See Text Properties.

`'FontSize'` — Font size

`11` (default) | scalar value greater than `0`

Font size, specified as a scalar value greater than `0` in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Setting the font size properties for the associated axes also affects the label font size. The label font size updates to equal the axes font size times the label scale factor. The `FontSize` property of the axes contains the axes font size. The `LabelFontSizeMultiplier` property of the axes contains the label scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the *y*-axis label font size is 11 points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'FontWeight'` — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

`'FontName'` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`'Color'` — Text color

`[0.15 0.15 0.15]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`'Interpreter'` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`

Modifier	Description	Example of String
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
`\alpha`	α	`\upsilon`	υ	`\sim`	~
`\angle`	∠	`\phi`	Φ	`\leq`	≤
`\ast`	*	`\chi`	χ	`\infty`	∞
`\beta`	ß	`\psi`	ψ	`\clubsuit`	♣
`\gamma`	γ	`\omega`	ω	`\diamondsui`	♦
`\delta`	δ	`\Gamma`	Γ	`\heartsuit`	♥
`\epsilon`	ε	`\Delta`	Δ	`\spadesuit`	♠
`\zeta`	ζ	`\Theta`	Θ	`\leftrighta`	↔
`\eta`	η	`\Lambda`	Λ	`\leftarrow`	←
`\theta`	Θ	`\Xi`	Ξ	`\Leftarrow`	⇐
`\vartheta`	ϑ	`\Pi`	Π	`\uparrow`	↑
`\iota`	ι	`\Sigma`	Σ	`\rightarrow`	→
`\kappa`	κ	`\Upsilon`	ϒ	`\Rightarrow`	⇒
`\lambda`	λ	`\Phi`	Φ	`\downarrow`	↓
`\mu`	µ	`\Psi`	Ψ	`\circ`	º
`\nu`	ν	`\Omega`	Ω	`\pm`	±
`\xi`	ξ	`\forall`	∀	`\geq`	≥

\rceil	⌉	\rangle	〉	\mid	|
\vee	∨	\langle	〈	\copyright	©

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

Output Arguments

h — Text object

text object

Text object used as the *y*-axis label. Use `h` to access and modify properties of the label after its created.

See Also

Functions

`num2str` | `text` | `title` | `xlabel` | `zlabel`

Properties

Text Properties

Introduced before R2006a

ymd

Year, month, and day numbers of datetime

Syntax

```
[y,m,d] = ymd(t)
```

Description

`[y,m,d] = ymd(t)` returns the year, month, and day numbers of the datetime values in `t` as separate numeric arrays. The `y`, `m`, and `d` outputs are the same size as `t`, and contain integer values.

The `ymd` function is equivalent to calling the `year`, `month`, and `day` functions on the same datetime array.

Examples

Find Year, Month, and Day Numbers of Dates

```
t = datetime(2013,05,31):calmonths(3):datetime(2014,06,15)
```

```
t =

   31-May-2013   31-Aug-2013   30-Nov-2013   28-Feb-2014   31-May-2014
```

```
[y,m,d] = ymd(t)
```

```
y =

        2013        2013        2013        2014        2014

m =
```

```
     5     8    11     2     5

d =

    31    31    30    28    31
```

`ymd` returns the year, month, and day values in separate arrays.

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

Output Arguments

`y` — ISO year numbers

scalar | vector | matrix | multidimensional array

ISO year numbers, returned as a scalar, vector, matrix, or multidimensional array of integer values. ISO year numbers include a year zero and represent years BCE using negative values. `y` is of type `double` and is the same size as `t`.

`m` — Month numbers

scalar | vector | matrix | multidimensional array

Month numbers, returned as a scalar, vector, matrix, or multidimensional array of integer values from 1 to 12. `m` is of type `double` and is the same size as `t`.

`d` — Day of month numbers

scalar | vector | matrix | multidimensional array

Day of month numbers, returned as a scalar, vector, matrix, or multidimensional array of integer values from 1 to 28, 29, 30, or 31, depending on the month and year. `d` is of type `double` and is the same size as `t`.

See Also

`day` | `hms` | `month` | `quarter` | `week` | `year`

Introduced in R2014b

yyyymmdd

Convert MATLAB datetime to YYYYMMDD numeric value

Syntax

```
d = yyyymmdd(t)
```

Description

`d = yyyymmdd(t)` returns a `double` array containing integers whose digits represent the datetime values in `t`. For example, the date July 16, 2014 is converted to the integer 20140716. The conversion is performed this way:

```
d = 10000*year(t) + 100*month(t) + day(t)
```

Examples

Convert Datetime Array to YYYYMMDD Numeric Values

Create an array of YYYYMMDD numeric values that represent dates.

```
d = [20140628 20140701 20140704]
```

```
d =

    20140628    20140701    20140704
```

Convert the dates to datetime values.

```
t = datetime(d,'ConvertFrom','yyyymmdd')
```

```
t =

   28-Jun-2014 00:00:00   01-Jul-2014 00:00:00   04-Jul-2014 00:00:00
```

Convert the datetime values back to YYYYMMDD numeric values.

```
d2 = yyyymmdd(t)
```

```
d2 =

    20140628     20140701     20140704
```

Input Arguments

t — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`datenum` | `datetime` | `exceltime` | `juliandate` | `posixtime`

Introduced in R2014b

zlabel

Label z-axis

Syntax

```
zlabel(str)
zlabel(str,Name,Value)

zlabel(ax, ___ )

h = zlabel( ___ )
```

Description

`zlabel(str)` labels the *z*-axis of the current axes with the string, `str`. Reissuing the `zlabel` command causes the new label to replace the old label.

`zlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

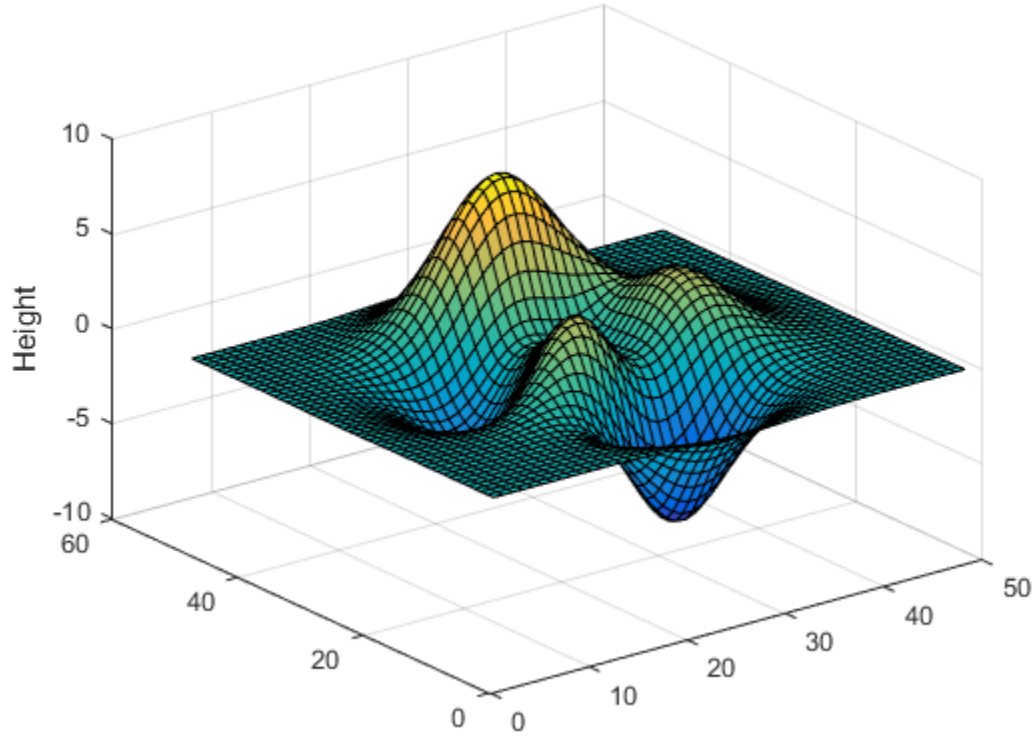
`zlabel(ax, ___ )` adds the label to the axes specified by `ax`. This syntax allows you to specify the axes to which to add a label. `ax` can precede any of the input argument combinations in the previous syntaxes.

`h = zlabel( ___ )` returns the handle to the text object used as the *z*-axis label. The handle is useful when making future modifications to the label.

Examples

Label z-Axis with String

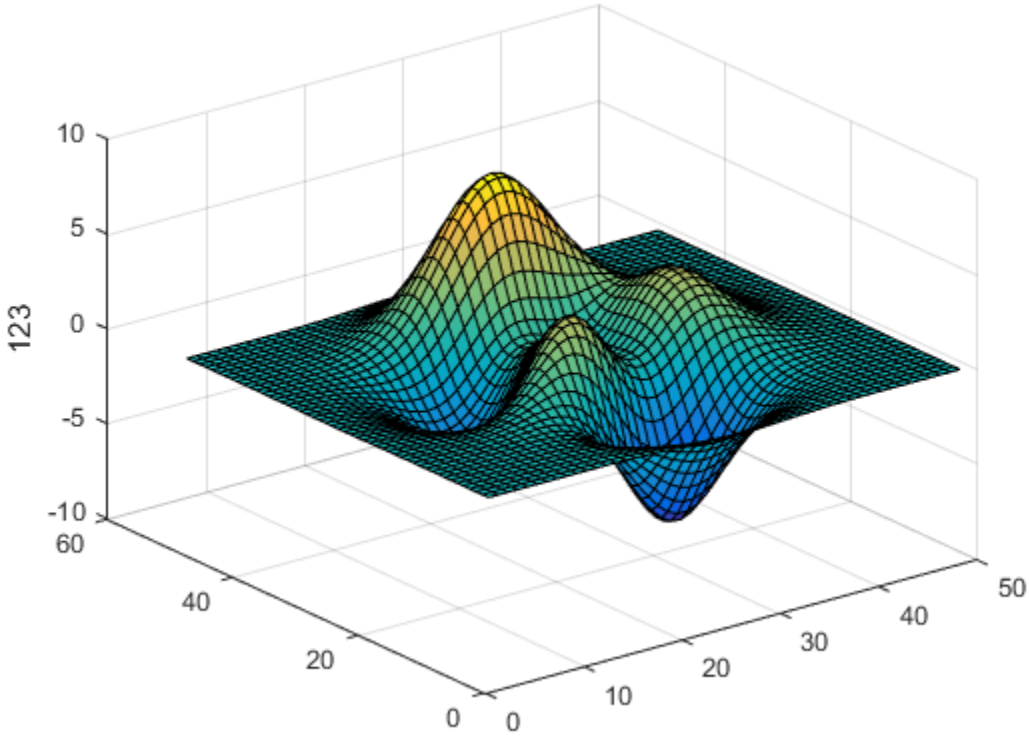
```
figure
surf(peaks)
zlabel('Height')
```



MATLAB® displays `Height` beside the *z*-axis.

Label z-Axis with Numeric Input

```
figure
surf(peaks)
zlabel(123)
```

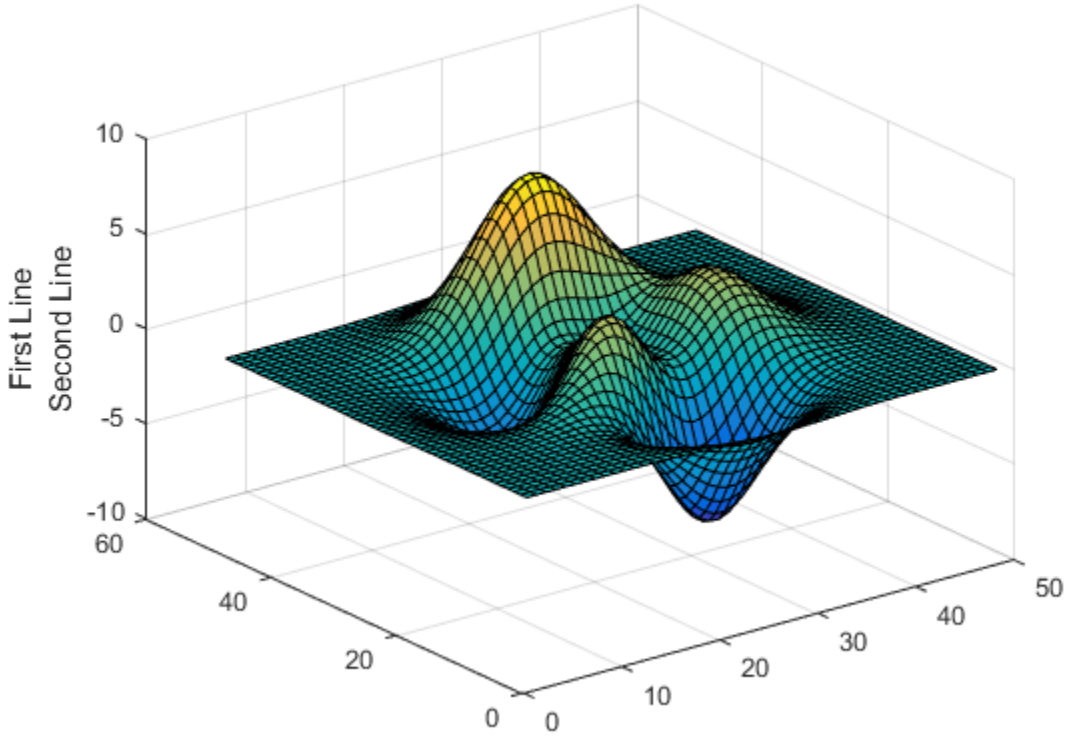


MATLAB® displays `123` beside the *z*-axis.

Create Multiline z-Axis Label

Create a multiline label using a multiline cell array.

