Revision History

December 1996	First printing	For MATLAB 5.0 (Release 8)
June 1997	Online only	Revised for MATLAB 5.1 (Release 9)
October 1997	Online only	Revised for MATLAB 5.2 (Release 10)
January 1999	Online only	Revised for MATLAB 5.3 (Release 11)
June 1999	Second printing	For MATLAB 5.3 (Release 11)
June 2001	Online only	Revised for MATLAB 6.1 (Release 12.1)
July 2002	Online only	Revised for 6.5 (Release 13)
June 2004	Online only	Revised for 7.0 (Release 14)
September 2006	Online only	Revised for 7.3 (Release 2006b)
March 2007	Online only	Revised for 7.4 (Release 2007a)
September 2007	Online only	Revised for Version 7.5 (Release 2007b)
March 2008	Online only	Revised for Version 7.6 (Release 2008a)
October 2008	Online only	Revised for Version 7.7 (Release 2008b)
March 2009	Online only	Revised for Version 7.8 (Release 2009a)
September 2009	Online only	Revised for Version 7.9 (Release 2009b)
March 2010	Online only	Revised for Version 7.10 (Release 2010a)
September 2010	Online only	Revised for Version 7.11 (Release 2010b)
April 2011	Online only	Revised for Version 7.12 (Release 2011a)
September 2011	Online only	Revised for Version 7.13 (Release 2011b)
March 2012	Online only	Revised for Version 7.14 (Release 2012a)
September 2012	Online only	Revised for Version 8.0 (Release 2012b)
March 2013	Online only	Revised for Version 8.1 (Release 2013a)
September 2013	Online only	Revised for Version 8.2 (Release 2013b)
March 2014	Online only	Revised for Version 8.3 (Release 2014a)
October 2014	Online only	Revised for Version 8.4 (Release 2014b)
March 2015	Online only	Revised for Version 8.5 (Release 2015a)

Relational Operators < > <= >= == ~=

Relational operations

Syntax

```
A < B

A > B

A <= B

A >= B

A == B

A ~= B
```

Description

The relational operators are <, >, <=, >=, ==, and ~=. Relational operators perform element-by-element comparisons between two arrays. They return a `logical` array of the same size, with elements set to logical `1` (`true`) where the relation is true, and elements set to logical `0` (`false`) where it is not.

The operators <, >, <=, and >= use only the real part of their operands for the comparison. The operators == and ~= test real and imaginary parts.

To test if two strings are equivalent, use `strcmp`, which allows vectors of dissimilar length to be compared.

Note For some toolboxes, the relational operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type `help` followed by the operator name. For example, type `help lt`. The toolboxes that overload `lt (<)` are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

Examples

If one of the operands is a scalar and the other a matrix, the scalar expands to the size of the matrix. For example, the two pairs of statements

```
X = 5; X >= [1 2 3; 4 5 6; 7 8 10]
X = 5*ones(3,3); X >= [1 2 3; 4 5 6; 7 8 10]
```

produce the same result:

```
ans =

     1     1     1
     1     1     0
     0     0     0
```

See Also

`all` | `any` | `find` | `Logical Operators: Short Circuit` | `strcmp`

Logical Operators: Short-Circuit && ||

Logical operations with short-circuiting

Syntax

```
expr1 && expr2
expr1 || expr2
```

Description

`expr1 && expr2` represents a logical `AND` operation that employs short-circuiting behavior. That is, `expr2` is not evaluated if `expr1` is logical `0` (`false`). Each expression must evaluate to a scalar logical result.

`expr1 || expr2` represents a logical `OR` operation that employs short-circuiting behavior. That is, `expr2` is not evaluated if `expr1` is logical `1` (`true`). Each expression must evaluate to a scalar logical result.

Examples

Use Scalar Logical Conditions

Create two vectors.

```
X = [1 0 0 1 1];
Y = [0 0 0 0 0];
```

Use the short-circuit OR operator with `X` and `Y`.

```
X || Y
```

```
Operands to the || and && operators must be convertible to logical scalar values.
```

The short-circuit operators operate only with scalar logical conditions.

Use the `any` and `all` functions to reduce each vector to a single logical condition.

```
any(X) || any(Y)

ans =

     1
```

The expression is equivalent to `1 || 0`, so it evaluates to logical `1` (`true`) after computing only the first condition, `any(X)`.

Specify Dependent Logical Conditions

Specify a logical statement where the second condition depends on the first. In the following statement, it doesn't make sense to evaluate the relation on the right if the divisor, `b`, is zero.

```
b = 1;
a = 20;
x = (b ~= 0) && (a/b > 18.5)

x =

     1
```

The result is logical `1` (`true`). However, if `(b ~= 0)` evaluates to `false`, MATLAB® assumes the entire expression to be `false` and terminates its evaluation of the expression early.

Specify `b = 0` and evaluate the same expression.

```
b = 0;
x = (b ~= 0) && (a/b > 18.5)

x =

     0
```

The result is logical `0` (`false`). The first statement evaluates to logical `0` (`false`), so the expression short-circuits.

Change Structure Field Value

Create a structure with fields named `'File'` and `'Format'`.

```
S = struct('File',{'myGraph'},'Format',[])
```

```
S =

      File: 'myGraph'
    Format: []
```

Short-circuit expressions are useful in *if* statements when you want multiple conditions to be true. The conditions can build on one another in such a way that it only makes sense to evaluate the second expression if the first expression is true.

Specify an *if* statement that executes only when `S` contains an empty field named `'Format'`.

```
if isfield(S,'Format') && isempty(S.Format)
  S.Format = '.png';
end
S
```

```
S =

      File: 'myGraph'
    Format: '.png'
```

The first condition tests if the string `'Format'` is the name of a field in structure `S`. The second statement then tests whether the `Format` field is empty. The truth of the second condition depends on the first. The second condition can never be true if the first condition is not true. Since `S` has an empty field named `'Format'`, the body statement executes and assigns `S.Format` the value `'.png'`.

More About

Logical Short-Circuiting

With logical short-circuiting, the second operand, `expr2`, is evaluated only when the result is not fully determined by the first operand, `expr1`.

Due to the properties of logical AND and OR, the result of a logical expression is sometimes fully determined before evaluating all of the conditions. The logical `and` operator returns logical `0` (`false`) if even a single condition in the expression is false. The logical `or` operator returns logical `1` (`true`) if even a single condition in the expression is true. When the evaluation of a logical expression terminates early by encountering one of these values, the expression is said to have *short-circuited*.

For example, in the expression `A && B`, MATLAB does not evaluate condition `B` at all if condition `A` is false. If `A` is false, then the value of `B` does not change the outcome of the operation.

When you use the element-wise `&` and `|` operators in the context of an `if` or `while` loop expression (and *only* in that context), they use short-circuiting to evaluate expressions.

Note: Always use the `&&` and `||` operators to enable short-circuit evaluation. Using the `&` and `|` operators for short-circuiting can yield unexpected results when the expressions do not evaluate to logical scalars.

Special Characters [ ] ( ) {} = ' . ... , ; : % ! @

Special characters

Syntax

```
[ ]
{ }
( )
=
'
.
.
.( )
..
...
,
;
:
%
%{ %}
!
@
```

Description

`[ ]` Brackets are used to form vectors and matrices. `[6.9 9.64 sqrt(-1)]` is a vector with three elements separated by blanks. `[6.9, 9.64, i]` is the same thing. `[1+j 2-j 3]` and `[1 +j 2 -j 3]` are not the same. The first has three elements, the second has five.

`[11 12 13; 21 22 23]` is a 2-by-3 matrix. The semicolon ends the first row.

Vectors and matrices can be used inside `[ ]` brackets. `[A B;C]` is allowed if the number of rows of `A` equals the number of rows of `B` and the number of columns of `A` plus the number of columns of `B` equals the number of columns of `C`. This rule generalizes to allow fairly complicated constructions.

`A = [ ]` stores an empty matrix in `A`. `A(m,:) = [ ]` deletes row `m` of `A`. `A(:,n) = [ ]` deletes column `n` of `A`. `A(n) = [ ]` reshapes `A` into a column vector and deletes the `n`th element.

`[A1,A2,A3...] = function` assigns function output to multiple variables.

For the use of `[` and `]` on the left of an "=" in multiple assignment statements, see `lu`, `eig`, `svd`, and so on.

`{ }` Curly braces are used in cell array assignment statements. For example, `A(2,1) = {[1 2 3; 4 5 6]}`, or `A{2,2} = ('str')`. See `help paren` for more information about `{ }`.

`( )` Parentheses are used to indicate precedence in arithmetic expressions in the usual way. They are used to enclose arguments of functions in the usual way. They are also used to enclose subscripts of vectors and matrices in a manner somewhat more general than usual. If `X` and `V` are vectors, then `X(V)` is `[X(V(1)), X(V(2)), ..., X(V(n))]`. The components of `V` must be integers to be used as subscripts. An error occurs if any such subscript is less than 1 or greater than the size of `X`. Some examples are

- `X(3)` is the third element of `X`.
- `X([1 2 3])` is the first three elements of `X`.

  See `help paren` for more information about `( )`.

If `X` has `n` components, `X(n:-1:1)` reverses them. The same indirect subscripting works in matrices. If `V` has `m` components and `W` has `n` components, then `A(V,W)` is the `m`-by-`n` matrix formed from the elements of `A` whose subscripts are the elements of `V` and `W`. For example, `A([1,5],:) = A([5,1],:)` interchanges rows 1 and 5 of `A`.

`=` Used in assignment statements. `B = A` stores the elements of `A` in `B`. == is the relational equals operator. See the Relational Operators page.

`'` Matrix transpose. `X'` is the complex conjugate transpose of `X`. `X.'` is the nonconjugate transpose.

Quotation mark. `'any text'` is a vector whose components are the ASCII codes for the characters. A quotation mark within the text is indicated by two quotation marks.

`.` Decimal point. `314/100`, `3.14`, and `.314e1` are all the same.

Element-by-element operations. These are obtained using `.*` , `.^`, `./`, or `.\`. See the Arithmetic Operators page.

`.` Field access. `S(m).f` when `S` is a structure, accesses the contents of field `f` of that structure.

`.( )` Dynamic Field access. `S.(df)` when `S` is a structure, accesses the contents of dynamic field `df` of that structure. Dynamic field names are defined at runtime.

`..` Parent folder. See `cd`.

`...` Continuation. Three or more periods at the end of a line continue the current function on the next line. Three or more periods before the end of a line cause the MATLAB software to ignore the remaining text on the current line and continue the function on the next line. This effectively makes a comment out of anything on the current line that follows the three periods. For an example, see "Continue Long Statements on Multiple Lines".

`,` Comma. Used to separate matrix subscripts and function arguments. Used to separate statements in multistatement lines. For multistatement lines, the comma can be replaced by a semicolon to suppress printing.

`;` Semicolon. Used inside brackets to end rows. Used after an expression or statement to suppress printing or to separate statements.

`:` Colon. Create vectors, array subscripting, and `for` loop iterations. See `colon (:)` for details.

`%` Percent. The percent symbol denotes a comment; it indicates a logical end of line. Any following text is ignored. MATLAB displays the first contiguous comment lines in a function or script file in response to a `help` command.

`%{ %}` Percent-brace. The text enclosed within the `%{` and `%}` symbols is a comment block. Use these symbols to insert comments that take up more than a single line in your script of function code. Any text between these two symbols is ignored by MATLAB.

With the exception of whitespace characters, the %{ and %} operators must appear alone on the lines that immediately precede and follow the block of help text. Do not include any other text on these lines.

`!` Exclamation point. Indicates that the rest of the input line is issued as a command to the operating system. See "Run External Commands, Scripts, and Programs" for more information.

`@`	Function handle. MATLAB data type that is a handle to a function. See `function_handle (@)` for details.

More About

Tips

Some uses of special characters have function equivalents, as shown:

Horizontal concatenation	`[A,B,C...]`	`horzcat(A,B,C...)`
Vertical concatenation	`[A;B;C...]`	`vertcat(A,B,C...)`
Subscript reference	`A(i,j,k...)`	`subsref(A,S)`. See help `subsref`.
Subscript assignment	`A(i,j,k...)= B`	`subsasgn(A,S,B)`. See help `subsasgn`.

Note For some toolboxes, the special characters are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given character, type `help` followed by the character name. For example, type `help transpose`. The toolboxes that overload `transpose` (`.'`) are listed. For information about using the character in that toolbox, see the documentation for the toolbox.

colon (:)

Create vectors, array subscripting, and `for`-loop iterators

Description

The colon is one of the most useful operators in MATLAB. It can create vectors, subscript arrays, and specify `for` iterations.

The colon operator uses the following rules to create regularly spaced vectors for scalar values `i`, `j`, and `k`:

`j:k`	is the same as `[j,j+1,j+2,...,j+m]`, where `m = fix(k-j)`. In the case where both `j` and `k` are integers, this is simply `[j,j+1,...,k]`. This syntax returns an empty matrix when `j > k`.
`j:i:k`	is the same as `[j,j+i,j+2i, ...,j+m*i]`, where `m = fix((k-j)/i)`. This syntax returns an empty matrix when `i == 0`, `i > 0` and `j > k`, or `i < 0` and `j < k`.

If `i`, `j`, or `k` is an empty input, then the colon operator returns an empty 1-by-0 matrix. If you specify nonscalar arrays, MATLAB interprets `j:i:k` as `j(1):i(1):k(1)`.

You can use the colon to create a vector of indices to select rows, columns, or elements of arrays, where:

`A(:,j)`	is the `j`th column of `A`.
`A(i,:)`	is the `i`th row of `A`.
`A(:,:)`	is the equivalent two-dimensional array. For matrices this is the same as `A`.
`A(j:k)`	is `A(j), A(j+1),...,A(k)`.
`A(:,j:k)`	is `A(:,j), A(:,j+1),...,A(:,k)`.
`A(:,:,k)`	is the `k`th page of three-dimensional array `A`.
`A(i,j,k,:)`	is a vector in four-dimensional array `A`. The vector includes `A(i,j,k,1)`, `A(i,j,k,2)`, `A(i,j,k,3)`, and so on.

`A(:)` is all the elements of `A`, regarded as a single column. On the left side of an assignment statement, `A(:)` fills `A`, preserving its shape from before. In this case, the right side must contain the same number of elements as `A`.

When you create a vector to index into a cell array or structure array (such as *`cellName`*`{:}` or *`structName`*`(:).`*`fieldName`*), MATLAB returns multiple outputs in a comma-separated list. For more information, see "How to Use the Comma-Separated Lists" in the MATLAB Programming Fundamentals documentation.

Examples

Using the colon with integers,

```
D = 1:4
```

results in

```
D =
    1    2    3    4
```

Using two colons to create a vector with arbitrary real increments between the elements,

```
E = 0:.1:.5
```

results in

```
E =
    0    0.1000    0.2000    0.3000    0.4000    0.5000
```

The command

```
A(:,:,2) = pascal(3)
```

generates a three-dimensional array whose first page is all zeros.

```
A(:,:,1) =
     0     0     0
     0     0     0
     0     0     0

A(:,:,2) =
     1     1     1
```

```
     1     2     3
     1     3     6
```

Using a colon with characters to iterate a for-loop,

```
for x='a':'d',x,end
```

results in

```
x =
    a
x =
    b
x =
    c
x =
    d
```

abs

Absolute value and complex magnitude

Syntax

```
Y = abs(X)
```

Description

`Y = abs(X)` returns the absolute value of each element in array `X`.

If `X` is complex, `abs(X)` returns the complex magnitude.

Examples

Absolute Value of Scalar

```
y = abs(-5)
```

```
y =

     5
```

Absolute Value of Vector

Create a numeric vector of real values.

```
x = [1.3 -3.56 8.23 -5 -0.01]'
```

```
x =

    1.3000
   -3.5600
    8.2300
   -5.0000
   -0.0100
```

Find the absolute value of the elements of the vector.

```
y = abs(x)

y =

    1.3000
    3.5600
    8.2300
    5.0000
    0.0100
```

Magnitude of Complex Number

```
y = abs(3+4i)

y =

     5
```

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. `X` can be a `single` array, `double` array, signed integer array, or `duration` array. The size and data type of the output array is the same as the input array.
Complex Number Support: Yes

More About

Absolute Value

The absolute value (or modulus) of a real number is the corresponding nonnegative value that disregards the sign.

For a real value, `a`, the absolute value is:

- `a`, if `a` is greater than or equal to zero
- `-a`, if `a` is less than zero

`abs(-0)` returns `0`.

Complex Magnitude

The complex magnitude (or modulus) is the length of a vector from the origin to a complex value plotted in the complex plane.

For a complex value, $|a+bi|$ is defined as $\sqrt{a^2+b^2}$.

Introduced before R2006a

accumarray

Construct array with accumulation

Syntax

```
A = accumarray(subs,val)
A = accumarray(subs,val,sz)
A = accumarray(subs,val,sz,fun)
A = accumarray(subs,val,sz,fun,fillval)
A = accumarray(subs,val,sz,fun,fillval,issparse)
```

Description

`A = accumarray(subs,val)` returns an array, `A`, by accumulating elements of vector `val` using the subscripts in `subs`. The values in each row of the *m*-by-*n* matrix `subs` define an *n*-dimensional subscript into the output, `A`. If `subs` is a column vector, the value in each row defines a row subscript into the output, which is also a column vector.

The ith row of `subs` corresponds to the ith element in the vector, `val`. The function collects all elements of `val` that have identical subscripts in `subs`, applies the function `@sum`, and then stores the result in the location of `A` corresponding to the subscript. Elements of `A` that are not referred to by any row of `subs` contain the value `0`.

`A = accumarray(subs,val,sz)` returns an array, `A`, with size `sz`. Specify `sz` as a vector of positive integers to define the size of the output, or as `[]` to let the subscripts in `subs` determine the size of the output. Use `sz` when `subs` does not reference trailing rows, columns, or dimensions that you would like to be present in the output.

`A = accumarray(subs,val,sz,fun)` applies the function `fun` to each subset of elements in `val` that have identical subscripts in `subs`. Specify `fun` using the `@` symbol (e.g., `@mean`), or as `[]` to use the default function, `@sum`.

`A = accumarray(subs,val,sz,fun,fillval)` fills all elements of `A` that are not referred to by any subscript in `subs` with the scalar value, `fillval`. The `fillval` input must have the same class as the values returned by `fun`. Specify `fillval` as `[]` to use the default value, `0`.

`A = accumarray(subs,val,sz,fun,fillval,issparse)` returns an array, `A`, that is sparse if the scalar `issparse` is `true` or `1`, and full if `issparse` is `false` or `0`. The output, `A`, is full by default.

Examples

Find Bin Counts

Create a vector of subscripts, `subs`.

```
subs = [1; 2; 4; 2; 4]
```

```
subs =
     1
     2
     4
     2
     4
```

Use `accumarray` with `val = 1` to count the number of identical subscripts in `subs`.

```
A = accumarray(subs,1)
```

```
A =

     1
     2
     0
     2
```

The result is a vector of bin counts. You can obtain the same answer with `histcounts(subs,'BinMethod','integers')`. However, `accumarray` also can compute bin counts over higher dimensional grids.

Accumulate Data

Create a vector of data, `val`, and a vector of subscript values with the same length, `subs`.

```
val = 101:105';
subs = [1; 3; 4; 3; 4]
```

```
subs =
```

```
     1
     3
     4
     3
     4
```

Use `accumarray` to sum the values in `val` that have identical subscripts in `subs`.

```
A = accumarray(subs,val)
```

```
A =
   101
     0
   206
   208
```

The result is a vector of accumulated values. Since the second and fourth elements of `subs` are equal to 3, `A(3)` is the sum of the second and fourth elements of `val`, that is, `A(3) = 102 + 104 = 206`. Also, `A(2) = 0` because `subs` does not contain the value `2`. Since `subs` is a vector, the output, `A`, is also a vector. The length of `A` is `max(subs, [],1)`.

Specify Output Size

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 101:106';
subs = [1 1; 2 2; 3 2; 1 1; 2 2; 4 1]
```

```
subs =

     1     1
     2     2
     3     2
     1     1
     2     2
     4     1
```

The subscripts in `subs` define a 4-by-2 matrix for the output.

Use `accumarray` to sum the values in `val` that have identical subscripts in `subs`.

```
A = accumarray(subs,val)
```

```
A =
```

```
   205     0
     0   207
     0   103
   106     0
```

The result is a 4-by-2 matrix of accumulated values.

Use the `sz` input of `accumarray` to return a 4-by-4 matrix. You can specify a size with each dimension equal to or greater than the default size, in this case 4-by-2, but not smaller.

```
A = accumarray(subs,val,[4 4])
```

```
A =

   205     0     0     0
     0   207     0     0
     0   103     0     0
   106     0     0     0
```

The result is a 4-by-4 matrix of accumulated values.

Use Custom Functions

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = [100.1 101.2 103.4 102.8 100.9 101.5]';
subs = [1 1; 1 1; 2 2; 3 2; 2 2; 3 2]
```

```
subs =

     1     1
     1     1
     2     2
     3     2
     2     2
     3     2
```

The subscripts in `subs` define a 3-by-2 matrix for the output.

Use the `fun` input of `accumarray` to calculate the within-group variances of data in `val` that have identical subscripts in `subs`. Specify `fun` as `@var`.

```
A1 = accumarray(subs,val,[],@var)
```

```
A1 =

    0.6050         0
         0    3.1250
         0    0.8450
```

The result is a 3-by-2 matrix of variance values.

Alternatively, you can specify `fun` as an anonymous function so long as it accepts vector inputs and returns a scalar. A common situation where this is useful is when you want to pass additional parameters to a function. In this case, use the `var` function with a normalization parameter.

```
A2 = accumarray(subs,val,[],@(x) var(x,1))
```

```
A2 =

    0.3025         0
         0    1.5625
         0    0.4225
```

The result is a 3-by-2 matrix of normalized variance values.

Sum Values Natively

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = int8(10:15);
subs = [1 1 1; 1 1 1; 1 1 2; 1 1 2; 2 3 1; 2 3 2]
```

```
subs =

     1     1     1
     1     1     1
     1     1     2
     1     1     2
     2     3     1
     2     3     2
```

The subscripts in `subs` define a 2-by-3-by-2 multidimensional array for the output.

Use `accumarray` to sum the data values in `val` that have identical subscripts in `subs`. You can use a function handle to sum the values in their native, `int8`, integer class by using the `'native'` option of the `sum` function.

```
A = accumarray(subs,val,[],@(x) sum(x,'native'))

A(:,:,1) =

   21    0    0
    0    0   14

A(:,:,2) =

   25    0    0
    0    0   15
```

The result is a 2-by-3-by-2 multidimensional array of class `int8`.

Group Values in Cell Array

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 1:10;
subs = [1 1;1 1;1 1;1 1;2 1;2 1;2 1;2 1;2 1;2 2]

subs =

     1     1
     1     1
     1     1
     1     1
     2     1
     2     1
     2     1
     2     1
     2     1
     2     2
```

The subscripts in `subs` define a 2-by-2 matrix for the output.

Use `accumarray` to group the elements of `val` into a cell array.

```
A = accumarray(subs,val,[],@(x) {x})

A =

    [4x1 double]      []
```

```
    [5x1 double]    [10]
```

The result is a 2-by-2 cell array.

Verify that the vector elements are in the same order as they appear in `val`.

```
A{2,1}
```

```
ans =

     5
     6
     7
     8
     9
```

Since the subscripts in `subs` are sorted, the elements of the numeric vectors in the cell array are in the same order as they appear in `val`.

Using Functions That Depend on Data Order

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 1:5;
subs = [1 2; 1 1; 1 2; 1 1; 2 3]
```

```
subs =

     1     2
     1     1
     1     2
     1     1
     2     3
```

The subscripts in `subs` define a 2-by-3 matrix for the output, but are unsorted with respect to the linear indices in the output, `A`.

Group the values in `val` into a cell array by specifying `fun = @(x) {x}`.

```
A = accumarray(subs,val,[],@(x) {x})
```

```
A =

    [2x1 double]    [2x1 double]     []
```

```
    []        []    [5]
```

The result is a 2-by-3 cell array.

Examine the vector in `A{1,2}`.

```
A{1,2}

ans =

     3
     1
```

The elements of the `A{1,2}` vector are in a different order than in `val`. The first element of the vector is 3 instead of 1. If the subscripts in `subs` are not sorted with respect to their linear indices, then `accumarray` might not always preserve the order of the data in `val` when it passes them to `fun`. In the unusual case that `fun` requires that its input values be in the same order as they appear in `val`, sort the indices in `subs` with respect to the linear indices of the output.

In this case, use the `sortrows` function with two inputs and two outputs to reorder `subs` and `val` concurrently with respect to the linear indices of the output.

```
[S,I] = sortrows(subs,[2,1]);
A = accumarray(S,val(I),[],@(x) {x});
A{1,2}

ans =

     1
     3
```

The elements of the `A{1,2}` vector are now in sorted order.

Fill Output with NaN Values

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = 101:106';
subs = [1 1; 2 2; 3 3; 1 1; 2 2; 4 4]

subs =
```

```
     1     1
     2     2
     3     3
     1     1
     2     2
     4     4
```

The subscripts in `subs` define a 4-by-4 matrix for the output, but only reference 4 out of the 16 elements. By default, the other 12 elements are `0` in the output.

Use the `fillval` input of `accumarray` to fill in the extra output elements with NaN values.

```
A = accumarray(subs,val,[],[],NaN)
```

```
A =

   205   NaN   NaN   NaN
   NaN   207   NaN   NaN
   NaN   NaN   103   NaN
   NaN   NaN   NaN   106
```

The result is a 4-by-4 matrix padded with NaN values.

Change Output Sparsity

Create a vector of data, `val`, and a matrix of subscripts, `subs`.

```
val = [34 22 19 85 53 77 99 6];
subs = [1 1; 400 400; 80 80; 1 1; 400 400; 400 400; 80 80; 1 1]
```

```
subs =

     1     1
   400   400
    80    80
     1     1
   400   400
   400   400
    80    80
     1     1
```

The subscripts in `subs` define a 400-by-400 matrix for the output, but only reference 3 out of the 160,000 elements. When the result of an operation with `accumarray` leads to

a large output array with low density of nonzero elements, you can save storage space by storing the output as a sparse matrix.

Use the `issparse` input of `accumarray` to return a sparse matrix.

```
A = accumarray(subs,val,[],[],[],true)
```

```
A =

   (1,1)       125
  (80,80)      118
 (400,400)     152
```

The result is a sparse matrix. You can obtain the same answer with `sparse(subs(:,1),subs(:,2),val)`.

Input Arguments

`subs` — Subscript matrix

vector of indices | matrix of indices | cell array of index vectors

Subscript matrix, specified as a vector of indices, matrix of indices, or cell array of index vectors. The indices must be positive integers:

- The value in each row of the m-by-n matrix, `subs`, specifies an n-dimensional index into the output, `A`. For example, if `subs` is a 3-by-2 matrix, it contains three 2-D subscripts. `subs` also can be a column vector of indices, in which case the output, `A`, is also a column vector.
- The ith row in `subs` corresponds to the ith data value in `val`.

Thus, `subs` determines which data in `val` to group, as well as its final destination in the output. If `subs` is a cell array of index vectors, each vector must have the same length, and the function treats the vectors as columns of a subscript matrix.

`val` — Data

vector | scalar

Data, specified as a vector or scalar:

- If `val` is a vector, it must have the same length as the number of rows in `subs`.

- If `val` is a scalar, it is scalar expanded.

In both cases, a one-to-one pairing is present between the subscripts in each row of `subs` and the data values in `val`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

`sz` — Size of output array

`[]` (default) | vector of positive integers

Size of output array, specified as a vector of positive integers or `[]` (default). When you specify `[]` for the default size, the values in `subs` determine the size of the output array, `A`.

When you specify `sz` as a vector of positive integers, it must satisfy these properties:

- If `subs` is a nonempty *m*-by-*n* matrix with `n > 1` columns, then `sz` must have *n* elements and pass the logical test `all(sz >= max(subs,[],1))`.
- If `subs` is a nonempty column vector, then `sz` must be `[m 1]` where `m >= max(subs)`.

Example: `sz = [3 3]`

`fun` — Function

`[]` (default) | function handle

Function, specified as a function handle or `[]` (default). The default function is `@sum`. The `fun` function must accept a column vector and return a numeric, `logical`, or `char` scalar, or a scalar `cell`. If the subscripts in `subs` are not sorted with respect to their linear indices, `fun` should not depend on the order of the values in its input data.

Example: `fun = @max`

Data Types: `function_handle`

`fillval` — Fill value

`[]` (default) | scalar

Fill value, specified as a scalar or `[]` (default). The default value of `fillval` is `0`. If `subs` does not reference each element in the output, `accumarray` fills in the output with

the value specified by `fillval`. The class of `fillval` must be the same as the values returned by `fun`.

`issparse` — Output sparsity

`false` (default) | `true` | `1` | `0`

Output sparsity, specified as `true`, `1`, `0`, or `false` (default). Specify `true` or `1` when you want the output array to be sparse. If `issparse` is `true` or `1`:

- `fillval` must be `0` or `[]`.
- The values in `val` and the output values of `fun` must both have type `double`.

Output Arguments

`A` — Output array

vector | matrix | multidimensional array

Output array, returned as a vector, matrix, or multidimensional array. `A` has the same class as the values returned by `fun`.

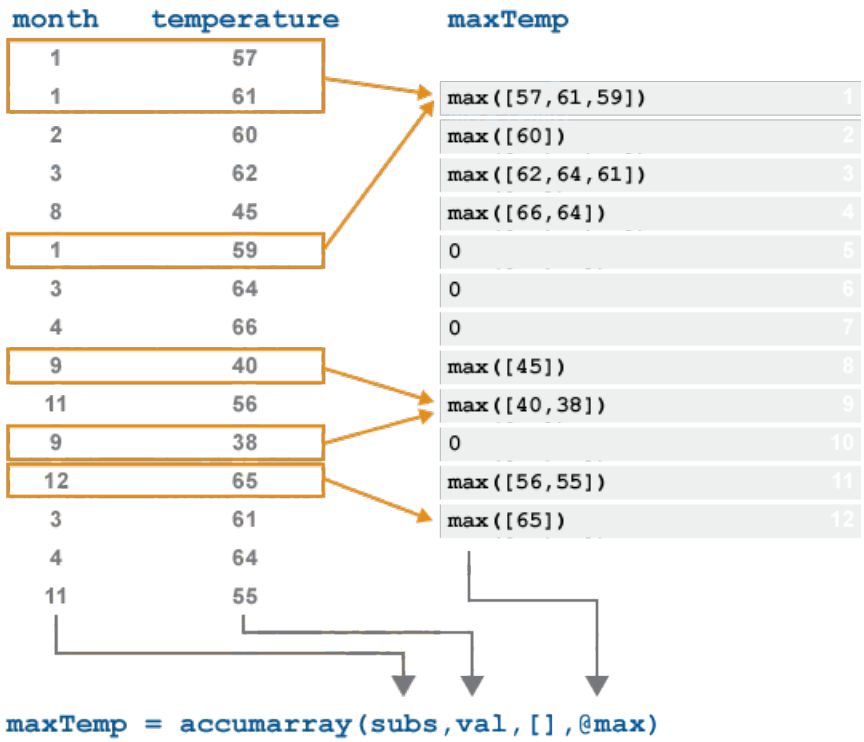
When `sz` is not specified, the size of `A` depends on the input `subs`:

- If `subs` is a nonempty matrix with `n > 1` columns, then `A` is an *n*-dimensional array of size `max(subs,[],1)`.
- If `subs` is an empty matrix with `n > 1` columns, then `A` is an *n*-dimensional empty array with size 0-by-0-by-...-by-0.
- If `subs` is a nonempty column vector, then `A` is a column vector of length `max(subs,[],1)`. The length of `A` is `0` when `subs` is empty.

More About

Accumulating Elements

The following graphic illustrates the behavior of `accumarray` on a vector of temperature data taken over a 12-month period. To find the maximum temperature reading for each month, `accumarray` applies the `max` function to each group of values in `temperature` that have identical subscripts in `month`.



No values in `month` point to the 5, 6, 7, or 10 positions of the output. These elements are `0` in the output by default, but you can specify a value to fill in using `fillval`.

Tips

- The behavior of `accumarray` is similar to that of the `histcounts` function. Both functions group data into bins.

  - `histcounts` groups continuous values into a 1-D range using bin edges. `accumarray` groups data using *n*-dimensional subscripts.
  - `histcounts` returns the bin counts and/or bin placement. However, `accumarray` can apply any function to the binned data.

  You can mimic the behavior of `histcounts` using `accumarray` with `val = 1`.

- The `sparse` function also has accumulation behavior similar to that of `accumarray`.

- `sparse` groups data into bins using 2-D subscripts, whereas `accumarray` groups data into bins using *n*-dimensional subscripts.
- `sparse` adds elements that have identical subscripts into the output. `accumarray` adds elements that have identical subscripts into the output by default, but can optionally apply any function to the bins.

acos

Inverse cosine in radians

Syntax

```
y = acos(x)
```

Description

`y = acos(x)` returns the "Inverse Cosine" on page 1-101 ($\cos^{-1}$) of the elements of x. The `acos` function operates element-wise on arrays. For real elements of x in the interval `[-1,1]`, `acos(x)` returns real values in the interval `[0,pi]`. For real values of x outside the interval `[-1,1]` and for complex values of x, `acos(x)` returns complex values. All angles are in radians.

Examples

Inverse Cosine of a Value

```
acos(0.3)
```

```
ans =
    1.2661
```

Inverse Cosine of a Vector of Complex Values

Find the inverse cosine of the elements of vector `x`. The `acos` function acts on `x` element-wise.

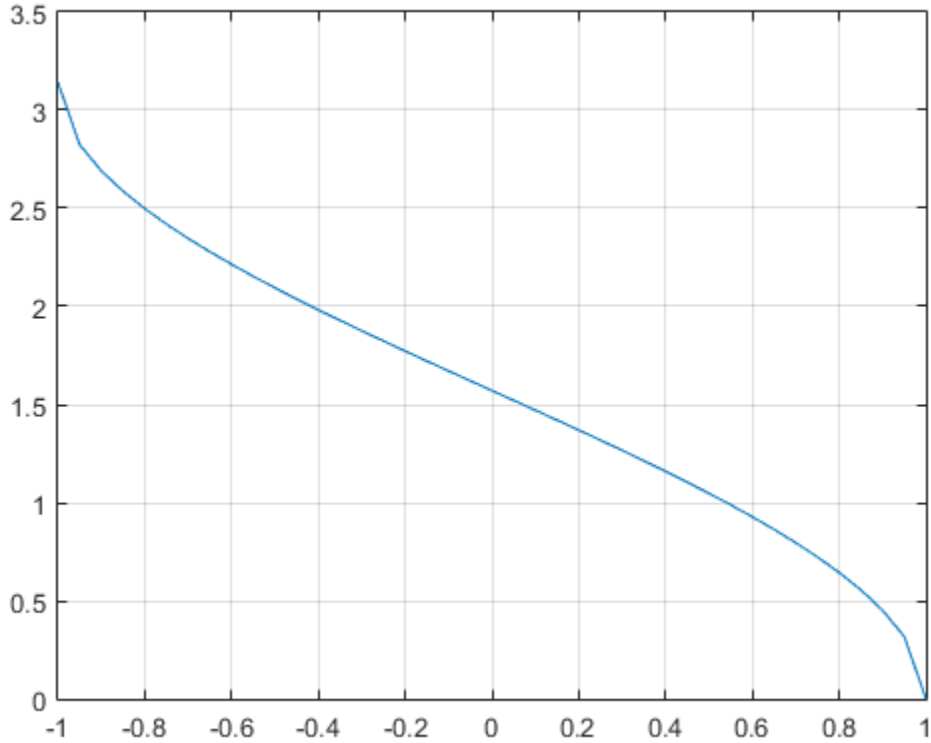
```
x = [0.5i 1+3i -2.2+i];
y = acos(x)
```

```
y =
   1.5708 - 0.4812i   1.2632 - 1.8642i   2.6799 - 1.5480i
```

Plot the Inverse Cosine Function

Plot the inverse cosine function over the domain $-1 \le x \le 1$.

```
x = -1:.05:1;
plot(x,acos(x))
grid on
```



Input Arguments

x — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

More About

Inverse Cosine

The inverse cosine is defined as

$$\cos^{-1}(z) = -i\log\left[z + i\left(1 - z^2\right)^{1/2}\right].$$

See Also

acosd | acosh | cos

Introduced before R2006a

acosd

Inverse cosine in degrees

Syntax

```
Y = acosd(X)
```

Description

`Y = acosd(X)` returns the inverse cosine ($\cos^{-1}$) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain [-1,1], `acosd` returns values in the range [0, 180]. For values of X outside this range, `acosd` returns complex values.

Examples

Inverse Cosine of 0

Verify that inverse cosine of 0 is exactly 90.

```
acosd(0)
```

```
ans =

     90
```

Round-Trip Calculation for Complex Angles

Show that the inverse cosine, followed by cosine, returns the original values of X.

```
cosd(acosd([2 3]))
```

```
ans =

    2.0000    3.0000
```

`acosd([2 3])` returns two complex angles, which are then passed to the `cosd` function. `cosd` returns the original values, `2` and `3`.

Input Arguments

X — Cosine of angle

scalar value | vector | matrix | N-D array

Cosine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acosd` operation is element-wise when X is non-scalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.

See Also

`acos` | `cos` | `cosd`

Introduced before R2006a

acosh

Inverse hyperbolic cosine

Syntax

```
Y = acosh(X)
```

Description

`Y = acosh(X)` returns the inverse hyperbolic cosine for each element of `X`.

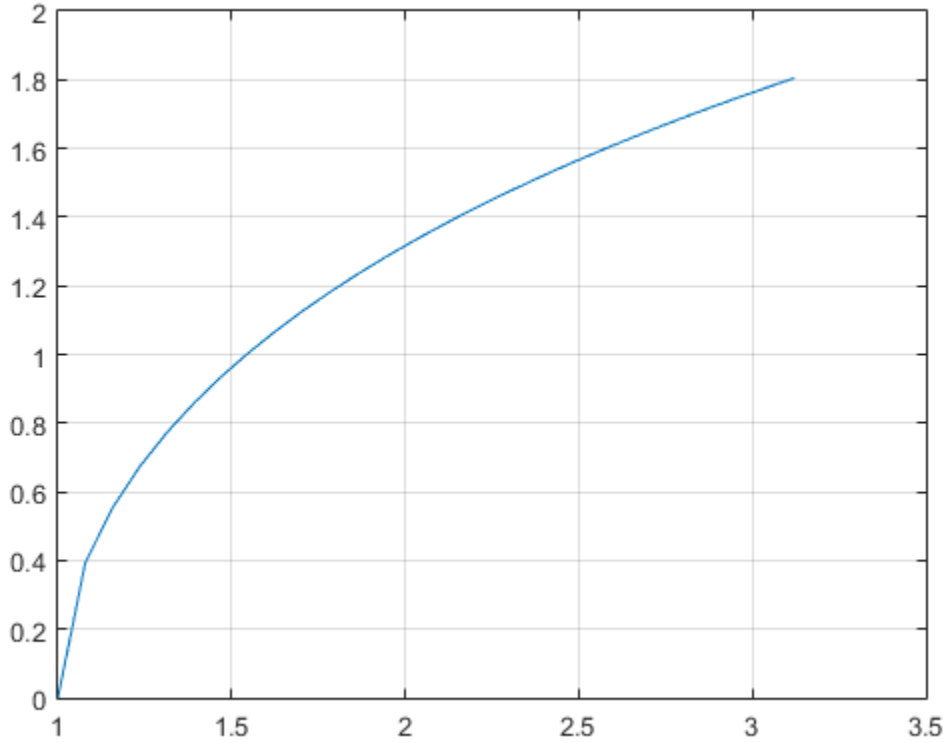
The `acosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Cosine Function

Graph the inverse hyperbolic cosine function over the domain $-1 \le x \le \pi$.

```
x = 1:pi/40:pi;
plot(x,acosh(x)), grid on
```



More About

Inverse Hyperbolic Cosine

The inverse hyperbolic cosine can be defined as

$$\cosh^{-1}(z) = \log\left[z + \left(z^2 - 1\right)^{1/2}\right].$$

Introduced before R2006a

acot

Inverse cotangent in radians

Syntax

```
Y = acot(X)
```

Description

`Y = acot(X)` returns the "Inverse Cotangent" on page 1-109 ($\cot^{-1}$) of the elements of X. The `acot` function operates element-wise on arrays. For real elements of X, `acot(X)` returns values in the interval `[-pi/2,pi/2]`. For complex values of X, `acot(X)` returns complex values. All angles are in radians.

Examples

Inverse Cotangent of a Value

```
acot(2.6)
```

```
ans =
    0.3672
```

Inverse Cotangent of a Vector of Complex Values

Find the inverse cotangent of the elements of vector `x`. The `acot` function acts on `x` element-wise.

```
x = [0.5i 1+3i -2.2+i];
Y = acot(x)
```

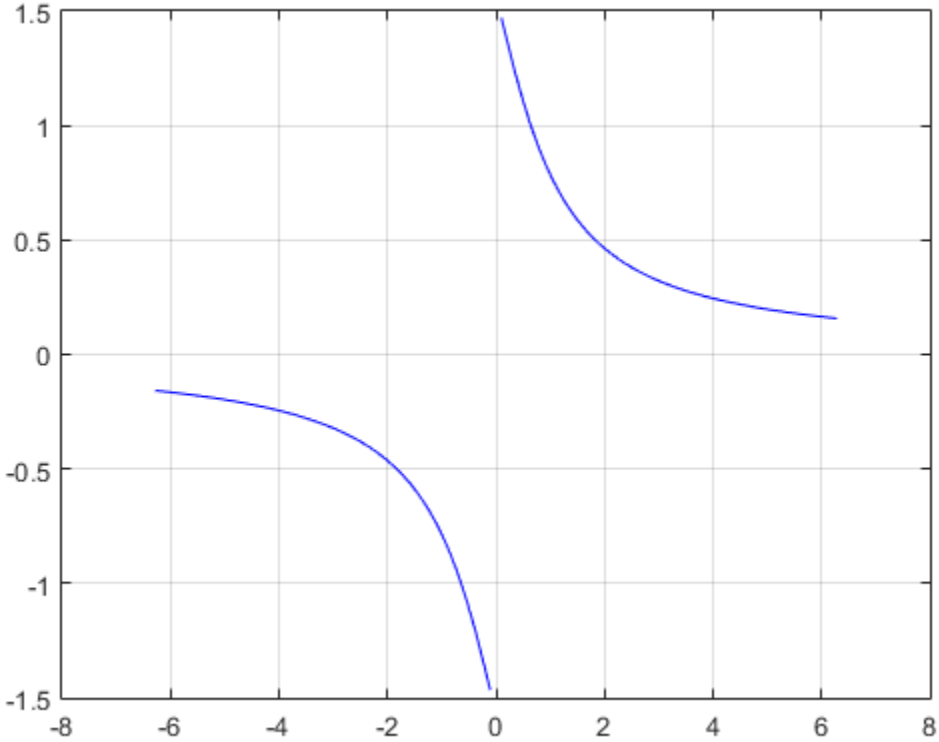
```
Y =
   1.5708 - 0.5493i   0.1093 - 0.3059i  -0.3689 - 0.1506i
```

Plot the Inverse Cotangent Function

Plot the inverse cotangent function over the intervals $-2\pi \le x < 0$ and $0 < x \le 2\pi$.

```
x1 = -2*pi:pi/30:-0.1;
```

```
x2 = 0.1:pi/30:2*pi;
plot(x1,acot(x1),'b')
hold on
plot(x2,acot(x2),'b')
grid on
```



Input Arguments

X — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Inverse Cotangent

The inverse cotangent is defined as

$$\cot^{-1}(z) = \tan^{-1}\left(\frac{1}{z}\right).$$

`acotd` | `acoth` | `cot`

Introduced before R2006a

acotd

Inverse cotangent in degrees

Syntax

```
Y = acotd(X)
```

Description

`Y = acotd(X)` returns the inverse cotangent ($\cot^{-1}$) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the range [-Inf,Inf], `acotd` returns values in the range [-90,90]. For complex values of X, `acotd` returns complex values.

Examples

Inverse Cotangent of Vector

```
x = [0 20 Inf];
y = acotd(x)
```

```
y =

   90.0000    2.8624         0
```

The `acotd` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cotangent of Complex Value

```
acotd(1+i)
```

```
ans =
```

```
31.7175 -23.0535i
```

Input Arguments

X — Cotangent of angle

scalar value | vector | matrix | N-D array

Cotangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acotd` operation is element-wise when X is non-scalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.

See Also

`acot` | `cot` | `cotd`

acoth

Inverse hyperbolic cotangent

Syntax

```
Y = acoth(X)
```

Description

`Y = acoth(X)` returns the inverse hyperbolic cotangent for each element of `X`.

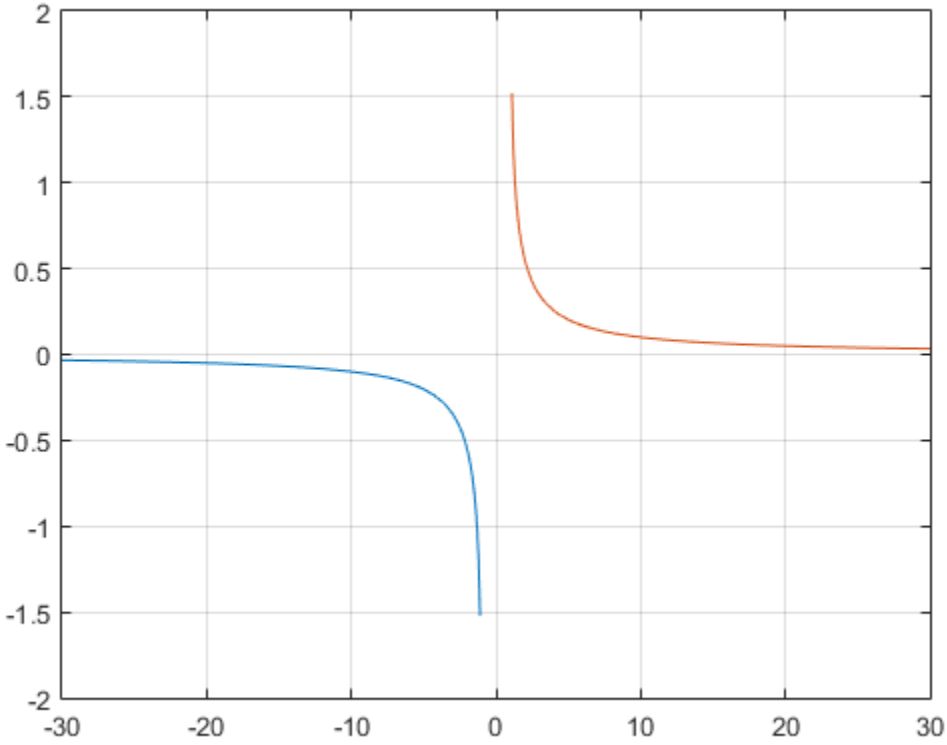
The `acoth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Cotangent Function

Graph the inverse hyperbolic cotangent function over the domains $-30 \le x < -1$ and $1 < x \le 30$.

```
x1 = -30:0.1:-1.1;
x2 = 1.1:0.1:30;
plot(x1,acoth(x1),x2,acoth(x2)), grid on
```



More About

Inverse Hyperbolic Cotangent

The inverse hyperbolic cotangent can be defined as

$$\coth^{-1}(z) = \tanh^{-1}\left(\frac{1}{z}\right).$$

Introduced before R2006a

acsc

Inverse cosecant in radians

Syntax

```
Y = acsc(X)
```

Description

`Y = acsc(X)` returns the "Inverse Cosecant" on page 1-117 ($\csc^{-1}$) of the elements of X. The `acsc` function operates element-wise on arrays. For real elements of X in intervals `[-Inf,-1]` and `[1,Inf]`, `acsc` returns real values in the interval `[-pi/2,pi/2]`. For real values of X in the interval `[-1,1]` and for complex values of X, `acsc` returns complex values. All angles are in radians.

Examples

Inverse Cosecant of a Value

```
acsc(3)
```

```
ans =
    0.3398
```

Inverse Cosecant of a Vector of Complex Angles

Find the inverse cosecant of the elements of vector `x`. The `acsc` function acts on `x` element-wise.

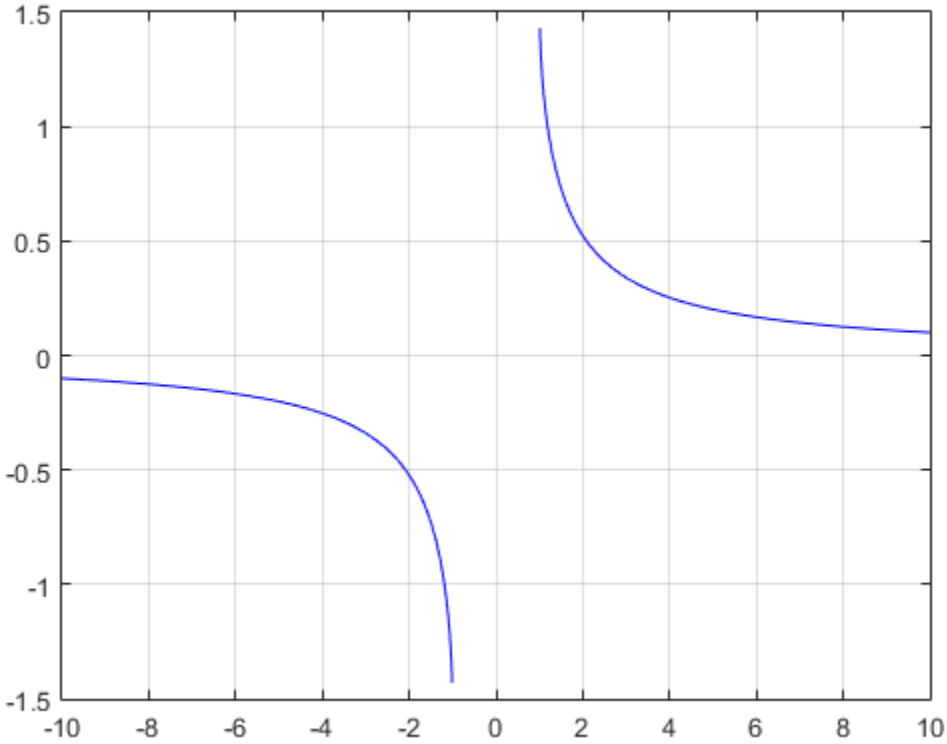
```
x = [0.5i 1+3i -2.2+i];
Y = acsc(x)
```

```
Y =
   0.0000 - 1.4436i   0.0959 - 0.2970i  -0.3795 - 0.1833i
```

Plot the Inverse Cosecant Function

Plot the inverse cosecant function over the intervals $-10 \le x < -1$ and $1 < x \le 10$.

```
x1 = -10:0.01:-1.01;
x2 = 1.01:0.01:10;
plot(x1,acsc(x1),'b')
hold on
plot(x2,acsc(x2),'b')
grid on
```



Input Arguments

X — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Inverse Cosecant

The inverse cosecant is defined as

$$\csc^{-1}(z) = \sin^{-1}\left(\frac{1}{z}\right).$$

`acscd` | `acsch` | `csc`

Introduced before R2006a

acscd

Inverse cosecant in degrees

Syntax

```
Y = acscd(X)
```

Description

`Y = acscd(X)` returns the inverse cosecant (cosec^{-1}) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain [-Inf,1] and [1,Inf], `acscd` returns values in the range [-90,90]. For values of X outside this range, `acscd` returns complex values.

Examples

Inverse Cosecant of Vector

```
x = [20 10 Inf];
y = acscd(x)
```

```
y =

    2.8660    5.7392         0
```

The `acscd` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Cosecant of Complex Value

```
acscd(1+i)
```

```
ans =
```

```
25.9136 -30.4033i
```

Input Arguments

X — Cosecant of angle

scalar value | vector | matrix | N-D array

Cosecant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `acscd` operation is element-wise when X is non-scalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.

See Also

`acsc` | `csc` | `cscd`

acsch

Inverse hyperbolic cosecant

Syntax

```
Y = acsch(X)
```

Description

`Y = acsch(X)` returns the inverse hyperbolic cosecant for each element of `X`.

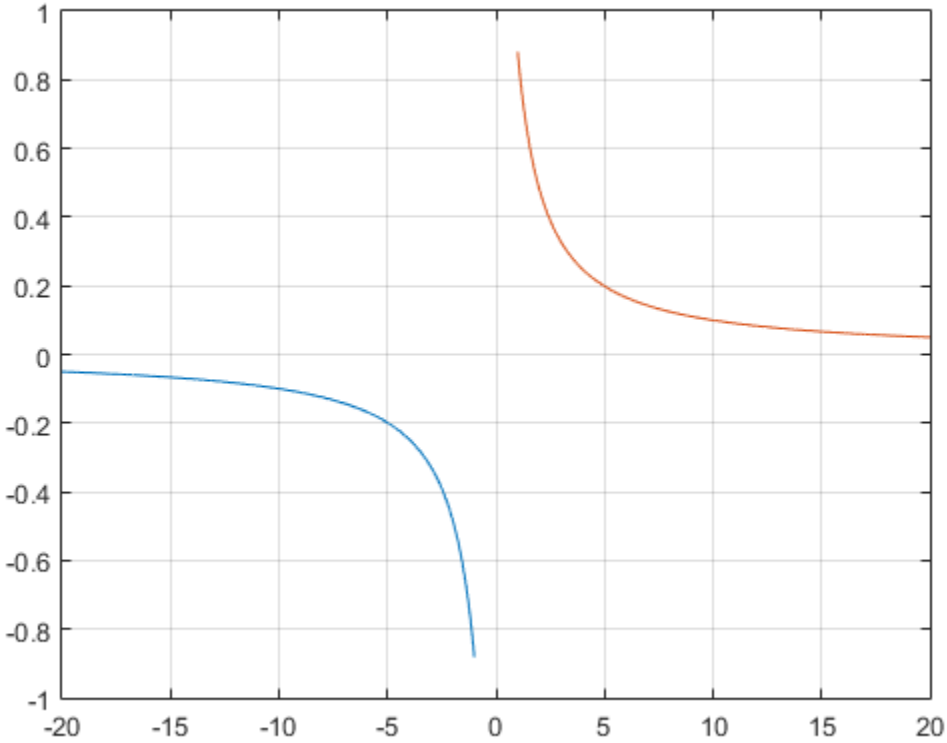
The `acsch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Cosecant Function

Graph the inverse hyperbolic cosecant function over the domains $-20 \le x \le -1$ and $1 \le x \le 20$.

```
x1 = -20:0.01:-1;
x2 = 1:0.01:20;
plot(x1,acsch(x1),x2,acsch(x2)), grid on
```



More About

Inverse Hyperbolic Cosecant

The inverse hyperbolic cosecant can be defined as

$$\operatorname{csch}^{-1}(z) = \sinh^{-1}\left(\frac{1}{z}\right).$$

`acsc` | `csch` | `asinh` | `acosh`

Introduced before R2006a

actxcontrol

Create Microsoft ActiveX control in figure window

Syntax

```
h = actxcontrol('progid')
h = actxcontrol('progid','param1',value1,...)
h = actxcontrol('progid',position)
h = actxcontrol('progid', position, fig_handle)
h = actxcontrol('progid',position,fig_handle,event_handler)
h =
actxcontrol('progid',position,fig_handle,event_handler,'filename')
```

Description

`h = actxcontrol('progid')` creates an ActiveX® control in a figure window. The programmatic identifier (`progid`) for the control determines the type of control created. (See the documentation provided by the control vendor to get this string.) The returned object, `h`, represents the default interface for the control.

You cannot use an ActiveX server for the `progid` because MATLAB software cannot insert ActiveX servers in a figure. See `actxserver` for use with ActiveX servers.

`h = actxcontrol('progid','param1',value1,...)` creates an ActiveX control using the optional parameter name/value pairs. Parameter names include:

- `position` — MATLAB position vector specifying the position of the control. The format is [left, bottom, width, height] using pixel units.
- `parent` — Handle to parent figure, model, or Command Window.
- `callback` — Name of event handler. To use the same handler for all events, specify a single name. To handle specific events, specify a cell array of event name/event handler pairs.
- `filename` — Sets the initial conditions to the previously saved control.
- `licensekey` — License key to create licensed ActiveX controls that require design-time licenses. See “Deploy ActiveX Controls Requiring Run-Time Licenses” for information on how to use controls that require run-time licenses.

One possible format is:

```
h = actxcontrol('myProgid','newPosition',[0 0 200 200],...
 'myFigHandle',gcf,...
 'myCallback',{'Click' 'myClickHandler';...
 'DblClick' 'myDblClickHandler';...
 'MouseDown' 'myMouseDownHandler'});
```

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the previous syntaxes are preferred.

`h = actxcontrol('progid',position)` creates an ActiveX control having the location and size specified in the vector, `position`. The format of this vector is:

```
[x y width height]
```

The first two elements of the vector determine where the control is placed in the figure window, with `x` and `y` being offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control. The last two elements, `width` and `height`, determine the size of the control itself.

The default `position` vector is `[20 20 60 60]`.

`h = actxcontrol('progid', position, fig_handle)` creates an ActiveX control at the specified `position` in an existing figure window. The Handle Graphics® handle, `fig_handle`, identifies this window.

The `gcf` command returns the current figure handle.

Note If the figure window designated by `fig_handle` is invisible, the control is invisible. If you want the control you are creating to be invisible, use the handle of an invisible figure window.

`h = actxcontrol('progid',position,fig_handle,event_handler)` creates an ActiveX control that responds to events. Controls respond to events by invoking a MATLAB function whenever an event (such as clicking a mouse button) is fired. The `event_handler` argument identifies one or more functions to be used in handling events. For more information, see “Specifying Event Handlers” on page 1-125.

```
h =
actxcontrol('progid',position,fig_handle,event_handler,'filename')
```

creates an ActiveX control with the first four arguments, and sets its initial state to that of a previously saved control. MATLAB loads the initial state from the file specified in the string `filename`.

If you do not want to specify an `event_handler`, you can use an empty string (`''`) as the fourth argument.

The `progid` argument must match the `progid` of the saved control.

Specifying Event Handlers

There is more than one valid format for the `event_handler` argument. Use this argument to specify one of the following:

- A different event handler routine for each event supported by the control
- One common routine to handle selected events
- One common routine to handle all events

In the first case, use a cell array for the `event_handler` argument, with each row of the array specifying an event and handler pair:

```
{'event' 'eventhandler'; 'event2' 'eventhandler2'; ...}
```

`event` is either a string containing the event name or a numeric event identifier (see Example 2). `eventhandler` is a string identifying the function you want the control to use in handling the event. Include only those events that you want enabled.

In the second case, use the same cell array syntax described, but specify the same `eventhandler` for each event. Again, include only those events that you want enabled.

In the third case, make `event_handler` a string (instead of a cell array) that contains the name of the one function that is to handle all events for the control.

There is no limit to the number of event and handler pairs you can specify in the `event_handler` cell array. However, if you register the same event name to the same callback handler multiple times, MATLAB executes the event only once.

Event handler functions accept a variable number of arguments.

Strings used in the `event_handler` argument are not case-sensitive.

Note Although using a single handler for all events might be easier in some cases, specifying an individual handler for each event creates more efficient code, resulting in better performance.

Examples

Handling Events

The `event_handler` argument specifies how you want the control to handle any events that occur. The control can handle all events with one common handler function, selected events with a common handler function, or each type of event can be handled by a separate function.

This command creates an `mwsamp` control that uses one event handler, `sampev`, to respond to all events:

```
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],...
   gcf,'sampev');
```

The next command also uses a common event handler, but will only invoke the handler when selected events, `Click` and `DblClick` are fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],...
   gcf,{'Click' 'sampev'; 'DblClick' 'sampev'});
```

This command assigns a different handler routine to each event. For example, `Click` is an event, and `myclick` is the routine that executes whenever a `Click` event is fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],...
   gcf,{'Click', 'myclick'; 'DblClick' 'my2click'; ...
   'MouseDown' 'mymoused'});
```

The next command does the same thing, but specifies the events using numeric event identifiers:

```
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],...
gcf,{-600, 'myclick'; -601 'my2click'; -605 'mymoused'});
```

For examples of event handler functions and how to register them with MATLAB, see "Sample Event Handlers".

More About

Tips

If the control implements any custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

When you no longer need the control, call `release` to release the interface and free memory and other resources used by the interface. Releasing the interface does not delete the control itself. To release the interface, use the `delete` function.

For more information on handling control events, see Writing Event Handlers.

For an example event handler, see the file `sampev.m` in the `toolbox\matlab\winfun\comcli` folder.

COM functions are available on Microsoft® Windows® systems only.

Note If you encounter problems creating Microsoft Forms 2.0 controls in MATLAB or other non-VBA container applications, see "Use Microsoft Forms 2.0 Controls".

`actxserver` | `delete (COM)` | `save (COM)` | `release` | `load (COM)` | `interfaces`

Introduced before R2006a

actxcontrollist

List currently installed Microsoft ActiveX controls

Syntax

```
info = actxcontrollist
```

Description

`info = actxcontrollist` returns a list of controls in `info`, a 1-by-3 cell array containing the name, programmatic identifier (ProgID), and file name for the control. Each control has one row, which MATLAB software sorts by file name.

COM functions are available on Microsoft Windows systems only.

Examples

Show information for two controls:

```
list = actxcontrollist;
for k = 1:2
  sprintf(' Name = %s\n ProgID = %s\n File = %s\n', list{k,:})
end
```

```
ans =
  Name = Calendar Control 11.0
  ProgID = MSCAL.Calendar.7
  File = C:\Program Files\MSOffice\OFFICE11\MSCAL.OCX

ans =
  Name = CTreeView Control
  ProgID = CTREEVIEW.CTreeViewCtrl.1
  File = C:\WINNT\system32\dmocx.dll
```

MATLAB displays controls specific to your system.

`actxcontrolselect` | `actxcontrol`

Introduced before R2006a

actxcontrolselect

Create Microsoft ActiveX control from UI

Syntax

```
h = actxcontrolselect
[h, info] = actxcontrolselect
```

Description

`h = actxcontrolselect` displays a UI listing all ActiveX controls installed on the system and creates the one you select from the list. Returns handle `h` for the object. Use the handle to identify this control when calling MATLAB COM functions.

`[h, info] = actxcontrolselect` returns a 1-by-3 cell array `info` containing the name, programmatic identifier (ProgID), and file name for the control.

COM functions are available on Microsoft Windows systems only.

- "Creating Control Objects Using a UI"

See Also

`actxcontrollist` | `actxcontrol`

Introduced before R2006a

actxGetRunningServer

Handle to running instance of Automation server

Syntax

```
h = actxGetRunningServer('progid')
```

Description

`h = actxGetRunningServer('progid')` gets a reference to a running instance of the OLE Automation server. `progid` is the programmatic identifier of the Automation server object and `h` is the handle to the default interface of the server object.

The function returns an error if the server specified by `progid` is not currently running or if the server object is not registered. When multiple instances of the Automation server are running, the operating system controls the behavior of this function.

COM functions are available on Microsoft Windows systems only.

Examples

Get a handle to the Microsoft Excel® program:

```
h = actxGetRunningServer('Excel.Application')
```

More About

- "MATLAB COM Automation Server Interface"

See Also

`actxcontrol` | `actxserver`

Introduced in R2007a

actxserver

Create COM server

Syntax

```
h = actxserver('progid')
h = actxserver('progid','machine','machineName')
h = actxserver('progid','interface','interfaceName')
h =
actxserver('progid','machine','machineName','interface','interfaceName')
h = actxserver('progid',machine)
```

Description

`h = actxserver('progid')` creates a local OLE Automation server, where `progid` is the programmatic identifier of an OLE-compliant COM server, and `h` is the handle of the server's default interface.

Get `progid` from the control or server vendor's documentation. To see the `progid` values for MATLAB software, refer to “Programmatic Identifiers”.

`h = actxserver('progid','machine','machineName')` creates an OLE Automation server on a remote machine, where `machineName` is a string specifying the name of the machine on which to start the server.

`h = actxserver('progid','interface','interfaceName')` creates a Custom interface server, where `interfaceName` is a string specifying the interface name of the COM object. Values for `interfaceName` are

- `IUnknown` — Use the IUnknown interface.
- The Custom interface name

You must know the name of the interface and have the server vendor's documentation in order to use the `interfaceName` value. For information about custom COM servers and interfaces, see “COM Server Types”.

Note: The MATLAB COM Interface does not support invoking functions with optional parameters.

`h = actxserver('progid','machine','machineName','interface','interfaceName')` creates a Custom interface server on a remote machine.

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the syntaxes described earlier are preferred:

`h = actxserver('progid',machine)` creates a COM server running on the remote system named by the `machine` argument. This can be an IP address or a DNS name. Use this syntax only in environments that support Distributed Component Object Model (for more information, see "Using MATLAB Application as DCOM Server").

COM functions are available on Microsoft Windows systems only.

Examples

Microsoft Excel Workbook Example

This example creates an OLE Automation server, Excel version 9.0, and manipulates a workbook in the application.

Create a COM server running Microsoft Excel.

```
e = actxserver('Excel.Application')
```

```
e =
    COM.Excel.application
```

Make the Excel frame window visible.

```
e.Visible = 1;
```

Use the `get` method on the Excel object `e` to list all properties of the application.

```
get(e)
```

Create an interface `eWorkBooks`.

```
eWorkbooks = e.Workbooks
```

```
eWorkbooks =
   Interface.Microsoft_Excel_9.0_Object_Library.Workbooks
```

List all methods for that interface.

```
invoke(eWorkbooks)
```

```
       Add: 'handle Add(handle, [Optional]Variant)'
     Close: 'void Close(handle)'
      Item: 'handle Item(handle, Variant)'
      Open: 'handle Open(handle, string, [Optional]Variant)'
  OpenText: 'void OpenText(handle, string, [Optional]Variant)'
          .
          .
          .
```

Add a new workbook `w`, also creating a new interface.

```
w = Add(eWorkbooks)
```

```
w =
   Interface.Microsoft_Excel_9.0_Object_Library._Workbook
```

Close Excel and delete the server.

```
Quit(e);
delete(e);
```

More About

Tips

For components implemented in a dynamic link library (DLL), `actxserver` creates an in-process server. For components implemented as an executable (EXE), `actxserver` creates an out-of-process server. Out-of-process servers can be created either on the client system or on any other system on a network that supports DCOM.

If the control implements any Custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

You can register events for COM servers.

Introduced before R2006a

add

Add single key-value pair to KeyValueStore

Syntax

```
add(KVStore,key,value)
```

Description

`add(KVStore,key,value)` adds a single key-value pair to `KVStore`, which is a `KeyValueStore` created during `mapreduce` execution. Use `add` in a map or reduce function written for use with `mapreduce` to store intermediate or final key-value pair information.

Input Arguments

`KVStore` — Key-value pair storage object

`KeyValueStore` object

Key-value pair storage object, specified as a `KeyValueStore` object. The `mapreduce` function automatically creates the `KeyValueStore` object during execution:

- In the map function, the name of the intermediate `KeyValueStore` object is the third input argument to the map function, `myMapper(data, info, intermKVStore)`. Use that same variable name to add intermediate key-value pairs with `add` or `addmulti` in the map function.
- In the reduce function, the name of the final `KeyValueStore` object is the third input argument to the reduce function, `myReducer(intermKey, intermValIter, outKVStore)`. Use that same variable name to add final key-value pairs with `add` or `addmulti` in the reduce function.

For more information, see Using KeyValueStore Objects.

`key` — Key

numeric scalar | string

Key, specified as a numeric scalar or string.

All of the keys added by the map function must have the same class. The keys added by the reduce function also must have the same class, but that class can differ from the class of the keys added by the map function.

Numeric keys cannot be `NaN`, complex, logical, or sparse.

Example: `add(intermKVStore,'Sum',sum(X))` adds a key-value pair to an intermediate `KeyValueStore` object (named `intermKVStore`) in a map function.

Example: `add(outKVStore,'Stats',[mean(X) max(X) min(X) var(X) std(X)])` adds a key-value pair to a final `KeyValueStore` object (named `outKVStore`) in a reduce function.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char`

`value` — Value

any MATLAB object

Value, specified as any MATLAB object. This includes all valid MATLAB data types.

The `OutputType` argument of `mapreduce` affects the type of values that the reduce function can add:

- If the `OutputType` is `'Binary'` (the default), then a value added by the reduce function can be any MATLAB object.
- If the `OutputType` is `'TabularText'`, then a value added by the reduce function can be a numeric scalar or string when using the `add` function. Additionally, you can use the `addmulti` function to add multiple values with a numeric vector, cell vector of strings, or cell vector of numeric scalars. In each case, the numeric values cannot be `NaN`, complex, logical, or sparse.

Note: The above key-value pair requirements may differ when using other products with mapreduce. See the documentation for the appropriate product to get product-specific key-value pair requirements.

Example: `add(intermKVStore,'Sum',sum(X))` specifies a single scalar value to pair with a key.

Example: `add(outKVStore,'Stats',[mean(X) max(X) min(X) var(X) std(X)])` specifies a numeric array as the value to pair with a key.

More About

Tips

- Avoid using `add` in a loop, as it can negatively affect `mapreduce` execution time. Instead, use cell arrays to collect multiple values (using vectorized operations if possible) and use a single call to `addmulti`.

- Using KeyValueStore Objects
- "Build Effective Algorithms with MapReduce"

`addmulti`

Introduced in R2014b

matlab.apputil.create

Create or modify app project file for packaging app into `.mlappinstall` file using interactive dialog box

Syntax

```
matlab.apputil.create
matlab.apputil.create(prjfile)
```

Description

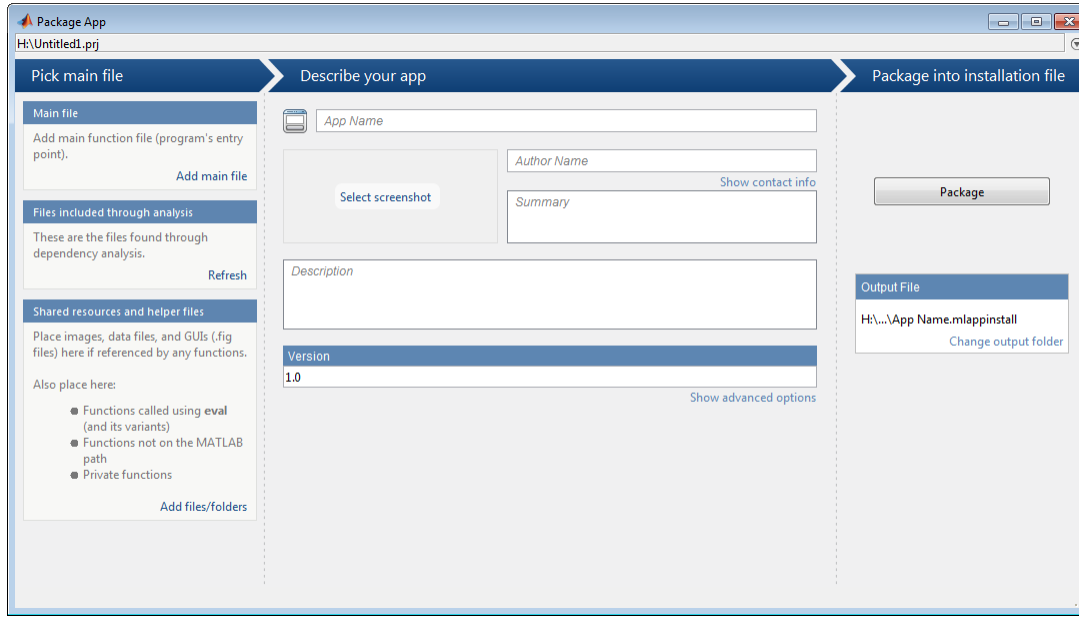
`matlab.apputil.create` opens the Package App dialog box that steps you through the process of creating an `.mlappinstall` file.

`matlab.apputil.create(prjfile)` loads the specified `.prj` file and populates the Package App dialog box with the information from the specified project file. Use this option if you need to update an existing app.

Examples

Open Dialog Box for Creating an App Package

```
matlab.apputil.create
```



Minimally, add a main file and specify an app name. MATLAB creates and continuously saves a `.prj` file, regardless of whether you click **Package**. However, MATLAB does not create a `.mlappinstall` file if you do not click **Package**.

Update Existing App Package

Assume you have an existing project file, `myapp.prj`. You want to add a file and update the description.

Open the Package App dialog box, specifying the previously created `.prj` file:

```
matlab.apputil.create('myapp.prj')
```

The dialog box opens populated with the data you previously specified for `myapp`. Adjust the information in the dialog box, as needed.

Input Arguments

`prjfile` — Full or partial path to the `.prj` file

string

Full or partial path to the `.prj` file you created previously with the Package App dialog box, specified as a string

Example: `'C:\myapp.prj'`

`matlab.apputil.package`

matlab.apputil.getInstalledAppInfo

List installed app information

Syntax

```
matlab.apputil.getInstalledAppInfo
```

```
appinfo = matlab.apputil.getInstalledAppInfo
```

Description

`matlab.apputil.getInstalledAppInfo` displays the ID and name of all installed custom apps. It does not display this information for apps packaged with MathWorks® products.

`appinfo = matlab.apputil.getInstalledAppInfo` returns structure to `appinfo`, which includes the status, ID, location, and name of all installed custom apps. It does not return this information for apps packaged with MathWorks products.

Examples

Display Installed Apps Information in the Command Window

Assume you installed two apps, `LinePlotter` and `PlotRandNumbers`. Display the app information in the Command Window.

```
 matlab.apputil.getInstalledAppInfo
```

```
ID                    Name
------------------    --------------
LinePlotterAPP        LinePlotter
PlotRandNumbersAPP    PlotRandNumbers
```

Store Installed App Information in a Variable

Assume you installed an app, `ColorPalette`. Get the app information and store it in a variable, `myappinfo`.

```
myappinfo = matlab.apputil.getInstalledAppInfo;
```

Store Installed App Information in a Variable and Display IDs

Assume you installed two apps, `LinePlotter` and `PlotRandNumbers`. Get and store the app information for both installed apps in a variable, `myappinfo`. Then, get the `id` for each app.

```
myappinfo = matlab.apputil.getInstalledAppInfo
```

```
myappinfo =

1x2 struct array with fields:
    id
    name
    status
    location
```

Get the id of each installed app:

```
appids={myappinfo.id}
```

```
appids =

    'LinePlotterAPP'    'PlotRandNumbersAPP'
```

Output Arguments

`appinfo` — Information about installed apps

structure array

Information about the installed app, returned as a structure array, with one element for each installed app. Each element of the structure array has the following fields:

`status` — Installation status

`'installed'`

Status of the installation, returned as the string `'installed'`.

`id` — Unique identifier for the installed app

string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

`location` — Folder where the app is installed
string

Folder where the app is installed, returned as a string

`name` — Name of the installed app
string

Name of the installed app as it appears in the apps gallery, returned as a string

More About

- "MATLAB App Installer File — mlappinstall"

See Also

`matlab.apputil.install` | `matlab.apputil.run` | `matlab.apputil.uninstall`

matlab.apputil.install

Install app from a `.mlappinstall` file

Syntax

```
appinfo = matlab.apputil.install(appfile)
```

Description

`appinfo = matlab.apputil.install(appfile)` installs the specified app file and returns information about the app.

Examples

Install App and Display Information About the Installation

Assume you have downloaded an app from File Exchange named `EmployeeData`. Install it and return information about the installation to the variable `appinfo`. Later, if you decide to deinstall the app programmatically, you have the app id required to do so.

```
appinfo = matlab.apputil.install...
   ('C:\myguis\myapps\EmployeeData.mlappinstall')
```

```
appinfo =

          id: 'EmployeeDataApp'
        name: 'EmployeeData'
      status: 'installed'
    location: 'C:\myguis\myapps\EmployeeData.mlappinstall'
```

Input Arguments

`appfile` — Full or partial path to `.mlappinstall` file

string

Full or partial path of the app file you want to install, specified as a string.

Example: `'C:\myguis\myapps\myapp.mlappinstall'`

Output Arguments

`appinfo` — Information about installed app

structure

Information about the installed app, returned as a structure with the fields:

`status` — Installation status

`'installed' | 'updated'`

Installation status, returned as a string:

- `'installed'` — New app is installed.
- `'updated'` — Previously installed app is updated.

`id` — Unique identifier

string

Unique identifier for the installed app, returned as a string

The ID is for use when running or uninstalling the app programmatically.

`location` — Folder where app is installed

string

Folder where app is installed, returned as a string

`name` — Name of installed app

string

Name of installed app as it appears in the apps gallery, returned as a string

More About

- "MATLAB App Installer File — mlappinstall"

See Also

`matlab.apputil.getInstalledAppInfo` | `matlab.apputil.package` | `matlab.apputil.uninstall`

matlab.apputil.package

Package app files into `.mlappinstall` file

Syntax

```
matlab.apputil.package(prjfile)
```

Description

`matlab.apputil.package(prjfile)` creates a `.mlappinstall` file based on the information in the specified prjfile.

Examples

Create mlappinstall File for Previously Created Project File

Assume you previously created `myprjfile.prj` using `matlab.apputil.create`. The following command creates the corresponding `.mlappinstall` file.

```
matlab.apputil.package('myprjfile.prj')
```

Input Arguments

`prjfile` — Full or partial path to app project (`.prj`) file

string

Full or partial path to app project (`.prj`) file, specified as a string.

Example: `'plotdata.prj'`

More About

Tips

- To create a `.prj` file, use `matlab.apputil.create`.

See Also

`matlab.apputil.create` | `matlab.apputil.install` | `matlab.apputil.run`

matlab.apputil.run

Run app programmatically

Syntax

```
matlab.apputil.run(appid)
```

Description

`matlab.apputil.run(appid)` runs the custom app specified by the unique identifier, appid.

Examples

Run Previously Installed App

Assume you installed two apps, `PlotData` and `setslider`. Run `PlotData` programmatically, using its ID.

Get IDs of all installed apps.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                    Name
------------------    ----------------
setsliderAPP          setslider
PlotDataAPP           PlotData
```

Run `PlotData`.

```
matlab.apputil.run('PlotDataAPP')
```

Input Arguments

`appid` — ID of custom app

string

ID of custom app you want to run, specified as a string.

Example: `'DataExplorationAPP'`

More About

Tips

- The ID of a custom app is returned when you install it. You can use `matlab.apputil.getInstalledAppInfo` to get the ID after you have installed an app.
- When a custom app runs, MATLAB adds any folders it needs to have added to the path, as identified when the app was packaged. When the app exits, MATLAB removes those folders from the path.
- You can run multiple, different custom apps concurrently. However, you cannot run two instances of the same app concurrently.

See Also

`matlab.apputil.create` | `matlab.apputil.getInstalledAppInfo` | `matlab.apputil.install`

matlab.apputil.uninstall

Uninstall app

Syntax

```
matlab.apputil.uninstall(appid)
```

Description

`matlab.apputil.uninstall(appid)` removes the app specified by the unique identifier, appid. MATLAB removes all files corresponding to the app and removes the app from the app gallery.

Examples

Uninstall App

Assume you previously installed two apps, `setslider` and `simplegui`. Get the IDs of all installed apps, and then use the ID for `simplegui` to uninstall it.

View the IDs of all apps

```
matlab.apputil.getInstalledAppInfo
```

```
ID                    Name
--------------------  ----------------
setsliderAPP          setslider
simpleguiAPP          simplegui
```

Uninstall the `simplegui` app.

```
matlab.apputil.uninstall('simpleguiAPP')
```

Confirm the app was removed, by running `matlab.apputil.getInstalledAppInfo` again.

```
matlab.apputil.getInstalledAppInfo
```

```
ID                    Name
--------------------  ----------------
setsliderAPP          setslider
```

Input Arguments

`appid` — ID of app

string

ID of app to be uninstalled, specified as a string.

Example: `'DataExplorationAPP'`

More About

Tips

- To determine the appid of an installed app, preserve the value returned when you install the app programmatically with `matlab.apputil.install`, or use `matlab.apputil.getInstalledAppInfo`.

See Also

`matlab.apputil.getInstalledAppInfo` | `matlab.apputil.install`

addevent

Add event to `timeseries` object

Syntax

```
ts = addevent(ts,e)
ts = addevent(ts,Name,Time)
```

Description

`ts = addevent(ts,e)` adds one or more `tsdata.event` objects, `e`, to the `timeseries` object `ts`. `e` is either a single `tsdata.event` object or an array of `tsdata.event` objects.

`ts = addevent(ts,Name,Time)` constructs one or more `tsdata.event` objects and adds them to the `Events` property of `ts`. `Name` is a cell array of event name strings. `Time` is a cell array of event times.

Examples

Create a time-series object and add an event to this object.

```
%% Import the sample data
load count.dat

%% Create time-series object
count1=timeseries(count(:,1),1:24,'name', 'data');

%% Modify the time units to be 'hours' ('seconds' is default)
count1.TimeInfo.Units = 'hours';

%% Construct and add the first event at 8 AM
e1 = tsdata.event('AMCommute',8);

%% Specify the time units of the time
e1.Units = 'hours';
```

View the properties (`EventData`, `Name`, `Time`, `Units`, and `StartDate`) of the event object.

```
get(e1)
```

MATLAB software responds with

```
    EventData: []
         Name: 'AMCommute'
         Time: 8
        Units: 'hours'
    StartDate: ''
%% Add the event to count1
count1 = addevent(count1,e1);
```

An alternative syntax for adding two events to the time series `count1` is as follows:

```
count1 = addevent(count1,{'AMCommute' 'PMCommute'},{8 18})
```

See Also

`timeseries` | `tsdata.event`

Introduced before R2006a

addmulti

Add multiple key-value pairs to KeyValueStore

Syntax

```
addmulti(KVStore,keys,values)
```

Description

`addmulti(KVStore,keys,values)` adds multiple key-value pairs to `KVStore`, which is a `KeyValueStore` created during `mapreduce` execution. Use `addmulti` in a map or reduce function written for use with `mapreduce` to store intermediate or final key-value pair information.

Input Arguments

`KVStore` — Key-value pair storage object

`KeyValueStore` object

Key-value pair storage object, specified as a `KeyValueStore` object. The `mapreduce` function automatically creates the `KeyValueStore` object during execution:

- In the map function, the name of the intermediate `KeyValueStore` object is the third input argument to the map function, `myMapper(data, info, intermKVStore)`. Use that same variable name to add intermediate key-value pairs with `add` or `addmulti` in the map function.
- In the reduce function, the name of the final `KeyValueStore` object is the third input argument to the reduce function, `myReducer(intermKey, intermValIter, outKVStore)`. Use that same variable name to add final key-value pairs with `add` or `addmulti` in the reduce function.

For more information, see Using KeyValueStore Objects.

`keys` — Keys

numeric scalar | numeric vector | string | cell vector of strings | cell vector of numeric scalars

Keys, specified as a numeric scalar, numeric vector, string, cell vector of strings, or cell vector of numeric scalars. If the keys are a numeric vector or cell vector, then each entry specifies a different key.

All of the keys added by the map function must have the same class. The keys added by the reduce function must also have the same class, but that class can differ from the class of the keys added by the map function.

Numeric keys cannot be `NaN`, complex, logical, or sparse.

Example: `addmulti(intermKVStore,{'Sum'; 'Count'; 'Variance'},{sum(X); numel(X); var(X)})` adds three key-value pairs to an intermediate `KeyValueStore` object (named `intermKVStore`) using a cell vector of strings to specify the keys.

Example: `addmulti(intermKVStore,[1 2 3 4],{sum(X); mean(X); max(X); min(X)})` adds four key-value pairs to an intermediate `KeyValueStore` object using a numeric vector to specify the keys.

Example: `addmulti(outKVStore,'Stats',{[mean(X) max(X) min(X) var(X) std(X)]})` adds a single key-value pair to a final `KeyValueStore` object (named `outKVStore`) using a string as the key.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char`

`values` — Values

cell array

Values, specified as a cell array. Each entry in the cell array specifies the value in a key-value pair, so `numel(values)` must be equal to the number of keys. The entries in the cell array can be any MATLAB object, including all valid MATLAB data types.

The `OutputType` argument of `mapreduce` affects the type of values that the reduce function can add:

- If the `OutputType` is `'Binary'` (the default), then a value added by the reduce function can be any MATLAB object.
- If the `OutputType` is `'TabularText'`, then a value added by the reduce function can be a numeric scalar or string when using the `add` function. Additionally, you can use the `addmulti` function to add multiple values with a numeric vector, cell vector of strings, or cell vector of numeric scalars. In each case, the numeric values cannot be `NaN`, complex, logical, or sparse.

Note: The above key-value pair requirements may differ when using other products with mapreduce. See the documentation for the appropriate product to get product-specific key-value pair requirements.

Example: `addmulti(intermKVStore,{'Sum'; 'Count'; 'Variance'},{sum(X); numel(X); var(X)})` adds three key-value pairs to an intermediate `KeyValueStore` object named `intermKVStore`.

Example: `addmulti(intermKVStore,[1 2 3 4],{sum(X); mean(X); max(X); min(X)})` adds four key-value pairs to an intermediate `KeyValueStore` object using a cell vector.

Example: `addmulti(outKVStore,'Stats',{[mean(X) max(X) min(X) var(X) std(X)]})` adds a single key-value pair to a final `KeyValueStore` object named `outKVStore`.

Example: `addmulti(outKVStore,{'Distance' 'Time'},{table.Distance table.Time})` adds two key-value pairs using variables in a table to specify the values.

More About

Tips

- Avoid using `add` in a loop, as it can negatively affect `mapreduce` execution time. Instead, use cell arrays to collect multiple values (using vectorized operations if possible) and use a single call to `addmulti`.

- Using KeyValueStore Objects
- "Build Effective Algorithms with MapReduce"

`add`

Introduced in R2014b

audioinfo

Information about audio file

Syntax

```
info = audioinfo(filename)
```

Description

`info = audioinfo(filename)` returns information about the contents of the audio file specified by `filename`.

Examples

Get Information About Audio File

Create a WAVE file from the example file `handel.mat`, and get information about the file.

Create a WAVE (.wav) file in the current folder.

```
load handel.mat
filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Use `audioinfo` to return information about the WAVE file.

```
info = audioinfo(filename)
```

```
info =
             Filename: 'S:\handel.wav'
    CompressionMethod: 'Uncompressed'
          NumChannels: 1
           SampleRate: 8192
         TotalSamples: 73113
             Duration: 8.9249
```

```
          Title: []
        Comment: []
         Artist: []
  BitsPerSample: 16
```

Input Arguments

`filename` — Name of file

string

Name of file, specified as a string. If a path is specified, it can be absolute, relative, or partial.

Example: `'myFile.mp3'`

Example: `'../myFile.mp3'`

Example: `'C:\temp\myFile.mp3'`

`audioinfo` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (`.wav`)
	OGG (`.ogg`)
	FLAC (`.flac`)
	AU (`.au`)
Windows 7 (or later), Macintosh, and Linux®	MP3 (`.mp3`)
	MPEG-4 AAC (`.m4a`, `.mp4`)

On Windows 7 platforms (or later), `audioinfo` might also return information about the contents of any files supported by Windows Media® Foundation.

On Linux platforms, `audioinfo` might also return information about the contents of any files supported by GStreamer.

`audioinfo` can extract audio metadata from MPEG-4 (`.mp4`, `.m4v`) video files on Windows 7 or later, Mac OS X 10.7 Lion or higher, and Linux, and from Windows Media Video (`.wmv`) and AVI (`.avi`) files on Windows 7 (or later) and Linux platforms.

Output Arguments

`info` — Information about audio file

structure

Information about audio file, returned as a structure. `info` can contain the following fields.

Field Name	Description	Data Type
`Filename`	Filename including the absolute path to the file and the file extension.	`string`
`CompressionMethod`	Compression method used.	`string`
`NumChannels`	Number of audio channels encoded in the audio file.	`double`
`SampleRate`	Sample rate of the audio data in the file, in hertz.	`double`
`TotalSamples`	Total number of audio samples in the file.	`double`
`Duration`	Duration of the file, in seconds.	`double`
`BitsPerSample`	Number of bits per sample encoded in the audio file. Only valid for WAVE (`.wav`) and FLAC (`.flac`) files.	`double`
`BitRate`	Number of kilobits per second (kbit/s) used for compressed audio files. Only valid for MP3 (`.mp3`) and MPEG-4 Audio (`.m4a`, `.mp4`) files.	`double`
`Title`	Value of `'Title'`, if any.	`string`
`Artist`	Value of `'Artist'`, if any.	`string`
`Comment`	Value of `'Comment'`, if any.	`string`

Note: The `BitRate` property returns the actual bit rate on Mac platforms, and not the encoded bit rate. This means that bit rate values might be lower than specified at the time of the encoding, depending on the source data.

Note: On Mac platforms, `audioinfo` returns metadata from `.m4a` and `.mp4` files only on Mac OS X 10.7 Lion or higher. Previous versions of Mac OS X will not read the `'Title'`, `'Author'`, or `'Comment'` fields.

Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 or later and Linux platforms, `audioinfo` might report fewer samples than expected. On Linux platforms, this is due to a limitation in the underlying GStreamer framework.
- On Linux platforms, `audioinfo` interprets single channel data in MPEG-4 AAC files as stereo data.

See Also

`audioread` | `audiowrite`

Introduced in R2012b

audioread

Read audio file

Syntax

```
[y,Fs] = audioread(filename)
[y,Fs] = audioread(filename,samples)

[y,Fs] = audioread( ___ ,dataType)
```

Description

`[y,Fs] = audioread(filename)` reads data from the file named `filename`, and returns sampled data,`y`, and a sample rate for that data, `Fs`.

`[y,Fs] = audioread(filename,samples)` reads the selected range of audio samples in the file, where `samples` is a vector of the form `[start,finish]`.

`[y,Fs] = audioread( ___ ,dataType)` returns sampled data in the data range corresponding to the `dataType` of `'native'` or `'double'`, and can include any of the input arguments in previous syntaxes.

Examples

Read Complete Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Create a WAVE (`.wav`) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
```

```
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread('handel.wav');
```

Play the audio.

```
sound(y,Fs);
```

Read Portion of Audio File

Create a FLAC file from the example file `handel.mat`, and then read only the first 2 seconds.

Create a FLAC (`.flac`) file in the current folder.

```
load handel.mat

filename = 'handel.flac';
audiowrite(filename,y,Fs);
```

Read only the first 2 seconds.

```
samples = [1,2*Fs];
clear y Fs
[y,Fs] = audioread(filename,samples);
```

Play the samples.

```
sound(y,Fs);
```

Return Audio in Native Integer Format

Create a FLAC file and read the first 2 seconds according to the previous Example. Then, view the data type of the sampled data `y`.

```
whos y
```

```
  Name          Size              Bytes  Class     Attributes

  y         16384x1             131072  double
```

The data type of `y` is `double`.

Request audio data in the native format of the file, and then view the data type of the sampled data `y`.

```
[y,Fs] = audioread(filename,'native');
whos y
```

```
  Name          Size             Bytes  Class    Attributes

  y         16384x1              32768  int16
```

The data type of `y` is now `int16`.

Input Arguments

`filename` — Name of file to read

string

Name of file to read, specified as a string that includes the file extension. If a path is specified, it can be absolute, relative or partial.

Example: `'myFile.mp3'`

Example: `'../myFile.mp3'`

Example: `'C:\temp\myFile.mp3'`

`audioread` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (`.wav`)
	OGG (`.ogg`)
	FLAC (`.flac`)
	AU (`.au`)
Windows 7 (or later), Macintosh, and Linux	MP3 (`.mp3`)
	MPEG-4 AAC (`.m4a`, `.mp4`)

On Windows platforms prior to Windows 7, `audioread` does not read WAVE files with MP3 encoded data.

On Windows 7 (or later) platforms, `audioread` might also read any files supported by Windows Media Foundation.

On Linux platforms, `audioread` might also read any files supported by GStreamer.

`audioread` can extract audio from MPEG-4 (`.mp4`, `.m4v`) video files on Windows 7 or later, Macintosh, and Linux, and from Windows Media Video (`.wmv`) and AVI (`.avi`) files on Windows 7 (or later) and Linux platforms.

`samples` — Audio samples to read

`[1,inf]` (default) | two-element vector of positive scalar integers

Audio samples to read, specified as a two-element vector of the form `[start,finish]`, where `start` and `finish` are the first and last samples to read, and are positive scalar integers.

- `start` must be less than or equal to `finish`.
- `start` and `finish` must be less than the number of audio samples in the file,
- You can use `inf` to indicate the last sample in the file.

Note: When reading a portion of some MP3 files on Windows 7 platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying Windows Media Foundation framework.

When reading a portion of MP3 and M4A files on Linux platforms, `audioread` might read a shifted range of samples. This is due to a limitation in the underlying GStreamer framework.

Example: `[1,100]`

Data Types: `double`

`dataType` — Data format of audio data, `y`

`'double'` (default) | `'native'`

Data format of audio data,`y`, specified as one of the following strings:

`'double'`	Double-precision normalized samples.

`'native'` Samples in the native format found in the file.

For compressed audio formats, such as MP3 and MPEG-4 AAC that do not store data in integer form, `'native'` defaults to `'single'`.

Output Arguments

y — Audio data

matrix

Audio data in the file, returned as an `m`-by-`n` matrix, where `m` is the number of audio samples read and `n` is the number of audio channels in the file.

- If you do not specify `dataType`, or `dataType` is `'double'`, then `y` is of type `double`, and matrix elements are normalized values between −1.0 and 1.0.
- If `dataType` is `'native'`, then `y` can be one of several MATLAB data types, depending on the file format and the `BitsPerSample` value of the input file. Call `audioinfo` to determine the `BitsPerSample` value of the file.

File Format	BitsPerSample	Data Type of y	Data Range of y
WAVE (`.wav`)	8	`uint8`	$0 \le y \le 255$
	16	`int16`	$-32768 \le y \le +32767$
	24	`int32`	$-2^{32} \le y \le 2^{32}-1$
	32	`int32`	$-2^{32} \le y \le 2^{32}-1$
	32	`single`	$-1.0 \le y \le +1.0$
	64	`double`	$-1.0 \le y \le +1.0$
FLAC (`.flac`)	8	`uint8`	$0 \le y \le 255$
	16	`int16`	$-32768 \le y \le +32767$
	24	`int32`	$-2^{32} \le y \le 2^{32}-1$
MP3 (`.mp3`), MPEG-4 AAC (`.m4a`, `.mp4`), OGG (`.ogg`), and certain compressed WAVE files	N/A	`single`	$-1.0 \le y \le +1.0$

Note: Where `y` is `single` or `double` and the `BitsPerSample` is 32 or 64, values in `y` might exceed −1.0 or +1.0.

`Fs` — Sample rate

positive scalar

Sample rate, in hertz, of audio data `y`, returned as a positive scalar.

Limitations

- For MP3 and MPEG-4 AAC audio files on Windows 7 or later and Linux platforms, `audioread` might read fewer samples than expected. On Windows 7 platforms, this is due to a limitation in the underlying Media Foundation framework. On Linux platforms, this is due to a limitation in the underlying GStreamer framework. If you require sample-accurate reading, work with WAV or FLAC files.
- On Linux platforms, `audioread` reads MPEG-4 AAC files that contain single-channel data as stereo data.

See Also

`audioinfo` | `audiowrite`

Introduced in R2012b

audiowrite

Write audio file

Syntax

```
audiowrite(filename,y,Fs)
audiowrite(filename,y,Fs,Name,Value)
```

Description

`audiowrite(filename,y,Fs)` writes a matrix of audio data, `y`, with sample rate `Fs` to a file called `filename`. The `filename` input also specifies the output file format. The output data type depends on the output file format and the data type of the audio data, `y`.

`audiowrite(filename,y,Fs,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Examples

Write an Audio File

Create a WAVE file from the example file `handel.mat`, and read the file back into MATLAB.

Write a WAVE (`.wav`) file in the current folder.

```
load handel.mat

filename = 'handel.wav';
audiowrite(filename,y,Fs);
clear y Fs
```

Read the data back into MATLAB using `audioread`.

```
[y,Fs] = audioread(filename);
```

Listen to the audio.

```
sound(y,Fs);
```

Specify Bits Per Sample and Metadata

Create a FLAC file from the example file `handel.mat` and specify the number of output bits per sample and a comment.

```
load handel.mat

filename = 'handel.flac';
audiowrite(filename,y,Fs,'BitsPerSample',24,...
'Comment','This is my new audio file.');
clear y Fs
```

View information about the new FLAC file.

```
info = audioinfo(filename)
```

```
info =

             Filename: 'S:\handel.flac'
    CompressionMethod: 'FLAC'
          NumChannels: 1
           SampleRate: 8192
         TotalSamples: 73113
             Duration: 8.9249
                Title: []
              Comment: 'This is my new audio file.'
               Artist: []
        BitsPerSample: 24
```

Input Arguments

`filename` — Name of file to write

string

Name of file to write, or the full path to the file, specified as a string that includes the file extension. If a path is specified, it can be absolute or relative. If you do not specify the path, then the destination directory is the current working directory.

`audiowrite` supports the following file formats.

Platform Support	File Format
All platforms	WAVE (`.wav`)
	OGG (`.ogg`)
	FLAC (`.flac`)
Windows and Mac	MPEG-4 AAC (`.m4a`, `.mp4`)

Example: `'myFile.m4a'`

Example: `'../myFile.m4a'`

Example: `'C:\temp\myFile.m4a'`

When writing AAC files on Windows, `audiowrite` pads the front and back of the output signal with extra samples of silence. The Windows AAC encoder also places a very sharp fade-in and fade-out on the audio. This results in audio with an increased number of samples after being written to disk.

y — Audio data to write

matrix

Audio data to write, specified as an `m`-by-`n` matrix, where `m` is the number of audio samples to write and `n` is the number of audio channels to write.

If either `m` or `n` is 1, then `audiowrite` assumes that this dimension specifies the number of audio channels, and the other dimension specifies the number of audio samples.

The maximum number of channels depends on the file format.

File Format	Maximum Number of Channels
WAVE (`.wav`)	256
OGG (`.ogg`)	255
FLAC (`.flac`)	8
MPEG-4 AAC (`.m4a`, `.mp4`)	2

The valid range for the data in `y` depends on the data type of `y`.

Data Type of y	Valid Range for y
`uint8`	$0 \le y \le 255$

Data Type of y	Valid Range for y
int16	-32768 ≤ y ≤ +32767
int32	-2^32 ≤ y ≤ 2^32–1
single	-1.0 ≤ y ≤ +1.0
double	-1.0 ≤ y ≤ +1.0

Data beyond the valid range is clipped.

If y is single or double, then audio data in y should be normalized to values in the range −1.0 and 1.0, inclusive.

Data Types: single | double | int16 | int32 | uint8

Fs — Sample rate
positive scalar

Sample rate, in hertz, of audio data y, specified as a positive scalar greater than 0. Values of Fs are truncated to integer boundaries. When writing to .m4a or .mp4 files on Windows platforms, audiowrite supports only samples rates of 44100 and 48000.

Example: 44100

Data Types: double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Title','Symphony No. 9','Artist','My Orchestra' instructs audiowrite to write an audio file with the title "Symphony No. 9" and the artist information "My Orchestra."

'BitsPerSample' — Number of output bits per sample
16 (default) | 8 | 24 | 32 | 64

Number of output bits per sample, specified as the comma-separated pair consisting of 'BitsPerSample' and a number.

Only available for WAVE (`.wav`) and FLAC (`.flac`) files. For FLAC files, only 8, 16, or 24 bits per sample are supported.

Example: `'BitsPerSample',32`

`'BitRate'` — Kilobits per second (kbit/s)

128 (default) | 64 | 96 | 160 | 192 | 256 | 320

Number of kilobits per second (kbit/s) used for compressed audio files, specified as the comma-separated pair consisting of `'BitRate'` and an integer. Noninteger values are truncated. On Windows 7 or later, the only valid values are 96, 128, 160, and 192.

In general, a larger `BitRate` value results in higher compression quality.

Only available for MPEG-4 (`.m4a`, `.mp4`) files.

Example: `'BitRate',96`

`'Quality'` — Quality setting for the Ogg Vorbis Compressor

75 (default) | value in the range [0 100]

Quality setting for the Ogg Vorbis Compressor, specified as the comma-separated pair consisting of `'Quality'` and a number in the range [0 100], where 0 is lower quality and higher compression, and 100 is higher quality and lower compression.

Only available for OGG (`.ogg`) files.

Example: `'Quality',25`

`'Title'` — Title information

[ ] (default) | string

Title information, specified as the comma-separated pair consisting of `'Title'` and a string.

`'Artist'` — Artist information

[ ] (default) | string

Artist information, specified as the comma-separated pair consisting of `'Artist'` and a string.

`'Comment'` — Additional information

[ ] (default) | string

Additional information, specified as the comma-separated pair consisting of `'Comment'` and a string.

Note: On Mac platforms, `audiowrite` writes metadata to WAVE, OGG, and FLAC files only, and will not write the `'Title'`, `'Author'`, or `'Comment'` fields to MPEG-4 AAC files.

More About

Algorithms

The output data type is determined by the file format, the data type of `y`, and the specified output `BitsPerSample`.

File Formats	Data Type of y	Output BitsPerSample	Output Data Type
WAVE (`.wav`),	`uint8`, `int16`, `int32`, `single`, `double`	8	`uint8`
		16	`int16`
		24	`int32`
	`uint8`, `int16`, `int32`	32	`int32`
	`single`, `double`	32	`single`
	`single`, `double`	64	`double`
FLAC (`.flac`)	`uint8`, `int16`, `int32`, `single`, `double`	8	`int8`
		16	`int16`
		24	`int32`
MPEG-4 (`.m4a`, `.mp4`), OGG (`.ogg`)	`uint8`, `int16`, `int32`, `single`, `double`	N/A	`single`

See Also

`audioinfo` | `audioread`

Introduced in R2012b

addframe (avifile)

Add frame to Audio/Video Interleaved (AVI) file

Note: `avifile` has been removed. Use `VideoWriter` instead.

Syntax

```
aviobj = addframe(aviobj,frame)
aviobj = addframe(aviobj,frame1,frame2,frame3,...)
aviobj = addframe(aviobj,mov)
aviobj = addframe(aviobj,h)
```

Description

`aviobj = addframe(aviobj,frame)` appends the data in *`frame`* to the AVI file identified by *`aviobj`*, which was created by a previous call to `avifile`. *`frame`* can be either an indexed image (`m`-by-`n`) or a truecolor image (`m`-by-`n`-by-3) of `double` or `uint8` precision. If *`frame`* is not the first frame added to the AVI file, it must be consistent with the dimensions of the previous frames.

`addframe` returns a handle to the updated AVI file object, *`aviobj`*. For example, `addframe` updates the `TotalFrames` property of the AVI file object each time it adds a frame to the AVI file.

`aviobj = addframe(aviobj,frame1,frame2,frame3,...)` adds multiple frames to an AVI file.

`aviobj = addframe(aviobj,mov)` appends the frames contained in the MATLAB movie *`mov`* to the AVI file *`aviobj`*. MATLAB movies that store frames as indexed images use the colormap in the first frame as the colormap for the AVI file, unless the colormap has been previously set.

`aviobj = addframe(aviobj,h)` captures a frame from the figure or axis handle *`h`* and appends this frame to the AVI file. `addframe` renders the figure into an offscreen array

before appending it to the AVI file. This ensures that the figure is written correctly to the AVI file even if the figure is obscured on the screen by another window or screen saver.

Examples

This example calls `addframe` to add frames to the AVI file object `aviobj`.

```
aviobj = avifile('example.avi','compression','None');

t = linspace(0,2.5*pi,40);
fact = 10*sin(t);
fig=figure;
[x,y,z] = peaks;
for k=1:length(fact)
    h = surf(x,y,fact(k)*z);
    axis([-3 3 -3 3 -80 80])
    axis off
    caxis([-90 90])

    F = getframe(fig);
    aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

More About

Tips

- `avifile` cannot write files larger than 2 GB. Use `VideoWriter` and `writeVideo` to create larger files.
- If you are creating an animation from a figure with an `EraseMode` property set to `'xor'`, you must use `getframe` to capture the graphics into a frame of a MATLAB movie. Add the frame to the AVI file using the syntax *`aviobj`* `= addframe(`*`aviobj`*`,`*`mov`*`)`. See the example for an illustration.

`VideoWriter` | `close (avifile)` | `avifile`

Introduced before R2006a

addOptional

Class: inputParser

Add optional positional argument to input parser scheme

Syntax

```
addOptional(p,argName,default)
addOptional(p,argName,default,validationFcn)
```

Description

`addOptional(p,argName,default)` adds optional input, `argName`, to the input parser scheme of `inputParser` object, `p`. When the inputs that you are checking do not include a value for this optional input, the input parser assigns the `default` value to the input.

`addOptional(p,argName,default,validationFcn)` specifies a validation function for the input argument.

Tips

- For optional string inputs, specify a validation function. Without a validation function, the input parser interprets valid string inputs as invalid parameter names and throws an error.
- Use `addOptional` to add an individual argument into the input parser scheme. If you want to parse an optional name-value pair, use `addParameter`.

Input Arguments

`p`

Object of class `inputParser`.

`argName`

String that specifies the internal name for the input argument.

Arguments added with `addOptional` are positional. When you call a function with positional inputs:

- Specify inputs in the same order that they are added into the input parser scheme.
- Specify a value for the `k`th argument by assigning values for the first `(k–1)` arguments in the input scheme.

`default`

Default value for the input. This value can be of any data type.

`validationFcn`

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Input

Create an `inputParser` object and add an optional input named `myinput` with a default value of `0` to the input scheme.

```
p = inputParser;
argName = 'myinput';
default = 0;
addOptional(p,argName,default);
```

Validate Optional Input

Check whether an optional input named `num` with a default value of `1` is a numeric scalar greater than zero.

```
p = inputParser;
argName = 'num';
```

```
default = 1;
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addOptional(p,argName,default,validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p,-1)
```

```
The value of 'num' is invalid. It must satisfy the function: @(x)isnumeric(x)&&isscalar(x)&&(x>0).
```

Validate Optional Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that optional input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;
argName = 'evenPosNum';
default = 1;
validationFcn = @(x) validateattributes(x,{'numeric'},...
    {'even','positive'});
addOptional(p,argName,default,validationFcn)
```

Parse an input string. Parse will fail.

```
parse(p,'hello')
```

```
The value of 'evenPosNum' is invalid. Expected input to be one of these types:

double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64

Instead its type was char.
```

Parse an odd number. Parse will fail.

```
 parse(p,13)
```

```
The value of 'evenPosNum' is invalid. Expected input to be even.
```

Parse an even, positive number. Parse will pass.

```
parse(p,42)
```

See Also

`addParameter` | `addRequired` | `function_handle` | `inputParser` | `validateattributes`

More About

- “Anonymous Functions”

addParameter

Class: inputParser

Add optional parameter name-value pair argument to input parser scheme

Syntax

```
addParameter(p,paramName,default)
addParameter(p,paramName,default,validationFcn)
addParameter(___,'PartialMatchPriority', matchPriorityValue)
```

Description

`addParameter(p,paramName,default)` adds parameter name and value argument `paramName` to the input parser scheme of `inputParser` object, `p`. When the inputs that you are checking do not include a value for this optional parameter, the input parser assigns the `default` value.

`addParameter(p,paramName,default,validationFcn)` specifies a validation function for the input argument.

`addParameter(___,'PartialMatchPriority', matchPriorityValue)` allows specification of matchPriorityValue to indicate priority for matching of conflicting partial parameter names and can include any of the input arguments in the previous syntaxes.

Input Arguments

`p`

Object of class `inputParser`.

`paramName`

String that specifies the internal name for the input parameter.

Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form `Name1,Value1,...,NameN,ValueN`.

`default`

Default value for the input. This value can be of any data type.

`matchPriorityValue`

Positive integer value indicating the priority for matching of conflicting partial parameter names. The input parser selects lower priority values over higher ones. If, within an input parser scheme, partial parameter names are ambiguous and have the same priority, `inputParser` will throw an error. If the names are ambiguous, but have different `PartialMatchPriority` values, `inputParser` issues a warning indicating the matched name.

Default: 1

`validationFcn`

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Parameter Value Input

Create an `inputParser` object and add an optional input named `myparam` with a default value of `0` to the input scheme.

```
p = inputParser;
paramName = 'myparam';
default = 0;
addParameter(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParameter` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p,'myparam',100);
p.Results
```

```
ans =

    myparam: 100
```

Validate Parameter Value

Check whether the value corresponding to `myparam` is a numeric scalar greater than zero.

```
p = inputParser;
paramName = 'myparam';
default = 1;
errorStr = 'Value must be positive, scalar, and numeric.';
validationFcn = @(x) assert(isnumeric(x) && isscalar(x) ...
    && (x > 0),errorStr);
addParameter(p,paramName,default,validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as `-1`:

```
parse(p,'myparam',-1)
```

```
The value of 'myparam' is invalid. Value must be positive, scalar, and numeric.
```

Validate Parameter Value Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that input parameter `myName` is a nonempty string.

```
p = inputParser;
paramName = 'myName';
default = 'John Doe';
validationFcn = @(x) validateattributes(x,{'char'},{'nonempty'});
addParameter(p,paramName,default,validationFcn)
```

Define `myName` as a number. The attempt to parse fails.

```
parse(p,'myName',1138)
```

```
The value of 'myName' is invalid. Expected input to be one of these types:

char

Instead its type was double.
```

Parse a string. The attempt to parse passes.

```
parse(p,'myName','George')
```

More About

- “Anonymous Functions”

addParamValue

Class: inputParser

(Not recommended) Add parameter name and value argument to Input Parser scheme

Compatibility

`addParamValue` is not recommended. Use `addParameter` instead.

Syntax

```
addParamValue(p,paramName,default)
addParamValue(p,paramName,default,validationFcn)
```

Description

`addParamValue(p,paramName,default)` adds parameter name and value argument `paramName` to the input scheme of `inputParser` object `p`. When the inputs that you are checking do not include a value for this optional parameter, the parser assigns the `default` value.

`addParamValue(p,paramName,default,validationFcn)` specifies a validation function for the input argument.

Tips

- If your parameter values do not require validation, you do not have to include them in the input scheme with `addParamValue`. As an alternative, set the `KeepUnmatched` property of the `inputParser` object to `true`. The parser stores extra parameter names and values in the `Unmatched` property rather than in the `Results` property of the object. For an example, see the `inputParser` reference page.

Input Arguments

p

Object of class `inputParser`.

paramName

String that specifies the internal name for the input parameter.

Parameter names and values are optional inputs. When calling the function, name and value pairs can appear in any order, with the general form `Name1,Value1,...,NameN,ValueN`.

default

Default value for the input. This value can be of any data type.

validationFcn

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Optional Parameter Value Input

Create an `inputParser` object and add an optional input named `myparam` with a default value of `0` to the input scheme.

```
p = inputParser;
paramName = 'myparam';
default = 0;
addParameter(p,paramName,default);
```

Unlike the positional inputs added with the `addRequired` and `addOptional` methods, each parameter added with `addParameter` corresponds to two input arguments: one for the name and one for the value of the parameter.

Pass both the parameter name and value to the `parse` method.

```
parse(p,'myparam',100);
p.Results
```

```
ans =

    myparam: 100
```

Validate Parameter Value

Check whether the value corresponding to `myparam` is a numeric scalar greater than zero.

```
p = inputParser;
paramName = 'myparam';
default = 1;
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addParamValue(p,paramName,default,validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid value, such as `-1`:

```
parse(p,'myparam',-1)
```

```
Argument 'myparam' failed validation @(x)isnumeric(x)&&isscalar(x)&&(x>0).
```

`addOptional` | `addParameter` | `addRequired` | `function_handle` | `inputParser`

More About

- “Anonymous Functions”

addcats

Add categories to categorical array

Syntax

```
B = addcats(A,newcats)
B = addcats(A,newcats,'Before',beforewhere)
B = addcats(A,newcats,'After',afterwhere)
```

Description

`B = addcats(A,newcats)` adds categories to the end of the category list for the input categorical array, `A`. The output categorical array, `B`, contains the same values as `A`. The output, `B`, does not contain any elements equal to the new categories until you assign values from `newcats` to elements in `B`.

If `A` is an ordinal categorical array, you must specify the `'Before',beforewhere` or `'After',afterwhere` input arguments.

`B = addcats(A,newcats,'Before',beforewhere)` adds categories before the category specified by beforewhere.

`B = addcats(A,newcats,'After',afterwhere)` adds categories after the category specified by afterwhere.

Examples

Add Categories at End

Create a nonordinal categorical array.

```
A = categorical({'republican' 'democrat' 'republican';...
    'democrat' 'republican' 'democrat'})
```

```
A =
```

```
     republican      democrat        republican
     democrat        republican      democrat
```

Display the categories of A.

```
categories(A)
```

```
ans =

    'democrat'
    'republican'
```

A is a 2-by-3 categorical array with two categories.

Add the categories, `independent` and `undeclared`, to the end of the category list

```
B = addcats(A,{'independent' 'undeclared'})
```

```
B =

     republican      democrat        republican
     democrat        republican      democrat
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =

    'democrat'
    'republican'
    'independent'
    'undeclared'
```

B is a 2-by-3 categorical array with four categories.

Add Categories and Specify Category to Precede

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'},...
```

```
    {'small' 'medium' 'large' 'xlarge'},'Ordinal',true)

A =

     medium      large
     small       xlarge
     large       medium
```

Display the categories of A.

```
categories(A)

ans =

    'small'
    'medium'
    'large'
    'xlarge'
```

Since A is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

Add the category `xsmall` before `small`.

```
B = addcats(A,'xsmall','Before','small')

B =

     medium      large
     small       xlarge
     large       medium
```

B contains the same values as A.

Display the categories of B.

```
categories(B)

ans =

    'xsmall'
    'small'
    'medium'
    'large'
    'xlarge'
```

The categories have the mathematical ordering `xsmall < small < medium < large < xlarge`.

Input Arguments

`A` — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

`newcats` — New categories

string | cell array of strings

New categories, specified as a string or a cell array of strings.

`beforewhere` — Category to precede

string

Category to precede, specified as a string.

`afterwhere` — Category to follow

string

Category to follow, specified as a string.

See Also

`categories` | `iscategory` | `mergecats` | `removecats` | `renamecats` | `reordercats` | `setcats`

addpath

Add folders to search path

Syntax

```
addpath(folderName1,...,folderNameN)
addpath(folderName1,...,folderNameN,position)

addpath( ___ ,'-frozen')

oldpath = addpath( ___ )
```

Description

`addpath(folderName1,...,folderNameN)` adds the specified folders to the top of the search path. Use `addpath` statements in a `startup.m` file to modify the search path programmatically at startup.

`addpath(folderName1,...,folderNameN,position)` adds the specified folders to the top or bottom of the search path, as specified by `position`.

`addpath( ___ ,'-frozen')` additionally disables folder change detection on Windows for folders being added, which conserves Windows change notification resources (Windows only). Type `help changenotification` in the Command Window for more information.

Add `'-frozen'` to the input arguments in any of the previous syntaxes. You can specify `'-frozen'` and `position` in either order.

`oldpath = addpath( ___ )` additionally returns the path prior to adding the specified folders.

Examples

Add Folder to Top of Search Path

If you do not have a folder called `c:/matlab/myfiles`, create the folder.

```
mkdir('c:/matlab/myfiles')
```

Add `c:/matlab/myfiles` to the top of the search path.

```
addpath('c:/matlab/myfiles')
```

Add Folder to End of Search Path

Add `c:/matlab/myfiles` to the end of the search path.

```
addpath('c:/matlab/myfiles','-end')
```

Add Folder and Its Subfolders to Search Path

Add `c:/matlab/myfiles` and its subfolders to the search path.

Call `genpath` inside of `addpath` to add all subfolders of `c:/matlab/myfiles` to the search path.

```
addpath(genpath('c:/matlab/myfiles'))
```

Add Folder to Search Path and Disable Folder Change Notification

On Windows, add the folder `c:/matlab/myfiles` to the top of the search path, disable folder change notification, and return the search path before adding the folder.

```
oldpath = addpath('c:/matlab/myfiles','-frozen');
```

Input Arguments

`folderName1,...,folderNameN` — Names of folders to add to search path

string

Names of folders to add to the search path, specified as strings. Use the full path name for each folder. Use `genpath` with `addpath` to add all subfolders of `folderName`.

Example: `'c:\matlab\work'`

Example: `'/home/user/matlab'`

Example: `'/home/user/matlab','/home/user/matlab/test'`

`position` — Position on the search path

`'-begin'` (default) | `'-end'`

Position on the search path, specified as one of the following strings.

Value of `position`	Description
`'-begin'`	Add specified folders to the top of the search path.
`'-end'`	Add specified folders to the bottom of the search path.

Output Arguments

`oldpath` — Path prior to addition of folders

string

Path prior to the addition of folders, returned as a string.

More About

Tips

- If you use `addpath` within a local function, the path change persists after program control returns from the function. That is, the scope of the path change is global.

- "What Is the MATLAB Search Path?"
- "Files and Folders that MATLAB Accesses"
- "Specify File Names"
- "Startup Options in MATLAB Startup File"

`genpath` | `path` | `pathsep` | `rmpath` | `savepath`

Introduced before R2006a

addpref

Add preference

Syntax

```
addpref('group','pref',val)
addpref('group',{'pref1','pref2',...'prefn'},{val1,val2,...valn})
```

Description

`addpref('group','pref',val)` creates the preference specified by `group` and `pref` and sets its value to `val`. It is an error to add a preference that already exists. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`addpref('group',{'pref1','pref2',...'prefn'},{val1,val2,...valn})` creates the preferences specified by the cell array of names `'pref1'`, `'pref2',...,'prefn'`, setting each to the corresponding value.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Add a preference called `version` to the `mytoolbox` group of preferences, setting its value to the cell array `{'1.0','beta'}`.

```
addpref('mytoolbox','version',{'1.0','beta'})
```

Add a preference called `documentation` to the `mytoolbox` group of preferences, setting its value to a struct you define as having four fields:

```
mydoc.docexists = 1;
mydoc.docpath = fullfile(docroot,'techdoc',...
   'matlab_env','examples');
mydoc.demoexists = 1;
mydoc.demopath = fullfile(docroot,'techdoc',...
   'matlab_env','examples','demo_examples');
addpref('mytoolbox','documentation',mydoc)
% Retrieve the preference with GETPREF
p = getpref('mytoolbox','documentation')

p =
     docexists: 1
       docpath: [1x109 char]
    demoexists: 1
      demopath: [1x123 char]
```

Introduced before R2006a

addpoints

Add points to animated line

To use this function, you must first create an animated line with the `animatedline` function. For more information on line animations, see Using Animated Line Objects.

Syntax

```
addpoints(h,x,y)
addpoints(h,x,y,z)
```

Description

`addpoints(h,x,y)` adds points defined by `x` and `y` to the animated line specified by `h`. To display the updates on the screen, use `drawnow` or `drawnow update`. New points automatically connect to previous points.

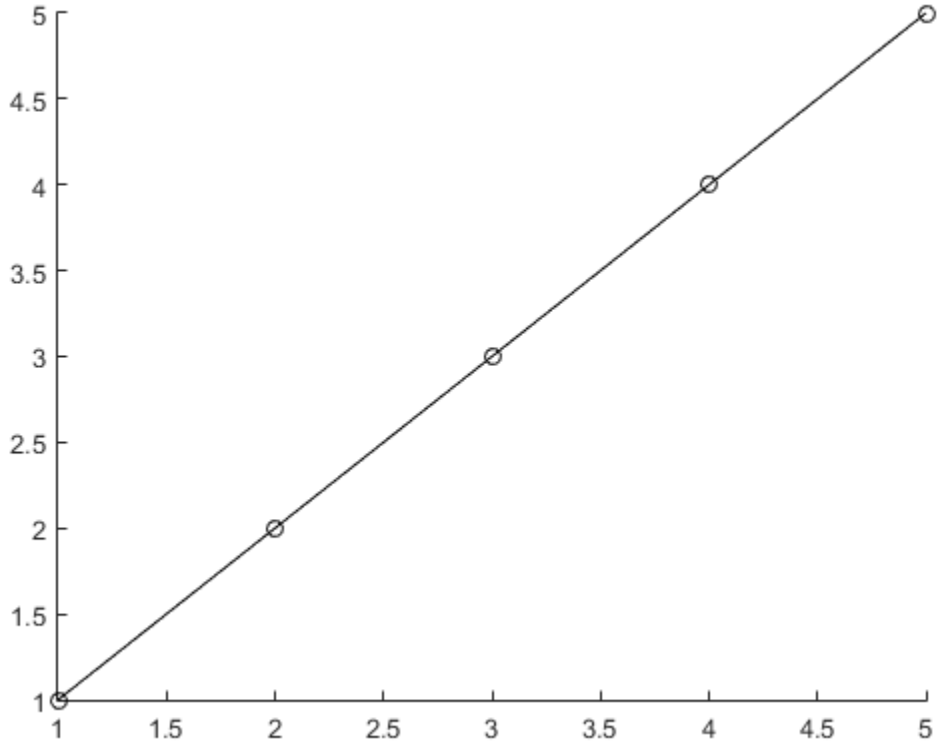
`addpoints(h,x,y,z)` adds points defined by `x`, `y`, and `z` to the 3-D animated line specified by `h`.

Examples

Add Five Points to Animated Line

Create an animated line object with no data. Then, add five points to the line. Use a circle to mark each point.

```
h = animatedline('Marker','o');
x = 1:5;
y = 1:5;
addpoints(h,x,y)
```



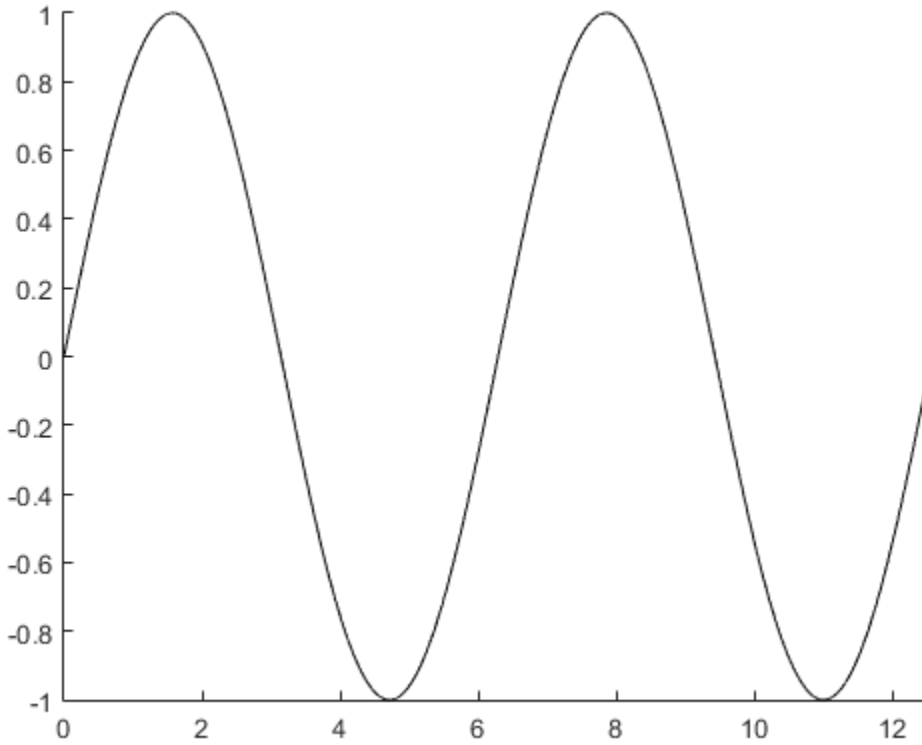
Add Points Within Loop to Animated Line

Create an animated line using the `animatedline` function. Then, add points to the line within a loop to create an animation. Set the axis limits before the loop to prevent the limits from changing.

```
figure
h = animatedline;
axis([0 4*pi -1 1])

for x = linspace(0,4*pi,10000)
    y = sin(x);
    addpoints(h,x,y)
    drawnow limitrate
```

```
end
```



Input Arguments

h — Animated line object

animated line object

Animated line object. Create an animated line using the `animatedline` function.

x — x values

scalar | vector

x values, specified as a scalar or a vector. The length of `x` must equal the length of `y`.

Example: `11:20`

Data Types: `double`

y — y values

scalar | vector

y values, specified as a scalar or a vector. The length of `y` must equal the length of `x`.

Example: `11:20`

Data Types: `double`

z — z values

scalar | vector

z values, specified as a scalar or a vector. The length of `z` must equal the length of `x` and `y`.

Example: `11:20`

Data Types: `double`

Functions

`animatedline` | `clearpoints` | `getpoints`

Using Objects

Using Animated Line Objects

addprop (dynamicprops)

Add dynamic property

Syntax

```
P = addprop(Hobj,'PropName')
```

Description

`P = addprop(Hobj,'PropName')` adds a property named `PropName` to each object in array `Hobj`. The class definition is not affected by the addition of dynamic properties. Note that you can add dynamic properties only to objects derived from the `dynamicprops` class. You can set and retrieve the data in dynamic properties as you would any property.

The output argument `P` is an array the same size as `Hobj` of `meta.DynamicProperty` objects, which you can use to assign `SetMethod` and `GetMethod` functions to the property. These functions operate just like property set and get access methods.

See "Dynamic Properties — Adding Properties to an Instance" for more information and examples.

See Also

`handle` | `dynamicprops`

addproperty

Add custom property to COM object

Syntax

```
addproperty(h,'name')
```

Description

`addproperty(h,'name')` adds custom property specified in string, `name`, to object or interface, `h`.

COM functions are available on Microsoft Windows systems only.

Examples

This example adds a custom property to the MATLAB sample control.

1 Create an instance of the control:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
get(h)
```

```
     Label: 'Label'
    Radius: 20
```

MATLAB also displays interfaces.

2 Add a custom property named `Position` and assign a value:

```
addproperty(h,'Position');
h.Position = [200 120];
get(h)
```

```
       Label: 'Label'
      Radius: 20
    Position: [200 120]
```

3 Delete the custom property `Position`:

```
deleteproperty(h,'Position');
get(h)
```

```
     Label: 'Label'
    Radius: 20
```

MATLAB displays the original list of properties:

Introduced before R2006a

addRequired

Class: inputParser

Add required positional argument to input parser scheme

Syntax

```
addRequired(p,argName)
addRequired(p,argName,validationFcn)
```

Description

`addRequired(p,argName)` adds required argument, `argName`, to the input parser scheme of `inputParser` object, `p`.

`addRequired(p,argName,validationFcn)` includes a validation function for the input argument.

Input Arguments

`p`

Object of class `inputParser`.

`argName`

String that specifies the internal name for the input argument.

Arguments added with `addRequired` are positional. When you call a function with positional inputs, you must specify inputs in the order that they are added to the input parser scheme.

`validationFcn`

Handle to a function that checks if the input argument is valid.

`inputParser` accepts two types of validation functions: functions that return `true` or `false`, and functions that pass or throw an error. Both types of validation functions must accept a single input argument.

Examples

Add Required Input

Create an `inputParser` object and add a required input named `myinput` to the input scheme.

```
p = inputParser;
argName = 'myinput';
addRequired(p,argName);
```

Validate Required Input

Check whether a required input named `num` is a numeric scalar greater than zero.

```
p = inputParser;
argName = 'num';
validationFcn = @(x) isnumeric(x) && isscalar(x) && (x > 0);
addRequired(p,argName,validationFcn)
```

The syntax `@(x)` creates a handle to an anonymous function with one input.

Attempt to parse an invalid input, such as `-1`:

```
parse(p,-1)
```

```
The value of 'num' is invalid. It must satisfy the function: @(x)isnumeric(x)&&isscalar(x)&&(x>0).
```

Validate Required Input with `validateattributes`

Create an `inputParser` object and define a validation function using `validateattributes` to test that required input is numeric, positive, and even. Add the required input to the scheme.

```
p = inputParser;
argName = 'evenPosNum';
validationFcn = @(x) validateattributes(x,{'numeric'},...
    {'even','positive'});
addRequired(p,argName,validationFcn)
```

Parse an input string. Parse will fail.

```
parse(p,'hello')
```

```
The value of 'evenPosNum' is invalid. Expected input to be one of these types:

double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64

Instead its type was char.
```

Parse an odd number. Parse will fail.

```
 parse(p,13)
```

```
The value of 'evenPosNum' is invalid. Expected input to be even.
```

Parse an even, positive number. Parse will pass.

```
parse(p,42)
```

`addOptional` | `addParameter` | `function_handle` | `inputParser` | `validateattributes`

More About

- “Anonymous Functions”

addsampletocollection

Add sample to `tscollection` object

Syntax

```
tsc = addsampletocollection(tsc,'time',Time,TS1Name,TS1Data,
TSnName,TSnData)
```

Description

`tsc = addsampletocollection(tsc,'time',Time,TS1Name,TS1Data, TSnName,TSnData)` adds data samples `TSnData` to the collection member `TSnName` in the `tscollection` object `tsc` at one or more `Time` values. Here, `TSnName` is the string that represents the name of a time series in `tsc`, and `TSnData` is an array containing data samples.

Examples

The following example shows how to create a `tscollection` that consists of two `timeseries` objects, where one `timeseries` does not have quality codes and the other does. The final step of the example adds a sample to the `tscollection`.

1. Create two `timeseries` objects, `ts1` and `ts2`.

   ```
   ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                    'name','acceleration');
   ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...
                    'name','speed');
   ```

2. Define a dictionary of quality codes and descriptions for `ts2`.

   ```
   ts2.QualityInfo.Code = [0 1];
   ts2.QualityInfo.Description = {'bad','good'};
   ```

3. Assign a quality of code of `1`, which is equivalent to `'good'`, to each data value in `ts2`.

   ```
   ts2.Quality = ones(5,1);
   ```

4 Create a time-series collection `tsc`, which includes time series `ts1` and `ts2`.

```
tsc = tscollection({ts1,ts2});
```

5 Add a data sample to the collection `tsc` at `3.5` seconds.

```
tsc = addsampletocollection(tsc,'time',3.5,'acceleration',10,'speed',{5 1});
```

The cell array for the `timeseries` object `'speed'` specifies both the data value 5 and the quality code `1`.

Note If you do not specify a quality code when adding a data sample to a time series that has quality codes, then the lowest quality code is assigned to the new sample by default.

More About

Tips

If you do not specify data samples for a time-series member in tsc, that time-series member will contain missing data at the times given by Time (for numerical time-series data), `NaN` values, or (for logical time-series data) `false` values.

When a time-series member requires `Quality` values, you can specify data quality codes together with the data samples by using the following syntax:

```
tsc = addsampletocollection(tsc,'time',time,TS1Name,...
         ts1cellarray,TS2Name,ts2cellarray,...)
```

Specify data in the first cell array element and `Quality` in the second cell array element.

Note If a time-series member already has `Quality` values but you only provide data samples, `0`s are added to the existing `Quality` array at the times given by `Time`.

`delsamplefromcollection` | `timeseries` | `tscollection`

Introduced before R2006a

addtodate

Modify date number by field

Syntax

```
R = addtodate(D, Q, F)
```

Description

`R = addtodate(D, Q, F)` adds quantity `Q` to the indicated date field `F` of a scalar serial date number `D`, returning the updated date number `R`.

The quantity `Q` to be added can be a positive or negative integer. The absolute value of `Q` must be less than or equal to 1e16. The date field `F` must be a 1-by-`N` character array equal to one of the following: `'year'`, `'month'`, `'day'`, `'hour'`, `'minute'`, `'second'`, or `'millisecond'`.

If the addition to the date field causes the field to roll over, the MATLAB software adjusts the next more significant fields accordingly. Adding a negative quantity to the indicated date field rolls back the calendar on the indicated field. If the addition causes the field to roll back, MATLAB adjusts the next less significant fields accordingly.

Examples

Modify the hours, days, and minutes of a given date:

```
t = datenum('07-Apr-2008 23:00:00');
datestr(t)
ans =
   07-Apr-2008 23:00:00

t= addtodate(t, 2, 'hour');
datestr(t)
ans =
   08-Apr-2008 01:00:00
```

```
t= addtodate(t, -7, 'day');
datestr(t)
ans =
   01-Apr-2008 01:00:00

t= addtodate(t, 59, 'minute');
datestr(t)
ans =
   01-Apr-2008 01:59:00
```

Adding 20 days to the given date in late December causes the calendar to roll over to January of the next year:

```
R = addtodate(datenum('12/24/2007 12:45'), 20, 'day');

datestr(R)
ans =
   13-Jan-2008 12:45:00
```

See Also

`date` | `datenum` | `datestr` | `datevec`

Introduced before R2006a

addts

Add `timeseries` object to `tscollection` object

Syntax

```
tsc = addts(tsc,ts)
tsc = addts(tsc,ts)
tsc = addts(tsc,ts,Name)
tsc = addts(tsc,Data,Name)
```

Description

`tsc = addts(tsc,ts)` adds the `timeseries` object ts to `tscollection` object tsc.

`tsc = addts(tsc,ts)` adds a cell array of `timeseries` objects ts to the `tscollection` tsc.

`tsc = addts(tsc,ts,Name)` adds a cell array of `timeseries` objects ts to `tscollection` tsc. Name is a cell array of strings that gives the names of the `timeseries` objects in `ts`.

`tsc = addts(tsc,Data,Name)` creates a new `timeseries` object from Data with the name Name and adds it to the `tscollection` object tsc. Data is a numerical array and Name is a string.

Examples

The following example shows how to add a time series to a time-series collection:

1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                 'name','acceleration');
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...
```

```
                    'name','speed');
```

2 Create a time-series collection `tsc`, which includes `ts1`.

```
tsc = tscollection(ts1);
```

3 Add `ts2` to the `tsc` collection.

```
tsc = addts(tsc, ts2);
```

4 To view the members of `tsc`, type

```
tsc
```

at the MATLAB prompt. the response is

```
Time Series Collection Object: unnamed

Time vector characteristics

      Start time            1 seconds
      End time              5 seconds

Member Time Series Objects:

      acceleration
      speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of the `timeseries` objects `ts1` and `ts2`, respectively.

More About

Tips

The `timeseries` objects you add to the collection must have the same time vector as the collection. That is, the time vectors must have the same time values and units.

Suppose that the time vector of a `timeseries` object is associated with calendar dates. When you add this `timeseries` to a collection with a time vector without calendar dates, the time vectors are compared based on the units and the values relative to the `StartDate` property. For more information about properties, see the `timeseries` reference page.

`removets` | `tscollection`

Introduced before R2006a

airy

Airy Functions

Syntax

```
W = airy(Z)
W = airy(k,Z)
W = airy(k,Z,scale)
```

Description

`W = airy(Z)` returns the Airy function, *Ai*(*Z*), for each element of *Z*.

`W = airy(k,Z)` returns any of four different Airy functions, depending on the value of `k`, such as the Airy function of the second kind or the first derivative of an Airy function.

`W = airy(k,Z,scale)` scales the resulting Airy function. `airy` applies a specific scaling function to `W` depending on your choice of `k` and `scale`.

Examples

Airy Function of Real-Valued x

Define `x`.

```
x = -10:0.01:1;
```

Calculate *Ai(x)*

```
ai = airy(x);
```

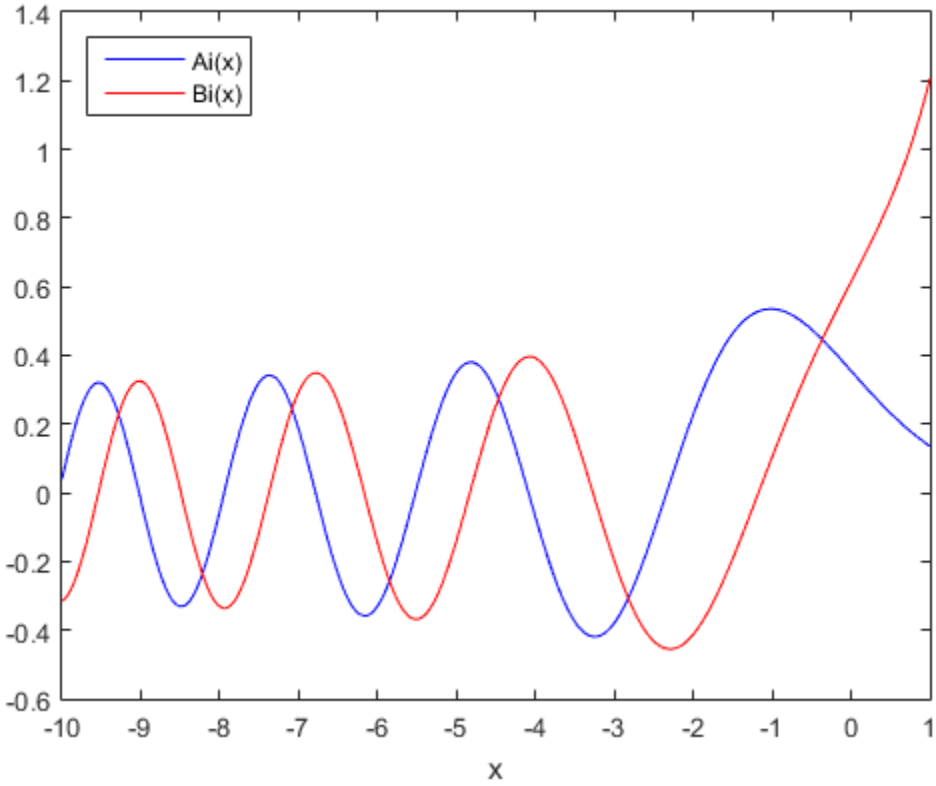
Calculate *Bi(x)* using $k = 2$.

```
bi = airy(2,x);
```

Plot both results together on the same axes.

```
figure
plot(x,ai,'-b',x,bi,'-r')
axis([-10 1 -0.6 1.4])
```

```
xlabel('x')
legend('Ai(x)','Bi(x)','Location','NorthWest')
```



Airy Function of Complex-Valued x

Compute the Airy function at a slice through the complex plane at $x + i$.

Take a slice through the complex plane.

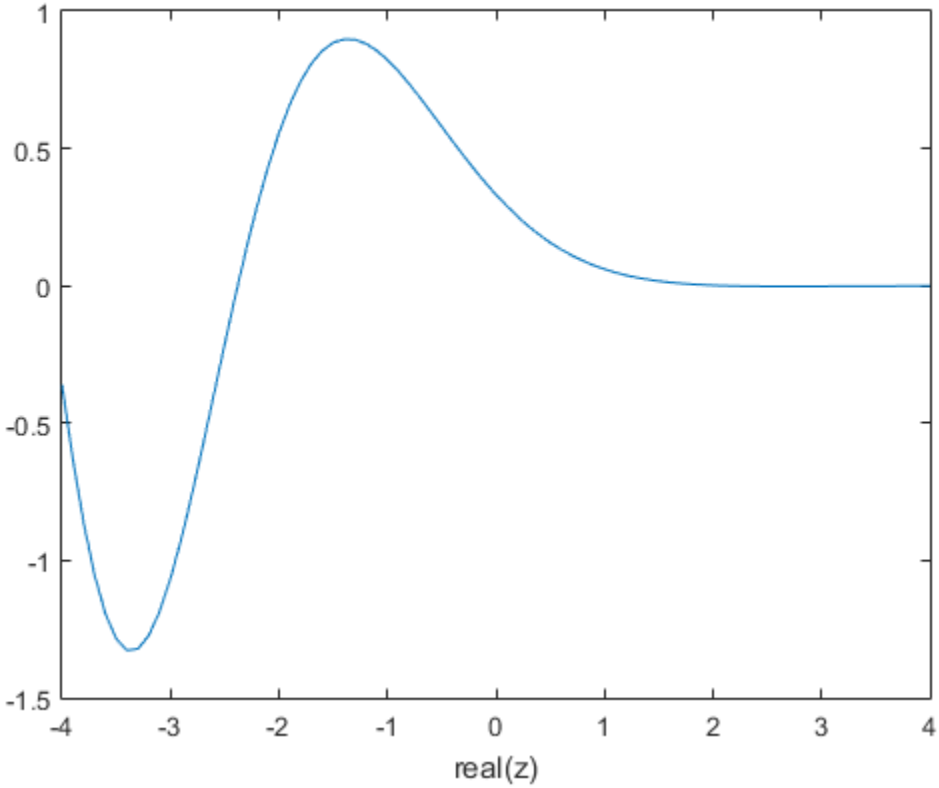
```
x = -4:0.1:4;
z = x+1i;
```

Calculate *Ai(z)*.

```
w = airy(z);
```

Plot the real part of the result.

```
figure
plot(x, real(w))
axis([-4 4 -1.5 1])
xlabel('real(z)')
```



Scaled Airy Function

Define `x`.

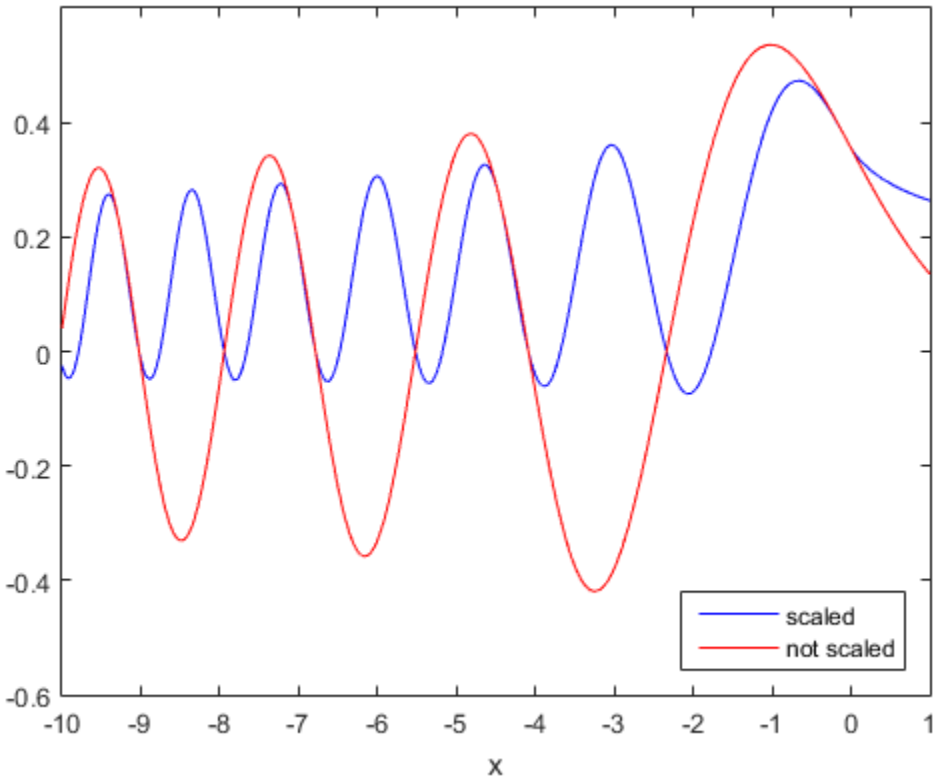
```
x = -10:0.01:1;
```

Calculate the scaled and unscaled Airy function.

```
scaledAi = airy(0,x,1);
noscaleAi =  airy(0,x,0);
```

Plot the real part of each result.

```
rscaled = real(scaledAi);
rnoscale = real(noscaleAi);
figure
plot(x,rscaled,'-b',x,rnoscale,'-r')
axis([-10 1 -0.60 0.60])
xlabel('x')
legend('scaled','not scaled','Location','SouthEast')
```



Input Arguments

Z — System variable

vector | matrix | N-D Array

System variable, specified as a real or complex vector, matrix, or N-D array.

Data Types: `single` | `double`
Complex Number Support: Yes

k — Type of Airy function

0 (default) | 1 | 2 | 3

Type of Airy function, specified as one of four values.

k	Returns
0	Airy function, $Ai(Z)$, which is the same as `airy(Z)`.
1	First derivative of Airy function, $Ai'(Z)$.
2	Airy function of the second kind, $Bi(Z)$
3	First derivative of Airy function of the second kind, $Bi'(Z)$

Data Types: `single` | `double`

`scale` — Scaling option

0 (default) | 1

Scaling option, specified as `0` or `1`. Use `scale = 1` to enable the scaling of `Z`. The values you specify for `k` and `scale` determine the scaling function `airy` applies to `Z`.

scale	k	Scaling applied to output
0	Any	None
1	0 or 1	$e^{\frac{2}{3}Z^{(3/2)}}$
1	2 or 3	$e^{-\left\lvert\frac{2}{3}Re\left(Z^{(3/2)}\right)\right\rvert}$

Data Types: `single` | `double`

Output Arguments

`W` — Airy function of `Z`

vector | matrix | N-D Array

Airy function of `Z`, returned as an array the same size as `Z`.

More About

Airy Functions

The Airy functions form a pair of linearly independent solutions to

$$\frac{d^2W}{dZ^2} - ZW = 0.$$

The relationship between the Airy and modified Bessel functions is

$$Ai(Z) = \left[\frac{1}{\pi}\sqrt{\frac{Z}{3}}\right] K_{1/3}(\zeta)$$

$$Bi(Z) = \sqrt{\frac{Z}{3}}\left[I_{-1/3}(\zeta) + I_{1/3}(\zeta)\right],$$

where

$$\zeta = \frac{2}{3}Z^{3/2}.$$

Introduced before R2006a

align

Align user interface controls (`uicontrols`) and axes

Syntax

```
align(HandleList,'HorizontalAlignment','VerticalAlignment')
Positions = align(HandleList, 'HorizontalAlignment',
'VerticalAlignment')
Positions = align(CurPositions, 'HorizontalAlignment',
'VerticalAlignment')
```

Description

`align(HandleList,'HorizontalAlignment','VerticalAlignment')` aligns the `uicontrol` and `axes` objects in `HandleList`, a vector of handles, according to the options `HorizontalAlignment` and `VerticalAlignment`. The following tables show the possible values for `HorizontalAlignment` and `VerticalAlignment`.

`HorizontalAlignment`	Definition
`None`	No horizontal alignment
`Left`	Shifts the objects' left edges to that of the first object selected
`Center`	Shifts objects to center their positions to the average of the extreme *x*-values of the group
`Right`	Shifts the objects' right edges to that of the first object selected
`Distribute`	Equalizes *x*-distances between all objects within the span of the extreme *x*-values
`Fixed`	Spaces objects to have a specified number of points between them in the *y*-direction

`VerticalAlignment`	Definition
`None`	No vertical alignment

VerticalAlignment	Definition
Top	Shifts the objects' top edges to that of the first object selected
Middle	Shifts objects to center their positions to the average of the extreme *y*-values of the group
Bottom	Shifts the objects' bottom edges to that of the first object selected
Distribute	Equalizes *y*-distances between all objects within the span of the extreme *y*-values
Fixed	Spaces objects to have a specified number of points between them in the *x*-direction

Aligning objects does not change their absolute sizes. All alignment options align the objects within the bounding box that encloses the objects. `Distribute` and `Fixed` align objects to the bottom left of the bounding box. `Distribute` evenly distributes the objects while `Fixed` distributes the objects with a fixed distance (in points) between them. When you specify both horizontal and vertical distance together, the keywords `'HorizontalAlignment'` and `'VerticalAlignment'` are not necessary.

If you use `Fixed` for `HorizontalAlignment` or `VerticalAlignment`, you must also specify the distance, in points, where 72 points equals 1 inch. For example:

```
align(HandleList,'Fixed',Distance,'VerticalAlignment')
```

distributes the specified components `Distance` points horizontally and aligns them vertically as specified.

```
align(HandleList,'HorizontalAlignment','Fixed',Distance)
```

aligns the specified components horizontally as specified and distributes them `Distance` points vertically.

```
align(HandleList,'Fixed',HorizontalDistance,...
      'Fixed',VerticalDistance)
```

distributes the specified components `HorizontalDistance` points horizontally and distributes them `VerticalDistance` points vertically.

`Positions = align(HandleList, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the specified objects as a vector of `Position` vectors. The position of the objects on the figure does not change.

`Positions = align(CurPositions, 'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the objects whose positions are contained in `CurPositions`, where `CurPositions` is a vector of `Position` vectors. The position of the objects on the figure does not change.

Examples

Create a UI containing three buttons, and use the `align` function to line up the buttons.

```
% Create a figure window and one button object:
f=figure;
u1 = uicontrol('Style','push', 'parent', f,'pos',...
[20 100 100 100],'string','button1');
% Create two more button objects, not aligned with
% each other or any part of the figure window:
u2 = uicontrol('Style','push', 'parent', f,'pos',...
[150 250 100 100],'string','button2');
u3 = uicontrol('Style','push', 'parent', f,'pos',...
[250 100 100 100],'string','button3');
% Align the button objects with the bottom of the first
% button object, equalizing the distance between the
% objects within the span of the extreme x-values:
align([u1 u2 u3],'distribute','bottom');
```

`uicontrol` | `uistack`

alim

Set or query axes alpha limits

Syntax

```
alpha_limits = alim
alim([amin amax])
alim_mode = alim('mode')
alim('alim_mode')
alim(axes_handle,...)
```

Description

`alpha_limits = alim` returns the alpha limits (`ALim` property) of the current axes.

`alim([amin amax])` sets the alpha limits to the specified values. `amin` is the value of the data mapped to the first alpha value in the alphamap, and `amax` is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

`alim_mode = alim('mode')` returns the alpha limits mode (`ALimMode` property) of the current axes.

`alim('alim_mode')` sets the alpha limits mode on the current axes. `alim_mode` can be

- `auto` — MATLAB automatically sets the alpha limits based on the alpha data of the objects in the axes.
- `manual` — MATLAB does not change the alpha limits.

`alim(axes_handle,...)` operates on the specified axes.

Examples

Map transparency to a surface plot of `z`-data and change the `alim` property to make all values below zero transparent:

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
% Plot the data, using the gradient of z as
% the alphamap:
surf(x,y,z+.001,'FaceAlpha','flat',...
'AlphaDataMapping','scaled',...
'AlphaData',gradient(z),...
'FaceColor','blue');
axis tight
% Adjust the alim property to see only where
% the gradient is between 0 and 0.15:
alim([0 .15])
```

all

Determine if all array elements are nonzero or `true`

Syntax

```
B = all(A)
B = all(A,dim)
```

Description

`B = all(A)` tests along the first array dimension of `A` whose size does not equal 1, and determines if the elements are all nonzero or logical `1` (`true`). In practice, `all` is a natural extension of the logical AND operator.

- If `A` is a vector, then `all(A)` returns logical `1` (`true`) if all the elements are nonzero and returns logical `0` (`false`) if one or more elements are zero.
- If `A` is a nonempty, nonvector matrix, then `all(A)` treats the columns of `A` as vectors and returns a row vector of logical `1`s and `0`s.
- If `A` is an empty 0-by-0 matrix, then `all(A)` returns logical `1` (`true`).
- If `A` is a multidimensional array, then `all(A)` acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes `1`, while the sizes of all other dimensions remain the same.

`B = all(A,dim)` tests elements along dimension `dim`. The `dim` input is a positive integer scalar.

Examples

Test Matrix Columns

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =
```

```
     0     0     3
     0     0     3
     0     0     3
```

Test each column for all nonzero elements.

```
B = all(A)

B =

     0     0     1
```

Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];
B = (A < 0.5)

B =

0   0   1   1   1   1   0
```

The output is a vector of logical values. The `all` function reduces such a vector of logical values to a single condition. In this case, `B = all(A < 0.5)` yields logical `0`.

This makes `all` particularly useful in `if` statements.

```
if all(A < 0.5)
    %do something
else
    %do something else
end
```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if all of its elements are less than 3.

```
A = rand(3,7,5) * 5;
```

```
B = all(A(:) < 3)

B =

     0
```

You can also test the array for elements that are greater than zero.

```
B = all(A(:) > 0)

B =

     1
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]

A =

     0     0     3
     0     0     3
     0     0     3
```

Test the rows of `A` for all nonzero elements by specifying `dim = 2`.

```
B = all(A,2)

B =

     0
     0
     0
```

Input Arguments

A — Input Array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

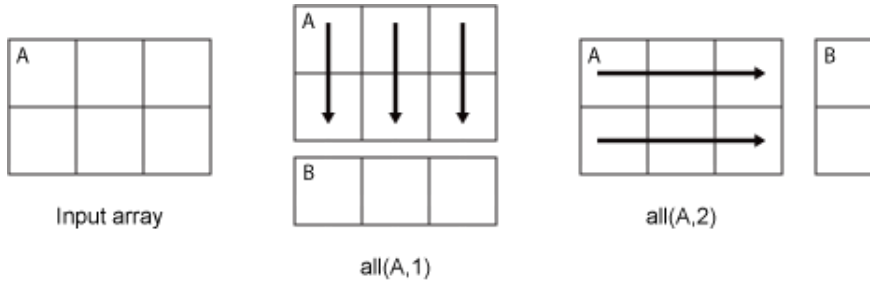
`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`:

- `all(A,1)` works on successive elements in the columns of `A` and returns a row vector of logical values.
- `all(A,2)` works on successive elements in the rows of `A` and returns a column vector of logical values.



Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`B` — Logical array

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of `A` acted on by `all` has size `1` in `B`.

Introduced before R2006a

allchild

Find all children of specified objects

Syntax

```
child_handles = allchild(handle_list)
```

Description

`child_handles = allchild(handle_list)` returns the list of all children (including ones with hidden handles) for each handle. If `handle_list` is a single element, `allchild` returns the output in a vector. If `handle_list` is a vector of handles, the output is a cell array.

Examples

Compare the results these two statements return:

```
axes
get(gca,'Children')
allchild(gca)
```

`findall` | `findobj`

Introduced before R2006a

alpha

Set transparency properties for objects in current axes

Syntax

```
alpha
alpha(object_handle,value)
alpha(face_alpha)
alpha(alpha_data)
alpha(alpha_data)
alpha(alpha_data_mapping)
```

Description

`alpha` sets one of three transparency properties, depending on what arguments you specify with the call to this function. For available arguments, see Inputs.

`alpha(object_handle,value)` sets the transparency property only on the object identified by `object_handle`.

Input Arguments

Face Alpha

`alpha(face_alpha)` sets the `FaceAlpha` property of all image, patch, and surface objects in the current axes. You can set `face_alpha` to

scalar	Set the `FaceAlpha` property to the specified value (for images, set the `AlphaData` property to the specified value).
`'flat'`	Set the `FaceAlpha` property to `flat`.
`'interp'`	Set the `FaceAlpha` property to `interp`.
`'texture'`	Set the `FaceAlpha` property to `texture`.
`'opaque'`	Set the `FaceAlpha` property to `1`.

`'clear'`	Set the `FaceAlpha` property to `0`.

See “Specifying Transparency” for more information.

AlphaData (Surface Objects)

`alpha(alpha_data)` sets the `AlphaData` property of all surface objects in the current axes. You can set `alpha_data` to

matrix the same size as `CData`	Set the `AlphaData` property to the specified values.
`'x'`	Set the `AlphaData` property to be the same as `XData`.
`'y'`	Set the `AlphaData` property to be the same as `YData`.
`'z'`	Set the `AlphaData` property to be the same as `ZData`.
`'color'`	Set the `AlphaData` property to be the same as `CData`.
`'rand'`	Set the `AlphaData` property to a matrix of random values equal in size to `CData`.

AlphaData (Image Objects)

`alpha(alpha_data)` sets the `AlphaData` property of all image objects in the current axes. You can set `alpha_data` to

matrix the same size as `CData`	Set the `AlphaData` property to the specified value.
`'x'`	Ignored.
`'y'`	Ignored.
`'z'`	Ignored.
`'color'`	Set the `AlphaData` property to be the same as `CData`.
`'rand'`	Set the `AlphaData` property to a matrix of random values equal in size to `CData`.

AlphaDataMapping

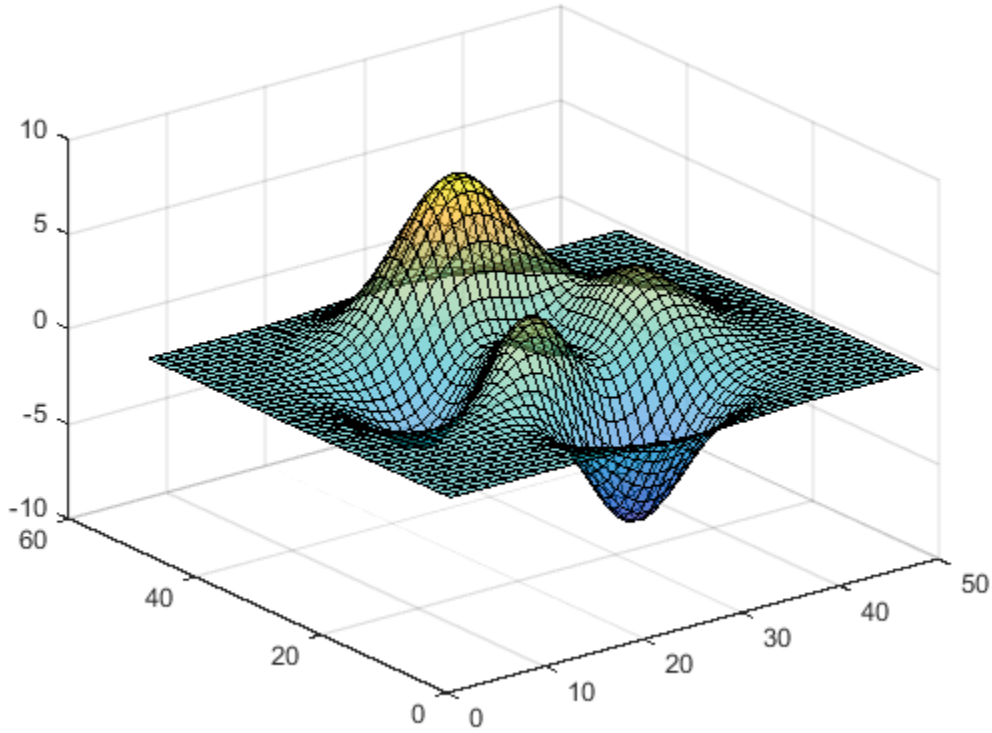
`alpha(alpha_data_mapping)` sets the `AlphaDataMapping` property of all image, patch, and surface objects in the current axes. You can set `alpha_data_mapping` to

`'scaled'`	Set the `AlphaDataMapping` property to `scaled`.
`'direct'`	Set the `AlphaDataMapping` property to `direct`.
`'none'`	Set the `AlphaDataMapping` property to `none`.

Examples

Create a surface plot and change its transparency using `alpha`:

```
surf(peaks)
alpha(0.5)
```



See Also

`alim` | `alphamap`

Introduced before R2006a

alphamap

Specify figure alphamap (transparency)

Syntax

```
alphamap(alpha_map)
alphamap('parameter')
alphamap('parameter',length)
alphamap('parameter',delta)
alphamap(figure_handle,...)
alphamap(axes_handle,...)
alpha_map = alphamap
alpha_map = alphamap(figure_handle)
alpha_map = alphamap(axes_handle)
alpha_map = alphamap('parameter')
```

Description

`alphamap(alpha_map)` sets the `AlphaMap` of the current figure to the specified `m`-by-1 array of alpha values, `alpha_map`.

`alphamap('parameter')` creates a new alphamap or modifies the current alphamap. You can specify the following parameters:

- `'default'` — Set the `AlphaMap` property to the figure's default alphamap.
- `'rampup'` — Create a linear alphamap with increasing opacity (default `length` equals the current alphamap length).
- `'rampdown'` — Create a linear alphamap with decreasing opacity (default `length` equals the current alphamap length).
- `'vup'` — Create an alphamap that is opaque in the center and becomes more transparent linearly towards the beginning and end (default `length` equals the current alphamap length).
- `'vdown'` — Create an alphamap that is transparent in the center and becomes more opaque linearly towards the beginning and end (default `length` equals the current alphamap length).

- `'increase'` — Modify the alphamap making it more opaque (default `delta` is `.1`, added to the current values).
- `'decrease'` — Modify the alphamap making it more transparent (default `delta` is `.1`, subtracted from the current values).
- `'spin'` — Rotate the current alphamap (default `delta` is 1; `delta` must be an integer).

`alphamap('parameter',length)` creates a new alphamap with the length specified by the integer `length` (used with parameters `'rampup'`, `'rampdown'`, `'vup'`, `'vdown'`).

`alphamap('parameter',delta)` modifies the existing alphamap using the value specified by the integer `delta` (used with parameters `'increase'`, `'decrease'`, `'spin'`).

`alphamap(figure_handle,...)` performs the operation on the alphamap of the figure identified by `figure_handle`.

`alphamap(axes_handle,...)` performs the operation on the alphamap of the axes identified by `axes_handle`.

`alpha_map = alphamap` returns the current alphamap.

`alpha_map = alphamap(figure_handle)` returns the current alphamap from the figure identified by `figure_handle`.

`alpha_map = alphamap(axes_handle)` returns the current alphamap from the axes identified by `axes_handle`.

`alpha_map = alphamap('parameter')` returns the alphamap modified by the `parameter`, but does not set the `AlphaMap` property.

Examples

Change Alphamap for Surface Plot

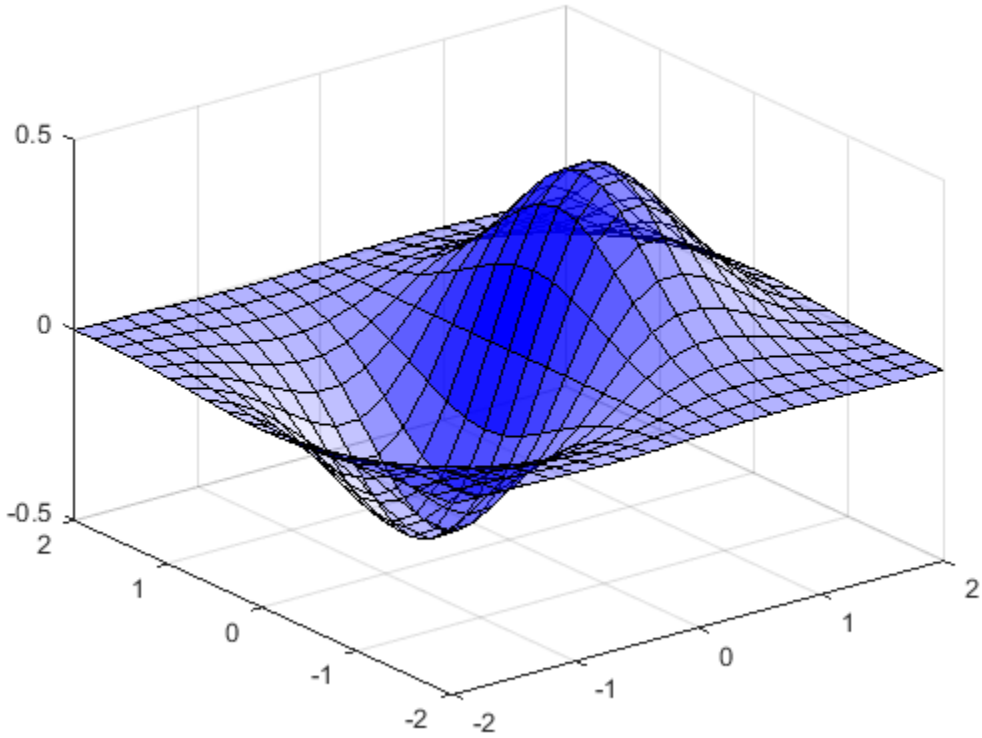
Create a surface plot and change the alphamap.

```
[x,y] = meshgrid([-2:.2:2]);
```

```
z = x.*exp(-x.^2-y.^2);
```

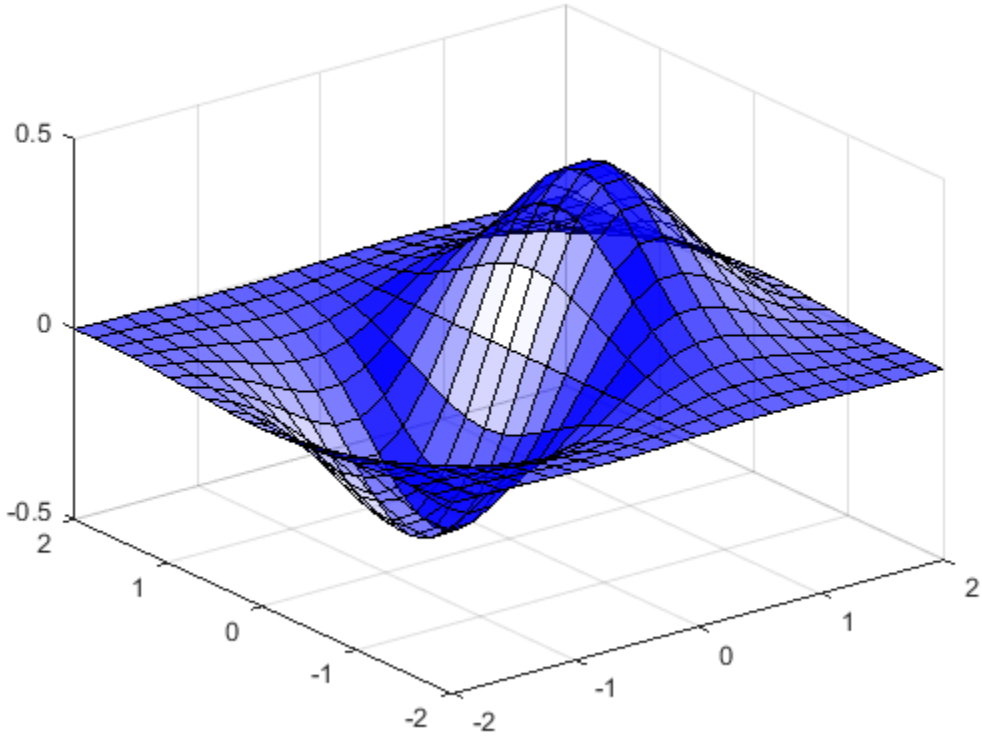
Plot the data, using the gradient of `z` as the alphamap.

```
figure
surf(x,y,z+.001,'FaceAlpha','flat',...
    'AlphaDataMapping','scaled',...
    'AlphaData',gradient(z),...
    'FaceColor','blue')
```



Change the alphamap to be opaque at the middle and transparent towards the ends.

```
alphamap('vup')
```



- “Making Objects Transparent”

See Also

`alim` | `alpha`

Introduced before R2006a

alphaShape

Polygons and polyhedra from points in 2-D and 3-D

Syntax

```
shp = alphaShape(x,y)
shp = alphaShape(x,y,z)
shp = alphaShape(P)
shp = alphaShape(___,a)
shp = alphaShape(___,Name,Value)
```

Description

`shp = alphaShape(x,y)` creates a 2-D alpha shape of the points `(x,y)` using the default alpha radius. The default alpha radius produces the tightest fitting alpha shape, which encloses all of the points.

`shp = alphaShape(x,y,z)` creates a 3-D alpha shape of the points `(x,y,z)` using the default alpha radius.

`shp = alphaShape(P)` specifies points `(x,y)` or `(x,y,z)` in the columns of matrix `P`.

`shp = alphaShape(___,a)` creates an alpha shape with alpha radius `a` using any of the arguments in the previous syntaxes.

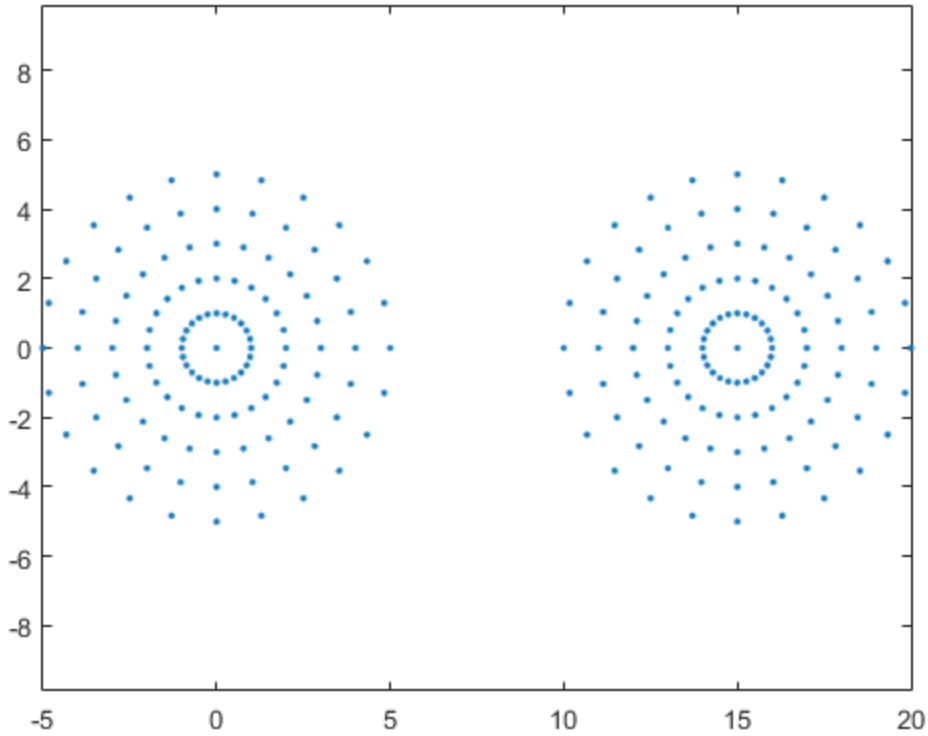
`shp = alphaShape(___,Name,Value)` uses additional options specified by one or more Name,Value pair arguments. For example, you can suppress interior holes or voids using `'HoleThreshold'`.

Examples

Alpha Shape from 2-D Point Cloud

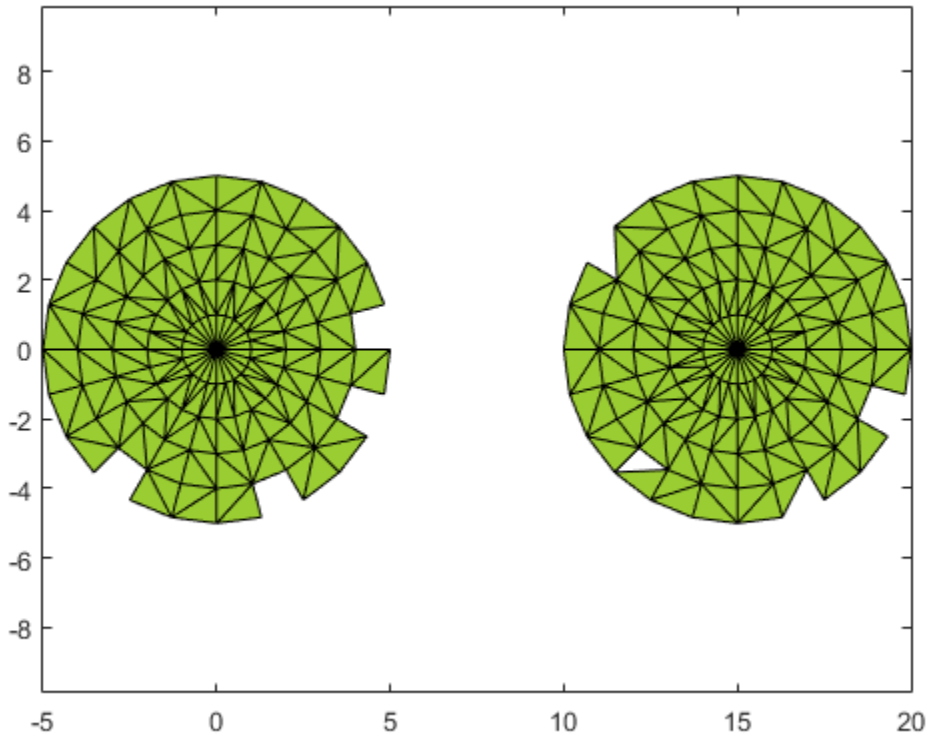
Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15];
y = [y1; y1];
plot(x,y,'.')
axis equal
```



Compute an alpha shape for the point set using the default alpha radius.

```
shp = alphaShape(x,y);
plot(shp)
```



Check the value of the default alpha radius.

```
shp.Alpha
```

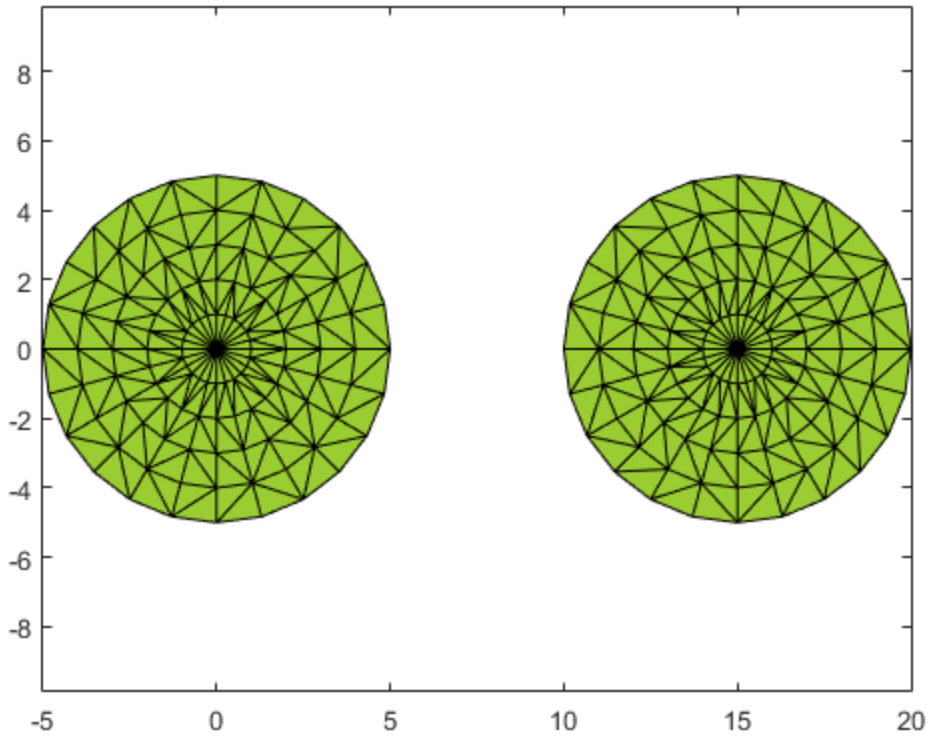
```
ans =

    0.7752
```

The default alpha radius results in an alpha shape with a jagged boundary. To better capture the boundary of the point set, try a larger alpha radius.

Compute an alpha shape using an alpha value of 2.5.

```
shp.Alpha = 2.5;
plot(shp)
```

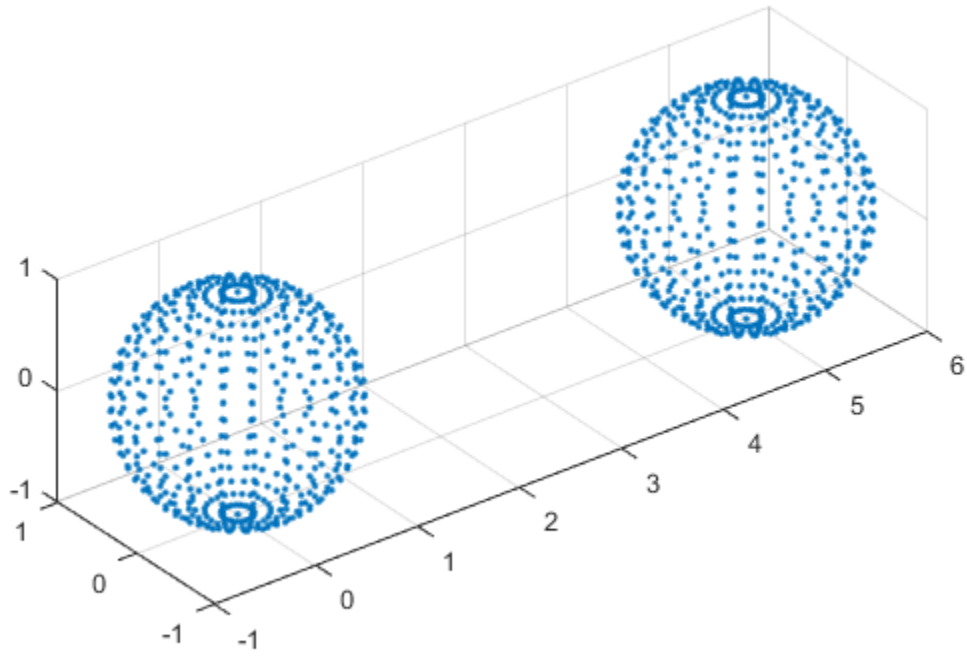


Alpha Shape from 3-D Point Cloud

Create and plot a set of 3-D points.

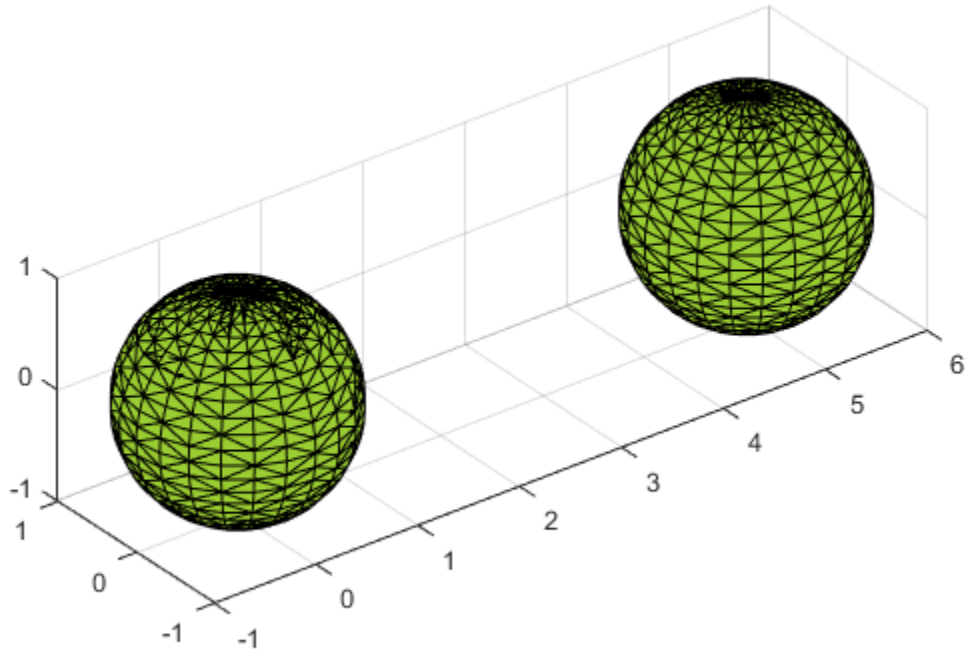
```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
```

```
P = unique(P,'rows');
plot3(P(:,1),P(:,2),P(:,3),'.')
axis equal
grid on
```



Compute a 3-D alpha shape using an alpha radius of 1.

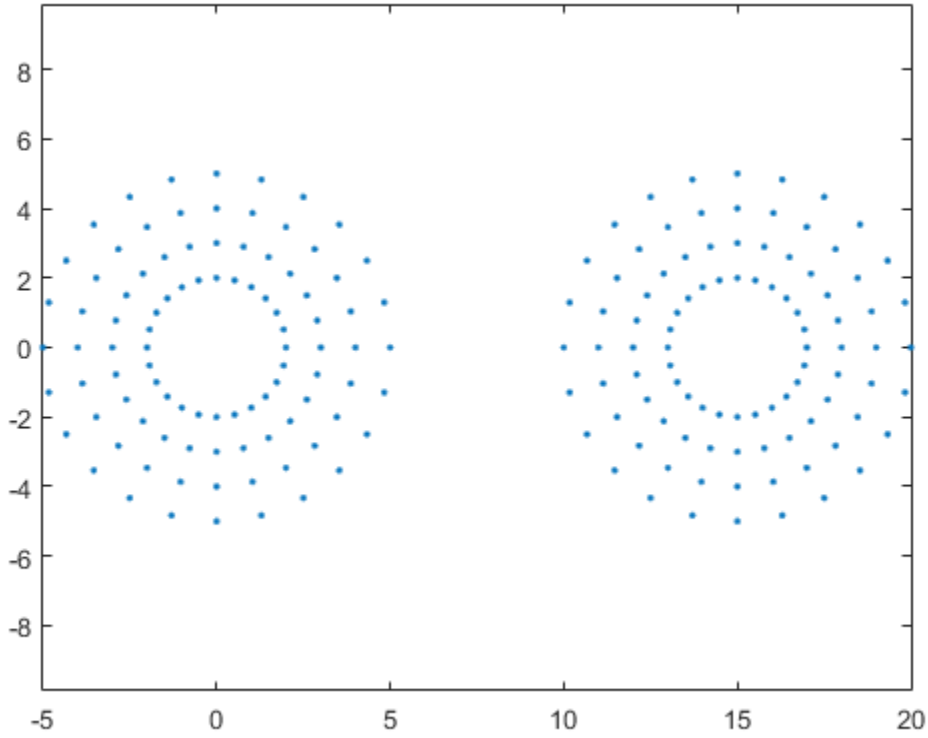
```
shp = alphaShape(P(:,1),P(:,2),P(:,3),1);
plot(shp)
axis equal
```



Fill Holes in 2-D Alpha Shape

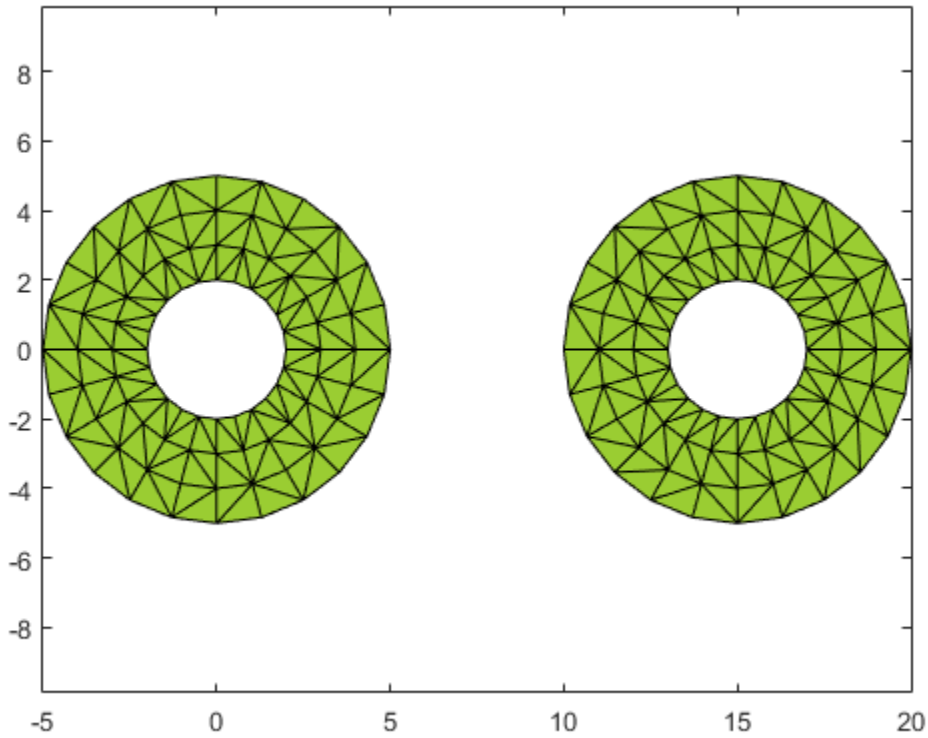
Create and plot a 2-D set of points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(2:5), numel(cos(th)*(2:5)),1);];
y1 = [reshape(sin(th)*(2:5), numel(sin(th)*(2:5)),1);];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y,'.')
axis equal
```



Compute an alpha shape for the point set using an alpha radius of 1.

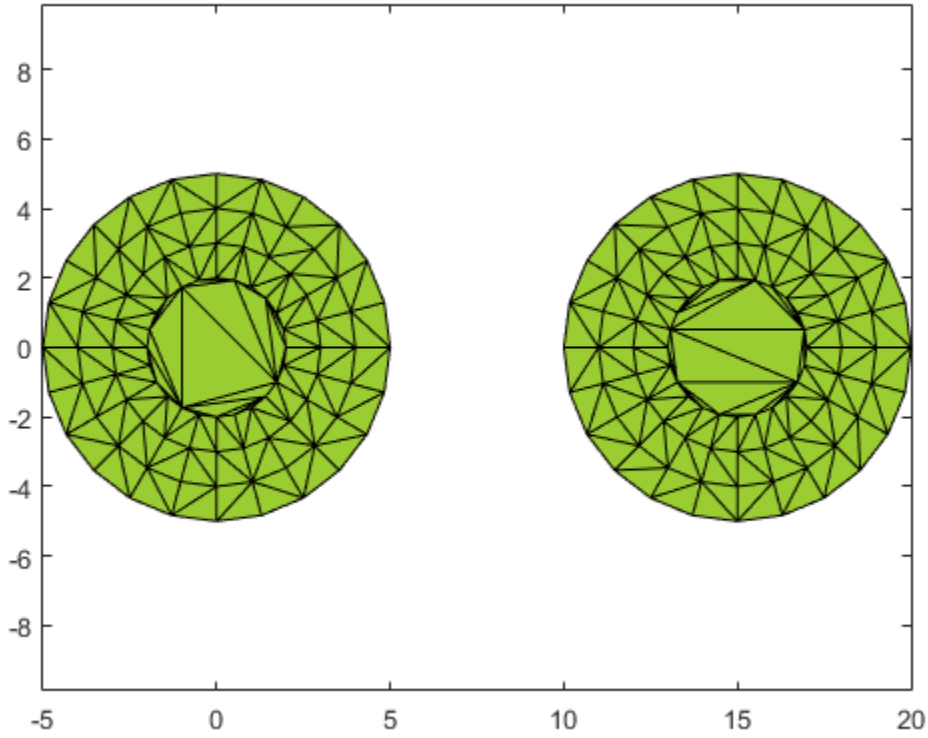
```
shp = alphaShape(x,y,1);
plot(shp)
```



An alpha radius of 1 results in an alpha shape with two regions containing holes. To suppress the small holes in the alpha shape, you can specify a `HoleThreshold` by estimating the area of the largest hole to fill. To fill all holes in the shape, you can assign an arbitrarily large value to `HoleThreshold`.

Create a new alpha shape that supresses the holes by specifying a `HoleThreshold` of 15.

```
shp = alphaShape(x,y,1,'HoleThreshold',15);
plot(shp)
```

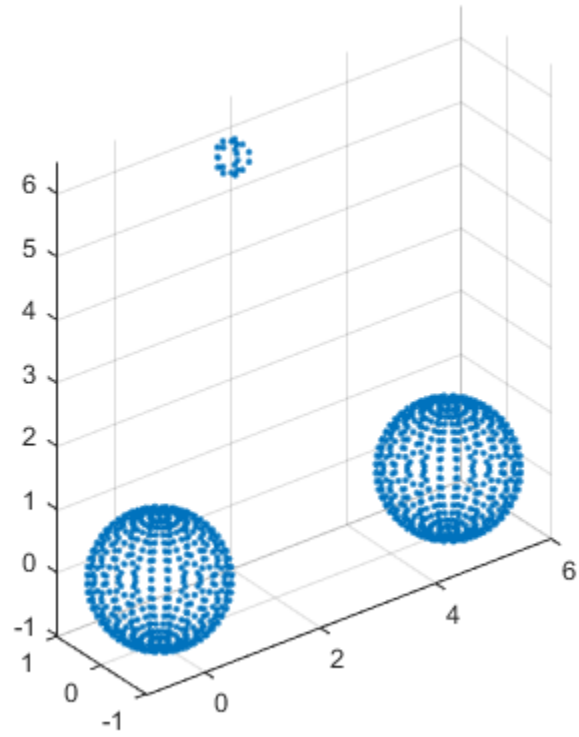


Discard Small Regions of 3-D Alpha Shape

Create and plot a set of 3-D points.