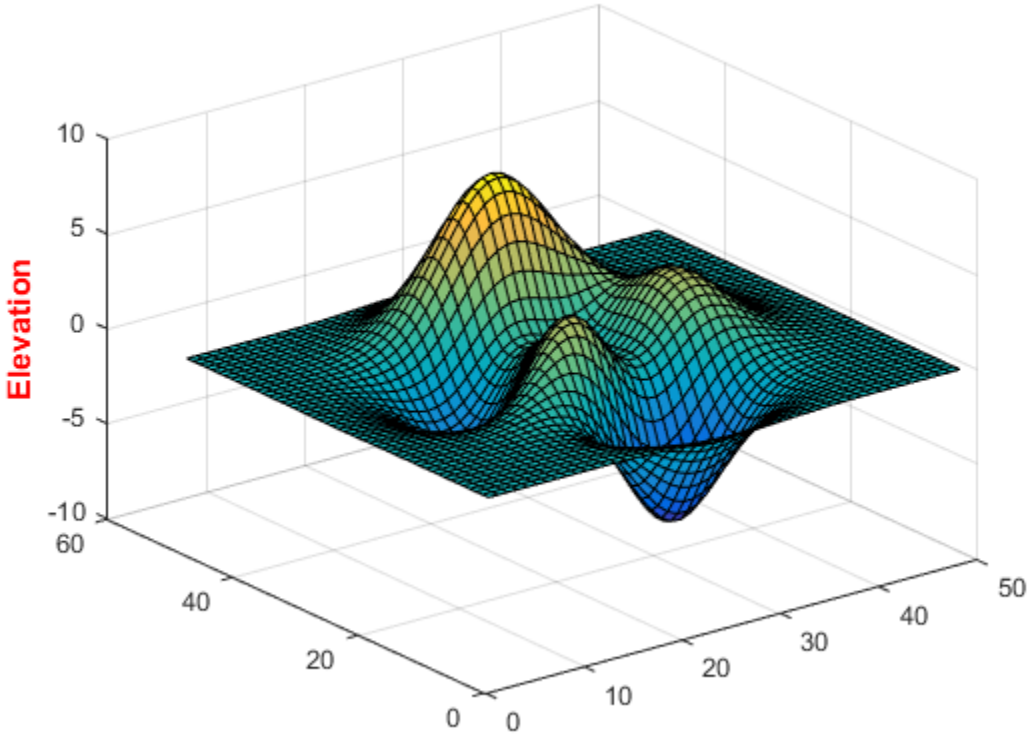
```
figure
surf(peaks)
zlabel({'First Line';'Second Line'})
```



Label z-Axis and Set Font Properties

Use `Name,Value` pairs to set the font size, font weight, and text color properties of the *z*-axis label.

```
figure
surf(peaks)
zlabel('Elevation','FontSize',12,...
       'FontWeight','bold','Color','r')
```

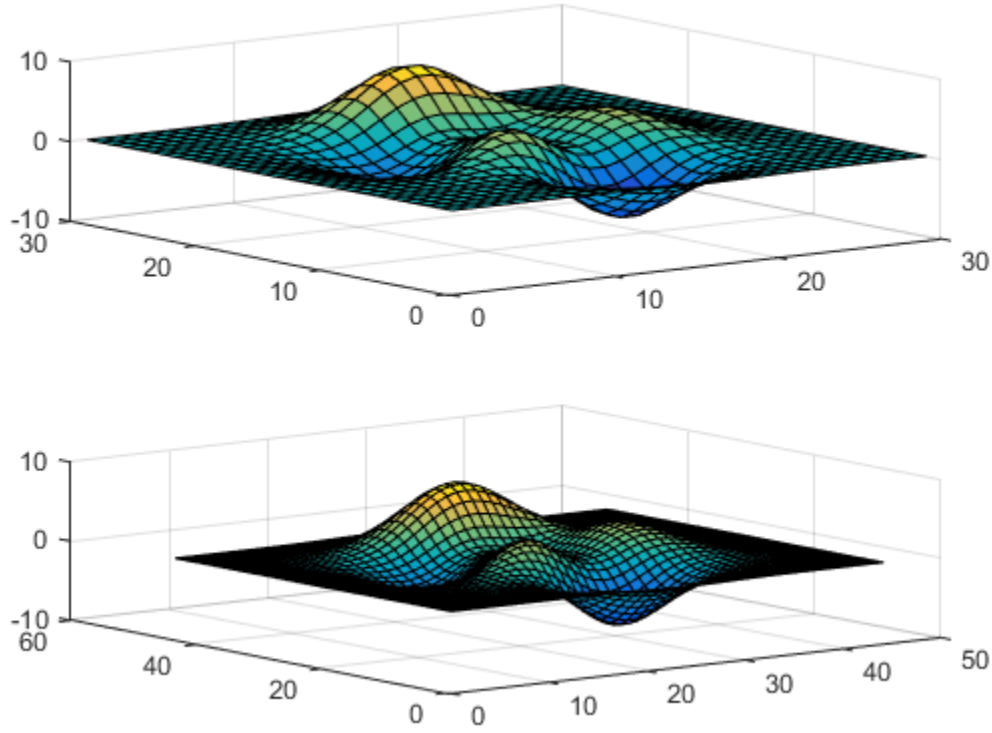


`'FontSize',12` displays the label text in 12-point font. `'FontWeight','bold'` makes the text bold. `'Color','r'` sets the text color to red.

Label z-Axis of Specific Axes

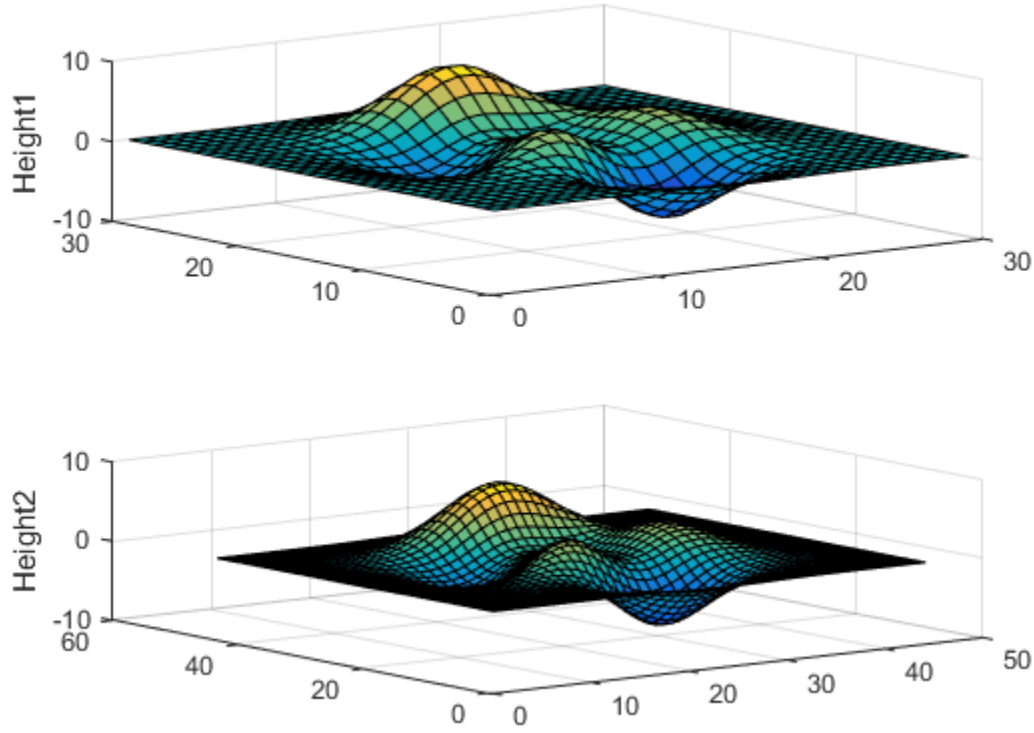
Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
surf(peaks(30))
s(2) = subplot(2,1,2);
surf(peaks(45))
```



Label the *z*-axis of each plot by referring to the axes handles, `s(1)` and `s(2)`.

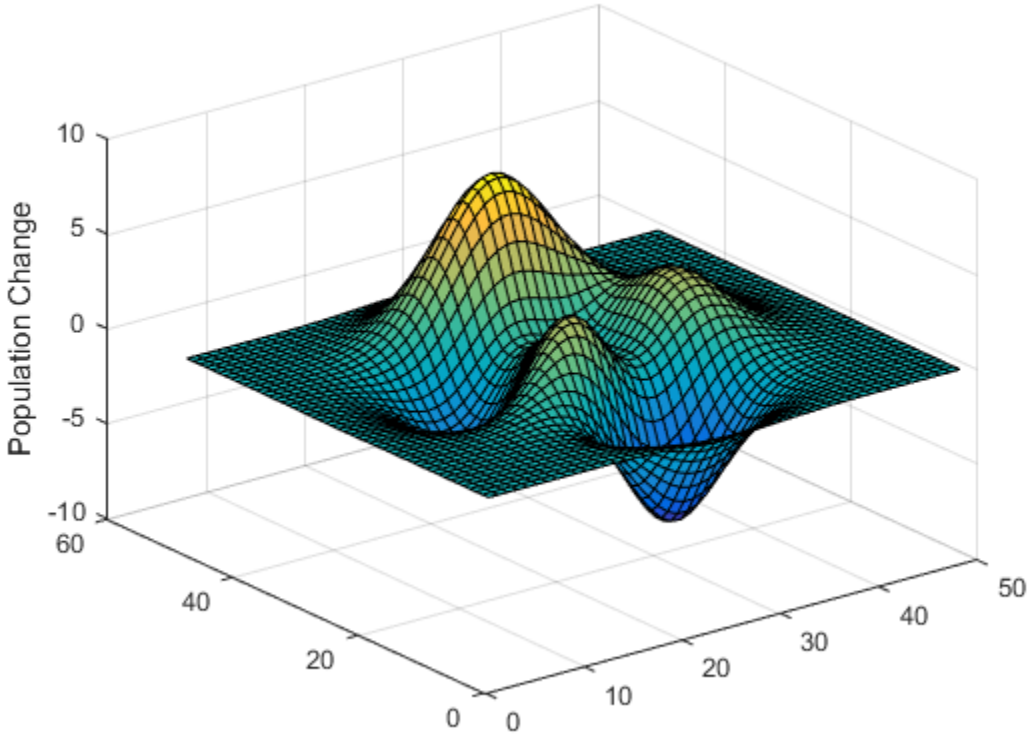
```
zlabel(s(1),'Height1')
zlabel(s(2),'Height2')
```



Label z-Axis and Return Object Handle

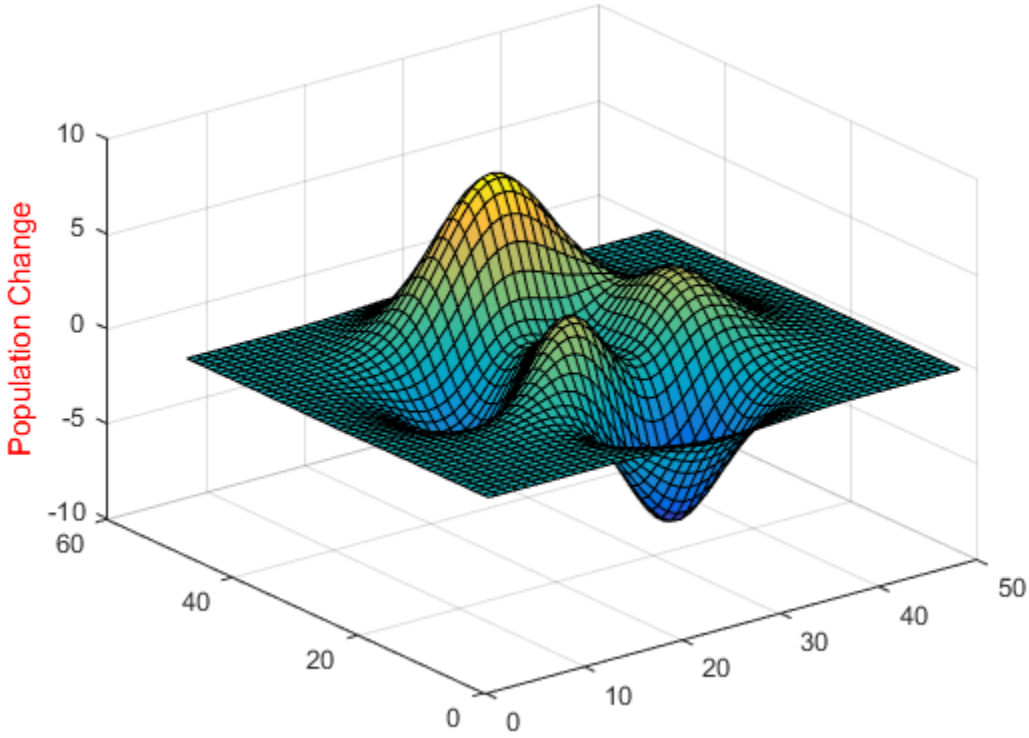
Label the *z*-axis and return the text object used as the label.

```
surf(peaks)
t = zlabel('Population Change');
```



Set the color of the label to red. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
t.Color = 'red';
```



- “Add Text to Graph Interactively”

Input Arguments

`str` — Axis label

character array | cell array | numeric value

Axis label, specified as a character array, cell array, or numeric value.

Example: `'my label'`

Example: `{'first line','second line'}`

Example: 123

To include numeric variables with text in a label, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the Interpreter property.

To create multiline labels:

- Use a cell array, where each cell contains a line of text, such as `{'first line','second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`.

Numeric labels are converted to text using `sprintf('%g',value)`. For example, `12345678` displays as `1.23457e+07`.

Note: The words `default`, `factory`, and `remove` are reserved words that will not appear in a label when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

---

ax — Axes object

axes object

Axes object. If you do not specify an axes, then the `zlabel` function uses the current axes.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','FontSize',12` specifies red, 12-point font.

In addition to the following, you can specify other text object properties using `Name,Value` pair arguments. See Text Properties.

`'FontSize'` — Font size

`11` (default) | scalar value greater than `0`

Font size, specified as a scalar value greater than `0` in point units. One point equals 1/72 inch. To change the font units, use the `FontUnits` property.

Setting the font size properties for the associated axes also affects the label font size. The label font size updates to equal the axes font size times the label scale factor. The `FontSize` property of the axes contains the axes font size. The `LabelFontSizeMultiplier` property of the axes contains the label scale factor. By default, the axes font size is 10 points and the scale factor is 1.1, so the *z*-axis label font size is 11 points.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'FontWeight'` — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

`'FontName'` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`'Color'` — Text color

`[0.15 0.15 0.15]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.6 0.7]`

Example: `'blue'`

`'Interpreter'` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`

Modifier	Description	Example of String
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

Output Arguments

h — Text object

text object

Text object used as the *z*-axis label. Use `h` to access and modify properties of the label after its created.

See Also

Functions

`num2str` | `text` | `title` | `xlabel` | `ylabel`

Properties

Text Properties

Introduced before R2006a

xlim

Set or query *x*-axis limits

Syntax

```
xlim(limits)

xlim auto
xlim manual

xl = xlim
m = xlim('mode')

___ = xlim(ax, ___ )
```

Description

`xlim(limits)` specifies the *x*-axis limits for the current axes. Specify `limits` as a two-element vector of the form `[xmin xmax]`, where `xmax` is a numeric value greater than `xmin`.

`xlim auto` lets the axes choose the *x*-axis limits. The axes chooses limits that span the range of the plotted data. This command sets the `XLimMode` property for the axes to `'auto'`.

`xlim manual` freezes the limits at the current values. Use this option if you want to retain the current limits when adding new data to the axes using the `hold on` command. This command sets the `XLimMode` property for the axes to `'manual'`.

`xl = xlim` returns a two-element vector containing the current limits.

`m = xlim('mode')` returns the current value of the limits mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify limits or set the mode to manual.

`___ = xlim(ax, ___ )` uses the axes specified by `ax` instead of the current axes. Specify an axes with any of the input or output arguments in previous syntaxes.