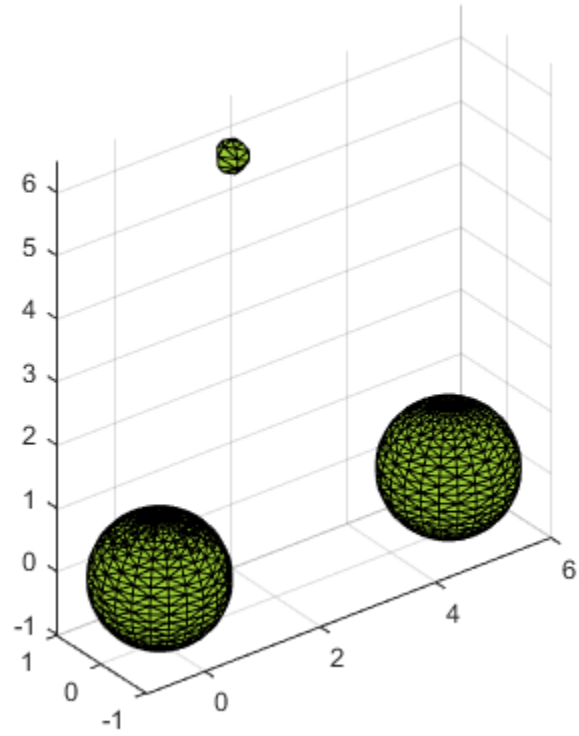
```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
[x3, y3, z3] = sphere(5);
x3 = x3(:)+5;
y3 = y3(:);
z3 = z3(:)+25;
P = [x1 y1 z1; x2 y1 z1; 0.25*x3 0.25*y3 0.25*z3];
```

```
P = unique(P,'rows');
plot3(P(:,1),P(:,2),P(:,3),'.')
axis equal
grid on
```



Compute an alpha shape for the point set using an alpha radius of 1.

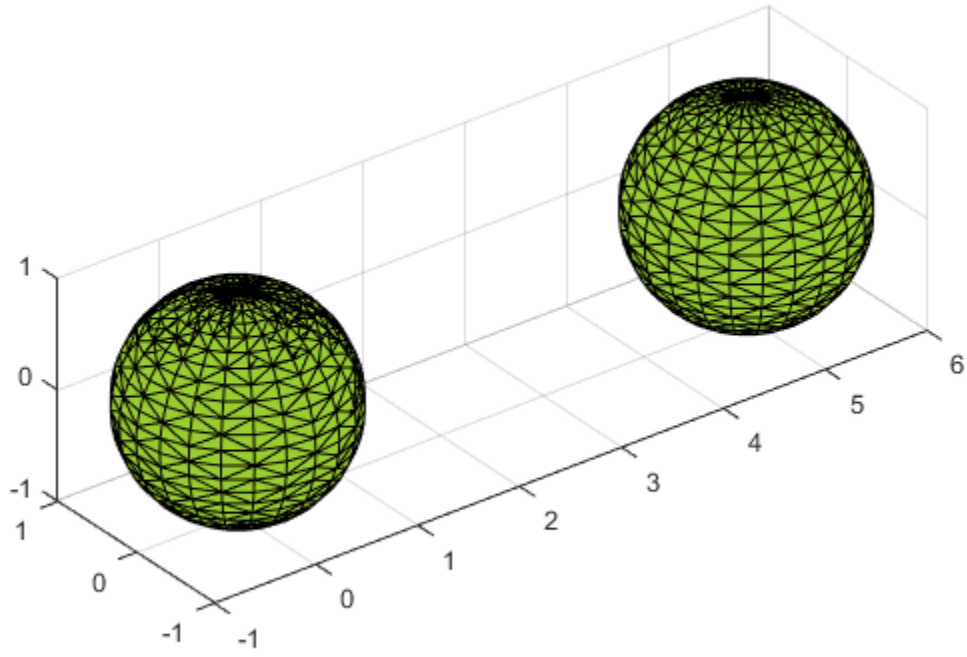
```
shp = alphaShape(P,1);
plot(shp)
axis equal
```



In this case, the alpha shape produces a small region above the two equal-sized spheres. To suppress this region, you can specify a `RegionThreshold` by estimating its volume.

Specify a `RegionThreshold` of 2. The resulting shape contains only the two larger regions.

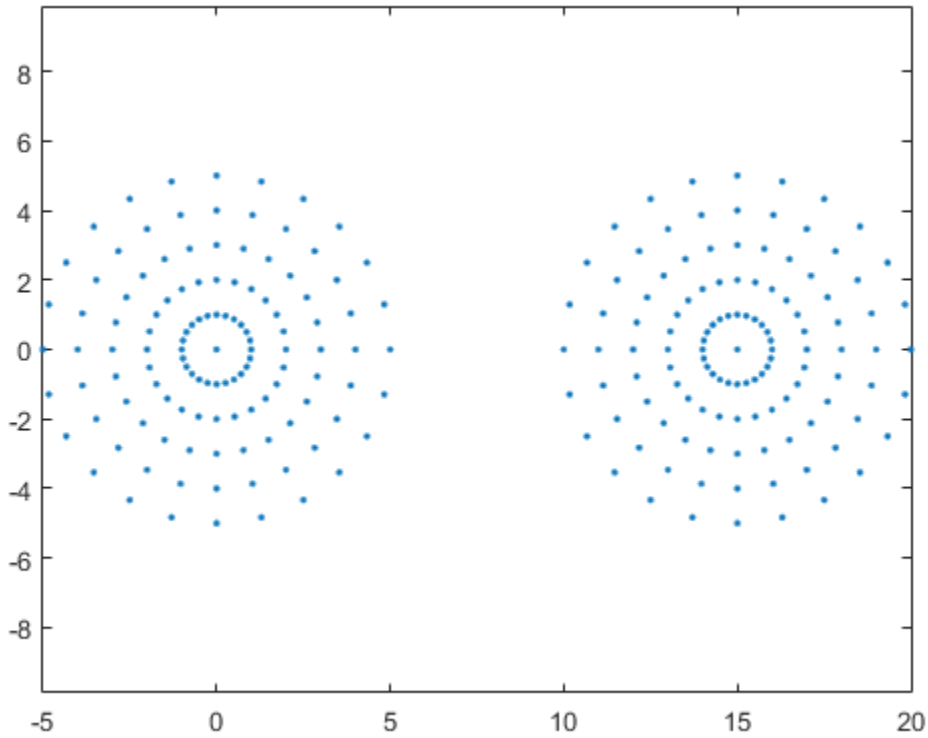
```
shp.RegionThreshold = 2;
plot(shp)
axis equal
```



Modify Points of 2-D Alpha Shape

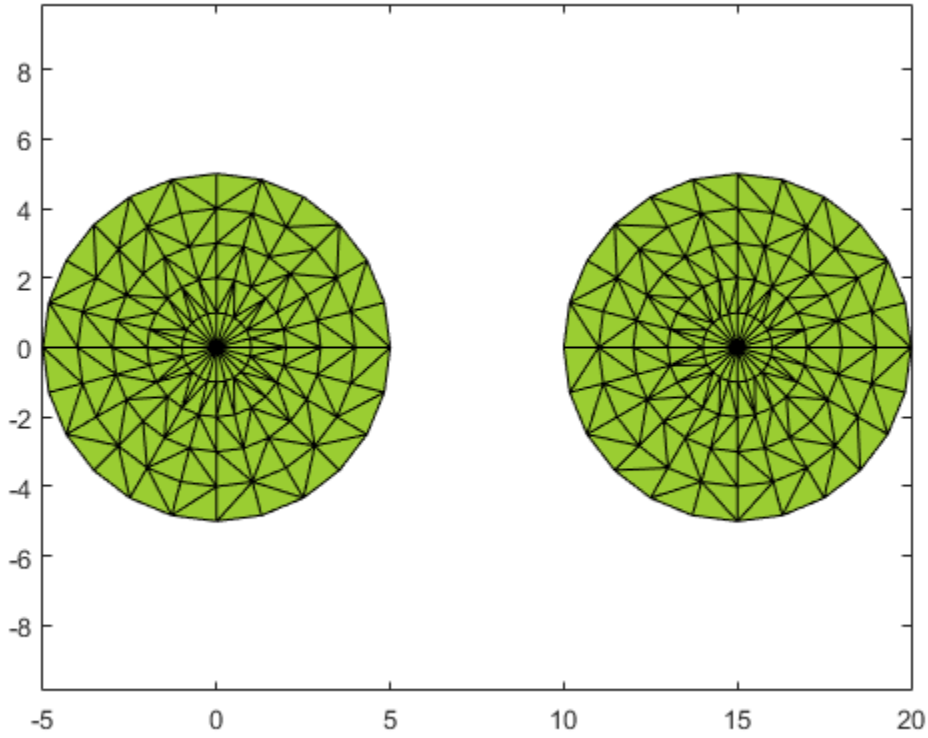
Create and plot a 2-D set of points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y,'.')
axis equal
```



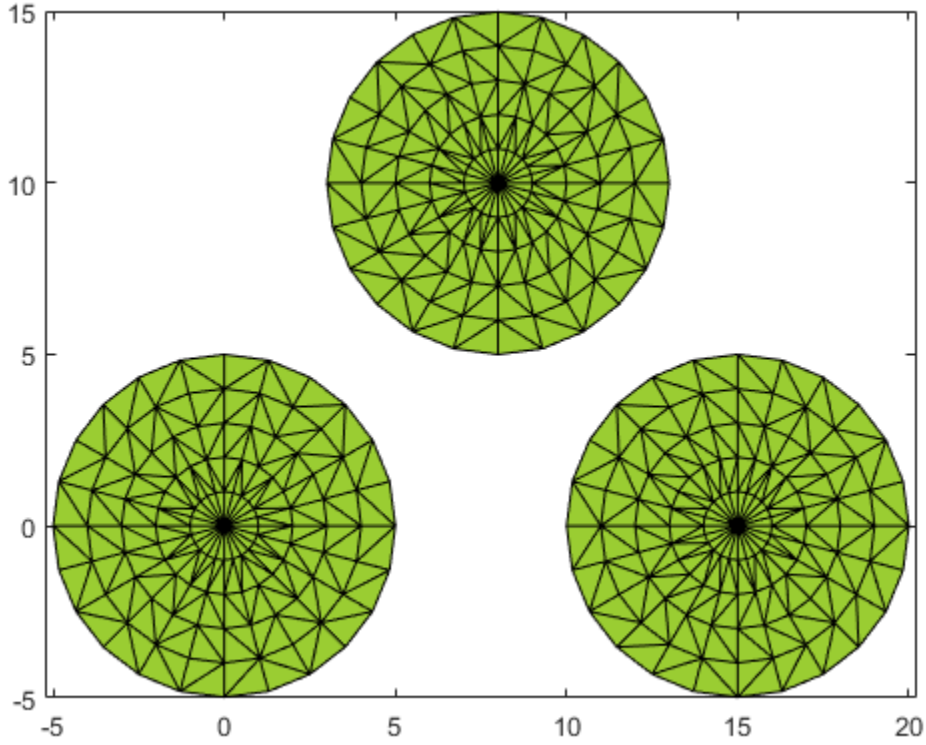
Compute an alpha shape for the point set using an alpha radius of 1. The resulting alpha shape has two regions.

```
shp = alphaShape(x,y,1);
plot(shp)
```



Now add a third region to the alpha shape by adding new points directly to the `shp.Points` matrix.

```
x3 = x1+8;
y3 = y1+10;
shp.Points(end+1,:) = [x3 y3];
plot(shp)
```



Input Arguments

x — x-coordinates of points

column vector

x-coordinates of points, specified as a column vector.

Data Types: `double`

y — y-coordinates of points

column vector

y-coordinates of points, specified as a column vector.

Data Types: `double`

z — z-coordinates of points

column vector

z-coordinates of points, specified as a column vector.

Data Types: `double`

P — Point coordinates

matrix with two columns | matrix with three columns

Point coordinates, specified as a matrix with two columns (for a 2-D alpha shape) or a matrix with three columns (for a 3-D alpha shape).

- For 2-D, the columns of `P` represent `x` and `y` coordinates, respectively.
- For 3-D, the columns of `P` represent `x`, `y`, and `z` coordinates, respectively.

Data Types: `double`

a — Alpha radius

nonnegative scalar

Alpha radius, specified as a nonnegative scalar. The default alpha radius is `a = criticalAlpha(shp,'all-points')`, which is the smallest alpha radius that produces an alpha shape that encloses all points.

Specify `a = criticalAlpha(shp,'one-region')` to use the smallest alpha radius that produces an alpha shape with only one region.

The extreme values of `a` are

- `Inf`, where `alphaShape` produces the convex hull.
- `0`, where `alphaShape` produces an empty alpha shape.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `shp = alphaShape(...,'HoleThreshold',10)`

`'HoleThreshold'` — Maximum area or volume of interior holes or voids to fill in

0 (default) | finite, nonnegative scalar

Maximum area or volume of interior holes or voids to fill in, specified as a finite, nonnegative scalar.

- For 2-D, `HoleThreshold` specifies the maximum area of interior holes to fill in.
- For 3-D, `HoleThreshold` specifies the maximum volume of interior voids to fill in. Holes extending completely through the alpha shape cannot be filled in.

When you specify both a `'HoleThreshold'` and a `'RegionThreshold'`, the application of the thresholds is order dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

`'RegionThreshold'` — Maximum area or volume of regions to suppress

0 (default) | finite, nonnegative scalar

Maximum area (2-D) or volume (3-D) of regions to suppress, specified as a finite, nonnegative scalar.

When you specify a `'HoleThreshold'` and a `'RegionThreshold'`, the application of the thresholds is order dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

Output Arguments

`shp` — 2-D or 3-D alpha shape

alphaShape object

2-D or 3-D alpha shape. For more information, see Using alphaShape Objects.

The `alphaShape` function returns regularized alpha shapes:

- In 2-D, `shp` represents a polygon. The polygon has no isolated points or edges, nor does it have dangling edges.
- In 3-D, `shp` represents a polyhedron. The polyhedron has the previously stated polygon traits, but it additionally does not have isolated faces or dangling faces.

Introduced in R2014b

alphaSpectrum

Alpha values giving distinct alpha shapes

Syntax

```
a = alphaSpectrum(shp)
```

Description

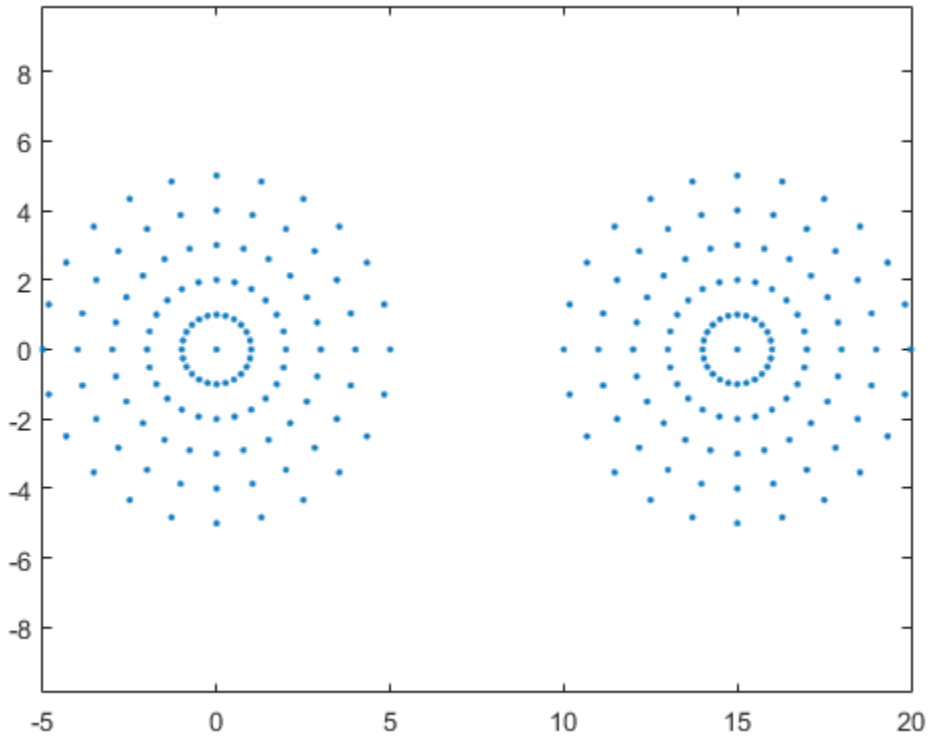
`a = alphaSpectrum(shp)` returns the values of the alpha radius that produce distinct alpha shapes. `a` is in descending sorted order. Each element in `a` represents a value of the alpha radius that results in a distinct shape. The length of `a` is equal to the number of unique shapes. Values of alpha that lie between the values in `a` do not produce unique alpha shapes.

Examples

Find Alpha Spectrum for 2-D Point Cloud

Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y,'.')
axis equal
```



Create an alpha shape for the point cloud using the default alpha radius.

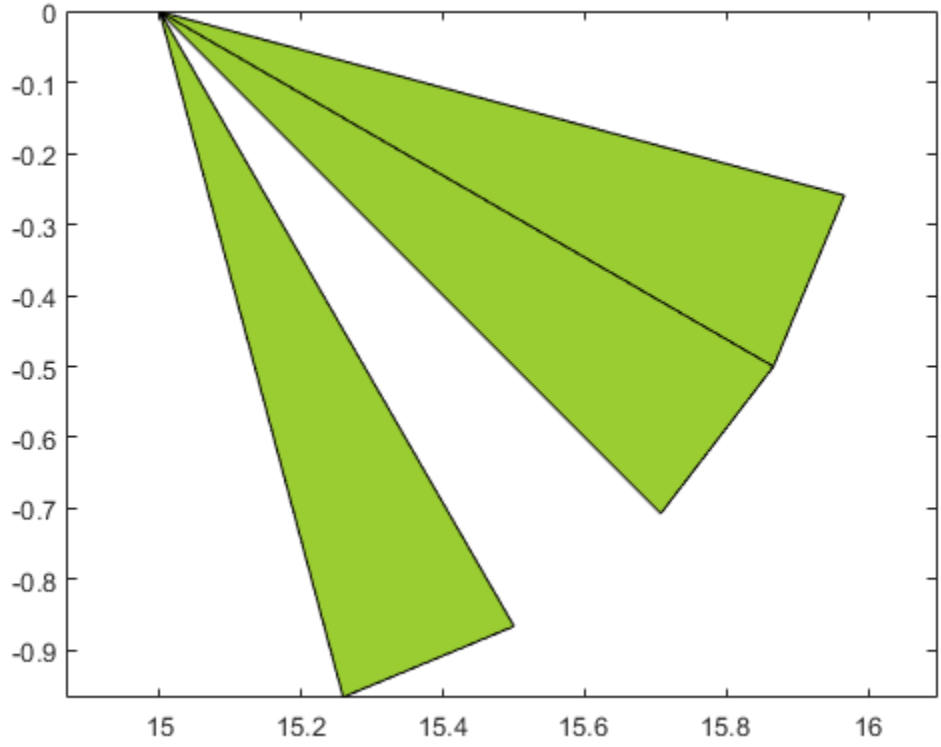
```
shp = alphaShape(x,y);
```

Find the spectrum of critical alpha values that produces unique alpha shapes for the point cloud.

```
alphaspec = alphaSpectrum(shp);
```

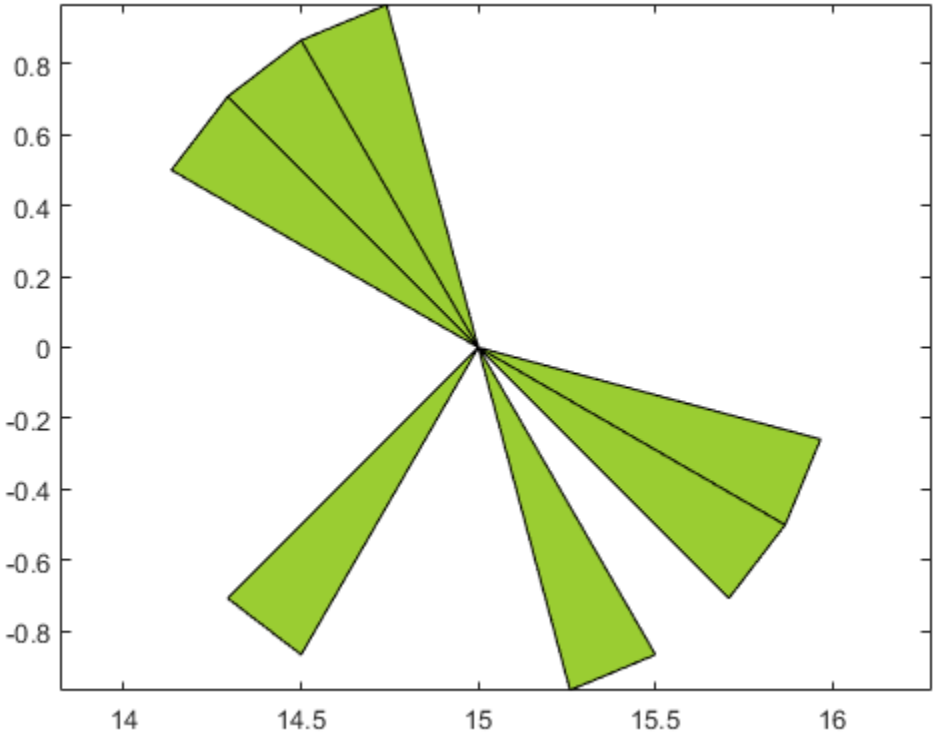
Plot the alpha shape corresonding to the smallest alpha value in the spectrum.

```
shp.Alpha = alphaspec(length(alphaspec));
plot(shp)
```



Compare this alpha shape to the one produced by the next smallest critical alpha value. The alpha shapes are unique.

```
shp.Alpha = alphaspec(length(alphaspec)-1);
plot(shp)
```



Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

Output Arguments

a — Alpha values for distinct alpha shapes

column vector

Alpha values for distinct alpha shapes, returned as a column vector in descending sorted order.

Introduced in R2014b

alphaTriangulation

Triangulation that fills alpha shape

Syntax

```
tri = alphaTriangulation(shp)
tri = alphaTriangulation(shp,RegionID)

[tri,P] = alphaTriangulation( ___ )
```

Description

`tri = alphaTriangulation(shp)` returns a triangulation that defines the domain of the alpha shape. Each row in `tri` specifies a triangle or tetrahedron defined by vertex IDs (the row numbers of the `shp.Points` matrix).

`tri = alphaTriangulation(shp,RegionID)` returns a triangulation for a region of the alpha shape. `RegionID` is the ID for the region and $1 \leq$ `RegionID` $\leq$ `numRegions(shp)`.

`[tri,P] = alphaTriangulation( ___ )` also returns a matrix of vertex coordinates, `P`, using any of the previous syntaxes.

Examples

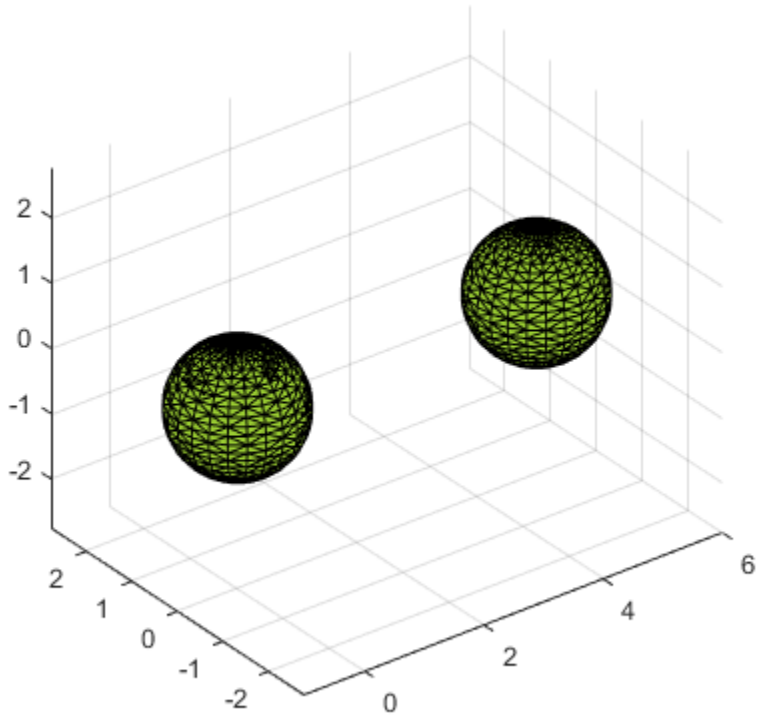
Compute Triangulation for 3-D Point Cloud

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P,'rows');
```

Create and plot an alpha shape for the point cloud using an alpha radius of 1.

```
shp = alphaShape(P,1);
plot(shp)
```



Use `alphaTriangulation` to recover the triangulation that defines the domain of the alpha shape.

```
tri = alphaTriangulation(shp);
```

Find the total number of tetrahedra that make up the alpha shape.

```
numtetrahedra = size(tri,1)
```

```
numtetrahedra =

        3729
```

Input Arguments

`shp` — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

`RegionID` — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between `1` and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

Output Arguments

`tri` — Triangulation

matrix

Triangulation, returned as a matrix. `tri` is of size `mtri`-by-`nv`, where `mtri` is the number of triangles or tetrahedra in the alpha shape and `nv` is the number of vertices. The value of `nv` is `3` for 2-D alpha shapes and `4` for 3-D alpha shapes.

`P` — Vertex coordinates

matrix

Vertex coordinates, returned as a matrix. `P` is of size `N`-by-`dim`, where `N` is the number of points in the alpha shape and `dim` is either `2` or `3` (for either a 2-D or 3-D alpha shape).

area

Area of 2-D alpha shape

Syntax

```
A = area(shp)
A = area(shp,RegionID)
```

Description

`A = area(shp)` returns the area of 2-D alpha shape `shp`.

`A = area(shp,RegionID)` returns the area of a region of the alpha shape. `RegionID` is the ID for the region and $1 \leq$ `RegionID` $\leq$ `numRegions(shp)`.

Examples

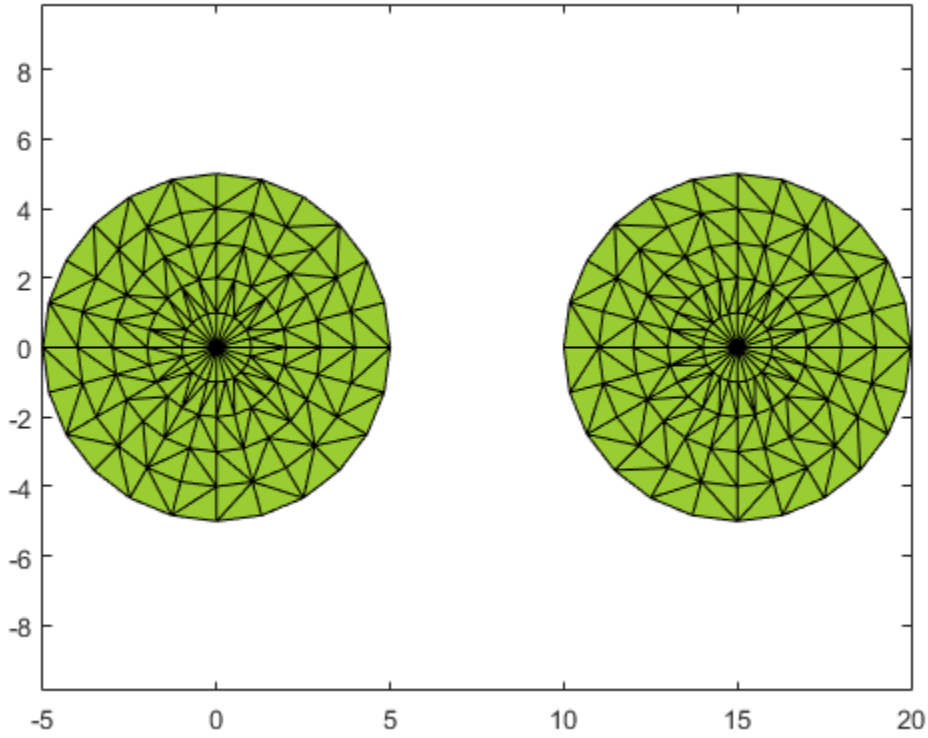
Find Area of 2-D Alpha Shape

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
```

Create and plot an alpha shape using an alpha radius of 2.5.

```
shp = alphaShape(x,y,2.5);
plot(shp)
```



Compute the area of the alpha shape.

```
totalarea = area(shp)
```

```
totalarea =

  155.2914
```

Compute the areas of each of the two regions separately.

```
regionareas = area(shp, 1:numRegions(shp))
```

```
regionareas =

   77.6457   77.6457
```

Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

RegionID — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between `1` and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

boundaryFacets

Boundary facets of alpha shape

Syntax

```
bf = boundaryFacets(shp)
bf = boundaryFacets(shp,RegionID)

[bf,P] = boundaryFacets( ___ )
```

Description

`bf = boundaryFacets(shp)` returns a matrix representing the facets that make up the boundary of the alpha shape. The facets represent edge segments in 2-D and triangles in 3-D. The vertices of the facets index into the `shp.Points` matrix.

`bf = boundaryFacets(shp,RegionID)` returns the boundary facets for a region of the alpha shape. `RegionID` is the ID for the region and $1 \le$ `RegionID` $\le$ `numRegions(shp)`.

`[bf,P] = boundaryFacets( ___ )` also returns a matrix of vertex coordinates, `P`, using any of the previous syntaxes.

Examples

Find Boundary of 3-D Alpha Shape

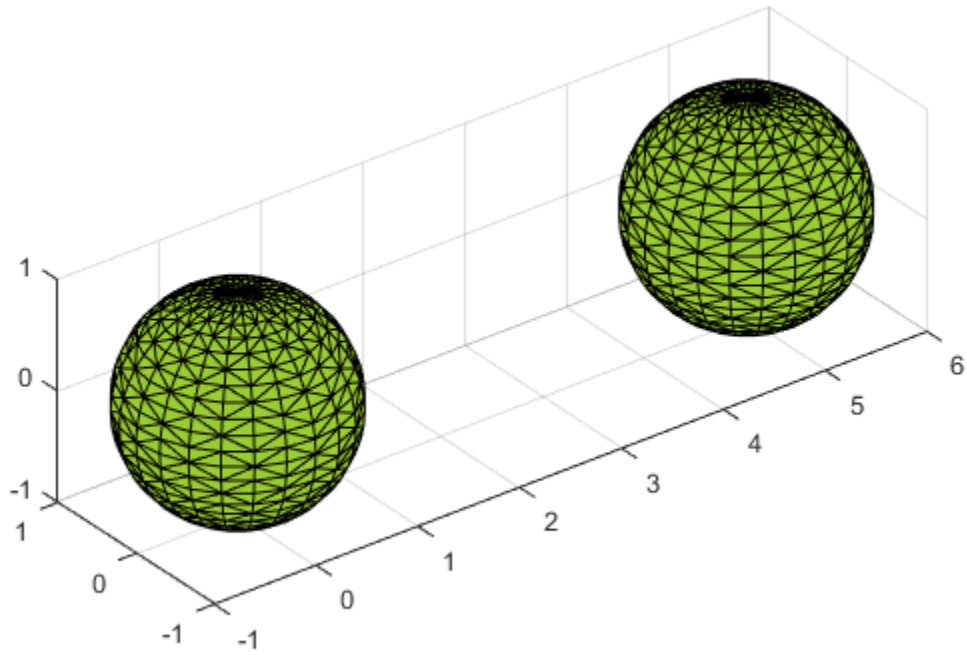
Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
```

```
P = [x1 y1 z1; x2 y1 z1];
P = unique(P,'rows');
```

Create and plot an alpha shape using an alpha radius of 1.5.

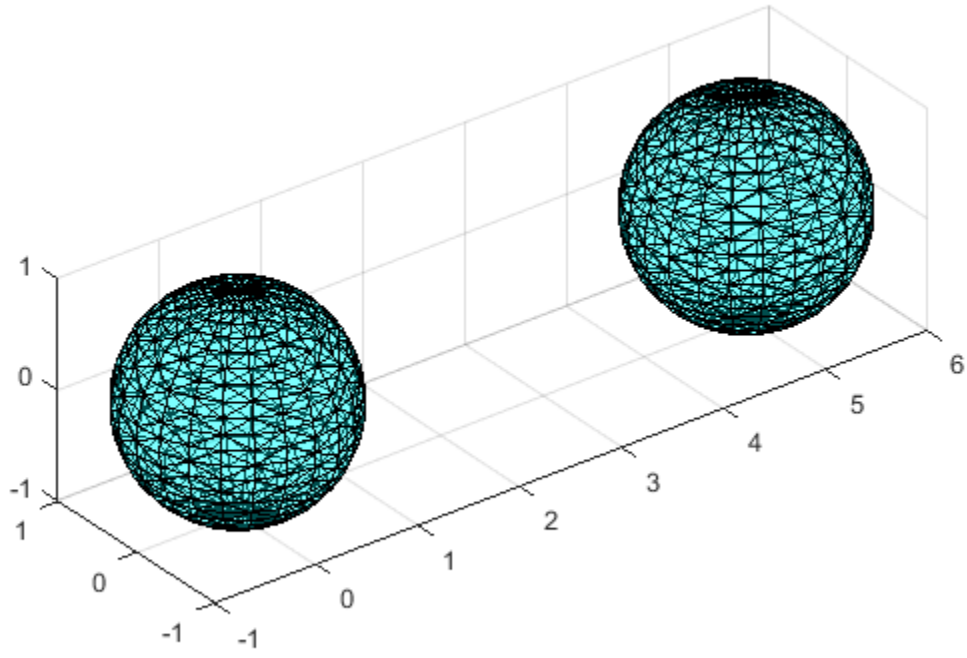
```
shp = alphaShape(P,1.5);
plot(shp)
axis equal
```



Compute and plot only the boundary of the alpha shape.

```
[tri, xyz] = boundaryFacets(shp);
trisurf(tri,xyz(:,1),xyz(:,2),xyz(:,3),...
    'FaceColor','cyan','FaceAlpha',0.3)
```

```
axis equal
```



Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

`RegionID` — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between `1` and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

Output Arguments

`bf` — Boundary facets

matrix

Boundary facets, returned as a matrix. `bf` is of size `m`-by-`n`, where `m` is the number of boundary facets and `n` is the number of vertices per facet.

`P` — Vertex coordinates

matrix

Vertex coordinates, returned as a matrix. `P` is of size `N`-by-`dim`, where `N` is the number of points on the boundary of the the alpha shape and `dim` is either `2` or `3` (for either a 2-D or 3-D alpha shape).

`alphaShape` | `plot` | `triangulation`

Introduced in R2014b

criticalAlpha

Alpha radius defining a critical transition in the shape

Syntax

```
a = criticalAlpha(shp,type)
```

Description

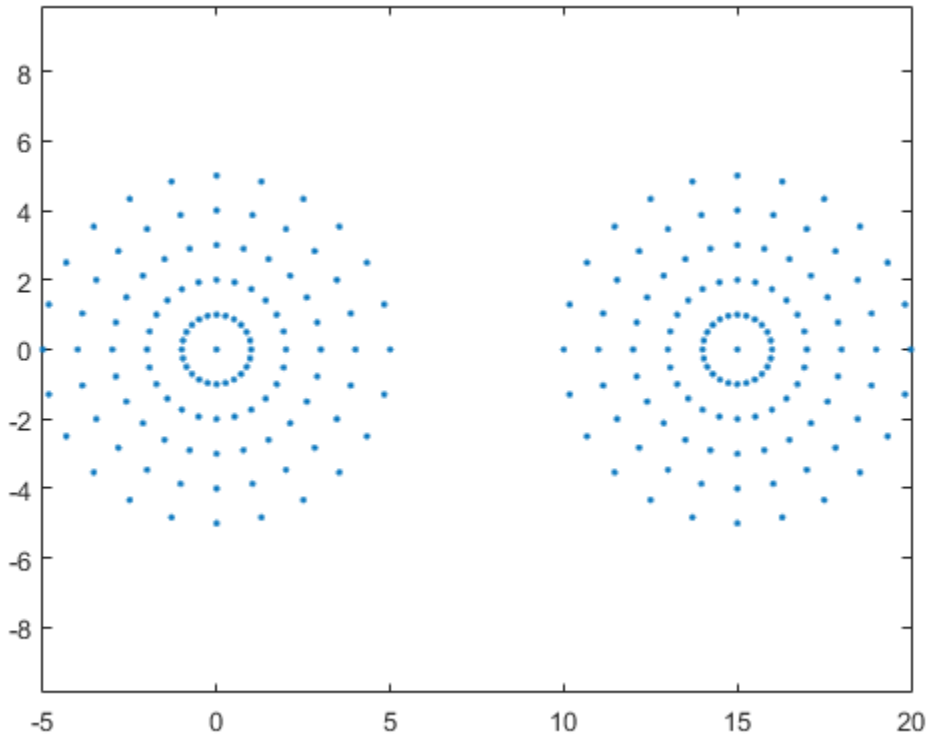
`a = criticalAlpha(shp,type)` returns the critical alpha radius that produces a notable transition in the alpha shape. Specifying `type` as `'all-points'` returns the smallest alpha radius producing an alpha shape that encloses all points. Specifying `type` as `'one-region'` returns the smallest alpha radius producing an alpha shape that encloses all points *and* has only one region.

Examples

Find Critical Alpha Values of 2-D Point Cloud

Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y,'.')
axis equal
```

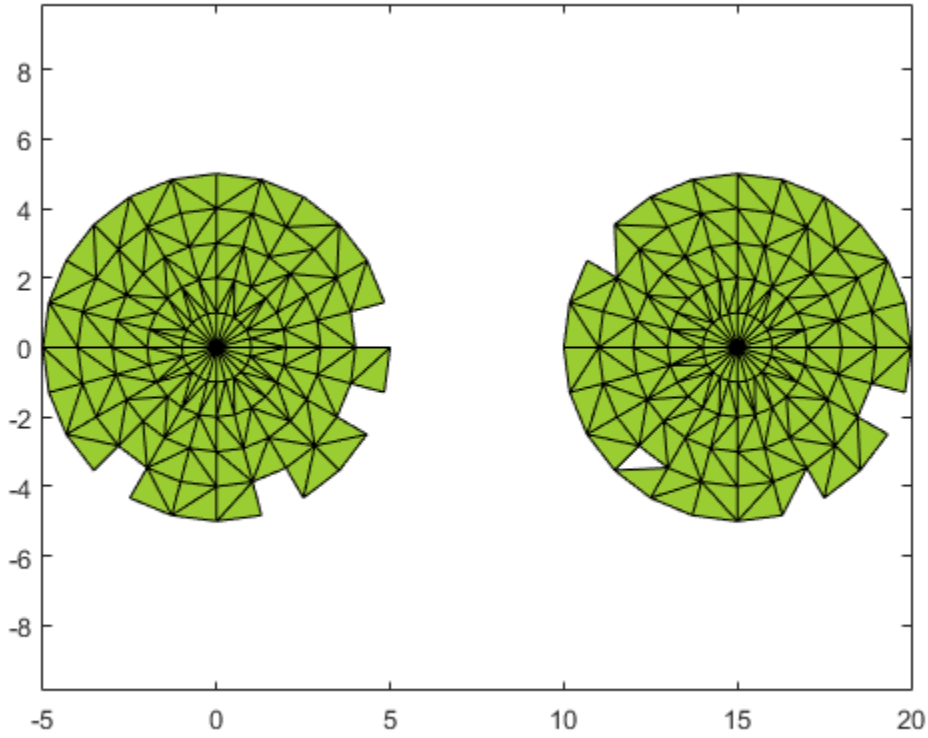


Create an alpha shape using the default alpha radius.

```
shp = alphaShape(x,y);
```

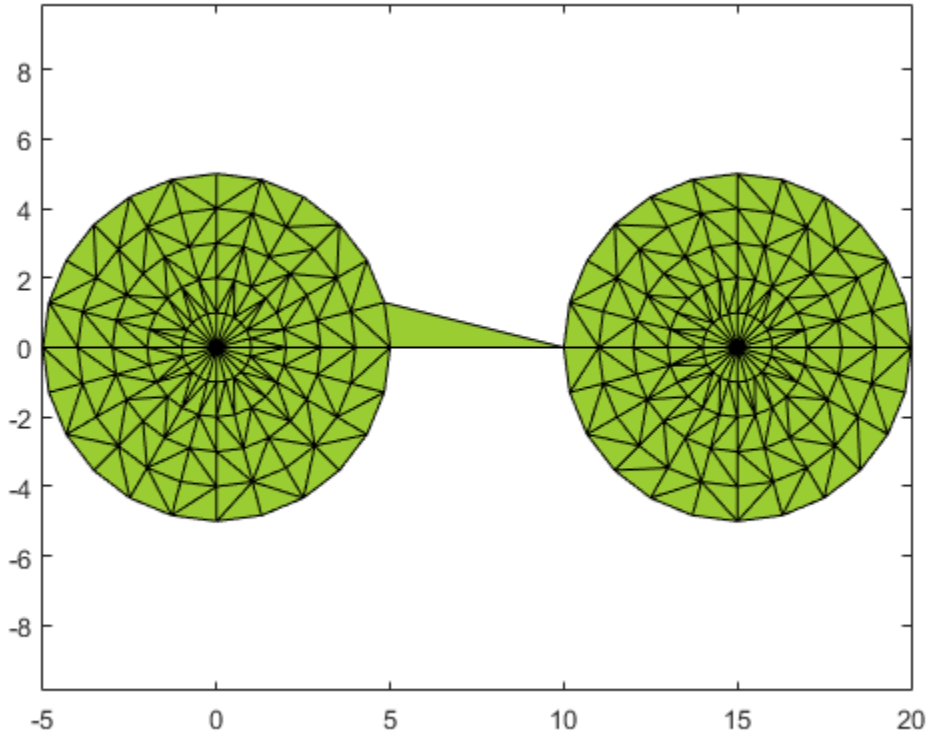
Compute the smallest alpha radius that produces an alpha shape enclosing all of the points and plot the corresponding alpha shape.

```
pc = criticalAlpha(shp,'all-points');
shp.Alpha = pc;
plot(shp)
```



Compute the smallest alpha radius that produces an alpha shape enclosing all of the points and having only one region.

```
shp = alphaShape(x,y);
pc = criticalAlpha(shp,'one-region');
shp.Alpha = pc;
plot(shp)
```



Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

`type` — Type of critical transition

`'all-points' | 'one-region'`

Type of critical transition, specified as either `'all-points'` or `'one-region'`.

- `'all-points'` corresponds to the smallest alpha radius producing an alpha shape that encloses all points.
- `'one-region'` corresponds to the smallest alpha radius producing an alpha shape that encloses all points *and* has only one region.

Data Types: `char`

Output Arguments

`a` — Critical alpha radius

scalar

Critical alpha radius, returned as a scalar. `a` is the value of the alpha radius that produces an alpha shape, which either encloses all points (if `type` is `'all-points'`), or encloses all points within a single region (if `type` is `'one-region'`).

After using `criticalAlpha` to find `a`, you can make the alpha radius of `shp` equal to `a` by typing `shp.Alpha = a`.

- Using alphaShape Objects

See Also

`alphaShape` | `alphaSpectrum`

Introduced in R2014b

inShape

Determine if point is inside alpha shape

Syntax

```
tf = inShape(shp,qx,qy)
tf = inShape(shp,qx,qy,qz)
tf = inShape(shp,QP)
tf = inShape( ___ ,RegionID)
[tf,ID] = inShape( ___ )
```

Description

`tf = inShape(shp,qx,qy)` returns logical `1` (`true`) values for the 2-D query points `(qx,qy)` that are within 2-D alpha shape `shp`. Otherwise, `inShape` returns values of logical `0` (`false`). The `qx` and `qy` arguments are numeric arrays whose corresponding elements specify the `(x,y)` query point coordinates.

`tf = inShape(shp,qx,qy,qz)` tests whether the 3-D query points `(qx,qy,qz)` are within 3-D alpha shape `shp`.

`tf = inShape(shp,QP)` specifies the 2-D or 3-D query point coordinates in a matrix with 2 or 3 columns.

`tf = inShape( ___ ,RegionID)` tests whether the query points are within a specific region of the alpha shape, using any of the previous syntaxes. `RegionID` is the ID for the region and $1 \le$ `RegionID` $\le$ `numRegions(shp)`.

`[tf,ID] = inShape( ___ )` also returns the IDs for the regions in the alpha shape that contain the query points. `ID` is `NaN` for query points that are not in the alpha shape.

Examples

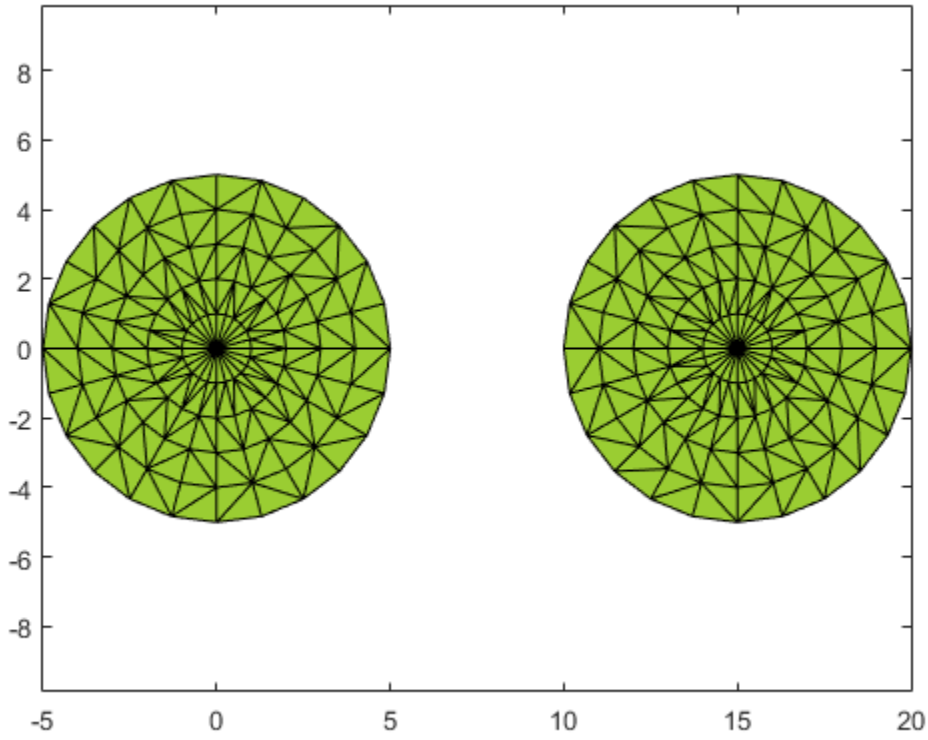
Query Points Inside and Outside of 2-D Alpha Shape

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
```

Create and plot an alpha shape using an alpha radius of 2.5.

```
shp = alphaShape(x,y,2.5);
plot(shp)
```

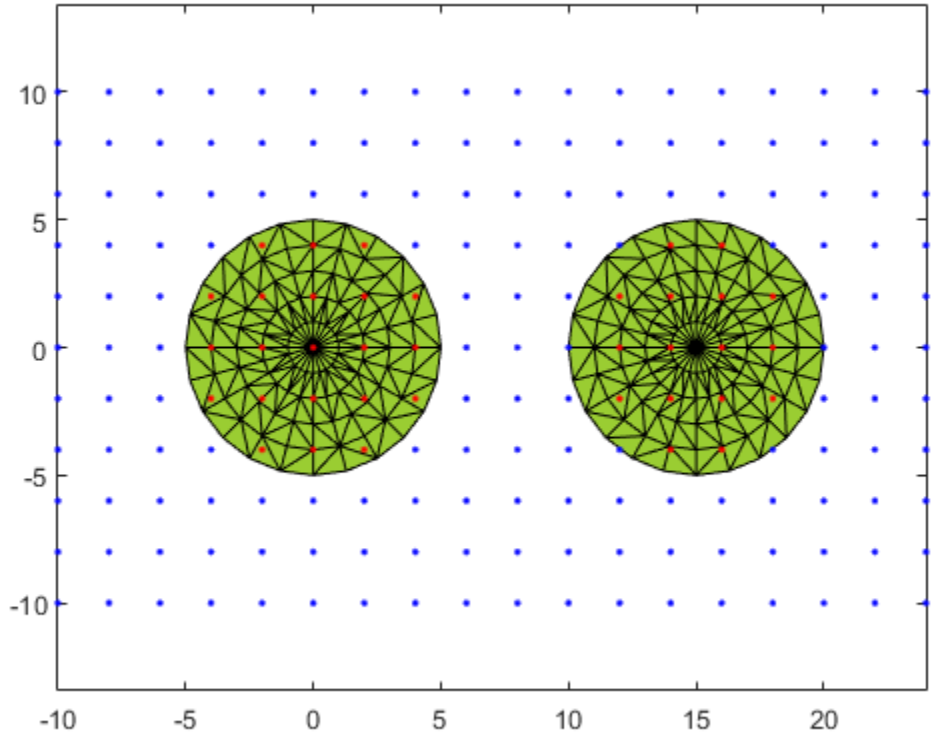


Create a Cartesian grid of query points near the alpha shape.

```
[qx, qy] = meshgrid(-10:2:25, -10:2:10);
```

Check if the query points are inside of the alpha shape, and if so, plot them red. Plot the query points that lie outside of the alpha shape in blue.

```
in = inShape(shp,qx,qy);
plot(shp)
hold on
plot(qx(in),qy(in),'r.')
plot(qx(~in),qy(~in),'b.')
```



Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

`qx` — Query point x-coordinates

numeric array

Query point x-coordinates, specified as a numeric array.

Data Types: `double`

`qy` — Query point y-coordinates

numeric array

Query point y-coordinates, specified as a numeric array.

Data Types: `double`

`qz` — Query point z-coordinates

numeric array

Query point z-coordinates, specified as a numeric array.

Data Types: `double`

`QP` — Query point coordinates

matrix with two columns | matrix with three columns

Query point coordinates, specified as a matrix with two columns (2-D) or a matrix with three columns (3-D).

- For 2-D, the columns of `QP` represent `x` and `y` coordinates, respectively.
- For 3-D, the columns of `QP` represent `x`, `y`, and `z` coordinates, respectively.

Data Types: `double`

`RegionID` — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between `1` and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

Output Arguments

`tf` — Containment status of query points

logical array

Status of the query points, returned as a logical array. The size of `tf` is equal to the size of the inputs that specify the query points (`qx`, `qy`, `qz`, or `QP`).

`inShape` returns logical `1` (`true`) values for points that are within the alpha shape or exactly on the boundary.

`ID` — IDs of the regions containing the query points

numeric array

IDs of regions containing query points, returned as a numeric array. `ID` is the same size as `tf`.

`alphaShape` | `plot`

Introduced in R2014b

nearestNeighbor

Determine nearest alpha shape boundary point

Syntax

```
I = nearestNeighbor(shp,qx,qy)
I = nearestNeighbor(shp,qx,qy,qz)
I = nearestNeighbor(shp,QP)

I = nearestNeighbor( ___ ,RegionID)

[I,D] = nearestNeighbor( ___ )
```

Description

`I = nearestNeighbor(shp,qx,qy)`, for a 2-D alpha shape `shp`, returns the indices of points on the boundary of `shp` closest to the query points. `I` is the array of nearest neighbor indices where each index corresponds to the row index in `shp.Points`. The `qx` and `qy` query coordinates must be the same size.

`I = nearestNeighbor(shp,qx,qy,qz)`, for a 3-D alpha shape, returns the indices of the boundary points of `shp` closest to `(qx,qy,qz)` and corresponds to the row indices in `shp.Points`. The `qx`, `qy`, and `qz` query coordinates must be the same size.

`I = nearestNeighbor(shp,QP)` specifies the query points as a matrix `QP`. For a 2-D alpha shape, `QP` is a matrix with two columns representing the `qx` and `qy` coordinates. For a 3-D alpha shape, `QP` has three columns representing the `qx`, `qy`, and `qz` coordinates.

`I = nearestNeighbor( ___ ,RegionID)` returns the index of the nearest point that lies on the boundary of the region specified by `RegionID`, where $1 \le$ `RegionID` $\le$ `numRegions(shp)`. You can include any of the input arguments in the previous syntaxes.

`[I,D] = nearestNeighbor( ___ )` additionally returns the Euclidean distance between the query point and its nearest neighbor. `D` has the same size as I.

Examples

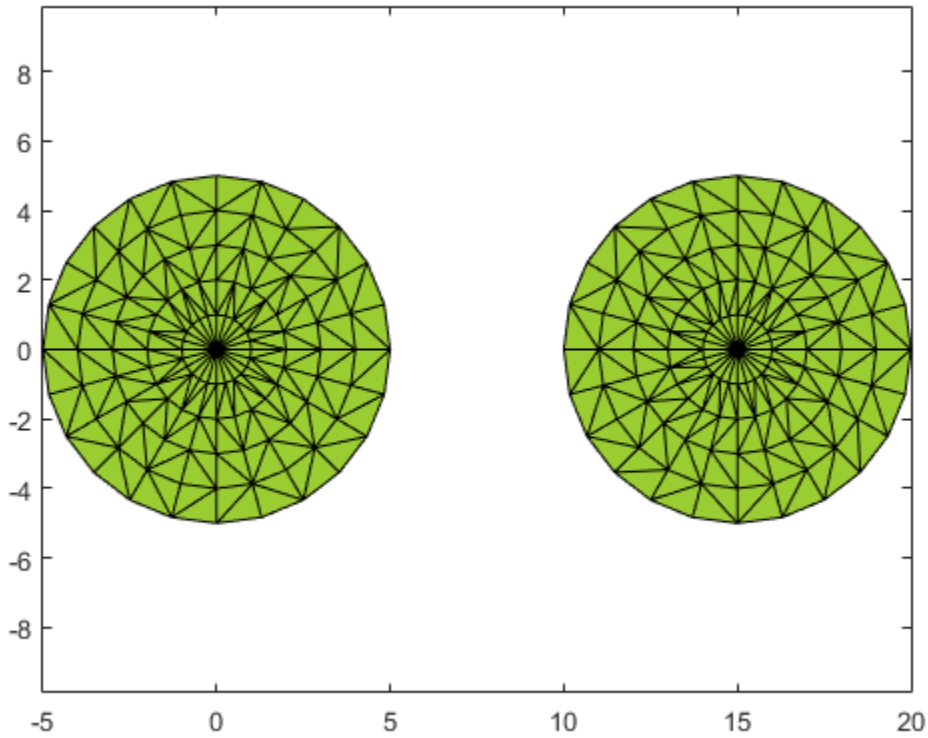
Nearest Alpha Shape Boundary Point

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15];
y = [y1; y1];
```

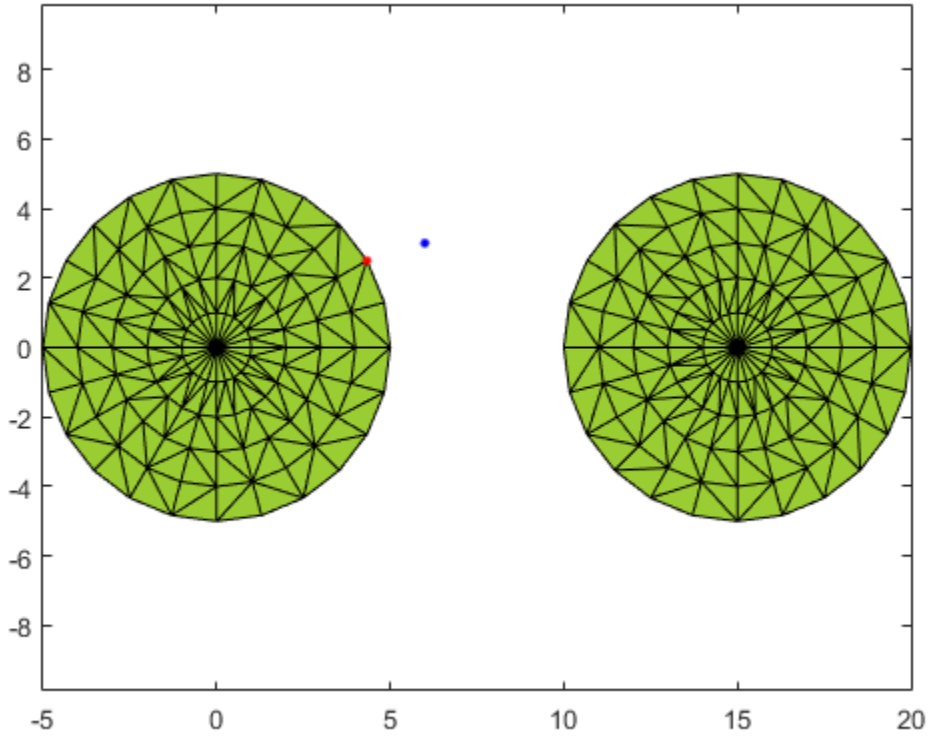
Create and plot an alpha shape with alpha radius equal to 1.

```
shp = alphaShape(x,y,1);
plot(shp)
hold on
```



Compute the nearest `shp` boundary point to the query point `QP`. Plot the query point in blue and the nearest boundary neighbor in red.

```
QP = [6 3];
plot(QP(1),QP(2),'b.','MarkerSize',10)
hold on
I = nearestNeighbor(shp, QP);
plot(shp.Points(I,1),shp.Points(I,2),'r.','MarkerSize',10)
```



Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

qx — Query point x-coordinates
numeric array

Query point x-coordinates, specified as a numeric array.

Data Types: `double`

qy — Query point y-coordinates
numeric array

Query point y-coordinates, specified as a numeric array.

Data Types: `double`

qz — Query point z-coordinates
numeric array

Query point z-coordinates, specified as a numeric array.

Data Types: `double`

QP — Query point coordinates
two-column matrix | three-column matrix

Query point coordinates, specified as a two-column matrix or a three-column matrix.

- For 2-D, the columns of `P` represent `qx` and `qy` coordinates, respectively.
- For 3-D, the columns of `P` represent `qx`, `qy`, and `qz` coordinates, respectively.

Data Types: `double`

RegionID — ID number for a region in the alpha shape
positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between `1` and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

Output Arguments

`I` — Nearest neighbor indices

integer-valued array

Nearest neighbor indices, returned as an integer-valued array. The indices correspond to the row index of `shp.Points` and indicate the points on the boundary of `shp` that are closest to the given query points.

`D` — Distance from query points to nearest neighbors

numeric array

Distance from query points to nearest neighbors, returned as a numeric array. `D` is the 2-D or 3-D Euclidean distance and is the same size as `I`.

More About

- Using alphaShape Objects

See Also

`alphaShape`

Introduced in R2015a

numRegions

Number of regions in alpha shape

Syntax

```
N = numRegions(shp)
```

Description

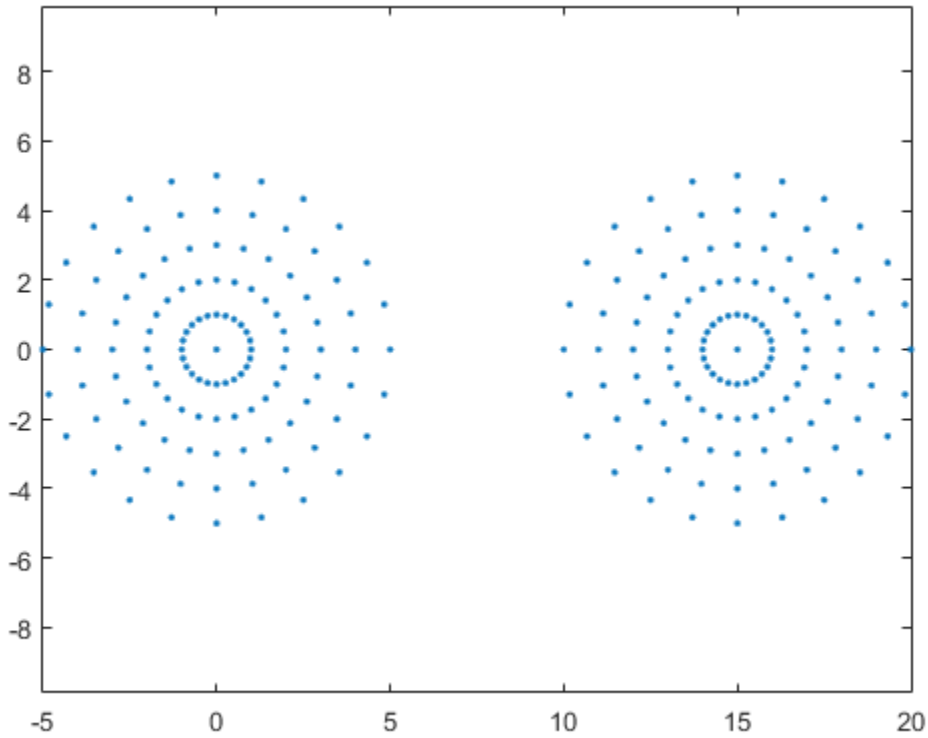
`N = numRegions(shp)` returns the number of distinct regions that make up the alpha shape. For an alpha radius of `Inf`, the alpha shape is the convex hull, and the number of regions is one. As the value of the alpha radius decreases the shape can break into separate regions, depending on the point set.

Examples

Find Number of Regions in 2-D Alpha Shape

Create and plot a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
plot(x,y,'.')
axis equal
```



Create an alpha shape using an alpha radius of 7 and query the number of distinct regions in the shape.

```
shp = alphaShape(x,y,7);
nregions = numRegions(shp)
```

```
nregions =

     1
```

Use a smaller alpha radius of 2.5 to better capture the boundary and then retrieve the new number of distinct regions.

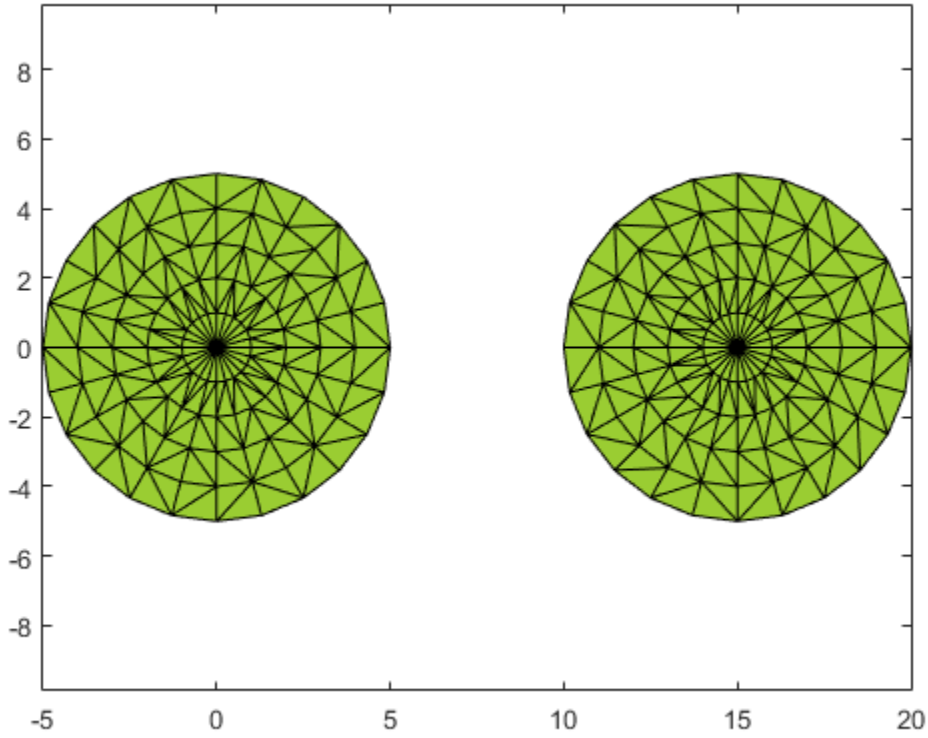
```
shp.Alpha = 2.5;
nregions = numRegions(shp)
```

```
nregions =

     2
```

Plot the alpha shape to check the boundary quality.

```
plot(shp)
```



Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

More About

- Using alphaShape Objects

See Also

`alphaShape`

Introduced in R2014b

perimeter

Perimeter of 2-D alpha shape

Syntax

```
L = perimeter(shp)
L = perimeter(shp,RegionID)
```

Description

`L = perimeter(shp)` returns the total perimeter of 2-D alpha shape `shp`, including the perimeter of any interior holes in the alpha shape.

`L = perimeter(shp,RegionID)` returns the perimeter of a region within the alpha shape. `RegionID` is the ID for the region and $1 \leq$ `RegionID` $\leq$ `numRegions(shp)`.

Examples

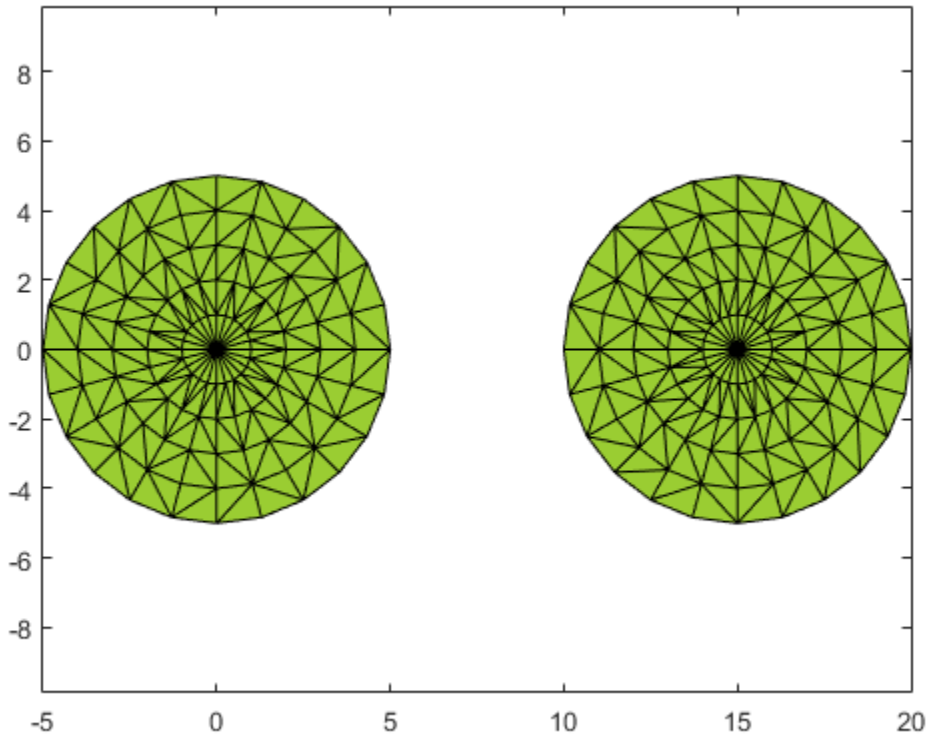
Find Perimeter of 2-D Alpha Shape

Create a set of 2-D points.

```
th = (pi/12:pi/12:2*pi)';
x1 = [reshape(cos(th)*(1:5), numel(cos(th)*(1:5)),1); 0];
y1 = [reshape(sin(th)*(1:5), numel(sin(th)*(1:5)),1); 0];
x = [x1; x1+15;];
y = [y1; y1];
```

Create and plot an alpha shape using an alpha radius of 2.5.

```
shp = alphaShape(x,y,2.5);
plot(shp)
```



Compute the perimeter of the alpha shape.

```
totalperim = perimeter(shp)
```

```
totalperim =

   62.6526
```

Compute the perimeters of each of the two regions separately.

```
regionperims = perimeter(shp, 1:numRegions(shp))
```

```
regionperims =

   31.3263   31.3263
```

Input Arguments

shp — 2-D alpha shape

`alphaShape` object

2-D alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

RegionID — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

plot

Plot alpha shape

Syntax

```
plot(shp)
plot(shp,Name,Value)
h = plot( ___ )
```

Description

`plot(shp)` plots alpha shape `shp` in a figure window.

`plot(shp,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For a complete list of allowed `Name,Value` pairs, see Patch Properties.

`h = plot( ___ )` returns a handle to a `Patch` object using any of the previous syntaxes.

Examples

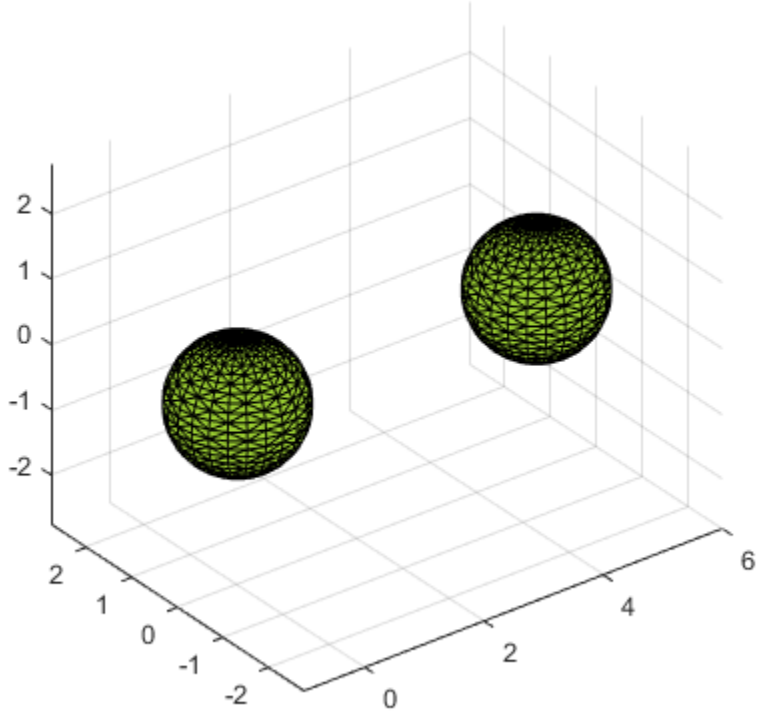
Plot 3-D Alpha Shape and Modify Patch Properties

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P,'rows');
```

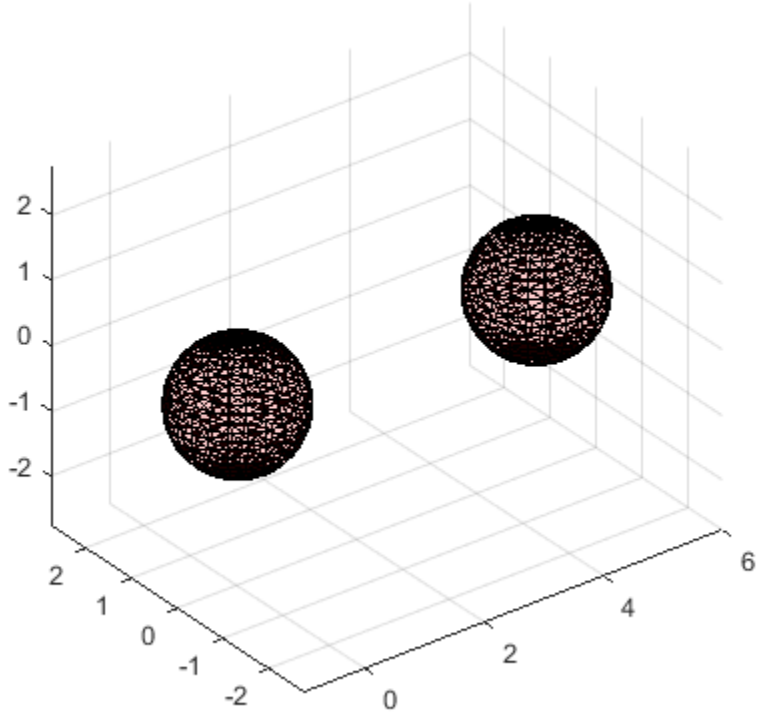
Create and plot an alpha shape using an alpha radius of 1.5.

```
shp = alphaShape(P,1.5);
plot(shp)
```



Plot the alpha shape with a specified color and transparency factor.

```
plot(shp,'FaceColor','red','FaceAlpha',0.1)
```



Input Arguments

shp — Alpha shape

`alphaShape` object

Alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`.

Example: `shp = alphaShape(x,y)` creates a 2-D `alphaShape` object from the `(x,y)` point coordinates.

Output Arguments

h — Handle to `Patch` object

handle

Handle to `Patch` object, returned as a handle. For more information, see "Introduction to Patch Objects".

surfaceArea

Surface area of 3-D alpha shape

Syntax

```
A = surfaceArea(shp)
A = surfaceArea(shp,RegionID)
```

Description

`A = surfaceArea(shp)` returns the total surface area of 3-D alpha shape `shp`, including the surface area of any interior voids in the alpha shape.

`A = surfaceArea(shp,RegionID)` returns the surface area of a region of the alpha shape. `RegionID` is the ID for the region and $1 \leq$ `RegionID` $\leq$ `numRegions(shp)`.

Examples

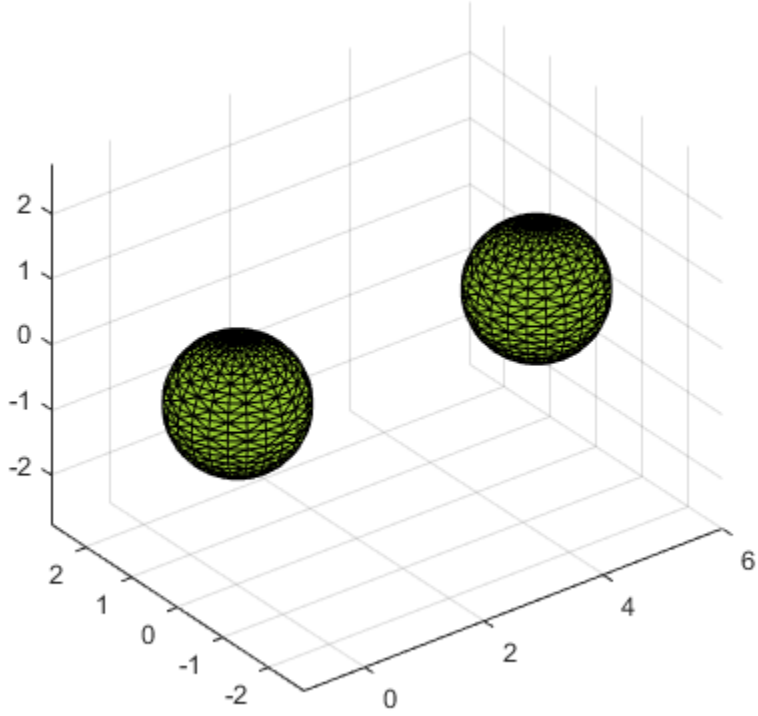
Find Surface Area of 3-D Alpha Shape

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P,'rows');
```

Create and plot an alpha shape using an alpha radius of 1.5.

```
shp = alphaShape(P,1.5);
plot(shp)
```



Compute the surface area of the alpha shape.

```
totalsurfarea = surfaceArea(shp)
```

```
totalsurfarea =

   24.9361
```

Compute the surface area of each region separately.

```
regionsurfareas = surfaceArea(shp, 1:numRegions(shp))
```

```
regionsurfareas =

   12.4680   12.4680
```

Input Arguments

shp — 3-D alpha shape

`alphaShape` object

3-D alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`

Example: `shp = alphaShape(x,y,z)` creates a 3-D `alphaShape` object from the `(x,y,z)` point coordinates.

RegionID — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

`alphaShape` | `area` | `volume`

Introduced in R2014b

volume

Volume of 3-D alpha shape

Syntax

```
V = volume(shp)
V = volume(shp,RegionID)
```

Description

`V = volume(shp)` returns the volume of 3-D alpha shape `shp`.

`V = volume(shp,RegionID)` returns the volume of a region of the alpha shape. `RegionID` is the ID for the region and $1 \le$ `RegionID` $\le$ `numRegions(shp)`.

Examples

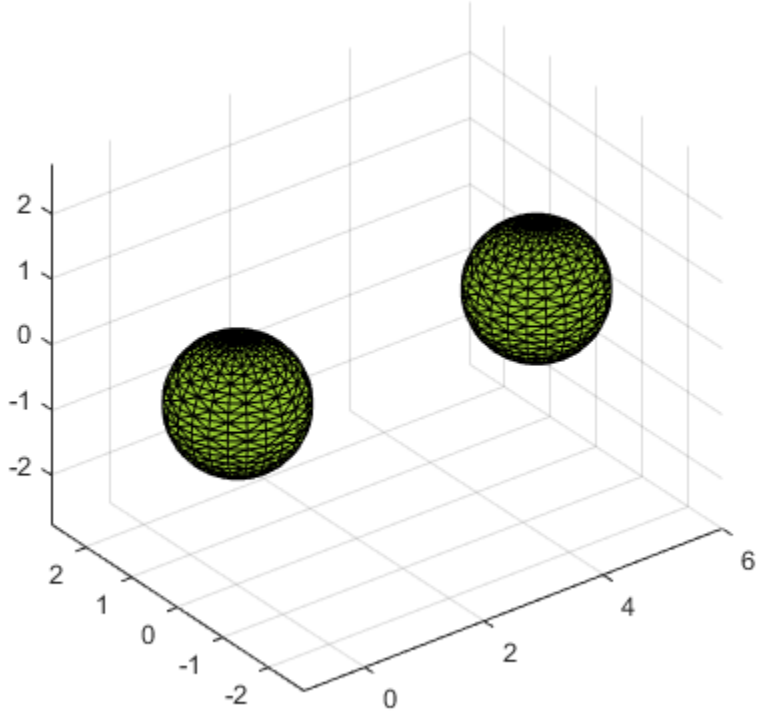
Find Volume of 3-D Alpha Shape

Create a set of 3-D points.

```
[x1, y1, z1] = sphere(24);
x1 = x1(:);
y1 = y1(:);
z1 = z1(:);
x2 = x1+5;
P = [x1 y1 z1; x2 y1 z1];
P = unique(P,'rows');
```

Create and plot an alpha shape using an alpha radius of 1.5.

```
shp = alphaShape(P,1.5);
plot(shp)
```



Compute the volume of the alpha shape.

```
totalvol = volume(shp)
```

```
totalvol =

    8.2468
```

Compute the volumes of each of the two regions separately.

```
regionvols = volume(shp, 1:numRegions(shp))
```

```
regionvols =

    4.1234    4.1234
```

Input Arguments

shp — 3-D alpha shape

`alphaShape` object

3-D alpha shape, specified as an `alphaShape` object. For more information, see `alphaShape`

Example: `shp = alphaShape(x,y,z)` creates a 3-D `alphaShape` object from the `(x,y,z)` point coordinates.

RegionID — ID number for a region in the alpha shape

positive integer scalar

ID number for region in alpha shape, specified as a positive integer scalar between 1 and `numRegions(shp)`.

An alpha shape can contain several smaller regions, depending on the point set and parameters. Each of these smaller regions is assigned a unique `RegionID`, which numbers the regions from the largest area or volume to the smallest. For example, consider a 3-D alpha shape with two regions. The region with the largest volume has a `RegionID` of 1, and the smaller region has a `RegionID` of 2.

Example: `shp.RegionThreshold = area(shp,numRegions(shp)-2);` suppresses the two smallest regions in 2-D alpha shape `shp`.

Data Types: `double`

amd

Approximate minimum degree permutation

Syntax

```
P = amd(A)
P = amd(A,opts)
```

Description

`P = amd(A)` returns the approximate minimum degree permutation vector for the sparse matrix `C = A + A'`. The Cholesky factorization of `C(P,P)` or `A(P,P)` tends to be sparser than that of `C` or `A`. The `amd` function tends to be faster than `symamd`, and also tends to return better orderings than `symamd`. Matrix `A` must be square. If `A` is a full matrix, then `amd(A)` is equivalent to `amd(sparse(A))`.

`P = amd(A,opts)` allows additional options for the reordering. The `opts` input is a structure with the two fields shown below. You only need to set the fields of interest:

- **dense** — A nonnegative scalar value that indicates what is considered to be dense. If A is n-by-n, then rows and columns with more than `max(16,(dense*sqrt(n)))` entries in `A + A'` are considered to be "dense" and are ignored during the ordering. MATLAB software places these rows and columns last in the output permutation. The default value for this field is 10.0 if this option is not present.
- **aggressive** — A scalar value controlling aggressive absorption. If this field is set to a nonzero value, then aggressive absorption is performed. This is the default if this option is not present.

MATLAB software performs an assembly tree post-ordering, which is typically the same as an elimination tree post-ordering. It is not always identical because of the approximate degree update used, and because “dense” rows and columns do not take part in the post-order. It well-suited for a subsequent `chol` operation, however, If you require a precise elimination tree post-ordering, you can use the following code:

```
P = amd(S);
C = spones(S)+spones(S');
[ignore, Q] = etree(C(P,P));
```

```
P = P(Q);
```

If `S` is already symmetric, omit the second line, `C = spones(S)+spones(S')`.

Examples

This example constructs a sparse matrix and computes a two Cholesky factors: one of the original matrix and one of the original matrix preordered by `amd`. Note how much sparser the Cholesky factor of the preordered matrix is compared to the factor of the matrix in its natural ordering:

```
A = gallery('wathen',50,50);
p = amd(A);
L = chol(A,'lower');
Lp = chol(A(p,p),'lower');

figure;
subplot(2,2,1);    spy(A);
title('Sparsity structure of A');

subplot(2,2,2); spy(A(p,p));
title('Sparsity structure of AMD ordered A');

subplot(2,2,3); spy(L);
title('Sparsity structure of Cholesky factor of A');

subplot(2,2,4); spy(Lp);
title('Sparsity structure of Cholesky factor of AMD ordered A');

set(gcf,'Position',[100 100 800 700]);
```

`colamd` | `colperm` | `symamd` | `symrcm`

ancestor

Ancestor of graphics object

Syntax

```
p = ancestor(h,type)
p = ancestor(h,type,'toplevel')
```

Description

`p = ancestor(h,type)` returns the handle of the closest ancestor of `h`, if the ancestor is one of the types of graphics objects specified by `type`. `type` can be:

- a string that is the name of a single type of object. For example, `'figure'`
- a cell array containing the names of multiple objects. For example, `{'hgtransform','hggroup','axes'}`

If MATLAB cannot find an ancestor of `h` that is one of the specified types, then `ancestor` returns `p` as empty. When `ancestor` searches the hierarchy, it includes the object itself in the search. Therefore, if the object with handle `h` is of one of the types listed in `type`, `ancestor` will return object `h`.

`ancestor` returns `p` as empty but does not issue an error if `h` is not the handle of a Handle Graphics object.

`p = ancestor(h,type,'toplevel')` returns the highest-level ancestor of `h`, if this type appears in the `type` argument.

Examples

Find the ancestors of a line object:

```
% Create some line objects and parent them
% to an hggroup object.
hgg = hggroup;
hgl = line(randn(5),randn(5),'Parent',hgg);
```

```
% Now get the ancestor of the lines:
p = ancestor(hgg,{'figure','axes','hggroup'});
get(p,'Type')
% Now get the top-level ancestor:
ptop=ancestor(hgg,{'figure','axes','hggroup'},'toplevel');
get(ptop,'type')
```

`findobj`

Introduced before R2006a

and, &

Find logical AND

Syntax

```
A & B & ...
and(A, B)
```

Description

`A & B & ...` performs a logical AND of all input arrays `A`, `B`, etc., and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if all input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input `A` is a 3-by-5 matrix and input `B` is the number 1, then `B` is treated as if it were a 3-by-5 matrix of ones.

`and(A, B)` is called for the syntax `A & B` when either `A` or `B` is an object.

Note The symbols & and && perform different operations in the MATLAB software. The element-wise AND operator described here is &. The short-circuit AND operator is &&.

Examples

If matrix `A` is

```
    0.4235    0.5798         0    0.7942         0
    0.5155         0    0.7833    0.0592    0.8744
```

```
    0.3340         0         0         0    0.0150
    0.4329    0.6405    0.6808    0.0503         0
```

and matrix B is

```
     0     1     0     1     0
     1     1     1     0     1
     0     1     1     1     0
     0     1     0     0     1
```

then

```
A & B
ans =
     0     1     0     1     0
     1     0     1     0     1
     0     0     0     0     0
     0     1     0     0     0
```

angle

Phase angle

Syntax

```
P = angle(Z)
```

Description

`P = angle(Z)` returns the phase angles, in radians, for each element of complex array `Z`. The angles lie between $\pm\pi$.

For complex `Z`, the magnitude `R` and phase angle `theta` are given by

```
R = abs(Z)
theta = angle(Z)
```

and the statement

```
Z = R.*exp(i*theta)
```

converts back to the original complex `Z`.

Examples

```
Z = [ 1 - 1i   2 + 1i   3 - 1i   4 + 1i
      1 + 2i   2 - 2i   3 + 2i   4 - 2i
      1 - 3i   2 + 3i   3 - 3i   4 + 3i
      1 + 4i   2 - 4i   3 + 4i   4 - 4i ]

P = angle(Z)

P =
   -0.7854    0.4636   -0.3218    0.2450
    1.1071   -0.7854    0.5880   -0.4636
   -1.2490    0.9828   -0.7854    0.6435
    1.3258   -1.1071    0.9273   -0.7854
```

More About

Algorithms

The `angle` function can be expressed as `angle(z) = imag(log(z)) = atan2(imag(z),real(z))`.

`abs` | `atan2` | `unwrap`

Introduced before R2006a

Using Animated Line Objects

Line animations

Animated line objects optimize line animations by accumulating data from a streaming data source. After you create the initial animated line using the `animatedline` function, you can add new points to the line without having to redefine the existing points. Modify the appearance of the animated line by setting its properties.

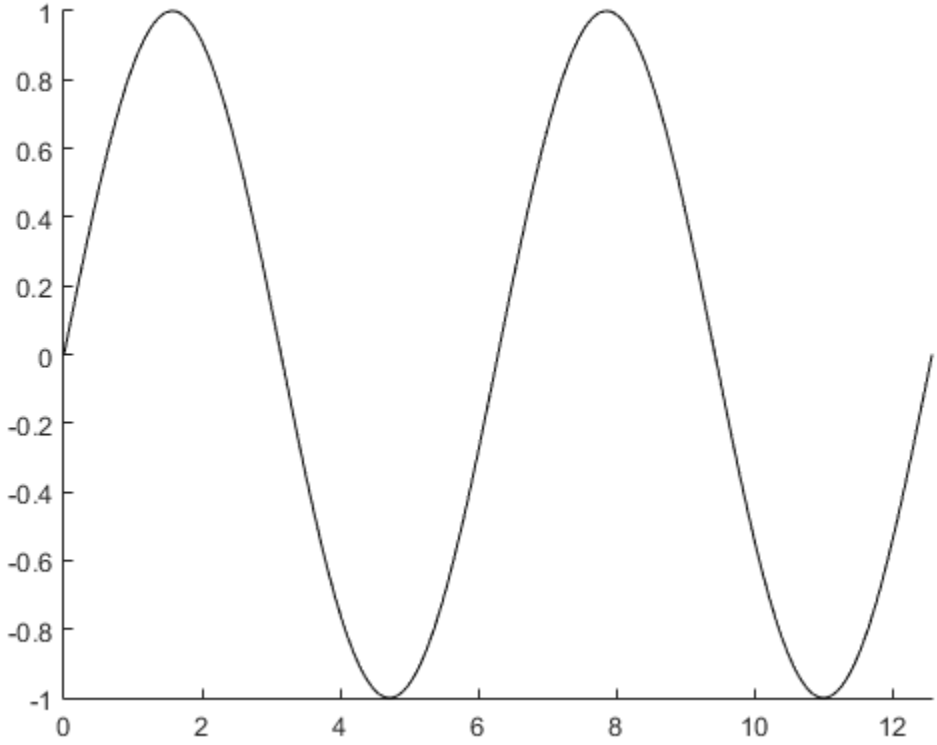
Examples

Display Line Animation

Create the initial animated line object. Then, use a loop to add 1,000 points to the line. After adding each new point, use `drawnow` to display the new point on the screen.

```
h = animatedline;
axis([0,4*pi,-1,1])

x = linspace(0,4*pi,1000);
y = sin(x);
for k = 1:length(x)
    addpoints(h,x(k),y(k));
    drawnow
end
```



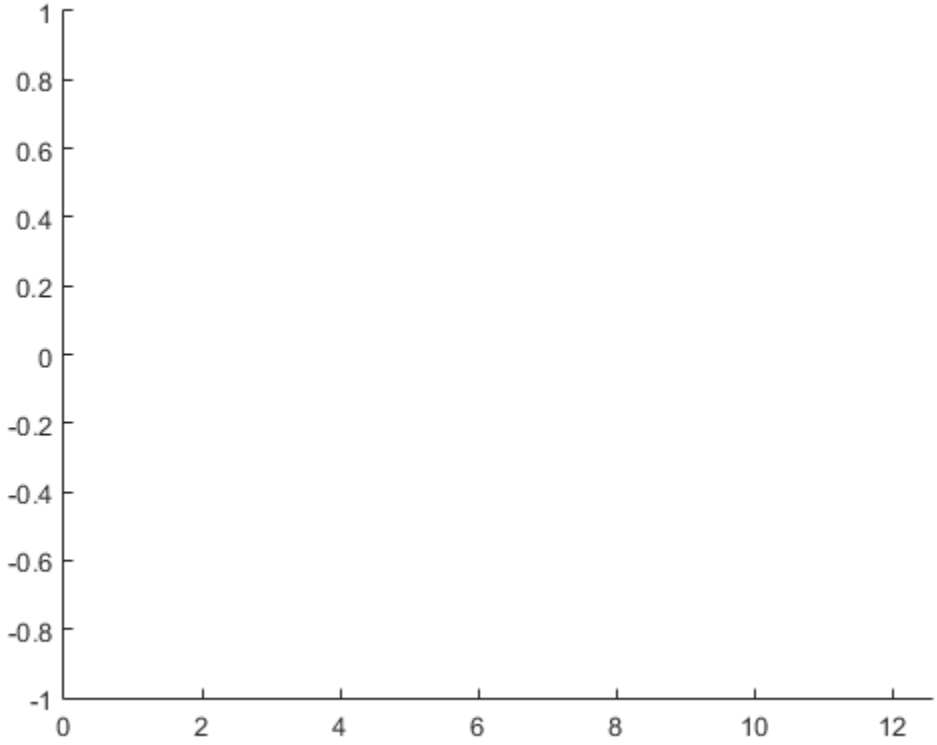
For faster rendering, add more than one point to the line each time through the loop or use `drawnow limitrate`.

Query the points of the line.

```
[xdata,ydata] = getpoints(h);
```

Clear the points from the line.

```
clearpoints(h)
drawnow
```



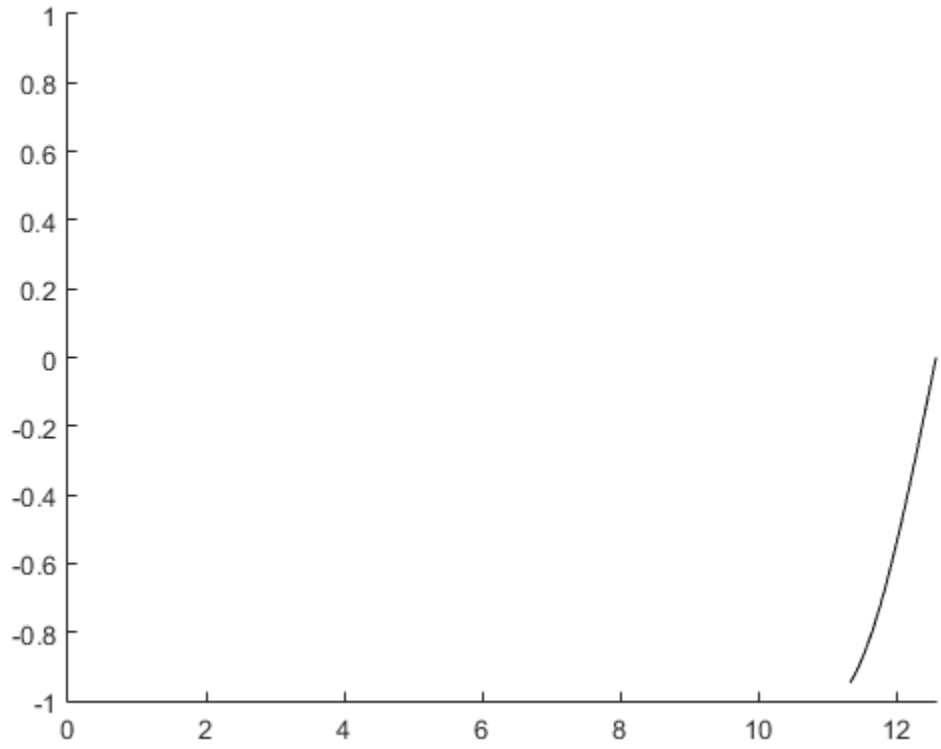
Set Maximum Number of Points

Limit the number of points in the animated line to 100. Use a loop to add one point to the line at a time. When the line contains 100 points, adding a new point to the line deletes the oldest point.

```
h = animatedline('MaximumNumPoints',100);
axis([0,4*pi,-1,1])

x = linspace(0,4*pi,1000);
y = sin(x);
for k = 1:length(x)
    addpoints(h,x(k),y(k));
    drawnow
```

```
end
```



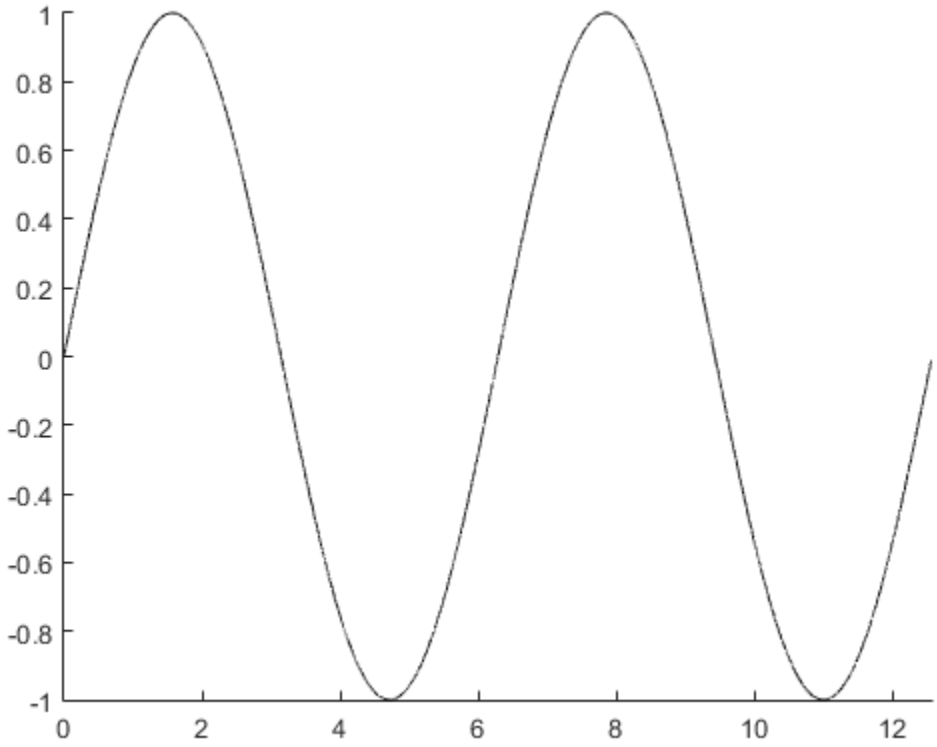
Add Points in Sets for Fast Animation

Use a loop to add 100,000 points to an animated line. Since the number of points is large, adding one point to the line each time through the loop might be slow. Instead, add 100 points to the line each time through the loop for a faster animation.

```
h = animatedline;
axis([0,4*pi,-1,1])

numpoints = 100000;
x = linspace(0,4*pi,numpoints);
y = sin(x);
for k = 1:100:numpoints-100
```

```
    xvec = x(k:k+99);
    yvec = y(k:k+99);
    addpoints(h,xvec,yvec)
    drawnow
end
```



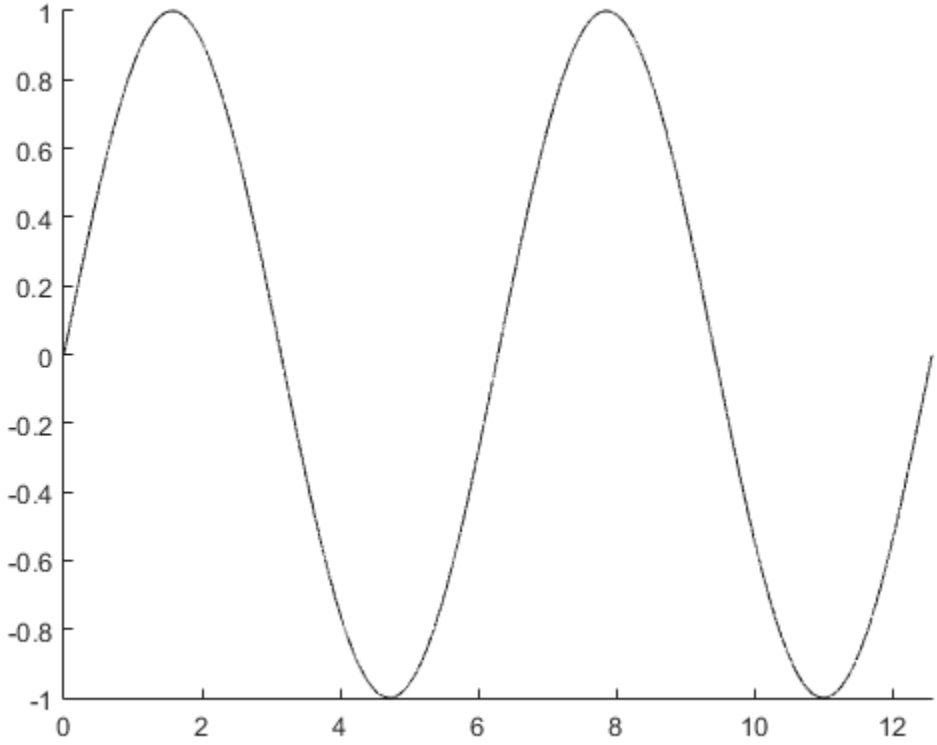
Another technique for creating faster animations is to use `drawnow limitrate` instead of `drawnow`.

Use drawnow limitrate for Fast Animation

Use a loop to add 100,000 points to an animated line. Since the number of points is large, using `drawnow` to display the changes might be slow. Instead, use `drawnow limitrate` for a faster animation.

```
h = animatedline;
axis([0,4*pi,-1,1])

numpoints = 100000;
x = linspace(0,4*pi,numpoints);
y = sin(x);
for k = 1:numpoints
    addpoints(h,x(k),y(k))
    drawnow limitrate
end
```



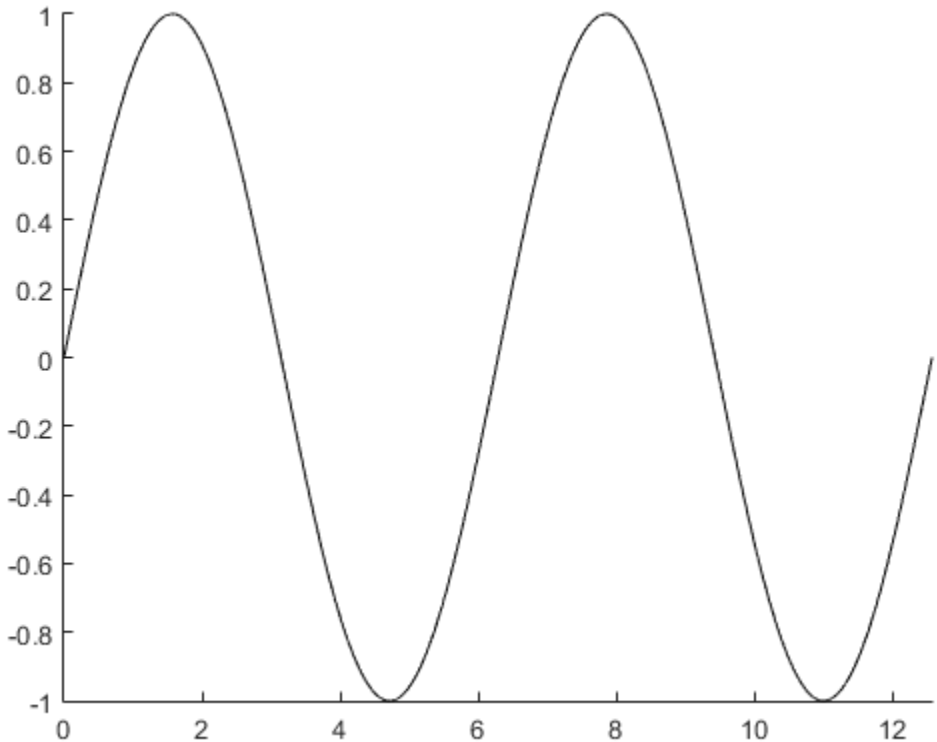
Control Animation Speed

Control the animation speed by running through several iterations of the animation loop before drawing the updates on the screen. Use this technique when `drawnow` is too slow and `drawnow limitrate` is too fast.

For example, update the screen every 1/30 seconds. Use the `tic` and `toc` commands to keep track of how much time passes between screen updates.

```
h = animatedline;
axis([0,4*pi,-1,1])
numpoints = 10000;
x = linspace(0,4*pi,numpoints);
y = sin(x);
```

```
a = tic; % start timer
for k = 1:numpoints
    addpoints(h,x(k),y(k))
    b = toc(a); % check timer
    if b > (1/30)
        drawnow % update screen every 1/30 seconds
        a = tic; % reset timer after updating
    end
end
drawnow % draw final frame
```



A smaller interval updates the screen more often and results in a slower animation. For example, use `b > (1/1000)` to slow down the animation.

`drawnow` | `movie`

animatedline

Create animated line

Syntax

```
h = animatedline
h = animatedline(x,y)
h = animatedline(x,y,z)

h = animatedline(___,Name,Value)
```

Description

`h = animatedline` creates an animated line that has no data and adds it to the current axes. Add points to the line in a loop to create a line animation. For more information, see Using Animated Line Objects.

`h = animatedline(x,y)` creates an animated line with initial data points defined by `x` and `y`.

`h = animatedline(x,y,z)` creates an animated line with initial data points defined by `x` , `y`, and `z`.

`h = animatedline(___,Name,Value)` specifies animated line properties using one or more `Name,Value` pair arguments. For example, `'Color','r'` sets the line color to red. Use this option with any of the input argument combinations in the previous syntaxes.

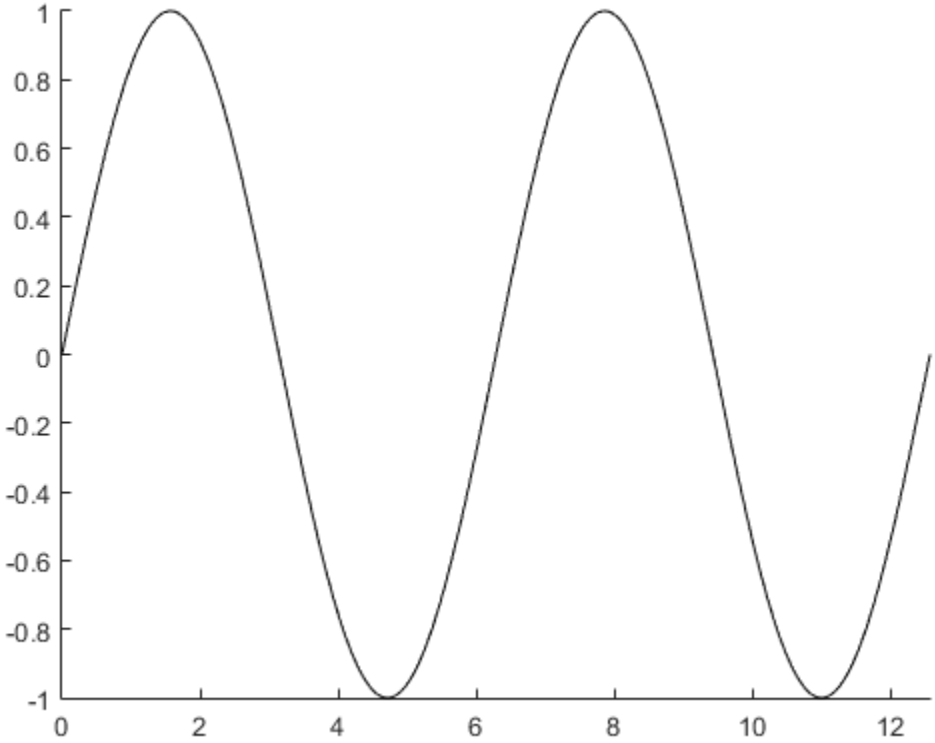
Examples

Display Line Animation

Create the initial animated line object. Then, use a loop to add 1,000 points to the line. After adding each new point, use `drawnow` to display the new point on the screen.

```
h = animatedline;
axis([0,4*pi,-1,1])

x = linspace(0,4*pi,1000);
y = sin(x);
for k = 1:length(x)
    addpoints(h,x(k),y(k));
    drawnow
end
```



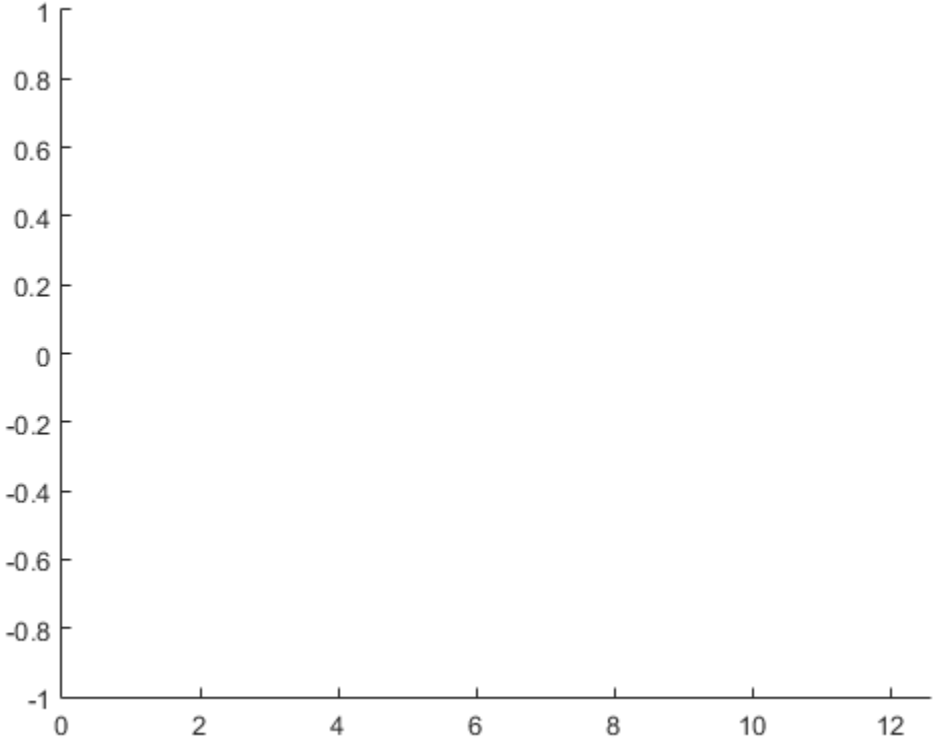
For faster rendering, add more than one point to the line each time through the loop or use `drawnow limitrate`.

Query the points of the line.

```
[xdata,ydata] = getpoints(h);
```

Clear the points from the line.

```
clearpoints(h)
drawnow
```

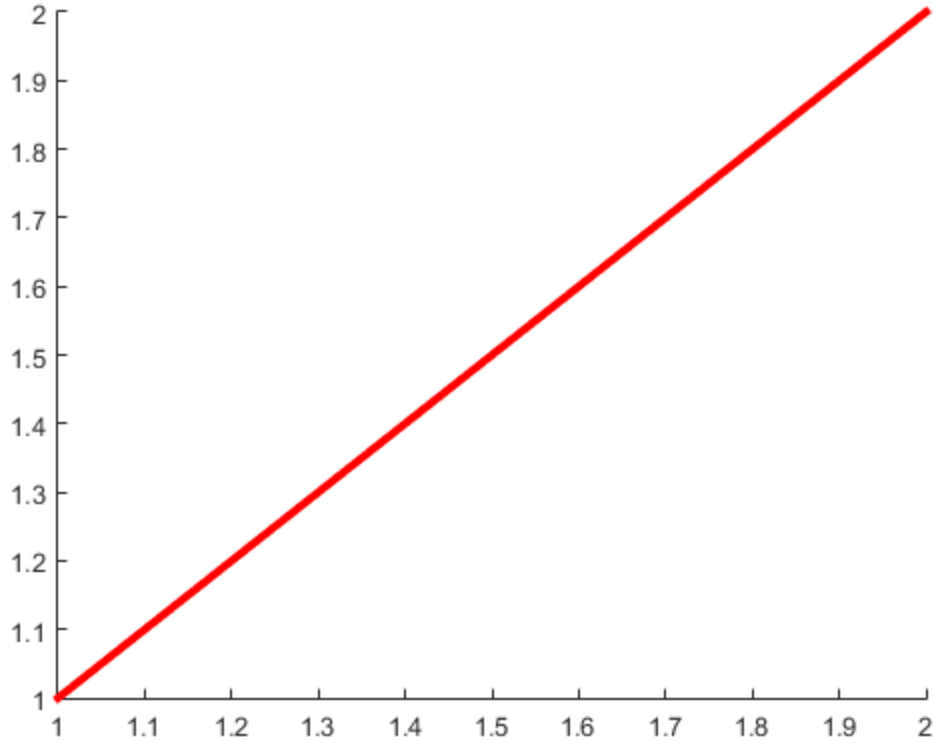


Specify Animated Line Color

Set the color of the animated line to red and set its line width to 3 points.

```
x = [1 2];
y = [1 2];
```

```
h = animatedline(x,y,'Color','r','LineWidth',3);
```



Input Arguments

x — Initial x values

[ ] (default) | scalar or vector

Initial *x* values for the animated line, specified as a scalar or vector. The input `x` must be equal in size to `y`.

Example: `1:10`

Data Types: `double`

y — Initial y values

[ ] (default) | scalar or vector

Initial *y* values for the animated line, specified as a scalar or vector. The input `y` must be equal in size to `x`.

Example: `1:10`

Data Types: `double`

z — Initial z values

[ ] (default) | scalar or vector

Initial *z* values for the animated line, specified as a scalar or vector. The input `z` must be equal in size to `x` and `y`.

Example: `1:10`

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

The animated line properties listed here are only a subset. For a complete list, see Animated Line Properties.

Example: `'Color','red','Marker','o'`

'Color' — Line color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the `Color` as `'none'`, then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

`[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`'LineStyle'` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	————
`'--'`	Dashed line	- - - - -
`':'`	Dotted line	.....
`'-.'`	Dash-dotted line	_._._._.-
`'none'`	No line	No line

`'LineWidth'` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`'Marker'` — Marker symbol

`'none'` (default) | `'o'` | `'+'` | `'*'` | `'.'` | ...

Marker symbol, specified as one of the marker symbol strings listed in this table. By default, the animated line object does not have markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
`'o'`	Circle
`'+'`	Plus sign
`'*'`	Asterisk
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

`'MarkerSize'` — Marker size

6 (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`'MarkerEdgeColor'` — Color of marker edge

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`'MarkerFaceColor'` — Color of marker interior

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `[0.3 0.2 0.1]`

Example: `'green'`

`'MaximumNumPoints'` — Maximum number of points stored and displayed

`1000000` (default) | positive value | `Inf`

Maximum number of points stored and displayed as part of the line, specified as a positive value or `Inf`. By default, the value is one million points. If the number of points exceeds the maximum value permitted, then the animated line keeps the most recently added points and drops points from the beginning of the line. These dropped points no longer display on the screen and are not returned when using `getpoints`.

Use this property to limit the number of points appearing on the screen at any given time or to limit the amount of memory used. If you specify the value as `Inf`, then the animated line does not drop any points, but the number of points stored is limited by the amount of memory available.

Example: `10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`h` — Animated line object

animated line object

Animated line object. Use `h` to modify the animated line object after its been created, such as changing property values or adding points to the line. For more information, see Using Animated Line Objects.

More About

Tips

- Animated lines do not support data tips.

Using Objects
Using Animated Line Objects

Properties
Animated Line Properties

Introduced in R2014b

Animated Line Properties

Control animated line appearance and behavior

Animated line properties control the appearance and behavior of an animated line object. By changing property values, you can modify certain aspects of the line. Use dot notation to refer to a particular object and property:

```
h = animatedline;
c = h.Color;
h.Color = 'red';
```

Line

`Color` — Line color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the `Color` as `'none'`, then the line is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	
`':'`	Dotted line	
`'-.'`	Dash-dotted line	`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. If the line has markers, then the line width also affects the marker edges.

Example: `0.75`

`MaximumNumPoints` — Maximum number of points stored and displayed

`1000000` (default) | positive value | `Inf`

Maximum number of points stored and displayed as part of the line, specified as a positive value or `Inf`. By default, the value is one million points. If the number of points exceeds the maximum value permitted, then the animated line keeps the most recently added points and drops points from the beginning of the line. These dropped points no longer display on the screen and are not returned when using `getpoints`.

Use this property to limit the number of points appearing on the screen at any given time or to limit the amount of memory used. If you specify the value as `Inf`, then the animated line does not drop any points, but the number of points stored is limited by the amount of memory available.

Example: 10

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

AlignVertexCenters — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the AlignVertexCenters property to eliminate the uneven appearance.

- 'off' — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- 'on' — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type opengl info. If it is supported, then the returned fields contain the line SupportsAlignVertexCenters: 1.

Markers

Marker — Marker symbol

'none' (default) | marker string

Marker symbol, specified as one of the marker strings listed in this table. By default, the animated line object does not display markers. Specifying a marker symbol adds markers at each data point or vertex.

String	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk

String	Marker Symbol
`'.'`	Point
`'x'`	Cross
`'square'` or `'s'`	Square
`'diamond'` or `'d'`	Diamond
`'^'`	Upward-pointing triangle
`'v'`	Downward-pointing triangle
`'>'`	Right-pointing triangle
`'<'`	Left-pointing triangle
`'pentagram'` or `'p'`	Five-pointed star (pentagram)
`'hexagram'` or `'h'`	Six-pointed star (hexagram)
`'none'`	No markers

Example: `'+'`

Example: `'diamond'`

`MarkerSize` — Marker size

`6` (default) | positive value

Marker size, specified as a positive value in point units.

Example: `10`

`MarkerEdgeColor` — Marker outline color

`'auto'` (default) | `'none'` | RGB triplet | color string

Marker outline color, specified as one of these values:

- `'auto'` — Use the same color as the Color property.
- `'none'` — Use no color, which makes unfilled markers invisible.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: `[0.5 0.5 0.5]`

Example: `'blue'`

`MarkerFaceColor` — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | color string

Marker fill color, specified as one of these values:

- `'none'` — Use no color, which makes the interior invisible.
- `'auto'` — Use the same color as the `Color` property for the axes.
- RGB triplet or color string — Use the specified color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]

Long Name	Short Name	RGB Triplet
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: [0.3 0.2 0.1]

Example: 'green'

Visibility

Visible — Visibility of animated line

'on' (default) | 'off'

Visibility of animated line, specified as one of these values:

- 'on' — Display the animated line.
- 'off' — Hide the animated line without deleting it. You still can access the properties of an invisible animated line object.

Clipping — Clipping of animated line to axes limits

'on' (default) | 'off'

Clipping of animated line to the axes limits, specified as one of these values:

- 'on' — Do not display parts of the animated line that are outside the axes limits.
- 'off' — Display the entire animated line, even if parts of it appear outside the axes limits. Parts of the animated line might appear outside the axes limits if you create a plot, set hold on, freeze the axis scaling, and then create the animated line that is larger than the original plot.

Identifiers

Type — Type of graphics object

'animatedline'

Type of graphics object, returned as 'animatedline'. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using findobj.

`Tag` — User-specified tag

`''` (default) | string

Tag to associate with the animated line, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with animated line

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the animated line object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the animated line.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the animated line object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the animated line from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the animated line object in the legend as one entry (default).
   - `'off'` — Do not include the animated line object in the legend.
   - `'children'` — Include only children of the animated line object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of animated line

axes object | group object | transform object

Parent of animated line, specified as an axes, group, or transform object.

`Children` — Children of animated line

empty `GraphicsPlaceholder` array

The animated line has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of animated line object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The animated line object handle is always visible.
- `'off'` — The animated line object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The animated line object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the animated line at the command-line, but allows callback functions to access it.

If the animated line object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the animated line. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The animated line object — You can access properties of the animated line object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the animated line. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the animated line when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the animated line.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the animated line that has a defined color. You cannot click a part that has an associated color property set to `'none'`. If the plot contains markers, then the entire marker is clickable if either the edge or the fill has a defined color. The HitTest property determines if the animated line responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the animated line passes the click to the object below it in the current view of the figure window. The HitTest property of the animated line has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the animated line. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the animated line that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the animated line object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the animated line is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the

---

`BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the animated line tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the animated line. Setting the `CreateFcn` property on an existing animated line has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during animated line creation. MATLAB executes the callback after creating the animated line and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The animated line object — You can access properties of the animated line object from within the callback function. You also can access the animated line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the animated line. MATLAB executes the callback before destroying the animated line so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The animated line object — You can access properties of the animated line object from within the callback function. You also can access the animated line object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of animated line

`'off'` (default) | `'on'`

Deletion status of animated line, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the animated line begins

execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the animated line no longer exists.

Check the value of the BeingDeleted property to verify that the animated line is not about to be deleted before querying or modifying it.

annotation

Create annotation objects

Syntax

```
annotation(annotation_type)
annotation('line',x,y)
annotation('arrow',x,y)
annotation('doublearrow',x,y)
annotation('textarrow',x,y)
annotation('textbox',[x y w h])
annotation('ellipse',[x y w h])
annotation('rectangle',[x y w h])
annotation(handle,...)
annotation(...,'PropertyName',PropertyValue,...)
anno_obj_handle = annotation(...)
```

Description

`annotation(annotation_type)` creates the specified annotation type using default values for all properties. *`annotation_type`* can be one of the following strings:

- `'line'`
- `'arrow'`
- `'doublearrow'` (two-headed arrow),
- `'textarrow'` (arrow with attached text box),
- `'textbox'`
- `'ellipse'`
- `'rectangle'`

`annotation('line',x,y)` creates a line annotation object that extends from the point defined by `x(1)`,`y(1)` to the point defined by `x(2)`,`y(2)`, specified in normalized figure units.

`annotation('arrow',x,y)` creates an arrow annotation object that extends from the point defined by `x(1)`,`y(1)` to the point defined by `x(2)`,`y(2)`, specified in normalized figure units.

`annotation('doublearrow',x,y)` creates a two-headed annotation object that extends from the point defined by `x(1)`,`y(1)` to the point defined by `x(2)`,`y(2)`, specified in normalized figure units.

`annotation('textarrow',x,y)` creates a textarrow annotation object that extends from the point defined by `x(1)`,`y(1)` to the point defined by `x(2)`,`y(2)`, specified in normalized figure units. The tail end of the arrow is attached to an editable text box.

`annotation('textbox',[x y w h])` creates an editable text box annotation with its lower left corner at the point `x`,`y`, a width `w`, and a height `h`, specified in normalized figure units. Specify `x`, `y`, `w`, and `h` in a single vector.

To type in the text box, enable plot edit mode (`plotedit`) and double-click within the box.

`annotation('ellipse',[x y w h])` creates an ellipse annotation with the lower left corner of the bounding rectangle at the point `x`,`y`, a width `w`, and a height `h`, specified in normalized figure units. Specify `x`, `y`, `w`, and `h` in a single vector.

`annotation('rectangle',[x y w h])` creates a rectangle annotation with the lower left corner of the rectangle at the point `x`,`y`, a width `w`, and a height `h`, specified in normalized figure units. Specify `x`, `y`, `w`, and `h` in a single vector.

`annotation(handle,...)` creates the annotation in the figure, uipanel, or uitab specified by `handle`.

`annotation(...,'PropertyName',PropertyValue,...)` creates the annotation and sets the specified properties to the specified values.

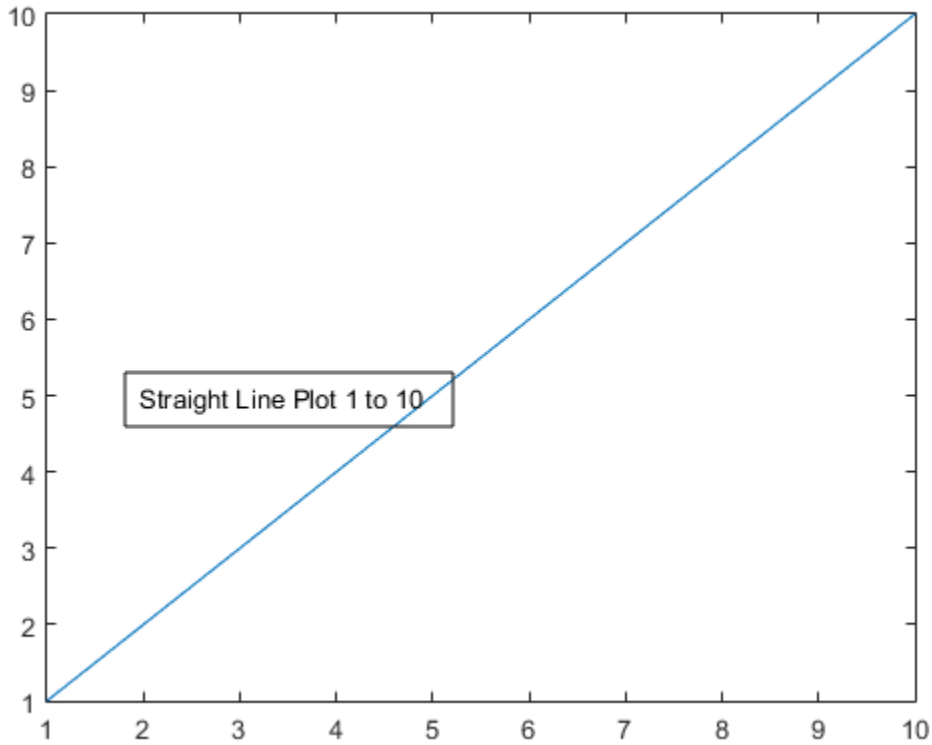
`anno_obj_handle = annotation(...)` returns the handle to the annotation objects.

Examples

Add Text Box to Graph

Annotate the graph with a text box. Specify the text box location in normalized figure coordinates.

```
figure; % new figure window
plot(1:10);
annotation('textbox', [0.2,0.4,0.1,0.1],...
           'String', 'Straight Line Plot 1 to 10');
```

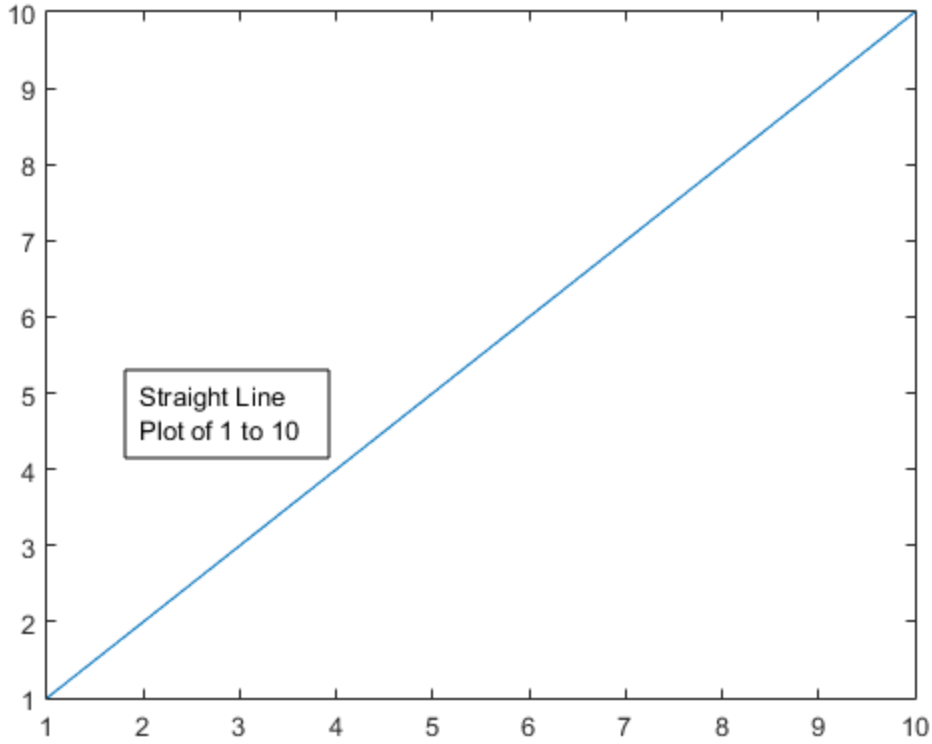


Add Text Box with Multiple Lines to Graph

Insert multiple lines in a text box by creating a cell array of strings. Each element is used as a separate line.

```
figure
plot(1:10)
str = {'Straight Line', 'Plot of 1 to 10'};
```

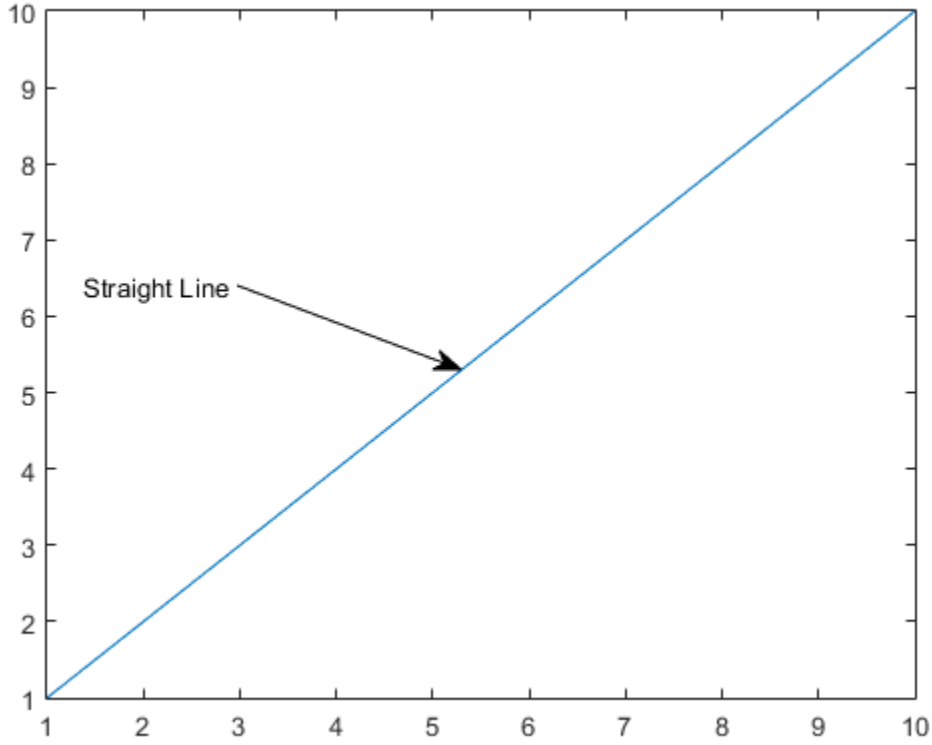
```
annotation('textbox', [0.2,0.4,0.1,0.1],...
           'String', str)
```



Add Text Arrow to Graph

Add a text arrow to the graph. Define the text arrow to start from `(0.3,0.6)` and extend to `(0.5,0.5)` in normalized figure coordinates.

```
figure
plot(1:10)
annotation('textarrow',[0.3,0.5],[0.6,0.5],...
           'String','Straight Line ')
```



Adding Annotations Interactively

It is often convenient to place annotations interactively. For details, see “Customize Graph Using Plot Tools”.

Annotation Arrow Properties

Control annotation arrow appearance and behavior

Annotation arrow properties control the appearance and behavior of an annotation arrow object. By changing property values, you can modify certain aspects of the arrow.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('arrow');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Color` — Arrow color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Arrow color, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you set the color to `'none'`, then the arrow is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`

Long Name	Short Name	RGB Triplet
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

LineStyle — Style of arrow stem

'-' (default) | '--' | ':' | '-.' | 'none'

Style of arrow stem, specified as one of the strings listed in this table.

String	Line Style	Result
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No stem	No stem

LineWidth — Width of arrow stem

0.5 (default) | positive value

Width of arrow stem, specified as a positive value in point units. One point equals 1/72 inch.

Example: 0.75

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

HeadStyle — Style of arrowhead

'vback2' (default) | string

Style of the arrowhead, specified as one of the strings in this table.

String	Result	String	Result
`'plain'`		`'fourstar'`	
`'ellipse'`		`'rectangle'`	
`'vback1'`		`'diamond'`	
`'vback2'` (default)		`'rose'`	
`'vback3'`		`'hypocycloid'`	
`'cback1'`		`'astroid'`	
`'cback2'`		`'deltoid'`	
`'cback3'`		`'none'`	No arrowhead

`HeadLength` — Length of arrowhead

10 (default) | scalar numeric value

Length of the arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The arrowhead extends backwards from the (*x*, *y*) coordinate defined by the first two elements in the Position property.

Example: 15

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`HeadWidth` — Width of arrowhead

10 (default) | scalar numeric value

Width of the arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 15

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Location and Size

X — Beginning and ending x-coordinates

`[0.3 0.4]` (default) | two-element vector

Beginning and ending *x*-coordinates, specified as a two-element vector of the form `[x_begin x_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.5]`

Y — Beginning and ending y-coordinates

`[0.3 0.4]` (default) | two-element vector

Beginning and ending *y*-coordinates, specified as a two-element vector of the form `[y_begin y_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.5]`

Position — Size and location

`[0.3 0.3 0.1 0.1]` (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x_begin y_begin dx dy]`. The first two elements specify the coordinates for the beginning of the arrow. The second two elements specify the slope of the arrow.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.5 0.5 0.2 0.3]`

Units — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

Units	Description
`'normalized'` (default)	Normalized with respect to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the figure window.

This property affects the Position property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume Units is set to the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the annotation arrow, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

Annotation Double Arrow Properties

Control annotation double arrow appearance and behavior

Annotation double arrow properties control the appearance and behavior of an annotation double arrow object. By changing property values, you can modify certain aspects of the double arrow.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('doublearrow');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Color` — Arrow color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Arrow color, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you set the color to `'none'`, then the arrow is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`

Long Name	Short Name	RGB Triplet
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

LineStyle — Style of arrow stem

'-' (default) | '--' | ':' | '-.' | 'none'

Style of arrow stem, specified as one of the strings listed in this table.

String	Line Style	Result
'-'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	'none'	No stem	No stem

LineWidth — Width of arrow stem

0.5 (default) | positive value

Width of arrow stem, specified as a positive value in point units. One point equals 1/72 inch.

Example: 0.75

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Head1Style — Style of first arrowhead

'vback2' (default) | string

Style of the first arrowhead, specified as one of the head style strings in this table. The first arrowhead is located at the point `(x_begin,y_begin)` determined by the X and Y properties.

String	Result	String	Result
`'plain'`		`'fourstar'`	
`'ellipse'`		`'rectangle'`	
`'vback1'`		`'diamond'`	
`'vback2'` (default)		`'rose'`	
`'vback3'`		`'hypocycloid'`	
`'cback1'`		`'astroid'`	
`'cback2'`		`'deltoid'`	
`'cback3'`		`'none'`	No arrowhead

`Head2Style` — Style of second arrowhead

`'vback2'` (default) | string

Style of the second arrowhead, specified as one of the head style strings in this table. The second arrowhead is located at the point `(x_end,y_end)` determined by the X and Y properties.

String	Result	String	Result
`'plain'`		`'fourstar'`	
`'ellipse'`		`'rectangle'`	
`'vback1'`		`'diamond'`	

String	Result	String	Result
`'vback2'` (default)		`'rose'`	
`'vback3'`		`'hypocycloid'`	
`'cback1'`		`'astroid'`	
`'cback2'`		`'deltoid'`	
`'cback3'`		`'none'`	No arrowhead

`Head1Length` — Length of first arrowhead

10 (default) | scalar numeric value

Length of the first arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The first arrowhead extends backwards from the point `(x_begin,y_begin)` determined by the X and Y properties.

Example: `15`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Head2Length` — Length of second arrowhead

10 (default) | scalar numeric value

Length of the second arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The second arrowhead extends backwards from the point `(x_end,y_end)` determined by the X and Y properties.

Example: `15`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Head1Width` — Width of first arrowhead

10 (default) | scalar numeric value

Width of the first arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The first arrowhead is located at the point `(x_begin,y_begin)` determined by the X and Y properties.

Example: 15

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Head2Width — Width of second arrowhead

10 (default) | scalar numeric value

Width of the second arrowhead, specified as a scalar numeric value in point units. One point equals 1/72 inch. The second arrowhead is located at the point (x_end,y_end) determined by the X and Y properties.

Example: 15

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Location and Size

X — Beginning and ending x-coordinates

[0.3 0.4] (default) | two-element vector

Beginning and ending *x*-coordinates, specified as a two-element vector of the form [x_begin x_end].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the Units property.

Example: [0.2 0.3]

Y — Beginning and ending y-coordinates

[0.3 0.4] (default) | two-element vector

Beginning and ending *y*-coordinates, specified as a two-element vector of the form [y_begin y_end].

By default, the units are normalized to the figure. The lower-left corner of the figure maps to (0,0) and the upper-right corner maps to (1,1). To change the units, use the Units property.

Example: [0.2 0.3]

`Position` — Size and location

`[0.3 0.3 0.1 0.1]` (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x_begin y_begin dx dy]`. The first two elements specify the coordinates for the beginning of the arrow. The second two elements specify the slope of the arrow.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.5 0.5 0.2 0.3]`

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

`Units`	Description
`'normalized'` (default)	Normalized with respect to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the figure window.

This property affects the Position property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume Units is set to the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the annotation double arrow, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

Annotation Ellipse Properties

Control annotation ellipse appearance and behavior

Annotation ellipse properties control the appearance and behavior of an annotation ellipse object. By changing property values, you can modify certain aspects of the ellipse.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('ellipse');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Color` — Outline color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Outline color, specified as an RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the `Color` as `'none'`, then the annotation ellipse outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`

Long Name	Short Name	RGB Triplet
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

FaceColor — Fill color

'none' (default) | RGB triplet | color string

Fill color, specified as 'none', an RGB triplet, or a color string. The 'none' option makes the fill invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	————
`'--'`	Dashed line	- — — — —
`':'`	Dotted line	.....
`'-.'`	Dash-dotted line	—·—·—·—·-
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width of ellipse outline, specified as a positive value in point units. One point equals 1/72 inch.

Example: `0.75`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Location and Size

`Position` — Size and location

`[0.3 0.3 0.1 0.1]` (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x y length height]`. The first two elements specify the coordinates of the lower-left corner of the smallest rectangle that enclose the ellipse. The second two elements specify length and height of the rectangle.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.3 0.4 0.5]`

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

Units	Description
`'normalized'` (default)	Normalized with respect to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the figure window.

This property affects the Position property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume Units is set to the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the annotation ellipse, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

Annotation Line Properties

Control annotation line appearance and behavior

Annotation line properties control the appearance and behavior of an annotation line object. By changing property values, you can modify certain aspects of the line.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('line');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	`'--'`	Dashed line	
`':'`	Dotted line	`'-.'`	Dash-dotted line	`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width, specified as a positive value in point units. One point equals 1/72 inch.

Example: `0.75`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Color` — Line color

`[0 0 0]` (default) | RGB triplet | color string

Line color, specified as an RGB triplet or a color string. The default RGB triplet value of `[0 0 0]` corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

Location and Size

`X` — Beginning and ending x-coordinates

`[0.3 0.4]` (default) | two-element vector

Beginning and ending *x*-coordinates, specified as a two-element vector of the form `[x_begin x_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.3]`

Y — Beginning and ending y-coordinates

`[0.3 0.4]` (default) | two-element vector

Beginning and ending *y*-coordinates, specified as a two-element vector of the form `[y_begin y_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.3]`

Position — Size and location

`[0.3 0.3 0.1 0.1]` (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x_begin y_begin dx dy]`. The first two elements specify the coordinates of the starting point of the line. The second two elements specify the slope of the line.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property. To change the units, use the `Units` property.

Example: `[0.2 0.2 0.3 0.3]`

Units — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

Units	Description
`'normalized'` (default)	Normalized with respect to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.

Units	Description
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the figure window.

This property affects the Position property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume Units is set to the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the annotation line, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

Annotation Rectangle Properties

Control annotation rectangle appearance and behavior

Annotation rectangle properties control the appearance and behavior of an annotation rectangle object. By changing property values, you can modify certain aspects of the rectangle.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('rectangle');
c = h.Color;
h.Color = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Color` — Outline color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Outline color, specified as an RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you specify the `Color` as `'none'`, then the annotation rectangle outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`

Long Name	Short Name	RGB Triplet
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

FaceColor — Fill color

'none' (default) | RGB triplet | color string

Fill color, specified as 'none', an RGB triplet, or a color string. The 'none' option makes the fill invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

FaceAlpha — Fill transparency

1 (default) | value in range [0,1]

Fill transparency, specified as a scalar value in the range [0,1]. A value of 1 is opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent.

Example: `0.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LineStyle` — Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	————
`'--'`	Dashed line	- — — — —
`':'`	Dotted line	.....
`'-.'`	Dash-dotted line	—·—·—·—
`'none'`	No line	No line

`LineWidth` — Line width

`0.5` (default) | positive value

Line width of rectangle outline, specified as a positive value in point units. One point equals 1/72 inch.

Example: `0.75`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Location and Size

`Position` — Size and location

`[0.3 0.3 0.1 0.1]` (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x y length height]`. The first two elements specify the coordinates of the lower left corner of the rectangle. The second two elements specify the length and height of the rectangle.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.3 0.4 0.5]`

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

`Units`	Description
`'normalized'` (default)	Normalized with respect to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the figure window.

This property affects the Position property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume Units is set to the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the annotation rectangle, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

Annotation Text Arrow Properties

Control annotation text arrow appearance and behavior

Annotation text arrow properties control the appearance and behavior of an annotation text arrow object. By changing property values, you can modify certain aspects of the text arrow.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('textarrow');
s = h.FontSize;
h.FontSize = 12;
```

If you are using an earlier release, use the `get` and `set` functions instead.

Text

`String` — Text to display

`''` (default) | character array | cell array | numeric value

Text to display, specified as a character array, cell array, or numeric value.

Example: `'my label'`

Example: `{'first line','second line'}`

Example: `123`

To include numeric variables with text, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the Interpreter property.

To create multiline text:

- Use a cell array, where each cell contains a line of text, such as `{'first line','second line'}`.

- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.
- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`. This property converts strings with new line characters to cell arrays.

Text that contains only a numeric value is converted to a string using `sprintf('%g',value)`. For example, `12345678` displays as `1.23457e+07`.

Note: The words `default`, `factory`, and `remove` are reserved words that will not appear in text when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

`Interpreter` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`

Modifier	Description	Example of String
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

`TextColor` — Text color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you set the color to `'none'`, then the text is invisible.

Note: Setting the Color property changes the `TextColor` property to the same value, unless you explicitly set the `TextColor` property.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

TextRotation — Text rotation angle in degrees

0 (default) | scalar numeric value

Text rotation angle in degrees, specified as a scalar numeric value. Set this property to a positive value to rotate the text counterclockwise. Angles are absolute and not relative to previous rotations. A rotation of 0 degrees is always horizontal.

Example: 90

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Font Style

FontAngle — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

Note: The 'oblique' value has been removed. Use 'italic' instead.

FontName — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`FontSize` — Font size

`10` (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the FontUnits property.

Example: `12`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`FontUnits` — Font size units

`'points'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'normalized'` | `'pixels'`

Font size units, specified as one of the values in this table.

`Units`	Description
`'points'`	Points. One point equals 1/72 inch.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'normalized'`	Interpreted as a fraction of the axes height. If you resize the axes, MATLAB modifies the font size accordingly. For example, if the `FontSize` is `0.1` in normalized units, then the text is 1/10 of the axes height.

Units	Description
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

If you set both the font size and the font units in one function call, you must set the FontUnits property first so that the axes correctly interprets the specified font size.

`FontWeight` — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

Text Box

`TextLineWidth` — Width of text box outline

`0.5` (default) | scalar numeric value

Width of text box outline, specified as a scalar numeric value in point units. One point equals `1/72` inch.

Example: `1.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TextEdgeColor` — Color of text box outline

`'none'` (default) | RGB triplet | color string

Color of text box outline, specified as `'none'`, a three-element RGB triplet, or a color string. If the color is `'none'`, the box outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`TextBackgroundColor` — Color of text box background

`'none'` (default) | RGB triplet | color string

Color of text box background, specified as `'none'`, a three-element RGB triplet, or a color string. If the color is `'none'`, the background color is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`

Long Name	Short Name	RGB Triplet
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

TextMargin — Space around text within text box

2 (default) | scalar numeric value

Space around the text within the text box, specified as a scalar numeric value in pixel units.

Example: 10

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Arrow

Color — Arrow color

[0 0 0] (default) | RGB triplet | color string | 'none'

Arrow color, specified as a three-element RGB triplet, a color string, or 'none'. The default RGB triplet value of [0 0 0] corresponds to black. If you set the color to 'none', then the arrow is invisible.

Note: Setting this property also changes the text color if you have not explicitly set the text color using the TextColor property.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	————
'--'	Dashed line	- - - - -
':'	Dotted line	.....
'-.'	Dash-dotted line	_._._._.-
'none'	No line	No line

LineWidth — Width of arrow stem

0.5 (default) | scalar numeric value

Width of arrow stem, specified as a scalar numeric value greater than zero in point units. One point equals 1/72 inch. The default value is 0.5 points.

Example: 0.75

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`HeadStyle` — Style of arrowhead

`'vback2'` (default) | head style string

Style of the arrowhead, specified as one of the head style strings in this table.

String	Result	String	Result
`'plain'`		`'fourstar'`	
`'ellipse'`		`'rectangle'`	
`'vback1'`		`'diamond'`	
`'vback2'` (default)		`'rose'`	
`'vback3'`		`'hypocycloid'`	
`'cback1'`		`'astroid'`	
`'cback2'`		`'deltoid'`	
`'cback3'`		`'none'`	No arrowhead

`HeadLength` — Length of arrowhead

10 (default) | scalar numeric value

Length of the arrowhead, specified as a scalar numeric value in point units. One point equals `1/72` inch.

Example: `15`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`HeadWidth` — Width of arrowhead

10 (default) | scalar numeric value

Width of the arrowhead, specified as a scalar numeric value in point units. One point equals `1/72` inch.

Example: `15`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Location and Size

`X` — Beginning and ending x-coordinates

`[0.3 0.4]` (default) | two-element vector

Beginning and ending *x*-coordinates for the arrow, specified as a two-element vector of the form `[x_begin x_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.3]`

`Y` — Beginning and ending y-coordinates

`[0.3 0.4]` (default) | two-element vector

Beginning and ending *y*-coordinates for the arrow, specified as a two-element vector of the form `[y_begin y_end]`.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.3]`

`Position` — Size and location

`[0.3 0.3 0.1 0.1]` (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x_begin y_begin length height]`. The first two elements specify the coordinates of the beginning of the arrow. The second two elements specify the length and height of the arrow. The text box extends from the beginning of the arrow.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Example: `[0.2 0.2 0.3 0.1]`

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

`Units`	Description
`'normalized'` (default)	Normalized with respect to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the figure window.

This property affects the Position property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume Units is set to the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the annotation text arrow, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

`HorizontalAlignment` — Horizontal alignment of text

`'left'` (default) | `'center'` | `'right'`

Horizontal alignment of the text, specified as one of the values in this table. This property is useful when aligning multiple lines of text.

Value	Result
`'left'`	`'center'`	`'right'`	

`VerticalAlignment` — Vertical alignment of text with respect to arrow

`'top'` (default) | `'cap'` | `'middle'` | `'baseline'` | `'bottom'`

Vertical alignment of the text with respect to the end of the arrow, specified as `'top'`, `'cap'`, `'middle'`, `'baseline'`, or `'bottom'`.

Annotation Text Box Properties

Control annotation text box appearance and behavior

Annotation text box properties control the appearance and behavior of an annotation text box object. By changing property values, you can modify certain aspects of the text box.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = annotation('textbox');
s = h.FontSize;
h.FontSize = 12;
```

If you are using an earlier release, use the `get` and `set` functions instead.

Text

`String` — Text to display

`''` (default) | character array | cell array | numeric value

Text to display, specified as a character array, cell array, or numeric value.

Example: `'my label'`

Example: `{'first line','second line'}`

Example: `123`

To include numeric variables with text, use the `num2str` function. For example:

```
x = 42;
str = ['The value is ',num2str(x)];
```

To include special characters, such as superscripts, subscripts, Greek letters, or mathematical symbols use TeX markup. For a list of supported markup, see the Interpreter property.

To create multiline text:

- Use a cell array, where each cell contains a line of text, such as `{'first line','second line'}`.
- Use a character array, where each row contains the same number of characters, such as `['abc'; 'ab ']`.

- Use `sprintf` to create a string with a new line character, such as `sprintf('first line \n second line')`. This property converts strings with new line characters to cell arrays.

Text that contains only a numeric value is converted to a string using `sprintf('%g',value)`. For example, `12345678` displays as `1.23457e+07`.

Note: The words `default`, `factory`, and `remove` are reserved words that will not appear in text when quoted as a normal string. To display any of these words individually, precede them with a backslash, such as `'\default'` or `'\remove'`.

`Interpreter` — Interpretation of text characters

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of text characters, specified as one of these values:

- `'tex'` — Interpret text strings using a subset of TeX markup. This is the default value.
- `'latex'` — Interpret text strings using LaTeX markup.
- `'none'` — Display literal characters.

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `Interpreter` property is set to `'tex'`. Modifiers remain in effect until the end of the string, except for superscripts and subscripts, which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`

Modifier	Description	Example of String
`\sl`	Oblique font (usually the same as italic font)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Font name — Set `specifier` as the name of a font family. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Font size — Set `specifier` as a numeric scalar value in point units to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Font color — Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Custom font color — Set `specifier` as a three-element RGB triplet.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
`\alpha`	α	`\upsilon`	υ	`\sim`	~
`\angle`	∠	`\phi`	Φ	`\leq`	≤
`\ast`	*	`\chi`	χ	`\infty`	∞
`\beta`	ß	`\psi`	ψ	`\clubsuit`	♣
`\gamma`	γ	`\omega`	ω	`\diamondsui`	♦
`\delta`	δ	`\Gamma`	Γ	`\heartsuit`	♥

LaTeX Markup

To use LaTeX markup, set the `Interpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The `FontName`, `FontWeight`, and `FontAngle` properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

Font Style

`Color` — Text color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`

Long Name	Short Name	RGB Triplet
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

FontAngle — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

Note: The 'oblique' value has been removed. Use 'italic' instead.

FontName — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

FontSize — Font size

10 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the FontUnits property.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

`FontUnits` — Font size units

`'points'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'normalized'` | `'pixels'`

Font size units, specified as one of the values in this table.

Units	Description
`'points'`	Points. One point equals 1/72 inch.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'normalized'`	Interpreted as a fraction of the axes height. If you resize the axes, MATLAB modifies the font size accordingly. For example, if the `FontSize` is `0.1` in normalized units, then the text is 1/10 of the axes height.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

If you set both the font size and the font units in one function call, you must set the FontUnits property first so that the axes correctly interprets the specified font size.

`FontWeight` — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

Text Box

`LineStyle` — Line style of box outline

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style of box outline, specified as one of the strings listed in this table.

String	Line Style
`'-'`	Solid line
`'--'`	Dashed line
`':'`	Dotted line
`'-.'`	Dash-dotted line
`'none'`	Box outline is invisible

`LineWidth` — Width of box outline

`0.5` (default) | scalar numeric value

Width of box outline, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: `1.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`EdgeColor` — Color of box outline

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Color of box outline, specified as a three-element RGB triplet, a color string, or `'none'`. The default RGB triplet value of `[0 0 0]` corresponds to black. If you set the color to `'none'`, then the box outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

`[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`BackgroundColor` — Color of text box background

`'none'` (default) | RGB triplet | color string

Color of text box background, specified as `'none'`, a three-element RGB triplet, or a color string. If you set the background color to `'none'`, then the background is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`

Long Name	Short Name	RGB Triplet
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

FaceAlpha — Transparency of background color

1 (default) | scalar value between 0 and 1 inclusive

Transparency of the background color, specified as a scalar value between 0 and 1. If the value is 1, then the color is opaque. To add transparency, set the property to a value closer to 0, where 0 is completely transparent.

FitBoxToText — Option to fit box width and height to text

'on' (default) | 'off'

Option to fit the box width and height to the text, specified as one of these values:

- 'on' — Resize the text box to fit the text.
- 'off' — Wrap the text strings to fit the width of the text box. Wrapping can cause some of the text string to extend below the text box.

If you resize a text box when in plot edit mode, or if you change the Position property, then the FitBoxToText property changes to 'off'.

Margin — Space around text within the text box

5 (default) | scalar numeric value

The space around the text within the text box, specified as a scalar numeric value in pixel units.

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

Location and Size

Position — Size and location

[0.3 0.3 0.1 0.1] (default) | four-element vector

Size and location, specified as a four-element vector of the form `[x_begin y_begin length height]`. The first two elements specify the coordinates for the lower-left corner of the text box. The second two elements specify the length and height of the text box.

By default, the units are normalized to the figure. The lower-left corner of the figure maps to `(0,0)`, and the upper-right corner maps to `(1,1)`. To change the units, use the `Units` property.

Note: If the `FitBoxToText` property is set to `'on'` and you change the `String` property, then the `Position` property might not reflect the latest changes until the next time the screen refreshes. To ensure that the position value reflects the latest changes, call `drawnow` before querying the position when working in a script or function.

Example: `[0.2 0.3 0.4 0.5]`

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

`Units`	Description
`'normalized'` (default)	Normalized with respect to the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the figure window.

This property affects the Position property. If you change the units, then it is good practice to return it to the default value after completing your computation to prevent affecting other functions that assume Units is set to the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the annotation text box, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

`HorizontalAlignment` — Horizontal alignment of text within text box

`'left'` (default) | `'center'` | `'right'`

Horizontal alignment of the text within the text box, specified as one of the values in this table.

Value	Result
`'left'`	
`'center'`	
`'right'`	

`VerticalAlignment` — Vertical alignment of text within text box

`'top'` (default) | `'middle'` | `'bottom'` | `'baseline'` | `'cap'`

Vertical alignment of the text within the text box, specified as one of the values in this table.

Value	Result
`'top'` or `'cap'`	

Value	Result
`'middle'`	
`'bottom'` or `'baseline'`

ans

Most recent answer

Syntax

```
ans
```

Description

The MATLAB software creates the `ans` variable automatically when you specify no output argument.

Examples

The statement

```
2+2
```

is the same as

```
ans = 2+2
```

`display`

Introduced before R2006a

any

Determine if any array elements are nonzero

Syntax

```
B = any(A)
B = any(A,dim)
```

Description

`B = any(A)` tests along the first array dimension of `A` whose size does not equal 1, and determines if any element is a nonzero number or logical `1` (`true`). In practice, `any` is a natural extension of the logical OR operator.

- If `A` is a vector, then `B = any(A)` returns logical `1` (`true`) if any of the elements of `A` is a nonzero number or is logical `1`, and returns logical `0` (`false`) if all the elements are zero.
- If `A` is a nonempty, nonvector matrix, then `B = any(A)` treats the columns of `A` as vectors, returning a row vector of logical `1`s and `0`s.
- If `A` is an empty 0-by-0 matrix, `any(A)` returns logical `0` (`false`).
- If `A` is a multidimensional array, `any(A)` acts along the first array dimension whose size does not equal 1 and returns an array of logical values. The size of this dimension becomes `1`, while the sizes of all other dimensions remain the same.

`B = any(A,dim)` tests elements along dimension `dim`. The dim input is a positive integer scalar.

Examples

Test Matrix Columns

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]
```

```
A =

     0     0     3
     0     0     3
     0     0     3
```

Test each column for nonzero elements.

```
B = any(A)

B =

     0     0     1
```

Reduce a Logical Vector to a Single Condition

Create a vector of decimal values and test which values are less than 0.5.

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69];
B = (A < 0.5)

B =

0   0   1   1   1   1   0
```

The output is a vector of logical values. The `any` function reduces such a vector of logical values to a single condition. In this case, `B = any(A < 0.5)` yields logical `1`.

This makes `any` particularly useful in `if` statements.

```
if any(A < 0.5)
    %do something
else
    %do something else
end
```

The code is executed depending on a single condition, rather than a vector of possibly conflicting conditions.

Test Arrays of Any Dimension

Create a 3-by-7-by-5 multidimensional array and test to see if any of its elements are greater than 3.

```
A = rand(3,7,5) * 5;
```

```
B = any(A(:) > 3)

B =

     1
```

You can also test the array for elements that are less than zero.

```
B = any(A(:) < 0)

B =

     0
```

The syntax `A(:)` turns the elements of `A` into a single column vector, so you can use this type of statement on an array of any size.

Test Matrix Rows

Create a 3-by-3 matrix.

```
A = [0 0 3;0 0 3;0 0 3]

A =

     0     0     3
     0     0     3
     0     0     3
```

Test the rows of `A` for nonzero elements by specifying `dim = 2`.

```
B = any(A,2)

B =

     1
     1
     1
```

Input Arguments

A — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. The `any` function ignores elements of `A` that are `NaN` (Not a Number).

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

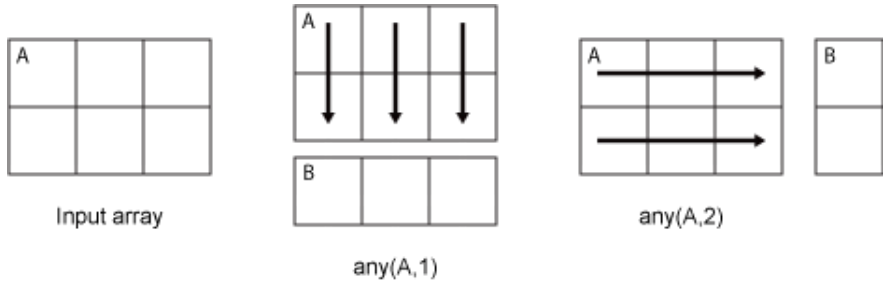
`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`:

- `any(A,1)` works on successive elements in the columns of `A` and returns a row vector of logical values.
- `any(A,2)` works on successive elements in the rows of `A` and returns a column vector of logical values.



Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`B` — Logical array

scalar | vector | matrix | multidimensional array

Logical array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of `A` acted on by `any` has size `1` in `B`.

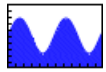
Introduced before R2006a

area

Filled area 2-D plot



Syntax

```
area(Y)
area(X,Y)
area(...,basevalue)
area(...,'PropertyName',PropertyValue,...)
area(axes_handle,...)
h = area(...)
```

Description

An area graph displays elements in `Y` as one or more curves and fills the area beneath each curve. When `Y` is a matrix, the curves are stacked showing the relative contribution of each row element to the total height of the curve at each x interval.

`area(Y)` plots the vector `Y` or plots each column in matrix `Y` as a separate curve and stacks the curves. The *x*-axis automatically scales to `1:size(Y,1)`.

`area(X,Y)` For vectors `X` and `Y`, `area(X,Y)` is the same as `plot(X,Y)` except that the area between `0` and `Y` is filled. When `Y` is a matrix, `area(X,Y)` plots the columns of `Y` as filled areas. For each `X`, the net result is the sum of corresponding values from the rows of `Y`.

If `X` is a vector, `length(X)` must equal `length(Y)`. If `X` is a matrix, `size(X)` must equal `size(Y)`.

`area(...,basevalue)` specifies the base value for the area fill. The default `basevalue` is `0`.

`area(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the patch graphics object created by `area`.

`area(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = area(...)` returns handles of `area` graphics objects.

Creating an area graph of an *m*-by-*n* matrix creates *n* area objects (that is, one per column), whereas a 1-by-*n* vector creates one area object.

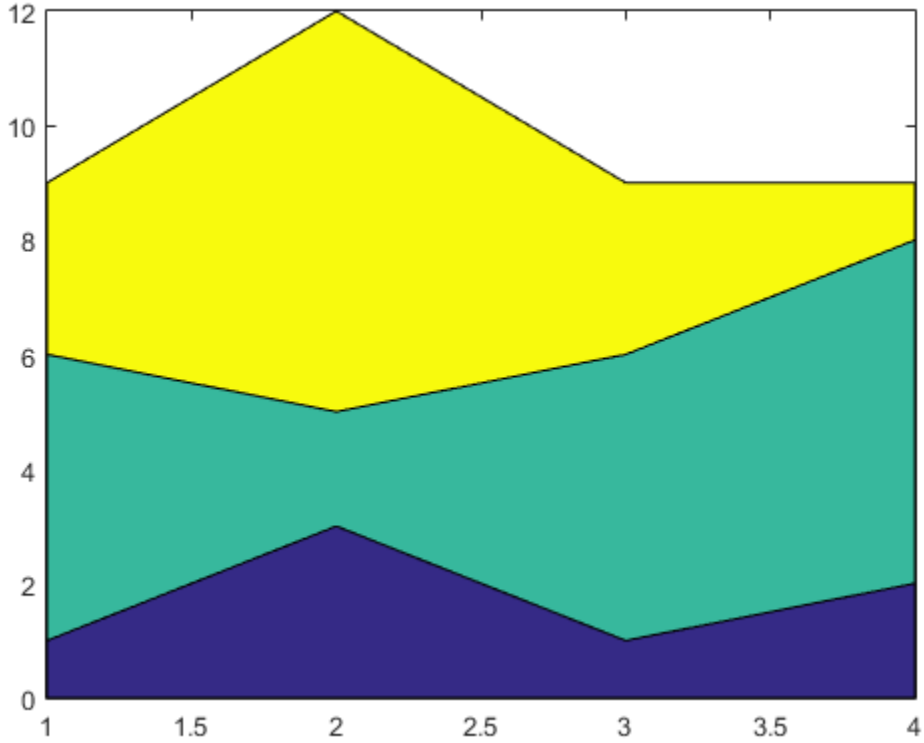
Some area object properties that you set on an individual area object set the values for all area objects in the graph. See Area Properties for information on specific properties.

Examples

Create Area Graph

Plot the data in matrix Y as an area graph.

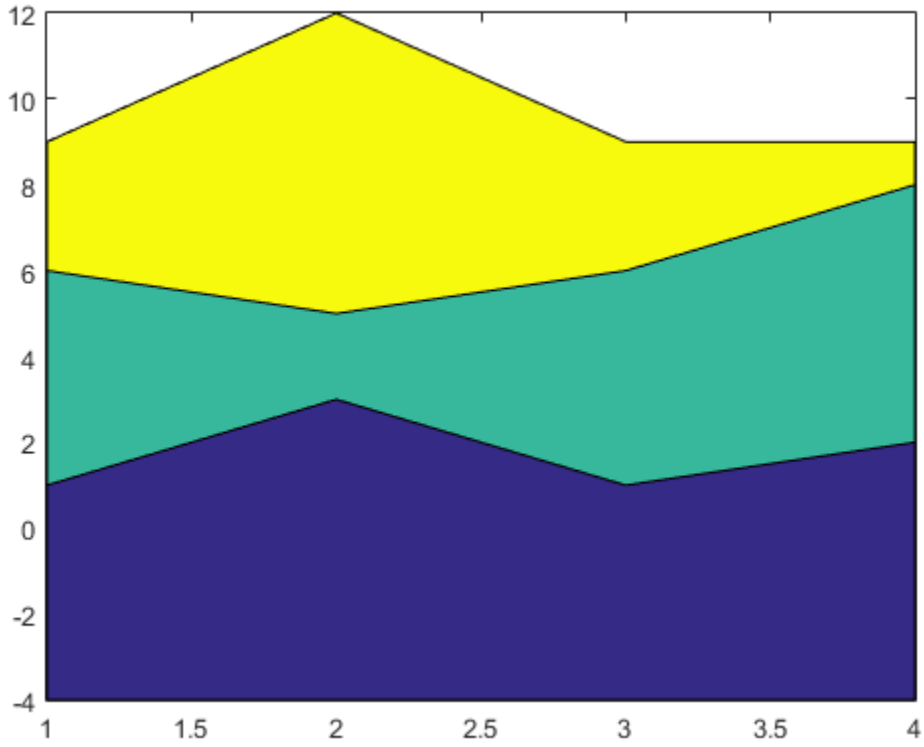
```
Y = [1, 5, 3;
     3, 2, 7;
     1, 5, 3;
     2, 6, 1];
figure
area(Y)
```



Adjust Base Value of Area Graph

By default, `area` uses the *y*-axis as the base value. Change the base value by setting the `basevalue` input argument to -4.

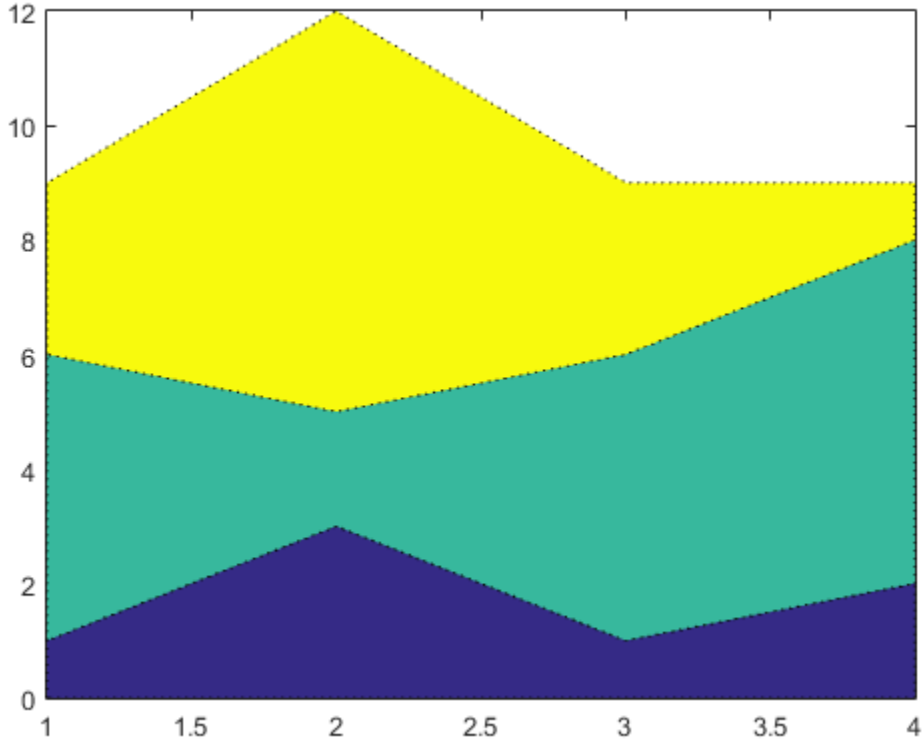
```
Y = [1, 5, 3;
     3, 2, 7;
     1, 5, 3;
     2, 6, 1];
figure
basevalue = -4;
area(Y,basevalue)
```



Specify Color and Line Style for Area Plot

Create an area plot of `Y` and use a dotted line style. Return the three area objects in array `h`. The `area` function creates one area object for each column in `Y`.

```
Y = [1, 5, 3;
     3, 2, 7;
     1, 5, 3;
     2, 6, 1];
h = area(Y,'LineStyle',':');
```



Change the area colors using RGB triplet color values. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
h(1).FaceColor = [0 0.25 0.25];
h(2).FaceColor = [0 0.5 0.5];
h(3).FaceColor = [0 0.75 0.75];
```

`bar` | `plot` | `sort`

Properties
Area Properties

Introduced before R2006a

Area Properties

Control area appearance and behavior

Area properties control the appearance and behavior of an area object. By changing property values, you can modify certain aspects of the area.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = area(1:10);
c = h.EdgeColor;
h.EdgeColor = 'red';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`EdgeColor` — Area outline color

`[0 0 0]` (default) | RGB triplet | color string | `'none'` | `'flat'`

Area outline color, specified as one of these values:

- `'none'` — Do not draw the outline.
- `'flat'` — Use colors from the axes colormap.
- RGB triplet or a color string — Specify a custom color. The default RGB triplet value of `[0 0 0]` corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

Example: 'blue'

Example: [0 0 1]

FaceColor — Area fill color

'flat' (default) | 'none' | RGB triplet | color string

Area fill color, specified as one of these values:

- 'flat' — Use colors from the axes colormap.
- 'none' — Do not use any color for the fill, which allows the background to show through.
- RGB triplet or a color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0,1], for example, [0.4 0.6 0.7]. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]

Long Name	Short Name	RGB Triplet
'black	'k'	[0 0 0]

LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	————
'--'	Dashed line	- - - - -
':'	Dotted line	.....
'-.'	Dash-dotted line	—·—·—·—
'none'	No line	No line

LineWidth — Area outline width

0.5 (default) | scalar numeric value

Area outline width, specified as a scalar numeric value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

AlignVertexCenters — Sharp vertical and horizontal lines

'off' (default) | 'on'

Sharp vertical and horizontal lines, specified as 'off' or 'on'.

If the associated figure has a GraphicsSmoothing property set to 'on' and a Renderer property set to 'opengl', then the figure applies a smoothing technique to plots. In some cases, this smoothing technique can cause vertical and horizontal lines to appear uneven in thickness or color. Use the AlignVertexCenters property to eliminate the uneven appearance.

- `'off'` — Do not sharpen vertical or horizontal lines. The lines might appear uneven in thickness or color.
- `'on'` — Sharpen vertical and horizontal lines to eliminate an uneven appearance.

Note: You must have a graphics card that supports this feature. To see if the feature is supported, type `opengl info`. If it is supported, then the returned fields contain the line `SupportsAlignVertexCenters: 1`.

Baseline

`BaseLine` — Baseline

baseline object

Baseline object. For a list of baseline properties, see Baseline Properties.

`BaseValue` — Baseline location

`0` (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

`ShowBaseLine` — Baseline visibility

`'on'` (default) | `'off'`

Baseline visibility, specified as one of these values:

- `'on'` — Show the baseline.
- `'off'` — Hide the baseline.

Data

`XData` — Values along x-axis

`[ ]` (default) | vector

Values along *x*-axis, specified as a vector. The input argument `X` to the `area` function determines the *x*-values. If you do not specify `X`, then `area` uses the indices of the values in `YData` to set the *x*-values. `XData` and `YData` must have equal lengths.

Setting this property sets the associate mode property XDataMode to manual.

Example: `1:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`YData` — Values along y-axis

`[ ]` (default) | vector

Values along *y*-axis, specified as a vector. The input argument `Y` to the `area` function determines the *y*-values. `XData` and `YData` must have equal lengths.

Example: `1:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`XDataSource` — Variable linked to `XData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`XDataMode` — Selection mode for `XData`

`'auto'` (default) | `'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the indices of the values in `YData`.
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or pass the input argument `X` to the `area` function.

Visibility

`Visible` — Visibility of area

`'on'` (default) | `'off'`

Visibility of area, specified as one of these values:

- `'on'` — Display the area.
- `'off'` — Hide the area without deleting it. You still can access the properties of an invisible area object.

`Clipping` — Clipping of area to axes limits

`'on'` (default) | `'off'`

Clipping of area to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the area that are outside the axes limits.
- `'off'` — Display the entire area, even if parts of it appear outside the axes limits. Parts of the area might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the area that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'area'`

Type of graphics object, returned as `'area'`. Use this property to find all objects of a given type within a plotting hierarchy, for example, searching for the type using `findobj`.

`Tag` — Tag to associate with area

`''` (default) | string

Tag to associate with the area, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: `char`

`UserData` — Data to associate with area

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the area object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the area.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form

`'dataN'`, where `N` is the number assigned to the area object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the area from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the area object in the legend as one entry (default).
   - `'off'` — Do not include the area object in the legend.
   - `'children'` — Include only children of the area object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of area

axes object | group object | transform object

Parent of area, specified as an axes, group, or transform object.

`Children` — Children of area

empty `GraphicsPlaceholder` array

The area has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of area object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The area object handle is always visible.
- `'off'` — The area object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The area object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the area at the command-line, but allows callback functions to access it.

If the area object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the area. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The area object — You can access properties of the area object from within the callback function.

- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the area. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the area when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the area.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.

- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The Visible property must be set to `'on'`. The HitTest property determines if the area responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the area passes the click to the object below it in the current view of the figure window. The HitTest property of the area has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the area. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the area that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the area object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for area

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for area, specified as one of these values:

- `'off'` — Click the area plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the area plot to select it, that is, anywhere within the rectangle that encloses the area plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the area is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the area tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the area. Setting the `CreateFcn` property on an existing area has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during area creation. MATLAB executes the callback after creating the area and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The area object — You can access properties of the area object from within the callback function. You also can access the area object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the area. MATLAB executes the callback before destroying the area so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The area object — You can access properties of the area object from within the callback function. You also can access the area object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of area

`'off'` (default) | `'on'`

Deletion status of area, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the area begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the area no longer exists.

Check the value of the BeingDeleted property to verify that the area is not about to be deleted before querying or modifying it.

array2table

Convert homogeneous array to table

Syntax

```
T = array2table(A)
T = array2table(A,Name,Value)
```

Description

`T = array2table(A)` converts the `m`-by-`n` array, `A`, to an `m`-by-`n` table, `T`. Each column of `A` becomes a variable in `T`.

`array2table` uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, `array2table` uses strings of the form `'Var1',...,'VarN'`, where *N* is the number of columns in `A`.

`T = array2table(A,Name,Value)` creates a table from an array, `A`, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify row names or variable names to include in the table.

Examples

Convert Numeric Array to Table

Create an array of numeric data.

```
A = [1 4 7; 2 5 8; 3 6 9]
```

```
A =

     1     4     7
     2     5     8
```

```
     3     6     9
```

Convert the array, A, to a table.

```
T = array2table(A)
```

```
T =

    A1    A2    A3
    __    __    __

    1     4     7
    2     5     8
    3     6     9
```

The table has variable names that append the column number to the input array name, A.

Convert Array to Table Including Variable Names

Create an array of numeric data.

```
A = [1 12 30.48; 2 24 60.96; 3 36 91.44]
```

```
A =

    1.0000   12.0000   30.4800
    2.0000   24.0000   60.9600
    3.0000   36.0000   91.4400
```

Convert the array, A, to a table and include variable names.

```
T = array2table(A,...
    'VariableNames',{'Feet' 'Inches' 'Centimeters'})
```

```
T =

    Feet    Inches    Centimeters
    ____    ______    ___________

    1       12        30.48
    2       24        60.96
    3       36        91.44
```

- “Access Data in a Table”

Input Arguments

A — Input array

matrix

Input array, specified as a matrix.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell`
Complex Number Support: Yes

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'RowNames',{'row1','row2','row3'}` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

'RowNames' — Row names for T

`{}` (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(A,1)`.

'VariableNames' — Variable names for T

cell array of nonempty, distinct strings

Variable names for `T`, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(A,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of *N* strings of the form `{'Var1' ... 'Var`*N*`'}` where *N* is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

Output Arguments

T — Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

More About

Tips

- If `A` is a cell array, use `cell2table(A)` to create a table from the contents of the cells in `A`. Each variable in the table is numeric or a cell array of strings. `array2table(A)` creates a table where each variable is a column of cells.

arrayfun

Apply function to each element of array

Syntax

```
[B1,...,Bm] = arrayfun(func,A1,...,An)
[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)
```

Description

`[B1,...,Bm] = arrayfun(func,A1,...,An)` calls the function specified by function handle `func` and passes elements from arrays `A1,...,An`, where `n` is the number of inputs to function `func`. Output arrays `B1,...,Bm`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax `[B1(i),...,Bm(i)] = func(A1(i),...,An(i))`. The `arrayfun` function does not perform the calls to function `func` in a specific order.

`[B1,...,Bm] = arrayfun(func,A1,...,An,Name,Value)` calls function `func` with additional options specified by one or more Name,Value pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

Input Arguments

`func`

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

`A1,...,An`

Arrays that contain the `n` inputs required for function `func`. Each array must have the same dimensions. Arrays can be numeric, character, logical, cell, structure, or user-defined object arrays.

If any input `A` is a user-defined object array, and you overloaded the `subsref` or `size` methods, `arrayfun` requires that:

- The `size` method returns an array of type `double`.
- The object array supports linear indexing.
- The product of the sizes returned by the `size` method does not exceed the limit of the array, as defined by linear indexing into the array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'UniformOutput'`

Logical value, as follows:

`true (1)`	Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type and size. The `arrayfun` function combines the outputs in arrays `B1,...,Bm`, where `m` is the number of function outputs. Each output array is of the same type as the individual function outputs.
`false (0)`	Requests that the `arrayfun` function combine the outputs into cell arrays `B1,...,Bm`. The outputs of function `func` can be of any size or type.

Default: `true`

`'ErrorHandler'`

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

`identifier`	Error identifier.

`message`	Error message text.
`index`	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments

`B1,...,Bm`

Arrays that collect the `m` outputs from function `func`. Each array `B` is the same size as each of the inputs `A1,...,An`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

Examples

To run the examples in this section, create a nonscalar structure array with arrays of different sizes in field `f1`.

```
s(1).f1 = rand(3, 6);
s(2).f1 = magic(12);
s(3).f1 = ones(5, 10);
```

Count the number of elements in each `f1` field.

```
counts = arrayfun(@(x) numel(x.f1), s)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
counts =
    18   144    50
```

Compute the size of each array in the `f1` fields.

```
[nrows, ncols] = arrayfun(@(x) size(x.f1), s)
```

This code returns

```
nrows =
     3    12     5
ncols =
     6    12    10
```

Compute the mean of each column in the `f1` fields of `s`. Because the output is nonscalar, set `UniformOutput` to `false`.

```
averages = arrayfun(@(x) mean(x.f1), s, 'UniformOutput', false)
```

This code returns

```
averages =
    [1x6 double]    [1x12 double]    [1x10 double]
```

Create additional nonscalar structures `t` and `u`, and test for equality between the arrays in fields `f1` across structures `s`, `t`, and `u`.

```
t = s;  t(1).f1(:)=0;
u = s;  u(2).f1(:)=0;

same = arrayfun(@(x,y,z) isequal(x.f1, y.f1, z.f1), s, t, u)
```

This code returns

```
same =
     0     0     1
```

Introduced before R2006a

ascii

Class: FTP

Set FTP transfer type to ASCII

Syntax

```
ascii(ftpobj)
```

Description

`ascii(ftpobj)` sets the download and upload FTP mode to ASCII, which converts new line characters. Use this method only for text files, including HTML pages and Rich Text Format (RTF) files.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

Examples

Connect to the MathWorks FTP server, and switch from binary (default) to ASCII mode:

```
mw=ftp('ftp.mathworks.com');
ascii(mw)
```

See Also

`binary` | `ftp`

Introduced before R2006a

asec

Inverse secant in radians

Syntax

```
Y = asec(X)
```

Description

`Y = asec(X)` returns the "Inverse Secant" on page 1-456 ($\sec^{-1}$) of the elements of X. The `asec` function operates element-wise on arrays. For real elements of X in the interval `[-Inf,-1]` and `[1,Inf]`, `asec` returns values in the interval `[0,pi]`. For real values of X in the interval `[-1,1]` and for complex values of X, `asec` returns complex values. All angles are in radians.

Examples

Inverse Secant of a Value

```
asec(-2.8)
```

```
ans =
    1.9360
```

Inverse Secant of a Vector of Complex Values

Find the inverse secant of the elements of vector `x`. The `asec` function acts on `x` element-wise.

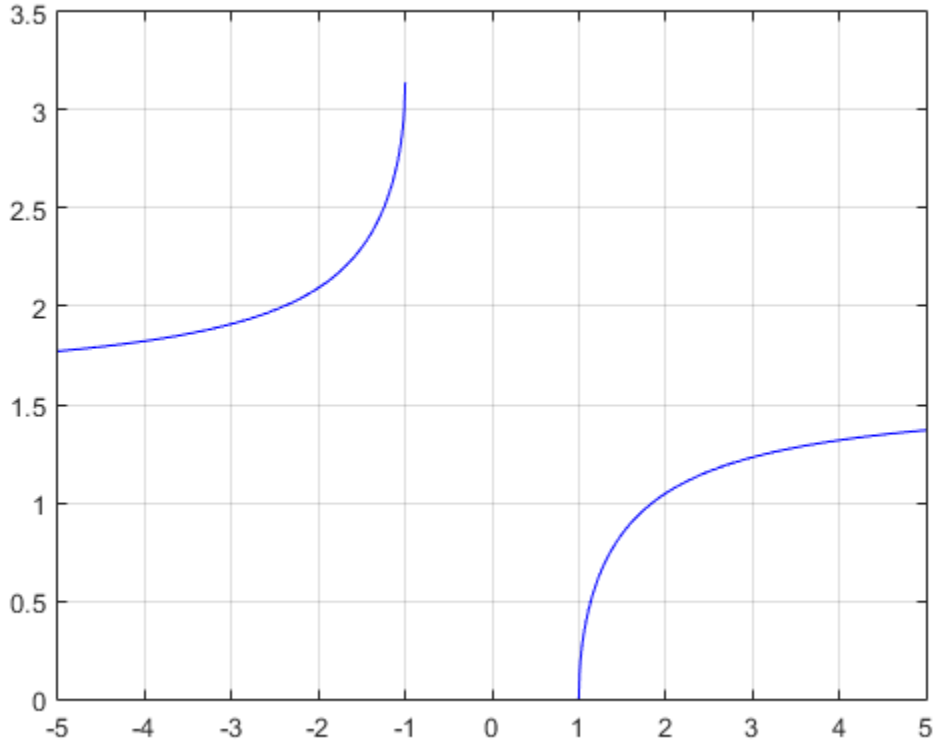
```
x = [0.5i 1+3i -2.2+i];
Y = asec(x)
```

```
Y =
   1.5708 + 1.4436i   1.4749 + 0.2970i   1.9503 + 0.1833i
```

Plot the Inverse Secant Function

Plot the inverse secant function over the intervals $-5 \le x \le -1$ and $1 \le x \le 5$.

```
x1 = -5:0.01:-1;
x2 = 1:0.01:5;
plot(x1,asec(x1),'b')
hold on
plot(x2,asec(x2),'b')
grid on
```



Input Arguments

X — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

More About

Inverse Secant

The inverse secant is defined as

$$\sec^{-1}(z) = \cos^{-1}\left(\frac{1}{z}\right).$$

See Also

`asecd` | `asech` | `sec`

Introduced before R2006a

asecd

Inverse secant in degrees

Syntax

```
Y = asecd(X)
```

Description

`Y = asecd(X)` returns the inverse secant ($\sec^{-1}$) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain [-Inf,1] and [1,Inf], `asecd` returns values in the range [0, 180]. For values of X outside this range, `asecd` returns complex values.

Examples

Inverse Secant of Vector

```
x = [10 1 Inf];
y = asecd(x)
```

```
y =

   84.2608         0   90.0000
```

The `asecd` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Secant of Complex Value

```
asecd(1+i)
```

```
ans =
```

```
64.0864 +30.4033i
```

Input Arguments

X — Secant of angle

scalar value | vector | matrix | N-D array

Secant of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `asecd` operation is element-wise when X is non-scalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.

See Also

`asec` | `sec` | `secd`

Introduced before R2006a

asech

Inverse hyperbolic secant

Syntax

```
Y = asech(X)
```

Description

`Y = asech(X)` returns the inverse hyperbolic secant for each element of `X`.

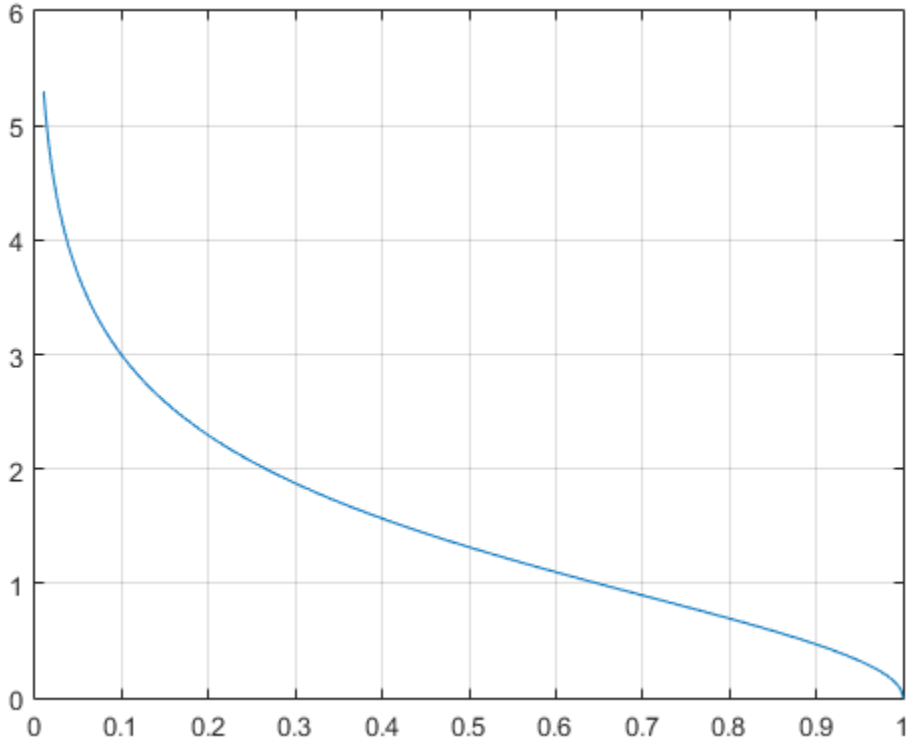
The `asech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Secant Function

Graph the inverse hyperbolic secant over the domain $0.01 \le x \le 1$.

```
x = 0.01:0.001:1;
plot(x,asech(x)), grid on
```



More About

Inverse Hyperbolic Secant

The inverse hyperbolic secant can be defined as

$$\operatorname{sech}^{-1}(z) = \cosh^{-1}\left(\frac{1}{z}\right).$$

See Also

`asec` | `sech` | `asinh` | `acosh`

Introduced before R2006a

asin

Inverse sine in radians

Syntax

```
y = asin(x)
```

Description

`y = asin(x)` returns the "Inverse Sine" on page 1-463 ($\sin^{-1}$) of the elements of `x`. The `asin` function operates element-wise on arrays. For real elements of `x` in the interval `[-1,1]`, `asin(x)` returns values in the interval `[-pi/2,pi/2]`. For real elements of `x` outside the interval `[-1,1]` and for complex values of `x`, `asin(x)` returns complex values. All angles are in radians.

Examples

Inverse Sine of a Value

```
asin(0.5)
```

```
ans =
    0.5236
```

Inverse Sine of a Vector of Complex Values

Find the inverse sine of the elements of vector `x`. The `asin` function acts on `x` element-wise.

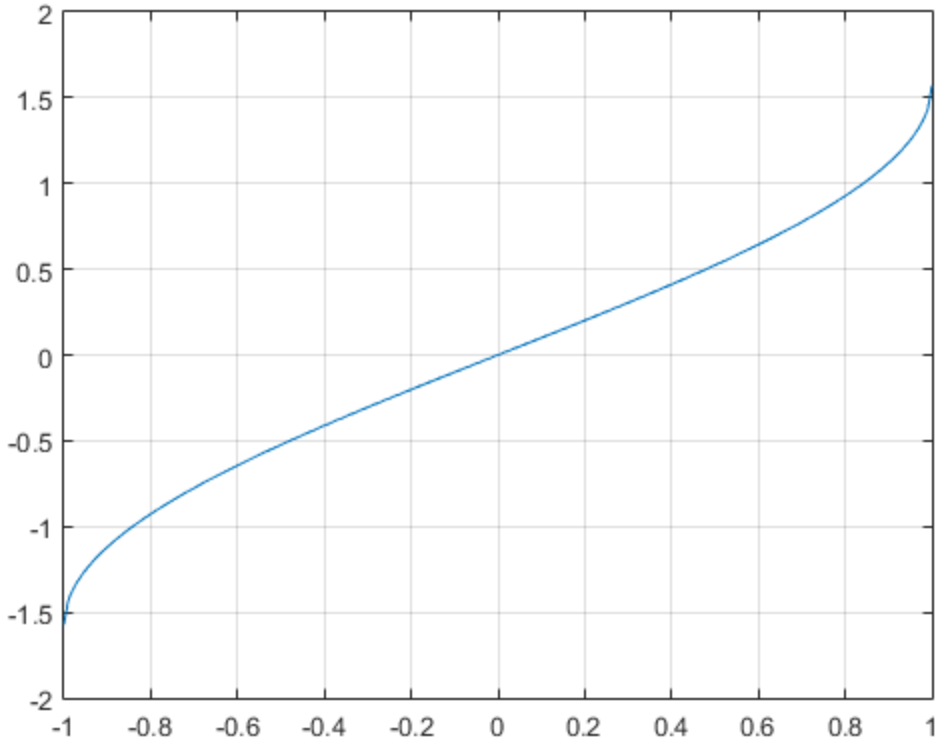
```
x = [0.5i 1+3i -2.2+i];
y = asin(x)
```

```
y =
   0.0000 + 0.4812i   0.3076 + 1.8642i  -1.1091 + 1.5480i
```

Graph of the Inverse Sine Function

Graph the inverse sine over the domain $-1 \le x \le 1$.

```
x = -1:.01:1;
plot(x,asin(x))
grid on
```



More About

Inverse Sine

The inverse sine is defined as

$$\sin^{-1}(z) = -i\log\left[iz + (1 - z^2)^{1/2}\right].$$

See Also

`asind` | `sin` | `sind`

Introduced before R2006a

asind

Inverse sine in degrees

Syntax

```
Y = asind(X)
```

Description

`Y = asind(X)` returns the inverse sine ($\sin^{-1}$) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain [-1,1], `asind` returns values in the range [-90,90]. For values of X outside this range, `asind` returns complex values.

Examples

Inverse Sine of Scalar

Show that the inverse sine of 1 is exactly 90°.

```
asind(1)
```

```
ans =

    90
```

Round-Trip Calculation for Complex Angles

Show that the inverse sine, followed by sine, returns the original values of X.

```
sind(asind([2 3]))
```

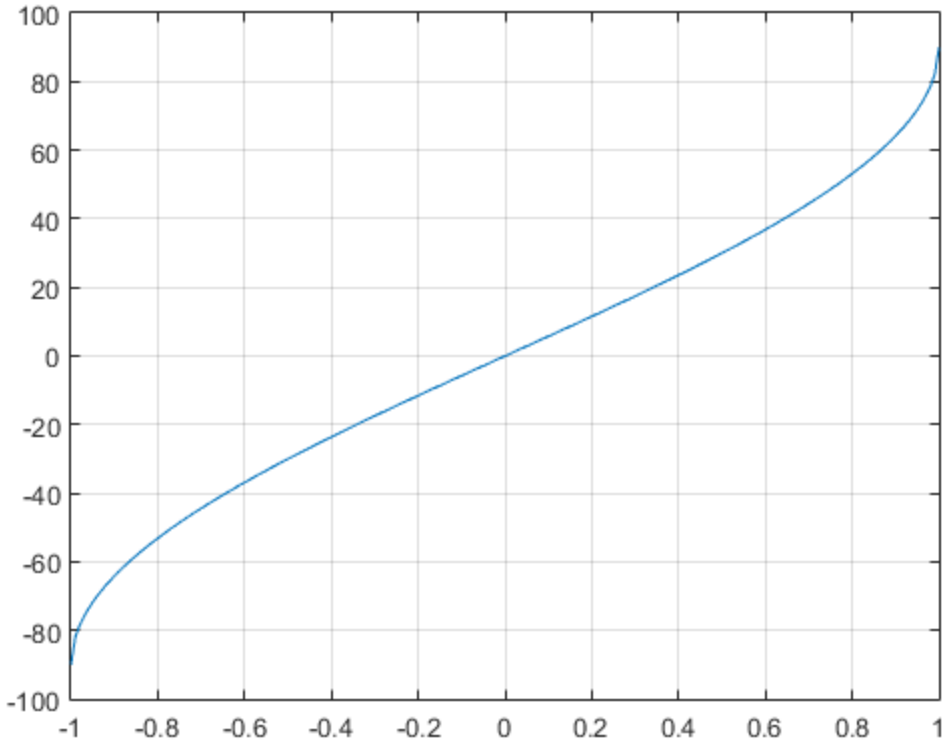
```
ans =

    2.0000    3.0000
```

Graph of Inverse Sine Function

Plot the inverse sine function over the domain $-1 \le x \le 1$.

```
x = -1:.01:1;
plot(x,asind(x))
grid on
```



Input Arguments

X — Sine of angle

scalar value | vector | matrix | N-D array

Sine of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `asind` operation is element-wise when X is nonscalar.