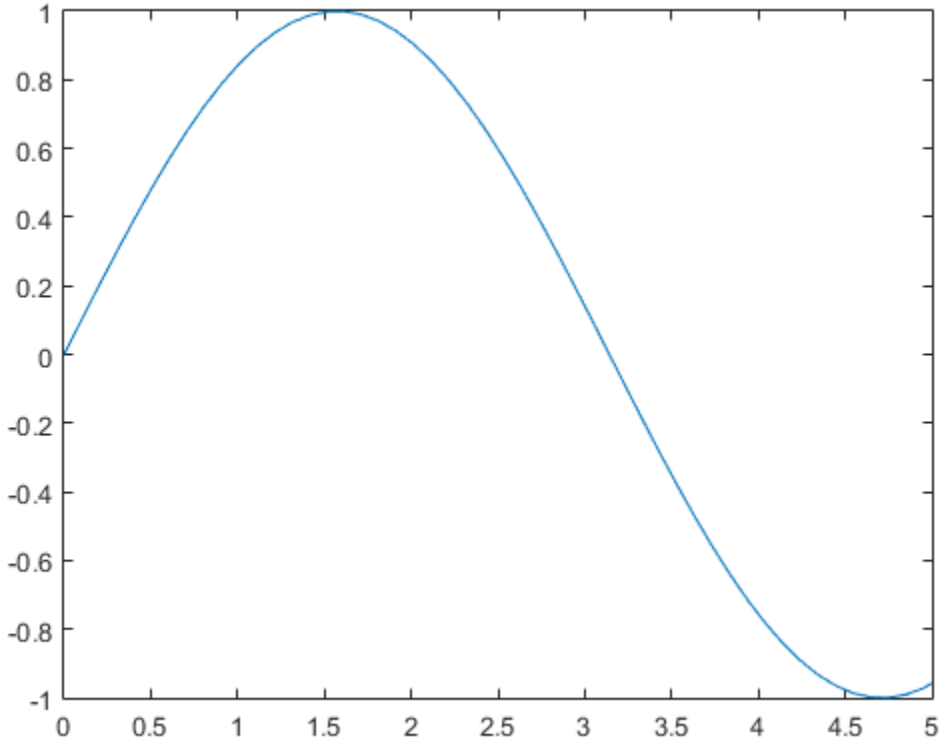
Use single quotes around input arguments that are character strings, for example, `xlim(ax,'auto')` and `xlim(ax,'manual')`.

Examples

Set *x*-Axis Limits

Plot a line and set the *x*-axis limits to range from 0 to 5.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
xlim([0 5])
```

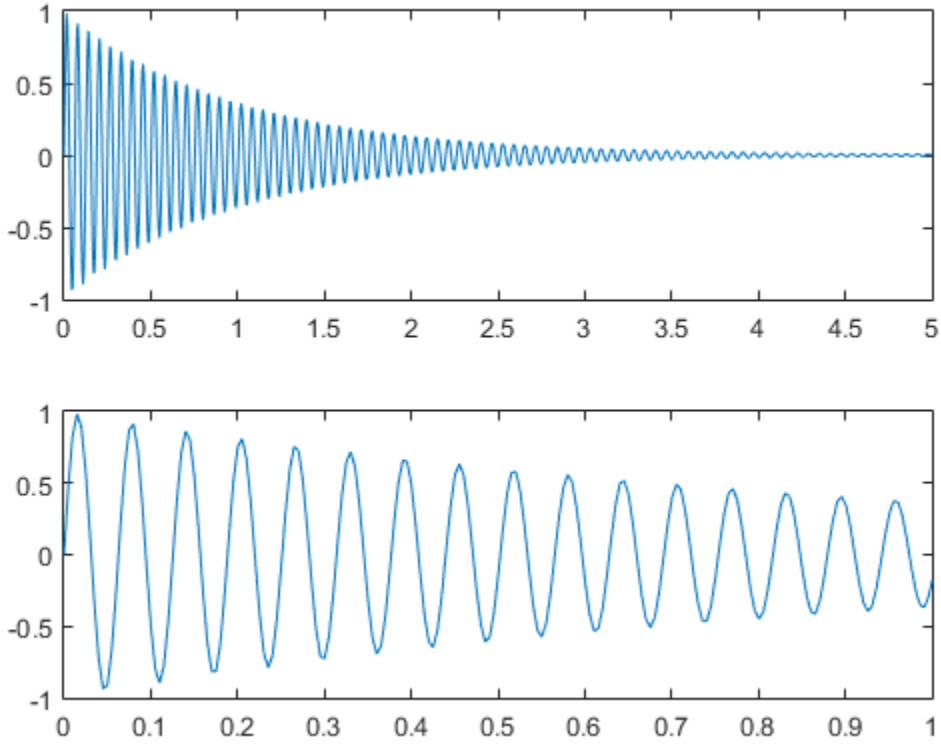


Set *x*-Axis Limits for Specific Axes

Create a figure with two subplots and plot the same data in each subplot. Set the *x*-axis limits for the bottom subplot.

```
x = linspace(0,5,1000);
y = sin(100*x)./exp(x);
ax1 = subplot(2,1,1);
plot(x,y)

ax2 = subplot(2,1,2);
plot(x,y)
xlim(ax2,[0 1])
```

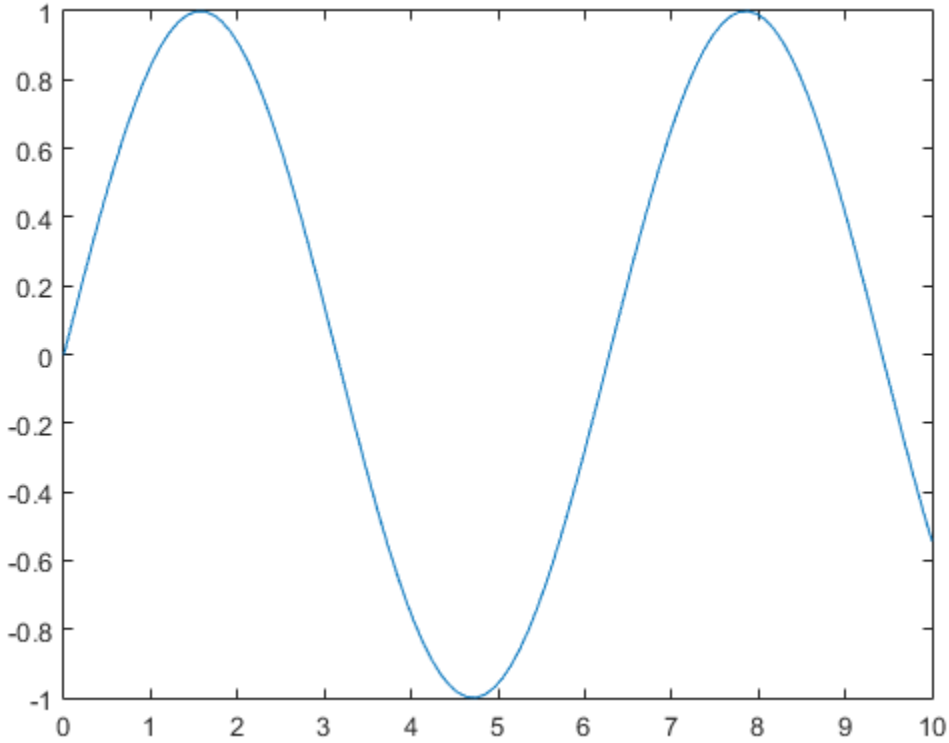


Maintain Current *x*-Axis Limits

Use manual mode to maintain the current x-axis limits when you add more plots to the axes.

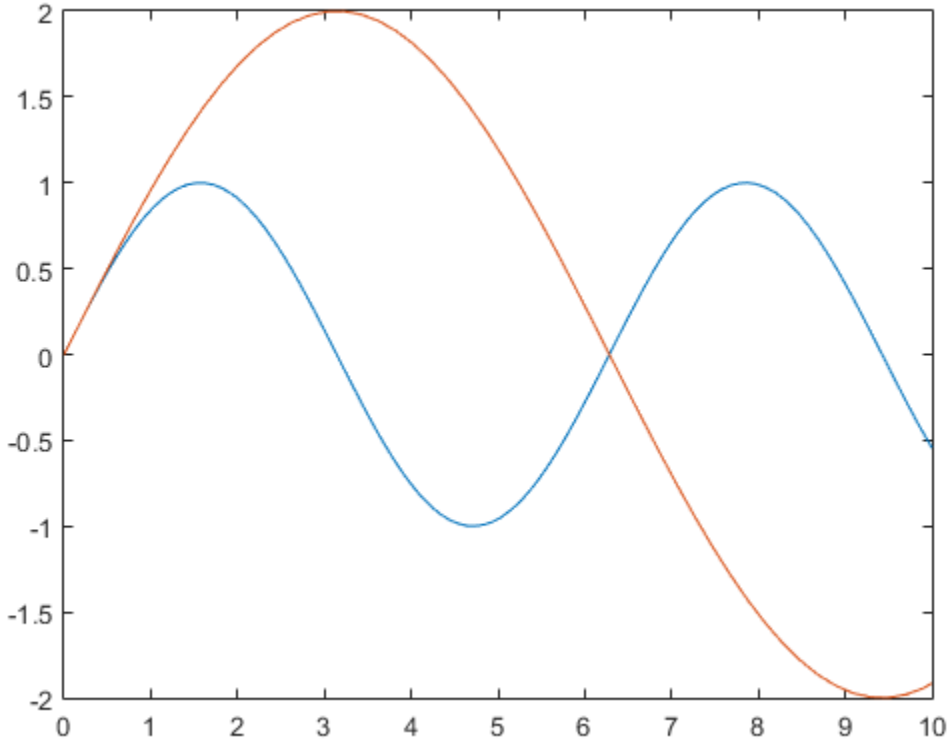
First, plot a line.

```
x = linspace(0,10);
y = sin(x);
plot(x,y);
```



Set the *x*-axis limits mode to manual so that the limits do not change. Use `hold on` to add a second plot to the axes.

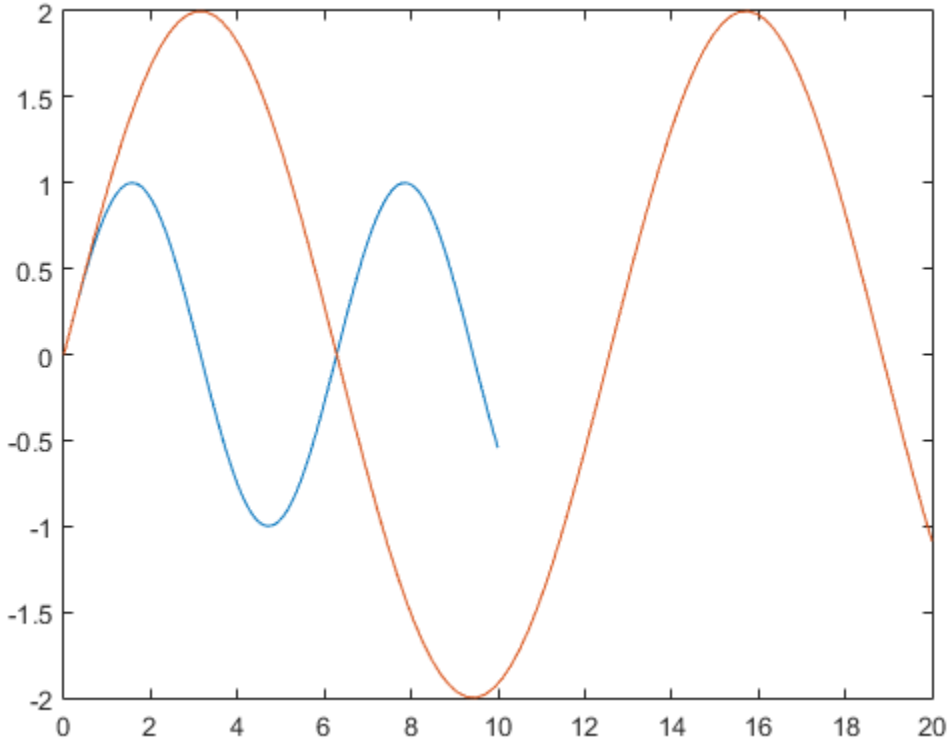
```
xlim manual
hold on
plot(2*x,2*y)
hold off
```



The *x*-axis limits do not update to incorporate the new plot.

Switch back to automatically updated limits by resetting the mode to automatic.

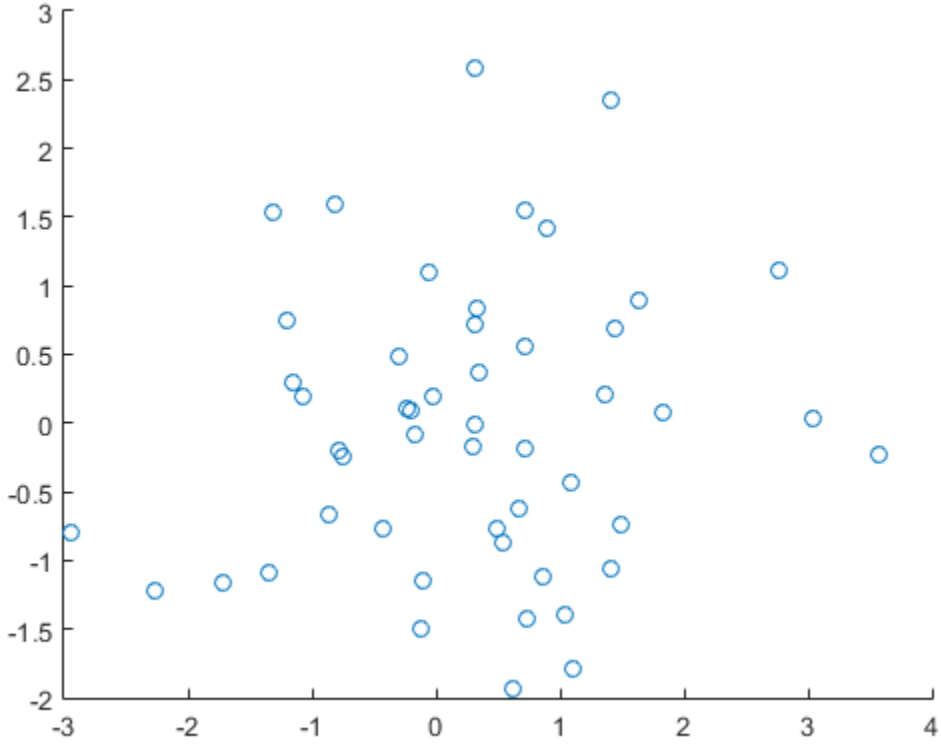
```
xlim auto
```



Return *x*-Axis Limits

Create a scatter plot of random data. Return the values of the *x*-axis limits.