Data Types: `single` | `double`

Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.

See Also

`asin` | `sin` | `sind`

Introduced before R2006a

asinh

Inverse hyperbolic sine

Syntax

```
Y = asinh(X)
```

Description

`Y = asinh(X)` returns the inverse hyperbolic sine for each element of `X`.

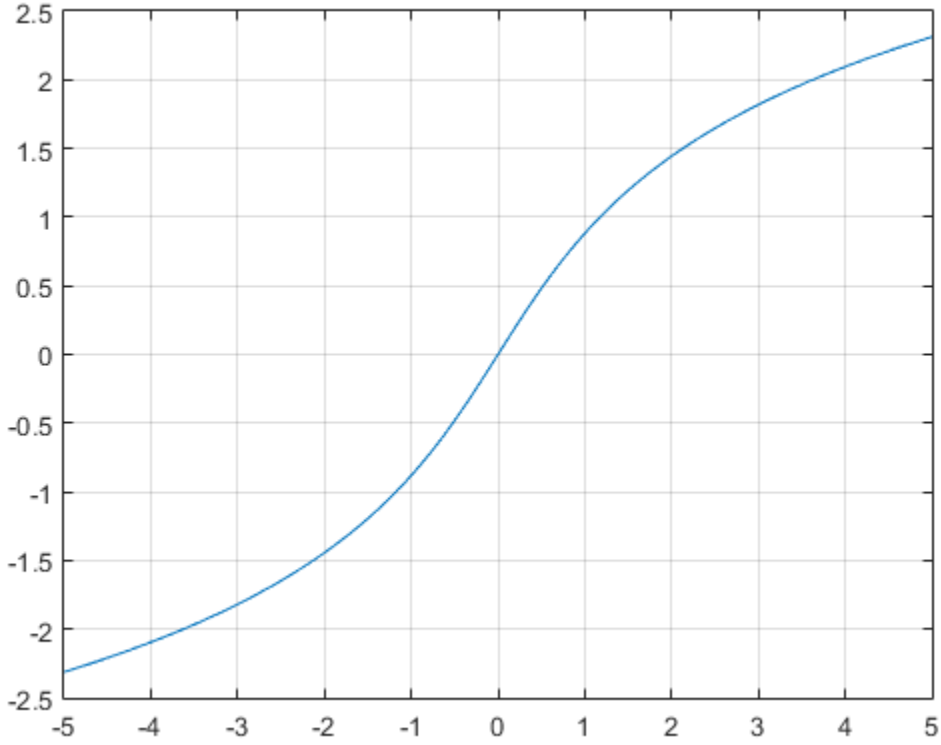
The `asinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph of Inverse Hyperbolic Sine Function

Graph the inverse hyperbolic sine over the domain $-5 \le x \le 5$.

```
x = -5:.01:5;
plot(x,asinh(x)), grid on
```



More About

Inverse Hyperbolic Sine

The inverse hyperbolic sine can be defined as

$$\sinh^{-1}(z) = \log\left[z + (z^2 + 1)^{1/2}\right].$$

See Also

`asin` | `sinh` | `acosh`

Introduced before R2006a

assert

Throw error if condition false

Syntax

```
assert(cond)

assert(cond,msg)
assert(cond,msg,A1,...,An)

assert(cond,msgID,msg)
assert(cond,msgID,msg,A1,...,An)
```

Description

`assert(cond)` throws an error if `cond` is false.

`assert(cond,msg)` throws an error and displays the error message, `msg`, if `cond` is false.

`assert(cond,msg,A1,...,An)` displays an error message that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function, if `cond` is false. Each conversion character in `msg` is converted to one of the values `A1,...,An`.

`assert(cond,msgID,msg)` throws an error, displays the error message, msg, and includes an error identifier on the exception, if `cond` is false. The identifier enables you to distinguish errors and to control what happens when MATLAB encounters the errors.

`assert(cond,msgID,msg,A1,...,An)` includes an error identifier on the exception and displays a formatted error message.

Examples

Value in Expected Range

Assert that the value, `x`, is greater than a specified minimum value.

```
minVal = 7;
x = 26;

assert(minVal < x)
```

The expression evaluates as true, and the assertion passes.

Assert that the value of `x` is between the specified minimum and maximum values.

```
maxVal = 13;

assert((minVal < x) && (x < maxVal))
```

```
Assertion failed.
```

The expression evaluates as false. The assertion fails and MATLAB throws an error.

Expected Data Type

Assert that the product of two numbers is a double-precision number.

```
a = 13;
b = single(42);
c = a*b;

assert(isa(c,'double'),'Product is not type double.')
```

```
Product is not type double.
```

Enhance the error message to display the data type of `c`.

```
assert(isa(c,'double'),'Product is type %s, not double.',class(c))
```

```
Product is type single, not double.
```

Expected Code Conditions

Use the `assert` function to test for conditions that should not happen in normal code execution. If the coefficients are numeric, the computed roots should be numeric. A quadratic equation using the specified coefficients and computed roots should be zero.

```
function x = quadraticSolver(C)

validateattributes(C,{'numeric'},{'size',[1 3]})
```

```
a = C(1);
b = C(2);
c = C(3);

x(1) = (-b+sqrt(b^2-4*a*c))/(2*a);
x(2) = (-b-sqrt(b^2-4*a*c))/(2*a);
assert(isnumeric(x),'quadraticSolver:nonnumericRoots',...
    'Computed roots are not numeric')

y1 = a*x(1)^2+b*x(1)+c;
y2 = a*x(2)^2+b*x(2)+c;
assert(y1 == 0,'quadraticSolver:root1Error','Error in first root')
assert(isequal(y2,0),'quadraticSolver:root2Error','Error in second root')

end
```

- " Capture Information About Exceptions"

Input Arguments

`cond` — Condition to assert

MATLAB expression

Condition to assert, specified as a valid MATLAB expression. If `cond` is false, the `assert` function throws an error. `cond` can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). Use the logical operators `and` and `or` to create compound expressions. MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

Example: `a<0`

Example: `exist('myfunction.m','file')`

`msg` — Information about assertion failure

string

Information about the assertion failure, specified as a string. This message displays as the error message. To format the string, use escape sequences, such as `\t` or `\n`. You also can use any format specifiers supported by the `sprintf` function, such as `%s` or `%d`. Specify values for the conversion specifiers via the `A1,...,An` input arguments. For more information, see "Formatting Strings".

Note: You must specify more than one input argument with `assert` if you want MATLAB to convert special characters (such as `\t`, `\n`, `%s`, and `%d`) in the error message string.

Example: `'Assertion condition failed.'`

`A1,...,An` — Numeric or character arrays

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array. This input argument provides the values that correspond to and replace the conversion specifiers in `msg`.

`msgID` — Identifier for assertion failure

string

Identifier for the assertion failure, specified as a string. Use the message identifier to help identify the source of the error or to control a selected subset of the errors in your program.

The message identifier includes a `component` and `mneumonic`. The identifier must always contain a colon and follows this simple format: `component:mnemonic`. The `component` and `mneumonic` fields must each begin with a letter. The remaining characters can be alphanumerics (A–Z, a–z, 0–9) and underscores. No whitespace characters can appear anywhere in msgID. For more information, see “Message Identifiers”.

Example: `'MATLAB:singularMatrix'`

Example: `'MATLAB:narginchk:notEnoughInputs'`

More About

Tips

- When you issue an error, MATLAB captures information about it and stores it in a data structure that is an object of the `MException` class. You can access information in the exception object by using `try/catch`. Or, if your program terminates because of an exception and returns control to the Command Prompt, you can use `MException.last`.

- If an assertion failure occurs within a `try` block, MATLAB does not cease execution of the program. In this case, MATLAB passes control to the `catch` block.

See Also

`MException` | `error`

Introduced in R2007a

assignin

Assign value to variable in specified workspace

Syntax

```
assignin(ws, 'var', val)
```

Description

`assignin(ws, 'var', val)` assigns the value `val` to the variable *`var`* in the workspace `ws`. The *`var`* input must be the array name only; it cannot contain array indices. If *`var`* does not exist in the specified workspace, `assignin` creates it. `ws` can have a value of `'base'` or `'caller'` to denote the MATLAB base workspace or the workspace of the caller function.

The `assignin` function is particularly useful for these tasks:

- Exporting data from a function to the MATLAB workspace
- Within a function, changing the value of a variable that is defined in the workspace of the caller function (such as a variable in the function argument list)

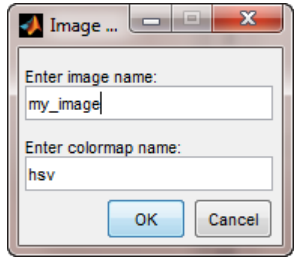
Examples

Example 1

This example creates a dialog box for the image display function, prompting a user for an image name and a colormap name. The `assignin` function is used to export the user-entered values to the MATLAB workspace variables `imfile` and `cmap`.

```
prompt = {'Enter image name:', 'Enter colormap name:'};
title = 'Image display - assignin example';
lines = 1;
def = {'my_image', 'hsv'};
answer = inputdlg(prompt, title, lines, def);
assignin('base', 'imfile', answer{1});
```

```
assignin('base', 'cmap', answer{2});
```



Example 2

`assignin` does not assign to specific elements of an array. The following statement generates an error:

```
X = 1:8;
assignin('base', 'X(3:5)', -1);
```

However, you can use the `evalin` function to do this:

```
evalin('base','X(3:5) = -1')
X =
     1     2    -1    -1    -1     6     7     8
```

More About

Tips

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the currently running function. Note that the base and caller workspaces are equivalent in the context of a function that is invoked from the MATLAB command line. For more information, see “Base and Function Workspaces”.

See Also

`evalin`

Introduced before R2006a

atan

Inverse tangent in radians

Syntax

```
Y = atan(X)
```

Description

`Y = atan(X)` returns the "Inverse Tangent" on page 1-480 ($\tan^{-1}$) of the elements of X. The `atan` function operates element-wise on arrays. For real elements of X, `atan(X)` returns values in the interval `[-pi/2,pi/2]`. For complex values of X, `atan(X)` returns complex values. All angles are in radians.

Examples

Inverse Tangent of a Value

```
atan(0.8)
```

```
ans =
    0.6747
```

Inverse Tangent of a Vector of Complex Values

Find the inverse tangent of the elements of vector `x`. The `atan` function acts on `x` element-wise.

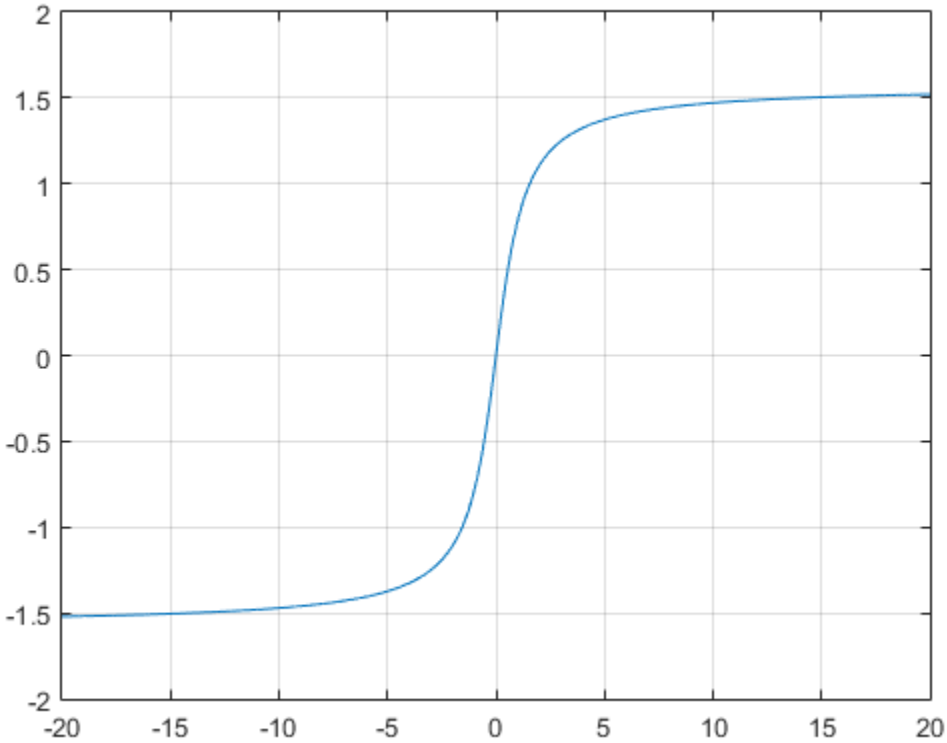
```
x = [0.5i 1+3i -2.2+i];
Y = atan(x)
```

```
Y =
   0.0000 + 0.5493i   1.4615 + 0.3059i  -1.2019 + 0.1506i
```

Plot the Inverse Tangent Function

Plot the inverse tangent function over the interval $-20 \leq x \leq 20$.

```
x = -20:0.01:20;
plot(x,atan(x))
grid on
```



Input Arguments

X — Numeric input

number | vector | matrix | multidimensional array

Numeric input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

Complex Number Support: Yes

More About

Inverse Tangent

The inverse tangent is defined as

$$\tan^{-1}(z) = \frac{i}{2}\log\left(\frac{i+z}{i-z}\right).$$

See Also

`atan2` | `atand` | `atanh` | `tan`

Introduced before R2006a

atan2

Four-quadrant inverse tangent

Syntax

```
P = atan2(Y,X)
```

Description

`P = atan2(Y,X)` returns the "Four-Quadrant Inverse Tangent" on page 1-484 ($\tan^{-1}$) of Y and X, which must be real. The `atan2` function acts on `Y` and `X` element-wise to return `P`, which is the same size as Y and X.

Examples

Find Four-Quadrant Inverse Tangent of a Point

Find the four-quadrant inverse tangent of the point `y = 4`, `x = -3`.

```
atan2(4,-3)
```

```
ans =
    2.2143
```

Convert Complex Number to Polar Coordinates

Convert `4 + 3i` into polar coordinates.

```
z = 4 + 3i;
r = abs(z)
theta = atan2(imag(z),real(z))
```

```
r =
     5
theta =
```

```
    0.6435
```

The radius `r` and the angle `theta` are the polar coordinate representation of `4 + 3i`.

Alternatively, use `angle` to calculate `theta`.

```
theta = angle(z)
```

```
theta =
    0.6435
```

Convert `r` and `theta` back into the original complex number.

```
z = r*exp(i*theta)
```

```
z =
   4.0000 + 3.0000i
```

Plot Four-Quadrant Inverse Tangent

Plot `atan2(Y,X)` for `-4<Y<4` and `-4<X<4`.

Define the interval to plot over.

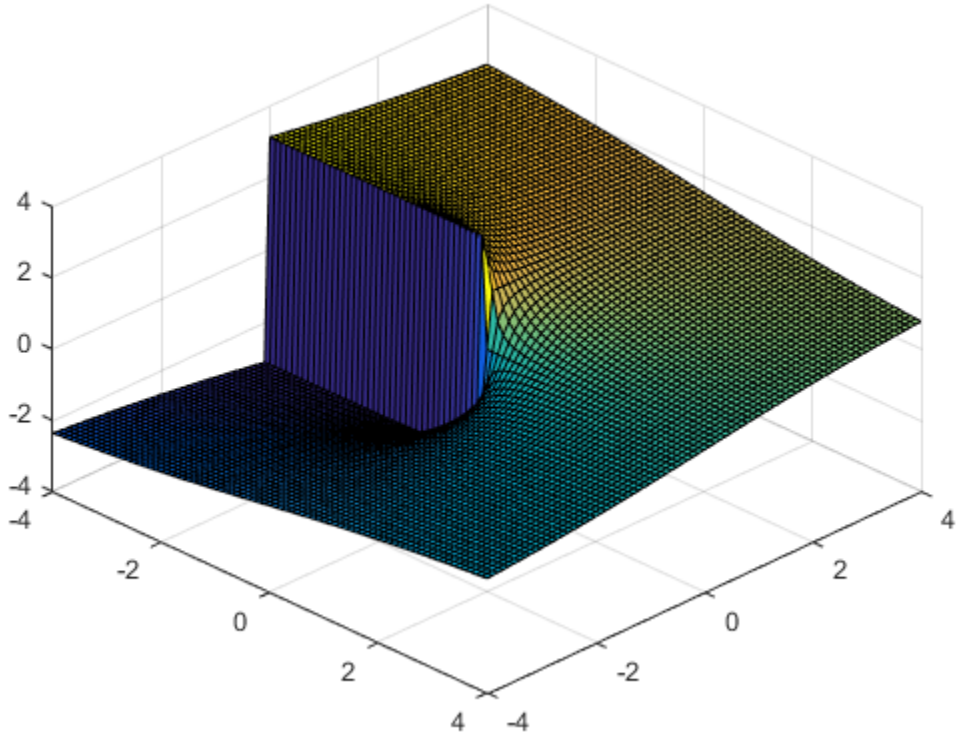
```
[X,Y] = meshgrid(-4:0.1:4,-4:0.1:4);
```

Find `atan2(Y,X)` over the interval.

```
P = atan2(Y,X);
```

Use `surf` to generate a surface plot of the function. Note that `plot` plots the discontinuity that exists at `Y=0` for all `X<0`.

```
surf(X,Y,P);
view(45,45);
```



Input Arguments

Y — Real valued input

number | vector | matrix | multidimensional array

Real valued input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

X — Real valued input

number | vector | matrix | multidimensional array

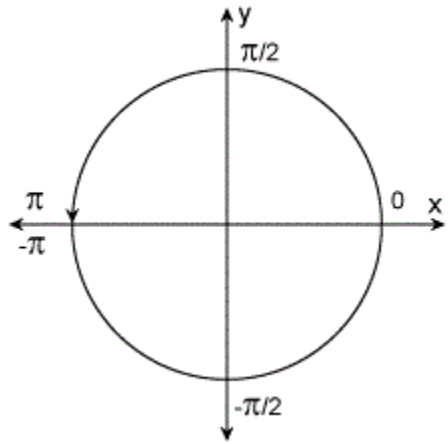
Real valued input, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

More About

Four-Quadrant Inverse Tangent

The four-quadrant tangent inverse, `atan2(Y,X)`, returns values in the closed interval `[-pi,pi]` based on the values of Y and X as shown in the graphic.



In contrast, `atan(Y,X)` returns results which are limited to the interval `(-pi/2,pi/2)`, which is the right side of this diagram.

See Also

`angle` | `atan` | `atan2d` | `atanh` | `tan`

Introduced before R2006a

atan2d

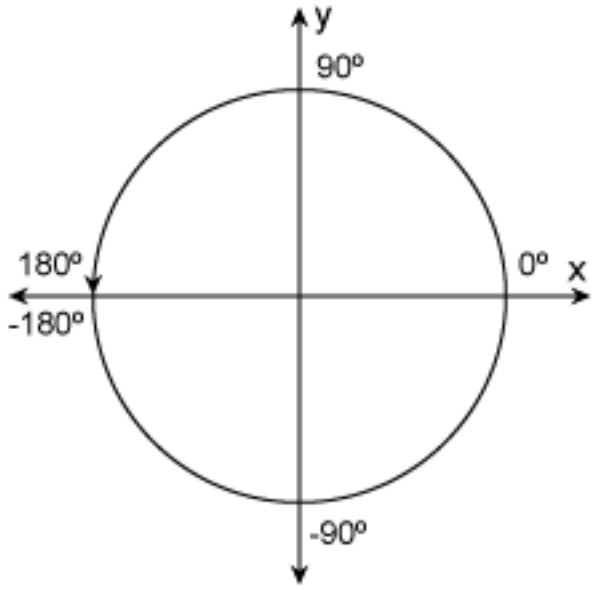
Four-quadrant inverse tangent in degrees

Syntax

```
D = atan2d(Y,X)
```

Description

`D = atan2d(Y,X)` returns the four-quadrant inverse tangent of points specified in the *x-y* plane. The result, `D`, is expressed in degrees.



Examples

Inverse Tangent of Four Points on the Unit Circle

```
x = [1 0 -1 0];
y = [0 1 0 -1];
d = atan2d(y,x)
```

```
d =

     0    90   180   -90
```

Input Arguments

Y — *y*-coordinates

scalar value | vector | matrix | N-D array

y-coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types: `single` | `double`

X — *x*-coordinates

scalar value | vector | matrix | N-D array

x-coordinates, specified as a real-valued scalar, vector, matrix, or N-D array.

Data Types: `single` | `double`

Output Arguments

D — Angles in degrees

scalar value | vector | matrix | N-D array

Angles in degrees, returned as a scalar, vector, matrix, or N-D array. These angles correspond to the points defined by `X` and `Y`, and they lie in the closed interval [–180,180].

More About

Tips

- Use `atand(Y/X)` for the inverse tangent with results on the interval [–90, 90].

See Also

atan | atan2 | atand | tan | tand

atand

Inverse tangent in degrees

Syntax

```
Y = atand(X)
```

Description

`Y = atand(X)` returns the inverse tangent ($\tan^{-1}$) of the elements of X in degrees. The function's domain and range include complex values. For real elements of X in the domain [-Inf, Inf], `atand` returns values in the range [-90, 90]. For complex values of X, `atand` returns complex values.

Examples

Inverse Tangent of Vector

```
x = [-50 -20 0 20 50];
y = atand(x)
```

```
y =

  -88.8542  -87.1376         0   87.1376   88.8542
```

The `atand` operation is element-wise when you pass a vector, matrix, or N-D array.

Inverse Tangent of Complex Value

```
atand(10+i)
```

```
ans =
```

```
84.3450 + 0.5618i
```

Input Arguments

X — Tangent of angle

scalar value | vector | matrix | N-D array

Tangent of angle, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `atand` operation is element-wise when X is non-scalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as X.

See Also

`atan` | `atan2d` | `tan` | `tand`

Introduced before R2006a

atanh

Inverse hyperbolic tangent

Syntax

```
Y = atanh(X)
```

Description

The `atanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

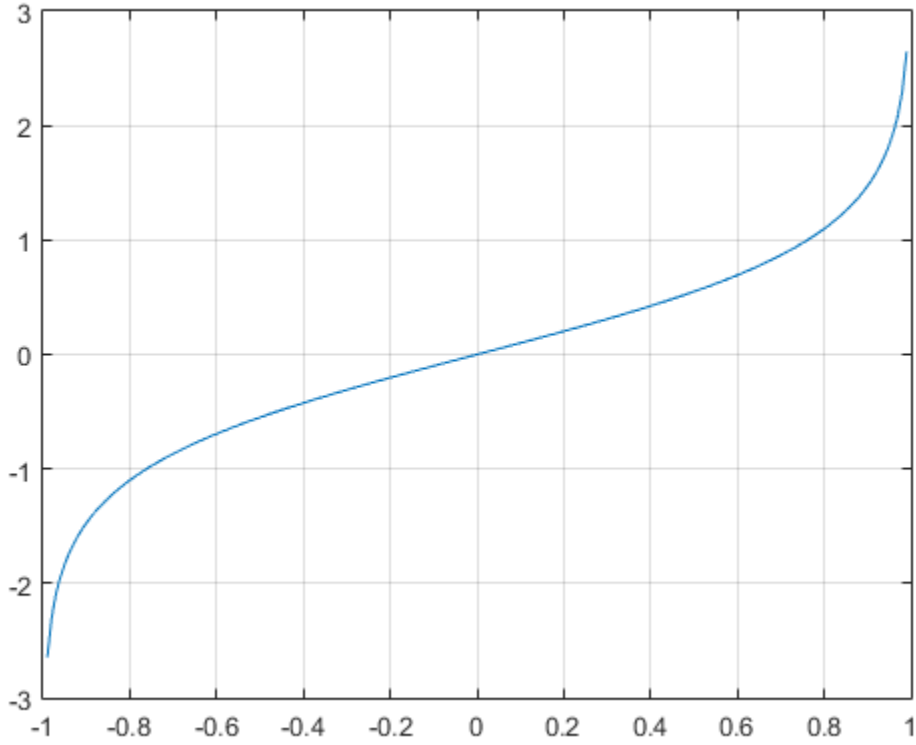
`Y = atanh(X)` returns the inverse hyperbolic tangent for each element of `X`.

Examples

Graph of Inverse Hyperbolic Tangent Function

Graph the inverse hyperbolic tangent over the domain $-1 < x < 1$.

```
x = -0.99:0.01:0.99;
plot(x,atanh(x)), grid on
```



More About

Inverse Hyperbolic Tangent

The inverse hyperbolic tangent can be defined as

$$\tanh^{-1}(z) = \frac{1}{2}\log\left(\frac{1+z}{1-z}\right).$$

See Also

`atan2` | `atan` | `tanh` | `asinh` | `acosh` | `tan`

Introduced before R2006a

audiodevinfo

Information about audio device

Syntax

```
info = audiodevinfo
nDevices = audiodevinfo(IO)
name = audiodevinfo(IO,ID)
DriverVersion = audiodevinfo(IO,ID,'DriverVersion')
support = audiodevinfo(IO,ID,Fs,nBits,nChannels)

ID = audiodevinfo(IO,name)
ID = audiodevinfo(IO,Fs,nBits,nChannels)
```

Description

`info = audiodevinfo` returns information about the input and output audio devices on the system.

`nDevices = audiodevinfo(IO)` returns the number of input devices on the system if `IO` is `1`, and returns the number of output devices on the system if `IO` is `0`.

`name = audiodevinfo(IO,ID)` returns the name of the audio device specified by the device identifier, `ID`.

`DriverVersion = audiodevinfo(IO,ID,'DriverVersion')` returns the name of the driver for the audio device specified by `ID`.

`support = audiodevinfo(IO,ID,Fs,nBits,nChannels)` returns `1` if the input or output audio device specified by `ID` supports the sample rate, number of bits, and number of channels specified by the values of `Fs`, `nBits`, and `nChannels`, respectively. Otherwise, `support` is `0`.

`ID = audiodevinfo(IO,name)` returns the device identifier of the input or output audio device identified by the device name, `name`. If no device is found with the specified name, then `audiodevinfo` returns an error.

`ID = audiodevinfo(IO,Fs,nBits,nChannels)` returns the device identifier of the first input or output device that supports the sample rate, number of bits, and the number of channels specified by the values of `Fs`, `nBits`, and `nChannels`, respectively. If no supporting device is found, then `ID` is `-1`.

Examples

View Information About Audio Devices

Call `audiodevinfo` with no inputs to view information about the input and output audio devices on a system.

```
info = audiodevinfo
```

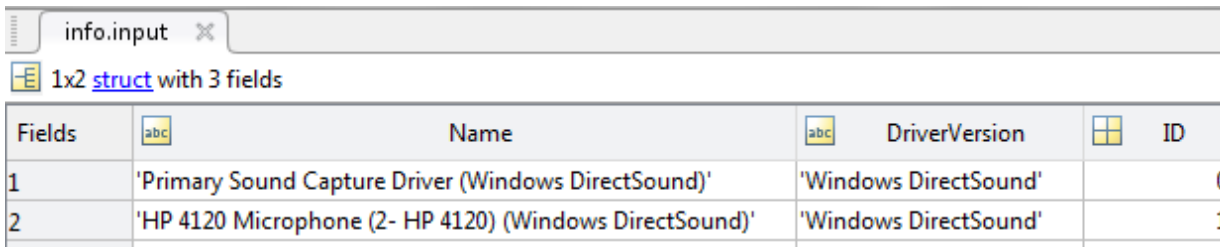
```
info =

     input: [1x2 struct]
    output: [1x3 struct]
```

`audiodevinfo` returns a structure containing two fields, `input` and `output`.

View the contents of the `input` field in the Variables editor.

```
openvar info.input
```



The Variables editor displays the input audio device names, driver used, and device identifiers. The values on your system might differ from this example.

View Number of Output Devices

View the number of output audio devices on the system, using an `IO` value of `0` to indicate output.

```
nDevices = audiodevinfo(0)
```

```
nDevices =

     3
```

This example shows three output devices, but your system might vary.

Check Support for Input Device

Check if the input audio device identified by the `ID` value, `0`, supports a sample rate of 44100 hertz, with 16 bits per sample, and two channels.

```
support = audiodevinfo(1,0,44100,16,2)
```

```
support =

     1
```

The input device supports the specified sample rate, number of bits and number of channels.

Input Arguments

`IO` — Input or output device

`1 | 0`

Input or output device, specified as `1` to indicate input, or `0` to indicate output.

`ID` — Audio device identifier

integer

Audio device identifier, specified as an integer. The device can be an input or output audio device.

`Fs` — Sample rate

scalar

Sample rate, in hertz, specified as a positive scalar.

Example: `44100`

Data Types: `single | double`

`nBits` — Number of bits per sample

scalar

Number of bits per sample, specified as a scalar.

Example: `16`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`nChannels` — Number of audio channels

`1` | `2`

Number of audio channels, specified as `1` (mono) or `2` (stereo).

`name` — Name of input or output device

string

Name of the input or output audio device, specified as a string.

Data Types: `char`

Output Arguments

`info` — Information about audio devices

structure array

Information about audio devices, returned as a structure array containing two fields, `input` and `output`. Each field is an array of structures, with each structure containing information about one of the audio input or output devices on the system. The individual device structure fields are:

- `Name` — Name of the device, returned as a string.
- `DriverVersion` — Name of the driver used to communicate with the device, returned as a string.
- `ID` — Device identifier, returned as a scalar.

`audioplayer` | `audiorecorder`

audioplayer

Create object for playing audio

Syntax

```
player = audioplayer(Y,Fs)
player = audioplayer(Y,Fs,nBits)
player = audioplayer(Y,Fs,nBits,ID)
player = audioplayer(recorder)
player = audioplayer(recorder,ID)
```

Description

`player = audioplayer(Y,Fs)` creates an `audioplayer` object for signal `Y`, using sample rate `Fs`. The function returns a handle to the `audioplayer` object, `player`.

`player = audioplayer(Y,Fs,nBits)` uses `nBits` bits per sample for signal `Y`.

`player = audioplayer(Y,Fs,nBits,ID)` uses the audio device identified by `ID` for output.

`player = audioplayer(recorder)` creates an `audioplayer` object using audio recorder object `recorder`.

`player = audioplayer(recorder,ID)` creates an object from `recorder` that uses the audio device identified by`ID` for output.

Input Arguments

`Y`

Audio signal represented by a vector or two-dimensional array containing `single`, `double`, `int8`, `uint8`, or `int16` values.

The value range of the input sample depends on the data type. The following table lists these ranges.

Data Type	Sample Value Range
`int8`	-128 to 127
`uint8`	0 to 255
`int16`	-32768 to 32767
`single`	-1 to 1
`double`	-1 to 1

`Fs`

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

`nBits`

Bits per sample. Specify only when signal Y is represented by floating-point values. Valid values depend on the audio hardware installed: `8`, `16`, or `24`.

Default: `16`

`ID`

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

Default: `-1` (default device)

`recorder`

Audio recorder object created by `audiorecorder`.

Methods

Note: When calling any method, include the `audioplayer` object name using function syntax, such as `stop(player)`.

`get`	Query properties of `audioplayer` object.

`isplaying`	Query whether playback is in progress: returns `true` or `false`.
`pause`	Pause playback.
`play`	Play audio from beginning to end.
`playblocking`	Play, and do not return control until playback completes.
`resume`	Restart playback from paused position.
`set`	Set properties of `audioplayer` object.
`stop`	Stop playback.

See the reference pages for `get`, `play`, `playblocking`, and `set` for additional syntax options.

Properties

`BitsPerSample`	Number of bits per sample. (Read-only)
`CurrentSample`	Current sample that the audio output device is playing. If the device is not playing, `CurrentSample` is the next sample to play with `play` or `resume`. (Read-only)
`DeviceID`	Identifier for audio device. (Read-only)
`NumberOfChannels`	Number of audio channels. (Read-only)
`Running`	Status of the audio player: `'on'` or `'off'`. (Read-only)
`SampleRate`	Sampling frequency in Hz.
`TotalSamples`	Total length of the audio data in samples. (Read-only)
`Tag`	String that labels the object.
`Type`	Name of the class: `'audioplayer'`. (Read-only)
`UserData`	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audioplayer` object and an *`event`* structure.

`StartFcn`	Function to execute one time when playback starts.
`StopFcn`	Function to execute one time when playback stops.

`TimerFcn`	Function to execute repeatedly during playback. To specify time intervals for the repetitions, use the `TimerPeriod` property.
`TimerPeriod`	Time in seconds between `TimerFcn` callbacks. Default: `.05`

Examples

Load and play a sample audio file of Handel's "Hallelujah Chorus:"

```
load handel;
player = audioplayer(y, Fs);
play(player);
```

`audiodevinfo` | `sound` | `audiorecorder`

Introduced before R2006a

audiorecorder

Create object for recording audio

Syntax

```
recorder = audiorecorder
recorder = audiorecorder(Fs,nBits,nChannels)
recorder = audiorecorder(Fs,nBits,nChannels,ID)
```

Description

`recorder = audiorecorder` creates an 8000 Hz, 8-bit, 1-channel `audiorecorder` object.

`recorder = audiorecorder(Fs,nBits,nChannels)` sets the sample rate `Fs` (in Hz), the sample size `nBits`, and the number of channels `nChannels`.

`recorder = audiorecorder(Fs,nBits,nChannels,ID)` sets the audio input device to the device specified by `ID`.

Input Arguments

`Fs`

Sampling rate in Hz. Valid values depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, 44100, 48000, and 96000 Hz.

Default: 8000

`nBits`

Bits per sample. Valid values depend on the audio hardware installed: `8`, `16`, or `24`.

Default: 8

`nChannels`

The number of channels: `1` (mono) or `2` (stereo).

Default: 1

`ID`

Device identifier. To obtain the ID of a device, use the `audiodevinfo` function.

Default: `-1` (default device)

Methods

Note: When calling any method, include the `audiorecorder` object name using function syntax, such as `stop(recorder)`.

`get`	Query properties of `audiorecorder` object.
`getaudiodata`	Create an array that stores the recorded signal values.
`getplayer`	Create an `audioplayer` object.
`isrecording`	Query whether recording is in progress: returns `true` or `false`.
`pause`	Pause recording.
`play`	Play recorded audio. This method returns an `audioplayer` object.
`record`	Start recording.
`recordblocking`	Record, and do not return control until recording completes. This method requires a second input for the length of the recording in seconds: `recordblocking(recorder,length)`
`resume`	Restart recording from paused position.
`set`	Set properties of `audiorecorder` object.
`stop`	Stop recording.

See the reference pages for `get`, `getaudiodata`, `play`, `record`, `recordblocking`, and `set` for additional syntax options.

Properties

`BitsPerSample`	Number of bits per sample. (Read-only)
`CurrentSample`	Current sample that the audio input device is recording. If the device is not recording, `CurrentSample` is the next sample to record with `record` or `resume`. (Read-only)
`DeviceID`	Identifier for audio device. (Read-only)
`NumberOfChannels`	Number of audio channels. (Read-only)
`Running`	Status of the audio recorder: `'on'` or `'off'`. (Read-only)
`SampleRate`	Sampling frequency in Hz. (Read-only)
`TotalSamples`	Total length of the audio data in samples. (Read-only)
`Tag`	String that labels the object.
`Type`	Name of the class: `'audiorecorder'`. (Read-only)
`UserData`	Any type of additional data to store with the object.

The following four properties apply to callback functions. The first two inputs to your callback function must be the `audiorecorder` object and an *`event`* structure.

`StartFcn`	Function to execute one time when recording starts.
`StopFcn`	Function to execute one time when recording stops.
`TimerFcn`	Function to execute repeatedly during recording. To specify time intervals for the repetitions, use the `TimerPeriod` property.
`TimerPeriod`	Time in seconds between `TimerFcn` callbacks. Default: `.05`

`audiorecorder` ignores any specified values for these properties, which will be removed in a future release.

`BufferLength`	Length of buffer in seconds.
`NumberOfBuffers`	Number of buffers.

Examples

Create an `audiorecorder` object for CD-quality audio in stereo, and view its properties:

```
recObj = audiorecorder(44100, 16, 2);
get(recObj)
```

Collect a sample of your speech with a microphone, and plot the signal data:

```
% Record your voice for 5 seconds.
recObj = audiorecorder;
disp('Start speaking.')
recordblocking(recObj, 5);
disp('End of Recording.');

% Play back the recording.
play(recObj);

% Store data in double-precision array.
myRecording = getaudiodata(recObj);

% Plot the waveform.
plot(myRecording);
```

More About

Tips

- To use an `audiorecorder` object, your system must have a properly installed and configured sound card.
- `audiorecorder` is not intended for long, high-sample-rate recording. `audiorecorder` uses system memory for storage and does not use disk buffering. When you attempt a large recording, your MATLAB performance sometimes degrades over time.

- "Characteristics of Audio Files"
- "Record Audio"
- "Record or Play Audio within a Function"

See Also

`audiodevinfo` | `sound` | `audioplayer`

Introduced before R2006a

aufinfo

Information about NeXT/SUN (`.au`) sound file

Note: `aufinfo` will be removed in a future release. Use `audioinfo` instead.

Syntax

```
[m d] = aufinfo(aufile)
```

Description

`[m d] = aufinfo(aufile)` returns information about the contents of the AU sound file specified by the string `aufile`.

`m` is the string `'Sound (AU) file'`, if `filename` is an AU file. Otherwise, it contains an empty string (`''`).

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If `filename` is not an AU file, it contains the string `'Not an AU file'`.

See Also

`audioread` | `audioinfo`

Introduced before R2006a

auread

Read NeXT/SUN (`.au`) sound file

Note: `auread` will be removed in a future release. Use `audioread` instead.

Syntax

```
y = auread(aufile)
[y,Fs] = auread(aufile)
[y,Fs,nbits] = auread(aufile)
[ ___ ] = auread(aufile,N)
[ ___ ] = auread(aufile,[N1 N2])
siz = auread(aufile,'size')
```

Description

`y = auread(aufile)` loads a sound file specified by the string *`aufile`*, returning the sampled data in *`y`*. The `.au` extension is appended if no extension is given. Amplitude values are in the range `[-1,+1]`. `auread` supports multichannel data in the following formats:

- 8-bit mu-law
- 8-, 16-, and 32-bit linear
- Floating-point

`[y,Fs] = auread(aufile)` returns the sample rate (*`Fs`*) in Hertz used to encode the data in the file.

`[y,Fs,nbits] = auread(aufile)` returns the number of bits per sample (*`nbits`*).

`[ ___ ] = auread(aufile,N)` returns only the first *`N`* samples from each channel in the file.

`[ ___ ] = auread(aufile,[N1 N2])` returns only samples *`N1`* through *`N2`* from each channel in the file.

siz = auread(*aufile*,'size') returns the size of the audio data contained in the file in place of the actual audio data, returning the vector *siz* = [*samples channels*].

Examples

Create a sound file from the example file handel.mat, and read portions of the file back into MATLAB:

```
% Create .au file in current folder.
load handel.mat

hfile = 'handel.au';
auwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits] = auread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = auread(hfile, nsamples);
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = auread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = auread(hfile, [startpos endpos]);
sound(y3, Fs);
```

See Also

audiowrite | audioinfo | audioplayer | audiorecorder | sound | audioread

Introduced before R2006a

auwrite

Write NeXT/SUN (`.au`) sound file

Note: `auwrite` will be removed in a future release.

Syntax

```
auwrite(y,aufile)
auwrite(y,Fs,aufile)
auwrite(y,Fs,N,aufile)
auwrite(y,Fs,N,method,aufile)
```

Description

`auwrite(y,aufile)` writes a sound file specified by the string *`aufile`*. The data should be arranged with one channel per column. Amplitude values outside the range `[-1,+1]` are clipped prior to writing. `auwrite` supports multichannel data for 8-bit mu-law and 8- and 16-bit linear formats.

`auwrite(y,Fs,aufile)` specifies the sample rate of the data in Hertz.

`auwrite(y,Fs,N,aufile)` selects the number of bits in the encoder. Allowable settings are *`N`* `= 8` and *`N`* `= 16`.

`auwrite(y,Fs,N,method,aufile)` allows selection of the encoding method, which can be either `'mu'` or `'linear'`. Note that mu-law files must be 8-bit. By default, *`method`* `= 'mu'`.

See Also

`audioread` | `audiowrite`

Introduced before R2006a

avifile

Create new Audio/Video Interleaved (AVI) file

Note: `avifile` has been removed. Use `VideoWriter` instead.

Syntax

```
aviobj = avifile(filename)
avifile(filename, ParameterName, ParameterValue)
```

Description

`aviobj = avifile(filename)` creates an `avifile` object, giving it the name specified in *`filename`*, using default values for all `avifile` object properties. If *`filename`* does not include an extension, `avifile` appends `.avi` to the file name. AVI is a file format for storing audio and video data.

`avifile` returns a handle to an AVI file object *`aviobj`*. Use this object to refer to the AVI file in other functions. An AVI file object supports properties and methods that control aspects of the AVI file created.

`aviobj` = `avifile(`*`filename`*`, `*`ParameterName`*`, `*`ParameterValue`*`)` accepts one or more comma-separated parameter name/value pairs. Set parameter values before any calls to `addframe`. The following table lists the available parameters and values.

Parameter Name	Value	Default
`'colormap'`	An *`m`*-by-3 matrix defining the colormap for indexed AVI movies, where *`m`* is no more than 256 (236 for `Indeo` compression). Valid only when the `'compression'` is `'MSVC'`, `'RLE'`, or `'None'`.	No default

Parameter Name	Value	Default
`'compression'`	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of `'None'`. On UNIX® operating systems, the only valid value is `'None'`. On Windows systems, valid values include: • `'MSVC'` • `'RLE'` • `'Cinepak'` on 32-bit systems. • `'Indeo3'` or `'Indeo5'` on 32-bit Windows XP systems. Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.	`'Indeo5'` on Windows systems. `'None'` on UNIX systems.
`'fps'`	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
`'keyframe'`	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
`'quality'`	A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes. Valid only for compressed movies.	75
`'videoname'`	A descriptive name for the video stream, no more than 64 characters.	*`filename`*

Examples

Create the AVI file `example.avi`:

```
aviobj = avifile('example.avi','compression','None');

t = linspace(0,2.5*pi,40);
fact = 10*sin(t);
fig=figure;
[x,y,z] = peaks;
for k=1:length(fact)
    h = surf(x,y,fact(k)*z);
    axis([-3 3 -3 3 -80 80])
    axis off
    caxis([-90 90])

    F = getframe(fig);
    aviobj = addframe(aviobj,F);
end
close(fig);
aviobj = close(aviobj);
```

Alternatives

Use `VideoWriter` rather than `avifile` to create AVI files. `VideoWriter` supports files larger than 2 GB, and by default, creates files with Motion JPEG compression, which all platforms support.

More About

Tips

- On some Windows systems, including all 64-bit systems, the default Indeo® 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer®. Consider specifying a `compression` value of `'None'`.
- `avifile` cannot write files larger than 2 GB.
- You can use dot notation to set `avifile` object properties. For example, set the `quality` property to 100:

```
aviobj = avifile('myavifile');
aviobj.quality = 100;
```

All property names of an `avifile` object are the same as the parameter names, except for the `keyframe` parameter, which corresponds to the `KeyFramePerSec` property. For example, change `keyframe` to `2.5`:

```
aviobj.KeyFramePerSec = 2.5;
```

See Also

`VideoWriter` | `addframe (avifile)` | `close (avifile)`

Introduced before R2006a

aviinfo

Information about Audio/Video Interleaved (AVI) file

Note: `aviinfo` will be removed in a future release. Use `VideoReader` and the `get` method instead.

Syntax

```
fileinfo = aviinfo(filename)
```

Description

`fileinfo = aviinfo(filename)` returns a structure whose fields contain information about the AVI file specified in the string `filename`. If `filename` does not include an extension, then `.avi` is used. The file must be in the current working directory or in a directory on the MATLAB path.

The set of fields in the `fileinfo` structure is shown below.

Field Name	Description
`AudioFormat`	String containing the name of the format used to store the audio data, if audio data is present
`AudioRate`	Integer indicating the sample rate in Hertz of the audio stream, if audio data is present
`Filename`	String specifying the name of the file
`FileModDate`	String containing the modification date of the file
`FileSize`	Integer indicating the size of the file in bytes
`FramesPerSecond`	Integer indicating the desired frames per second
`Height`	Integer indicating the height of the AVI movie in pixels

Field Name	Description
`ImageType`	String indicating the type of image. Either `'truecolor'` for a truecolor (RGB) image, or `'indexed'` for an indexed image.
`NumAudioChannels`	Integer indicating the number of channels in the audio stream, if audio data is present
`NumFrames`	Integer indicating the total number of frames in the movie
`NumColormapEntries`	Integer specifying the number of colormap entries. For a truecolor image, this value is 0 (zero).
`Quality`	Number between 0 and 100 indicating the video quality in the AVI file. Higher quality numbers indicate higher video quality; lower quality numbers indicate lower video quality. This value is not always set in AVI files and therefore can be inaccurate.
`VideoCompression`	String containing the compressor used to compress the AVI file. If the compressor is not Microsoft Video 1, Run Length Encoding (RLE), Cinepak, or Intel® Indeo, `aviinfo` returns the four-character code that identifies the compressor.
`Width`	Integer indicating the width of the AVI movie in pixels

See also

`mmfileinfo`, `VideoReader`, `VideoWriter`

Introduced before R2006a

aviread

Read Audio/Video Interleaved (AVI) file

Note `aviread` has been removed. Use `VideoReader` instead.

Syntax

```
mov = aviread(filename)
mov = aviread(filename, index)
```

Description

`mov = aviread(filename)` reads the AVI movie *`filename`* into the MATLAB movie structure *`mov`*. If *`filename`* does not include an extension, then `.avi` is used. Use the `movie` function to view the movie *`mov`*. On UNIX platforms, *`filename`* must be an uncompressed AVI file.

`mov` has two fields, `cdata` and `colormap`. The content of these fields varies depending on the type of image.

Image Type	cdata Field	colormap Field
`Truecolor`	Height-by-width-by-3 array of `uint8` values	Empty
`Indexed`	Height-by-width array of `uint8` values	`m`-by-3 array of `double` values

`aviread` supports 8-bit frames, for indexed and grayscale images, 16-bit grayscale images, or 24-bit truecolor images. Note, however, that `movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale image frames.

`mov = aviread(filename, index)` reads only the frames specified by *`index`*. *`index`* can be a single index or an array of indices into the video stream. In AVI files, the first frame has the index value 1, the second frame has the index value 2, and so on.

Introduced before R2006a

axes

Create axes graphics object

Syntax

```
axes
axes('PropertyName',propertyvalue,...)
axes(h)
h = axes(...)
```

Properties

For a list of properties, see Axes Properties.

Description

`axes` creates an axes graphics object in the current figure using default property values. `axes` is the low-level function for creating axes graphics objects. MATLAB automatically creates an axes, if one does not already exist, when you issue a command that creates a graph.

`axes('PropertyName',propertyvalue,...)` creates an axes object having the specified property values. For a description of the properties, see Axes Properties. MATLAB uses default values for any properties that you do not explicitly define as arguments. The `axes` function accepts property name/property value pairs, structure arrays, and cell arrays as input arguments (see the `set` and `get` commands for examples of how to specify these data types). While the basic purpose of an axes object is to provide a coordinate system for plotted data, axes properties provide considerable control over the way MATLAB displays data.

`axes(h)` makes existing axes `h` the current axes and brings the figure containing it into focus. It also makes `h` the first axes listed in the figure's `Children` property and sets the figure's `CurrentAxes` property to `h`. The current axes is the target for functions that draw image, line, patch, rectangle, surface, and text graphics objects.

If you want to make an axes the current axes without changing the state of the parent figure, set the `CurrentAxes` property of the figure containing the axes:

```
set(figure_handle,'CurrentAxes',axes_handle)
```

This command is useful if you want a figure to remain minimized or stacked below other figures, but want to specify the current axes.

`h = axes(...)` returns the handle of the created axes object.

Use the `set` function to modify the properties of an existing axes or the `get` function to query the current values of axes properties. Use the `gca` command to obtain the handle of the current axes.

The `axis` (not `axes`) function provides simplified access to commonly used properties that control the scaling and appearance of axes.

Set default axes properties on the figure and root levels:

```
set(groot,'DefaultAxesPropertyName',PropertyValue,...)
set(gcf,'DefaultAxesPropertyName',PropertyValue,...)
```

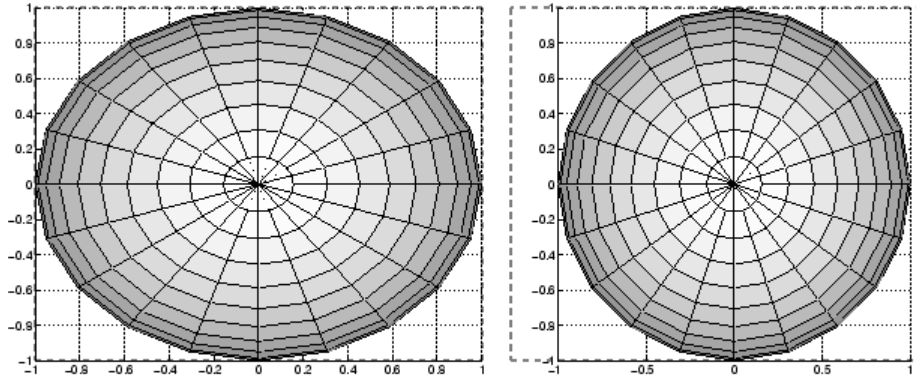
`PropertyName` is the name of the axes property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access axes properties.

Stretch-to-Fill

By default, MATLAB stretches the axes to fill the axes position rectangle (the rectangle defined by the last two elements in the `Position` property). This results in graphs that use the available space in the rectangle. However, some 3-D graphs (such as a sphere) appear distorted because of this stretching, and are better viewed with a specific three-dimensional aspect ratio.

Stretch-to-fill is active when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto (the default). However, stretch-to-fill is turned off when the `DataAspectRatio`, `PlotBoxAspectRatio`, or `CameraViewAngle` is user-specified, or when one or more of the corresponding modes is set to manual (which happens automatically when you set the corresponding property value).

This picture shows the same sphere displayed both with and without the stretch-to-fill. The dotted lines show the axes rectangle.



When stretch-to-fill is disabled, MATLAB sets the size of the axes to be as large as possible within the constraints imposed by the `Position` rectangle without introducing distortion. In the picture above, the height of the rectangle constrains the axes size.

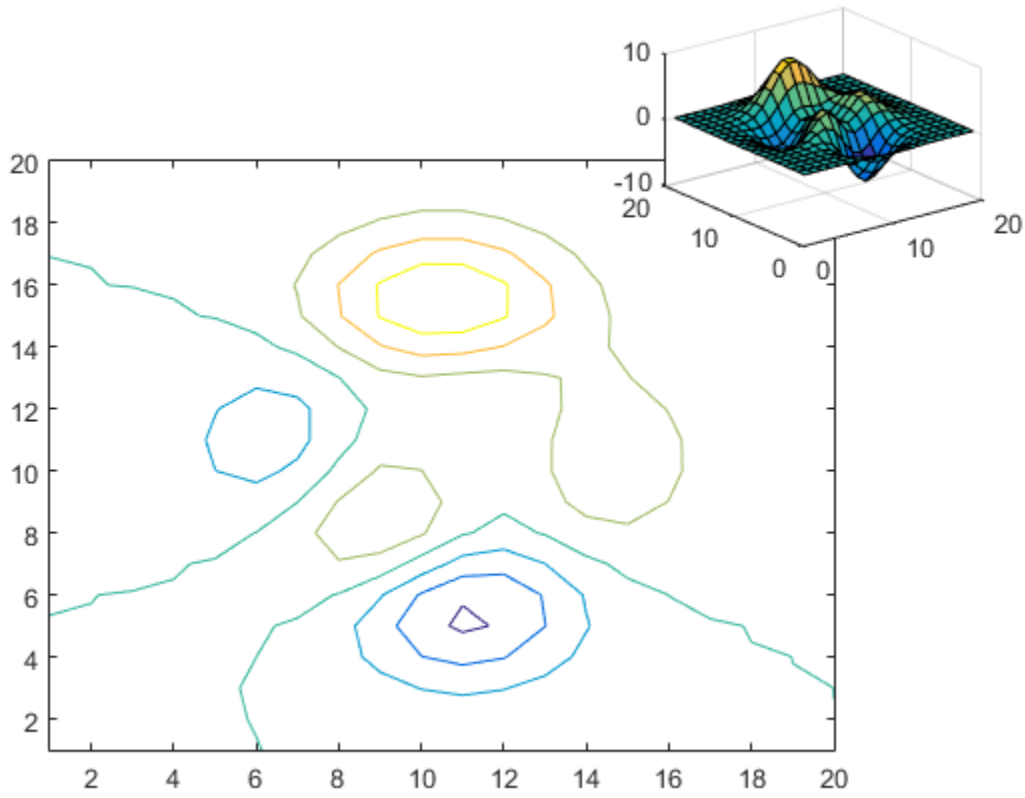
Examples

Define Multiple Axes in Figure Window

Define multiple axes in a single figure window.

```
axes('Position',[0.1,0.1,0.7,0.7])
contour(peaks(20))

axes('Position',[0.65,0.7,0.28,0.28])
surf(peaks(20))
```



Alternatives

To create a figure select **New > Figure** from the figure window **File** menu. To add an axes to a figure, click one of the *New Subplots* icons in the Figure Palette, and slide right to select an arrangement of new axes. For details, see “Customize Graph Using Plot Tools”.

Functions

`axis` | `cla` | `clf` | `figure` | `gca` | `grid` | `subplot` | `title` | `view` | `xlabel` | `ylabel` | `zlabel`

Properties

Axes Properties

Introduced before R2006a

Axes Properties

Control axes appearance and behavior

Axes properties control the appearance and behavior of an axes object. By changing property values, you can modify certain aspects of the axes.

Starting in R2014b, you can use dot notation to query and set properties.

```
ax = gca;
c = ax.Color;
ax.Color = 'blue';
```

If you are using an earlier release, use the `get` and `set` functions instead.

Appearance

`Color` — Color of axes back planes

`[1 1 1]` (default) | RGB triplet | color string | `'none'`

Color of axes back planes, specified as an RGB triplet, a color string, or `'none'`. If you set the color to `'none'`, then the axes is invisible and the figure color shows through.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`

Long Name	Short Name	RGB Triplet
'black	'k'	[0 0 0]

Example: [0 0 1]

Example: 'b'

Example: 'blue'

Box — Axes box outline

'off' (default) | 'on'

Axes box outline, specified as one of these values:

- 'off' — Do not display the box outline around the axes.
- 'on' — Display the box outline around the axes. In a 3-D view, the outline appears around the axes back planes. Use the BoxStyle property to change the extent of the outline.

The XColor, YColor, and ZColor properties control the color of the outline.

BoxStyle — Style of axes box outline

'back' (default) | 'full'

Style of axes box outline, specified as one of these values:

- 'back' — Outline the back planes of the 3-D box.
- 'full' — Outline the entire 3-D box.

The BoxStyle property affects only 3-D views.

XColor, YColor, ZColor — Color of axes outline and tick marks

[0.15 0.15 0.15] (default) | RGB triplet | color string | 'none'

Color of the axes outline in the *x*, *y*, or *z* direction and the associated tick marks, specified as an RGB triplet, a color string, or 'none'. If you set the color to 'none', then the axes outline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range

`[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Setting this property sets the associated mode property to manual.

Example: `[1 1 0]`

Example: `'y'`

Example: `'yellow'`

`XColorMode`, `YColorMode`, `ZColorMode` — Selection mode for axes outline color

`'auto'` (default) | `'manual'`

Selection mode for the axes outline color, specified as one of these values:

- `'auto'` — Use the default color. For related information about grid-line selection, see the `GridColorMode` property.
- `'manual'` — Use the manually specified color. To specify the color, set the XColor, YColor, or ZColor property.

`LineWidth` — Width of axes outline, tick marks, and grid lines

`0.5` (default) | scalar value

Width of axes outline, tick marks, and grid lines, specified as a scalar value in point units. One point equals 1/72 inch.

Example: `1.5`

Individual Axis Lines

`XAxisLocation` — Location of x-axis

`'bottom'` (default) | `'top'`

Location of the *x*-axis, specified as one of these values:

- `'bottom'` — Display *x*-axis at bottom of axes.
- `'top'` — Display *x*-axis at top of axes.

This property applies only to 2-D views.

`YAxisLocation` — Location of y-axis

`'left'` (default) | `'right'`

Location of *y*-axis, specified as one of these values:

- `'left'` — Display *y*-axis on right side of axes.
- `'right'` — Display *y*-axis on left side of axes.

This property applies only to 2-D views.

`XDir`, `YDir`, `ZDir` — Direction of increasing values along axis

`'normal'` (default) | `'reverse'`

Direction of increasing values along axis, specified as one of these values:

- `'normal'` — Normal direction of increasing values:
  - *x*-axis values increase from left to right.
  - *y*-axis values increase from bottom to top (2-D view) or front to back (3-D view).
  - *z*-axis values increase pointing out of the screen (2-D view) or from bottom to top (3-D view).
- `'reverse'` — Reverse direction of increasing values:
  - *x*-axis values decrease from left to right.
  - *y*-axis values decrease from bottom to top (2-D view) or front to back (3-D view).
  - *z*-axis values decrease pointing out of the screen (2-D view) or from bottom to top (3-D view).

XScale, YScale, ZScale — Scale of values along axis

'linear' (default) | 'log'

Scale of values along axis, specified as 'linear' or 'log'.

XLim, YLim, ZLim — Minimum and maximum axis limits

[0 1] (default) | two-element vector of the form [min max]

Minimum and maximum *x*-axis, *y*-axis, or *z*-axis limits, specified as a two-element vector of the form [min max].

If the associated mode property is set to 'auto', then MATLAB chooses the axis limits. If you assign a value to this property, then MATLAB sets the mode to 'manual' and does not automatically compute the limits.

XLimMode, YLimMode, ZLimMode — Selection mode for axis limits

'auto' (default) | 'manual'

Selection mode for the axis limits, specified as one of these values:

- 'auto' — Select axis limits based on the data plotted, that is, the total span of the XData, YData, or ZData of all the objects displayed in the axes.
- 'manual' — Use manually specified axis limits. To specify the axis limits, set the XLim, YLim, or ZLim property.

Tick Values and Labels

XTick, YTick, ZTick — Tick mark locations

[ ] (default) | vector of increasing values

Tick mark locations, specified as a vector of increasing values.

If the associated mode property is set to 'auto', then MATLAB chooses the tick values. If you assign a value to this property, then MATLAB sets the mode to 'manual' and does not automatically recompute the tick values.

Example: [2 4 6 8 10]

Example: 0:10:100

Data Types: single | double

XTickMode, YTickMode, ZTickMode — Selection mode for tick mark locations

'auto' (default) | 'manual'

Selection mode for the tick mark locations, specified as one of these values:

- 'auto' — Select the tick mark locations based on the range of data for the axis.
- 'manual' — Use manually specified tick mark locations. To specify the values, set the XTick, YTick, or ZTick property.

XTickLabel, YTickLabel, ZTickLabel — Tick mark labels

'' (default) | cell array of strings

Tick mark labels, specified as a cell array of strings. If you do not specify enough strings for all the ticks marks, then the axes cycles through the specified strings. Tick mark labels support TeX and LaTeX markup. See the TickLabelInterpreter property for more information.

If the associated mode property is set to 'auto', then MATLAB chooses the labels. If you assign a value to this property, then MATLAB sets the mode to 'manual' and does not automatically choose the labels.

XTickLabelMode, YTickLabelMode, ZTickLabelMode — Selection mode for tick mark labels

'auto' (default) | 'manual'

Selection mode for the tick mark labels, specified as one of these values:

- 'auto' — Label tick marks with numeric values that span the range of the plotted data.
- 'manual' — Use manually specified tick mark labels. To specify the labels, set the XTickLabel, YTickLabel, or ZTickLabel property.

TickLabelInterpreter — Interpretation of characters in tick labels

'tex' (default) | 'latex' | 'none'

Interpretation of tick label characters, specified as one of these values:

- 'tex' — Interpret strings using a subset of TeX markup.
- 'latex' — Interpret strings using LaTeX markup.
- 'none' — Display literal characters

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to `'tex'`, which is the default value. Modifiers remain in effect until the end of the string, except for superscripts and subscripts which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (rarely available)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Set `specifier` as the name of a font family to change the font style. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Set `specifier` as a scalar numeric value to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Set `specifier` as a three-element RGB triplet to change the font color.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\alpha	α	\upsilon	υ	\sim	~
\angle	∠	\phi	Φ	\leq	≤
\ast	*	\chi	χ	\infty	∞

LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The FontName, FontWeight, and FontAngle properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project website at http://www.latex-project.org/.

`XTickLabelRotation`, `YTickLabelRotation`, `ZTickLabelRotation` — Rotation of tick labels

`0` (default) | scalar value in degrees

Rotation of tick labels, specified as a scalar value in degrees. Negative values give clockwise rotation.

Example: `90`

`XMinorTick`, `YMinorTick`, `ZMinorTick` — Display of minor tick marks

`'off'` (default) | `'on'`

Display of minor tick marks, specified as one of these values:

- `'off'` — Do not display minor tick marks.
- `'on'` — Display minor tick marks between the major tick marks on the axis. The space between the major tick marks determines the number of minor tick marks.

`TickLength` — Tick mark length

`[0.01 0.025]` (default) | two-element vector

Tick mark length, specified as a two-element vector of the form `[2Dlength 3Dlength]`. The first element is the tick mark length in 2-D views and the second element is the tick mark length in 3-D views. Specify the values in units normalized relative to the longest of the visible *x*-axis, *y*-axis, or *z*-axis lines.

Example: `[0.02 0.035]`

`TickDir` — Tick mark direction

`'in'` (default) | `'out'`

Tick mark direction, specified as one of these values:

- `'in'` — Direct tick marks inward from the axis lines. This is the default for 2-D views.
- `'out'` — Direct tick marks outward from the axis lines. This is the default for 3-D views.

If the associated mode property is set to `'auto'`, then MATLAB chooses the tick label direction. If you set this property, then MATLAB sets the mode to `'manual'` and does not automatically choose the tick label direction.

`TickDirMode` — Selection mode for `TickDir`

`'auto'` (default) | `'manual'`

Selection mode for the TickDir property, specified as one of these values:

- `'auto'` — Use default tick direction.
- `'manual'` — Use manually specified tick mark direction. To specify the tick mark direction, set the TickDir property.

Grid Lines

`XGrid`, `YGrid`, `ZGrid` — Display of grid lines

`'off'` (default) | `'on'`

Display of grid lines, specified as one of these values:

- `'off'` — Do not display the grid lines.
- `'on'` — Display grid lines perpendicular to the axis, for example, along lines of constant *x*, *y*, or *z* values. Use the `grid` command to set all three properties `'on'` or `'off'`.

`XMinorGrid`, `YMinorGrid`, `ZMinorGrid` — Display of minor grid lines

`'off'` (default) | `'on'`

Display of minor grid lines, specified as one of these values:

- `'off'` — Do not display grid lines.
- `'on'` — Display grid lines aligned with the minor tick marks of the axis. You do not need to enable minor ticks to display minor grid lines.

`GridLineStyle` — Line style for grid lines

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style used for grid lines, specified as one of the strings shown in this table.

String	Line Style
`'-'`	Solid line
`'--'`	Dashed line
`':'`	Dotted line
`'-.'`	Dash-dotted line
`'none'`	No line

To display the grid lines, use the `grid on` command or set the XGrid, YGrid, or ZGrid property to `'on'`.

`MinorGridLineStyle` — Line style for minor grid lines

`':'` (default) | `'-'` | `'--'` | `'-.'` | `'none'`

Line style used for minor grid lines, specified as one of the strings shown in this table.

String	Line Style
`'-'`	Solid line

String	Line Style
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dotted line
'none'	No line

To display minor grid lines, use the `grid minor` command or set the XGridMinor, YGridMinor, or ZGridMinor property to `'on'`.

`GridColor` — Color of grid lines

`[0.15 0.15 0.15]` (default) | RGB triplet | color string | `'none'`

Color of grid lines, specified as an RGB triplet, a color string, or `'none'`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
'yellow'	'y'	[1 1 0]
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

To set the colors for the axes box outline, use the XColor, YColor, and ZColor properties.

Setting this property sets the associated mode property to manual.

Example: `[0 0 1]`

Example: `'b'`

Example: `'blue'`

`GridColorMode` — Selection mode for `GridColor`

`'auto'` (default) | `'manual'`

Selection mode for the GridColor property, specified as `'auto'` or `'manual'`. The color is based on the values of the GridColorMode, `XColorMode`, `YColorMode`, and `ZColorMode` properties.

These tables list the grid line colors for different combinations of color modes.

GridColorMode Property	XColorMode Property	x-Axis Grid-Line Color
`'auto'`	`'auto'`	Use `GridColor` property.
`'auto'`	`'manual'`	Use `XGridColor` property.
`'manual'`	`'auto'`	Use `GridColor` property.
`'manual'`	`'manual'`	Use `GridColor` property.

GridColorMode Property	YColorMode Property	y-Axis Grid-Line Color
`'auto'`	`'auto'`	Use `GridColor` property.
`'auto'`	`'manual'`	Use `YGridColor` property.
`'manual'`	`'auto'`	Use `GridColor` property.
`'manual'`	`'manual'`	Use `GridColor` property.

GridColorMode Property	ZColorMode Property	z-Axis Grid-Line Color
`'auto'`	`'auto'`	Use `GridColor` property.
`'auto'`	`'manual'`	Use `ZGridColor` property.
`'manual'`	`'auto'`	Use `GridColor` property.
`'manual'`	`'manual'`	Use `GridColor` property.

`MinorGridColor` — Color of minor grid lines

`[0.1 0.1 0.1]` (default) | RGB triplet | color string

Color of minor grid lines, specified as an RGB triplet, a color string, or `'none'`.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0 0 1]`

Example: `'b'`

Example: `'blue'`

`MinorGridColorMode` — Selection mode for `MinorGridColor`

`'auto'` (default) | `'manual'`

Selection mode for the MinorGridColor property, specified as `'auto'` or `'manual'`. The minor grid line color is based on the values of the MinorGridColorMode, `XColorMode`, `YColorMode`, and `ZColorMode` properties.

These tables list the minor grid line colors for different combinations of color modes.

MinorGridColorMode Property	XColorMode Property	x-Axis Minor Grid-Line Color
`'auto'`	`'auto'`	Use `MinorGridColor` property.
`'auto'`	`'manual'`	Use `XGridColor` property.

MinorGridColorMode Property	XColorMode Property	x-Axis Minor Grid-Line Color
`'manual'`	`'auto'`	Use `MinorGridColor` property.
`'manual'`	`'manual'`	Use `MinorGridColor` property.

MinorGridColorMode Property	YColorMode Property	y-Axis Minor Grid-Line Color
`'auto'`	`'auto'`	Use `MinorGridColor` property.
`'auto'`	`'manual'`	Use `YGridColor` property.
`'manual'`	`'auto'`	Use `MinorGridColor` property.
`'manual'`	`'manual'`	Use `MinorGridColor` property.

MinorGridColorMode Property	ZColorMode Property	z-Axis Minor Grid-Line Color
`'auto'`	`'auto'`	Use `MinorGridColor` property.
`'auto'`	`'manual'`	Use `ZGridColor` property.
`'manual'`	`'auto'`	Use `MinorGridColor` property.
`'manual'`	`'manual'`	Use `MinorGridColor` property.

`GridAlpha` — Grid-line transparency

`0.15` (default) | value in the range `[0,1]`

Grid-line transparency, specified as a value in the range `[0,1]`. A value of `1` means opaque and a value of `0` means completely transparent.

Setting this property sets the associated mode property to manual.

Example: `0.5`

`GridAlphaMode` — Selection mode for `GridAlpha`

`'auto'` (default) | `'manual'`

Selection mode for the GridAlpha property, specified as one of these values:

- `'auto'` — Use default transparency value of `0.15`.
- `'manual'` — Use the manually specified transparency value. To specify the value, set the GridAlpha property.

`MinorGridAlpha` — Minor grid-line transparency

`0.25` (default) | value in the range `[0,1]`

Minor grid-line transparency, specified as a value in the range `[0,1]`. A value of `1` means opaque and a value of `0` means completely transparent.

Setting this property sets the associated mode property to manual.

Example: `0.5`

`MinorGridAlphaMode` — Selection mode for `MinorGridAlpha`

`'auto'` (default) | `'manual'`

Selection mode for the `MinorGridAlpha` property, specified as one of these values:

- `'auto'` — Use the default transparency value of `0.15`.
- `'manual'` — Use the manually specified transparency value. To specify the value, set the MinorGridAlpha property.

`Layer` — Placement of grid lines and tick marks in relation to graphic objects

`'bottom'` (default) | `'top'`

Placement of grid lines and tick marks in relation to graphic objects, specified as one of these values:

- `'bottom'` — Display tick marks and grid lines under graphics objects.
- `'top'` — Display tick marks and grid lines over graphics objects.

This property affects only 2-D views.

Font Style

`FontName` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`FontSize` — Font size

`10` (default) | scalar numeric value

Font size, specified as a scalar numeric value. The FontSize, LabelFontSizeMultiplier, and TitleFontSizeMultiplier properties determine the size of the text used for the axis labels and the title. The FontUnits property determines the units used to interpret the font size.

Example: `12`

`TitleFontSizeMultiplier` — Scale factor for title font size

`1.1` (default) | numeric value greater than 0

Scale factor for title font size, specified as a numeric value greater than 0. The axes applies this scale factor to the value of the FontSize property to determine the font size for the title.

Example: `1.75`

`LabelFontSizeMultiplier` — Scale factor for label font size

`1.1` (default) | numeric value greater than 0

Scale factor for label font size, specified as a numeric value greater than 0. The axes applies this scale factor to the value of the FontSize property to determine the font size for the *x*-axis, *y*-axis, and *z*-axis labels.

Example: `1.5`

`FontUnits` — Font size units

`'points'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'normalized'` | `'pixels'`

Font size units, specified as one of the values in this table.

Units	Description
`'points'`	Points. One point equals 1/72 inch.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'normalized'`	Interpreted as a fraction of the axes height. If you resize the axes, MATLAB modifies the font size accordingly. For example, if the `FontSize` is `0.1` in normalized units, then the text is 1/10 of the axes height.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

If you set both the font size and the font units in one function call, you must set the FontUnits property first so that the axes correctly interprets the specified font size.

`FontAngle` — Character slant

`'normal'` (default) | `'italic'`

Character slant, specified as `'normal'` or `'italic'`. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

Note: The `'oblique'` value has been removed. Use `'italic'` instead.

FontWeight — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- 'normal' — Default weight as defined by the particular font
- 'bold' — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The 'light' and 'demi' font weight values have been removed. Use 'normal' instead.

TitleFontWeight — Thickness of title text

'bold' (default) | 'normal'

Thickness of the title text, specified as one of these values:

- 'bold' — Thicker characters outlines than normal.
- 'normal' — Default weight as defined by the particular font.

FontSmoothing — Text smoothing

'on' (default) | 'off'

Text smoothing, specified as one of these values:

- 'on' — Use antialiasing to make text appear smoother on the screen.
- 'off' — Do not use antialiasing. Use this setting if the text seems blurry. In certain cases, smoothed text blends against the background color and results in a blurring effect.

Title and Axis Labels

Title — Text object for axes title

text object (default)

Text object for axes title. Refer to this text object to change properties of the title.

```
ax = gca;
ax.Title.String = 'My Graph Title';
ax.Title.FontWeight = 'normal';
```

Note: To access the axes title text object, use the Title property or the `title` function. This text object is not contained in the axes `Children` property, it cannot be returned by `findobj`, and it does not use default values defined for text objects.

`XLabel`, `YLabel`, `ZLabel` — Text object for axis label

text object (default)

Text object for *x*-axis, *y*-axis, or *z*-axis label. Refer to this text object to change properties of the axis label.

```
ax = gca;
ax.YLabel.String = 'Y Axis';
ax.YLabel.FontSize = 12;
```

Note: To access the axis label text objects, use the XLabel, YLabel, and ZLabel properties or the `xlabel`, `ylabel`, and `zlabel` functions. These text objects are not contained in the axes `Children` property, they cannot be returned by `findobj`, and they do not use default values defined for text objects.

Line Colors and Line Styles

`ColorOrder` — Colors for multiline plots

seven predefined colors (default) | three-column matrix of RGB triplets

Colors for multiline plots, specified as a three-column matrix of RGB triplets. Each row of the matrix defines one color in the color order. The default color order has seven colors.

Default Color Order	Associated RGB Triplets

	`[ 0 0.4470 0.7410`
	`0.8500 0.3250 0.0980`
	`0.9290 0.6940 0.1250`
	`0.4940 0.1840 0.5560`

Default Color Order	Associated RGB Triplets
	0.4660 0.6740 0.1880 0.3010 0.7450 0.9330 0.6350 0.0780 0.1840]

The functions that create line plots cycle through the colors to color each line. The hold state for the axes affects the colors used.

- If the hold state is off (when the NextPlot property is set to `'replace'`), then high-level plotting functions such as `plot` reset the color order to the default colors before plotting. If you want to specify new colors for the color order and do not want high-level plotting functions to reset them, then set the NextPlot property to `'replacechildren'`. Alternatively, you can specify a new default value for the ColorOrder property on the root using the `set` function. For example, use `set(groot,'defaultAxesColorOrder',[0 1 0; 0 0 1])`.
- If the hold state for the axes is on (when the NextPlot property is set to `'add'`), then plotting functions cycle through the colors starting from the place in the color order where the last plot ended.

Data Types: `single` | `double`

`LineStyleOrder` — Line styles and markers for multiline plots

`'-'` solid line (default) | cell array of specifiers

Line styles and markers for multiline plots, specified as a cell array of one or more specifiers in this table, for example, `{'-*',':','o'}`.

Specifier	Line Style
`'-'`(default)	Solid line
`'--'`	Dashed line
`':'`	Dotted line
`'-.'`	Dash-dotted line
`'+'`	Plus sign markers
`'o'`	Circle markers
`'*'`	Star markers
`'.'`	Point markers

Specifier	Line Style
'x'	Cross markers
's'	Square markers
'd'	Diamond markers
'^'	Upward-pointing triangle markers
'v'	Downward-pointing triangle markers
'>'	Right-pointing triangle markers
'<'	Left-pointing triangle markers
'p'	Five-pointed star (pentagram) markers
'h'	Six-pointed star (hexagram) markers

Combine strings to specify lines with markers, such as `'-*'`. The plot cycles through the line styles only after using all the colors contained in the `ColorOrder` property. If the hold state for the axes is off (when the NextPlot property of the axes is set to `'replace'`), then high-level plotting functions such as `plot` reset the line style order to the default line styles before plotting. If you want to specify a set of line styles that is different from the default and do not want high-level plotting functions to reset the `LineStyleOrder` property, then set NextPlot to `'replacechildren'`. Alternatively, you can specify a new default value for the LineStyleOrder property on the root using the `set` function. For example, use `set(groot,'defaultAxesLineStyleOrder',{'-*',':','o'})`.

Example: `{'-*',':','o'}`

`ColorOrderIndex` — Next color to use in color order

1 (default) | positive integer

Next color to use in the color order, specified as a positive integer. New plots added to the axes use colors based on the current value of the color order index. To use the first color for the next plot added to the axes, set the property to `1`.

After a `hold on` command, subsequently called plotting functions continue to cycle through the color-order, beginning with the current value of the color order index. Reset the color-order by setting the index to `1`.

If the specified index exceeds the number of colors defined by the current `ColorOrder` property, then plotting functions use the `mod` function to determine the index value as:

```
mod(ColorOrderIndex value, number of colors in ColorOrder)
```

Example: 5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`LineStyleOrderIndex` — Next line style to use in line style order

1 (default) | positive integer

Next line style to use in line style order, specified as a positive integer. New plots added to the axes use line styles based on the current value of the line style order index. To use the first line style, set this property to `1`.

After a `hold on` command, subsequently called plotting functions continue to cycle through the line-style order, beginning with the current value of the line style order index.

If the specified index exceeds the number of line styles defined by the current `LineStyleOrder` property, plotting functions use the `mod` function to determine the index value as:

```
mod(LineStyleOrderIndex value,number of line styles  in LineStyleOrder)
```

Note: The default LineStyleOrder has only one line style.

Example: 1

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Color and Transparency Mapping

`CLim` — Color limits for objects using colormap

`[0 1]` (default) | two-element vector of the form `[cmin cmax]`

Color limits for objects in axes that use the colormap, specified as a two-element vector of the form `[cmin cmax]`. This property determines how data values map to the colors in the colormap where:

- `cmin` specifies the data value that maps to the first color in the colormap.
- `cmax` specifies the data value that maps to the last color in the colormap.

The axes linearly interpolates data values between `cmin` and `cmax` across the colormap. Values outside this range use either the first or last color, whichever is closest.

For information on changing the colormap, see the `colormap` function. For information on color mapping, see the `caxis` function.

If the associated mode property is set to `'auto'`, then MATLAB chooses the color limits. If you assign a value to this property, then MATLAB sets the mode to `'manual'` and does not automatically choose the color limits.

`CLimMode` — Selection mode for `CLim`

`'auto'` (default) | `'manual'`

Selection mode for the CLim property, specified as one of these values:

- `'auto'` — Set the CLim property to span the CData limits of the graphics objects displayed in the axes.
- `'manual'` — Use the manually specified values. To specify the values, set the CLim property. The axes does not change the values when the limits of the axes children change.

`ALim` — Alpha limits for images, patches, and surfaces with transparency

`[0 1]` (default) | two-element vector of the form `[amin amax]`

Alpha limits for images, patches, and surfaces with transparency, specified as a two-element vector of the form `[amin amax]`. This property determines how values in the AlphaData properties of image, patch, and surface objects map to the figure alpha map, where:

- `amin` specifies the data value mapped to the first alpha value in the figure alpha map.
- `amax` specifies the data value mapped to the last alpha value in the figure alpha map.

The axes linearly interpolates data values between `amin` and `amax` across the figure alpha map. Values outside this range use either the first or last alpha map value, whichever is closest.

The `Alphamap` property of the figure contains the alpha map. For more information, see the `alpha` function.

If the associated mode property is set to `'auto'`, then MATLAB chooses the alpha limits. If you set this property, then MATLAB sets the mode to `'manual'` and does not automatically choose the alpha limits.

`ALimMode` — Selection mode for `ALim`

`'auto'` (default) | `'manual'`

Selection mode for the ALim property, specified as one of these values:

- `'auto'` — Use values that span the AlphaData of the axes children contained in the Children property.
- `'manual'` — Use the manually specified values. To specify the values, set the ALim property.

`AmbientLightColor` — Background light color

`[1 1 1]` (default) | RGB triplet | color string

Background light color, specified as an RGB triplet or a color string. Ambient light is a directionless light that shines uniformly on all objects in the axes when there is a visible light object in the axes.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[1 0 1]`

Example: `'m'`

Example: `'magenta'`

Multiple Plots

`NextPlot` — Properties to reset when adding new plot

`'replace'` (default) | `'add'` | `'replacechildren'`

Properties to reset when adding a new plot to the axes, specified as one of these values:

- `'replace'` — Reset all axes properties, except Position and Units, to their default values and delete all axes children before displaying the new plot. Using this value is similar to using `cla reset`.
- `'add'` — Use the existing axes to add more plots to the axes and do not reset properties.
- `'replacechildren'` — Remove all child objects before adding new plots, but do not reset axes properties. This is similar to using `cla`.

The `newplot` function simplifies the use of the NextPlot property and is useful for writing custom graphing functions. Figures also have a `NextPlot` property.

`SortMethod` — Order for rendering objects

`'depth'` (default) | `'childorder'`

Order for rendering objects, specified as one of these values:

- `'depth'` — Draw objects in back-to-front order based on the current view. Use this value to ensure that objects in front of other objects are drawn correctly.
- `'childorder'` — Draw objects in the order in which they are created by graphics functions, without considering the relationship of the objects in three dimensions. This value can result in faster rendering, particularly if the figure is very large, but can also result in improper depth sorting of the objects displayed

Visibility

`Visible` — Visibility of axes

`'on'` (default) | `'off'`

Visibility of axes, specified as one of these values:

- `'on'` — Display the axes.
- `'off'` — Hide the axes without deleting it. You still can access the properties of an invisible axes object.

`Clipping` — Clipping of objects to axes limits

`'on'` (default) | `'off'`

Clipping of objects to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of plotted objects that are outside the axes limits.
- `'off'` — Display all plotted objects, even if parts of them appear outside the axes limits. Parts can appear outside the limits if you create a plot, set `hold on`, freeze the axis scaling, and then add a plot that is larger than the original plot.

The axes and individual objects in the axes have a `Clipping` property that controls the clipping behavior. If the `Clipping` property for the axes is `'on'`, then each individual object in the axes controls its own clipping behavior. To disable clipping for all objects in the axes, set the `Clipping` property for the axes to `'off'`. This table lists the results for different combinations of `Clipping` property values.

Clipping Property for Axes	Clipping Property for Individual Object	Result
`'on'`	`'on'`	Individual object is clipped (default)
`'on'`	`'off'`	Individual object is not clipped
`'off'`	`'on'`	No objects in axes are clipped
`'off'`	`'off'`	No objects in axes are clipped

`ClippingStyle` — Boundaries used for clipping

`'3dbox'` (default) | `'rectangle'`

Boundaries used for clipping, specified as one of these values:

- `'3dbox'` — Clip plotted objects to the six sides of the axes box defined by the axis limits.

- `'rectangle'` — Clip plotted objects to a rectangular boundary enclosing the axes in any given view.

The ClippingStyle property does not affect the display of objects if the `Clipping` property is set to `'off'` for either the object or the axes.

Location and Size

`Position` — Size and position of axes within figure or uipanel

`[0.1300 0.1100 0.7750 0.8150]` (default) | four-element vector

Size and position of the axes within the figure or uipanel that contains the axes, specified as a four-element vector of the form `[left bottom width height]`. The `left` and `bottom` elements define the distance from the lower-left corner of the container to the lower-left corner of the axes. The `width` and `height` elements are the axes dimensions.

By default, the values are measured in units normalized to the container. To change the units, set the `Units` property.

The axes dimensions are the largest possible values that conform to all other properties and do not extend outside the `Position` rectangle. Other axes properties that affect the axes size and shape include `DataAspectRatio`, `PlotBoxAspectRatio`, and `CameraViewAngle`.

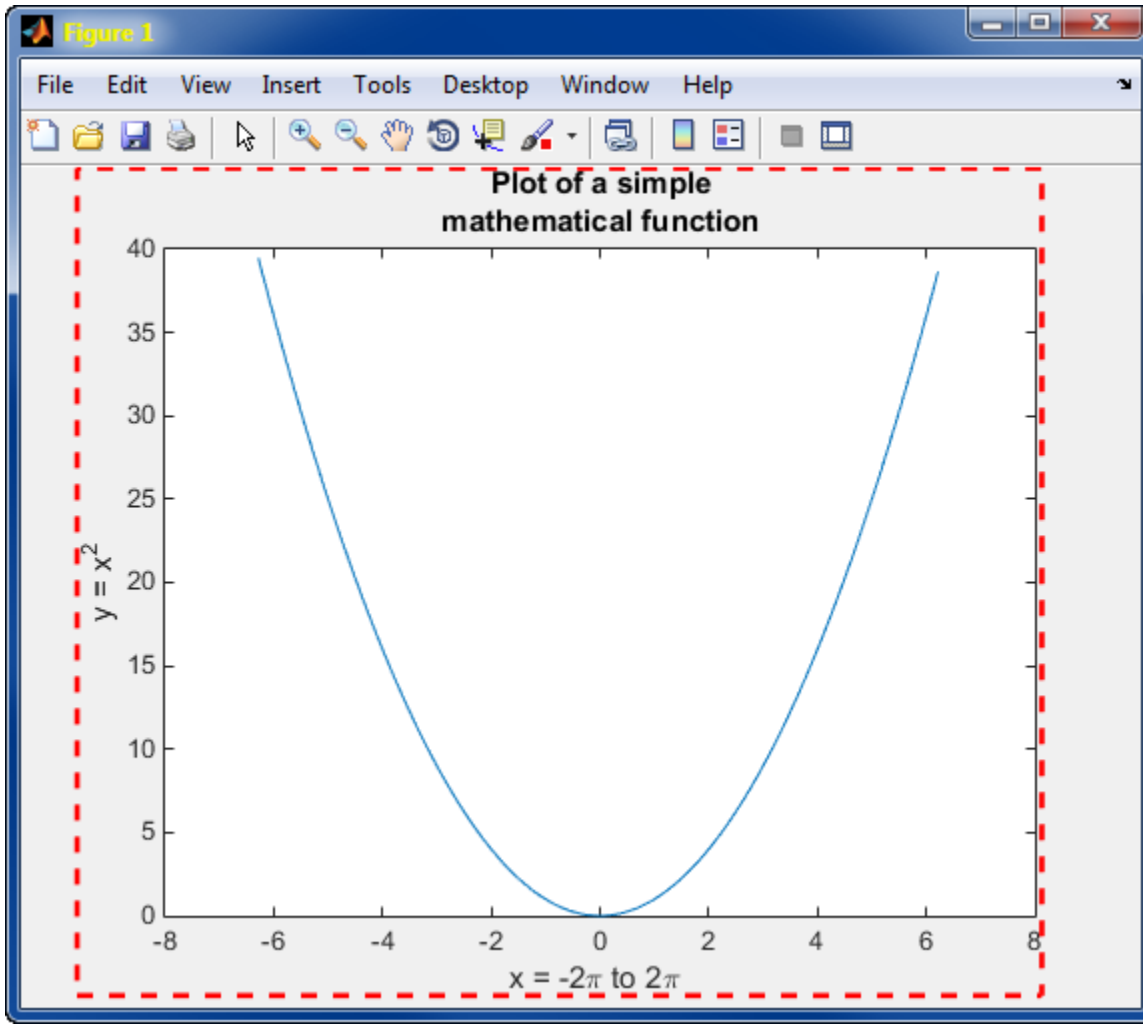
Example: `[0 0 1 1]`

`TightInset` — Margins for text labels

four-element vector of the form `[left bottom right top]`

Margins for the text labels, specified as a four-element vector of the form `[left bottom right top]`. The elements define the distances between the bounds of the Position property and the extent of the axes text labels and title. By default, the values are measured in units normalized to the figure or uipanel that contains the axes. To change the units, set the `Units` property.

The Position property and the TightInset property define the tightest bounding box that encloses the axes and its labels and title. The figure shows the region defined by combining the TightInset values and the Position values.



For more information, see “Axes Resize to Accommodate Titles and Labels”.

`OuterPosition` — Size and location of axes, including labels and margins

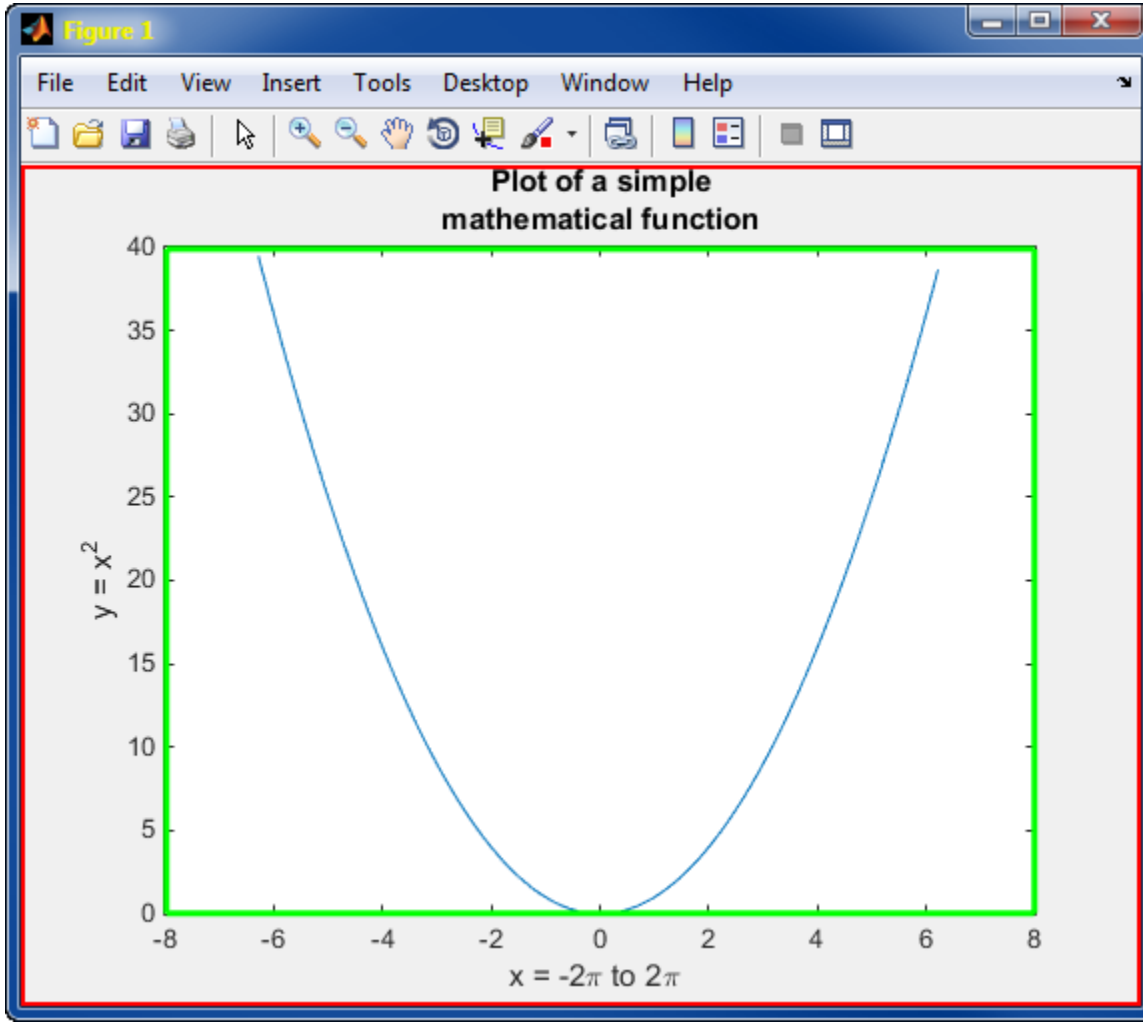
`[0 0 1 1]` (default) | four-element vector

Size and location of axes, including the labels and margins, specified as a four-element vector of the form `[left bottom width height]`. This vector defines the extents of

the rectangle that encloses the outer bounds of the axes. The `left` and `bottom` elements define the distance from the lower-left corner of the figure or uipanel that contains the axes to the lower-left corner of the rectangle. The `width` and `height` elements are the rectangle dimensions.

By default, the values are measured in units normalized to the container. To change the units, set the `Units` property. The default value of `[0 0 1 1]` includes the whole interior of the container.

The figure shows the region defined by the OuterPosition enclosed in the red rectangle. The green rectangle is the region defined by the Position property.



For more information, see “Axes Resize to Accommodate Titles and Labels”.

`ActivePositionProperty` — Position property to hold constant during resize operation
`'outerposition'` (default) | `'position'`

Position property to hold constant during resize operation, specified as one of these values:

- `'outerposition'` — Hold the `OuterPosition` property constant. Resizing the figure does not clip any of the text.
- `'position'` — Hold the `Position` property constant.

A figure can change size if you interactively change resize it or during a printing or exporting operation.

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'points'` | `'pixels'` | `'characters'`

Position units, specified as one of the values in this table.

`Units`	Description
`'normalized'` (default)	Normalized with respect to the container, which is typically the figure or a uipanel. The lower-left corner of the container maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.
`'pixels'`	Pixels. Pixel size depends on the screen resolution.

When specifying the units as a `Name,Value` pair during object creation, you must set the `Units` property before specifying the properties that you want to use these units, such as `Position`.

Aspect Ratio

`Projection` — Type of projection onto 2-D screen

`'orthographic'` (default) | `'perspective'`

Type of projection onto 2-D screen, specified as one of these values:

- `'orthographic'` — Maintain the correct relative dimensions of graphics objects regarding the distance of a given point from the viewer, and draw lines that are parallel in the data on the screen.
- `'perspective'` — Incorporate foreshortening, which allows you to perceive depth in 2-D representations of 3-D objects. Perspective projection does not preserve the relative dimensions of objects. Instead, it displays a distant line segment smaller than a nearer line segment of the same length. Lines that are parallel in the data might not appear parallel on screen.

`DataAspectRatio` — Relative length of data units along each axis

`[1 1 1]` (default) | three-element vector of the form `[dx dy dz]`

Relative length of data units along each axis, specified as a three-element vector of the form `[dx dy dz]`. This vector defines the relative *x*, *y*, and *z* data scale factors. For example, specifying this property as `[1 2 1]` sets the length of one unit of data in the *x*-direction to be the same length as two units of data in the *y*-direction and one unit of data in the *z*-direction.

The DataAspectRatio property interacts with the `PlotBoxAspectRatio`, `XLimMode`, `YLimMode`, and `ZLimMode` properties to control how MATLAB scales the *x*-axis, *y*-axis, and *z*-axis.

Setting a value for the DataAspectRatio disables the "stretch-to-fill figure shape" behavior if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all set to `'auto'`.

If the associated mode property is set to `'auto'`, then MATLAB chooses the ratio values. If you set this property, then MATLAB sets the mode to `'manual'`.

Example: `[1 1 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`DataAspectRatioMode` — Selection mode for `DataAspectRatio`

`'auto'` (default) | `'manual'`

Selection mode for the DataAspectRatio property, specified as one of these values:

- `'auto'` — Use values that make best use of the area provided by the figure.
- `'manual'` — Use the manually specified values. To specify the values, set the DataAspectRatio property. Changing DataAspectRatioMode to `'manual'` disables the "stretch-to-fill figure shape" behavior if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all `'auto'`.

  This table describes the behavior for various combinations of properties when you disable the stretch-to-fill behavior.

XLimitMode, YLimitMode, and ZLimitMode	DataAspectRatioMode	PlotBoxAspectRatioMode	Behavior
`'auto'`	`'auto'`	`'auto'`	The axes chooses limits that span the data range in all dimensions.
`'auto'`	`'auto'`	`'manual'`	The axes chooses limits that span the data range in all dimensions and modifies DataAspectRatio to achieve the specified PlotBoxAspectRatio within the limits.
`'auto'`	`'manual'`	`'auto'`	The axes chooses limits that span the data range in all dimensions and modifies PlotBoxAspectRatio to achieve the specified DataAspectRatio within the limits.
`'auto'`	`'manual'`	`'manual'`	The axes chooses limits that completely fit and center the plot within the specified PlotBoxAspectRatio given the specified

XLimitMode, YLimitMode, and ZLimitMode	DataAspectRatioMode	PlotBoxAspectRatioMode	Behavior
			DataAspectRatio (this might produce empty space around 2 of the 3 dimensions).
`'manual'`	`'auto'`	`'auto'`	The axes honors the specified limits and modifies the DataAspectRatio and PlotBoxAspectRatio as necessary.
`'manual'`	`'auto'`	`'manual`	The axes honors the specified limits and PlotBoxAspectRatio values and modifies the DataAspectRatio values as necessary.
`'manual'`	`'manual'`	`'auto'`	The axes honors the specified limits and DataAspectRatio values and modifies the PlotBoxAspectRatio values as necessary.
One set to `'manual'` and two set to `'auto'`	`'manual'`	`'manual'`	The axes selects the remaining limits to honor the specified aspect ratios and limit.
Two set to `'manual'` and one set to `'auto'`, or all three set to `'manual'`	`'manual'`	`'manual'`	The axes ignores the PlotBoxAspectRatio value and uses the specified limits and DataAspectRatio

`PlotBoxAspectRatio` — Relative length of each axis

`[1 1 1]` (default) | three-element vector of the form `[px py pz]`

Relative length of each axis, specified as a three-element vector of the form `[px py pz]` defining the relative *x*-axis, *y*-axis, and *z*-axis scale factors. The plot box is a box enclosing the axes data region as defined by the axis limits.

The PlotBoxAspectRatio property interacts with the DataAspectRatio, XLimMode, YLimMode, and ZLimMode properties. Setting the PlotBoxAspectRatio disables the "stretch-to-fill figure shape" behavior, if DataAspectRatioMode, PlotBoxAspectRatioMode, and CameraViewAngleMode are all `'auto'`.

If the associated mode property is set to `'auto'`, then MATLAB chooses the ratio values. If you set this property, then MATLAB sets the mode to `'manual'`.

Example: `[1,0.75,0.75]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`PlotBoxAspectRatioMode` — Selection mode for `PlotBoxAspectRatio`

`'auto'` (default) | `'manual'`

Selection mode for the PlotBoxAspectRatio property, specified as one of these values:

- `'auto'` — Use values that make best use of the area provided by the figure.
- `'manual'` — Use the manually specified values. To specify the values, set the PlotBoxAspectRatio property. Changing PlotBoxAspectRatioMode to `'manual'` disables the "stretch-to-fill figure shape" behavior if PlotBoxAspectRatioMode, DataAspectRatioMode, and CameraViewAngleMode are all `'auto'`.

This table describes the behavior for various combinations of properties when you disable the stretch-to-fill behavior.

XLimitMode, YLimitMode, and ZLimitMode	DataAspectRatioMode	PlotBoxAspectRatioMode	Behavior
`'auto'`	`'auto'`	`'auto'`	The axes chooses limits that span the data range in all dimensions.
`'auto'`	`'auto'`	`'manual'`	The axes chooses limits that span the data range in all dimensions and modifies DataAspectRatio to

XLimitMode, YLimitMode, and ZLimitMode	DataAspectRatioMode	PlotBoxAspectRatioMode	Behavior
			achieve the specified PlotBoxAspectRatio within the limits.
'auto'	'manual'	'auto'	The axes chooses limits that span the data range in all dimensions and modifies PlotBoxAspectRatio to achieve the specified DataAspectRatio within the limits.
'auto'	'manual'	'manual'	The axes chooses limits that completely fit and center the plot within the specified PlotBoxAspectRatio given the specified DataAspectRatio (this might produce empty space around 2 of the 3 dimensions).
'manual'	'auto'	'auto'	The axes honors the specified limits and modifies the DataAspectRatio and PlotBoxAspectRatio as necessary.
'manual'	'auto'	'manual	The axes honors the specified limits and PlotBoxAspectRatio values and modifies the DataAspectRatio values as necessary.

XLimitMode, YLimitMode, and ZLimitMode	DataAspectRatioMode	PlotBoxAspectRatioMode	Behavior
`'manual'`	`'manual'`	`'auto'`	The axes honors the specified limits and DataAspectRatio values and modifies the PlotBoxAspectRatio values as necessary.
One set to `'manual'` and two set to `'auto'`	`'manual'`	`'manual'`	The axes selects the remaining limits to honor the specified aspect ratios and limit.
Two set to `'manual'` and one set to `'auto'`, or all three set to `'manual'`	`'manual'`	`'manual'`	The axes ignores the PlotBoxAspectRatio value and uses the specified limits and DataAspectRatio

View

`CameraPosition` — Location of camera

three-element vector of the form `[x y z]`

Location of camera, or the viewpoint, specified as a three-element vector of the form `[x y z]`. This vector defines the axes coordinates of the location. Changing the CameraPosition property changes the point from which you view the axes.

The camera is oriented along the view axis, which is a straight line that connects the camera position and the camera target. For an illustration, see “Camera Graphics Terminology”.

If the `Projection` is `'perspective'`, then as you change the CameraPosition, the amount of perspective also changes.

If the associated mode property is set to `'auto'`, then MATLAB chooses the camera location. If you set this property, then MATLAB sets the mode to `'manual'`.

Data Types: `single | double`

CameraPositionMode — Selection mode for CameraPosition

'auto' (default) | 'manual'

Selection mode for the CameraPosition property, specified as one of these values:

- 'auto' — Calculate the CameraPosition value such that the camera lies a fixed distance from the target along the azimuth and elevation specified by the current view, as returned by the view function. Functions like rotate3d, zoom, and pan, change this mode to 'auto' to perform their actions.
- 'manual' — Use the manually specified value. To specify the value, set the CameraPosition property.

This table summarizes the camera behavior for various combinations of CameraViewAngleMode, CameraTargetMode, and CameraPositionMode property values.

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
'auto'	'auto'	'auto'	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
'auto'	'auto'	'manual'	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene.
'auto'	'manual'	'auto'	Sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
'auto'	'manual'	'manual'	Sets CameraViewAngle to capture entire scene.
'manual'	'auto'	'auto'	Sets CameraTarget to plot box centroid, sets CameraPosition along the view axis.
'manual'	'auto'	'manual'	Sets CameraTarget to plot box centroid.

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
'manual'	'manual'	'auto'	Sets CameraPosition along the view axis.
'manual'	'manual'	'manual'	Uses specified camera values

CameraTarget — Point used as camera target

three-element vector of the form `[x y z]`

Point used as camera target, specified as a three-element vector of the form `[x y z]`. This vector defines the axes coordinates of the point. The camera is oriented along the view axis, which is a straight line that connects the camera position and the camera target. For an illustration, see "Camera Graphics Terminology".

If the associated mode property is set to `'auto'`, then MATLAB chooses the camera target point. If you set this property, then MATLAB sets the mode to `'manual'`.

Data Types: `single | double`

CameraTargetMode — Selection mode for CameraTarget

`'auto'` (default) | `'manual'`

Selection mode for the CameraTarget property, specified as one of these values:

- `'auto'` — Position the camera target at the centroid of the axes plot box.
- `'manual'` — Use the manually specified camera target value. To specify a value, set the `CameraTarget` property.

This table summarizes the camera behavior for various combinations of CameraViewAngleMode, CameraTargetMode, and CameraPositionMode property values.

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
'auto'	'auto'	'auto'	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
'auto'	'auto'	'manual'	Sets CameraTarget to plot box centroid, sets

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
			CameraViewAngle to capture entire scene.
'auto'	'manual'	'auto'	Sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
'auto'	'manual'	'manual'	Sets CameraViewAngle to capture entire scene.
'manual'	'auto'	'auto'	Sets CameraTarget to plot box centroid, sets CameraPosition along the view axis.
'manual'	'auto'	'manual'	Sets CameraTarget to plot box centroid.
'manual'	'manual'	'auto'	Sets `CameraPosition` along the view axis.
'manual'	'manual'	'manual'	Uses specified camera values

`CameraUpVector` — Vector defining upwards direction

`[0 1 0]` (default for 2-D view) | `[0 0 1]` (default for 3-D view) | three-element direction vector of the form `[x y z]`

Vector defining upwards direction, specified as a three-element direction vector of the form `[x y z]`. For an illustration, see "Camera Graphics Terminology".

If the associated mode property is set to `'auto'`, then MATLAB chooses the vector values. If you set this property, then MATLAB sets the mode to `'manual'`.

Example: `[sin(45) cos(45) 1]`

`CameraUpVectorMode` — Selection mode for `CameraUpVector`

`'auto'` (default) | `'manual'`

Selection mode for the CameraUpVector property, specified as one of these values:

- `'auto'` — Use `[0 0 1]` for 3-D views so that the positive *z*-direction is up. Use `[0 1 0]` for 2-D views so that the positive *y*-direction is up.

- `'manual'` — Use the manually specified vector defining the upwards direction. To specify a value, set the `CameraUpVector` property.

`CameraViewAngle` — Field of view

`6.6086` (default) | scalar angle in range [0,180)

Field of view, specified as a scalar angle greater than 0 and less than or equal to 180. Changing the camera view angle affects the size of graphics objects displayed in the axes, but does not affect the degree of perspective distortion. The greater the angle, the larger the field of view and the smaller objects appear in the scene. For an illustration, see "Camera Graphics Terminology".

If the associated mode property is set to `'auto'`, then MATLAB chooses the field of view value. If you set this property, then MATLAB sets the mode to `'manual'`.

Example: `15`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`CameraViewAngleMode` — Selection mode for `CameraViewAngle`

`'auto'` (default) | `'manual'`

Selection mode for the CameraViewAngle property, specified as one of these values:

- `'auto'` — Select the field of view as the minimum angle that captures the entire scene, up to 180 degrees.
- `'manual'` — Use the manually specified field of view. To specify a value, set the `CameraViewAngle` property.

  This table summarizes the camera behavior for various combinations of CameraViewAngleMode, CameraTargetMode, and CameraPositionMode property values.

`CameraViewAngleMode`	`CameraTargetMode`	`CameraPositionMode`	Behavior
`'auto'`	`'auto'`	`'auto'`	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.

CameraViewAngleMode	CameraTargetMode	CameraPositionMode	Behavior
'auto'	'auto'	'manual'	Sets CameraTarget to plot box centroid, sets CameraViewAngle to capture entire scene.
'auto'	'manual'	'auto'	Sets CameraViewAngle to capture entire scene, sets CameraPosition along the view axis.
'auto'	'manual'	'manual'	Sets CameraViewAngle to capture entire scene.
'manual'	'auto'	'auto'	Sets CameraTarget to plot box centroid, sets CameraPosition along the view axis.
'manual'	'auto'	'manual'	Sets CameraTarget to plot box centroid.
'manual'	'manual'	'auto'	Sets `CameraPosition` along the view axis.
'manual'	'manual'	'manual'	Uses specified camera values

`View` — (obsolete) Azimuth and elevation of view

`[0 90]` (default) | two-element vector of the form `[azimuth elevation]`

Azimuth and elevation of view, specified as a two-element vector of the form `[azimuth elevation]` defined in degree units.

This property is obsolete. Use the CameraPosition, CameraTarget, CameraUpVector, and CameraViewAngle properties instead.

Example: `[45 45]`

Identifiers

`Type` — Type of graphics object

`'axes'`

Type of graphics object returned as the string `'axes'`.

`Tag` — Tag to associate with axes

`''` (default) | any string

Tag to associate with the axes, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with axes

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the axes object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent of axes

figure object | uipanel object | uitab object

Parent of axes, specified as figure object, uipanel object, or uitab object.

`Children` — Children of axes

empty `GraphicsPlaceholder` array | array of graphics objects

Children of axes, returned as an array of graphics objects. Use this property to view a list of the children or to reorder the children by setting the property to a permutation of itself.

You cannot add or remove children using the `Children` property of the axes. To add a child to this list, set the `Parent` property of the child graphics object to the axes object.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of axes object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The axes object handle is always visible.
- `'off'` — The axes object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The axes object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the axes at the command-line, but allows callback functions to access it.

If the axes object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`CurrentPoint` — Location of last mouse click

2-by-3 array

Location of last mouse click, specified as a 2-by-3 array in the axes coordinate system. The CurrentPoint property contains the coordinates of two points defined by the location of the pointer at the last mouse click, with respect to the requested axes.

If the click is within the axes in orthogonal projection, then the two points lie on the line that is perpendicular to the plane of the screen and that passes through the pointer. This is true for both 2-D and 3-D views.

The 3-D coordinates are the points, in the axes coordinate system, where this line intersects the front and back surfaces of the axes volume (which is defined by the axes x, y, and z limits).

The returned matrix is of the form:

```
[xfront yfront zfront
 xback  yback  zback]
```

The first row defines the point nearest to the camera position. The second row specified the point furthest from the camera position.

If the click is outside the axes in orthogonal projection, but within the figure, the returned values are:

- Back point — Point in the plane of the camera target (which is perpendicular to the viewing axis).
- Front point — Point in the camera position plane (which is perpendicular to the viewing axis).

These points lie on a line that passes through the pointer and is perpendicular to the camera target and camera position planes.

The values of the current point when using perspective projection can be different from the same point in orthographic projection because the shape of the axes volume can be different.

Clicking outside of the axes volume in perspective projection returns the front point as the current camera position at all times. Only the back point updates with the coordinates of a point that lies on a line extending from the camera position through the pointer and intersecting the camera target at that point.

For related information, see the axes `Projection`, `CameraPosition`, and `CameraTarget` properties. Also, see the figure `CurrentPoint` properties.

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the axes. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The axes object — You can access properties of the axes object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the axes. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the axes when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the axes.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'all'` | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The Visible property must be set to `'on'`. The HitTest property determines if the axes responds to the click or if an ancestor does.
- `'all'` — Can capture mouse clicks regardless of visibility. The Visible property can be set to `'on'` or `'off'`. The HitTest property determines if the axes responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the axes passes the click to the object below it in the current view of the figure window, which is typically the axes or the figure. The HitTest property has no effect.

If you want an object to be clickable when it is underneath other objects that you do not want to be clickable, then set the `PickableParts` property of the other objects to `'none'` so that the click passes through them.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the axes. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the axes that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the axes object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the axes is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the axes tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the axes. Setting the `CreateFcn` property on an existing axes has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during axes creation. MATLAB executes the callback after creating the axes and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The axes object — You can access properties of the axes object from within the callback function. You also can access the axes object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the axes. MATLAB executes the callback before destroying the axes so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The axes object — You can access properties of the axes object from within the callback function. You also can access the axes object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of axes

`'off'` (default) | `'on'`

Deletion status of axes, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the axes begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the axes no longer exists.

Check the value of the BeingDeleted property to verify that the axes is not about to be deleted before querying or modifying it.

axis

Set axis limits and appearance

Syntax

```
axis(limits)

axis style
axis mode
axis ydirection
axis visibility

lim = axis
[m,v,d] = axis('state')

___ = axis(ax,___)
```

Description

`axis(limits)` sets the *x*-axis and *y*-axis limits for the current axes. Specify `limits` as a four-element of the form `[xmin xmax ymin ymax]`. To additionally set the *z*-axis limits, specify a six-element vector. To additionally set the color limits, specify an eight-element vector.

`axis style` uses a predefined style to set the limits and scaling. For example, specify the style as `equal` to use equal data unit lengths along each axis.

`axis mode` sets whether the axes automatically chooses the limits or not. Specify the mode as `manual`, `auto`, or one of the semiautomatic options, for example, `'auto x'`.

`axis ydirection` controls the placement of the coordinate system origin and the direction of increasing *y* values. Set `ydirection` to `ij` to place the origin at the upper left corner of the axes. The *y* values increase from top to bottom. Set `ydirection` to `xy` to place the origin at the lower left corner. The *y* values increase from bottom to top. This is the default value.

`axis visibility` controls the visibility of the axes background. Set `visibility` to `off` to turn off the display of the axes background. Plots in the axes still display. Set `visibility` to `on` to display the axes background. This is the default value.

`lim = axis` returns the *x*-axis and *y*-axis limits for the current axes. For 3-D axes, it additionally returns the *z*-axis limits.

`[m,v,d] = axis('state')` returns the current settings for the axis limit selection, the axes visibility, and the *y*-axis direction.

Note: This syntax will be removed in a future release. Use the `XLimMode`, `YLimMode`, `ZLimMode`, `Visible`, and `YDir` properties of the axes to the get values instead.

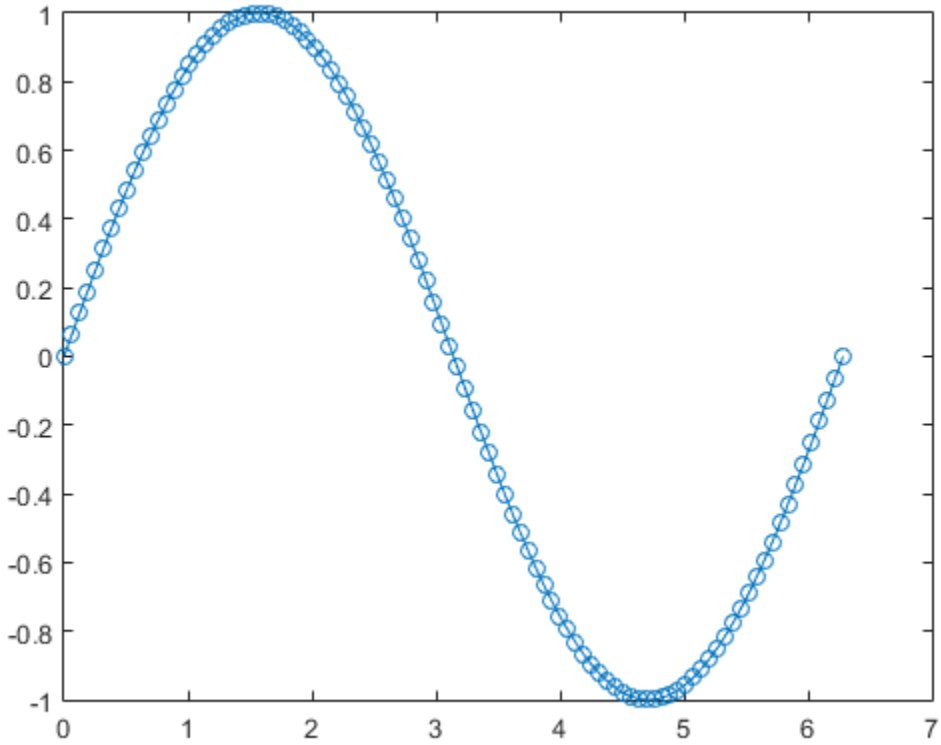
`___ = axis(ax, ___)` uses the axes specified by `ax` instead of the current axes. You can specify an axes with any of the input or output arguments in the previous syntaxes. When you specify an axes, use single quotes around input arguments that are character strings, for example, `axis(ax,'equal')`.

Examples

Set Axis Limits

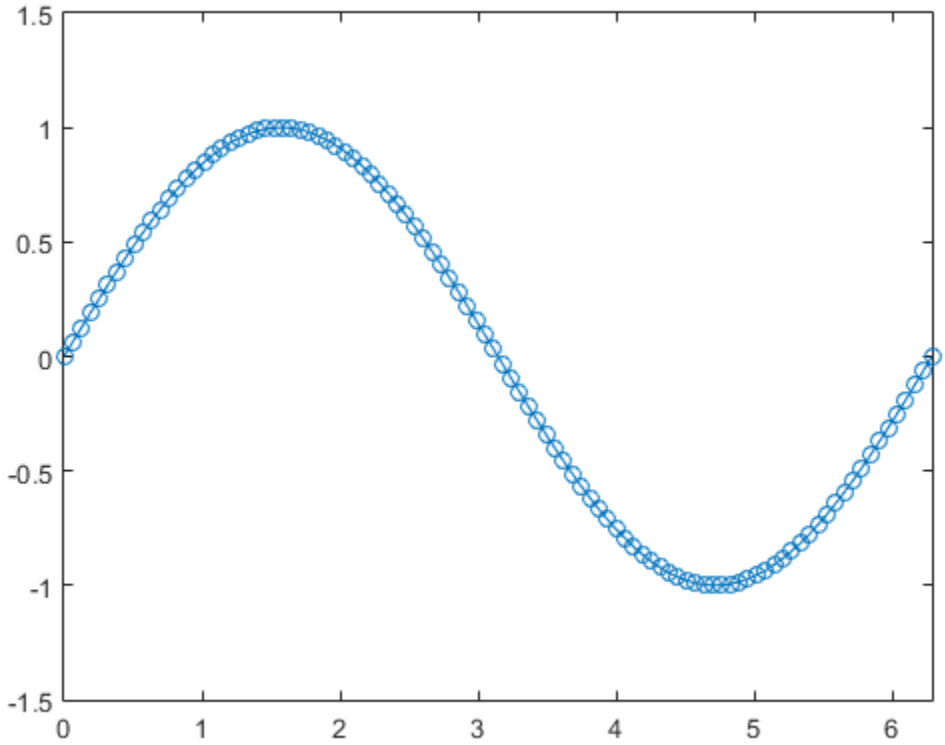
Plot the sine function.

```
x = linspace(0,2*pi);
y = sin(x);
plot(x,y,'-o')
```



Change the axis limits so that the *x*-axis ranges from 0 to 2π and the *y*-axis ranges from -1.5 to 1.5.

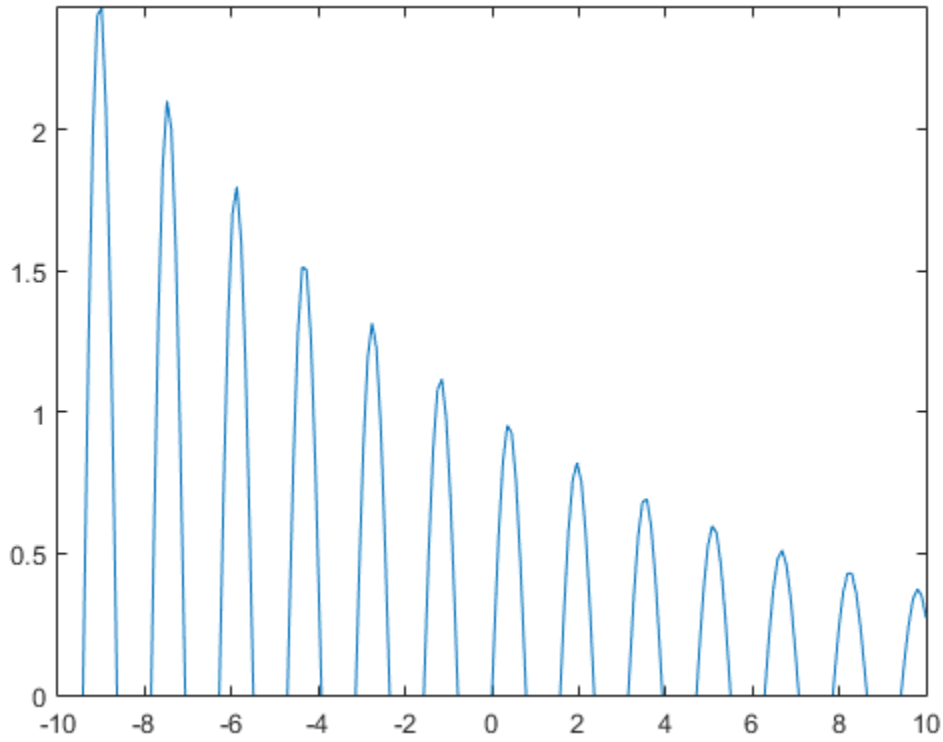
```
axis([0 2*pi -1.5 1.5])
```



Use Semiautomatic Axis Limits

Create a plot. Set the limits for the *x*-axis and set the minimum *y*-axis limit. Use an automatically calculated value for the maximum *y*-axis limit.

```
x = linspace(-10,10,200);
y = sin(4*x)./exp(.1*x);
plot(x,y)
axis([-10 10 0 inf])
```



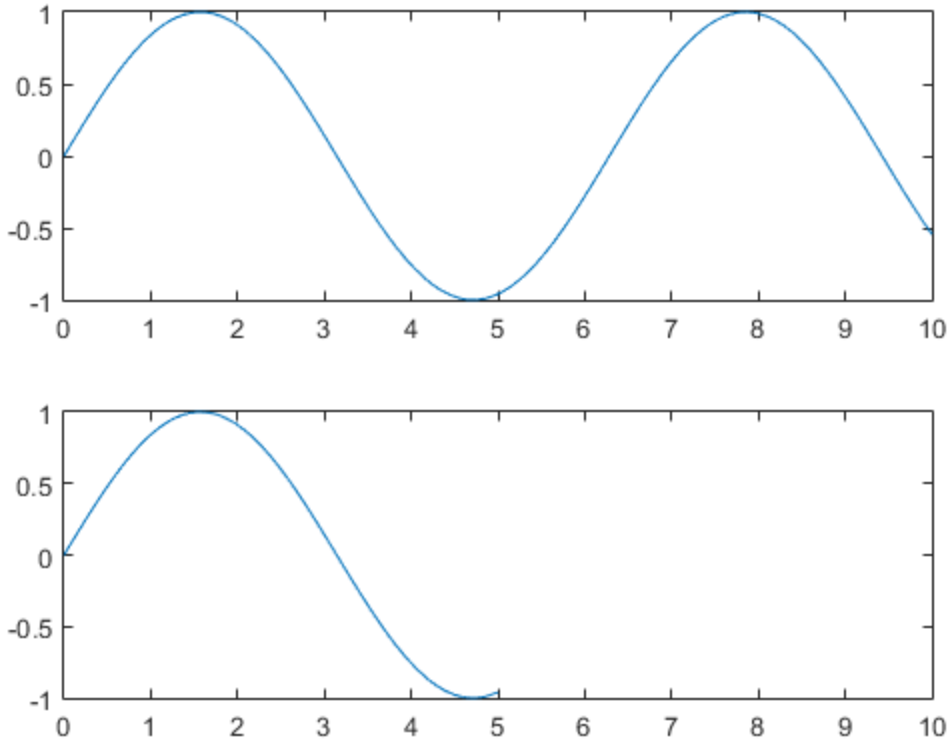
Set Axis Limits for Multiple Axes

Create a figure with two subplots. Plot a sine wave in each subplot. Then, set the axis limits for the subplots to the same values.

```
x1 = linspace(0,10,100);
y1 = sin(x1);
ax1 = subplot(2,1,1);
plot(ax1,x1,y1)

x2 = linspace(0,5,100);
y2 = sin(x2);
ax2 = subplot(2,1,2);
plot(ax2,x2,y2)
```

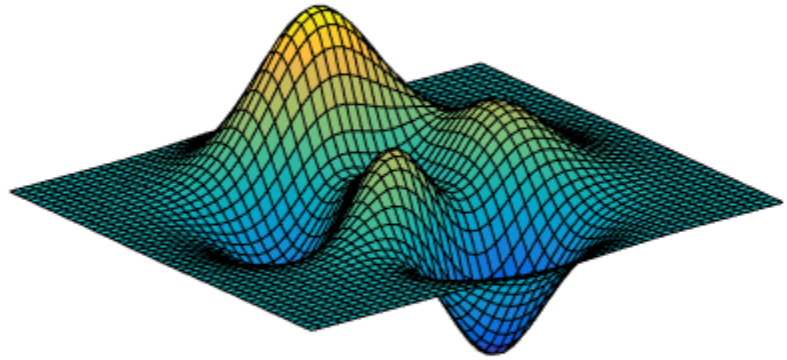
```
axis([ax1 ax2],[0 10 -1 1])
```



Display Plot Without Axes Background

Plot a surface without displaying the axes lines and background.

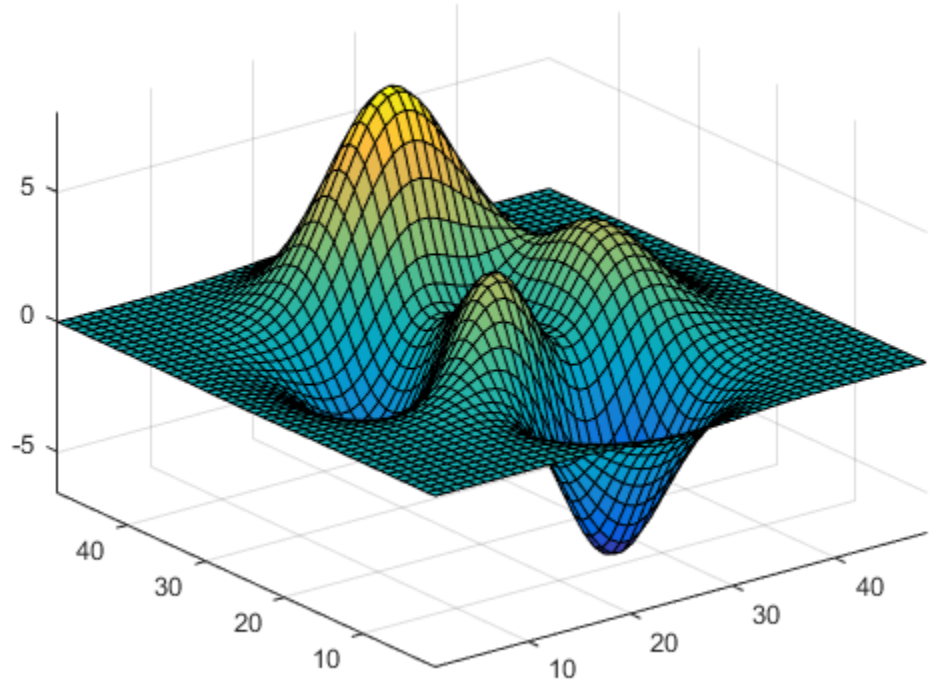
```
surf(peaks)
axis off
```



Use Tight Axis Limits and Return Values

Plot a surface. Set the axis limits to equal the range of the data so that the plot extends to the edges of the axes.

```
surf(peaks)
axis tight
```



Return the values of the current axis limits.

```
l = axis
```

```
l =

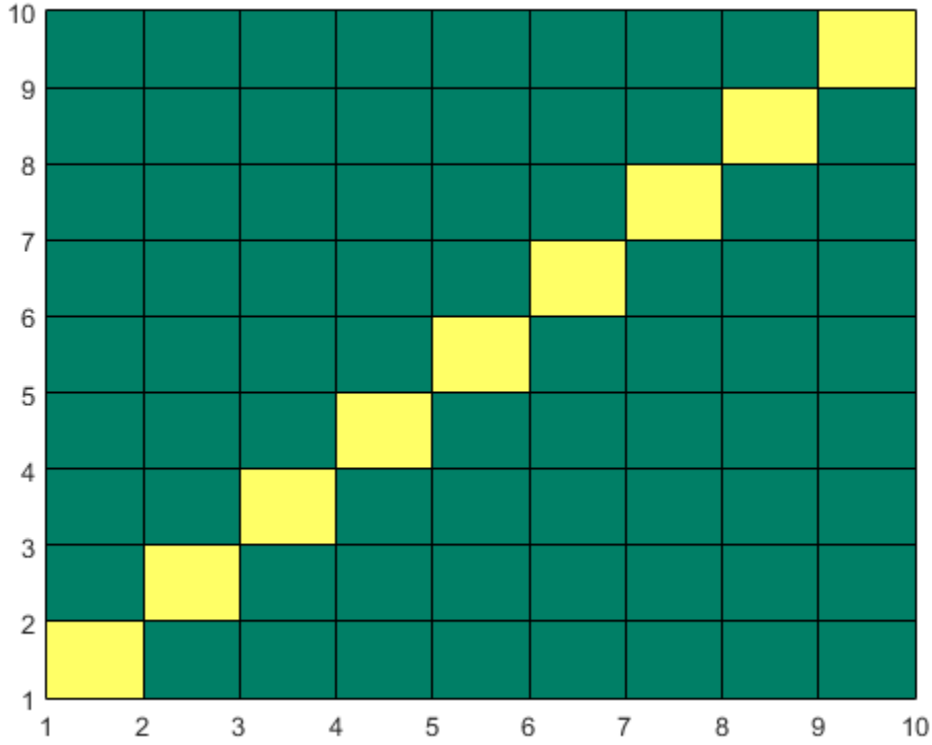
    1.0000   49.0000    1.0000   49.0000   -6.5466    8.0752
```

Change Direction of Coordinate System

Create a checkerboard plot and change the direction of the coordinate system.

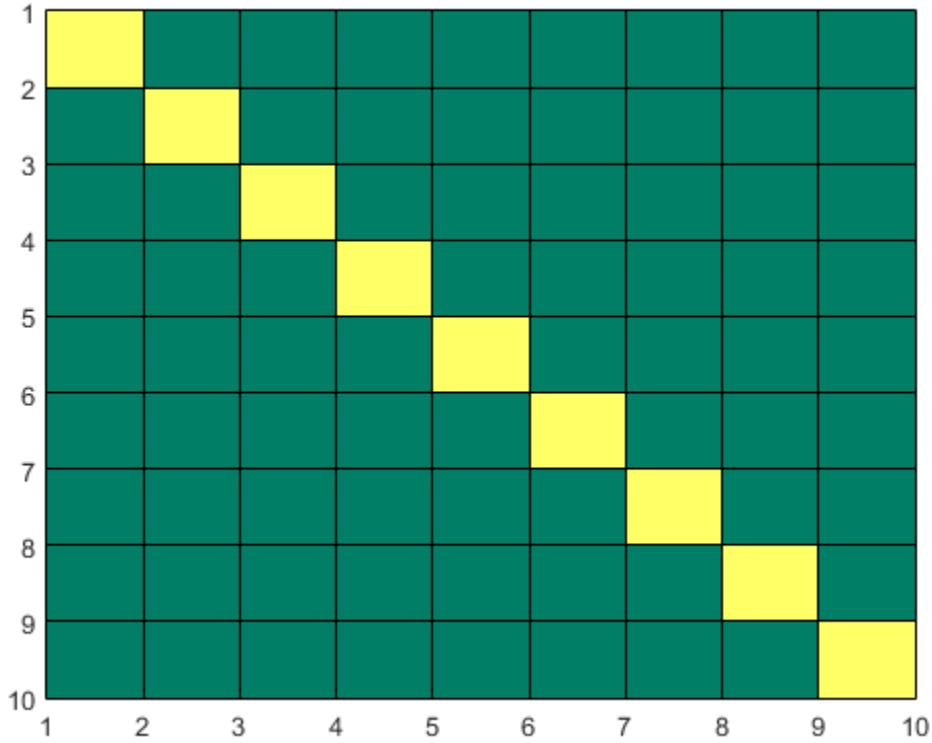
First, create the plot using the `summer` colormap. By default, the *x* values increase from left to right and the *y* values increase from bottom to top.

```
C = eye(10);
pcolor(C)
colormap summer
```



Reverse the coordinate system so that the *y* values increase from top to bottom.

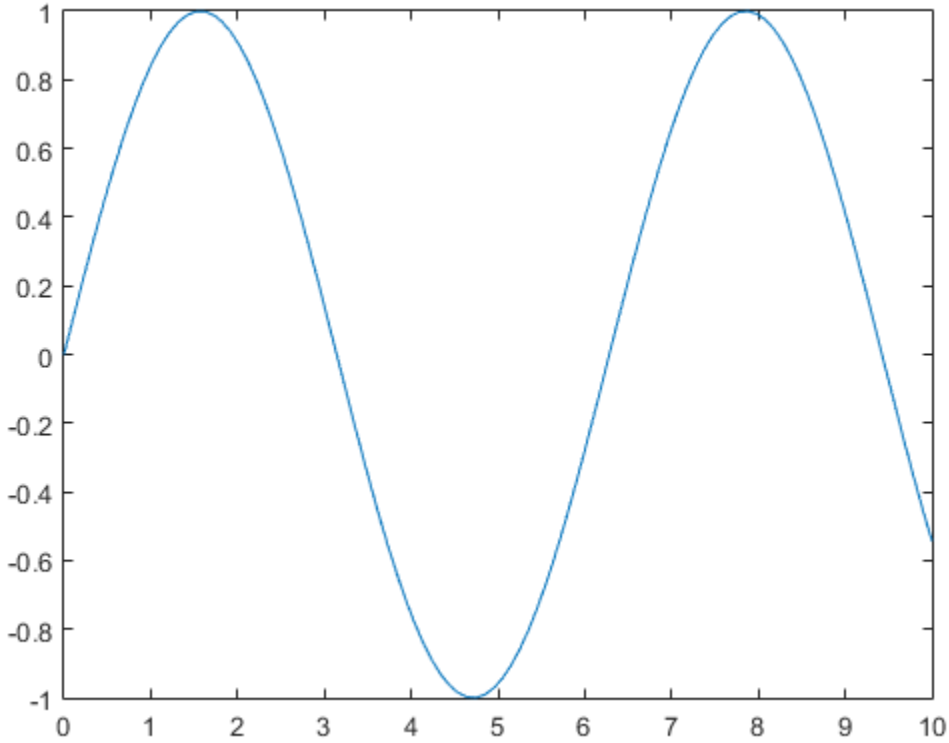
```
axis ij
```



Retain Current Axis Limits When Adding New Plots

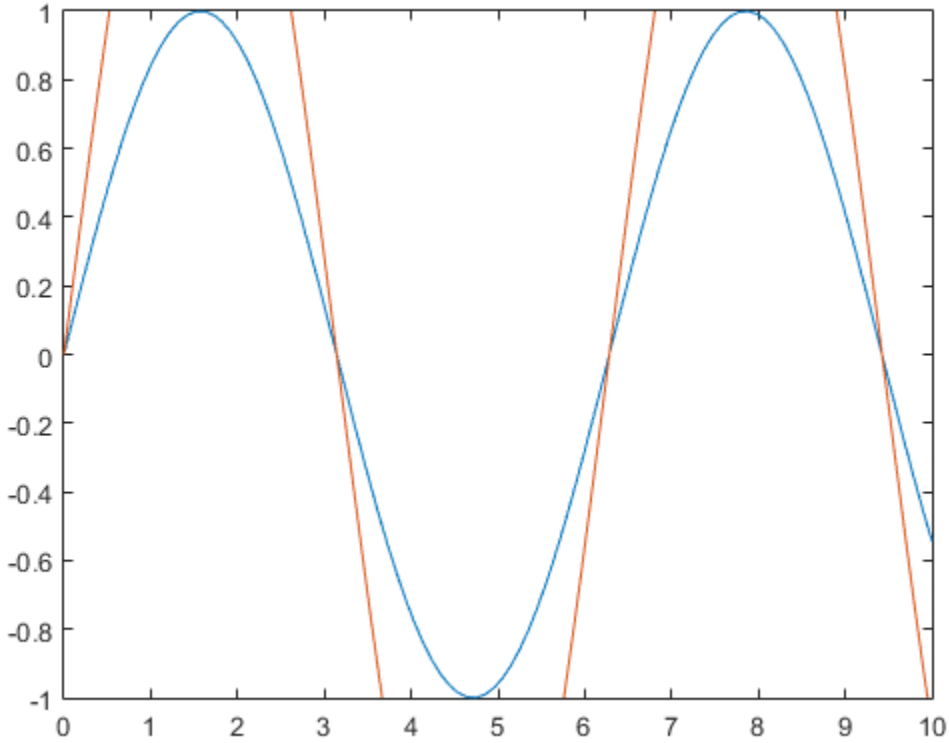
Plot a sine wave.

```
x = linspace(0,10);
y = sin(x);
plot(x,y)
```



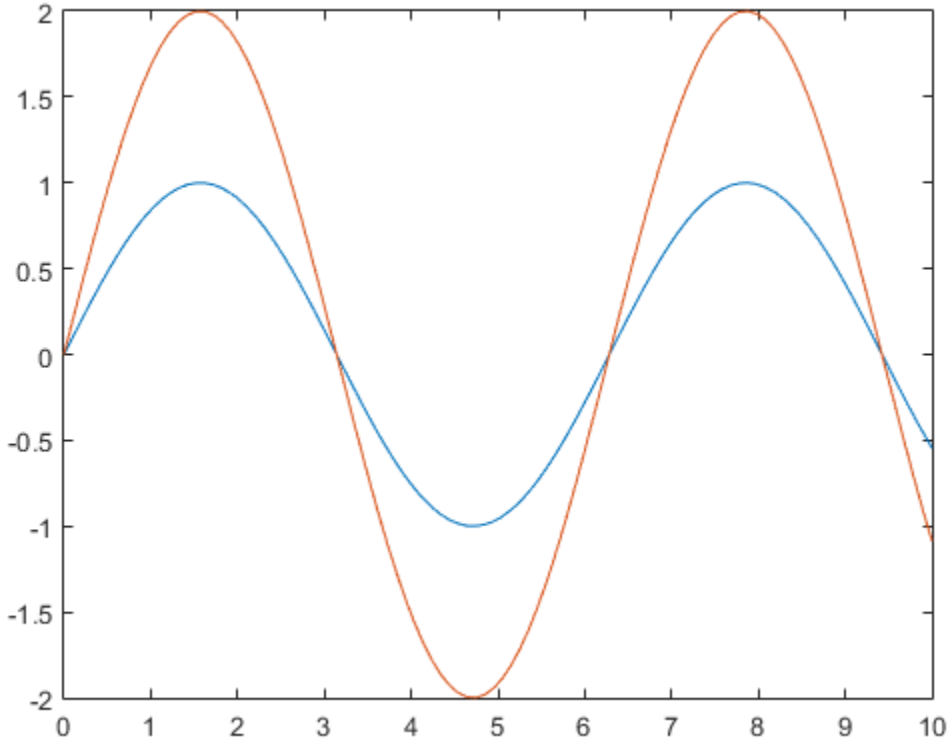
Add another sine wave to the axes using `hold on`. Keep the current axis limits by setting the limits mode to manual.

```
y2 = 2*sin(x);
hold on
axis manual
plot(x,y2)
hold off
```



If you want the axes to choose the appropriate limits, set the limits mode back to automatic.

```
axis auto
```



Input Arguments

`limits` — Axis limits

four-element vector | six-element vector | eight-element vector

Axis limits, specified as a vector of four, six, or eight elements in one of these forms:

- `[xmin xmax ymin ymax]` — Set the *x*-axis limits to range from `xmin` to `xmax`. Set the *y*-axis limits to range from `ymin` to `ymax`.
- `[xmin xmax ymin ymax zmin zmax]` — Additionally set the *z*-axis limits to range from `zmin` to `zmax`.

- `[xmin xmax ymin ymax zmin zmax cmin cmax]` — Additionally set the color limits. `cmin` is the data value that maps to the first color in the colormap. `cmax` is the data value that maps to the last color in the colormap.

Note: For partially automatic limits, use `inf` or `-inf` for the limits you want the axes to choose automatically. For example, `axis([-inf 10 0 inf])` lets the axes choose the appropriate minimum *x*-axis limit and maximum *y*-axis limit. It uses the specified values for the maximum *x*-axis limit and minimum *y*-axis limit.

If you specify the limits, then the `XLim`, `YLim`, `ZLim`, and `CLim` properties for the axes change to the specified values. Additionally, the associated mode properties change to `'manual'`.

Example: `[0 1 0 1]`

Example: `[0 1 0 1 0 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`mode` — Manual, automatic, or semiautomatic selection of axis limits

`manual` | `auto` | `'auto x'` | `'auto y'` | `'auto z'` | `'auto xy'` | `'auto xz'` | `'auto yz'`

Manual, automatic, or semiautomatic selection of axis limits, specified as one of the values in this table.

Value	Description	Axes Properties That Change
`manual`	Freeze all axis limits at their current values.	Sets `XLimMode`, `YLimMode`, and `ZLimMode` to `'manual'`.
`auto`	The axes automatically chooses all axis limits.	Sets `XLimMode`, `YLimMode`, and `ZLimMode` to `'auto'`.
`'auto x'`	The axes automatically chooses the *x*-axis limits.	Sets `XLimMode` to `'auto'`.
`'auto y'`	The axes automatically chooses the *y*-axis limits.	Sets `YLimMode` to `'auto'`.
`'auto z'`	The axes automatically chooses the *z*-axis limits.	Sets `ZLimMode` to `'auto'`.

Value	Description	Axes Properties That Change
`'auto xy'`	The axes automatically chooses the *x*-axis and *y*-axis limits.	Sets `XLimMode` and `YLimMode` to `'auto'`.
`'auto xz'`	The axes automatically chooses the *x*-axis and *z*-axis limits.	Sets `XLimMode` and `ZLimMode` to `'auto'`.
`'auto yz'`	The axes automatically chooses the *y*-axis and *z*-axis limits.	Sets `YLimMode` and `ZLimMode` to `'auto'`.

`style` — Axis limits and scaling

`tight | fill | equal | image | square | vis3d | normal`

Axis limits and scaling, specified as one of these values.

Value	Description	Axes Properties That Change
`tight`	Fit the axes box tightly around the data by setting the axis limits equal to the range of the data.	`XLimMode`, `YLimMode`, and `ZLimMode` change to `'auto'`. The limits automatically update to incorporate new data added to the axes. To keep the limits from changing when using `hold on`, use `axis tight manual`.
`equal`	Use the same length for the data units along each axis.	Sets `DataAspectRatio` to `[1 1 1]`, sets `PlotBoxAspectRatio` to `[3 4 4]`, and sets the associated mode properties to manual. Disables the "stretch-to-fill" behavior.
`image`	Use the same length for the data units along each axis and fit the axes box tightly around the data.	Sets `DataAspectRatio` to `[1 1 1]`and sets the associated mode property to manual. Disables the "stretch-to-fill" behavior.

Value	Description	Axes Properties That Change
`square`	Use axis lines with equal lengths. Adjust the increments between data units accordingly.	Sets `PlotBoxAspectRatio` to `[1 1 1]` and sets the associated mode property to manual. Disables the "stretch-to-fill" behavior.
`fill`	Enable the "stretch-to-fill" behavior (the default). The lengths of each axis line fill the position rectangle defined in the `Position` property of the axes.	Sets the plot box aspect ratio mode and data aspect ratio mode properties to auto.
`vis3d`	Freeze the aspect ratio properties.	Sets the plot box aspect ratio mode and data aspect ratio mode properties to manual.
`normal`	Restore the default behavior.	Sets the plot box aspect ratio mode and data aspect ratio mode properties to auto.

For more information on the plot box aspect ratio and the data aspect ratio, see the `PlotBoxAspectRatio` and `DataAspectRatio` properties for the axes.

You can combine style options. The options are evaluated from left to right, so subsequent options can overwrite properties set by prior ones.

`ydirection` — *y*-axis direction

`xy` (default) | `ij`

y-axis direction, specified as one of these values:

- `xy` — Default direction. For axes with a 2-D view, the *y*-axis is vertical with values increasing from bottom to top.
- `ij` — Reverse direction. For axes with a 2-D view, the *y*-axis is vertical with values increasing from top to bottom.

`visibility` — Axes lines and background visibility

`on` (default) | `off`

Axes lines and background visibility, specified as either `on` or `off`. Specifying the visibility sets the `Visible` property of the axes to the same value.

ax — Axes objects

scalar | vector

Axes objects, specified as a scalar or a vector. If you do not specify an axes, then `axis` sets the limits for the current axes (`gca`).

When you specify an axes, use single quotes around other input arguments that are character strings.

Example: `axis(ax,'tight')`

Example: `axis(ax,limits)`

Example: `axis(ax,'manual')`

Output Arguments

lim — Current limit values

four-element vector | six-element vector

Current limit values, returned as a four-element or six-element vector. For axes with a 2-D view, `lim` is of the form `[xmin xmax ymin ymax]`. For axes with a 3-D view, `lim` is of the form `[xmin xmax ymin ymax zmin zmax]`.

The `XLim`, `YLim`, and `ZLim` properties for the axes contain the limit values.

More About

Tips

- If an axes does not exist, the `axis` function creates one.
- Use `hold on` to keep plotting functions from overriding preset axis limits.

Properties

Axes Properties

Introduced before R2006a

Using alphaShape Objects

Polygons and polyhedra from points in 2-D and 3-D

An `alphaShape` creates a bounding area or volume that envelops a set of 2-D or 3-D points. You can manipulate the `alphaShape` object to tighten or loosen the fit around the points to create a nonconvex region. Additionally, you can add or remove points or suppress holes or regions.

After you create an `alphaShape` object, you can perform geometric queries. For example, you can determine if a point is inside the shape or find the number of regions that make up the shape. You can also calculate useful quantities like area, perimeter, surface area, or volume as well as plot the shape for visual inspection.

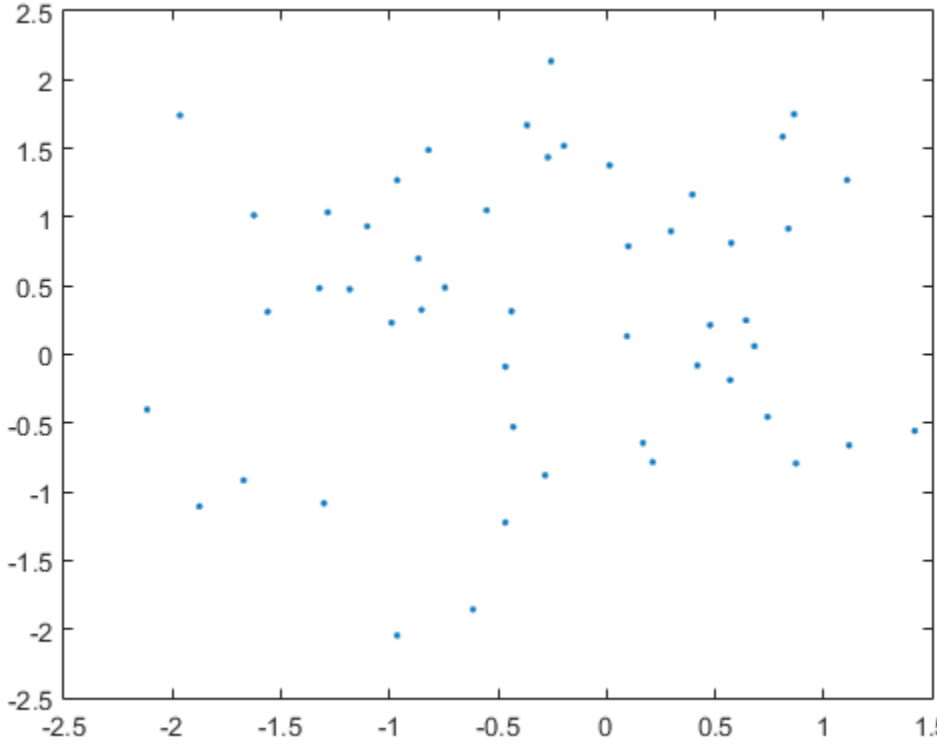
Examples

Using alphaShape Objects

This example shows how to change an alpha shape object and compute useful quantities that describe the alpha shape.

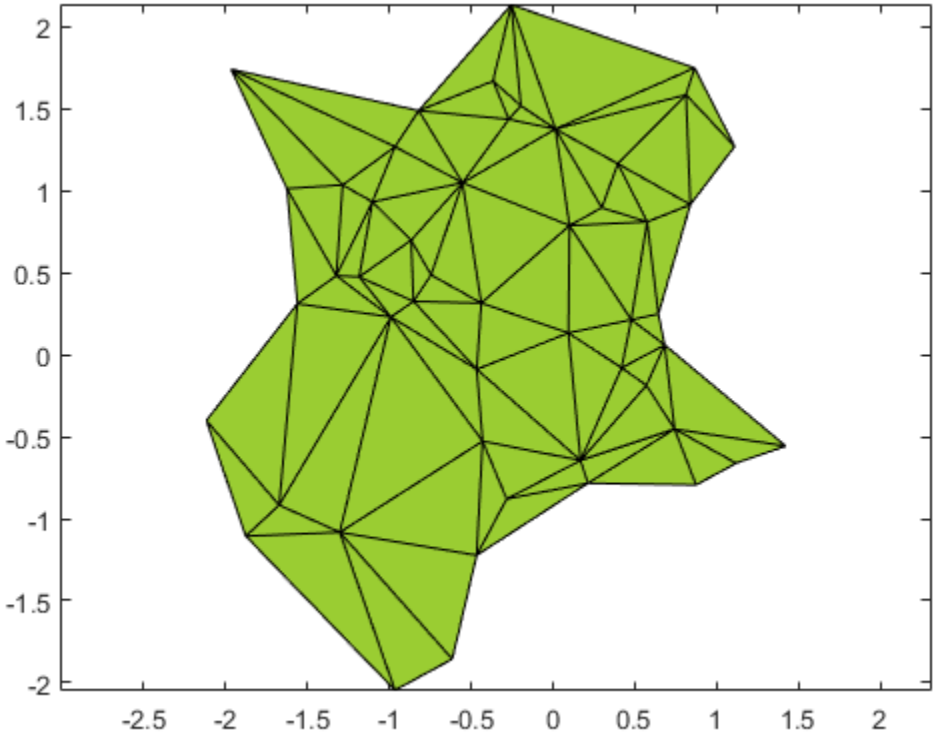
Create and plot a set of 2-D points.

```
x = gallery('normaldata',50,1,1);
y = gallery('normaldata',50,1,2);
plot(x,y,'.')
```



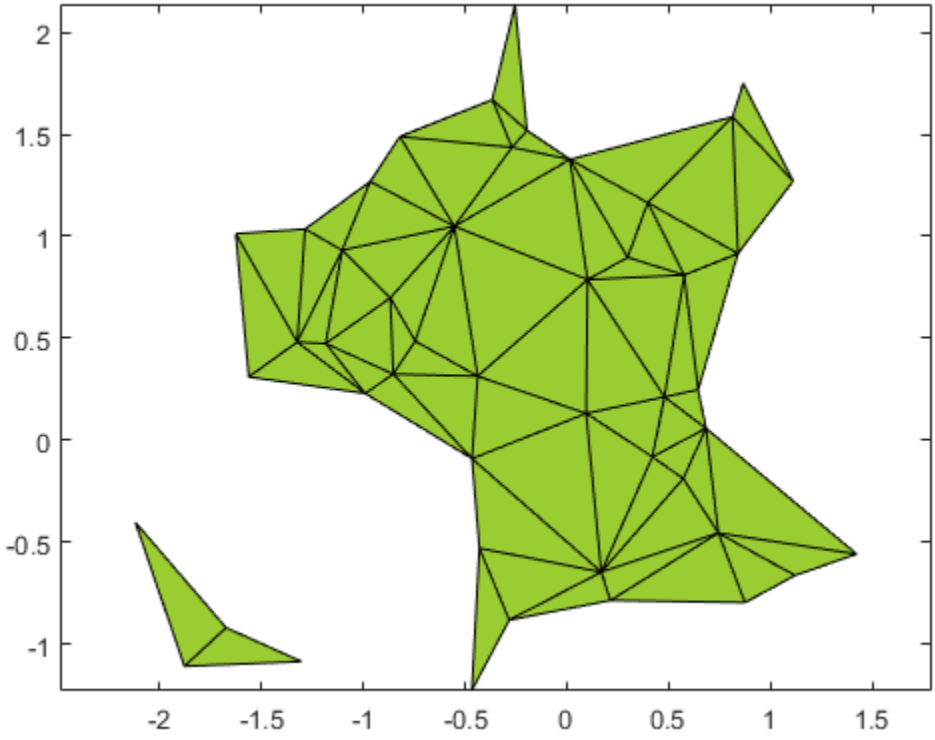
Create and plot an alpha shape using an alpha radius of 0.7.

```
shp = alphaShape(x,y,0.7);
plot(shp)
```



Change the alpha radius to 0.5 to tighten the boundary around the set of points.

```
shp.Alpha = 0.5;
plot(shp)
```



Query the number of regions that make up the new alpha shape.

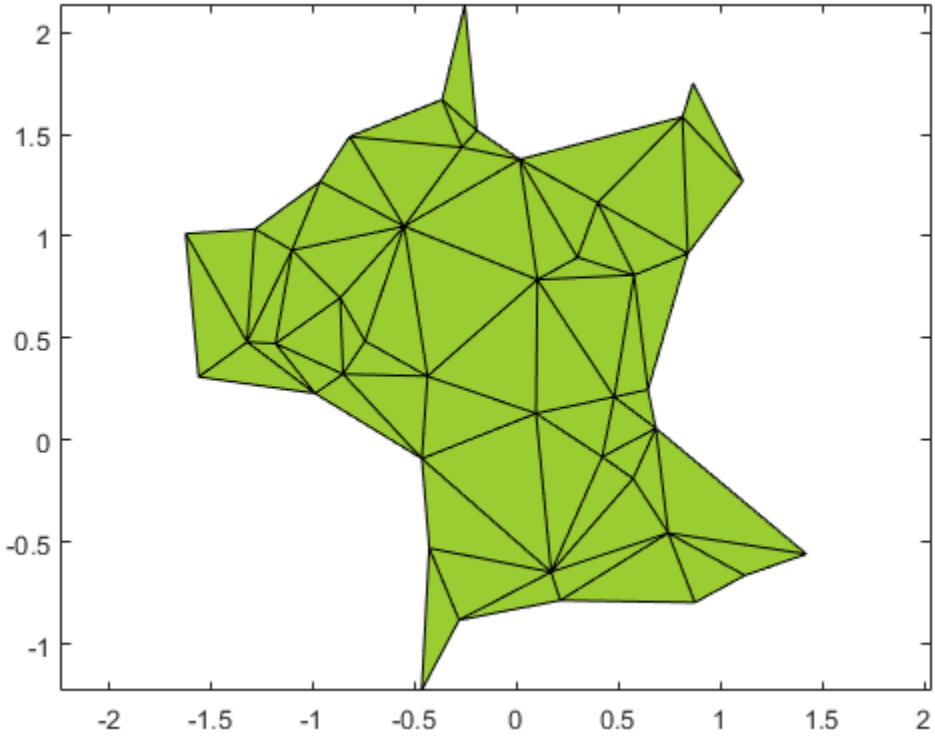
```
numRegions(shp)
```

```
ans =

     2
```

Suppress the smaller of the two regions.

```
shp.RegionThreshold = 1;
plot(shp)
```



Compute the perimeter and area of the remaining region.

```
regionperims = perimeter(shp)
regionareas = area(shp)
```

```
regionperims =

   11.8543

regionareas =

    4.5407
```

Properties

`Points` — Coordinates of points
matrix

Coordinates of points, specified as a matrix with two or three columns (for 2-D or 3-D point sets). These points are initially used to create the alpha shape, excluding duplicates.

Data Types: `double`

`Alpha` — Alpha radius
nonnegative scalar

Alpha radius, specified as a nonnegative scalar. The alpha radius is the radius of the alpha disk or sphere which sweeps over the points to create the alpha shape.

The default alpha radius is `a = criticalAlpha(shp,'all-points')`, which is the smallest alpha radius that produces an alpha shape enclosing all points. Specify `a = criticalAlpha(shp,'one-region')` to use the smallest alpha radius that produces an alpha shape with only one region.

The extreme values of `Alpha`:

- If `Alpha` is `Inf`, then `alphaShape` produces the convex hull.
- If `Alpha` is `0`, then the resulting `alphaShape` is empty.

Data Types: `double`

`HoleThreshold` — Maximum area (2-D) or volume (3-D) of interior holes or voids to fill in
`0` (default) | finite nonnegative scalar

Maximum area or volume of interior holes or voids to fill in, specified as a finite nonnegative scalar.

- For 2-D, `HoleThreshold` specifies the maximum area of interior holes to fill in.
- For 3-D, `HoleThreshold` specifies the maximum volume of interior voids to fill in. Holes extending completely through the 3-D alpha shape cannot be filled in.

The default value is `0`, so that `alphaShape` does not suppress any holes or voids. The application of the `HoleThreshold` and `RegionThreshold` properties is order-dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

`RegionThreshold` — Maximum area (2-D) or volume (3-D) of regions to suppress

`0` (default) | finite nonnegative scalar

Maximum area (2-D) or volume (3-D) of regions to suppress, specified as a finite nonnegative scalar.

The default value is `0`, so that `alphaShape` does not suppress any regions. The application of the `HoleThreshold` and `RegionThreshold` properties is order-dependent. `alphaShape` fills in holes before suppressing regions.

Data Types: `double`

`boundary`

balance

Diagonal scaling to improve eigenvalue accuracy

Syntax

```
[T,B] = balance(A)
[S,P,B] = balance(A)
B = balance(A)
B = balance(A,'noperm')
```

Description

`[T,B] = balance(A)` returns a similarity transformation `T` such that `B = T\A*T`, and `B` has, as nearly as possible, approximately equal row and column norms. `T` is a permutation of a diagonal matrix whose elements are integer powers of two to prevent the introduction of roundoff error. If `A` is symmetric, then `B == A` and `T` is the identity matrix.

`[S,P,B] = balance(A)` returns the scaling vector `S` and the permutation vector `P` separately. The transformation `T` and balanced matrix `B` are obtained from `A`, `S`, and `P` by `T(:,P) = diag(S)` and `B(P,P) = diag(1./S)*A*diag(S)`.

`B = balance(A)` returns just the balanced matrix `B`.

`B = balance(A,'noperm')` scales `A` without permuting its rows and columns.

Examples

This example shows the basic idea. The matrix `A` has large elements in the upper right and small elements in the lower left. It is far from being symmetric.

```
A = [1   100   10000; .01   1   100; .0001   .01   1]
A =
   1.0e+04 *
    0.0001    0.0100    1.0000
    0.0000    0.0001    0.0100
    0.0000    0.0000    0.0001
```

Balancing produces a diagonal matrix T with elements that are powers of two and a balanced matrix B that is closer to symmetric than A.

```
[T,B] = balance(A)
T =
   1.0e+03 *
    2.0480         0         0
         0    0.0320         0
         0         0    0.0003
B =
    1.0000    1.5625    1.2207
    0.6400    1.0000    0.7813
    0.8192    1.2800    1.0000
```

To see the effect on eigenvectors, first compute the eigenvectors of A, shown here as the columns of V.

```
[V,E] = eig(A); V
V =
0.9999         -0.9999             -0.9999
0.0100          0.0059 + 0.0085i    0.0059 - 0.0085i
0.0001          0.0000 - 0.0001i    0.0000 + 0.0001i
```

Note that all three vectors have the first component the largest. This indicates V is badly conditioned; in fact `cond(V)` is `8.7766e+003`. Next, look at the eigenvectors of B.

```
[V,E] = eig(B); V
V =
0.6933         -0.6993             -0.6993
0.4437          0.2619 + 0.3825i    0.2619 - 0.3825i
0.5679          0.2376 - 0.4896i    0.2376 + 0.4896i
```

Now the eigenvectors are well behaved and `cond(V)` is `1.4421`. The ill conditioning is concentrated in the scaling matrix; `cond(T)` is `8192`.

This example is small and not really badly scaled, so the computed eigenvalues of A and B agree within roundoff error; balancing has little effect on the computed results.

Limitations

Balancing can destroy the properties of certain matrices; use it with some care. If a matrix contains small elements that are due to roundoff error, balancing might scale them up to make them as significant as the other elements of the original matrix.

More About

Tips

- Nonsymmetric matrices can have poorly conditioned eigenvalues. Small perturbations in the matrix, such as roundoff errors, can lead to large perturbations in the eigenvalues. The condition number of the eigenvector matrix,

  ```
  cond(V) = norm(V)*norm(inv(V))
  ```

  where

  ```
  [V,T] = eig(A)
  ```

  relates the size of the matrix perturbation to the size of the eigenvalue perturbation. Note that the condition number of `A` itself is irrelevant to the eigenvalue problem.

  Balancing is an attempt to concentrate any ill conditioning of the eigenvector matrix into a diagonal scaling. Balancing usually cannot turn a nonsymmetric matrix into a symmetric matrix; it only attempts to make the norm of each row equal to the norm of the corresponding column.

  Note The MATLAB eigenvalue function, `eig(A)`, automatically balances `A` before computing its eigenvalues. Turn off the balancing with `eig(A,'nobalance')`.

`eig`

bandwidth

Lower and upper matrix bandwidth

Syntax

```
B = bandwidth(A,type)
```

```
[lower,upper] = bandwidth(A)
```

Description

`B = bandwidth(A,type)` returns the bandwidth of matrix `A` specified by `type`. Specify `type` as `'lower'` for the lower bandwidth, or `'upper'` for the upper bandwidth.

`[lower,upper] = bandwidth(A)` returns the lower bandwidth, `lower`, and upper bandwidth, `upper`, of matrix `A`.

Examples

Find Bandwidth of Triangular Matrix

Create a 6-by-6 lower triangular matrix.

```
A = tril(magic(6))
```

```
A =

    35     0     0     0     0     0
     3    32     0     0     0     0
    31     9     2     0     0     0
     8    28    33    17     0     0
    30     5    34    12    14     0
     4    36    29    13    18    11
```

Find the lower bandwidth of `A` by specifying `type` as `'lower'`.

```
B = bandwidth(A,'lower')
```

```
B =

     5
```

The result is 5 because every diagonal below the main diagonal has nonzero elements.

Find the upper bandwidth of A by specifying `type` as `'upper'`.

```
B = bandwidth(A,'upper')
```

```
B =

     0
```

The result is 0 because there are no nonzero elements above the main diagonal.

Find Bandwidth of Sparse Block Matrix

Create a 100-by-100 sparse block matrix.

```
B = kron(speye(25),ones(4));
```

View a 10-by-10 section of elements from the top left of B.

```
full(B(1:10,1:10))
```

```
ans =

     1     1     1     1     0     0     0     0     0     0
     1     1     1     1     0     0     0     0     0     0
     1     1     1     1     0     0     0     0     0     0
     1     1     1     1     0     0     0     0     0     0
     0     0     0     0     1     1     1     1     0     0
     0     0     0     0     1     1     1     1     0     0
     0     0     0     0     1     1     1     1     0     0
     0     0     0     0     1     1     1     1     0     0
     0     0     0     0     0     0     0     0     1     1
     0     0     0     0     0     0     0     0     1     1
```

B has 4-by-4 blocks of ones centered on the main diagonal.

Find both the lower and upper bandwidths of B by specifying two output arguments.

```
[lower,upper] = bandwidth(B)
```

```
lower =
```

```
     3

upper =

     3
```

The lower and upper bandwidths are both 3.

Input Arguments

A — Input matrix

2-D numeric matrix

Input matrix, specified as a 2-D numeric matrix. A can be either full or sparse.

Data Types: single | double
Complex Number Support: Yes

type — Bandwidth type

'lower' | 'upper'

Bandwidth type, specified as 'lower' or 'upper'.

- Specify 'lower' for the lower bandwidth (below the main diagonal).
- Specify 'upper' for the upper bandwidth (above the main diagonal).

Data Types: char

Output Arguments

B — Lower or upper bandwidth

nonnegative integer scalar

Lower or upper bandwidth, returned as a nonnegative integer scalar.

- If type is 'lower', then $0 \le B \le$ size(A,1)-1.
- If type is 'upper', then $0 \le B \le$ size(A,2)-1.

`lower` — Lower bandwidth

nonnegative integer scalar

Lower bandwidth, returned as a nonnegative integer scalar. `lower` is in the range `0 ≤ lower ≤ size(A,1)-1`.

`upper` — Upper bandwidth

nonnegative integer scalar

Upper bandwidth, returned as a nonnegative integer scalar. `upper` is in the range `0 ≤ upper ≤ size(A,2)-1`.

More About

Upper and Lower Bandwidth

The upper and lower bandwidths of a matrix are measured by finding the last diagonal (above or below the main diagonal, respectively) that contains nonzero values.

That is, for a matrix A with elements A_{ij}:

- The upper bandwidth B_1 is the smallest number such that $A_{ij} = 0$ whenever $j - i > B_1$.
- The lower bandwidth B_2 is the smallest number such that $A_{ij} = 0$ whenever $i - j > B_2$.

Note that this measurement does not disallow intermediate diagonals in a band from being all zero, but instead focuses on the location of the last diagonal containing nonzeros. By convention, the upper and lower bandwidths of an empty matrix are both zero.

Tips

- Use the `isbanded` function to test if a matrix is within a specific lower and upper bandwidth.

Introduced in R2014a

bar

Bar graph

Syntax

```
bar(y)
bar(x,y)

bar(___,width)
bar(___,style)
bar(___,color)
bar(___,Name,Value)

bar(ax,___)

b = bar(___)
```

Description

`bar(y)` creates a bar graph with one bar for each element in `y`. If `y` is a matrix, then `bar` groups the bars according to the rows in `y`.

`bar(x,y)` draws the bars at the locations specified by `x`.

`bar(___,width)` sets the relative bar width, which controls the separation of bars within a group. Specify `width` as a scalar value. Use this option with any of the input argument combinations in the previous syntaxes.

`bar(___,style)` specifies the style of the bar groups. For example, use `'stacked'` to display each group as one multicolored bar.

`bar(___,color)` sets the color for all the bars. For example, use `'r'` for red bars.

`bar(___,Name,Value)` sets bar series properties using one or more `Name,Value` pair arguments. The settings apply to all bars plotted. For example, use `'EdgeColor','black'` to outline all the bars in black.

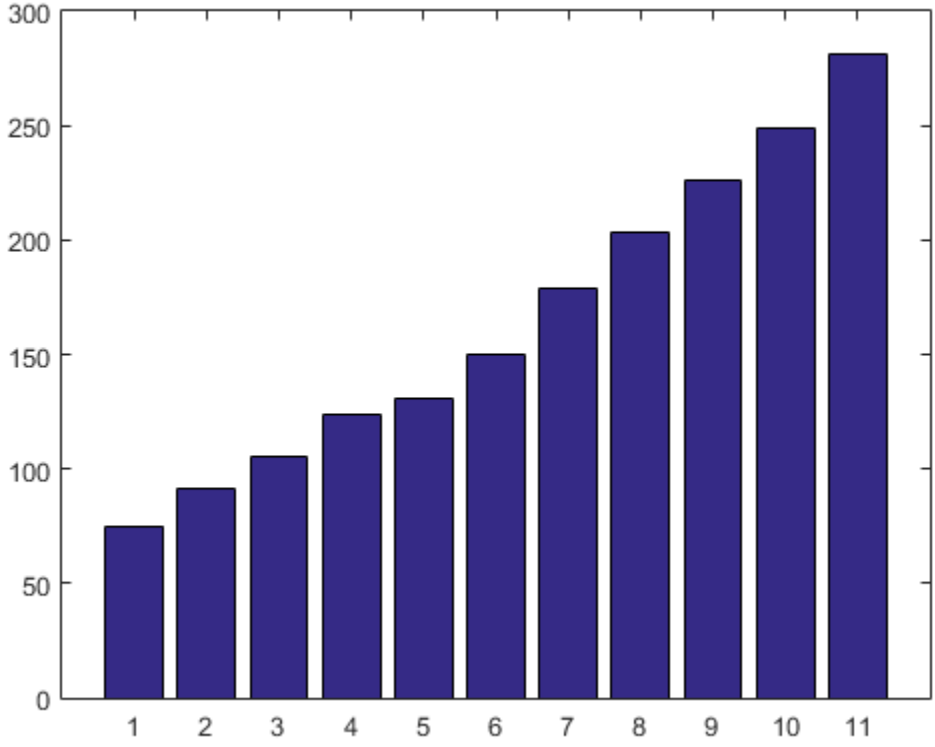
`bar(ax, ___ )` plots into the axes specified by `ax` instead of into the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`b = bar( ___ )` returns one or more bar series objects. If `y` is a vector, then `bar` creates one bar series object. If `y` is a matrix, then `bar` creates a bar series object for each column. Use `b` to make future modifications to the bars after they are created.

Examples

Create Bar Graph

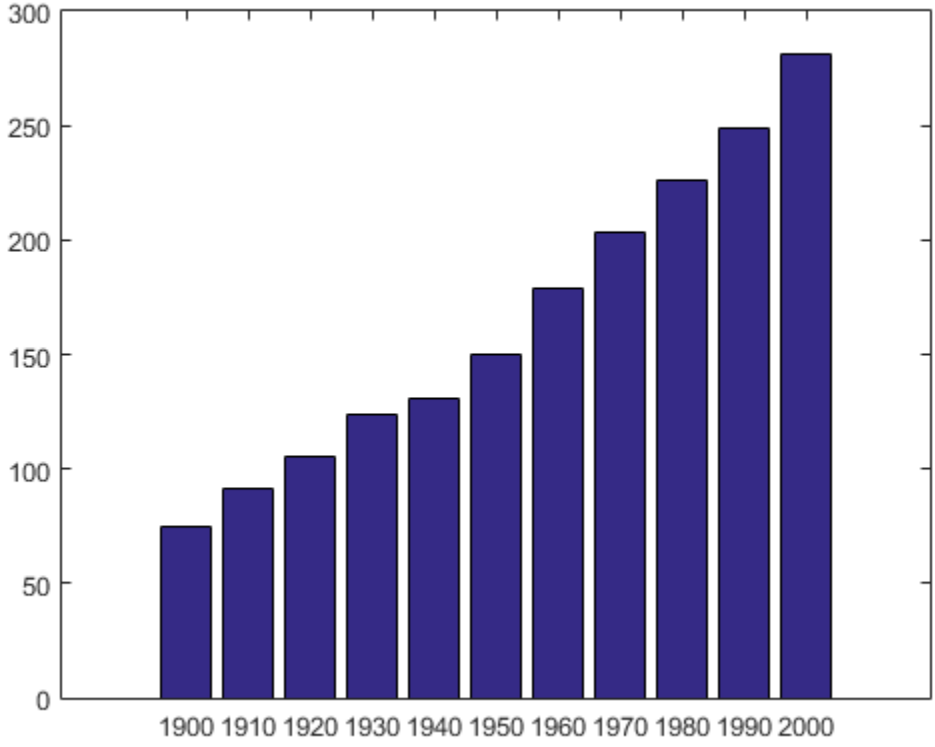
```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y)
```



Specify Bar Locations

Specify the bar locations along the *x*-axis.

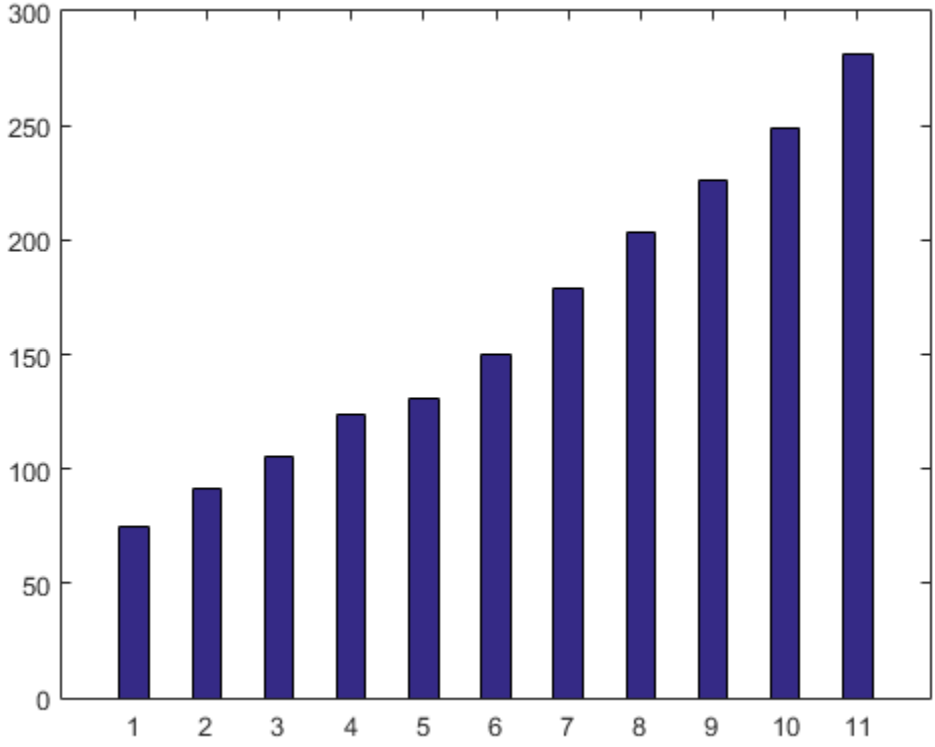
```
x = 1900:10:2000;
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(x,y)
```



Specify Bar Width

Set the width of each bar to 40 percent of the total space available for each bar.

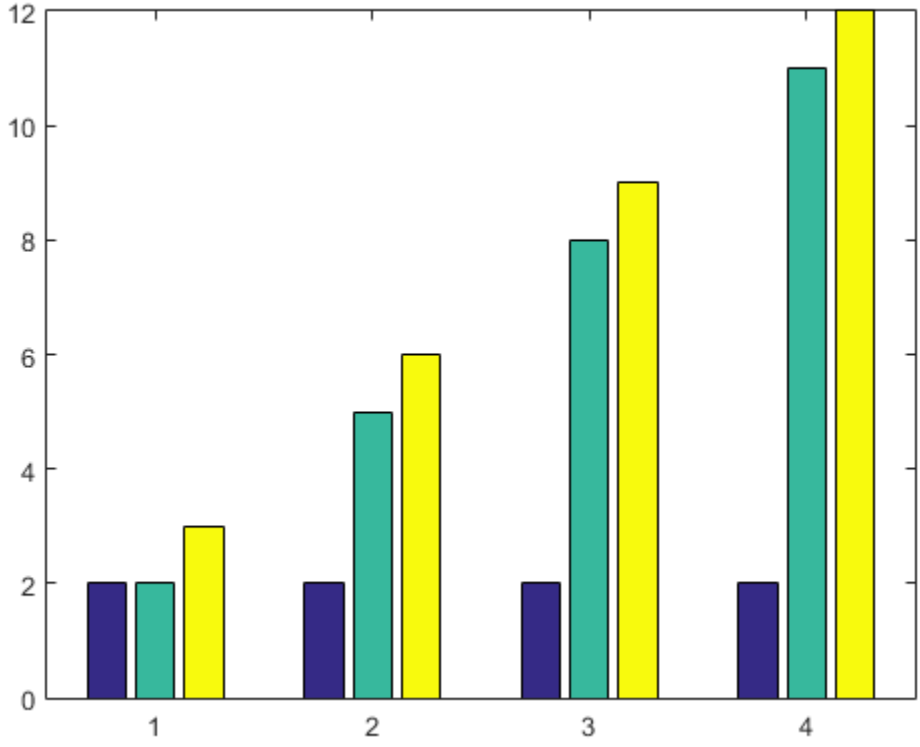
```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y,0.4)
```



Display Groups of Bars

Display four groups of three bars.

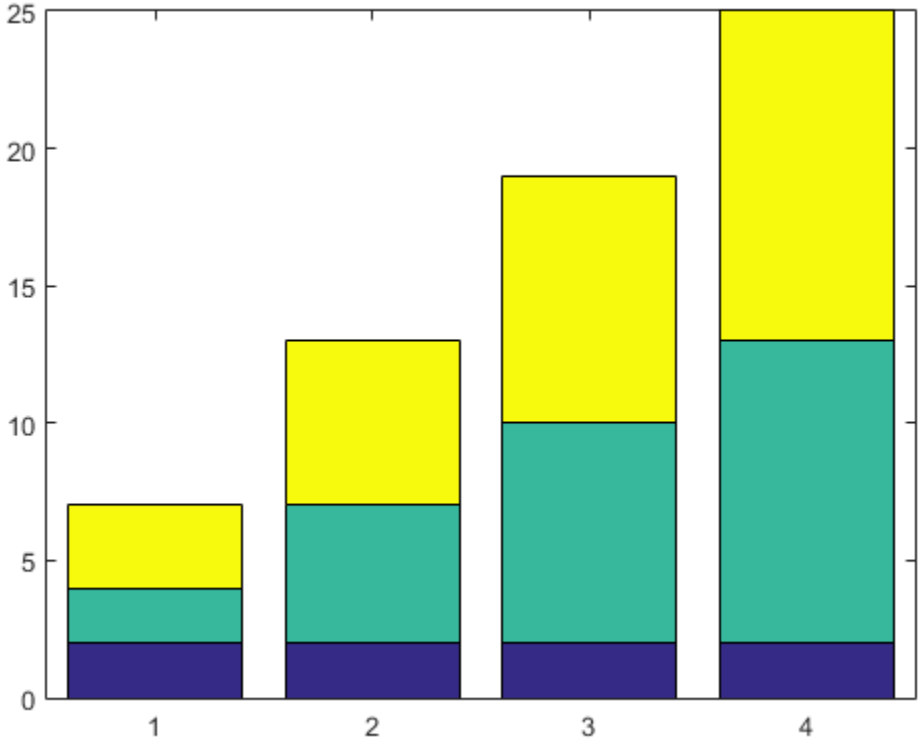
```
y = [2 2 3; 2 5 6; 2 8 9; 2 11 12];
bar(y)
```



Display Stacked Bars

Display one bar for each row of the matrix. The height of each bar is the sum of the elements in the row.

```
y = [2 2 3; 2 5 6; 2 8 9; 2 11 12];
bar(y,'stacked')
```

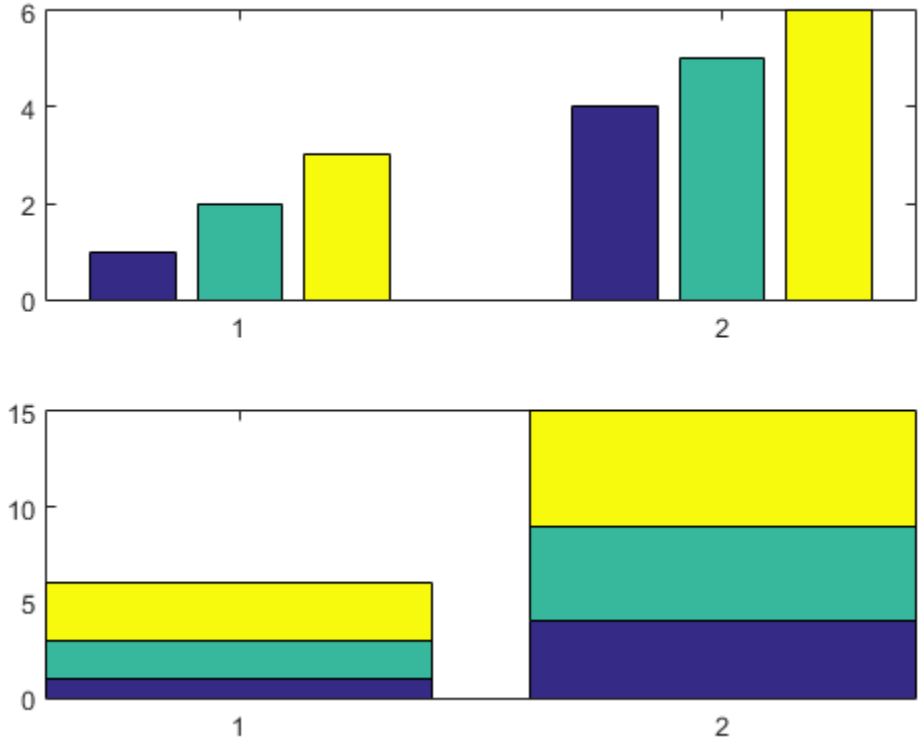


Specify Subplot for Bar Graph

Create a figure with two subplots. In the upper subplot, plot a bar graph. In the lower subplot, plot a stacked bar graph of the same data.

```
y = [1 2 3; 4 5 6];
ax1 = subplot(2,1,1);
bar(ax1,y)

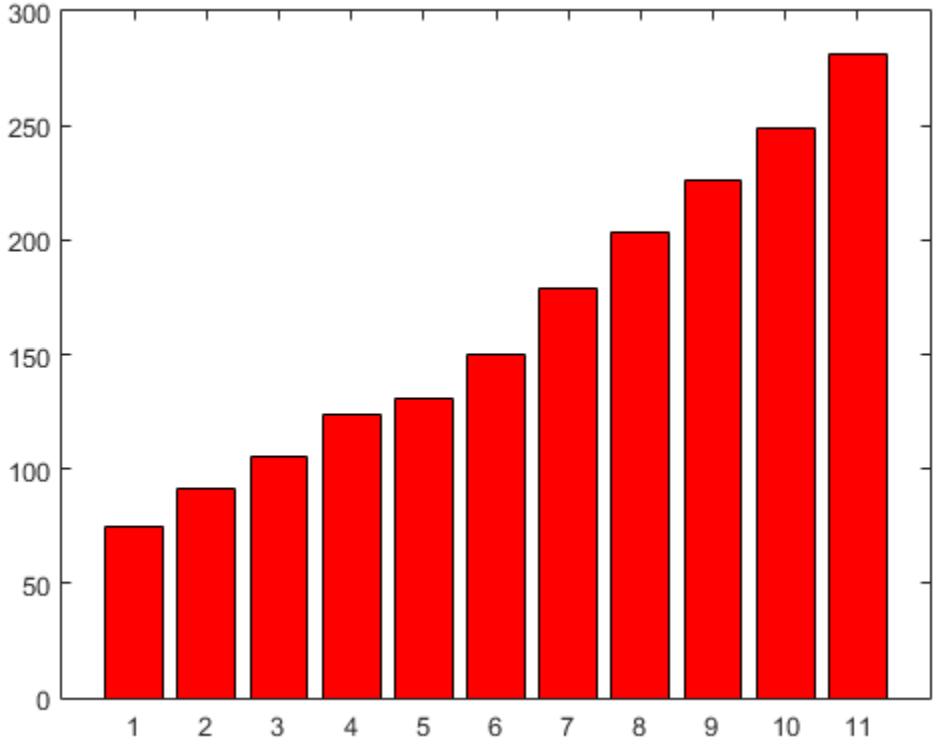
ax2 = subplot(2,1,2);
bar(ax2,y,'stacked')
```



Specify Bar Color

Create a bar graph using red bars.

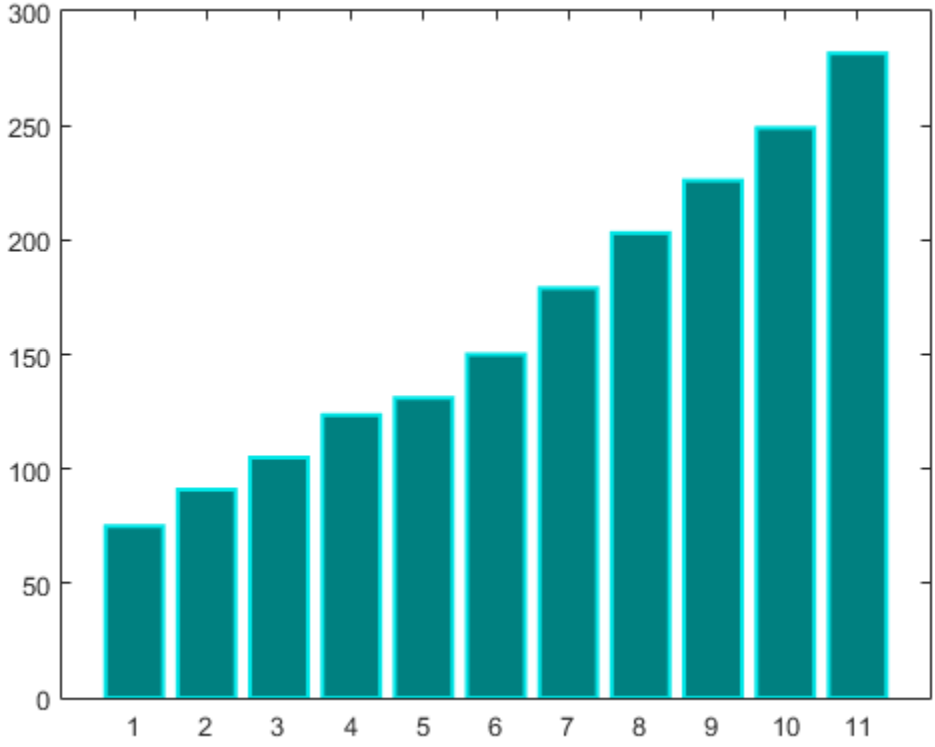
```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y,'r')
```



Specify Bar and Outline Colors

Set the bar interior color and outline color using RGB triplets. Set the width of the bar outline.