```
x = randn(50,1);
y = randn(50,1);
scatter(x,y)
```



```
xl = xlim
```

```
xl =

    -3     4
```

Input Arguments

`limits` — Minimum and maximum limits

two-element vector

Minimum and maximum limits, specified as a two-element vector of the form `[xmin xmax]`. Specifying the *x*-axis limits sets the *x*-axis limits mode to manual. The `XLim` and `XLimMode` properties for the corresponding axes store the *x*-axis limits and the limits mode, respectively.

Changing the *x*-axis limits can cause other limits to change, unless their corresponding mode properties are set to manual.

Example: `[0 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`ax` — Axes object

axes object

Axes object. If you do not specify an axes, then `xlim` sets the limits for the current axes (`gca`).

Output Arguments

`xl` — Current limits

two-element vector

Current limits, returned as a two-element vector of the form `[xmin xmax]`.

Querying the limits returns the `XLim` property value for the corresponding axes.

`m` — Current limits mode

`'auto'` | `'manual'`

Current limits mode, returned as one of these values:

- `'auto'` — The limits automatically update to reflect changes in the data.
- `'manual'` — The limits do not update to reflect changes in the data.

Querying the *x*-axis limits mode returns `XLimMode` property value for the corresponding axes.

See Also

`axis` | `grid` | `hold` | `xlabel` | `ylim` | `zlim`

Introduced before R2006a

ylim

Set or query *y*-axis limits

Syntax

```
ylim(limits)

ylim auto
ylim manual

yl = ylim
m = ylim('mode')

___ = ylim(ax, ___ )
```

Description

`ylim(limits)` sets the *y*-axis limits for the current axes. Specify `limits` as a two-element vector of the form `[ymin ymax]`, where `ymax` is a numeric value greater than `ymin`.

`ylim auto` lets the axes choose the *y*-axis limits. The axes chooses limits that span the range of the plotted data. This command sets the `YLimMode` property for the axes to `'auto'`.

`ylim manual` freezes the limits at the current values. Use this option if you want to retain the current limits when adding new data to the axes using the `hold on` command. This command sets the `YLimMode` property for the axes to `'manual'`.

`yl = ylim` returns a two-element vector containing the current limits.

`m = ylim('mode')` returns the current value of the limits mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify limits or set the mode to manual.

`___ = ylim(ax, ___ )` uses the axes specified by `ax` instead of the current axes. Specify an axes with any of the input or output arguments in previous syntaxes.

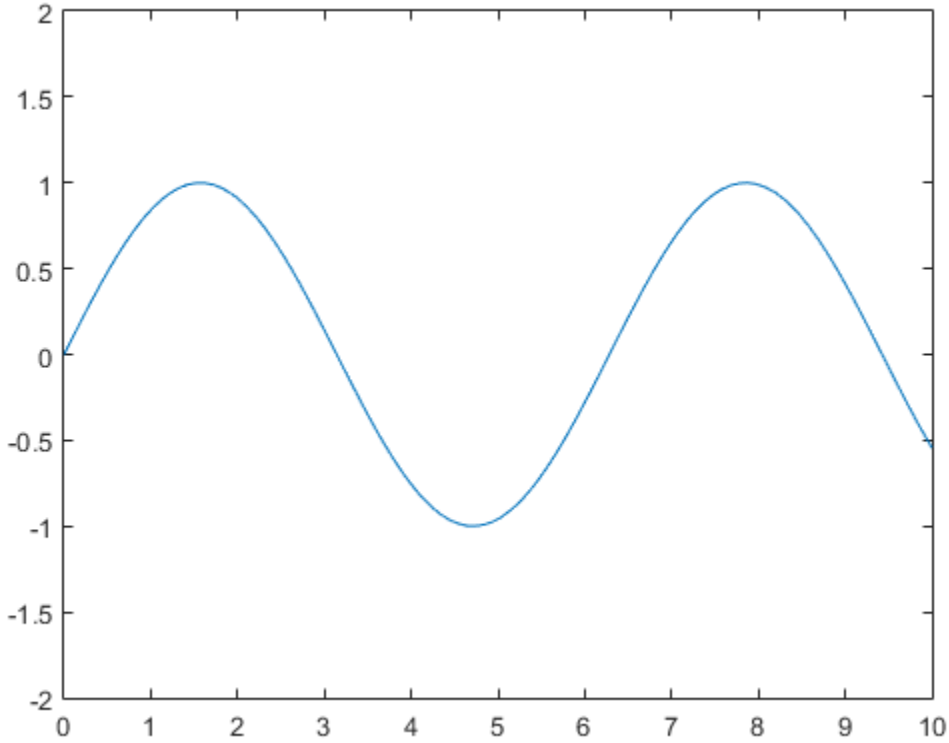
Use single quotes around input arguments that are character strings, for example, `ylim(ax,'auto')` and `ylim(ax,'manual')`.

Examples

Set *y*-Axis Limits

Plot a line and set the *y*-axis limits to range from -2 to 2.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
ylim([-2 2])
```

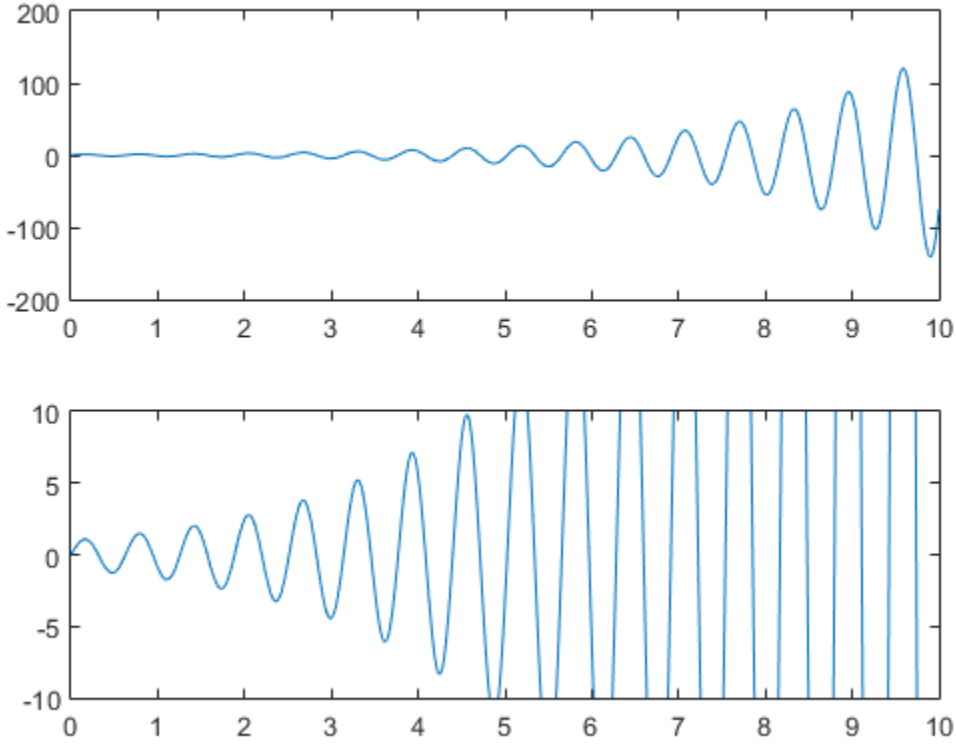


Set *y*-Axis Limits for Specific Axes

Create a figure with two subplots and plot the same data in each subplot. Set the *y*-axis limits for the bottom subplot.

```
x = linspace(0,10,1000);
y = sin(10*x).*exp(.5*x);
ax1 = subplot(2,1,1);
plot(x,y)

ax2 = subplot(2,1,2);
plot(x,y)
ylim(ax2,[-10 10])
```

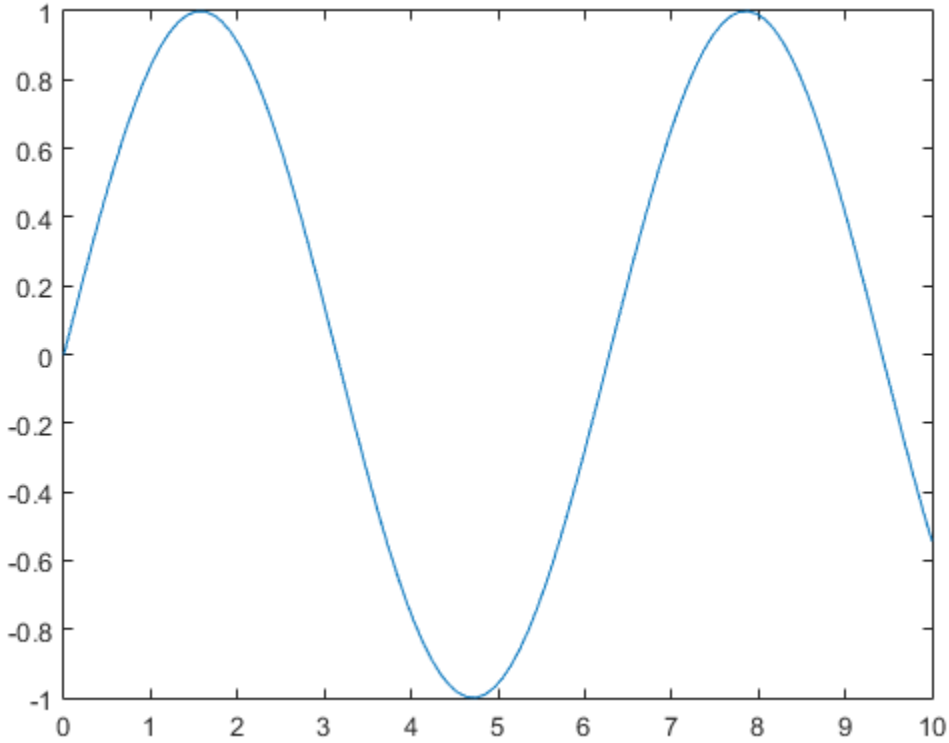


Maintain Current *y*-Axis Limits

Use manual mode to maintain the current *y*-axis limits when you add more plots to the axes.

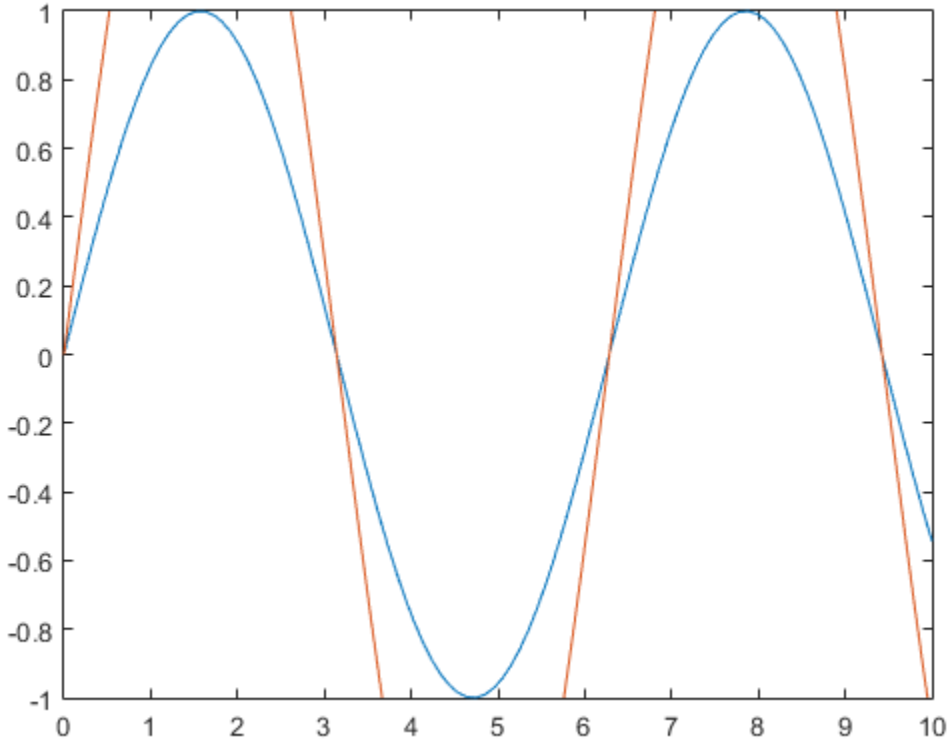
First, plot a line.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
```



Set the *y*-axis limits mode to manual so that the limits to not change. Use `hold on` to add a second plot to the axes.

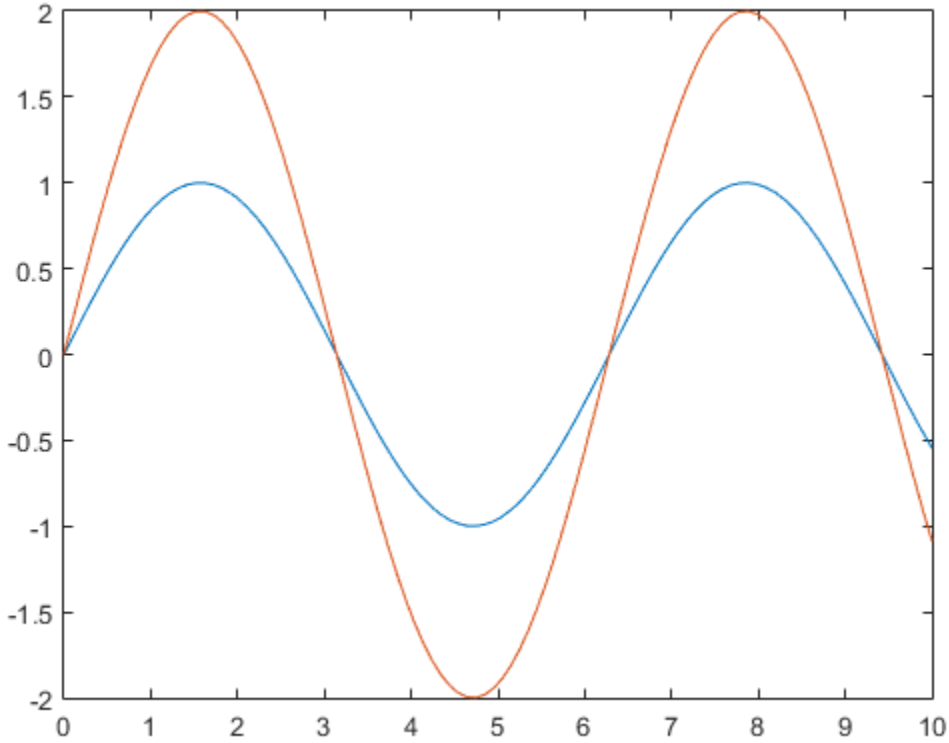
```
ylim manual
hold on
y2 = 2*sin(x);
plot(x,y2)
hold off
```



The *y*-axis limits do not update to incorporate the new plot.

Switch back to automatically updated limits by resetting the mode to automatic.

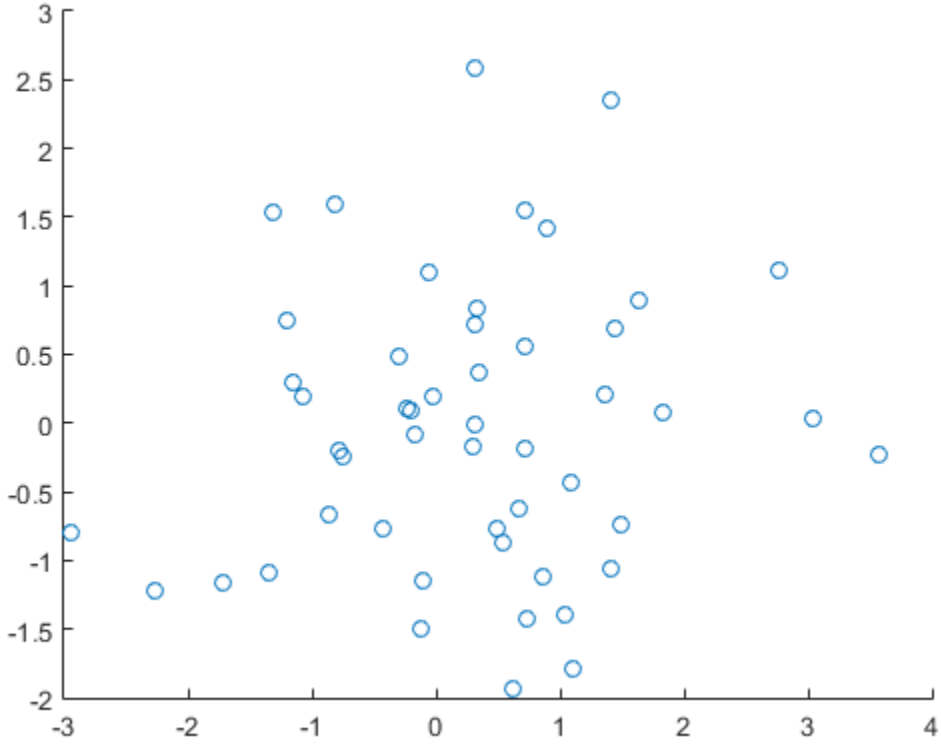
```
ylim auto
```



Return *y*-Axis Limits

Create a scatter plot of random data. Return the values of the *y*-axis limits.