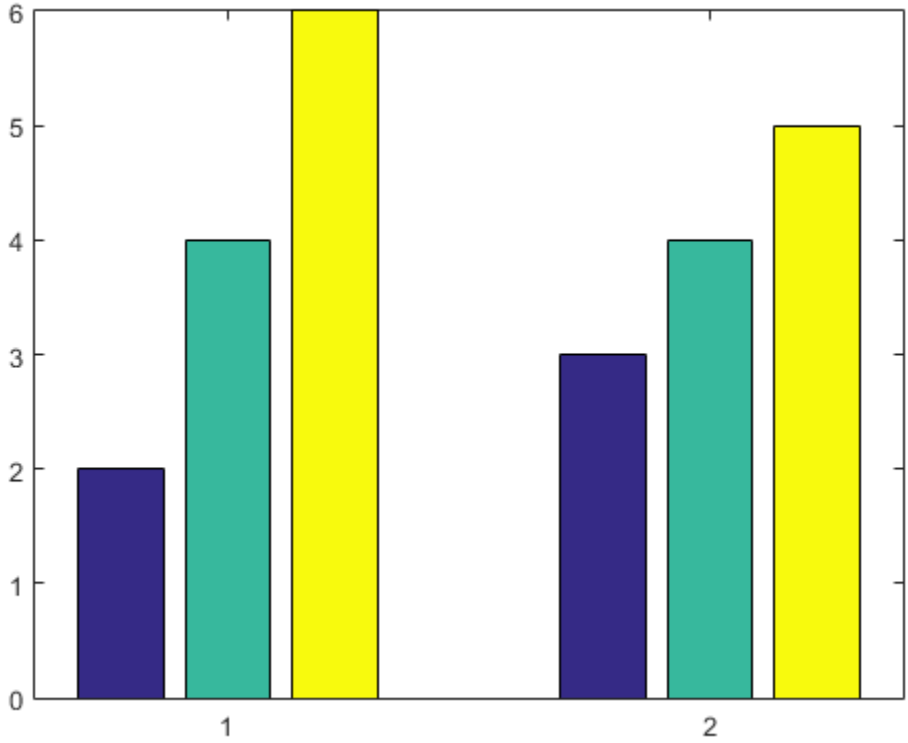
```
y = [75 91 105 123.5 131 150 179 203 226 249 281.5];
bar(y,'FaceColor',[0 .5 .5],'EdgeColor',[0 .9 .9],'LineWidth',1.5)
```



Change Properties for Specific Bar Series

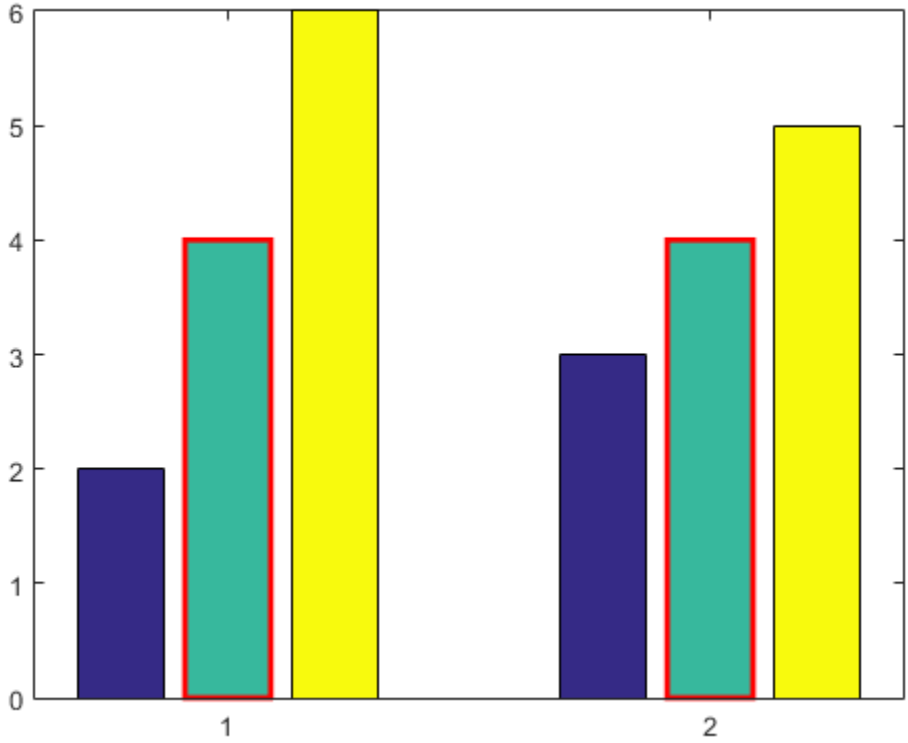
Create a bar graph with a three-column matrix input and return the three bar series objects. `bar` creates one bar series for each column in the matrix.

```
y = [2 4 6; 3 4 5];
b = bar(y);
```



Change properties for a specific bar series by indexing into the object array. For example, change properties of the bars representing the second column of y using `b(2)`. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
b(2).LineWidth = 2;
b(2).EdgeColor = 'red';
```



- “Modify Baseline of Bar Graph”
- “Overlay Bar Graphs”
- “Overlay Line Plot on Bar Graph Using Different y-Axes”

Input Arguments

x — x values

vector | matrix

x values, specified as a vector or a matrix. If `x` and `y` are both vectors, then they must be equal length. If `x` and `y` are both matrices, then they must be equal size. If `x` is a vector and `y` is a matrix, then the length of `x` must equal the number of rows in `y`.

The *x* values do not have to be in order, but they cannot contain duplicate values. If `x` is a matrix, then it cannot contain duplicate values across columns.

Example: `1:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`y` — y values

vector | matrix

y values, specified as a vector or a matrix.

- If `y` is a vector, then `bar` draws one bar for each element. The `bar` function treats all vectors as column vectors.
- If `y` is a matrix, then `bar` groups the bars according to the rows in `y`.

Example: `[10 8 5 7 3 9 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`width` — Bar width

`0.8` (default) | scalar

Bar width, specified as a fraction of the total space available for each bar. The default of `0.8` means the bar width is 80% of the space from the previous bar to the next bar, with 10% of that space on each side.

If the width is `1`, then the bars within a group touch one another.

Example: `0.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`style` — Bar group style

`'grouped'` (default) | `'stacked'` | `'hist'` | `'histc'`

Bar group style, specified by one of these values.

Style	Purpose
`'grouped'`	Display one group for each row in `y`.

Style	Purpose
	• If `y` is an *m*-by-*n* matrix, then `bar` displays *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in `y`. • If `y` is a vector of length *n*, then `bar` displays one group of *n* bars. The `bar` function treats all vectors as column vectors.
`'stacked'`	Display one bar for each row in `y`. • If `y` is an *m*-by-*n* matrix, then `bar` displays *m* bars where each bar height is the sum of the elements in the row. Each bar is multicolored. Colors correspond to distinct elements and show the relative contribution each row element makes to the total sum. • If `y` is a vector of length *n*, then `bar` displays *n* bars. The `bar` function treats all vectors as column vectors.
`'histc'`	Display the graph in histogram format, in which bars touch one another.
`'hist'`	Display the graph in histogram format, but center each bar over the *x*-ticks, rather than making bars span *x*-ticks as the `histc` option does.

`color` — Bar color

`'b' | 'r' | 'g' | 'c' | 'm' | 'y' | 'k' | 'w'`

Bar color, specified as one of the strings in this table.

String	Color
`'b'`	Blue
`'r'`	Red
`'g'`	Green

String	Color
'c'	Cyan
'm'	Magenta
'y'	Yellow
'k'	Black
'w'	White

ax — Axes object

axes object

Axes object. If you do not specify an axes, then `bar` uses the current axes for the bar graph.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

The bar series properties listed here are only a subset. For a complete list, see Bar Series Properties.

Note: You cannot specify `Name,Value` pairs when using the `'hist'` or `'histc'` bar group style options.

Example: `'EdgeColor','g'` specifies a green outline around the bars.

'EdgeColor' — Bar outline color

`[0 0 0]` (default) | `'flat'` | `'none'` | RGB triplet | color string

Bar outline color, specified as one of these values:

- `'flat'` — Colors based on axes colormap. To change the colormap, use the `colormap` function.
- `'none'` — No color, which makes the outlines invisible.

- RGB triplet or color string — Specify a custom color. The default RGB triplet value of `[0 0 0]` corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`'FaceColor'` — Bar fill color

`'flat'` (default) | `'none'` | RGB triplet | color string

Bar fill color, specified as one of these values:

- `'flat'` — Colors based on the axes colormap.
- `'none'` — No color, which makes the fill invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`

Long Name	Short Name	RGB Triplet
'magenta'	'm'	[1 0 1]
'cyan'	'c'	[0 1 1]
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

'BaseValue' — Baseline location

0 (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

'LineStyle' — Line style of bar outlines

'-' (default) | '--' | ':' | '-.' | 'none'

Line style of bar outlines, specified as one of the strings in this table.

String	Line Style	Resulting Line
'-'	Solid line	
'--'	Dashed line	':'	Dotted line	'-.'	Dash-dotted line	'none'	No line	No line

'LineWidth' — Width of bar outlines

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

b — Bar series objects

single object | array of objects

Bar series objects, returned as a single object or an array of objects. Each bar series object comprises a set of bars that have the same color. Use the elements in `b` to access and modify properties of a specific bar series object after it has been created.

More About

Tips

- The default bar colors are based on the axes colormap. You can change the axes colormap using the `colormap` function.

Functions

`bar3` | `bar3h` | `barh` | `histogram` | `hold` | `stairs`

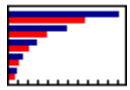
Properties

Bar Series Properties

Introduced before R2006a

barh

Plot bar graph horizontally



Syntax

```
barh(Y)
barh(X,Y)
barh(...,width)
barh(...,'style')
barh(...,'bar_color')
barh(...,'PropertyName',PropertyValue,...)
barh(axes_handle,...)
h = barh(...)
```

Description

A `barh` graph displays the values in a vector or matrix as horizontal bars.

`barh(Y)` draws one horizontal bar for each element in `Y`. If `Y` is a matrix, `barh` groups the bars produced by the elements in each row. The *x*-axis scale ranges from 1 up to `length(Y)` when `Y` is a vector, and `1` to `size(Y,1)`, which is the number of rows, when `Y` is a matrix. The default is to assign an appropriate progression of tick values according to the data. If you want the *x*-axis scale to end exactly at the last bar, set the axis limits as,

```
set(gca,'XLim',[1 length(Y)])
```

`barh(X,Y)` draws a bar for each element in `Y` at locations specified in `x`, where `X` is a vector defining the *x*-axis intervals for the vertical bars. The *x*-values can be

nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `barh` groups the elements of each row in `Y` at corresponding locations in `X`.

`barh(...,width)` sets the relative bar width and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `X`, the bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another. The value of `width` must be a scalar.

`barh(...,'style')` specifies the style of the bars. `'style'` is `'grouped'` or `'stacked'`. Default mode of display is `'grouped'`.

- `'grouped'` displays *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.
- `'histc'` displays the graph in histogram format, in which bars touch one another.
- `'hist'` also displays the graph in histogram format, but centers each bar over the *x*-ticks, rather than making bars span *x*-ticks as the `histc` option does.

Note: When you use either the `hist` or `histc` option, you cannot also use parameter/value syntax. These two options create patch objects rather than bar series.

`barh(...,'bar_color')` displays all bars using the color specified by the single-letter abbreviation `'r'`, `'g'`, `'b'`, `'c'`, `'m'`, `'y'`, `'k'`, or `'w'`.

`barh(...,'PropertyName',PropertyValue,...)` sets the named property or properties to the specified values. You cannot specify properties when `hist` or `histc` options are used. See Bar Series Properties for more information.

`barh(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = barh(...)` returns a vector of bar series handles. When `Y` is a matrix, `barh` creates one bar series per column in `Y`.

Bar Series

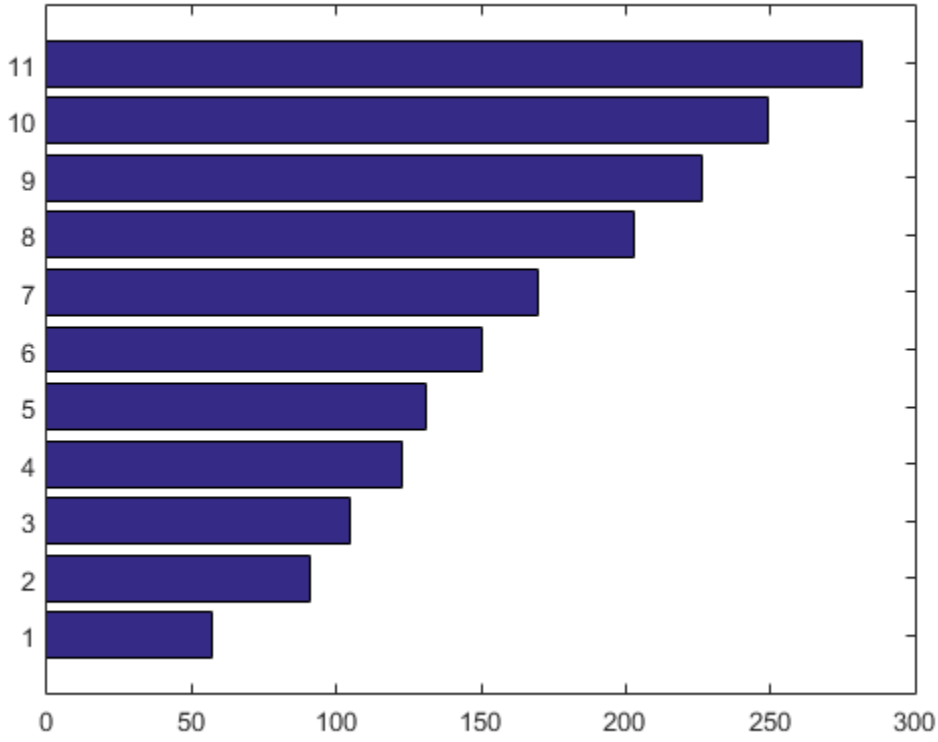
Creating a bar graph of an *m*-by-*n* matrix creates *m* groups of *n* bars. Each bar series comprises a set of bars that have the same color. Use the bar series handle to change properties for all bars in a series.

Examples

Horizontal Bar Graph of Single Data Series

Create a horizontal bar graph of vector data.

```
y = [57,91,105,123,131,150,...
     170,203,226.5,249,281.4];
figure
barh(y)
```



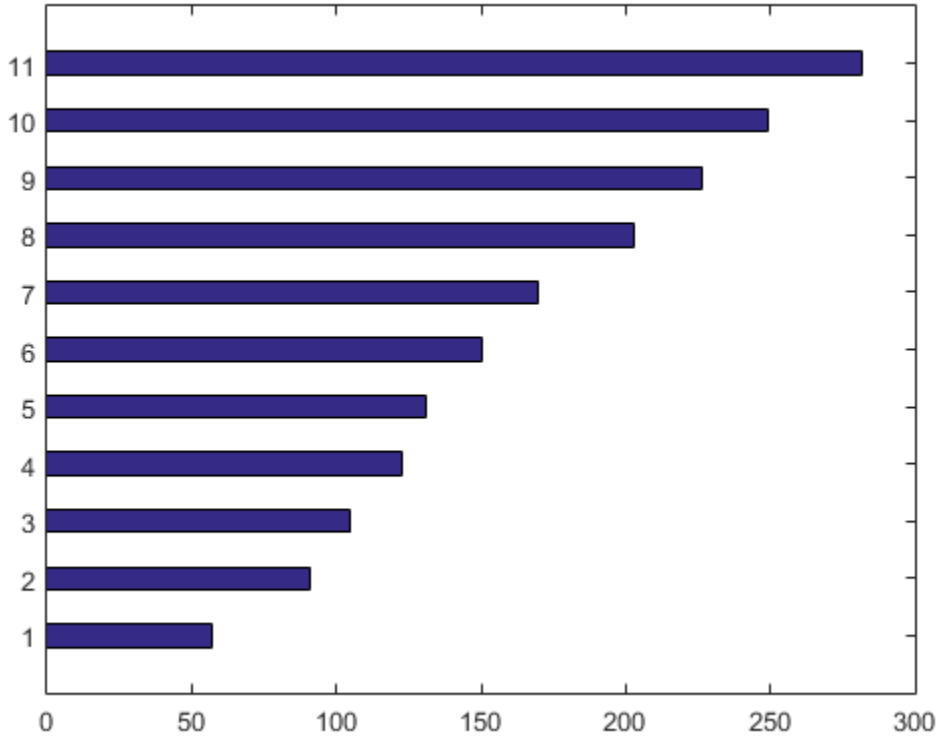
`barh` draws one horizontal bar for each element in `y`.

Specify Width for Horizontal Bar Graph

Specify the bar width to 0.4.

```
y = [57,91,105,123,131,150,...
     170,203,226.5,249,281.4];

figure;
width = 0.4;
barh(y,width);
```



Specify Style for Horizontal Bar Graph

Create a figure with four subplots. In each subplot, create a horizontal bar graph using a different style option for each graph.

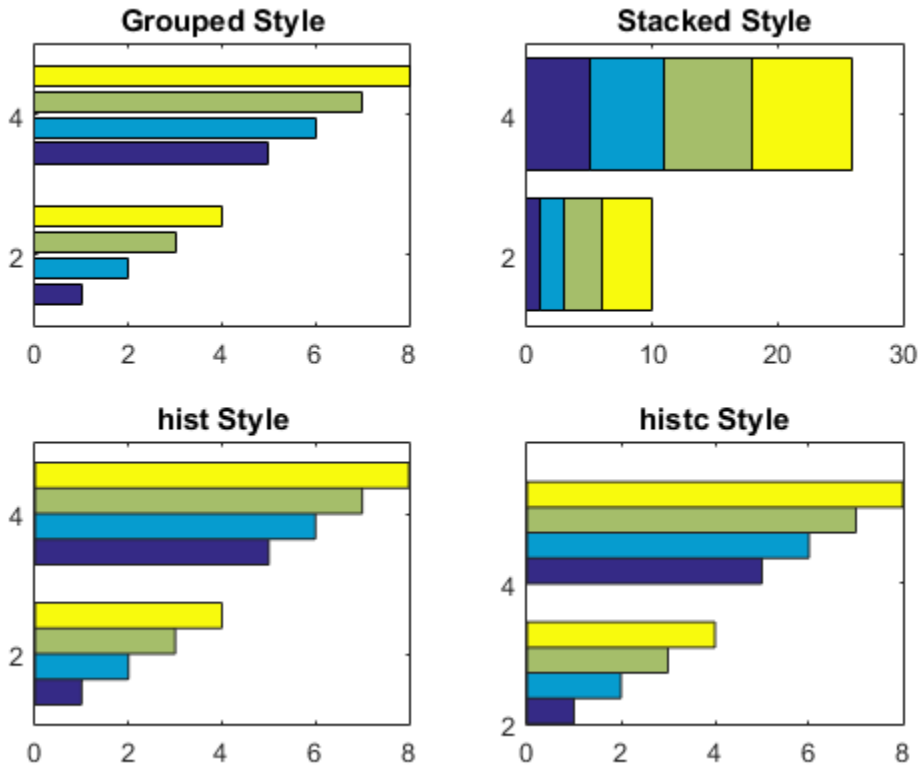
```
x = [2,4];
y = [1,2,3,4;...
     5,6,7,8];

figure;
subplot(2,2,1);
barh(x,y,'grouped'); % groups by row
title('Grouped Style')
```

```
subplot(2,2,2);
barh(x,y,'stacked'); % stacks values in each row together
title('Stacked Style')

subplot(2,2,3);
barh(x,y,'hist'); % centers bars over x values
title('hist Style')

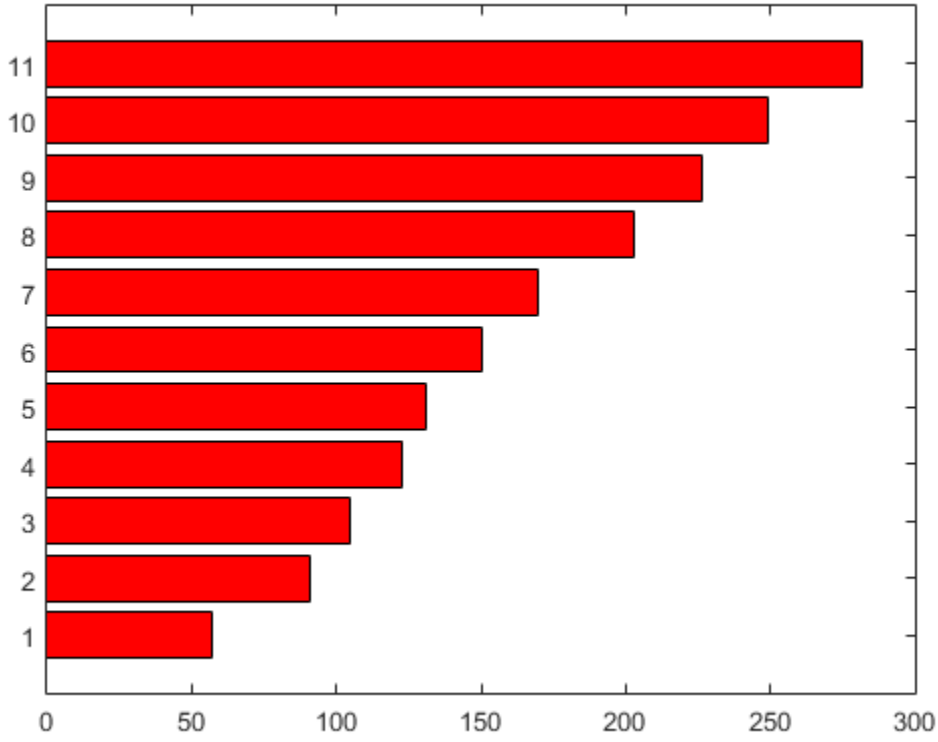
subplot(2,2,4);
barh(x,y,'histc'); % spans bars over x values
title('histc Style')
```



Specify Color for Horizontal Bar Graph

Create a horizontal bar graph and change the color of the bars to red.

```
y = [57,91,105,123,131,150,...
     170,203,226.5,249,281.4];
figure
barh(y,'r')
```

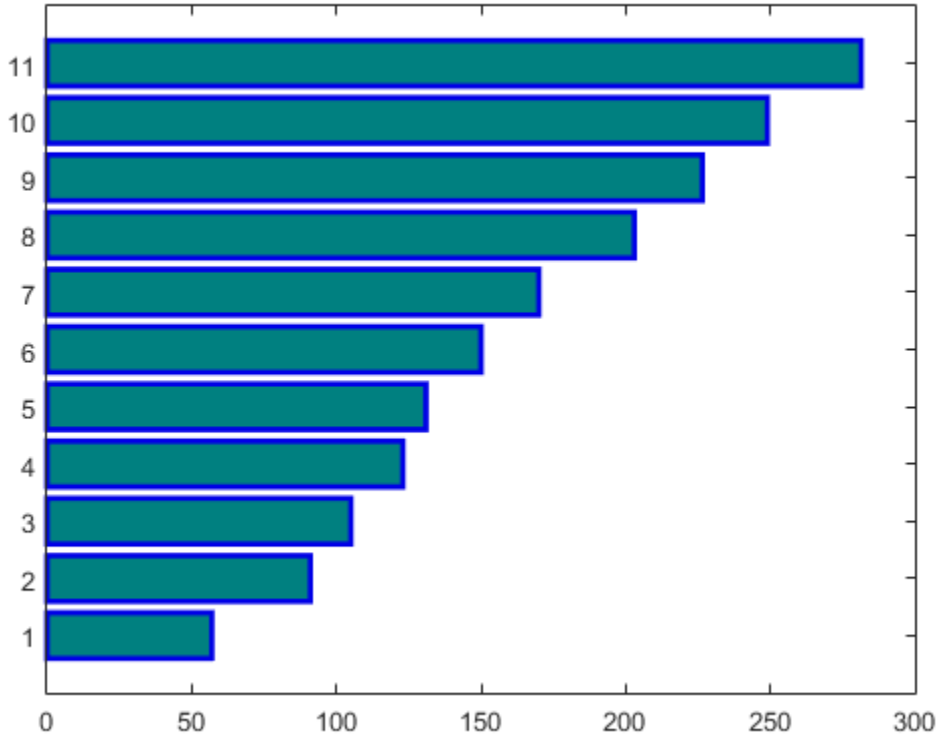


Specify Bar Properties Using Name-Value Pairs

Create a horizontal bar graph and set the line width to 2. Use RGB triplets to set the face color and edge color for the bars.

```
y = [57,91,105,123,131,150,...
     170,203,226.5,249,281.4];

figure
barh(y,'FaceColor',[0,0.5,0.5],...
       'EdgeColor',[0,0,0.9],...
       'LineWidth',2)
```



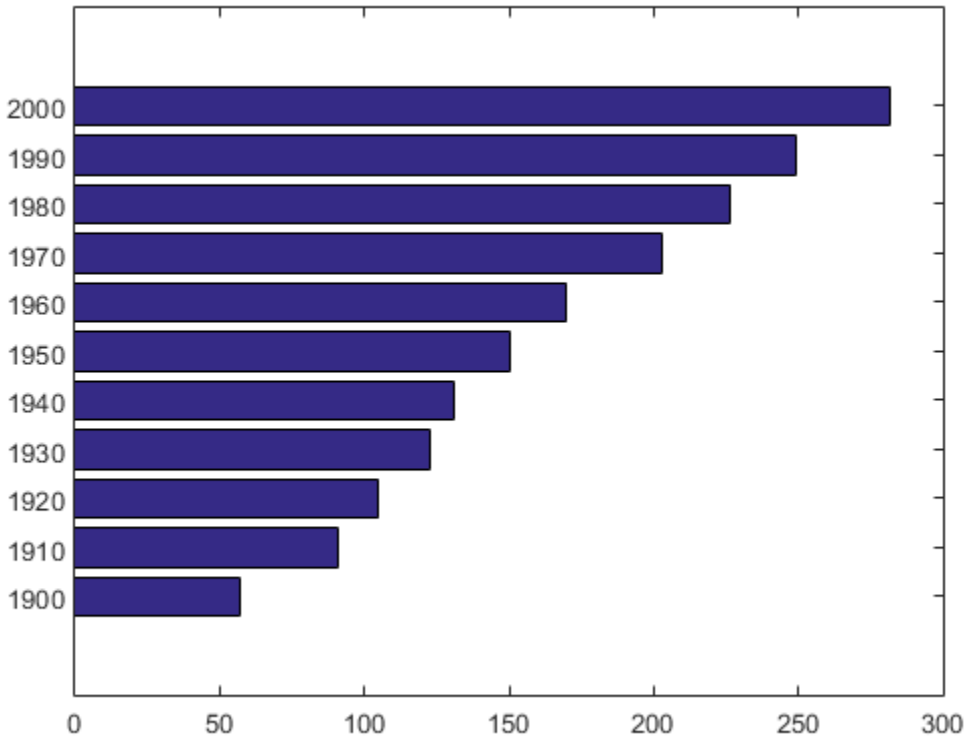
Specify Horizontal Bar Locations

Define `x` and `y` as vectors of data.

```
x = 1900:10:2000;
y = [57,91,105,123,131,150,...
     170,203,226.5,249,281.4];
```

Create a horizontal bar graph of the data in `y`. Use `x` to specify the bar locations along the *y*-axis.

```
figure
barh(x,y)
```



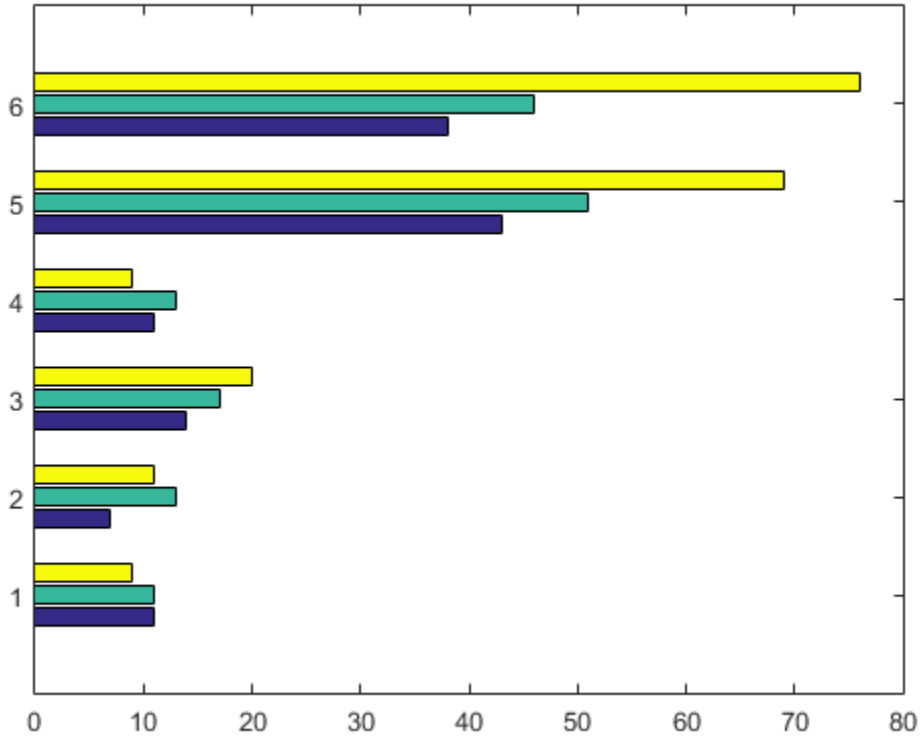
Horizontal Bar Graph of Matrix Data

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat
y = count(1:6,:);
```

Create a horizontal bar graph of matrix `y`.

```
figure
barh(y)
```



By default, `barh` groups the bars by row.

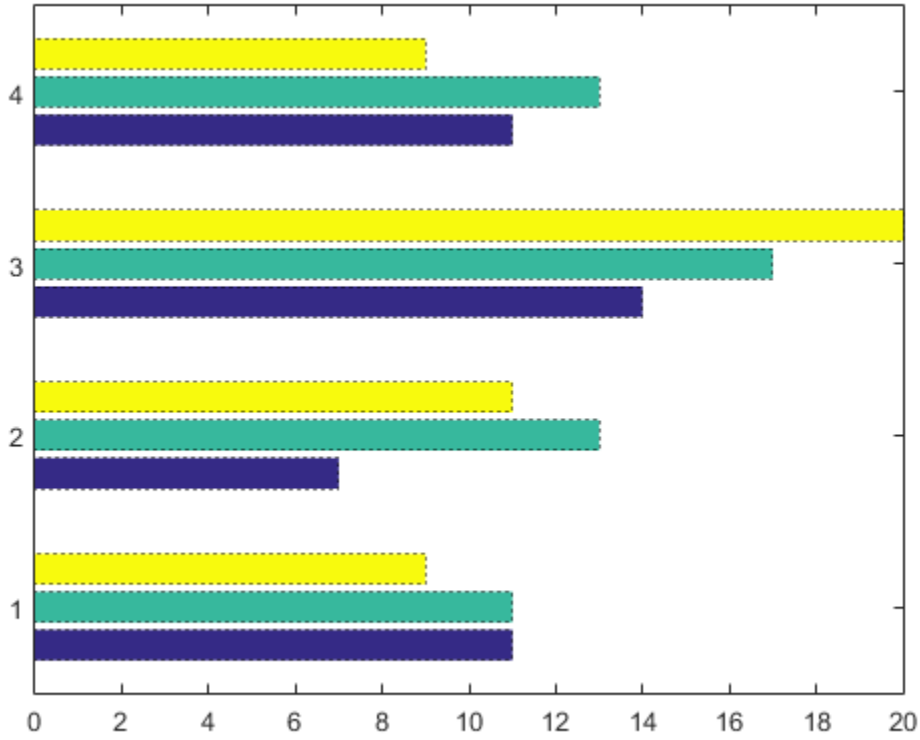
Specify Different Properties For Each Bar Series

Load the data set, `count.dat`, that returns a three-column matrix, `count`. Define `y` as the first four rows of count.

```
load count.dat
y = count(1:4,:);
```

Create a horizontal bar graph of `y` using a dotted line style. Return the three bar series handles. `barh` creates a bar series for each column in `y`.

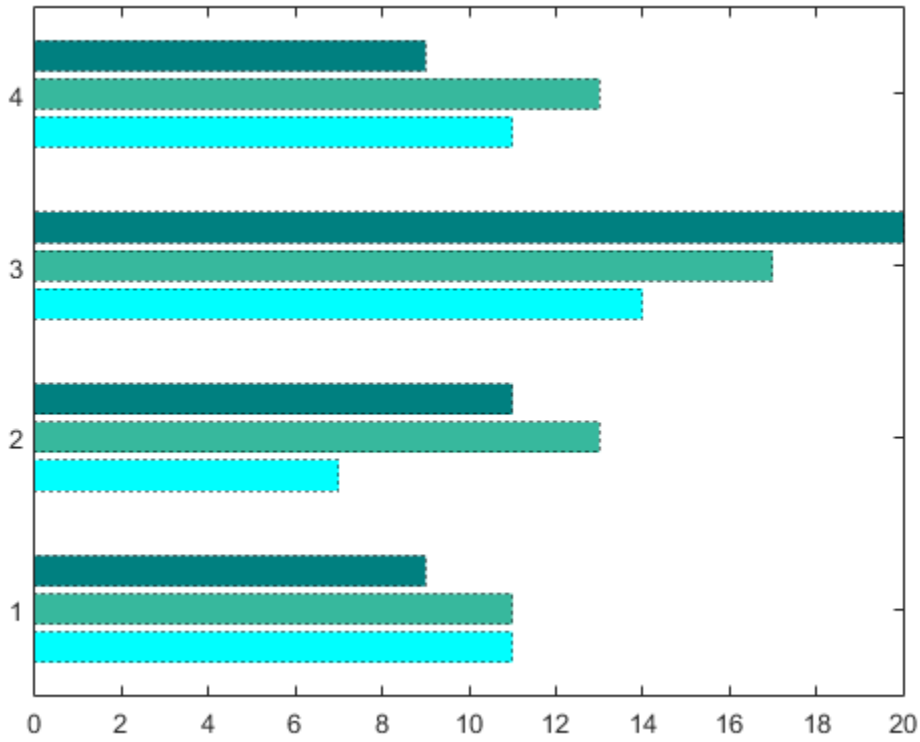
```
h = barh(y,'LineStyle',':');
```



Use the handles in `h` to set different property values for each bar series. Change the face color of the first bar series to cyan by setting the `FaceColor` property to `cyan`. Set the face color for the third bar series using an RGB triplet.

Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
h(1).FaceColor = 'cyan';
h(3).FaceColor = [0,0.5,0.5];
```



Change Baseline Value for Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `y` as the first six rows of `count`.

```
load count.dat
y = count(1:6,:);
```

Create a horizontal bar graph of `y` and set the basevalue to 25.

```
figure
barh(y,'BaseValue',25)
```

Functions

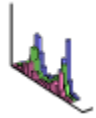
`bar` | `bar3` | `bar3h` | `ColorSpec` | `histogram` | `stairs`

Properties
Bar Series Properties

Introduced before R2006a

bar3

Plot 3-D bar graph



Syntax

```
bar3(Y)
bar3(x,Y)
bar3(...,width)
bar3(...,'style')
bar3(...,LineSpec)
bar3(axes_handle,...)
h = bar3(...)
```

Description

`bar3` draws a three-dimensional bar graph.

`bar3(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the *x*-axis scale ranges from `1` to `length(Y)`. When `Y` is a matrix, the *x*-axis scale ranges from `1` to `size(Y,1)` and the elements in each row are grouped together.

`bar3(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the *y*-axis intervals for vertical bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `x`, bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another.

`bar3(...,'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. Default mode of display is `'detached'`.

- `'detached'` displays the elements of each row in `Y` as separate blocks behind one another in the *x* direction.
- `'grouped'` displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3(...,LineSpec)` displays all bars using the color specified by `LineSpec`.

`bar3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3(...)` returns a vector of handles to surface objects, one for each created. When `Y` is a matrix, `bar3` creates one surface object per column in `Y`.

Examples

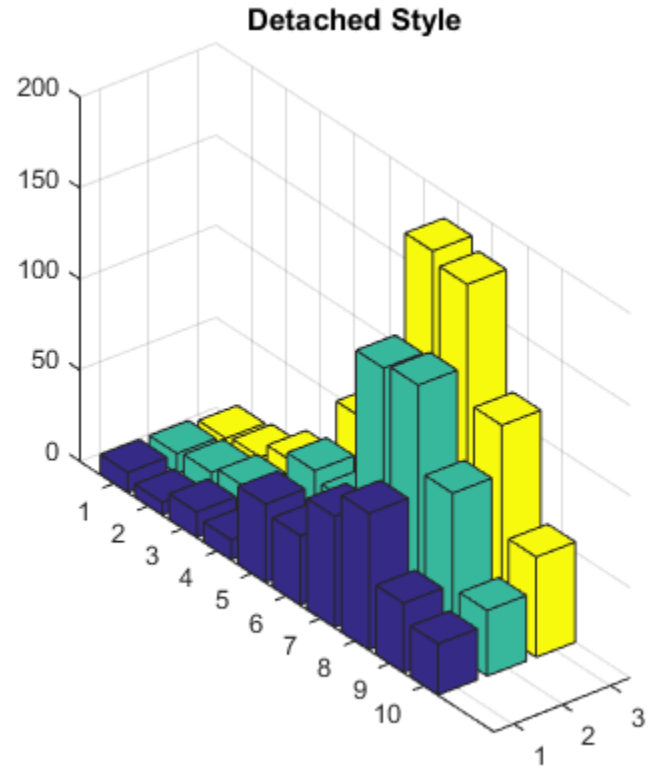
Create 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. By default, the style is `detached`.

```
figure
bar3(Y)
title('Detached Style')
```



Specify Bar Width for 3-D Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

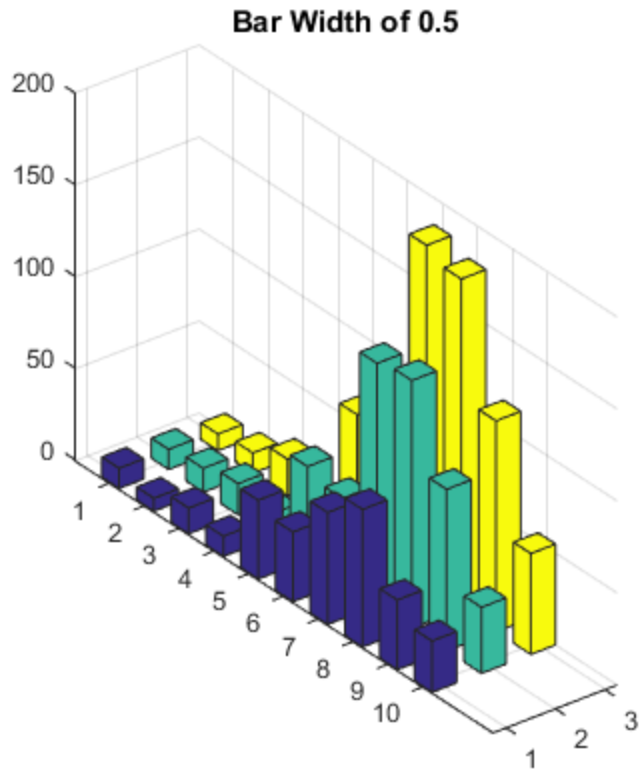
```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of Y and set the bar width to 0.5.

```
width = 0.5;

figure
bar3(Y,width)
```

```
title('Bar Width of 0.5')
```



3-D Bar Graph with Grouped Style

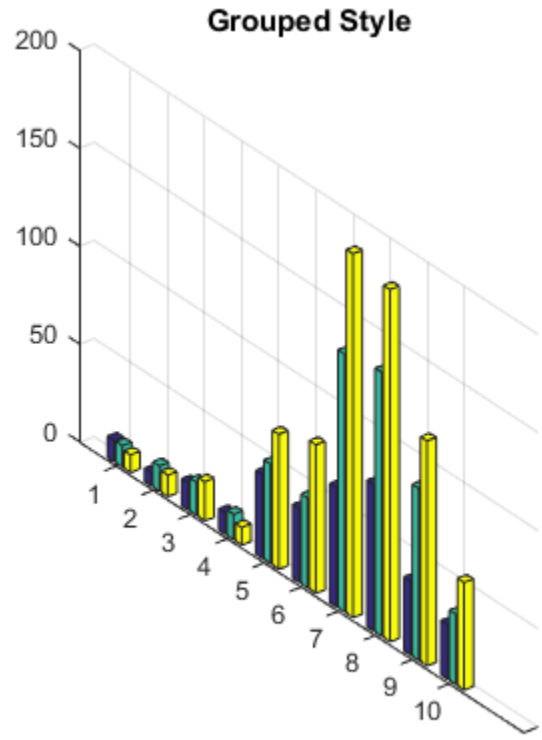
Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. Group the elements in each row of `Y` by specifying the style option as `grouped`.

```
figure
```

```
bar3(Y,'grouped')
title('Grouped Style')
```



3-D Bar Graph with Stacked Style

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first 10 rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D bar graph of `Y`. Stack the elements in each row of `Y` by specifying the style option as `stacked`.

```
figure
```

```
bar3(Y,'stacked')
title('Stacked Style')
```

`bar` | `barh` | `bar3h` | `LineSpec`

Introduced before R2006a

bar3h

Plot horizontal 3-D bar graph

Syntax

```
bar3h(Y)
bar3h(x,Y)
bar3h(...,width)
bar3h(...,'style')
bar3h(...,LineSpec)
bar3h(axes_handle,...)
h = bar3h(...)
```

Description

`bar3h` draws three-dimensional horizontal bar charts.

`bar3h(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the *y*-axis scale ranges from `1` to `length(Y)`. When `Y` is a matrix, the *y*-axis scale ranges from `1` to `size(Y,1)` and the elements in each row are grouped together.

`bar3h(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the *y*-axis intervals for horizontal bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3h(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `x`, bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another.

`bar3h(...,'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. Default mode of display is `'detached'`.

- `'detached'` displays the elements of each row in `Y` as separate blocks behind one another in the *y* direction.
- `'grouped'` displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar length is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3h(...,LineSpec)` displays all bars using the color specified by `LineSpec`.

`bar3h(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar3h(...)` returns a vector of handles to surface objects, one for each created. When `Y` is a matrix, `bar3h` creates one surface object per column in `Y`.

Examples

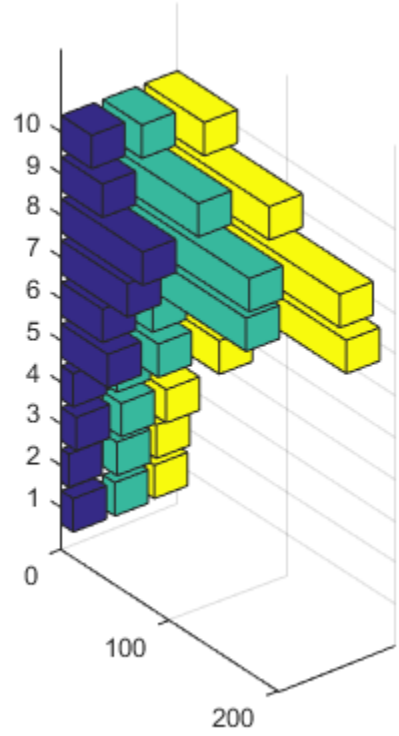
Create 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y`. By default, the style is `detached`.

```
figure
bar3h(Y)
```



Specify Bar Width for 3-D Horizontal Bar Graph

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

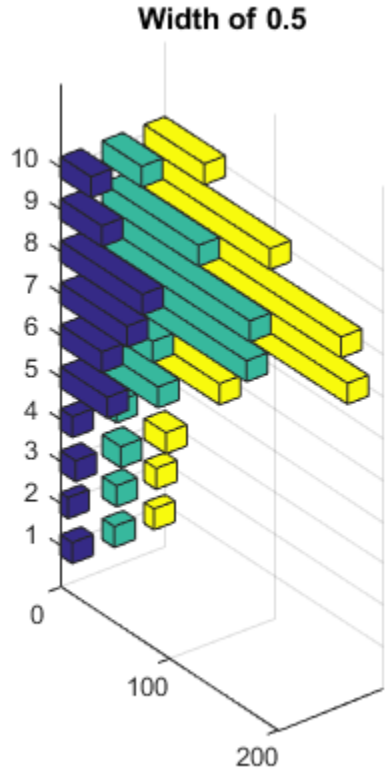
```
load count.dat;
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of `Y` and set the bar width to 0.5.

```
width = 0.5;

figure
bar3h(Y,width)
```

```
title('Width of 0.5')
```



3-D Horizontal Bar Graph with Grouped Style

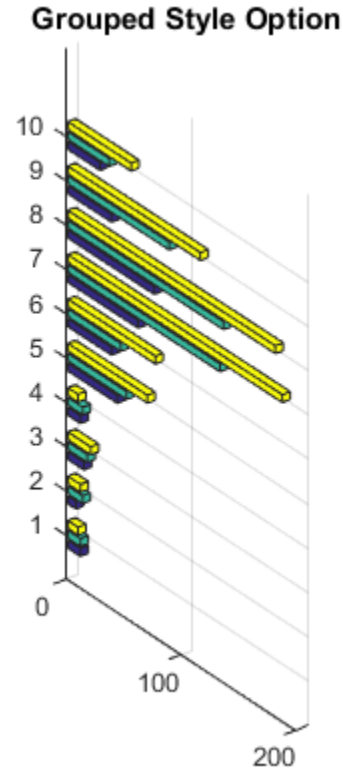
Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of Y and specify the style option as `grouped`.

```
figure
bar3h(Y,'grouped')
```

```
title('Grouped Style Option')
```



3-D Horizontal Bar Graph with Stacked Option

Load the data set `count.dat`, which returns a three-column matrix, `count`. Store `Y` as the first ten rows of `count`.

```
load count.dat
Y = count(1:10,:);
```

Create a 3-D horizontal bar graph of Y and specify the style option as `stacked`.

```
figure
bar3h(Y,'stacked')
```

```
title('Stacked Style Option')
```

Introduced before R2006a

Bar Series Properties

Control bar series appearance and behavior

Bar series properties control the appearance and behavior of a bar series object. By changing property values, you can modify certain aspects of the bar series.

Starting in R2014b, you can use dot notation to query and set properties.

```
h = bar(1:10);
w = h.BarWidth;
h.BarWidth = 1;
```

If you are using an earlier release, use the `get` and `set` functions instead.

Bars

`BarWidth` — Relative width of individual bars

`0.8` (default) | scalar in range `[0,1]`

Relative width of individual bars, specified as a scalar value in the range `[0,1]`. Use this property to control the separation of bars within a group. The default value is `0.8`, which means that MATLAB separates the bars slightly. If you set this property to `1`, then adjacent bars touch.

Example: `0.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`EdgeColor` — Bar outline color

`[0 0 0]` (default) | `'flat'` | `'none'` | RGB triplet | color string

Bar outline color, specified as one of these values:

- `'flat'` — Colors based on axes colormap. To change the colormap, use the `colormap` function.
- `'none'` — No color, which makes the outlines invisible.
- RGB triplet or color string — Specify a custom color. The default RGB triplet value of `[0 0 0]` corresponds to black.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`FaceColor` — Bar fill color

`'flat'` (default) | `'none'` | RGB triplet | color string

Bar fill color, specified as one of these values:

- `'flat'` — Colors based on the axes colormap.
- `'none'` — No color, which makes the fill invisible.
- RGB triplet or color string — Specify a custom color.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

`LineStyle` — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	————
'--'	Dashed line	- - - - -
':'	Dotted line	.....
'-.'	Dash-dotted line	—·—·—·—
'none'	No line	No line

`LineWidth` — Width of bar outlines

0.5 (default) | positive value

Width of bar outlines, specified as a positive value in point units. One point equals 1/72 inch.

Example: 1.5

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Bar Graph Type

`BarLayout` — Arrangement of bars

'grouped' (default) | 'stacked'

Arrangement of bars, specified as one of these values:

- `'grouped'` — Group bars by rows in `Y`, where `Y` is the input argument to the `bar` or `barh` function that created the bar chart.
- `'stacked'` — Display one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored. Colors correspond to distinct elements and show the relative contribution each row element makes to the total sum.

`Horizontal` — Horizontal bar chart

`'off'` (default) | `'on'`

Horizontal bar chart, specified as one of these values:

- `'on'` — Display bars horizontally. If you create a graph with `barh`, then the `Horizontal` property is set to `'on'`.
- `'off'` — Display bars vertically. If you create the chart with `bar`, then the `Horizontal` property is set to `'off'`.

Baseline

`BaseLine` — Baseline

baseline object

Baseline object. For a list of baseline properties, see Baseline Properties.

`BaseValue` — Baseline location

`0` (default) | numeric scalar value

Baseline location, specified as a numeric scalar value.

`ShowBaseLine` — Baseline visibility

`'on'` (default) | `'off'`

Baseline visibility, specified as one of these values:

- `'on'` — Show the baseline.
- `'off'` — Hide the baseline.

Data

XData — Bar locations

vector of real values

Bar locations, specified as a vector. For vertical bar charts, the values in `XData` are the bar locations along the *x*-axis. For horizontal bar charts, the values are the bar locations along the *y*-axis. You cannot specify the same value twice.

The input argument `X` to the `bar` and `barh` functions determines the bar locations. If you do not specify `X`, then the indices of the values in `YData` determine the bar locations. `XData` and `YData` must have equal lengths.

Setting this property sets the associated mode property to manual.

Example: `1:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

YData — Bar lengths

vector

Bar lengths, specified as a vector. The input argument `Y` to the `bar` and `barh` functions determines the bar lengths.

`XData` and `YData` must have equal lengths.

Example: `1:10`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

XDataSource — Variable linked to XData

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`XDataMode` — Selection mode for `XData`

`'auto'` (default) | `'manual'`

Selection mode for `XData`, specified as one of these values:

- `'auto'` — Use the indices of the values in `YData` (or `ZData` for 3-D plots).
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property or specify the input argument `X` to the plotting function.

Visibility

`Visible` — Visibility of bar series

`'on'` (default) | `'off'`

Visibility of bar series, specified as one of these values:

- `'on'` — Display the bar series.

- `'off'` — Hide the bar series without deleting it. You still can access the properties of an invisible bar series object.

`Clipping` — Clipping of bar series to axes limits

`'on'` (default) | `'off'`

Clipping of bar series to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the bar series that are outside the axes limits.
- `'off'` — Display the entire bar series, even if parts of it appear outside the axes limits. Parts of the bar series might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the bar series that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'bar'` (default)

Type of graphics object, returned as `'bar'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

`Tag` — Tag to associate with bar series

`''` (default) | string

Tag to associate with the bar series, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

Data Types: `char`

`UserData` — Data to associate with bar series

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the bar series object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the bar series.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the bar series object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the bar series from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the bar series object in the legend as one entry (default).
   - `'off'` — Do not include the bar series object in the legend.
   - `'children'` — Include only children of the bar series object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of bar series

axes object | group object | transform object

Parent of bar series, specified as an axes, group, or transform object.

`Children` — Children of bar series

empty `GraphicsPlaceholder` array

The bar series has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of bar series object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The bar series object handle is always visible.
- `'off'` — The bar series object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The bar series object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the bar series at the command-line, but allows callback functions to access it.

If the bar series object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the bar series. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The bar series object — You can access properties of the bar series object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the bar series. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the bar series when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the bar series.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks when visible. The Visible property must be set to `'on'` and you must click a part of the bar series that has a defined color. You cannot click a part that has an associated color property set to `'none'`. The HitTest property determines if the bar series responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the bar series passes the click to the object below it in the current view of the figure window. The HitTest property of the bar series has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the bar series. If you have defined the UIContextMenu property, then invoke the context menu.

- `'off'` — Trigger the callbacks for the nearest ancestor of the bar series that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the bar series object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for bar series

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for bar series, specified as one of these values:

- `'off'` — Click the bar series plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the bar series plot to select it, that is, anywhere within the rectangle that encloses the bar series plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the bar series is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the bar series tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.

- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the bar series. Setting the `CreateFcn` property on an existing bar series has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during bar series creation. MATLAB executes the callback after creating the bar series and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The bar series object — You can access properties of the bar series object from within the callback function. You also can access the bar series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the bar series. MATLAB executes the callback before destroying the bar series so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The bar series object — You can access properties of the bar series object from within the callback function. You also can access the bar series object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of bar series

`'off'` (default) | `'on'`

Deletion status of bar series, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the bar series begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the bar series no longer exists.

Check the value of the BeingDeleted property to verify that the bar series is not about to be deleted before querying or modifying it.

baryToCart

Class: TriRep

(Will be removed) Convert point coordinates from barycentric to Cartesian

---

Note: `baryToCart(TriRep)` will be removed in a future release. Use `barycentricToCartesian(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
XC = baryToCart(TR, SI, B)
```

Description

`XC = baryToCart(TR, SI, B)` returns the Cartesian coordinates `XC` of each point in `B` that represents the barycentric coordinates with respect to its associated simplex `SI`.

Input Arguments

`TR`	Triangulation representation.
`SI`	Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`
`B`	`B` is a matrix that represents the barycentric coordinates of the points to convert with respect to the simplices `SI`. `B` is of size `m`-by-`k`, where `m = length(SI)`, the number of points to convert, and `k` is the number of vertices per simplex.

Output Arguments

`XC`	Matrix of cartesian coordinates of the converted points. `XC` is of size `m`-by-`n`, where `n` is the dimension of the space where the triangulation resides. That is, the Cartesian coordinates of the point `B(j)` with respect to simplex `SI(j)` is `XC(j)`.

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(dt); hold on;
plot(cc(:,1), cc(:,2), '*r'); hold off;
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);
y = [0 0 0 0 16 16 16 16]';
tr = TriRep(tri,x,y)
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(tr); hold on;
plot(xc(:,1), xc(:,2), '*r'); hold off;
axis equal;
```

base2dec

Convert base N number string to decimal number

Syntax

```
d = base2dec('strn', base)
```

Description

`d = base2dec('strn', base)` converts the string number *`strn`* of the specified `base` into its decimal (base 10) equivalent. `base` must be an integer between 2 and 36. *`strn`* must represent a nonnegative integer value. If *`strn`* represents an integer value greater than 2^52, `base2dec` might not return an exact conversion.

If *`strn`* is a character array, each row is interpreted as a string in the specified `base`.

Examples

The expression `base2dec('212',3)` converts 212_3 to decimal, returning 23.

`dec2base`

Baseline Properties

Control baseline appearance and behavior

Baseline objects are created as part of bar charts, area charts, and stem charts. Baseline properties control the appearance and behavior of a baseline object. By changing property values, you can modify certain aspects of the baseline. Use dot notation to refer to a particular object and property:

```
b = bar(1:10);
bl = b.BaseLine;
c = bl.Color;
bl.Color = 'red';
```

Appearance

`Color` — Line color

RGB triplet | color string | `'none'`

Line color, specified as an RGB triplet, a color string, or `'none'`. If you specify the color as `'none'`, then the baseline is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

`LineStyle` — Line style

`'-' | '--' | ':' | '-.' | 'none'`

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
`'-'`	Solid line	
`'--'`	Dashed line	
`':'`	Dotted line	
`'-.'`	Dash-dotted line	`'none'`	No line	No line

`LineWidth` — Line width

positive value

Line width, specified as a positive value in point units.

Example: `0.75`

Location and Visibility

`BaseValue` — Value of baseline

scalar

Value of the baseline, specified as a scalar.

Typically, baselines are associated with bar series, stem series, or area objects. The `BaseValue` property for the associated object and the `BaseValue` property for the baseline object always have the same value. Setting one property also sets the other property. The `BaseLine` property for the associated object contains the baseline object.

Example: `0.75`

`Visible` — Baseline visibility

`'on' | 'off'`

Baseline visibility, specified as one of these values:

- `'on'` — Display the baseline.
- `'off'` — Hide the baseline without deleting it. You can access the properties of an invisible baseline.

Typically, baselines are associated with bar series, stem series, or area objects. The `ShowBaseline` property for the associated object and the `Visible` property for the baseline object always have the same value. Setting one property also sets the other property. The `BaseLine` property for the associated object contains the baseline object.

beep

Produce operating system beep sound

Syntax

```
beep
beep on
beep off

status = beep
```

Description

`beep` produces your computer's default beep sound, if it is enabled.

`beep on` enables the beep sound.

`beep off` disables the beep sound.

`status = beep` returns the current beep mode (`on` or `off`).

Examples

Produce Beep Sound

Produce your system's default beep sound after a period of silence.

Pause for 5 seconds of silence, and then produce your system's default beep sound.

```
pause(5)
beep
```

More About

Tips

- If you have configured your system not to produce any sound, then `beep` is silent.

- `beep` produces the operating system's default beep sound. To produce a sound and specify its pitch and duration in MATLAB, use the `sound` function.

sound

Introduced before R2006a

BeginInvoke

Initiate asynchronous .NET delegate call

Syntax

```
result = BeginInvoke(arg1,...,argN,callback,object)
```

Description

`result = BeginInvoke(arg1,...,argN,callback,object)` initiates asynchronous call to a .NET delegate. You must call `EndInvoke` to complete the asynchronous call.

Input Arguments

`arg1,...,argN`

Input arguments for delegate. The type and number of arguments must agree with the delegate signature.

`callback`

.NET System.AsyncCallback delegate, or `[]` null value.

`object`

User-defined object, or `[]` null value.

Output Arguments

`result`

.NET System.IAsyncResult object. Used to monitor the progress of the asynchronous call. Input argument to `EndInvoke`.

`EndInvoke`

Introduced in R2011a

bench

MATLAB benchmark

Syntax

```
bench
bench(N)
bench(O)
t = bench(N)
```

Description

`bench` times six different MATLAB tasks and compares the execution speed with the speed of several other computers. The six tasks are:

Test	Description	Performance Factors
LU	Perform LU of a full matrix	Floating-point, regular memory access
FFT	Perform FFT of a full vector	Floating-point, irregular memory access
ODE	Solve van der Pol equation with ODE45	Data structures and MATLAB function files
Sparse	Solve a symmetric sparse linear system	Mixed integer and floating-point
2-D	Plot Lissajous curves	2-D line drawing graphics
3-D	Display colormapped `peaks` with clipping and transforms	3-D animated OpenGL graphics

A final bar chart shows speed, which is inversely proportional to time. The longer bars represent faster machines, and the shorter bars represent the slower ones.

`bench(N)` runs each of the six tasks N times.

`bench(O)` just displays the results from other machines.

`t = bench(N)` returns an N-by-6 array with the execution times.

More About

Tips

Note: A benchmark is intended to compare performance of one particular version of MATLAB on different machines. It does not offer direct comparisons between different versions of MATLAB because tasks and problem sizes change from version to version.

The LU and FFT tasks involve large matrices and long vectors. The 2-D and 3-D tasks measure graphics performance, including software or hardware support for OpenGL®. The command

```
opengl info
```

describes the OpenGL support available on a particular machine.

Fluctuations of five or ten percent in the measured times of repeated runs on a single machine are normal.

besselh

Bessel function of third kind (Hankel function)

Syntax

```
H = besselh(nu,K,Z)
H = besselh(nu,Z)
H = besselh(nu,K,Z,1)
```

Definitions

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} + \left(z^2 - \nu^2\right) y = 0,$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*. $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν. $Y_\nu(z)$ is a second solution of Bessel's equation—linearly independent of $J_\nu(z)$—defined by

$$Y_\nu(z) = \frac{J_\nu(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}.$$

The relationship between the Hankel and Bessel functions is

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$
$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z),$$

where $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`.

Description

`H = besselh(nu,K,Z)` computes the Hankel function $H_\nu^{(K)}(z)$ where `K` = 1 or 2, for each element of the complex array `Z`. If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, `besselh` expands it to the other input's size.

`H = besselh(nu,Z)` uses `K` = 1.

`H = besselh(nu,K,Z,1)` scales $H_\nu^{(K)}(z)$ by `exp(-i*Z)` if `K` = 1, and by `exp(+i*Z)` if `K` = 2.

Examples

Modulus and Phase of Hankel Function

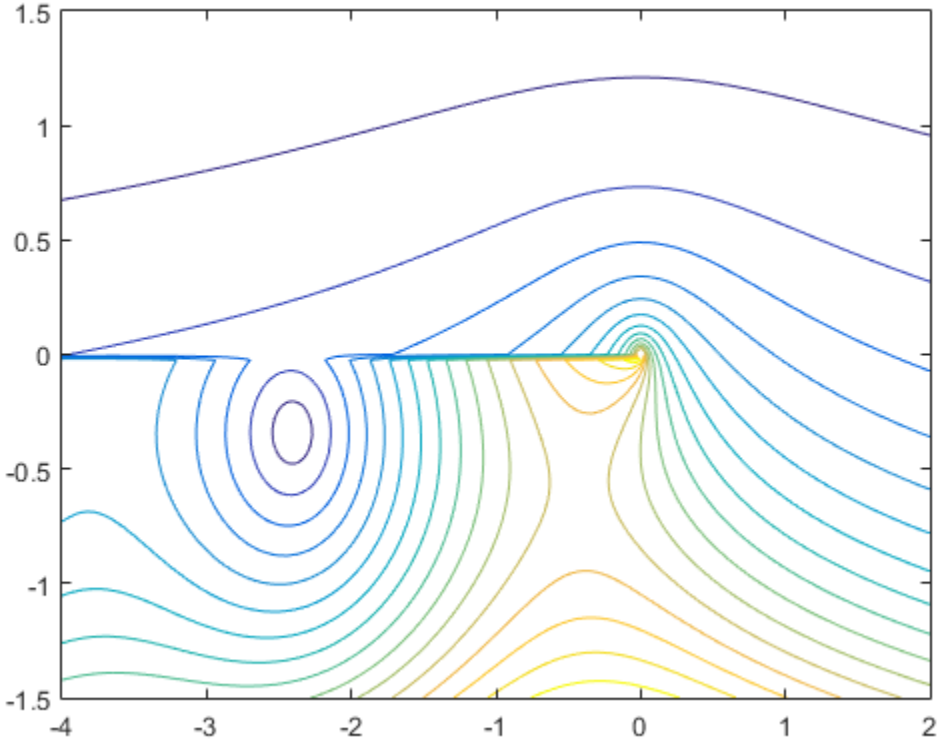
This example generates the contour plots of the modulus and phase of the Hankel function $H_0^{(1)}(z)$ shown on page 359 of Abramowitz and Stegun, *Handbook of Mathematical Functions* [1].

Create a grid of values for the domain.

```
[X,Y] = meshgrid(-4:0.025:2,-1.5:0.025:1.5);
```

Calculate the Hankel function over this domain and generate the modulus contour plot.

```
H = besselh(0,1,X+1i*Y);
contour(X,Y,abs(H),0:0.2:3.2)
hold on
```



In the same figure, add the contour plot of the phase.

```
contour(X,Y,(180/pi)*angle(H),-180:10:180)
hold off
```

`besselj` | `bessely` | `besseli` | `besselk`

besseli

Modified Bessel function of first kind

Syntax

```
I = besseli(nu,Z)
I = besseli(nu,Z,1)
```

Definitions

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} - \left(z^2 + \nu^2\right)y = 0,$$

where ν is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

$I_\nu(z)$ and $I_{-\nu}(z)$ form a fundamental set of solutions of the modified Bessel's equation. $I_\nu(z)$ is defined by

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{(k=0)}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k!\Gamma(\nu + k + 1)},$$

where $\Gamma(a)$ is the gamma function.

$K_\nu(z)$ is a second solution, independent of $I_\nu(z)$. It can be computed using `besselk`.

Description

`I = besseli(nu,Z)` computes the modified Bessel function of the first kind, $I_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`I = besseli(nu,Z,1)` computes `besseli(nu,Z).*exp(-abs(real(Z)))`.

Examples

Vector of Function Values

Create a column vector of domain values.

```
z = (0:0.2:1)';
```

Calculate the function values using `besseli` with `nu = 1`.

```

besselj

Bessel function of first kind

Syntax

```
J = besselj(nu,Z)
J = besselj(nu,Z,1)
```

Definitions

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} + \left(z^2 - v^2\right)y = 0,$$

where v is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

$J_v(z)$ and $J_{-v}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger v. $J_v(z)$ is defined by

$$J_v(z) = \left(\frac{z}{2}\right)^v \sum_{(k=0)}^{\infty} \frac{\left(\frac{-z^2}{4}\right)^k}{k!\Gamma(v+k+1)}$$

where $\Gamma(a)$ is the gamma function.

$Y_v(z)$ is a second solution of Bessel's equation that is linearly independent of $J_v(z)$. It can be computed using `bessely`.

Description

`J = besselj(nu,Z)` computes the Bessel function of the first kind, $J_v(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`J = besselj(nu,Z,1)` computes `besselj(nu,Z).*exp(-abs(imag(Z)))`.

Examples

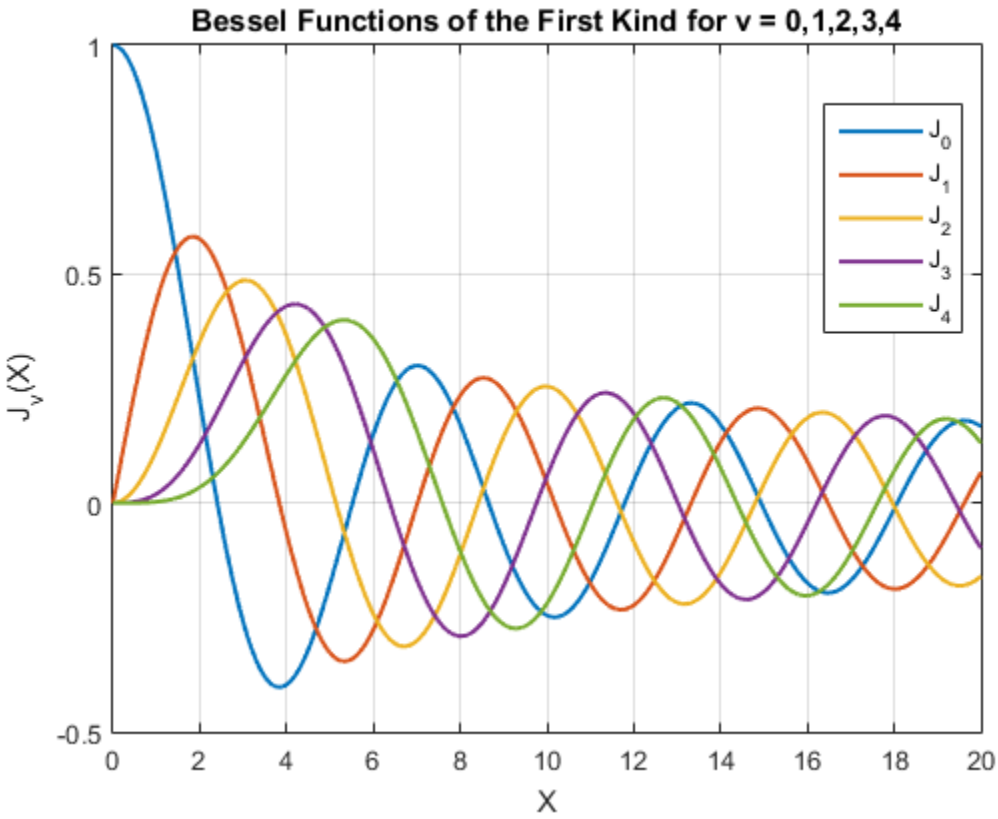
legend('J_0','J_1','J_2','J_3','J_4','Location','Best')
title('Bessel Functions of the First Kind for v = 0,1,2,3,4')
xlabel('X')
ylabel('J_v(X)')
```



More About

Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind, by the formula

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$
$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z)$$

where $H_\nu^{(K)}(z)$ is `besselh`, $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

See Also

`besselh` | `besseli` | `besselk` | `bessely`

besselk

Modified Bessel function of second kind

Syntax

```
K = besselk(nu,Z)
K = besselk(nu,Z,1)
```

Definitions

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} - \left(z^2 + \nu^2\right) y = 0,$$

where ν is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

A solution $K_\nu(z)$ of the second kind can be expressed as:

$$K_\nu(z) = \left(\frac{\pi}{2}\right)\frac{I_{-\nu}(z) - I_\nu(z)}{\sin(\nu\pi)},$$

where $I_\nu(z)$ and $I_{-\nu}(z)$ form a fundamental set of solutions of the modified Bessel's equation,

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k!\Gamma(\nu + k + 1)}$$

and $\Gamma(a)$ is the gamma function. $K_\nu(z)$ is independent of $I_\nu(z)$.

$I_\nu(z)$ can be computed using `besseli`.

Description

`K = besselk(nu,Z)` computes the modified Bessel function of the second kind, $K_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`K = besselk(nu,Z,1)` computes `besselk(nu,Z).*exp(Z)`.

Examples

bessely

Bessel function of second kind

Syntax

```
Y = bessely(nu,Z)
Y = bessely(nu,Z,1)
```

Definitions

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} + \left(z^2 - \nu^2\right)y = 0,$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

A solution $Y_\nu(z)$ of the second kind can be expressed as

$$Y_\nu(z) = \frac{J_\nu(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

where $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(-\frac{z^2}{4}\right)^k}{k!\Gamma(\nu + k + 1)},$$

and $\Gamma(a)$ is the gamma function. $Y_\nu(z)$ is linearly independent of $J_\nu(z)$.

$J_v(z)$ can be computed using `besselj`.

Description

`Y = bessely(nu,Z)` computes Bessel functions of the second kind, $Y_v(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size.

`Y = bessely(nu,Z,1)` computes `bessely(nu,Z).*exp(-abs(imag(Z)))`.

Examples

Vector of Function Values

Create a column vector of domain values.

```
z = (0:0.2:1)';
```

Calculate the function values using `bessely` with `nu = 1`.

```
format long
bessely(1,z)
```

```
ans =

                -Inf
  -3.323824988111848
  -1.780872044270052
  -1.260391347177388
  -0.978144176683359
  -0.781212821300289
```

Plot Bessel Functions of Second Kind

Define the domain.

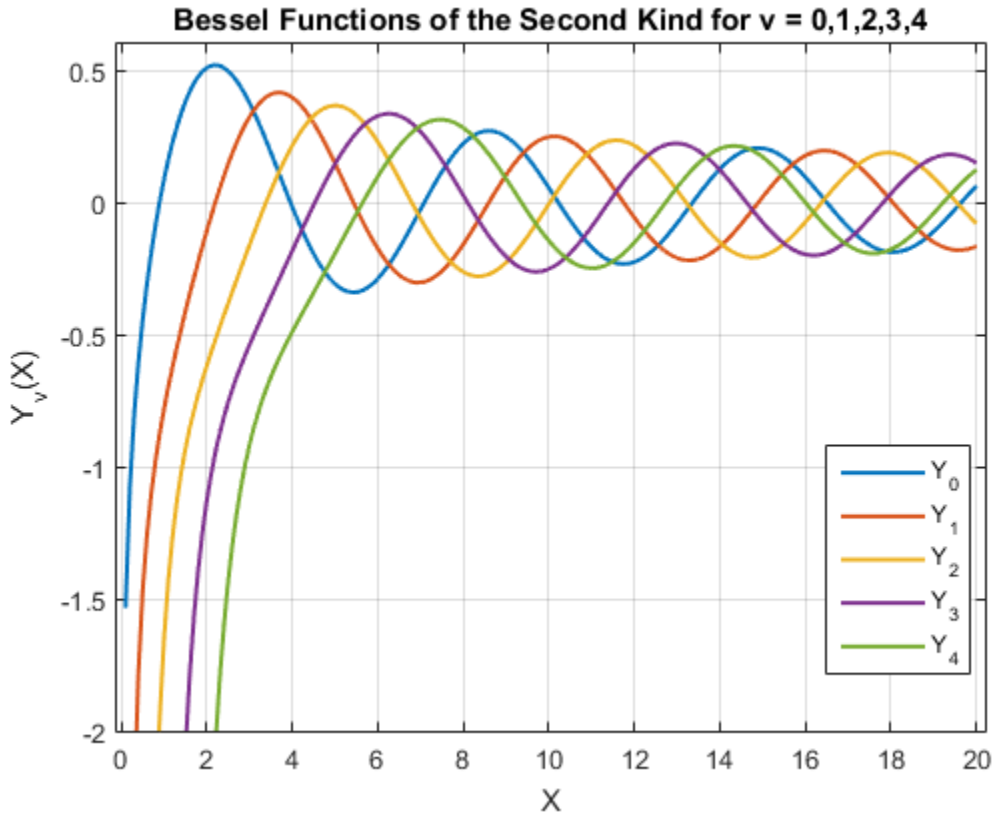
```
X = 0:0.1:20;
```

Calculate the first five Bessel functions of the second kind.

```
Y = zeros(5,201);
for i = 0:4
    Y(i+1,:) = bessely(i,X);
end
```

Plot the results.

```
plot(X,Y,'LineWidth',1.5)
axis([-0.1 20.2 -2 0.6])
grid on
legend('Y_0','Y_1','Y_2','Y_3','Y_4','Location','Best')
title('Bessel Functions of the Second Kind for v = 0,1,2,3,4')
xlabel('X')
ylabel('Y_v(X)')
```



More About

Tips

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_\nu^{(1)}(z) = J_\nu(z) + iY_\nu(z)$$
$$H_\nu^{(2)}(z) = J_\nu(z) - iY_\nu(z),$$

where $H_\nu^{(K)}(z)$ is `besselh`, $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

`besselh` | `besseli` | `besselj` | `besselk`

beta

Beta function

Syntax

```
B = beta(Z,W)
```

Definitions

The beta function is

$$B(z,w) = \int_0^1 t^{z-1}(1-t)^{w-1}dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

where $\Gamma(z)$ is the gamma function.

Description

`B = beta(Z,W)` computes the beta function for corresponding elements of arrays `Z` and `W`. The arrays must be real and nonnegative. They must be the same size, or either can be scalar.

Examples

In this example, which uses integer arguments,

```
beta(n,3)
   = (n-1)!*2!/(n+2)!
   = 2/(n*(n+1)*(n+2))
```

is the ratio of fairly small integers, and the rational format is able to recover the exact result.

```
format rat
```

```
beta((0:10)',3)

ans =

     1/0
     1/3
     1/12
     1/30
     1/60
     1/105
     1/168
     1/252
     1/360
     1/495
     1/660
```

More About

Algorithms

```
beta(z,w) = exp(gammaln(z)+gammaln(w)-gammaln(z+w))
```

See Also

`betainc` | `betaln` | `gammaln`

Introduced before R2006a

betainc

Incomplete beta function

Syntax

```
I = betainc(X,Z,W)
I = betainc(X,Z,W,tail)
```

Definitions

The incomplete beta function is

$$I_x(z,w) = \frac{1}{B(z,w)} \int_0^x t^{z-1}(1-t)^{w-1} dt$$

where $B(z,w)$, the beta function, is defined as

$$B(z,w) = \int_0^1 t^{z-1}(1-t)^{w-1} dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

and $\Gamma(z)$ is the gamma function.

Description

`I = betainc(X,Z,W)` computes the incomplete beta function for corresponding elements of the arrays `X`, `Z`, and `W`. The elements of `X` must be in the closed interval [0,1]. The arrays `Z` and `W` must be nonnegative and real. All arrays must be the same size, or any of them can be scalar.

`I = betainc(X,Z,W,tail)` specifies the tail of the incomplete beta function. Choices are:

`'lower'` (the default)	Computes the integral from `0` to `x`

`'upper'`	Computes the integral from `x` to `1`

These functions are related as follows:

`1-betainc(X,Z,W) = betainc(X,Z,W,'upper')`
Note that especially when the upper tail value is close to `0`, it is more accurate to use the `'upper'` option than to subtract the `'lower'` value from `1`.

Examples

```
format long
betainc(.5,(0:10)',3)

ans =
   1.00000000000000
   0.87500000000000
   0.68750000000000
   0.50000000000000
   0.34375000000000
   0.22656250000000
   0.14453125000000
   0.08984375000000
   0.05468750000000
   0.03271484375000
   0.01928710937500
```

See Also

`beta` | `betaln`

Introduced before R2006a

betaincinv

Beta inverse cumulative distribution function

Syntax

```
x = betaincinv(y,z,w)
x = betaincinv(y,z,w,tail)
```

Description

`x = betaincinv(y,z,w)` computes the inverse incomplete beta function for corresponding elements of `y`, `z`, and `w`, such that `y = betainc(x,z,w)`. The elements of `y` must be in the closed interval [0,1], and those of `z` and `w` must be nonnegative. `y`, `z`, and `w` must all be real and the same size (or any of them can be scalar).

`x = betaincinv(y,z,w,tail)` specifies the tail of the incomplete beta function. Choices are `'lower'` (the default) to use the integral from 0 to `x`, or `'upper'` to use the integral from `x` to 1. These two choices are related as follows: `betaincinv(y,z,w,'upper') = betaincinv(1-y,z,w,'lower')`. When `y` is close to 0, the `'upper'` option provides a way to compute `x` more accurately than by subtracting `y` from 1.

Definitions

The incomplete beta function is defined as

$$I_x(z,w) = \frac{1}{\beta(z,w)} \int_0^x t^{(z-1)}(1-t)^{(w-1)}\,dt$$

`betaincinv` computes the inverse of the incomplete beta function with respect to the integration limit `x` using Newton's method.

See Also

`betainc` | `beta` | `betaln`

betaln

Logarithm of beta function

Syntax

```
L = betaln(Z,W)
```

Description

`L = betaln(Z,W)` computes the natural logarithm of the `beta` function `log(beta(Z,W))`, for corresponding elements of arrays `Z` and `W`, without computing `beta(Z,W)`. Since the beta function can range over very large or very small values, its logarithm is sometimes more useful.

`Z` and `W` must be real and nonnegative. They must be the same size, or either can be scalar.

Examples

```
x = 510
betaln(x,x)

ans =
      -708.8616
```

`-708.8616` is slightly less than `log(realmin)`. Computing `beta(x,x)` directly would underflow (or be denormal).

More About

Algorithms

```
betaln(z,w) = gammaln(z)+gammaln(w)-gammaln(z+w)
```

Introduced before R2006a

between

Calendar math differences

Syntax

```
dt = between(t1,t2)
dt = between(t1,t2,components)
```

Description

`dt = between(t1,t2)` returns the differences between the datetime values in `t1` and `t2`. The `dt` output is a `calendarDuration` array in terms of the calendar components years, months, days, and time, such that `t2 = t1+dt`.

`dt = between(t1,t2,components)` returns the differences between datetime values in terms of the specified calendar or time components.

Examples

Differences Between Two Datetime Arrays

Create two `datetime` arrays.

```
t1 = datetime('now')
```

```
t1 =

   23-Feb-2015 10:06:51
```

```
t2 = datetime('tomorrow','Format','dd-MMM-yyyy HH:mm:ss') + caldays(0:2)
```

```
t2 =

   24-Feb-2015 00:00:00   25-Feb-2015 00:00:00   26-Feb-2015 00:00:00
```

Find the difference between the two arrays.

```
dt = between(t1,t2)
```

```
dt =

      13h 53m 8.551s   1d 13h 53m 8.551s   2d 13h 53m 8.551s
```

`between` returns a `calendarDuration` array containing differences in terms of days, hours, minutes, and seconds.

Difference Between Datetime Values in Calendar Days

Create a sequence of datetimes over a 6-month period. Then, find the number of days between the first date and each of the dates in the sequence.

```
t1 = datetime(2013,1,1);
t2 = dateshift(t1,'end','month',0:4)
```

```
t2 =

   31-Jan-2013   28-Feb-2013   31-Mar-2013   30-Apr-2013   31-May-2013
```

```
dt = between(t1,t2,'Days')
```

```
dt =

    30d    58d    89d   119d   150d
```

Input Arguments

`t1` — Input date and time

`datetime` array | datetime string | cell array of datetime strings

Input date and time, specified as a `datetime` array, datetime string, or cell array of datetime strings. At least one of inputs `t1` and `t2` must be a `datetime` array. `t1` and `t2` must be the same size unless one is a scalar.

t2 — Input date and time

datetime array | datetime string | cell array of datetime strings

Input date and time, specified as a datetime array, datetime string, or cell array of datetime strings. At least one of inputs t1 and t2 must be a datetime array. t1 and t2 must be the same size unless one is a scalar.

components — Calendar or time components

'years' | 'quarters' | 'months' | 'weeks' | 'days' | 'time' | cell array of strings

Calendar or time components, specified as one of the following strings, or a cell array containing one ore more of these strings:

- 'years'
- 'quarters'
- 'months'
- 'weeks'
- 'days'
- 'time'

Except for 'time', the above components are flexible lengths of time. For example, 1 month represents a different length of time when added to a datetime in January than when added to a datetime in February.

between operates on the calendar or time components in decreasing order, starting with the largest component.

In general, t2 is not equal to t1 + dt, unless you include 'time' in components.

Example: {'years','quarters'}

Data Types: char | cell

Output Arguments

dt — Difference array

calendarDuration array

Difference array, returned as a calendarDuration array.

More About

Tips

- To compute differences between datetime values in `t1` and `t2` as exact, fixed-length durations, use `t2-t1`.

`caldiff` | `calendarDuration` | `diff` | `minus`

Introduced in R2014b

bicg

Biconjugate gradients method

Syntax

```
x = bicg(A,b)
bicg(A,b,tol)
bicg(A,b,tol,maxit)
bicg(A,b,tol,maxit,M)
bicg(A,b,tol,maxit,M1,M2)
bicg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicg(A,b,...)
[x,flag,relres] = bicg(A,b,...)
[x,flag,relres,iter] = bicg(A,b,...)
[x,flag,relres,iter,resvec] = bicg(A,b,...)
```

Description

`x = bicg(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle, `afun`, such that `afun(x,'notransp')` returns `A*x` and `afun(x,'transp')` returns `A'*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicg` converges, it displays a message to that effect. If `bicg` fails to converge after the maximum number of iterations or halts for any reason, it prints a warning message that includes the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`bicg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicg` uses the default, `1e-6`.

`bicg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicg` uses the default, `min(n,20)`.

`bicg(A,b,tol,maxit,M)` and `bicg(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `bicg` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x,'notransp')` returns `M\x` and `mfun(x,'transp')` returns `M'\x`.

`bicg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicg` uses the default, an all-zero vector.

`[x,flag] = bicg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`bicg` converged to the desired tolerance `tol` within `maxit` iterations.
1	`bicg` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`bicg` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `bicg` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicg(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = bicg(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = bicg(A,b,...)` also returns a vector of the residual norms at each iteration including `norm(b-A*x0)`.

Examples

Using bicg with a Matrix Input

This example shows how to use `bicg` with a matrix input. `bicg`. The following code:

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = bicg(A,b,tol,maxit,M1,M2);
```

displays this message:

```
bicg converged at iteration 9 to a solution with relative
residual 5.3e-009
```

Using bicg with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_bicg` that

- Calls `bicg` with the `@afun` function handle as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_bicg` are available to `afun`.

Place the following into a file called `run_bicg`:

```
function x1 = run_bicg
n = 100;
on = ones(n,1);
b = afun(on,'notransp');
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = bicg(@afun,b,tol,maxit,M1,M2);

    function y = afun(x,transp_flag)
       if strcmp(transp_flag,'transp')      % y = A'*x
          y = 4 * x;
          y(1:n-1) = y(1:n-1) - 2 * x(2:n);
          y(2:n) = y(2:n) - x(1:n-1);
```

```
        elseif strcmp(transp_flag,'notransp') % y = A*x
           y = 4 * x;
           y(2:n) = y(2:n) - 2 * x(1:n-1);
           y(1:n-1) = y(1:n-1) - x(2:n);
        end
    end
end
```

When you enter

```
x1 = run_bicg;
```

MATLAB software displays the message

```
bicg converged at iteration 9 to a solution with ...
relative residual
5.3e-009
```

Using bicg with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `bicg` to find a solution at the requested tolerance and number of iterations.

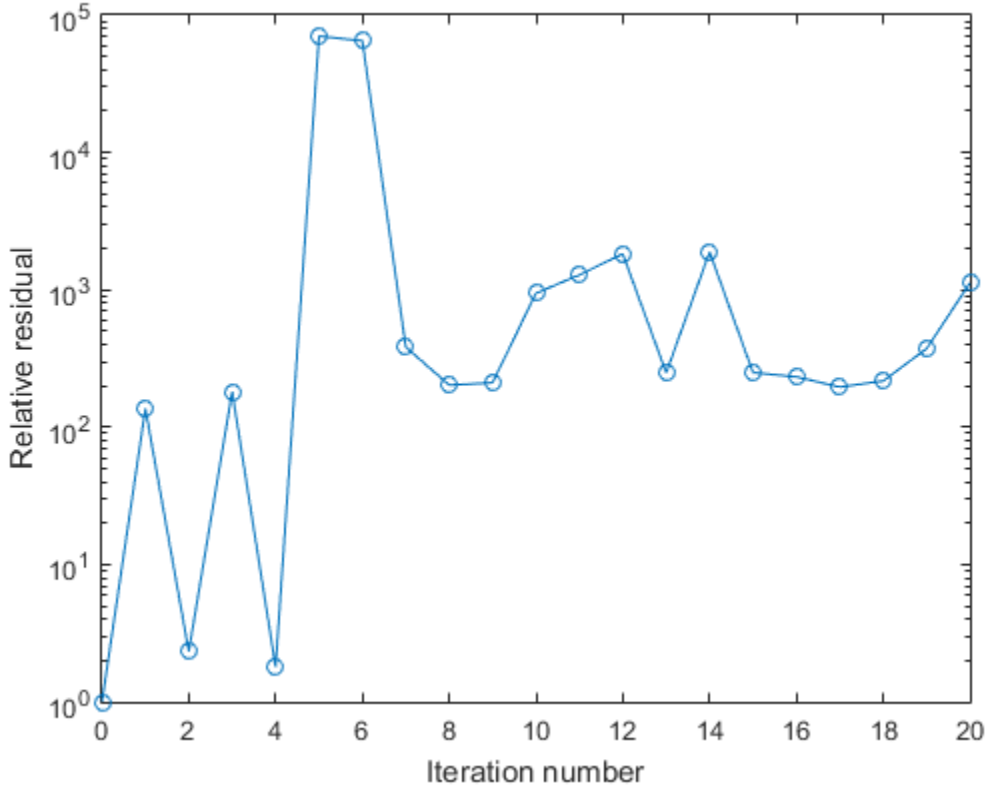
```
[x0,fl0,rr0,it0,rv0] = bicg(A,b,tol,maxit);
```

`fl0` is 1 because `bicg` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `bicg` is so poor that the initial guess (`x0`

`= zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicg`.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));

Error using ilu
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = bicg(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `bicg` drives the relative residual to `4.1410e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`, and the output `rv1(7)` is `norm(b-A*x2)`.

You can follow the progress of `bicg` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

`bicgstab` | `cgs` | `function_handle` | `gmres` | `ilu` | `lsqr` | `minres` | `mldivide` | `pcg` | `qmr` | `symmlq`

Introduced before R2006a

bicgstab

Biconjugate gradients stabilized method

Syntax

```
x = bicgstab(A,b)
bicgstab(A,b,tol)
bicgstab(A,b,tol,maxit)
bicgstab(A,b,tol,maxit,M)
bicgstab(A,b,tol,maxit,M1,M2)
bicgstab(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstab(A,b,...)
[x,flag,relres] = bicgstab(A,b,...)
[x,flag,relres,iter] = bicgstab(A,b,...)
[x,flag,relres,iter,resvec] = bicgstab(A,b,...)
```

Description

`x = bicgstab(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicgstab` converges, a message to that effect is displayed. If `bicgstab` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`bicgstab(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicgstab` uses the default, `1e-6`.

`bicgstab(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicgstab` uses the default, `min(n,20)`.

`bicgstab(A,b,tol,maxit,M)` and `bicgstab(A,b,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `bicgstab` applies no preconditioner. `M` can be a function handle `mfun`, such that `mfun(x)` returns `M\x`.

`bicgstab(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicgstab` uses the default, an all zero vector.

`[x,flag] = bicgstab(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`bicgstab` converged to the desired tolerance `tol` within `maxit` iterations.
1	`bicgstab` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`bicgstab` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `bicgstab` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicgstab(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = bicgstab(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`. `iter` can be an integer + 0.5, indicating convergence halfway through an iteration.

`[x,flag,relres,iter,resvec] = bicgstab(A,b,...)` also returns a vector of the residual norms at each half iteration, including `norm(b-A*x0)`.

Examples

Using bicgstab with a Matrix Input

This example first solves `Ax = b` by providing `A` and the preconditioner `M1` directly as arguments.

The code:

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = bicgstab(A,b,tol,maxit,M1);
```

displays the message:

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

Using bicgstab with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in a file `run_bicgstab` that

- Calls `bicgstab` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_bicgstab` are available to `afun` and `mfun`.

The following shows the code for `run_bicgstab`:

```
function x1 = run_bicgstab
n = 21;
b = afun(ones(n,1));
tol = 1e-12;
maxit = 15;
x1 = bicgstab(@afun,b,tol,maxit,@mfun);

    function y = afun(x)
       y = [0; x(1:n-1)] + ...
           [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
           [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
```

```
    end
end
```

When you enter

```
x1 = run_bicgstab;
```

MATLAB software displays the message

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 2e-014.
```

Using bicgstab with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

Use `bicgstab` to find a solution at the requested tolerance and number of iterations.

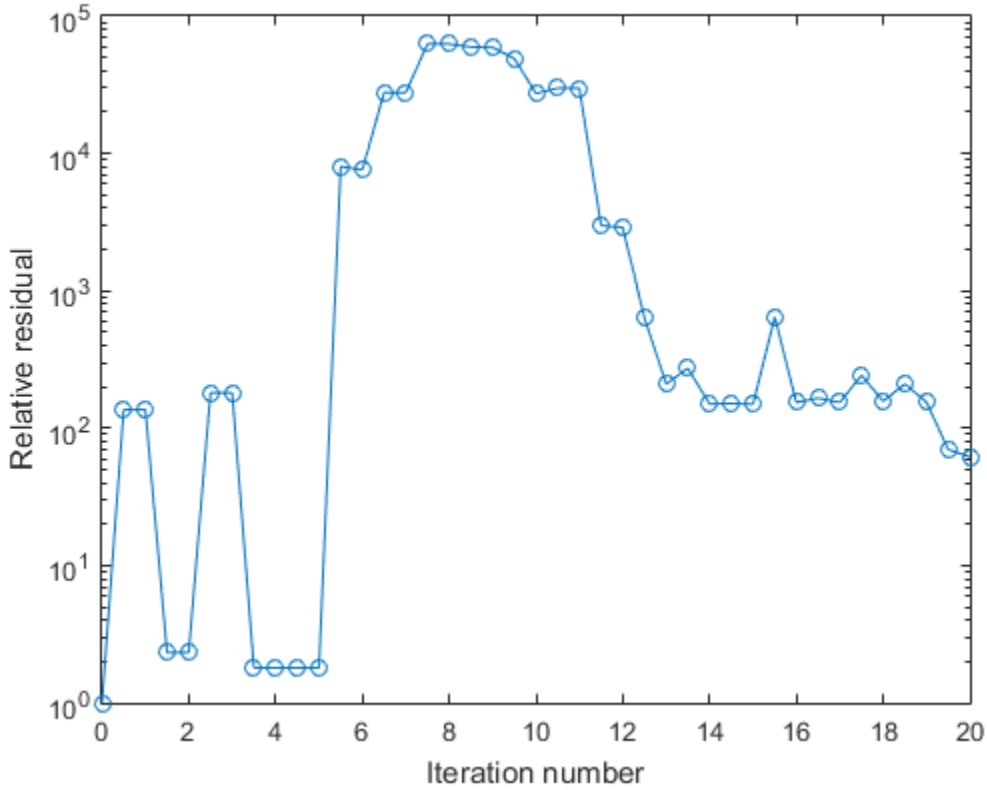
```
[x0,fl0,rr0,it0,rv0] = bicgstab(A,b,tol,maxit);
```

`fl0` is 1 because `bicgstab` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `bicgstab` is so bad that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicgstab`.

```
semilogy(0:0.5:maxit,rv0/norm(b),'-o');
```

```
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

```
Error using ilu
There is a pivot equal to zero. Consider decreasing
the drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = bicgstab(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `bicgstab` drives the relative residual to `5.9829e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the third iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)` and the output `rv1(7)` is `norm(b-A*x2)` since `bicgstab` uses half iterations.

You can follow the progress of `bicgstab` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');
xlabel('Iteration Number');
ylabel('Relative Residual');
```

bicgstabl

Biconjugate gradients stabilized (l) method

Syntax

```
x = bicgstabl(A,b)
x = bicgstabl(afun,b)
x = bicgstabl(A,b,tol)
x = bicgstabl(A,b,tol,maxit)
x = bicgstabl(A,b,tol,maxit,M)
x = bicgstabl(A,b,tol,maxit,M1,M2)
x = bicgstabl(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstabl(A,b,...)
[x,flag,relres] = bicgstabl(A,b,...)
[x,flag,relres,iter] = bicgstabl(A,b,...)
[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)
```

Description

`x = bicgstabl(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and the right-hand side column vector `b` must have length `n`.

`x = bicgstabl(afun,b)` accepts a function handle `afun` instead of the matrix `A`. `afun(x)` accepts a vector input `x` and returns the matrix-vector product `A*x`. In all of the following syntaxes, you can replace `A` by `afun`.

`x = bicgstabl(A,b,tol)` specifies the tolerance of the method. If `tol` is [] then `bicgstabl` uses the default, 1e-6.

`x = bicgstabl(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is [] then `bicgstabl` uses the default, `min(N,20)`.

`x = bicgstabl(A,b,tol,maxit,M)` and `x = bicgstabl(A,b,tol,maxit,M1,M2)` use preconditioner `M` or `M=M1*M2` and effectively solve the system `A*inv(M)*x = b` for

x. If `M` is [] then a preconditioner is not applied. `M` may be a function handle returning `M\x`.

`x = bicgstabl(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is [] then `bicgstabl` uses the default, an all zero vector.

`[x,flag] = bicgstabl(A,b,...)` also returns a convergence `flag`:

Flag	Convergence
0	`bicgstabl` converged to the desired tolerance `tol` within `maxit` iterations.
1	`bicgstabl` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`bicgstabl` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `bicgstabl` became too small or too large to continue computing.

`[x,flag,relres] = bicgstabl(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = bicgstabl(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`. `iter` can be `k/4` where `k` is some integer, indicating convergence at a given quarter iteration.

`[x,flag,relres,iter,resvec] = bicgstabl(A,b,...)` also returns a vector of the residual norms at each quarter iteration, including `norm(b-A*x0)`.

Examples

Using bicgstabl with Inputs or with a Function

You can pass inputs directly to `bicgstabl`:

```
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
```

```
tol = 1e-12;
maxit = 15;
M = diag([10:-1:1 1 1:10]);
x = bicgstabl(A,b,tol,maxit,M);
```

You can also use a matrix-vector product function:

```
function y = afun(x,n)
y = [0; x(1:n-1)] + [((n-1)/2:-1:0)';
(1:(n-1)/2)'].*x+[x(2:n); 0];
```

and a preconditioner backsolve function:

```
function y = mfun(r,n)
y = r ./ [((n-1)/2:-1:1)';
1;
(1:(n-1)/2)'];
```

as inputs to `bicgstabl`:

```
x1 = bicgstabl(@(x)afun(x,n),b,tol,maxit,@(x)mfun(x,n));
```

Using bicgstabl with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

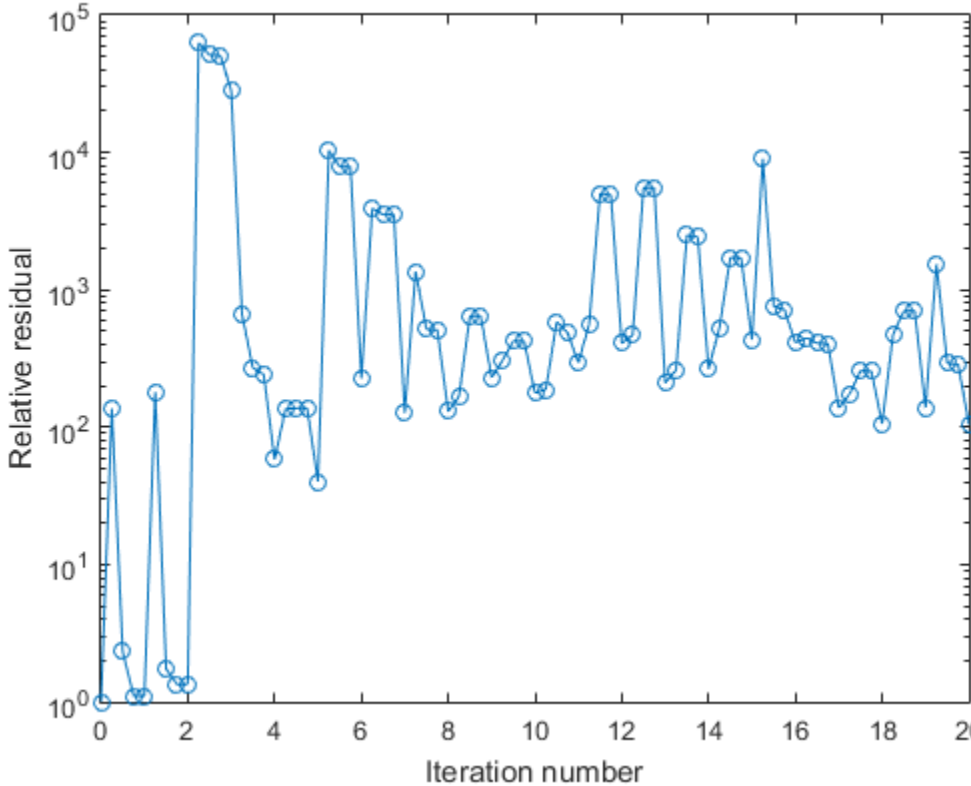
Use `bicgstabl` to find a solution at the requested tolerance and number of iterations.

```
[x0,fl0,rr0,it0,rv0] = bicgstabl(A,b,tol,maxit);
```

`fl0` is 1 because `bicgstabl` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `bicgstabl` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `bicgstabl`.