```
x = randn(50,1);
y = randn(50,1);
scatter(x,y)
```



```
yl =  ylim

yl =

    -2     3
```

Input Arguments

`limits` — Minimum and maximum limits

two-element vector

Minimum and maximum limits, specified as a two-element vector of the form `[ymin ymax]`. Specifying the *y*-axis limits sets the *y*-axis limits mode to manual. The `YLim` and `YLimMode` properties for the corresponding axes store the *y*-axis limits and the limits mode, respectively.

Changing the *y*-axis limits can cause other limits to change, unless their corresponding mode properties are set to manual.

Example: `[0 1]`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

`ax` — Axes object
axes object

Axes object. If you do not specify an axes, then `ylim` sets the limits for the current axes (`gca`).

Output Arguments

`yl` — Current limits
two-element vector

Current limits, returned as a two-element vector of the form `[ymin ymax]`.

Querying the limits returns the `YLim` property value for the corresponding axes.

`m` — Current limits mode
`'auto' | 'manual'`

Current limits mode, returned as one of these values:

- `'auto'` — The limits update to reflect changes in the data.
- `'manual'` — The limits do not update to reflect changes in the data.

Querying the *y*-axis limits mode returns `YLimMode` property value for the corresponding axes.

See Also
`axis | grid | hold | xlim | ylabel | zlim`

Introduced before R2006a

zlim

Set or query *z*-axis limits

Syntax

```
zlim(limits)

zlim auto
zlim manual

zl = zlim
m = zlim('mode')

___ = zlim(ax, ___ )
```

Description

`zlim(limits)` sets the *z*-axis limits for the current axes. Specify `limits` as a two-element vector of the form `[zmin zmax]`, where `zmax` is a numeric value greater than `zmin`.

`zlim auto` lets the axes choose the *z*-axis limits. The axes chooses limits that span the range of the plotted data. This command sets the `ZLimMode` property for the axes to `'auto'`..

`zlim manual` freezes the limits at the current values. Use this option if you want to retain the current limits when adding new data to the axes using the `hold on` command. This command sets the `ZLimMode` property for the axes to `'manual'`.

`zl = zlim` returns a two-element vector containing the current limits.

`m = zlim('mode')` returns the current value of the limits mode, which is either `'auto'` or `'manual'`. By default, the mode is automatic unless you specify limits or set the mode to manual.

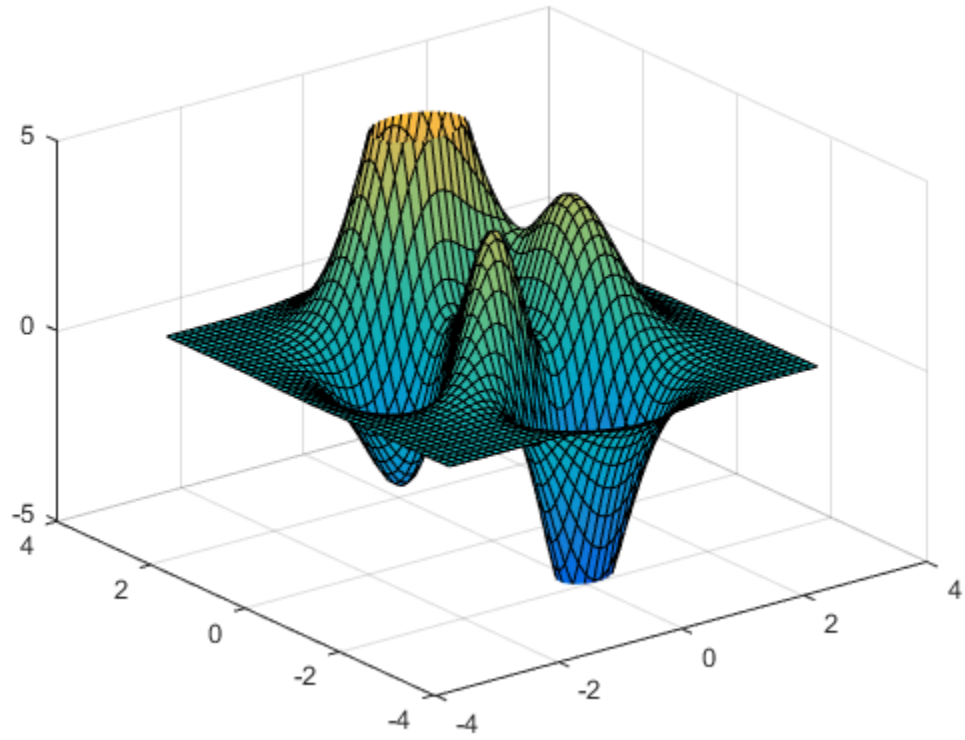
`___ = zlim(ax, ___ )` uses the axes specified by `ax` instead of the current axes. Specify an axes with any of the input or output arguments in previous syntaxes. Use single quotes around input arguments that are character strings, for example, `zlim(ax,'auto')` and `zlim(ax,'manual')`.

Examples

Set *z*-Axis Limits

Plot a surface and set the *z*-axis limits to range from -5 to 5.

```
[X,Y,Z] = peaks;
surf(X,Y,Z);
zlim([-5 5])
```

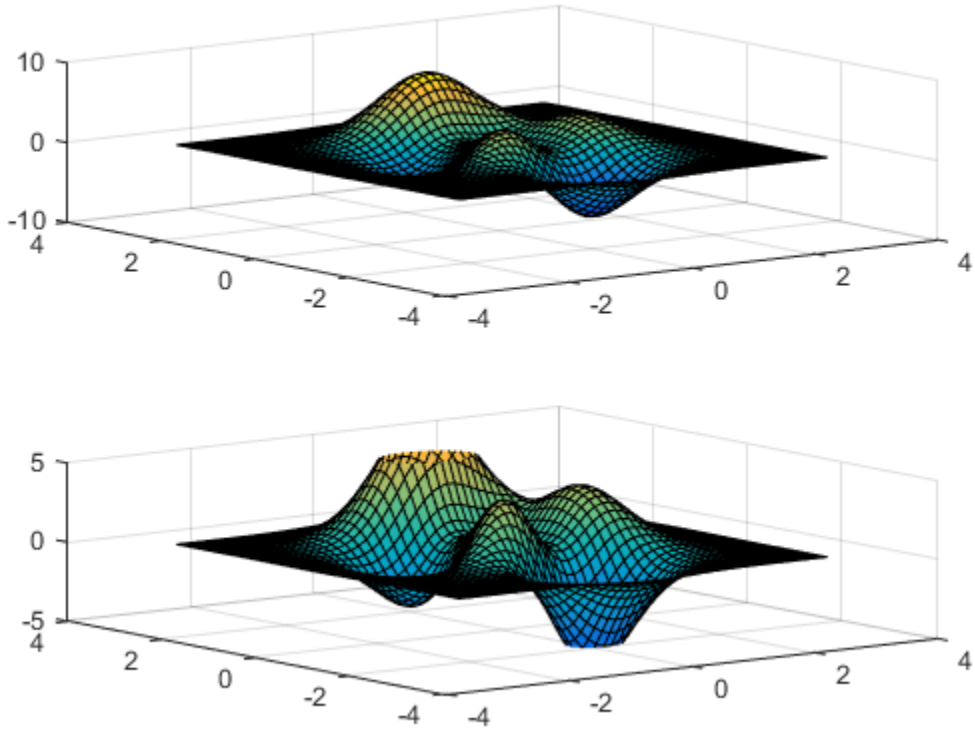


Set *z*-Axis Limits for Specific Axes

Create a figure with two subplots and plot the same data in each subplot. Set the *z*-axis limits for the bottom subplot.

```
[X,Y,Z] = peaks;
ax1 = subplot(2,1,1);
surf(X,Y,Z)

ax2 = subplot(2,1,2);
surf(X,Y,Z)
zlim(ax2,[-5 5])
```

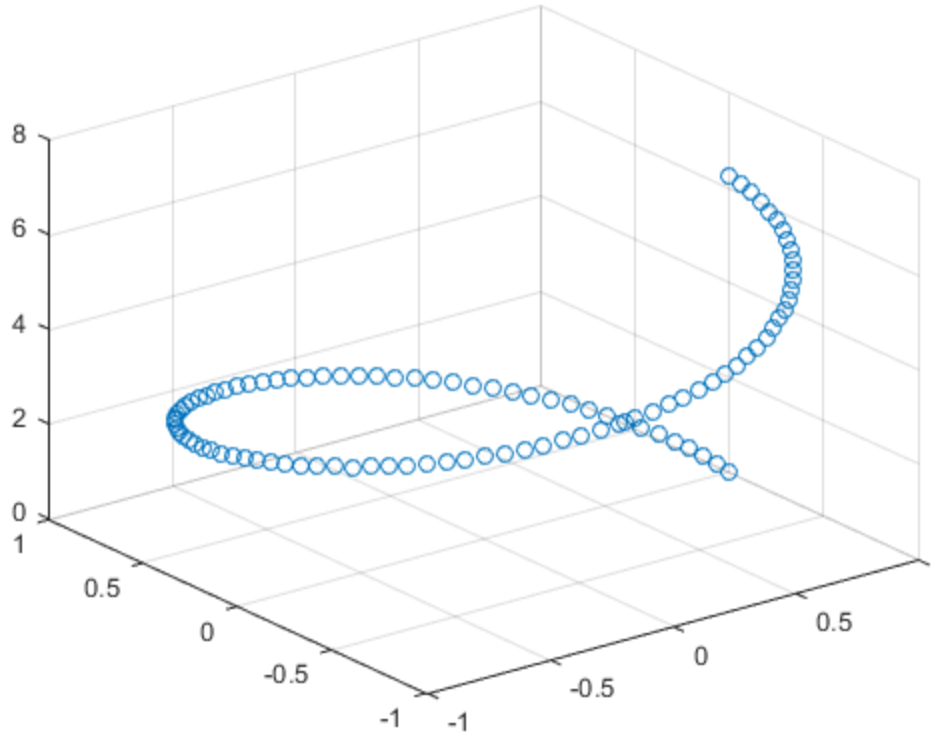


Maintain Current *z*-Axis Limits

Use manual mode to maintain the current z-axis limits when you add more plots to the axes.

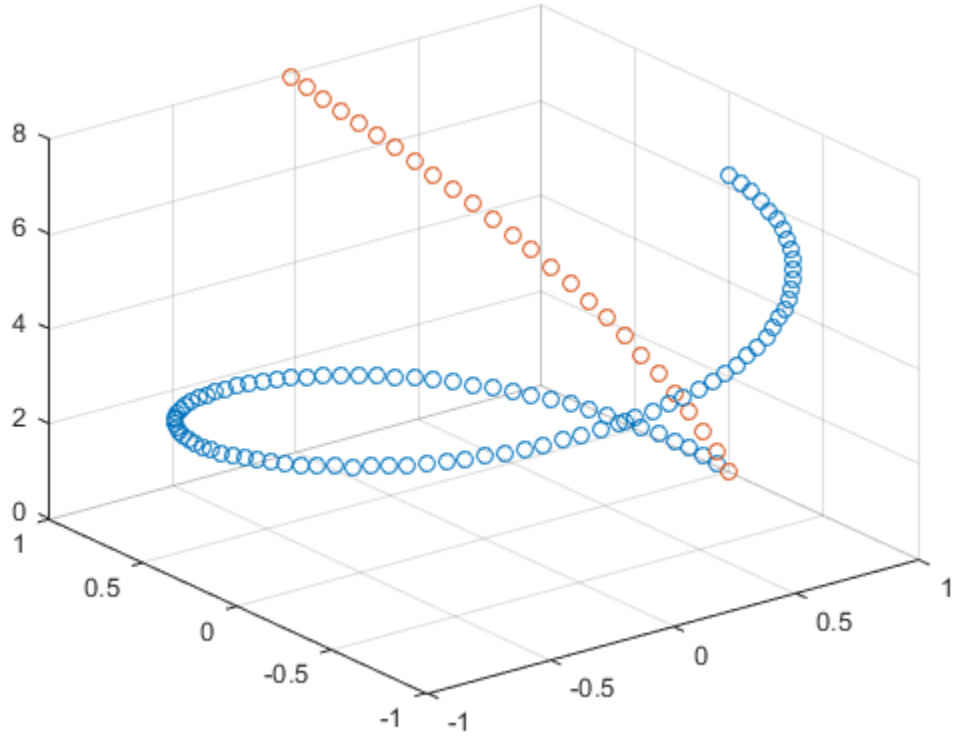
First, create a 3-D scatter plot.

```
theta = linspace(0,2*pi);
X = cos(theta);
Y = sin(theta);
Z = theta;
scatter3(X,Y,Z)
```



Set the *z*-axis limits mode to manual so that the limits to not change. Use `hold on` to add a second plot to the axes.

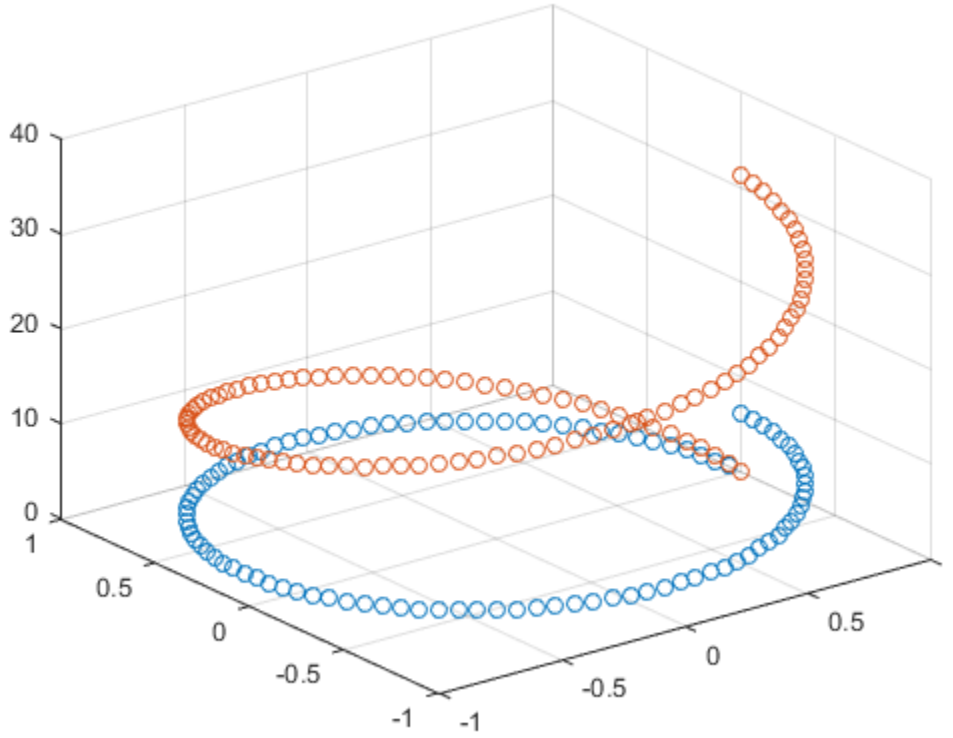
```
zlim manual
hold on
Znew = 5*theta;
scatter3(X,Y,Znew)
hold off
```



The *z*-axis limits do not update to incorporate the new plot.

Switch back to automatically updated limits by setting the mode to automatic.

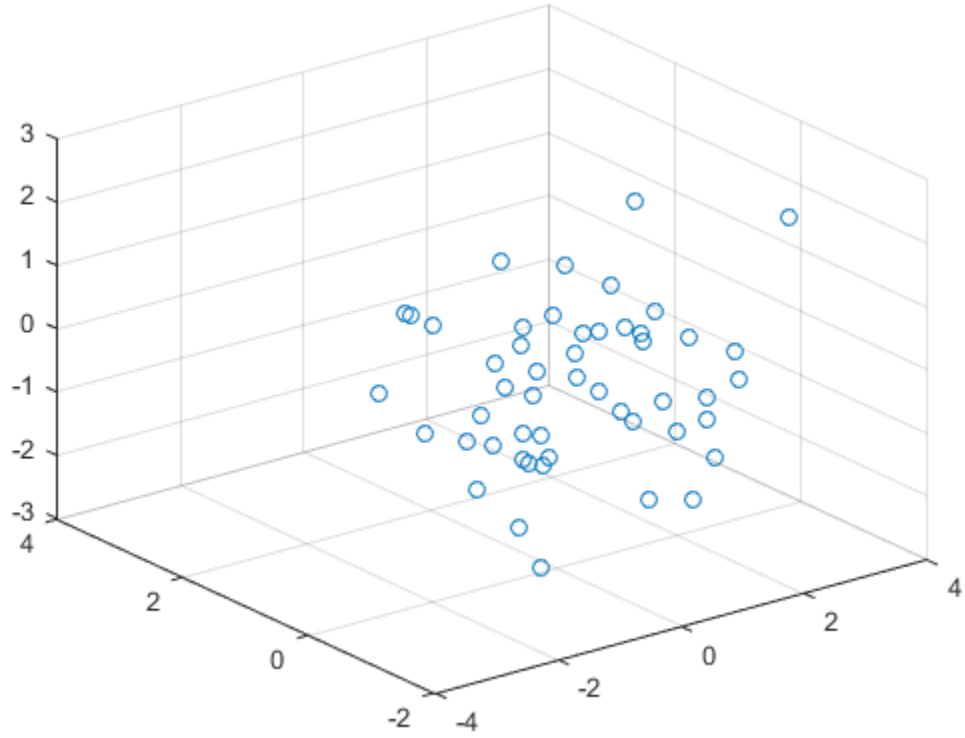
```
zlim auto
```



Return *z*-Axis Limits

Create a 3-D scatter plot of random data. Return the values of the *z*-axis limits.

```
x = randn(50,1);
y = randn(50,1);
z = randn(50,1);
scatter3(x,y,z)
```



```
zl = zlim
```

```
zl =

    -3     3
```

Input Arguments

`limits` — Minimum and maximum limits

two-element vector

Minimum and maximum limits, specified as a two-element vector of the form `[zmin zmax]`. Specifying the *z*-axis limits sets the *z*-axis limits mode to manual. The `ZLim` and `ZLimMode` properties for the corresponding axes store the *z*-axis limits and the limits mode, respectively.

Changing the *z*-axis limits can cause other limits to change, unless their corresponding mode properties are set to manual.

Example: `[0 1]`

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

`ax` — Axes object

axes object

Axes object. If you do not specify an axes, then `zlim` sets the limits for the current axes (`gca`).

Output Arguments

`zl` — Current limits

two-element vector

Current limits, returned as a two-element vector of the form `[zmin zmax]`.

Querying the limits returns the `ZLim` property value for the corresponding axes.

`m` — Current limits mode

`'auto' | 'manual'`

Current limits mode, returned as one of these values:

- `'auto'` — The limits update to reflect changes in the data.
- `'manual'` — The limits do not update to reflect changes in the data.

Querying the *z*-axis limits mode returns `ZLimMode` property value for the corresponding axes.

`axis | grid | hold | xlim | ylim | zlabel`

Introduced before R2006a

xlsfinfo

Determine if file contains Microsoft Excel spreadsheet

Syntax

```
status = xlsfinfo(filename)
[status,sheets] = xlsfinfo(filename)
[status,sheets,xlFormat] = xlsfinfo(filename)
```

Description

`status = xlsfinfo(filename)` indicates if `filename` is a file that the `xlsread` function can read.

`[status,sheets] = xlsfinfo(filename)` additionally returns the name of each spreadsheet in the file.

`[status,sheets,xlFormat] = xlsfinfo(filename)` also returns the format description that Excel returns for the file. On systems without Excel for Windows, `xlFormat` is an empty string, `''`.

Examples

View Information About Spreadsheet File

Create a sample Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First', 'Second', 'Third'};
xlswrite('myExample.xlsx', [headers; values]);
```

Call `xlsfinfo` to get information about the file.

```
[status,sheets,xlFormat] = xlsfinfo('myExample.xlsx')
```

```
status =
```

```
Microsoft Excel Spreadsheet

sheets =

    'Sheet1'    'Sheet2'    'Sheet3'

xlFormat =

xlOpenXMLWorkbook
```

`status` is a descriptive string indicating that the `xlsread` function can read the sample file.

Input Arguments

`filename` — Name of file

string

Name of file, specified as a string.

Example: `'myFile.xlsx'`

Data Types: `char`

Output Arguments

`status` — Type of file

string

Type of file, returned as a string.

- If `filename` is a file that `xlsread` can read, then `status` is a descriptive string, such as `'Microsoft Excel Spreadsheet'`.
- If `filename` is not a file that `xlsread` can read, then `status` is an empty string, `''`.
- If MATLAB cannot find the file, then `xlsfinfo` returns an error.

`sheets` — Worksheet names

1-by-`n` cell array of strings

Worksheet names, returned as a 1-by-`n` cell array of strings, where `n` is the number of worksheets in the file. Each cell contains the name of a worksheet. If `xlsread` cannot read a particular worksheet, the corresponding cell contains an error message.

If `xlsfinfo` cannot read the file, then `sheets` contains an error message.

`xlFormat` — File format description returned by Excel

string

File format description returned by Excel, returned as a string.

On Windows systems with Excel software, `xlFormat` is a nonempty string, such as one of the following.

`'xlOpenXMLWorkbook'`	Spreadsheet in XLSX format (Excel 2007 or later)
`'xlWorkbookNormal'` or `'xlExcel8'`	Spreadsheet in XLS format (compatible with Excel 97-2003)
`'xlCSV'`	File in comma-separated value (CSV) format
`'xlHtml'` or `'xlWebArchive'`	Spreadsheet exported to HTML format

On all other systems, `xlFormat` is an empty string, `''`.

Limitations

- `xlsfinfo` supports only 7-bit ASCII characters.

More About

Tips

- If `xlsfinfo` warns that it cannot start an ActiveX server, then the COM server, which is part of the typical Excel installation, is unavailable. In this case, consider reinstalling your Excel software. On systems with Excel for Windows, `xlsfinfo` uses the COM server to obtain information.

See Also

`xlsread` | `xlswrite`

Introduced before R2006a

xlsread

Read Microsoft Excel spreadsheet file

Syntax

```
num = xlsread(filename)
num = xlsread(filename,sheet)
num = xlsread(filename,xlRange)
num = xlsread(filename,sheet,xlRange)
num = xlsread(filename,sheet,xlRange,'basic')
[num,txt,raw] = xlsread(___)

___ = xlsread(filename,-1)

[num,txt,raw,custom] = xlsread(filename,sheet,xlRange,'',processFcn)
```

Description

`num = xlsread(filename)` reads the first worksheet in the Microsoft Excel spreadsheet workbook named filename and returns the numeric data in a matrix.

`num = xlsread(filename,sheet)` reads the specified worksheet.

`num = xlsread(filename,xlRange)` reads from the specified range of the first worksheet in the workbook. Use Excel range syntax, such as `'A1:C3'`.

`num = xlsread(filename,sheet,xlRange)` reads from the specified worksheet and range.

`num = xlsread(filename,sheet,xlRange,'basic')` reads data from the spreadsheet in `basic` import mode. If your computer does not have Excel for Windows, `xlsread` automatically operates in `basic` import mode, which supports XLS, XLSX, XLSM, XLTX, and XLTM files.

If you do not specify all the arguments, use empty strings as placeholders, for example, `num = xlsread(filename,'','','basic')`.

`[num,txt,raw] = xlsread( ___ )` additionally returns the text fields in cell array txt, and both numeric and text data in cell array raw, using any of the input arguments in the previous syntaxes.

`___ = xlsread(filename,-1)` opens an Excel window to interactively select data. Select the worksheet, drag and drop the mouse over the range you want, and click **OK**. This syntax is supported only on Windows computers with Microsoft Excel software installed.

`[num,txt,raw,custom] = xlsread(filename,sheet,xlRange,'',processFcn)`, where `processFcn` is a function handle, reads from the spreadsheet, calls `processFcn` on the data, and returns the final results as numeric data in array `num`. The `xlsread` function returns the text fields in cell array `txt`, both the numeric and text data in cell array `raw`, and the second output from `processFcn` in array `custom`. The `xlsread` function does not change the data stored in the spreadsheet. This syntax is supported only on Windows computers with Excel software.

Examples

Read Worksheet Into Numeric Matrix

Create an Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First','Second','Third'};
xlswrite('myExample.xlsx',[headers; values]);
```

`Sheet1` of `myExample.xlsx` contains:

First	Second	Third
1	2	3
4	5	x
7	8	9

Read numeric data from the first worksheet.

```
filename = 'myExample.xlsx';
A = xlsread(filename)
```

```
A =
     1     2     3
     4     5   NaN
```

```
     7     8     9
```

Read Range of Cells

Read a specific range of data from the Excel file in the previous example.

```
filename = 'myExample.xlsx';
sheet = 1;
xlRange = 'B2:C3';

subsetA = xlsread(filename,sheet,xlRange)
```

```
subsetA =
     2     3
     5   NaN
```

Read Column

Read the second column from the Excel file in the first example.

```
filename = 'myExample.xlsx';

columnB = xlsread(filename,'B:B')
```

```
columnB =
     2
     5
     8
```

For better performance, include the row numbers in the range, such as `'B1:B3'`.

Request Numeric, Text, and Raw Data

Request the numeric data, text data, and combined data from the Excel file in the first example.

```
[num,txt,raw] = xlsread('myExample.xlsx')
```

```
num =
     1     2     3
     4     5   NaN
     7     8     9

txt =
    'First'    'Second'    'Third'
    ''         ''          ''
```

```
    ''          ''          'x'

raw =
    'First'     'Second'    'Third'
    [     1]    [     2]    [     3]
    [     4]    [     5]    'x'
    [     7]    [     8]    [     9]
```

Execute a Function on a Worksheet

In the Editor, create a function to process data from a worksheet. In this case, set values outside the range `[0.2,0.8]` to `0.2` or `0.8`.

```
function [Data] = setMinMax(Data)

minval = 0.2;
maxval = 0.8;

for k = 1:Data.Count
  v = Data.Value{k};
  if v > maxval
    Data.Value{k} = maxval;
  elseif v < minval
    Data.Value{k} = minval;
  end
end
```

In the Command Window, add random data to `myExample.xlsx`.

```
A = rand(5);
xlswrite('myExample.xlsx',A,'MyData')
```

The worksheet named `MyData` contains values ranging from 0 to 1.

Read the data from the worksheet, and reset any values outside the range `[0.2,0.8]`. Specify the sheet name, but use `''` as placeholders for the xlRange and 'basic' inputs.

```
trim = xlsread('myExample.xlsx','MyData','','',@setMinMax);
```

Request Custom Output

Execute a function on a worksheet and display the custom index output.

In the Editor, modify the function `setMinMax` from the previous example to return the indices of the changed elements (custom output).

```
function [Data,indices] = setMinMax(Data)

minval = 0.2;
maxval = 0.8;
indices = [];

for k = 1:Data.Count
  v = Data.Value{k};
  if v > maxval
    Data.Value{k} = maxval;
    indices = [indices k];
  elseif v < minval
    Data.Value{k} = minval;
    indices = [indices k];
  end
end
```

Read the data from the worksheet `MyData`, and request the custom index output, `idx`.

```
[trim,txt,raw,idx] = xlsread('myExample.xlsx',...
    'MyData','','',@setMinMax);
```

Input Arguments

`filename` — File name

string

File name, specified as a string. If you do not include an extension, `xlsread` searches for a file with the specified name and a supported Excel extension. `xlsread` can read data saved in files that are currently open in Excel for Windows.

Example: `'myFile.xlsx'`

Data Types: `char`

`sheet` — Worksheet

string | positive integer

Worksheet, specified as one of the following:

- String that contains the worksheet name. The string cannot contain a colon (`:`). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`. For XLS files in `basic` mode, `sheet` is case sensitive.

- Positive integer that indicates the worksheet index. This option is not supported for XLS files in `basic` mode.

`xlRange` — Rectangular range

string

Rectangular range, specified as a string.

Specify `xlRange` using two opposing corners that define the region to read. For example, `'D2:H4'` represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help).

Range selection is not supported when reading XLS files in `basic` mode. In this case, use `''` in place of `xlRange`.

If you do not specify sheet, then `xlRange` must include both corners and a colon character, even for a single cell (such as `'D2:D2'`). Otherwise, `xlsread` interprets the input as a worksheet name (such as `'sales'` or `'D2'`).

If you specify `sheet`, then `xlRange`:

- Does not need to include a colon and opposite corner to describe a single cell.
- Can refer to a named range that you defined in the Excel file (see the Excel help).

When the specified `xlRange` overlaps merged cells:

- On Windows computers with Excel, `xlsread` expands the range to include all merged cells.
- On computers without Excel for Windows, `xlsread` returns data for the specified range only, with empty or `NaN` values for merged cells.

Data Types: `char`

`'basic'` — Flag to request reading in `basic` mode

literal string

Flag to request reading in `basic` mode, specified as the literal string, `'basic'`.

`basic` mode is the default for computers without Excel for Windows. In `basic` mode, `xlsread`:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support an `xlRange` input when reading XLS files. In this case, use `''` in place of `xlRange`.
- Does not support function handle inputs.
- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

`processFcn` — Handle to a custom function

function handle

Handle to a custom function. This argument is supported only on Windows computers with Excel software. `xlsread` reads from the spreadsheet, executes your function on a copy of the data, and returns the final results. `xlsread` does not change the data stored in the spreadsheet.

When `xlsread` calls the custom function, it passes a range interface from the Excel application to provide access to the data. The custom function must include this interface both as an input and output argument. (See “Execute a Function on a Worksheet” on page 1-9105)

Example: `@myFunction`

Output Arguments

`num` — Numeric data

matrix

Numeric data, returned as a matrix of `double` values. The array does not contain any information from header lines, or from outer rows or columns that contain nonnumeric data. Text data in inner spreadsheet rows and columns appear as `NaN` in the `num` output.

`txt` — Text data

cell array

Text data, returned as a cell array. Numeric values in inner spreadsheet rows and columns appear as empty strings, `''`, in `txt`.

For XLS files in `basic` import mode, the `txt` output contains empty strings, `''`, in place of leading columns of numeric data that precede text data in the spreadsheet. In all other cases, `txt` does not contain these additional columns.

Undefined values (such as `'#N/A'`) appear in the `txt` output as `'#N/A'`, except for XLS files in `basic` mode.

`raw` — Numeric and text data
cell array

Numeric and text data from the worksheet, returned as a cell array.

On computers with Excel for Windows, undefined values (such as `'#N/A'`) appear in the `raw` output as `'ActiveX VT_ERROR:'`. For XLSX, XLSM, XLTX, and XLTM files on other computers, undefined values appear as `'#N/A'`.

`custom` — Second output of the function corresponding to `processFcn`
defined by the function

Second output of the function corresponding to `processFcn`. The value and data type of `custom` are determined by the function.

Limitations

- `xlsread` reads only 7-bit ASCII characters.
- `xlsread` does not support non-contiguous ranges.

More About

Algorithms

- `xlsread` imports formatted dates as strings (such as `'10/31/96'`), except in `basic` mode and on computers without Excel for Windows.
- "Import and Export Dates to Excel Files"

See Also

`function_handle` | `importdata` | `readtable` | `uiimport` | `xlsfinfo` | `xlswrite`

Introduced before R2006a

xlswrite

Write Microsoft Excel spreadsheet file

Syntax

```
xlswrite(filename,A)
xlswrite(filename,A,sheet)
xlswrite(filename,A,xlRange)
xlswrite(filename,A,sheet,xlRange)

status = xlswrite( ___ )
[status,message] = xlswrite( ___ )
```

Description

`xlswrite(filename,A)` writes matrix `A` to the first worksheet in the Microsoft Excel spreadsheet workbook `filename` starting at cell `A1`.

`xlswrite(filename,A,sheet)` writes to the specified worksheet.

`xlswrite(filename,A,xlRange)` writes to the rectangular region specified by `xlRange` in the first worksheet of the workbook. Use Excel range syntax, such as `'A1:C3'`.

`xlswrite(filename,A,sheet,xlRange)` writes to the specified worksheet and range.

`status = xlswrite( ___ )` returns the status of the write operation, using any of the input arguments in previous syntaxes. When the operation is successful, status is `1`. Otherwise, status is `0`.

`[status,message] = xlswrite( ___ )` additionally returns any warning or error message generated by the write operation in structure `message`.

Examples

Write Vector to Spreadsheet

Write a 7-element vector to an Excel file.

```
filename = 'testdata.xlsx';
A = [12.7 5.02 -98 63.9 0 -.2 56];
xlswrite(filename,A)
```

Write to Specific Sheet and Range in Spreadsheet

Write mixed text and numeric data to an Excel file starting at cell `E1` of `Sheet2`.

```
filename = 'testdata.xlsx';
A = {'Time','Temperature'; 12,98; 13,99; 14,97};
sheet = 2;
xlRange = 'E1';
xlswrite(filename,A,sheet,xlRange)
```

Input Arguments

`filename` — File name

string

File name, specified as a string.

If `filename` does not exist, `xlswrite` creates a file, determining the format based on the specified extension. To create a file compatible with Excel 97-2003 software, specify an extension of `.xls`. To create files in Excel 2007 formats, specify an extension of `.xlsx`, `.xlsb`, or `.xlsm`. If you do not specify an extension, `xlswrite` uses the default, `.xls`.

Example: `'myFile.xlsx'`

Example: `'C:\myFolder\myFile.xlsx'`

A — Input matrix

matrix

Input matrix, specified as a two-dimensional numeric or character array, or, if each cell contains a single element, a cell array.

If `A` is a cell array containing something other than a scalar numeric or a string, then `xlswrite` silently leaves the corresponding cell in the spreadsheet empty.

The maximum size of array `A` depends on the associated Excel version. For more information on Excel specifications and limits, see the Excel help.

Example: `[10,2,45;-32,478,50]`

Example: `{92.0,'Yes',45.9,'No'}`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell`

`sheet` — Worksheet name

string | positive integer

Worksheet name, specified as one of the following:

- String that contains the worksheet name. The string cannot contain a colon (`:`). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`.
- Positive integer that indicates the worksheet index.

If `sheet` does not exist, `xlswrite` adds a new sheet at the end of the worksheet collection. If `sheet` is an index larger than the number of worksheets, `xlswrite` appends empty sheets until the number of worksheets in the workbook equals `sheet`. In either case, `xlswrite` generates a warning indicating that it has added a new worksheet.

`xlRange` — Rectangular range

string

Rectangular range, specified as a string.

Specify `xlRange` using two opposing corners that define the region to write. For example, `'D2:H4'` represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help). `xlswrite` does not recognize named ranges.

- If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as `'D2:D2'`). Otherwise, `xlswrite` interprets the input as a worksheet name (such as `'D2'`).
- If you specify sheet, then `xlRange` can specify only the first cell (such as `'D2'`). `xlswrite` writes input array `A` beginning at this cell.
- If `xlRange` is larger than the size of input array `A`, Excel software fills the remainder of the region with `#N/A`. If `xlRange` is smaller than the size of `A`, then `xlswrite` writes only the subset that fits into `xlRange` to the file.

Output Arguments

`status` — Status of the write operation

`1 | 0`

Status of the write operation, returned as either `1` (`true`) or `0` (`false`). When the write operation is successful, `status` is `1`. Otherwise, `status` is `0`.

`message` — Error or warning generated during the write operation

structure array

Error or warning generated during the write operation, returned as a structure array containing two fields:

`message`	Text of the warning or error message, returned as a string.
`identifier`	Message identifier, returned as a string.

Limitations

- If your computer does not have Excel for Windows, or if the COM server (part of the typical installation of Excel) is unavailable, then the `xlswrite` function:
  - Writes array A to a text file in comma-separated value (CSV) format. `A` must be a numeric matrix.
  - Ignores the sheet and xlRange arguments.

More About

Tips

- If your computer has Microsoft Office 2003 software, but you want to create a file in an Excel 2007 format, install the Office 2007 Compatibility Pack.
- Excel and MATLAB can store dates as strings (such as `'10/31/96'`) or serial date numbers (such as `729329`). If your array includes serial date numbers, convert the dates to strings using `datestr` before calling `xlswrite`. Alternatively, see “Import and Export Dates to Excel Files”.

- To write data to Excel files with custom formats (such as fonts or colors), access the Windows COM server directly using `actxserver` rather than `xlswrite`. For example, this MathWorks Support Answer uses `actxserver` to establish a connection between MATLAB and Excel, writes data to a worksheet, and specifies the colors of the cells.

Algorithms

Excel converts `Inf` values to `65535`. MATLAB converts `NaN` values to empty cells.

`writetable` | `xlsfinfo` | `xlsread`

Introduced before R2006a

xmlread

Read XML document and return Document Object Model node

Syntax

```
DOMnode = xmlread(filename)
```

Description

`DOMnode = xmlread(filename)` reads the specified XML file and returns a Document Object Model node representing the document.

Input Arguments

`filename`

String enclosed in single quotation marks that specifies the name of the local file or URL.

Output Arguments

`DOMnode`

Document Object Model node, as defined by the World Wide Web consortium. For more information, see "What Is an XML Document Object Model (DOM)?".

Examples

The root element in an XML file sometimes includes an `xsi:noNamespaceSchemaLocation` attribute. The value of this attribute is the name of the preferred schema file. Call the `getAttribute` method to get this value:

```
xDoc = xmlread(fullfile(matlabroot,'toolbox',...
               'matlab','general','info.xml'));

xRoot = xDoc.getDocumentElement;
```

```
schema = char(xRoot.getAttribute('xsi:noNamespaceSchemaLocation'))
```

This code returns:

```
schema =
http://www.mathworks.com/namespace/info/v1/info.xsd
```

Create functions that parse data from an XML file into a MATLAB structure array with fields `Name`, `Attributes`, `Data`, and `Children`:

```
function theStruct = parseXML(filename)
% PARSEXML Convert XML file to a MATLAB structure.
try
   tree = xmlread(filename);
catch
   error('Failed to read XML file %s.',filename);
end

% Recurse over child nodes. This could run into problems
% with very deeply nested trees.
try
   theStruct = parseChildNodes(tree);
catch
   error('Unable to parse XML file %s.',filename);
end

% ----- Local function PARSECHILDNODES -----
function children = parseChildNodes(theNode)
% Recurse over node children.
children = [];
if theNode.hasChildNodes
   childNodes = theNode.getChildNodes;
   numChildNodes = childNodes.getLength;
   allocCell = cell(1, numChildNodes);

   children = struct(             ...
      'Name', allocCell, 'Attributes', allocCell,    ...
      'Data', allocCell, 'Children', allocCell);

    for count = 1:numChildNodes
        theChild = childNodes.item(count-1);
        children(count) = makeStructFromNode(theChild);
    end
end
```

```
% ----- Local function MAKESTRUCTFROMNODE -----
function nodeStruct = makeStructFromNode(theNode)
% Create structure of node info.

nodeStruct = struct(                        ...
   'Name', char(theNode.getNodeName),       ...
   'Attributes', parseAttributes(theNode),  ...
   'Data', '',                              ...
   'Children', parseChildNodes(theNode));

if any(strcmp(methods(theNode), 'getData'))
   nodeStruct.Data = char(theNode.getData);
else
   nodeStruct.Data = '';
end

% ----- Local function PARSEATTRIBUTES -----
function attributes = parseAttributes(theNode)
% Create attributes structure.

attributes = [];
if theNode.hasAttributes
   theAttributes = theNode.getAttributes;
   numAttributes = theAttributes.getLength;
   allocCell = cell(1, numAttributes);
   attributes = struct('Name', allocCell, 'Value', ...
                       allocCell);

   for count = 1:numAttributes
      attrib = theAttributes.item(count-1);
      attributes(count).Name = char(attrib.getName);
      attributes(count).Value = char(attrib.getValue);
   end
end
```

More About

Tips

The display for a properly parsed document is `[#document: null]`. For example,

```
xDoc = xmlread('info.xml')
```

returns

```
xDoc =
[#document: null]
```

`xmlwrite` | `xslt`

Introduced before R2006a

xmlwrite

Write XML Document Object Model node

Syntax

```
xmlwrite(filename,DOMnode)
str = xmlwrite(DOMnode)
```

Description

`xmlwrite(filename,DOMnode)` writes the Document Object Model (DOM) node `DOMnode` to the file `filename`.

`str = xmlwrite(DOMnode)` serializes the DOM node to a string.

Input Arguments

`filename`

String enclosed in single quotation marks that specifies the name of a local file or a URL.

`DOMnode`

Document Object Model node, as defined by the World Wide Web consortium. For more information, see "What Is an XML Document Object Model (DOM)?"

Output Arguments

`str`

String that contains the serialized DOM node as it appears in an XML file.

Examples

Create and view an XML document:

```
docNode = com.mathworks.xml.XMLUtils.createDocument...
    ('root_element')
docRootNode = docNode.getDocumentElement;
docRootNode.setAttribute('attr_name','attr_value');
for i=1:20
    thisElement = docNode.createElement('child_node');
    thisElement.appendChild...
        (docNode.createTextNode(sprintf('%i',i)));
    docRootNode.appendChild(thisElement);
end
docNode.appendChild(docNode.createComment('this is a comment'));

xmlFileName = [tempname,'.xml'];
xmlwrite(xmlFileName,docNode);
type(xmlFileName);
```

xor

Logical exclusive-OR

Syntax

```
C = xor(A, B)
```

Description

`C = xor(A, B)` performs an exclusive OR operation on the corresponding elements of arrays `A` and `B`. The resulting element `C(i,j,...)` is logical true (`1`) if `A(i,j,...)` or `B(i,j,...)`, but not both, is nonzero.

A	B	C
Zero	Zero	0
Zero	Nonzero	1
Nonzero	Zero	1
Nonzero	Nonzero	0

Examples

Given `A = [0 0 pi eps]` and `B = [0 -2.4 0 1]`, then

```
C = xor(A,B)
C =
   0   1   1   0
```

To see where either `A` or `B` has a nonzero element and the other matrix does not,

```
spy(xor(A,B))
```

Introduced before R2006a

xslt

Transform XML document using XSLT engine

Syntax

```
result = xslt(source, style, dest)
[result,style] = xslt( ___ )
xslt( ___ ,'-web')
```

Description

`result = xslt(source, style, dest)` transforms an XML document using a stylesheet and returns the resulting document's URL. The function uses these inputs, the first of which is required:

- `source` is the filename or URL of the source XML file. `source` can also specify a DOM node.
- `style` is the filename or URL of an XSL stylesheet.
- `dest` is the filename or URL of the desired output document. If `dest` is absent or empty, the function uses a temporary filename. If `dest` is `'-tostring'`, the function returns the output document as a MATLAB string.

`[result,style] = xslt( ___ )` returns a processed stylesheet appropriate for passing to subsequent XSLT calls as `style`. This prevents costly repeated processing of the stylesheet.

`xslt( ___ ,'-web')` displays the resulting document in the Help Browser.

Examples

This example converts the file `info.xml` using the stylesheet `info.xsl`, writing the output to the file `info.html`. It launches the resulting HTML file in the MATLAB Web Browser.

```
xslt('info.xml', 'info.xsl', 'info.html', '-web')
```

More About

Tips

MATLAB uses the Saxon XSLT processor, version 6.5.5, which supports XSLT 1.0 expressions. For more information, see http://saxon.sourceforge.net/saxon6.5.5/

For additional information on writing XSL stylesheets, see the World Wide Web Consortium (W3C®) web site, http://www.w3.org/Style/XSL/.

`xmlread` | `xmlwrite`

Introduced before R2006a

zeros

Create array of all zeros

Syntax

```
X = zeros
X = zeros(n)
X = zeros(sz1,...,szN)
X = zeros(sz)

X = zeros(___,typename)
X = zeros(___,'like',p)
```

Description

`X = zeros` returns the scalar `0`.

`X = zeros(n)` returns an `n`-by-`n` matrix of zeros.

`X = zeros(sz1,...,szN)` returns an `sz1`-by-...-by-`szN` array of zeros where `sz1,...,szN` indicate the size of each dimension. For example, `zeros(2,3)` returns a 2-by-3 matrix.

`X = zeros(sz)` returns an array of zeros where size vector `sz` defines `size(X)`. For example, `zeros([2 3])` returns a 2-by-3 matrix.

`X = zeros(___,typename)` returns an array of zeros of data type `typename`. For example, `zeros('int8')` returns a scalar, 8-bit integer `0`. You can use any of the input arguments in the previous syntaxes.

`X = zeros(___,'like',p)` returns an array of zeros like `p`; that is, of the same data type (class), sparsity, and complexity (real or complex) as `p`. You can specify `typename` or `'like'`, but not both.

Examples

Matrix of Zeros

Create a 4-by-4 matrix of zeros.

```
X = zeros(4)
```

```
X =

     0     0     0     0
     0     0     0     0
     0     0     0     0
     0     0     0     0
```

3-D Array of Zeros

Create a 2-by-3-by-4 array of zeros.

```
X = zeros(2,3,4);
size(X)
```

```
ans =

     2     3     4
```

Clone Size from Existing Array

Create an array of zeros that is the same size as an existing array.

```
A = [1 4; 2 5; 3 6];
sz = size(A);
X = zeros(sz)
```

```
X =

     0     0
     0     0
     0     0
```

It is a common pattern to combine the previous two lines of code into a single line:

```
X = zeros(size(A));
```

Specify Data Type of Zeros

Create a 1-by-3 vector of zeros whose elements are 32-bit unsigned integers.

```
X = zeros(1,3,'uint32')
X =
           0           0           0
class(X)
ans =
uint32
```

Clone Complexity from Existing Array

Create a scalar `0` that is complex like an existing array instead of real valued.

First, create a complex vector.

```
p = [1+2i 3i];
```

Create a scalar `0` that is complex like `p`.

```
X = zeros('like',p)
X =
   0.0000 + 0.0000i
```

Clone Sparsity from Existing Array

Create a 10-by-10 sparse matrix.

```
p = sparse(10,10,pi);
```

Create a 2-by-3 matrix of zeros that is sparse like `p`.

```
X = zeros(2,3,'like',p)
X =
   All zero sparse: 2-by-3
```

Clone Size and Data Type from Existing Array

Create a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of zeros that is the same size and data type as `p`.

```
X = zeros(size(p),'like',p)
```

```
X =

    0    0    0
    0    0    0
```

```
class(X)
```

```
ans =

uint8
```

Clone Distributed Array

If you have Parallel Computing Toolbox, create a 1000-by-1000 distributed array of zeros with underlying data type `int8`. For the `distributed` data type, the `'like'` syntax clones the underlying data type in addition to the primary data type.

```
p = zeros(1000,'int8','distributed');
```

Create an array of zeros that is the same size, primary data type, and underlying data type as `p`.

```
X = zeros(size(p),'like',p);
```

```
class(X)
```

```
ans =

distributed
```

```
classUnderlying(X)
```

```
ans =

int8
```

Input Arguments

n — Size of square matrix

integer value

Size of square matrix, specified as an integer value.

- If `n` is `0`, then `X` is an empty matrix.
- If `n` is negative, then it is treated as `0`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz1,...,szN` — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `zeros` ignores trailing dimensions with a size of `1`. For example, `zeros([3,1,1,1])` produces a 3-by-1 vector of zeros.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension:

- If the size of any dimension is `0`, then `X` is an empty array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `zeros` ignores trailing dimensions with a size of `1`. For example, `zeros([3,1,1,1])` produces a 3-by-1 vector of zeros.

Example: `sz = [2,3,4]` creates a 2-by-3-by-4 array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`typename` — Data type (class) to create

`'double'` (default) | `'single'` | `'int8'` | `'uint8'` | ...

Data type (class) to create, specified as the string `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, `'uint64'`, or the name of another class that provides `zeros` support.

p — Prototype of array to create

numeric array

Prototype of array to create, specified as a numeric array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

Introduced before R2006a

zip

Compress files into zip file

Syntax

```
zip(zipfile,files)
zip(zipfile,files,rootfolder)
entrynames = zip(zipfile,files,rootfolder)
```

Description

`zip(zipfile,files)` creates a zip file with the name `zipfile` from the list of files and folders specified in `files`. Folders recursively include all of their content.

`zip(zipfile,files,rootfolder)` specifies the path for `files` relative to `rootfolder` instead of the current folder.

`entrynames = zip(zipfile,files,rootfolder)` returns a string cell array of the names of the files contained in `zipfile`. Specifying `rootfolder` is optional.

Input Arguments

`zipfile`

String that specifies the name of the zip file. If `zipfile` has no extension, MATLAB appends the `.zip` extension.

If `files` includes relative paths, the zip file also contains relative paths. The zip file does not include absolute paths.

`files`

String or cell array of strings containing the list of files or folders to include in `zipfile`.

Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.

Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with `~/` or `~username/`, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

`rootfolder`

String that specifies the root of the paths for the files to zip.

Relative paths in the zip file reflect the relative paths in `files`, and do not include path information from `rootfolder`.

Default: current folder (`'.'`)

Output Arguments

`entrynames`

Cell array of strings that contain the paths to the files in `zipfile`. If files includes relative paths, `entrynames` also contains relative paths.

Examples

Zip a File

Create a zip file of the file `membrane.m`, which is in the MATLAB `general` folder. Save the zip file `tmwlogo.zip` in the current folder.

```
file = fullfile(matlabroot,'toolbox','matlab','general','membrane.m');
zip('tmwlogo',file);
```

Zip Selected Files

Suppose that your system has a folder named `d:/myfiles`. Zip the files `membrane.m` and `logo.m`, which are on the MATLAB search path, into a file named `tmwlogo.zip`.

```
myfile = fullfile('d:','myfiles','tmwlogo.zip');
zip(myfile,{'membrane.m','logo.m'});
```

Zip all `.m` and `.mat` files in the current folder to the file `backup.zip`.

```
zip('backup',{'*.m','*.mat'});
```

Zip a Folder

Suppose that your current folder contains a subfolder named `mywork`. Zip the contents of all subfolders of `mywork`, and store the relative paths in the zip file.

```
zip('myfiles.zip','mywork');
```

Zip Between Folders

Suppose that you have files `thesis.doc` and `defense.ppt` in `d:/PhD`. Zip these files into `thesis.zip`, one level up from the current folder.

```
zip('../thesis.zip',{'thesis.doc','defense.ppt'},'d:/PhD');
```

Create Zip Archive of Web Page

Create a zip archive of a Web page.

Locate the list of files at the MATLAB Central File Exchange uploaded within the past 7 days, that contain "Simulink."

```
filex = 'http://www.mathworks.com/matlabcentral/fileexchange/';
params = {'duration','7','term','simulink'};
```

Save the Web content to a file.

```
urlwrite(filex,'contains_simulink.html','get',params);
```

Create a zip archive of the retrieved Web page, using the `zip` function.

```
zip('simulink_matches.zip','contains_simulink.html');
```

`zip` creates a zip archive named `simulink_matches.zip` that contains the file, `contains_simulink.html`.

Alternatives

To zip files in the Current Folder browser, select the files, right-click to open the context menu, and then select **Create Zip File**.

`gzip` | `gunzip` | `tar` | `untar` | `unzip`

Introduced before R2006a

zoom

Turn zooming on or off or magnify by factor

Syntax

```
zoom on
zoom off
zoom out
zoom reset
zoom
zoom xon
zoom yon
zoom(factor)
zoom(fig, option)
h = zoom(figure_handle)
```

Description

`zoom on` turns on interactive zooming. When interactive zooming is enabled in a figure, pressing a mouse button while your cursor is within an axes zooms into the point or out from the point beneath the mouse. Zooming changes the axes limits. When using zoom mode, you

- Zoom in by positioning the mouse cursor where you want the center of the plot to be and either
  - Press the mouse button or
  - Rotate the mouse scroll wheel away from you (upward).
- Zoom out by positioning the mouse cursor where you want the center of the plot to be and either
  - Simultaneously press **Shift** and the mouse button, or
  - Rotate the mouse scroll wheel toward you (downward).

Each mouse click or scroll wheel click zooms in or out by a factor of 2.

Clicking and dragging over an axes when zooming in is enabled draws a rubberband box. When you release the mouse button, the axes zoom in to the region enclosed by the rubberband box.

Double-clicking over an axes returns the axes to its initial zoom setting in both zoom-in and zoom-out modes.

`zoom off` turns interactive zooming off.

`zoom out` returns the plot to its initial zoom setting.

`zoom reset` remembers the current zoom setting as the initial zoom setting. Later calls to `zoom out`, or double-clicks when interactive `zoom` mode is enabled, will return to this zoom level.

`zoom` toggles the interactive zoom status between off and on (restoring the most recently used zoom tool).

`zoom xon` and `zoom yon` set `zoom on` for the *x*- and *y*-axis, respectively.

`zoom(factor)` zooms in or out by the specified zoom factor, without affecting the interactive zoom mode. Values greater than 1 zoom in by that amount, while numbers greater than 0 and less than 1 zoom out by `1/factor`.

`zoom(fig, option)` Any of the preceding options can be specified on a figure other than the current figure using this syntax.

`h = zoom(figure_handle)` returns a zoom *mode object* for the figure `figure_handle` for you to customize the mode's behavior.

Using Zoom Mode Objects

You can access the following properties.

- *`Enable`* `'on'|'off'` — Specifies whether this figure mode is currently enabled on the figure
- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set
- *`Motion`* `'horizontal'|'vertical'|'both'` — The type of zooming enabled for the figure

- *`Direction`* `'in'|'out'` — The direction of the zoom operation
- *`RightClickAction`* `'InverseZoom'|'PostContextMenu'` — The behavior of a right-click action

  A value of `'InverseZoom'` causes a right-click to zoom out. A value of `'PostContextMenu'` displays a context menu. This setting persists between MATLAB sessions.
- `UIContextMenu <handle>` — Specifies a custom context menu to be displayed during a right-click action

  This property is ignored if the `RightClickAction` property has been set to `'on'`.

Zoom Mode Callbacks

You can program the following callbacks for zoom mode operations.

- `ButtonDownFilter <function_handle>` — Function to intercept `ButtonDown` events

  The application can inhibit the zoom operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function [res] = myfunction(obj,event_obj)
% obj          handle to the object clicked on
% event_obj    struct for event data (empty in this release)
% res [output] a logical flag determines whether the zoom
%              operation should take place(for 'res' set
%              to 'false' or the 'ButtonDownFcn' property
%              of the object should take precedence (when
%              'res' is 'true')
```

- `ActionPreCallback <function_handle>` — Function to execute before zooming

  Set this callback if you want to execute code when a zoom operation starts. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj          handle to the figure clicked on
% event_obj    object containing struct of event data
```

The event data has the following field.

`Axes`	The handle of the axes that is being zoomed

- `ActionPostCallback <function_handle>` — Function to execute after zooming

  Set this callback if you want to execute code when a zoom operation finishes. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj         handle to the figure clicked on
% event_obj   object containing struct of event data
%             (same as the event data of the
%             'ActionPreCallback' callback)
```

Zoom Mode Utility Functions

The following functions in zoom mode query and set certain of its properties.

- `flags = isAllowAxesZoom(h,axes)` — Function querying permission to zoom axes

  Calling the function `isAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a zoom operation is permitted on the axes objects.

- `setAllowAxesZoom(h,axes,flag)` — Function to set permission to zoom axes

  Calling the function `setAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a zoom operation on the axes objects.

- *`info`* `= getAxesZoomMotion(h,axes)` — Function to get style of zoom operations

  Calling the function `getAxesZoomMotion` on the zoom object, `H`, with a vector of axes handles, `axes`, as input returns a character cell array of the same dimension as the axes handle vector, which indicates the type of zoom operation for each axes. Possible values for the type of operation are `'horizontal'`, `'vertical'`, or `'both'`.

- `setAxesZoomMotion(h,axes,style)` — Function to set style of zoom operations

Calling the function `setAxesZoomMotion` on the zoom object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of zooming on each axes.

Examples

Example 1 — Entering Zoom Mode

Plot a graph and turn on Zoom mode:

```
plot(1:10);
zoom on
% zoom in on the plot
```

Example 2 — Constrained Zoom

Create zoom mode object and constrain to *x*-axis zooming:

```
plot(1:10);
h = zoom;
h.Motion = 'horizontal';
h.Enable = 'on';
% zoom in on the plot in the horizontal direction.
```

Example 3 — Constrained Zoom in Subplots

Create four axes as subplots and set zoom style differently for each by setting a different property for each axes handle:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = zoom;
ax2 = subplot(2,2,2);
plot(rand(3));
setAllowAxesZoom(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesZoomMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesZoomMotion(h,ax4,'vertical');
```

```
% Zoom in on the plots.
```

Example 4 — Coding a ButtonDown Callback

Create a buttonDown callback for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zooming behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
hLine.ButtonDownFnc = 'disp(''This executes'')';
hLine.Tag = 'DoNotIgnore';
h = zoom;
h.ButtonDownFilter = @mycallback;
h.Enable = 'on';
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = obj.Tag;
if strcmpi(objTag,'DoNotIgnore')
   flag = true;
else
   flag = false;
end
```

Example 5 — Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-buttonDown events for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zoom behavior:

```
function demo
% Listen to zoom events
plot(1:10);
h = zoom;
h.ActionPreCallback = @myprecallback;
h.ActionPostCallback = @mypostcallback;
h.Enable = 'on';
%
function myprecallback(obj,evd)
disp('A zoom is about to occur.');
%
function mypostcallback(obj,evd)
```

```
newLim = evd.Axes.XLim;
msgbox(sprintf('The new X-Limits are [%.2f %.2f].',newLim));
```

Example 6 — Creating a Context Menu for Zoom Mode

Coding a context menu that lets the user to switch to Pan mode by right-clicking:

```
figure
plot(magic(10))
hCMZ = uicontextmenu;
hZMenu = uimenu('Parent',hCMZ,'Label','Switch to pan',...
'Callback','pan(gcbf,''on'')');
hZoom = zoom(gcf);
hZoom.UIContextMenu = hCMZ;
zoom('on')
```

You cannot add items to the built-in zoom context menu, but you can replace it with your own.

Alternatives

Use the Zoom tools  on the figure toolbar to zoom in or zoom out on a plot, or select **Zoom In** or **Zoom Out** from the figure's **Tools** menu. For details, see “Zooming in Graphs”.

More About

Tips

`zoom` changes the axes limits by a factor of 2 (in or out) each time you press the mouse button while the cursor is within an axes. You can also click and drag the mouse to define a zoom area, or double-click to return to the initial zoom level.

You can create a zoom mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

Note: Do not change figure callbacks within an interactive mode. While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change

any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a UI that updates a figure's callbacks, the UI should somehow keep track of which interactive mode is active, if any, before attempting to do this.

When you assign different zoom behaviors to different `subplot` axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.