```
semilogy(0:0.25:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));

Error using ilu
There is a pivot equal to zero.  Consider decreasing the
drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = bicgstabl(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `bicgstabl` drives the relative residual to `1.0257e-015` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the sixth iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)`, and the output `rv1(9)` is `norm(b-A*x2)` since `bicgstabl` uses quarter iterations.

You can follow the progress of `bicgstabl` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.25:it1,rv1/norm(b),'-o');

h = gca;
h.XTick = 0:0.25:it1;

xlabel('Iteration number');
ylabel('Relative residual');
```

bin2dec

Convert binary number string to decimal number

Syntax

```
bin2dec(binarystr)
```

Description

`bin2dec(binarystr)` interprets the binary string `binarystr` and returns the equivalent decimal number. `binarystr` must represent a nonnegative integer value smaller than or equal to 2^52.

`bin2dec` ignores any space (`' '`) characters in the input string.

Examples

Binary `010111` converts to decimal `23`:

```
bin2dec('010111')
ans =
    23
```

Because space characters are ignored, this string yields the same result:

```
bin2dec(' 010   111 ')
ans =
    23
```

See Also

`dec2bin`

binary

Class: FTP

Set FTP transfer type to binary

Syntax

```
binary(ftpobj)
```

Description

`binary(ftpobj)` sets the FTP download and upload mode to binary, which does not convert new line characters. Binary mode is the default for FTP objects. If you previously called the `ascii` method, use this method before transferring a nontext file, such as an executable or ZIP archive.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

Examples

Connect to the MathWorks FTP server, and set the transfer mode to binary:

```
mw=ftp('ftp.mathworks.com');
binary(mw)
```

See Also

`ascii` | `ftp`

Introduced before R2006a

bitand

Bit-wise AND

Syntax

```
intout = bitand(integ1,integ2)
intout = bitand(integ1,integ2,assumedtype)

objout = bitand(netobj1,netobj2)
```

Description

`intout = bitand(integ1,integ2)` returns the bit-wise AND of values integ1 and integ2.

`intout = bitand(integ1,integ2,assumedtype)` assumes that integ1 and integ2 are of assumedtype.

`objout = bitand(netobj1,netobj2)` returns the bit-wise AND of the .NET enumeration objects netobj1 and netobj2.

Examples

Truth Table

Create a truth table for the logical AND operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitand(A, B)
```

```
TTable =

    0    0
    0    1
```

`bitand` returns 1 only if both bit-wise inputs are 1.

Negative Values

Explore how `bitand` handles negative values

MATLAB encodes signed integers using two's complement. Thus, the bit-wise AND of –5 (11111011) and 6 (00000110) is 2 (00000010).

```
C = -5;
D = 6;
bitand(C,D,'int8')
```

```
ans =

     2
```

- "Creating .NET Enumeration Bit Flags"

Input Arguments

`integ1, integ2` — Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. integ1 and integ2 must be the same data type, or one must be a scalar double value.

- If integ1 and integ2 are double arrays, and assumedtype is not specified, then MATLAB treats integ1 and integ2 as unsigned 64-bit integers.
- If assumedtype is specified, then all elements in integ1 and integ2 must have integer values within the range of assumedtype.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`assumedtype` — Assumed data type of `integ1` and `integ2`

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of integ1 and integ2, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If integ1 and integ2 are double arrays, then assumedtype can specify any valid integer type, but defaults to `'uint64'`.
- If integ1 and integ2 are integer type arrays, then assumedtype must specify that same integer type.

Data Types: `char`

`netobj1`, `netobj2` — Input values

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitand` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

Output Arguments

`intout` — Bit-wise AND result

signed integer array | unsigned integer array | double array

Bit-wise AND result, returned as a signed integer array, unsigned integer array, or double array. intout is the same data type and size as integ1 and integ2.

- If either integ1 or integ2 is a scalar double, and the other is a non-double integer type, intout is the non-double integer type.

`objout` — Bit-wise AND result

.NET enumeration object

Bit-wise AND result, returned as a .NET enumeration objects.

`bitcmp` | `bitget` | `bitnot` | `bitor` | `bitset` | `bitshift` | `bitxor` | `intmax`

Introduced before R2006a

bitcmp

Bit-wise complement

Compatibility

`bitcmp(A,N)` has been removed. Use `bitcmp(A)` or `bitcmp(A,assumedtype)` instead.

Syntax

```
cmp = bitcmp(A)
cmp = bitcmp(A,assumedtype)

cmp = bitcmp(A,N)
```

Description

`cmp = bitcmp(A)` returns the bit-wise complement of A.

`cmp = bitcmp(A,assumedtype)` assumes that A is of assumedtype.

`cmp = bitcmp(A,N)` returns an N-bit complement of A. Elements of A cannot exceed 2^N-1.

Examples

Complement of a Negative Integer

```
A = int8(-11);
cmp = bitcmp(A)

cmp =

   10
```

You can see the complement operation when the numbers are shown in binary.

```
original = bitget(A,8:-1:1)
complement = bitget(bitcmp(A),8:-1:1)
```

```
original =

    1    1    1    1    0    1    0    1

complement =

    0    0    0    0    1    0    1    0
```

Complement of Unsigned Integers

```
cmp = bitcmp(64,'uint8')
maxint = intmax('uint8') - 64
```

```
cmp =

   191

maxint =

  191
```

The complement of an unsigned integer is equal to itself subtracted from the maximum integer of its data type.

Input Arguments

A — Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If A is a double array, and assumedtype is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If assumedtype is specified, then all elements in A must have integer values within the range of assumedtype.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`assumedtype` — Assumed data type of A

`'uint64' | 'uint32' | 'uint16' | 'uint8' | 'int64' | 'int32' | 'int16' | 'int8'`

Assumed data type of A, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If A is a double array, then assumedtype can specify any valid integer type, but defaults to `'uint64'`.
- If A is an integer type array, then assumedtype must specify that same integer type.

Data Types: `char`

`N` — number of returned bits

integer

Number of returned bits, specified as an integer. N cannot exceed the number of bits in the integer type of A.

Data Types: `double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

Output Arguments

`cmp` — Bit-wise complement

signed integer array | unsigned integer array | double array

Bit-wise complement, returned as a signed integer array, unsigned integer array, or double array. cmp is the same size and type as A.

See Also

`bitand | bitget | bitor | bitset | bitshift | bitxor | intmax`

Introduced before R2006a

bitget

Get bit at specified position

Syntax

```
b = bitget(A,bit)
b = bitget(A,bit,assumedtype)
```

Description

`b = bitget(A,bit)` returns the bit value at position bit in integer array A.

`b = bitget(A,bit,assumedtype)` assumes that A is of assumedtype.

Examples

Maximum Integer

Find the difference in the binary representation between the maximum integer of signed and unsigned integers.

```
a1 = intmax('int8');
a2 = intmax('uint8');
b1 = bitget(a1,8:-1:1)
b2 = bitget(a2,8:-1:1)
```

```
b1 =

    0     1     1     1     1     1     1     1

b2 =

    1     1     1     1     1     1     1     1
```

The signed integers require a bit to accommodate negative integers.

Negative Numbers Using Two's Complement

Find the 8-bit representation of a negative number.

```
A = -29;
b = bitget(A,8:-1:1,'int8')
```

```
b =

     1     1     1     0     0     0     1     1
```

Input Arguments

A — Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If A is a double array, and assumedtype is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If assumedtype is specified, then all elements in A must have integer values within the range of assumedtype.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

bit — Bit position

integer | integer array

Bit position, specified as an integer or integer array. bit must be between 1 (the least-significant bit) and the number of bits in the integer class of A.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

assumedtype — Assumed data type of A

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of A, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If A is a double array, then assumedtype can specify any valid integer type, but defaults to `'uint64'`.
- If A is an integer type array, then assumedtype must specify that same integer type.

Data Types: `char`

Output Arguments

b — Bit value at `bit`

0 | 1

Bit value at bit, returned as `0` or `1`. b is the same data type as A.

See Also

`bitand` | `bitcmp` | `bitor` | `bitset` | `bitshift` | `bitxor` | `intmax`

Introduced before R2006a

bitmax

Maximum double-precision floating-point integer

Compatibility

`bitmax` has been removed. Use `flintmax` instead.

Syntax

```
bitmax
```

Description

`bitmax` returns the maximum unsigned double-precision floating-point integer for your computer. It is the value when all bits are set, namely the value $2^{53} - 1$.

Note Instead of integer-valued double-precision variables, use unsigned integers for bit manipulations and replace `bitmax` with `intmax`.

Examples

Display in different formats the largest floating point integer and the largest 32 bit unsigned integer:

```
format long e
bitmax
ans =
   9.007199254740991e+015

intmax('uint32')
ans =
   4294967295
```

```
format hex
bitmax
ans =
   433fffffffffffff

intmax('uint32')
ans =
   ffffffff
```

In the second bitmax statement, the last 13 hex digits of `bitmax` are `f`, corresponding to 52 1's (all 1's) in the mantissa of the binary representation. The first 3 hex digits correspond to the sign bit 0 and the 11 bit biased exponent `10000110011` in binary (`1075` in decimal), and the actual exponent is (`1075-1023`) = 52. Thus the binary value of `bitmax` is `1.111...111 x 2^52` with 52 trailing 1's, or `2^53-1`.

`bitand` | `bitcmp` | `bitget` | `bitor` | `bitset` | `bitshift` | `bitxor`

Introduced before R2006a

bitnot

.NET enumeration object bit-wise NOT instance method

Syntax

```
objout = bitnot(netobj)
```

Description

`objout = bitnot(netobj)` reverses all bits of the .NET enumeration objects netobj.

Examples

- "Creating .NET Enumeration Bit Flags"

Input Arguments

`netobj` — Input value

.NET enumeration objects

Input value, specified as .NET enumeration object. You must be running a version of Windows to use .NET enumeration objects as input arguments.

Output Arguments

`objout` — Bit-wise NOT result

.NET enumeration object

Bit-wise NOT result, returned as a .NET enumeration object.

Limitations

- The method is an instance method for MATLAB enumeration objects created from a .NET enumeration. This method does not have an equivalent MATLAB function.

See Also

`bitand` | `bitor` | `bitxor`

bitor

Bit-wise OR

Syntax

```
intout = bitor(integ1,integ2)
intout = bitor(integ1,integ2,assumedtype)

objout = bitor(netobj1,netobj2)
```

Description

`intout = bitor(integ1,integ2)` returns the bit-wise OR of integ1 and integ2.

`intout = bitor(integ1,integ2,assumedtype)` assumes that integ1 and integ2 are of assumedtype.

`objout = bitor(netobj1,netobj2)` returns the bit-wise OR of the .NET enumeration objects netobj1 and netobj2.

Examples

Truth Table

Create a truth table for the logical OR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitor(A, B)
```

```
TTable =

    0    1
    1    1
```

`bitor` returns 1 if either bit-wise input is 1.

Negative Values

Explore how `bitor` handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise OR of -5 (11111010) and 6 (00000110) is -1 (11111110).

```
C = -5;
D = 6;
bitor(C,D,'int8')
```

```
ans =

    -1
```

- "Creating .NET Enumeration Bit Flags"

Input Arguments

`integ1, integ2` — Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. integ1 and integ2 must be the same data type, or one must be a scalar double value.

- If integ1 and integ2 are double arrays, and assumedtype is not specified, then MATLAB treats integ1 and integ2 as unsigned 64-bit integers.
- If assumedtype is specified, then all elements in integ1 and integ2 must have integer values within the range of assumedtype.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`assumedtype` — Assumed data type of `integ1` and `integ2`

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of integ1 and integ2, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If integ1 and integ2 are double arrays, then assumedtype can specify any valid integer type, but defaults to `'uint64'`.
- If integ1 and integ2 are integer type arrays, then assumedtype must specify that same integer type.

Data Types: `char`

`netobj1`, `netobj2` — Input values

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitor` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

Output Arguments

`intout` — Bit-wise OR result

signed integer array | unsigned integer array | double array

Bit-wise OR result, returned as a signed integer array, unsigned integer array, or double array. intout is the same data type and size as integ1 and integ2.

- If either integ1 or integ2 is a scalar double, and the other is a non-double integer type, intout is the non-double integer type.

`objout` — Bit-wise OR result

.NET enumeration object

Bit-wise OR result, returned as a .NET enumeration objects.

See Also

`bitand` | `bitcmp` | `bitget` | `bitnot` | `bitset` | `bitshift` | `bitxor` | `intmax`

Introduced before R2006a

bitset

Set bit at specific location

Syntax

```
intout = bitset(A,bit)
intout = bitset(A,bit,assumedtype)

intout = bitset(A,bit,V)
intout = bitset(A,bit,V,assumedtype)
```

Description

`intout = bitset(A,bit)` returns the value of A with position bit set to 1 (on).

`intout = bitset(A,bit,assumedtype)` assumes A is of type assumedtype.

`intout = bitset(A,bit,V)` returns A with position bit set to the value of V.

- If V is zero, then the bit position bit is set to 0 (off).
- If V is nonzero, then the bit position bit is set to 1 (on).

`intout = bitset(A,bit,V,assumedtype)` assumes A is of type assumedtype.

Examples

Set Bits to On

Add powers of 2 onto a number.

```
A = 4;
intout = bitset(A,4:6)
```

```
intout =

    12    20    36
```

You can see that `bitset` sequentially turns on bits 4 through 6.

```
c = dec2bin(intout)
```

```
c =

001100
010100
100100
```

Out of Range of Integer Type

MATLAB throws an error if you specify an integer outside the range of assumedtype.

```
intout = bitset(300,5,'int8')
```

```
Error using bitset
Double inputs must have integer values in the range of ASSUMEDTYPE.
```

You can avoid this error by limiting your input to the range of the specified datatype.

Set Bits to Off

Repeatedly subtract powers of 2 from a number.

```
a = intmax('uint8')
for k = 0:7
   a = bitset(a, 8-k, 0);
   b(1,k+1) = a;
end
b
```

```
a =

  255

b =

   127    63    31    15     7     3     1     0
```

Set Multiple Bits

Set multiple bits to different values

```
bits = 2:6;
```

```
val = [1 0 0 1 1];
intout = bitset(0,bits,val,'int8')

intout =

      2     0     0    16    32
```

Input Arguments

A — Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If A is a double array, and assumedtype is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If assumedtype is specified, then all elements in A must have integer values within the range of assumedtype.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`bit` — Bit position

integer | integer array

Bit position, specified as an integer or integer array. bit must be between 1 (the least significant bit) and the number of bits in the integer class of A.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`assumedtype` — Assumed data type of A

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of A, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If A is a double array, then assumedtype can specify any valid integer type, but defaults to `'uint64'`.
- If A is an integer type array, then assumedtype must specify that same integer type.

Data Types: `char`

`V` — bit value

scalar | numeric array

Bit value, specified as a scalar or a numeric array. If V and bit are arrays, they must be the same size.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Output Arguments

`intout` — Adjusted integer

signed integer array | unsigned integer array | double array

Adjusted integer, returned as a signed integer array, unsigned integer array, or double array. intout is the same size and type as A.

See Also

`bitand` | `bitcmp` | `bitget` | `bitor` | `bitshift` | `bitxor` | `intmax`

Introduced before R2006a

bitshift

Shift bits specified number of places

Compatibility

`bitshift(A,k,N)` has been removed. Use `bitshift(A,k)` or `bitshift(A,k,assumedtype)` instead.

`bitshift` no longer interprets double values as 53-bit unsigned integers by default, but as `uint64` values.

Syntax

```
intout = bitshift(A,k)
intout = bitshift(A,k,assumedtype)

intout = bitshift(A,k,N)
```

Description

`intout = bitshift(A,k)` returns A shifted to the left by k bits, equivalent to multiplying by 2^k. Negative values of k correspond to shifting bits right or dividing by $2^{|k|}$ and rounding to the nearest integer towards negative infinity. Any overflow bits are truncated.

- If A is an array of signed integers, then `bitshift` returns the arithmetic shift results, preserving the signed bit when k is negative, and not preserving the signed bit when k is positive.
- If k is positive, MATLAB shifts the bits to the left and inserts k 0-bits on the right.
- If k is negative and A is nonnegative, then MATLAB shifts the bits to the right and inserts |k| 0-bits on the left.
- If k is negative and A is negative, then MATLAB shifts the bits to the right and inserts |k| 1-bits on the left.

`intout = bitshift(A,k,assumedtype)` assumes A is of type assumedtype.

`intout = bitshift(A,k,N)` truncates any bits that overflow N bits.

Examples

Shifted 8-bit Integer

Repeatedly shift the bits of an unsigned 8-bit value to the left until all the nonzero bits overflow.

```
a = intmax('uint8');
s1 = 'Initial uint8 value %5d is %08s in binary\n';
s2 = 'Shifted uint8 value %5d is %08s in binary\n';
fprintf(s1,a,dec2bin(a))
 for i = 1:8
    a = bitshift(a,1);
    fprintf(s2,a,dec2bin(a))
 end
```

```
Initial uint8 value   255 is 11111111 in binary
Shifted uint8 value   254 is 11111110 in binary
Shifted uint8 value   252 is 11111100 in binary
Shifted uint8 value   248 is 11111000 in binary
Shifted uint8 value   240 is 11110000 in binary
Shifted uint8 value   224 is 11100000 in binary
Shifted uint8 value   192 is 11000000 in binary
Shifted uint8 value   128 is 10000000 in binary
Shifted uint8 value     0 is 00000000 in binary
```

Different Results for Different Integer Types

Find the shift for a number using different assumed integer types.

```
uintout = bitshift(6,5:7,'uint8')
intout = bitshift(6,5:7,'int8')
```

```
uintout =

   192   128     0

intout =
```

```
   -64  -128     0
```

Input Arguments

A — Input value

signed integer array | unsigned integer array | double array

Input value, specified as a signed integer array, unsigned integer array, or double array.

- If A is a double array, and assumedtype is not specified, then MATLAB treats A as an unsigned 64-bit integer.
- If assumedtype is specified, then all elements in A must have integer values within the range of assumedtype.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

k — Number of switched bits

integer | integer array

Number of switched bits, specified as an integer or integer array.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

assumedtype — Assumed data type of A

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of A, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If A is an integer type array, then assumedtype must specify that same integer type.
- If A is a double array, then assumedtype can specify any valid integer type.

Data Types: `char`

N — Number of bits kept

nonnegative integer | nonnegative integer array

Number of bits kept, specified as a nonnegative integer or integer array. N must be less than or equal to the number of bits in the unsigned integer class of A.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`intout` — Shifted value

signed integer array | unsigned integer array | double array

Shifted value, returned as signed integer array, unsigned integer array, or double array. intout is the same size and type as A.

See Also

`bitand` | `bitcmp` | `bitget` | `bitor` | `bitset` | `bitxor` | `intmax`

Introduced before R2006a

bitxor

Bit-wise XOR

Syntax

```
intout = bitxor(integ1,integ2)
intout = bitxor(integ1,integ2,assumedtype)

objout = bitxor(netobj1,netobj2)
```

Description

`intout = bitxor(integ1,integ2)` returns the bit-wise XOR of integ1 and integ2.

`intout = bitxor(integ1,integ2,assumedtype)` assumes that integ1 and integ2 are of assumedtype.

`objout = bitxor(netobj1,netobj2)` returns the bit-wise XOR of the .NET enumeration objects netobj1 and netobj2.

Examples

Truth Table

Create a truth table for the logical XOR operation.

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);
TTable = bitxor(A, B)
```

```
TTable =

    0    1
    1    0
```

`bitxor` returns 0 if both bit-wise inputs are equal.

Negative Values

Explore how `bitxor` handles negative values.

MATLAB encodes negative integers using two's complement. Thus, the bit-wise XOR of -5 (11111010) and 6 (00000110) is -3 (11111100).

```
C = -5;
D = 6;
bitxor(C,D,'int8')
```

```
ans =

    -3
```

- "Creating .NET Enumeration Bit Flags"

Input Arguments

`integ1, integ2` — Input values

signed integer arrays | unsigned integer arrays | double arrays

Input values, specified as signed integer arrays, unsigned integer arrays, or double arrays. integ1 and integ2 must be the same data type, or one must be a scalar double value.

- If integ1 and integ2 are double arrays, and assumedtype is not specified, then MATLAB treats integ1 and integ2 as unsigned 64-bit integers.
- If assumedtype is specified, then all elements in integ1 and integ2 must have integer values within the range of assumedtype.

Data Types: `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`assumedtype` — Assumed data type of `integ1` and `integ2`

`'uint64'` | `'uint32'` | `'uint16'` | `'uint8'` | `'int64'` | `'int32'` | `'int16'` | `'int8'`

Assumed data type of integ1 and integ2, specified as `'uint64'`, `'uint32'`, `'uint16'`, `'uint8'`, `'int64'`, `'int32'`, `'int16'`, or `'int8'`.

- If integ1 and integ2 are double arrays, then assumedtype can specify any valid integer type, but defaults to `'uint64'`.
- If integ1 and integ2 are integer type arrays, then assumedtype must specify that same integer type.

Data Types: `char`

`netobj1`, `netobj2` — Input values

.NET enumeration objects

Input values, specified as .NET enumeration objects. You must be running a version of Windows to use .NET enumeration objects as input arguments.

`bitxor` is an instance method for MATLAB enumeration objects created from a .NET enumeration.

Output Arguments

`intout` — Bit-wise XOR result

signed integer array | unsigned integer array | double array

Bit-wise XOR result, returned as a signed integer array, unsigned integer array, or double array. intout is the same data type and size as integ1 and integ2.

- If either integ1 or integ2 is a scalar double, and the other is a non-double integer type, intout is the non-double integer type.

`objout` — Bit-wise XOR result

.NET enumeration object

Bit-wise XOR result, returned as a .NET enumeration objects.

Introduced before R2006a

blanks

Create string of blank characters

Syntax

```
blanks(n)
```

Description

`blanks(n)` is a string of `n` blanks.

Examples

`blanks` is useful with the `display` function. For example,

```
disp(['xxx' blanks(20) 'yyy'])
```

displays twenty blanks between the strings `'xxx'` and `'yyy'`.

`disp(blanks(n)')` moves the cursor down `n` lines.

See Also

`clc` | `format` | `home`

Introduced before R2006a

blkdiag

Construct block diagonal matrix from input arguments

Syntax

```
out = blkdiag(a,b,c,d,...)
```

Description

`out = blkdiag(a,b,c,d,...)`, where `a`, `b`, `c`, `d`, `...` are matrices, outputs a block diagonal matrix of the form

$$\begin{bmatrix} a & 0 & 0 & 0 & 0 \\ 0 & b & 0 & 0 & 0 \\ 0 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & \ldots \end{bmatrix}$$

The input matrices do not have to be square, nor do they have to be of equal size.

See Also

`diag` | `horzcat` | `vertcat`

Introduced before R2006a

boundary

Boundary of a set of points in 2-D or 3-D

Syntax

```
k = boundary(x,y)
k = boundary(x,y,z)
k = boundary(P)
k = boundary( ___ ,s)
[k,v] = boundary( ___ )
```

Description

`k = boundary(x,y)` returns a vector of point indices representing a single conforming 2-D boundary around the points `(x,y)`. The points `(x(k),y(k))` form the boundary. Unlike the convex hull, the boundary can shrink towards the interior of the hull to envelop the points.

`k = boundary(x,y,z)` returns a triangulation representing a single conforming 3-D boundary around the points `(x,y,z)`. Each row of `k` is a triangle defined in terms of the point indices.

`k = boundary(P)` specifies points `(x,y)` or `(x,y,z)` in the columns of matrix `P`.

`k = boundary( ___ ,s)` specifies shrink factor `s` using any of the previous syntaxes. `s` is a scalar between `0` and `1`. Setting `s` to `0` gives the convex hull, and setting `s` to `1` gives a compact boundary that envelops the points. The default shrink factor is `0.5`.

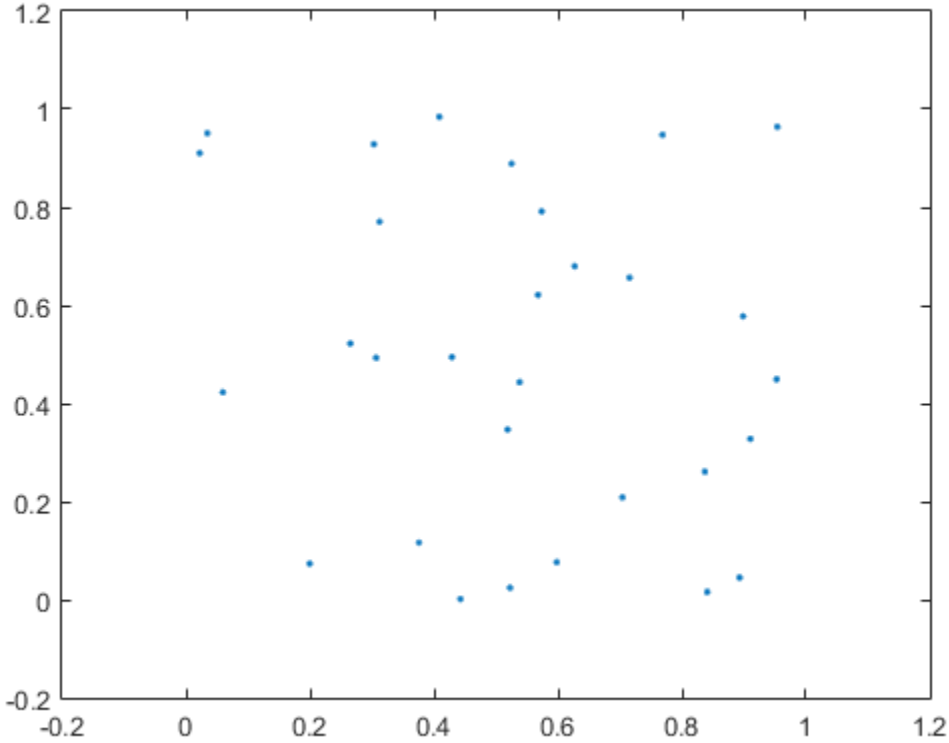
`[k,v] = boundary( ___ )` also returns a scalar `v`, which is the area (2-D) or volume (3-D) which boundary `k` encloses.

Examples

Boundary of 2-D Point Cloud

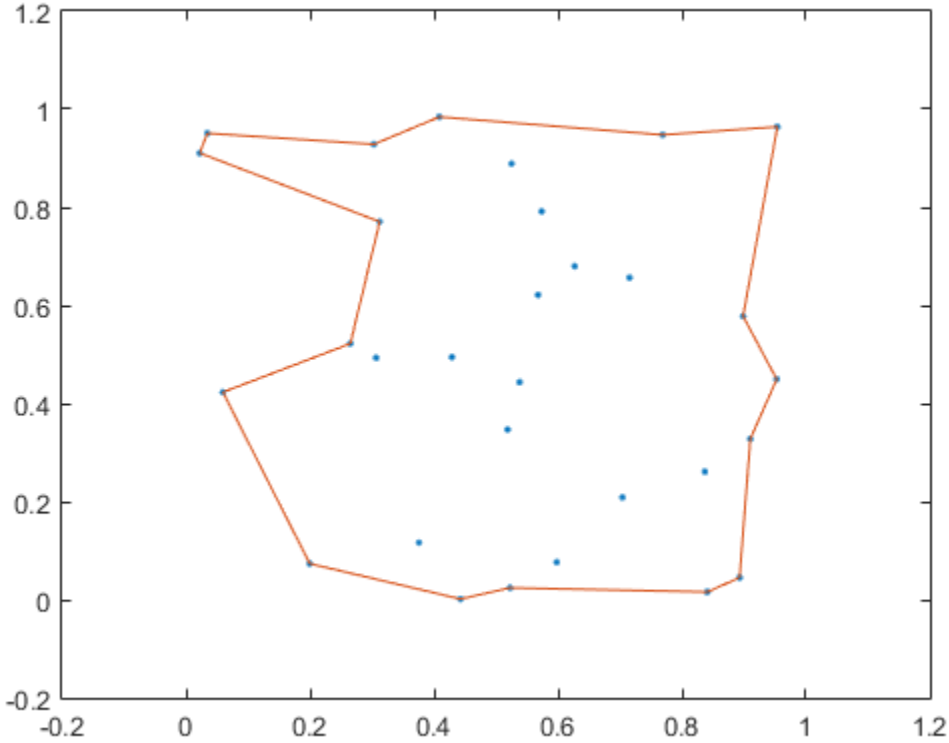
Create and plot a set of random 2-D points.

```
x = gallery('uniformdata',30,1,1);
y = gallery('uniformdata',30,1,10);
plot(x,y,'.')
xlim([-0.2 1.2])
ylim([-0.2 1.2])
```



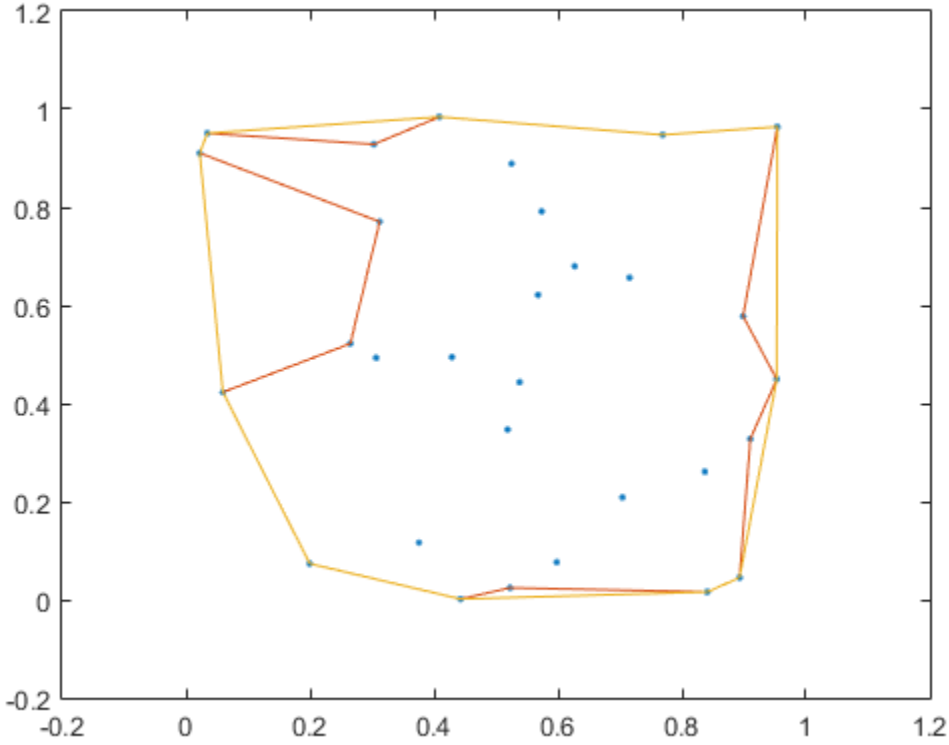
Compute a boundary around the points using the default shrink factor.

```
k = boundary(x,y);
hold on;
plot(x(k),y(k));
```



Create a new boundary around the points using a shrink factor of 0.1. The result is a less compact boundary enveloping the points.

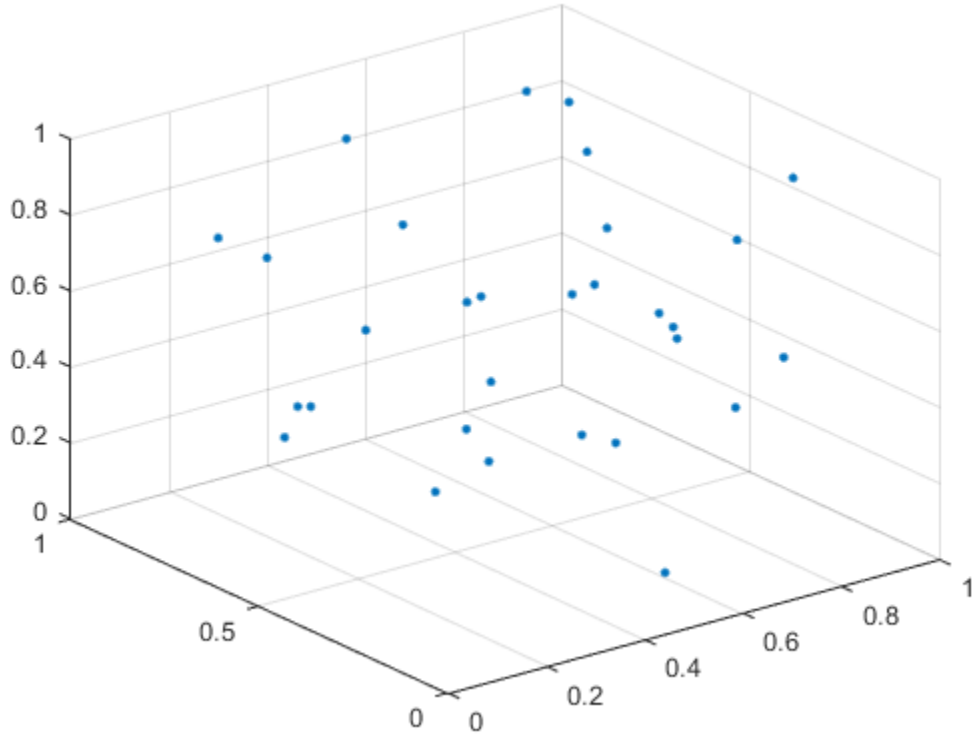
```
j = boundary(x,y,0.1);
hold on;
plot(x(j),y(j));
```



Boundary of 3-D Point Cloud

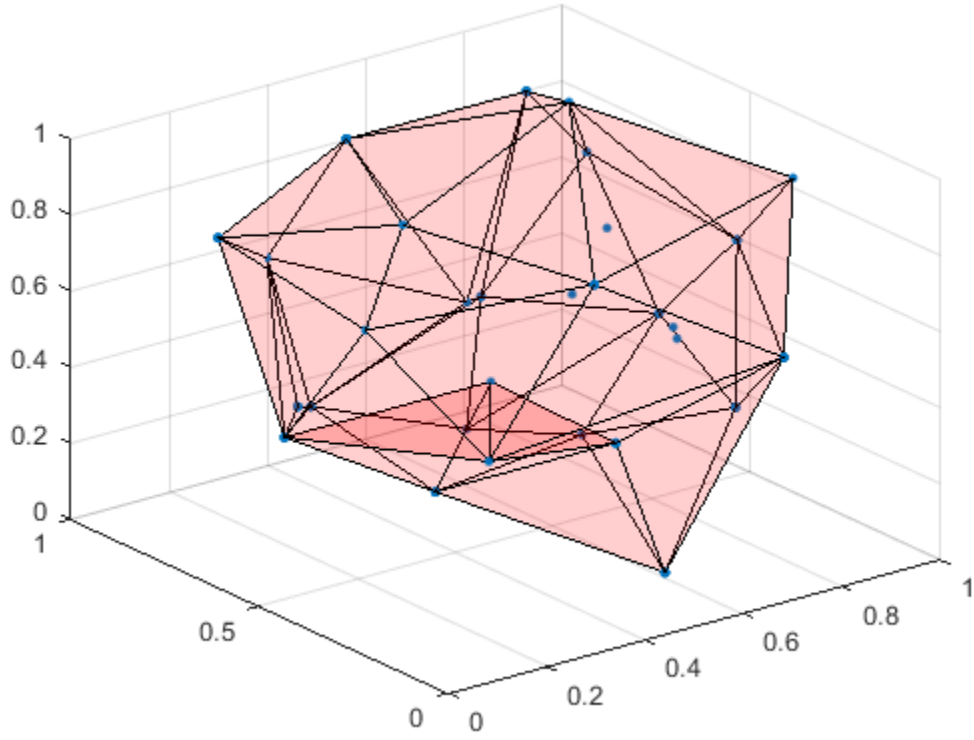
Create and plot a set of random 3-D points.

```
P = gallery('uniformdata',30,3,5);
plot3(P(:,1),P(:,2),P(:,3),'.','MarkerSize',10)
grid on
```



Plot the boundary using the default shrink factor.

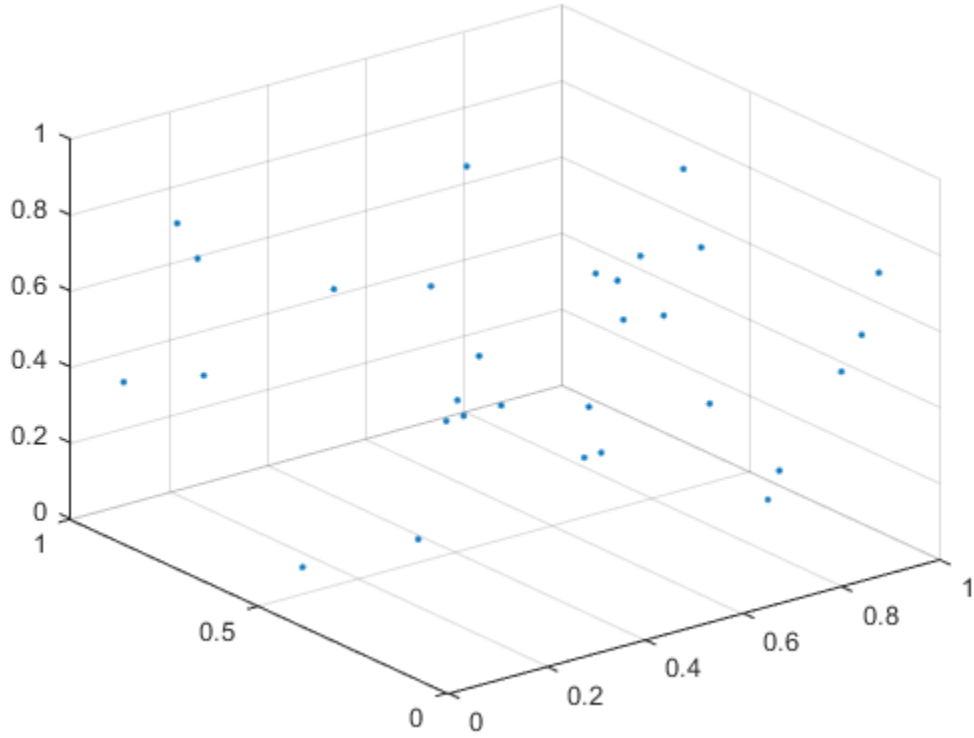
```
k = boundary(P);
hold on
trisurf(k,P(:,1),P(:,2),P(:,3),'Facecolor','red','FaceAlpha',0.1)
```



Shrink Factor Effect on 3-D Boundary

Create and plot a set of random 3-D points.

```
P = gallery('uniformdata',30,3,8);
plot3(P(:,1),P(:,2),P(:,3),'.')
grid on
```



Compute two boundaries: one with a shrink factor of 0 and the other with a shrink factor of 1.

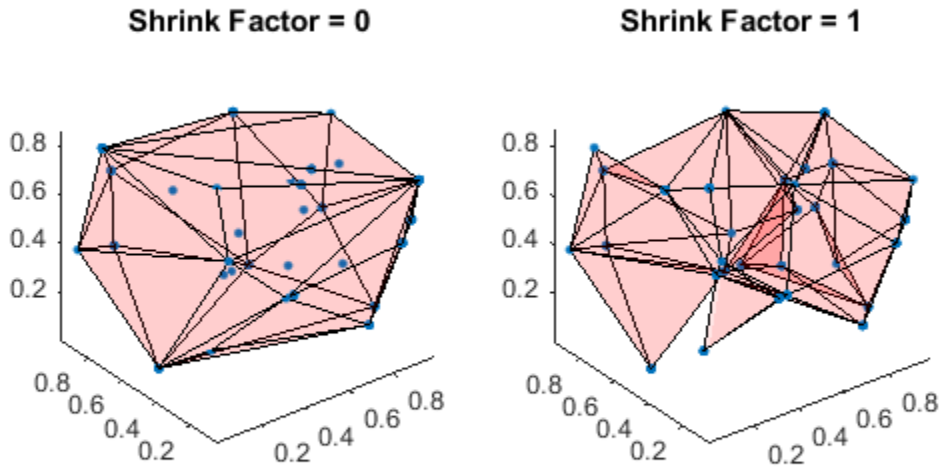
```
k = boundary(P,0);
j = boundary(P,1);
```

Compare the shrink factors by plotting the original points and the two boundaries side-by-side.

```
subplot(1,2,1);
plot3(P(:,1),P(:,2),P(:,3),'.','MarkerSize',10)
hold on
trisurf(k,P(:,1),P(:,2),P(:,3),'Facecolor','red','FaceAlpha',0.1)
axis equal
```

```
title('Shrink Factor = 0')

subplot(1,2,2);
plot3(P(:,1),P(:,2),P(:,3),'.','MarkerSize',10)
hold on
trisurf(j,P(:,1),P(:,2),P(:,3),'Facecolor','red','FaceAlpha',0.1)
axis equal
title('Shrink Factor = 1')
```

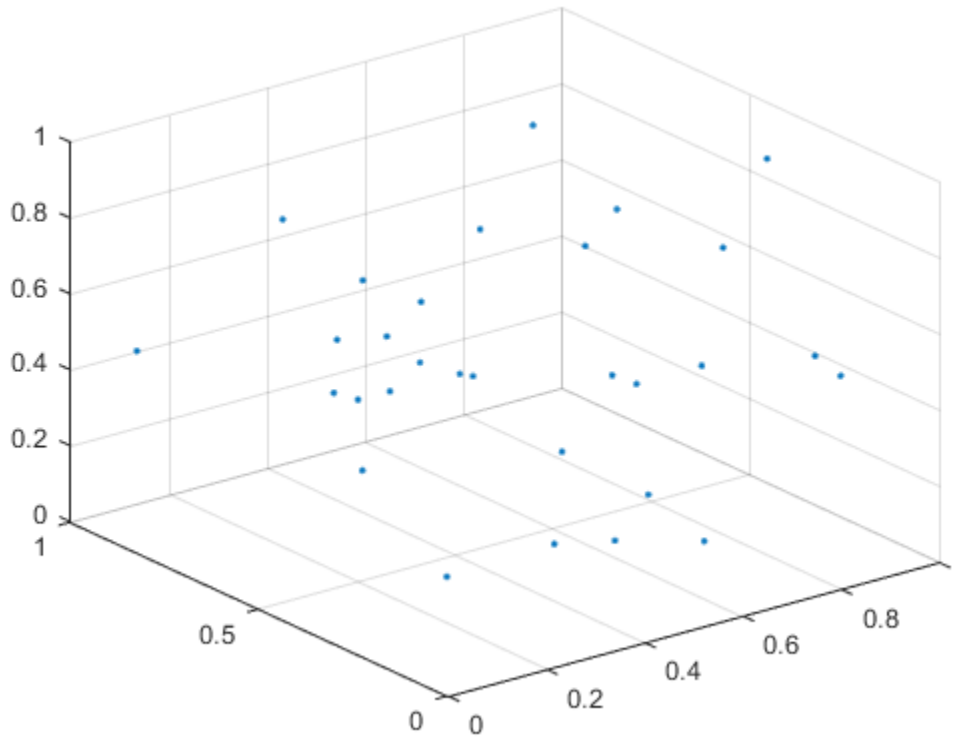


Volume of 3-D Boundary

Create and plot a set of random 3-D points.

```
P = gallery('uniformdata',30,3,1);
```

```
plot3(P(:,1),P(:,2),P(:,3),'.')
grid on
```



Use the `boundary` function to compute a boundary around the points, and find the volume of the resulting shape.

```
[~, vol] = boundary(P);
vol
```

```
vol =

    0.3012
```

Input Arguments

x — x-coordinates of points

column vector

x-coordinates of points, specified as a column vector.

Data Types: `double`

y — y-coordinates of points

column vector

y-coordinates of points, specified as a column vector.

Data Types: `double`

z — z-coordinates of points

column vector

z-coordinates of points, specified as a column vector.

Data Types: `double`

P — Point coordinates

matrix with two columns | matrix with three columns

Point coordinates, specified as a matrix with two columns (for a 2-D alpha shape) or a matrix with three columns (for a 3-D alpha shape).

- For 2-D, the columns of `P` represent `x` and `y` coordinates, respectively.
- For 3-D, the columns of `P` represent `x`, `y`, and `z` coordinates, respectively.

Data Types: `double`

s — Shrink factor

`0.5` (default) | scalar in range `[0,1]`

Shrink factor, specified as a scalar in the range of `[0,1]`.

- `s = 0` corresponds to the convex hull of the points.

- `s = 1` corresponds to the tightest single-region boundary around the points.

The default shrink factor is `0.5`. Specify a larger or smaller shrink factor to tighten or loosen the boundary around the points, respectively.

Example: `k = boundary(x,y,0.76)` specifies a shrink factor of `0.76`, producing a tighter boundary than the default.

Output Arguments

k — Boundary point indices

vector | matrix

Boundary point indices, returned as a vector or matrix. `k` contains the indices of the input points that lie on the boundary.

- For 2-D problems, `k` is a column vector of point indices representing the sequence of points around the boundary, which is a polygon.
- For 3-D problems, `k` is a triangulation matrix of size `mtri`-by-`3`, where `mtri` is the number of triangular facets on the boundary. Each row of `k` defines a triangle in terms of the point indices, and the triangles collectively form a bounding polyhedron.

v — Area or volume enclosed by boundary

scalar

Area or volume enclosed by boundary, returned as a scalar.

- For 2-D problems, `v` is the area enclosed by boundary `k`.
- For 3-D problems, `v` is the volume enclosed by boundary `k`.

`alphaShape` | `convhull` | `delaunayTriangulation` | `triangulation` | `trisurf`

Introduced in R2014b

box

Axes border

Syntax

```
box on
box off
box
box(axes_handle,...)
```

Description

`box on` displays the boundary of the current axes.

`box off` does not display the boundary of the current axes.

`box` toggles the visible state of the current axes boundary.

`box(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

More About

Algorithms

The `box` function sets the axes `Box` property to `on` or `off`.

See Also

`axes` | `grid`

Introduced before R2006a

break

Terminate execution of for or while loop

Syntax

```
break
```

Description

`break` terminates the execution of a `for` or `while` loop. Statements in the loop after the `break` statement do not execute.

In nested loops, `break` exits only from the loop in which it occurs. Control passes to the statement that follows the `end` of that loop.

Examples

Exit Loop Before Expression Is False

Sum a sequence of random numbers until the next random number is greater than an upper limit. Then, exit the loop using a `break` statement.

```
limit = 0.8;
s = 0;

while 1
    tmp = rand;
    if tmp > limit
        break
    end
    s = s + tmp;
```

```
end
```

More About

Tips

- The `break` statement exits a `for` or `while` loop completely. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- `break` is not defined outside a `for` or `while` loop. To exit a function, use `return`.

See Also

`continue` | `end` | `for` | `return` | `while`

Introduced before R2006a

brighten

Brighten or darken colormap

Syntax

```
brighten(beta)
brighten(h,beta)
newmap = brighten(beta)
newmap = brighten(cmap,beta)
```

Description

`brighten(beta)` increases or decreases the color intensities in a colormap by replacing the current colormap with a brighter or darker colormap of essentially the same colors. The modified colormap is brighter if `0 < beta < 1` and darker if `-1 < beta < 0`. `brighten(beta)`, followed by `brighten(-beta)`, where `beta < 1`, restores the original map.

`brighten(h,beta)` brightens all objects that are children of the figure having the handle `h`.

`newmap = brighten(beta)` returns a brighter or darker version of the current colormap without changing the display.

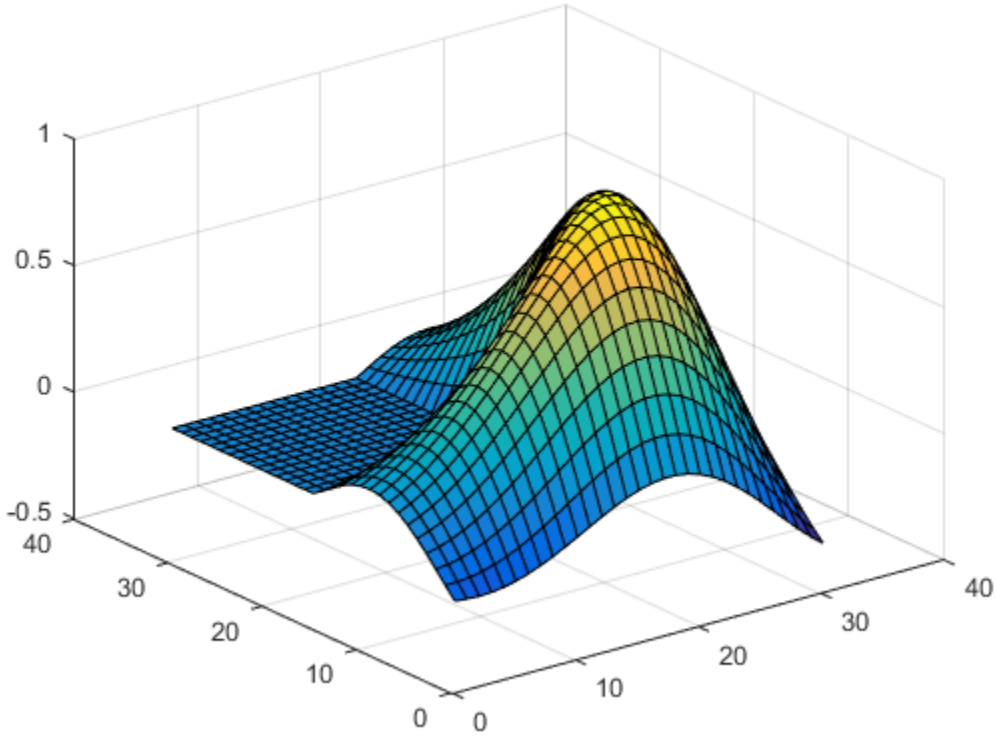
`newmap = brighten(cmap,beta)` returns a brighter or darker version of the colormap `cmap` without changing the display.

Examples

Brighten Colormap

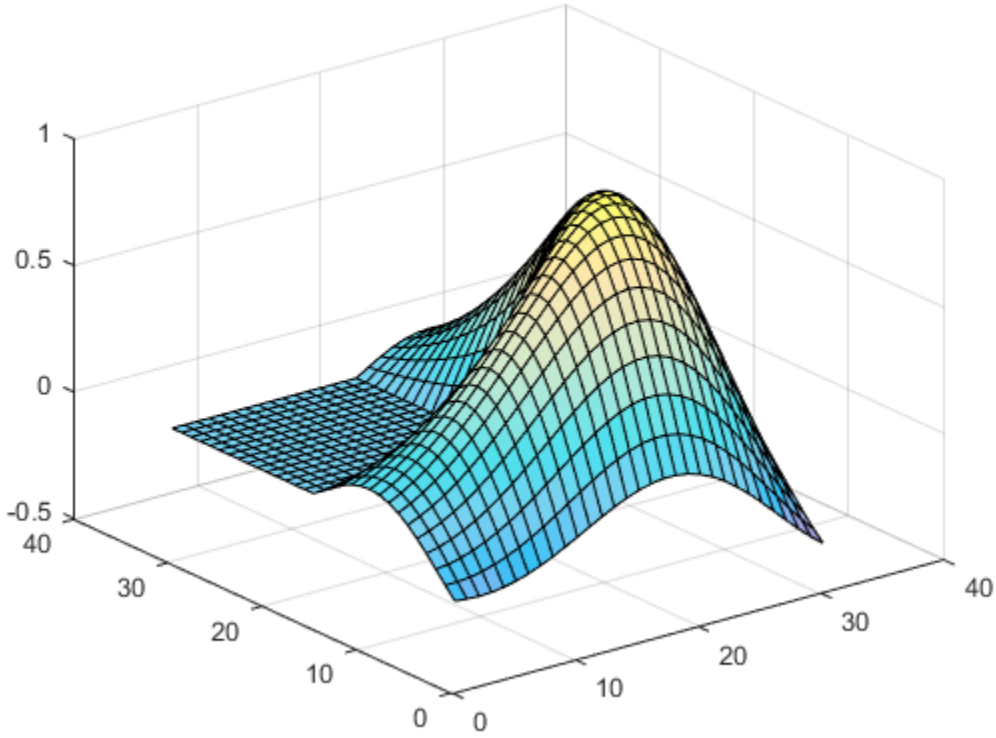
Display a surface plot of `membrane`.

```
surf(membrane)
```



Brighten the colormap.

```
beta = .7;
brighten(beta)
```



More About

Algorithms

`brighten` raises values in the colormap to the power of gamma, where gamma is

$$\gamma = \begin{cases} 1-\beta, & \beta > 0 \\ \dfrac{1}{1+\beta}, & \beta \le 0 \end{cases}$$

`brighten` has no effect on graphics objects defined with true color.

- “Altering Colormaps”

See Also

`colormap` | `rgbplot`

Introduced before R2006a

brush

Interactively mark, delete, modify, and save observations in graphs

Syntax

```
brush on
brush off
brush
brush color
brush(figure_handle,...)
brushobj = brush(figure_handle)
```

Description

Data brushing is a mode for interacting with graphs in figure windows in which you can click data points or drag a selection rectangle around data points to highlight observations in a color of your choice. Highlighting takes different forms for different types of graphs, and brushing marks persist—even in other interactive modes—until removed by deselecting them.

`brush on` turns on interactive data brushing mode.

`brush off` turns brushing mode off, leaving any brushed observations still highlighted.

`brush` by itself toggles the state of the data brushing tool.

`brush color` sets the current color used for brushing graphics to the specified `ColorSpec`. Changing brush color affects subsequent brushing, but does not change the color of observations already brushed or the brush tool's state.

`brush(figure_handle,...)` applies the function to the specified figure handle.

`brushobj = brush(figure_handle)` returns a *brush mode object* for that figure, useful for controlling and customizing the figure's brushing state. The following properties of such objects can be modified using `get` and `set`:

`Enable 'on' | {'off'}`	Specifies whether this figure mode is currently enabled on the figure.
`FigureHandle`	The associated figure handle. This property supports `get` only.
`Color`	Specifies the color to be used for brushing.

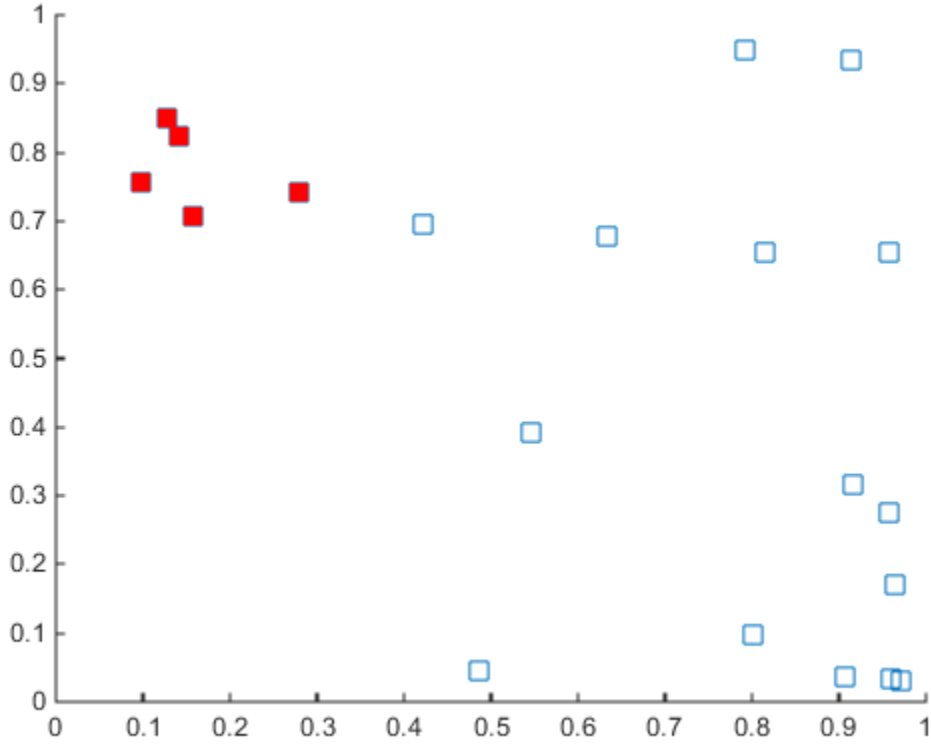
`brush` cannot return a brush mode object at the same time you are calling it to set a brushing option.

Examples

Example 1

On a scatter plot, drag out a rectangle to brush the graph:

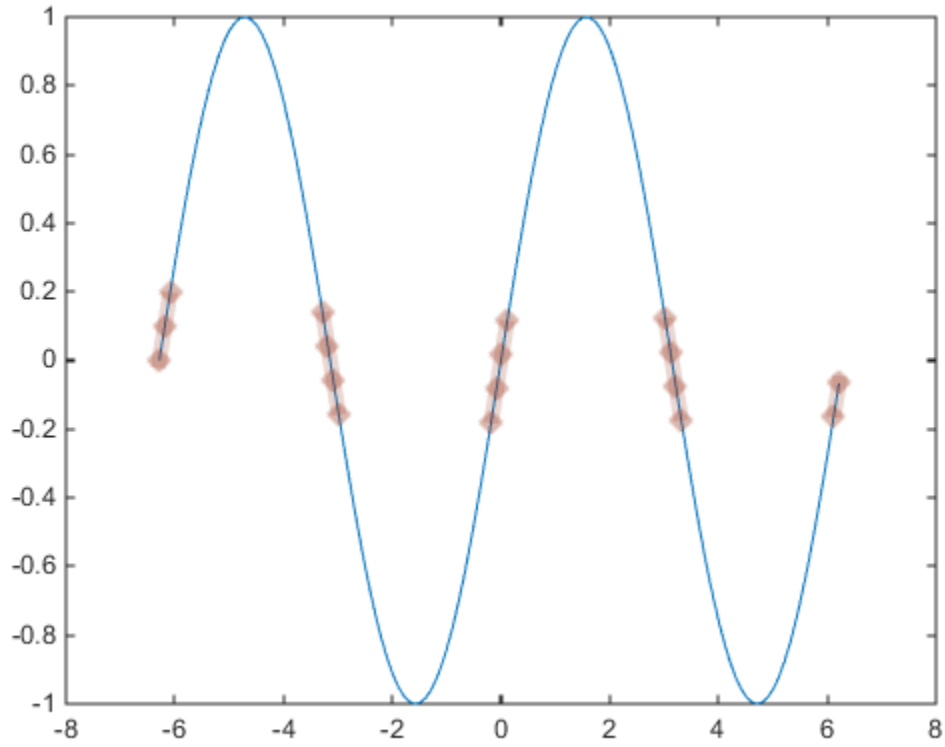
```
x = rand(20,1);
y = rand(20,1);
scatter(x,y,80,'s')
brush on
```



Example 2

Brush observations from -.2 to .2 on a line plot in dark red:

```
x = [-2*pi:.1:2*pi];
y = sin(x);
plot(x,y);
h = brush;
set(h,'Color',[.6 .2 .1],'Enable','on');
```



More About

Tips

Types of Plots You Can Brush

Data brushing places lines and patches on plots to create highlighting, marking different types of graphs as follows (brushing marks are shown in red):

Graph Type	Brushing Annotation	Overlays?	Example
line	Colored lines slightly wider than those in the line with a marker distinct from those on the line (filled circles if none) to identify brushed vertices. Only those line segments that connect brushed vertices are highlighted	Y	scatter	Line with `LineStyle 'none'` and a marker with a color distinct from and slightly larger than the base scatter marker.	Y	stem	The brushed stems and stem heads are shaded in the brushing color.	Y	bar	The interior of selected bars is filled in the brushing color.	N	
Graph Type	Brushing Annotation	Overlays?	Example
area	Patches filling the region between selected points and the *x*-axis in the brushing color.	N	
surface	Faces with edges slightly wider than the surface line width and with a marker distinct from that of the surface (**X** if none) to identify brushed vertices. Faces are plotted only when all four vertices that define them are brushed. The brushed observations are the set of marked vertices, not the faces.	N	
When using the linked plots feature, a graph can become brushed when you brush another graph that displays some of the same data, potentially brushing the same observations more than once. The overlaid brushing marks (whether lines or markers) are slightly wider than the brushing marks that they overlay; this makes multiply brushed observations visually distinct. The wider brushing marks are placed under the narrower ones, so that if they happen to have different colors, you can see all the colors. See the subsection "How Data Linking Affects Data Brushing" on page 1-791 for more information about brushing linked figures.

As the above table indicates, only line, scatter, and stem brushing marks can be overlaid in this manner. Although you can brush them, you cannot overlay brushing marks on area, bar, or surface.

Plot Types You Cannot Brush

Currently, not all plot types enable data brushing. Graph functions that *do not* support brushing are:

- Line plots created with `line`
- Scatter plots created with `spy`
- Contour plots created with `contour`, `contourf`, or `contour3`

- Pie charts created with `pie` or `pie3`
- Radial graphs created with `polar`, `compass`, or `rose`
- Direction graphs created with `feather`, `quiver`, or `comet`
- Area and image plots created with `fill`, `image`, `imagesc`, or `pcolor`
- Bar graphs created with `pareto` or `errorbar`
- Functional plots created with `ezcontour` or `ezcontourf`
- 3-D plot types *other than* `plot3`, `stem3`, `scatter3`, `mesh`, `meshc`, `surf`, `surfl`, and `surfc`

You can use some of these functions to display base data that do not need to be brushable. For example, use `line` to plot mean *y*-values as horizontal lines that you do not need or want to brush.

Mode Exclusivity and Persistence

Data brushing mode is *exclusive*, like zoom, pan, data cursor, or plot edit mode. However, brush marks created in data brushing mode *persist* through all changes in mode. Brush marks that appear in other graphs while they are linked via `linkdata` also persist even when data linking is subsequently turned off. That is, severing connections to a graph's data sources does not remove brushing marks from it. The only ways to remove brushing marks are (in brushing mode):

- Brush an empty area in a brushed graph.
- Right-click and select **Clear all brushing** from the context menu.

Changing the brushing color for a figure does not recolor existing brush marks. If you change the brushing color and hold down the **Shift** key when brushing new data, all existing brush marks change to the new color. All brush marks that appear on linked plots in the same or different figure also change to the new color if the brushing action affects them. The behavior is the same whether you select a brushing color from the Brush Tool dropdown palette, set it by calling `brush(colorspec)`, or by setting the `Color` property of a brush mode object (e.g., `set(brushobj,'Color',colorspec)`).

How Data Linking Affects Data Brushing

When you use the Data Linking tool or call the `linkdata` function, brushing marks that you make on one plot appear on other plots that depict the same variable you are

brushing—if those plots are also linked. This happens even if the affected plot is not in Brushing mode. That is, brushing marks appear on a linked plot *in any mode* when you brush another plot linked to it via a common variable or brush that variable in the Variables editor. Be aware that the following conditions apply, however:

- The graph type must support data brushing (see "Types of Plots You Can Brush" on page 1-789 and "Plot Types You Cannot Brush" on page 1-790)
- The graphed variable must not be complex; if you can plot a complex variable you can brush it, but such graphs do not respond when you brush the complex variable in another linked plot. For more information about linking complex variables, see Example 3 in the `linkdata` reference page.
- Observations that you brush display in the same color in all linked graphs. The color is the brush color you have selected in the window you are interacting with, and can differ from the brushing colors selected in the other affected figures. When you brush linked plots, the brushing color is associated with the variable(s) you brush

The last bullet implies that brush marks on an unlinked graph can change color when data linking is turned on for that figure. Brushing marks can, in fact, vanish and be replaced by marks in the same or different color when the plot enters a linked state. In the linked state, brushing is tied to variables (data sources), not just the graphics. If different observations for the same variable on a linked figure are brushed, those variables override the brushed graphics on the newly linked plot. In other words, the newly linked graph loses all its previous brush marks when it "joins the club" of common data sources.

Mouse Gestures for Data Brushing

You can brush graphs in several ways. The basic operation is to drag the mouse to highlight all observations within the rectangle you define. The following table lists data brushing gestures and their effects.

Action	Gesture	Result
Select data using a Region Of Interest	ROI mouse drag	Region of interest (ROI) rectangle (or rectangular prism for 3-D axes) appears during the gesture and all brushable observations within the rectangle are highlighted. All other brushing marks in the axes are removed. The ROI rectangle disappears when the mouse button is released.

Action	Gesture	Result
Select a single point	Single left-click on a graphic object that supports data brushing	Produces an equivalent result to ROI rectangle, brushing where the rectangle encloses only the single vertex on the graphical object closest to the mouse. All other brushing annotations in the figure are removed.
Add a point to the selection or remove a highlighted one	Single left-click on a graphic object that supports data brushing, with the **Shift** key down	Equivalent brushing by dragging an ROI rectangle that encloses only the single vertex on the graphic object closest to the mouse. All other brushed regions in the figure remain brushed.
Select all data associated with a graphic object	Double left-click on a graphic object that supports data brushing	All vertices for the graphic object are brushed.
Add to or subtract from region of interest	Click or ROI drag with the **Shift** or **Ctrl** keys down	Region of interest grows; all unbrushed vertices within the rectangle become brushed and all brushed observations in it become unbrushed. All brushed vertices outside the ROI remain brushed.
Copy brushed data to Editor, Command Window, Variables editor, or Workspace Browser	Drag brushed data to another window or to a program/ icon on the system desktop	Equivalent to copying brushed data and pasting into other window or an existing/new variable.

Brush Mode Callbacks

You can program the following callbacks for brush mode operations.

- `ActionPreCallback <function_handle>` — Function to execute before brushing

  Use this callback to execute code when a brush operation begins. The function handle should reference a function with two implicit arguments:

  ```
  function myfunction(src,event_data)
  ```

```
% src         handle to the figure that has been clicked
% event_data   object containing event data
end
```

The event data has the following property:

`Axes`	The handle of the axes that is being brushed

- `ActionPostCallback <function_handle>` — Function to execute after brushing

  Use this callback to execute code when a brush operation ends. The function handle should reference a function with two implicit arguments:

```
function myfunction(src,event_data)
% src         handle to the figure that has been clicked
% event_data   object containing event data
%        (same as the event data of the
%             'ActionPreCallback' callback)
end
```

bsxfun

Apply element-by-element binary operation to two arrays with singleton expansion enabled

Syntax

```
C = bsxfun(fun,A,B)
```

Description

`C = bsxfun(fun,A,B)` applies the element-by-element binary operation specified by the function handle `fun` to arrays `A` and `B`, with singleton expansion enabled. `fun` can be one of the following built-in functions:

`@plus`	Plus
`@minus`	Minus
`@times`	Array multiply
`@rdivide`	Right array divide
`@ldivide`	Left array divide
`@power`	Array power
`@max`	Binary maximum
`@min`	Binary minimum
`@rem`	Remainder after division
`@mod`	Modulus after division
`@atan2`	Four-quadrant inverse tangent; result in radians
`@atan2d`	Four-quadrant inverse tangent; result in degrees
`@hypot`	Square root of sum of squares
`@eq`	Equal

`@ne`	Not equal
`@lt`	Less than
`@le`	Less than or equal to
`@gt`	Greater than
`@ge`	Greater than or equal to
`@and`	Element-wise logical AND
`@or`	Element-wise logical OR
`@xor`	Logical exclusive OR

`fun` can also be a handle to any binary element-wise function not listed above. A binary element-wise function of the form `C = fun(A,B)` accepts arrays `A` and `B` of arbitrary, but equal size and returns output of the same size. Each element in the output array `C` is the result of an operation on the corresponding elements of `A` and `B` only. `fun` must also support scalar expansion, such that if `A` or `B` is a scalar, `C` is the result of applying the scalar to every element in the other input array.

The corresponding dimensions of `A` and `B` must be equal to each other or equal to one. Whenever a dimension of `A` or `B` is singleton (equal to one), `bsxfun` virtually replicates the array along that dimension to match the other array. In the case where a dimension of `A` or `B` is singleton, and the corresponding dimension in the other array is zero, `bsxfun` virtually diminishes the singleton dimension to zero.

The size of the output array `C` is equal to:
`max(size(A),size(B)).*(size(A)>0 & size(B)>0)`.

Examples

Deviations from Mean

Use `bsxfun` to subtract the column mean from the corresponding column elements of a matrix, `A`.

```
A = [1 2 10; 1 4 20;1 6 15] ;
C = bsxfun(@minus, A, mean(A))
```

```
C =

     0    -2    -5
```

```
     0     0     5
     0     2     0
```

Singleton Expansion with Custom Function

Call a custom-defined binary function with `bsxfun` by specifying a handle to the function.

```
fun = @(A,B) A.*sin(B);
A = 1:7;
B = pi*[0 1/4 1/3 1/2 2/3 3/4 1].';
C = bsxfun(fun,A,B)
```

```
C =

         0         0         0         0         0         0         0
    0.7071    1.4142    2.1213    2.8284    3.5355    4.2426    4.9497
    0.8660    1.7321    2.5981    3.4641    4.3301    5.1962    6.0622
    1.0000    2.0000    3.0000    4.0000    5.0000    6.0000    7.0000
    0.8660    1.7321    2.5981    3.4641    4.3301    5.1962    6.0622
    0.7071    1.4142    2.1213    2.8284    3.5355    4.2426    4.9497
    0.0000    0.0000    0.0000    0.0000    0.0000    0.0000    0.0000
```

Singleton expansion allows `bsxfun` to expand the input vectors into a full matrix.

`repmat` | `arrayfun`

builddocsearchdb

Build searchable documentation database

Syntax

```
builddocsearchdb(folder)
```

Description

`builddocsearchdb(folder)` builds a searchable database, also referred to as a search index, from HTML files in the specified folder.

The `builddocsearchdb` function creates a subfolder, `helpsearch-v3`, to contain the database files. The database enables MATLAB to search for content within the HTML files assuming the MATLAB version is the same version used to create the database.

Beginning with MATLAB R2014b, you can maintain search indexes side by side. For instance, if you already have a search index for MATLAB R2014a or earlier, run `builddocsearchdb` against your help files using MATLAB R2014b or later. Then, when you run any MATLAB release, the help browser automatically uses the appropriate index for searching your documentation database.

Examples

Search Custom Help Files

Build a search database for custom help files.

MATLAB includes a set of sample files to demonstrate how to create a custom toolbox and supporting documentation. This sample toolbox is called the *Upslope Area Toolbox*. The `upslope` folder includes a file named `info.xml`, which is required to display custom documentation, and a subfolder named `html`, which contains HTML documentation and supporting files.

Copy the sample files to a temporary folder, and add the copied files to the path.

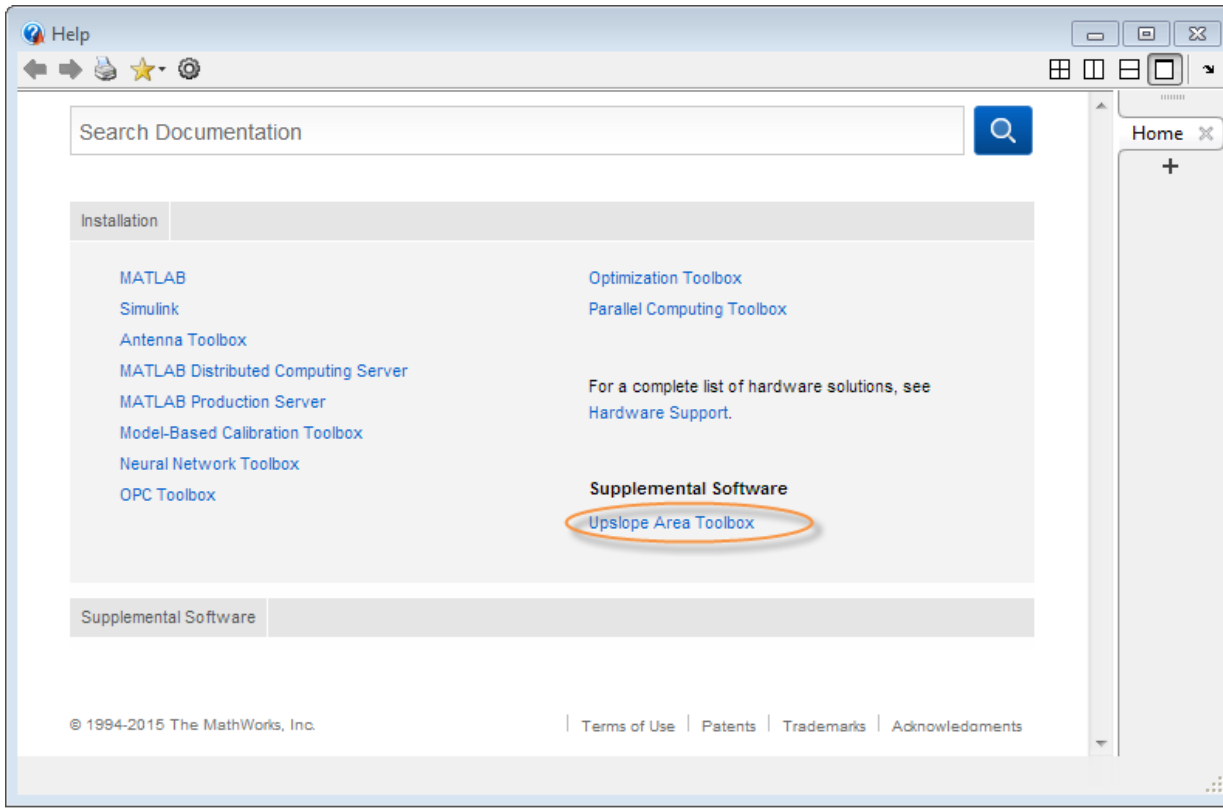
```
sample = fullfile(...
         matlabroot,'help','techdoc','matlab_env',...
```

```
        'examples','upslope');
tmp = tempname;
mkdir(tmp);
copyfile(sample,tmp);
addpath(tmp);
```

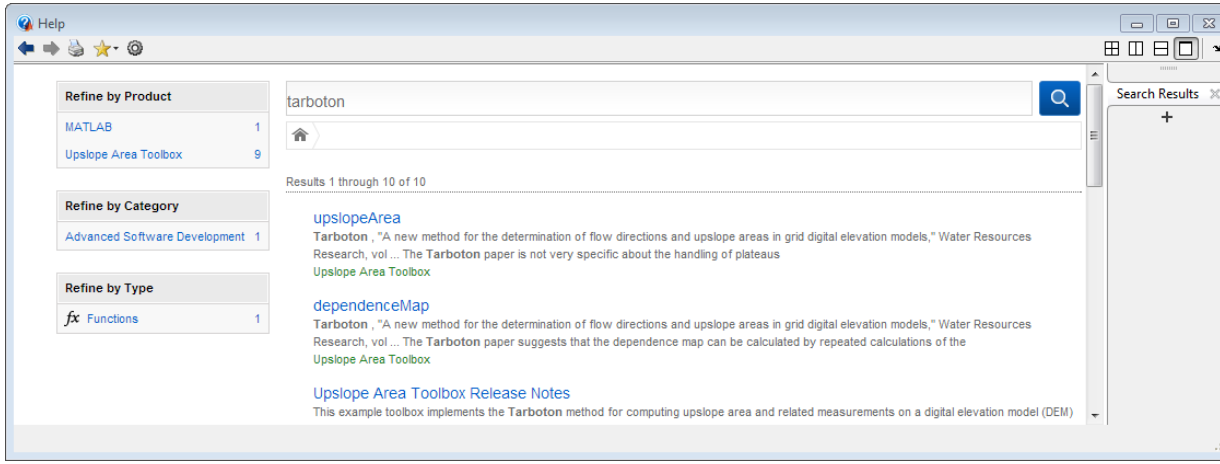
Create a search database.

```
folder = fullfile(tmp,'html');
builddocsearchdb(folder)
```

Under the Supplemental Software heading, click **Upslope Area Toolbox**.



Search the supplemental documentation for the term *tarboton*, which appears in several of the example help files. The search returns several results from the Upslope Area Toolbox.



Remove the temporary example files.

```
rmpath(tmp)
rmdir(tmp,'s')
```

Note: Your help appears alongside the MathWorks documentation only when you are viewing installed documentation. If you are viewing documentation on the web, your documentation displays in a help browser separate from the MathWorks documentation.

Input Arguments

`folder` — Full path to folder with HTML files

string

Full path to a folder with HTML files, specified as a string. The folder must be:

- On the MATLAB search path
- Outside the *`matlabroot`* folder
- Outside any installed Hardware Support Package help folder

To include a particular HTML document in the search database, the `builddocsearchdb` function requires that:

- The document has a title.

- The content is different from the title.

Example: `builddocsearchdb('c:\myfiles\html')`

`doc` | `help`

builtin

Execute built-in function from overloaded method

Syntax

```
builtin(function,x1,...,xn)
[y1,...,yn] = builtin(function,x1,...,xn)
```

Description

`builtin(function,x1,...,xn)` executes the built-in `function` with the input arguments `x1` through `xn`. Use `builtin` to execute the original built-in from within a method that overloads the function. To work properly, you must never overload `builtin`.

`[y1,...,yn] = builtin(function,x1,...,xn)` stores any output from `function` in `y1` through `yn`.

Examples

Run an Overloaded Function within a Class Definition

Execute the built-in functionality from within an overloaded method.

Create a simple class describing the speed of a particle and providing a `disp` method by pasting the following code into a file called `MyParticle.m`.

```
classdef MyParticle
    properties
        velocity;
    end
    methods
        function p = MyParticle(x,y,z)
            p.velocity.x = x;
            p.velocity.y = y;
            p.velocity.z = z;
        end
```

```
        function disp(p)
            builtin('disp',p) %call builtin
            if isscalar(p)
                disp('  Velocity')
                disp(['  x: ',num2str(p.velocity.x)])
                disp(['  y: ',num2str(p.velocity.y)])
                disp(['  z: ',num2str(p.velocity.z)])
            end
        end
    end
end
```

Create an instance `MyParticle`.

```
p = MyParticle(1,2,4)
```

```
p =

  MyParticle

  Properties:
    velocity: [1x1 struct]

  Methods

  Velocity
  x: 1
  y: 2
  z: 4
```

Input Arguments

`function` — Built-in function name

string

Valid built-in function name in the MATLAB path, specified as a string. `function` cannot be a function handle.

`x1,...,xn` — Valid input arguments for `function`

supported data types

Valid input arguments for `function`, specified by supported data types.

More About

built-in function

A built-in function is part of the MATLAB executable. MATLAB does not implement these functions in the MATLAB language. Although most built-in functions have a `.m` file associated with them, this file only supplies documentation for the function.

You can use the syntax `which` *`function`* to check whether a function is built-in.

`feval` | `which`

Introduced before R2006a

bvp4c

Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp4c(odefun,bcfun,solinit)
sol = bvp4c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

`odefun`	A function handle that evaluates the differential equations $f(x,y)$. It can have the form
	`dydx = odefun(x,y)`
	`dydx = odefun(x,y,parameters)`
	For a scalar `x` and a column vector `y`, `odefun(x,y)` must return a column vector, `dydx`, representing $f(x,y)$. `parameters` is a vector of unknown parameters.

`bcfun`	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a),y(b))$, `bcfun` can have the form
	`res = bcfun(ya,yb)`
	`res = bcfun(ya,yb,parameters)`
	where `ya` and `yb` are column vectors corresponding to $y(a)$ and $y(b)$. `parameters` is a vector of unknown parameters. The output `res` is a column vector.
	See "Multipoint Boundary Value Problems" on page 1-808 for a description of `bcfun` for multipoint boundary value problems.

`solinit`	A structure containing the initial guess for a solution. You create `solinit` using the function `bvpinit`. `solinit` has the following fields.

	`x`	Ordered nodes of the initial mesh. Boundary conditions are imposed at a = `solinit.x(1)` and b = `solinit.x(end)`.
	`y`	Initial guess for the solution such that `solinit.y(:,i)` is a guess for the solution at the node `solinit.x(i)`.
	`parameters`	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named `x`, `y`, and `parameters`. You can form `solinit` with the helper function `bvpinit`. See `bvpinit` for details.	
`options`	Optional integration argument. A structure you create using the `bvpset` function. See `bvpset` for details.	

Description

`sol = bvp4c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$y' = f(x,y)$

on the interval [a,b] subject to two-point boundary value conditions $bc(y(a),y(b)) = 0$.

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

"Parameterizing Functions" explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary.

`bvp4c` can also solve multipoint boundary value problems. See "Multipoint Boundary Value Problems" on page 1-808. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`. See the reference page for `bvpinit` for more information.

The `bvp4c` solver can also find unknown parameters p for problems of the form

$y' = f(x,y,p)$

$0 = bc(y(a),y(b),p)$

where p corresponds to `parameters`. You provide `bvp4c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp4c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp4c` produces a solution that is continuous on `[a,b]` and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp4c` to evaluate the solution at specific points `xint` in the interval `[a,b]`.

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp4c` has the following fields:

`sol.x`	Mesh selected by `bvp4c`
`sol.y`	Approximation to $y(x)$ at the mesh points of `sol.x`
`sol.yp`	Approximation to $y'(x)$ at the mesh points of `sol.x`
`sol.parameters`	Values returned by `bvp4c` for the unknown parameters, if any
`sol.solver`	`'bvp4c'`
`sol.stats`	Computational cost statistics (also displayed when the `stats` option is set with `bvpset`).

The structure `sol` can have any name, and `bvp4c` creates the fields `x`, `y`, `yp`, `parameters`, and `solver`.

`sol = bvp4c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Singular Boundary Value Problems

`bvp4c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form

$y' = S \cdot y/x + F(x,y,p)$
$0 = bc(y(0),y(b),p)$

The interval is required to be [0, b] with $b > 0$. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the `'SingularTerm'` option of `bvpset`, and `odefun` evaluates only $f(x,y,p)$. The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Multipoint Boundary Value Problems

`bvp4c` can solve multipoint boundary value problems where $a = a_0 < a_1 < a_2 < ... < a_n = b$ are boundary points in the interval $[a,b]$. The points $a_1,a_2,...,a_{n-1}$ represent interfaces that divide $[a,b]$ into regions. `bvp4c` enumerates the regions from left to right (from a to b), with indices starting from 1. In region k, $[a_{k-1},a_k]$, `bvp4c` evaluates the derivative as

```
yp = odefun(x,y,k)
```

In the boundary conditions function

```
bcfun(yleft,yright)
```

`yleft(:,k)` is the solution at the left boundary of $[a_{k-1},a_k]$. Similarly, `yright(:,k)` is the solution at the right boundary of region k. In particular,

```
yleft(:,1) = y(a)
```

and

```
yright(:,end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit,yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x,k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bpv4c`, `sol.x` has

double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

Note: The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If $S(x)$ approximates the solution $y(x)$, `bvp4c` controls the residual $|S'(x) - f(x,S(x))|$. This controls indirectly the true error $|y(x) - S(x)|$. `bvp5c` controls the true error directly. `bvp5c` is more efficient than `bvp4c` for small error tolerances.

Examples

Using Initial Guess to Indicate Desired Solution

Boundary value problems can have multiple solutions. One purpose of the initial guess is to indicate which solution, among several, that you want.

The second-order differential equation

$$y'' + |y| = 0$$

has exactly two solutions that satisfy the boundary conditions

$$y(0) = 0,$$

$$y(4) = -2.$$

Before using `bvp4c` to solve the problem, you need to rewrite the differential equation as a system of two first-order ODEs,

$$y_1' = y_2,$$

$$y_2' = -|y_1|,$$

where $y_1 = y$ and $y_2 = y'$. This system has the required form

$$y' = f(x, y),$$

$$bc(y(a), y(b)) = 0.$$

The function, *f*, and the boundary conditions, *bc*, are coded in MATLAB as the functions `twoode` and `twobc`.

```
function dydx = twoode(x,y)
dydx = [ y(2); -abs(y(1)) ];

function res = twobc(ya,yb)
res = [ ya(1); yb(1) + 2 ];
```

Form a guess structure consisting of an initial mesh of five equally spaced points in [0,4] and a guess of the constant values

$$y_1(x) = 1,$$

$$y_2(x) = 0.$$

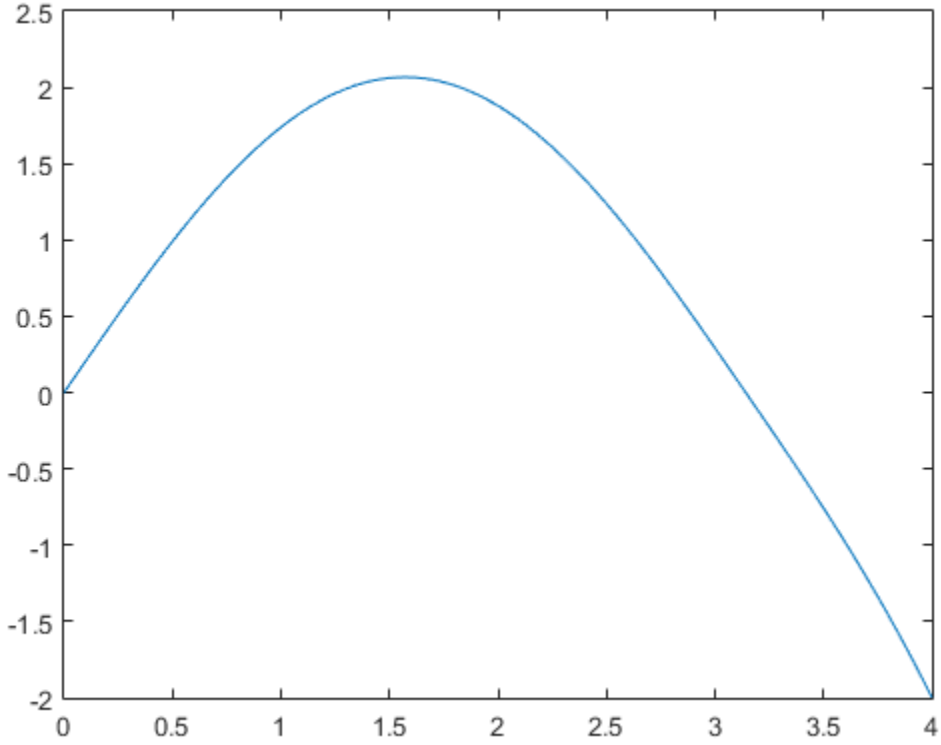
```
solinit = bvpinit(linspace(0,4,5),[1 0]);
```

Solve the problem using `bvp4c`.

```
sol = bvp4c(@twoode,@twobc,solinit);
```

Evaluate the numerical solution at 100 equally spaced points and plot *y(x)*.

```
x = linspace(0,4);
y = deval(sol,x);
plot(x,y(1,:))
```

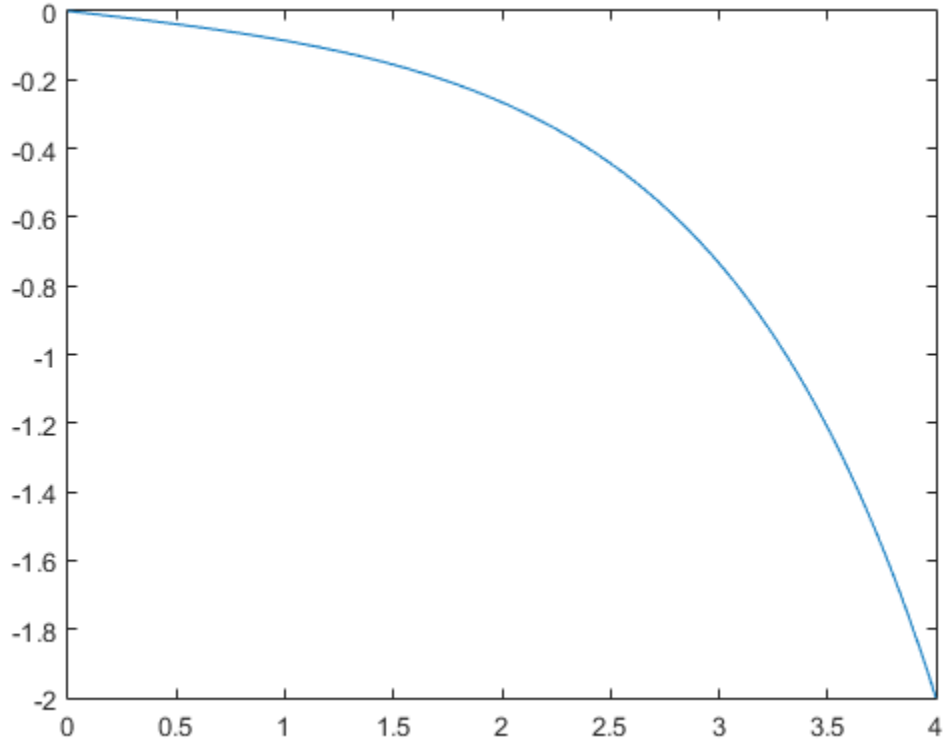


To obtain the other solution of this problem, use the initial guess

$$y_1(x) = -1,$$

$$y_2(x) = 0.$$

```
solinit = bvpinit(linspace(0,4,5),[-1 0]);
sol = bvp4c(@twoode,@twobc,solinit);
x = linspace(0,4);
y = deval(sol,x);
plot(x,y(1,:))
```



Compute Fourth Eigenvalue of Mathieu's Equation

This boundary value problem involves an unknown parameter. The task is to compute the fourth ($q = 5$) eigenvalue λ of Mathieu's equation

$$y'' + (\lambda - 2q\cos 2x)y = 0.$$

Because the unknown parameter λ is present, this second-order differential equation is subject to *three* boundary conditions:

$y'(0) = 0$
$y'(\pi) = 0$
$y(0) = 1$

It is convenient to use local functions to place all the functions required by `bvp4c` in a single file.

```
function mat4bvp

lambda = 15;
solinit = bvpinit(linspace(0,pi,10),@mat4init,lambda);
sol = bvp4c(@mat4ode,@mat4bc,solinit);

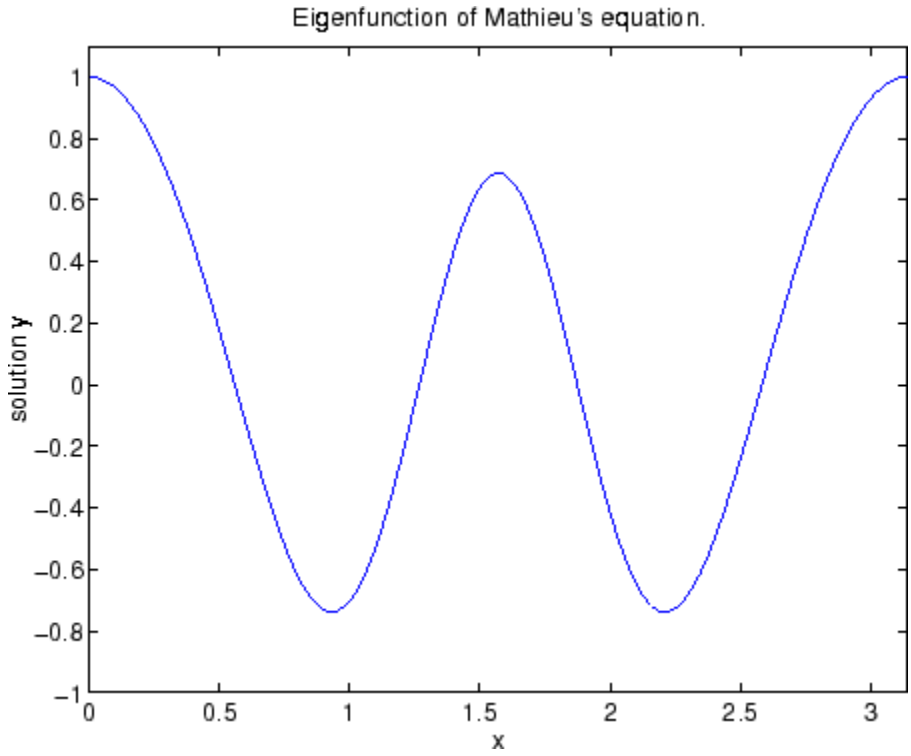
fprintf('The fourth eigenvalue is approximately %7.3f.\n',...
        sol.parameters)

xint = linspace(0,pi);
Sxint = deval(sol,xint);
plot(xint,Sxint(1,:))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xlabel('x')
ylabel('solution y')
% --------------------------------------------------------------
function dydx = mat4ode(x,y,lambda)
q = 5;
dydx = [  y(2)
         -(lambda - 2*q*cos(2*x))*y(1) ];
% --------------------------------------------------------------
function res = mat4bc(ya,yb,lambda)
res = [  ya(2)
         yb(2)
        ya(1)-1 ];
% --------------------------------------------------------------
function yinit = mat4init(x)
yinit = [  cos(4*x)
          -4*sin(4*x) ];
```

The differential equation (converted to a first-order system) and the boundary conditions are coded as local functions `mat4ode` and `mat4bc`, respectively. Because unknown parameters are present, these functions must accept three input arguments, even though some of the arguments are not used.

The guess structure `solinit` is formed with `bvpinit`. An initial guess for the solution is supplied in the form of a function `mat4init`. We chose $y = \cos 4x$ because it satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes). In the call to `bvpinit`, the third argument (`lambda = 15`) provides an initial guess for the unknown parameter λ.

After the problem is solved with `bvp4c`, the field `sol.parameters` returns the value $\lambda = 17.097$, and the plot shows the eigenfunction associated with this eigenvalue.



More About

Algorithms

`bvp4c` is a finite difference code that implements the three-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1-continuous solution that is fourth-order accurate uniformly in `[a,b]`. Mesh selection and error control are based on the residual of the continuous solution.

Introduced before R2006a

bvp5c

Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp5c(odefun,bcfun,solinit)
sol = bvp5c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

`odefun`	A function handle that evaluates the differential equations $f(x,y)$. It can have the form
	`dydx = odefun(x,y)`
	`dydx = odefun(x,y,parameters)`
	For a scalar `x` and a column vector `y`, `odefun(x,y)` must return a column vector, `dydx`, representing $f(x,y)$. `parameters` is a vector of unknown parameters.	

`bcfun`	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a),y(b))$, `bcfun` can have the form
	`res = bcfun(ya,yb)`
	`res = bcfun(ya,yb,parameters)`
	where `ya` and `yb` are column vectors corresponding to $y(a)$ and $y(b)$. `parameters` is a vector of unknown parameters. The output `res` is a column vector.	

`solinit`	A structure containing the initial guess for a solution. You create `solinit` using the function `bvpinit`. `solinit` has the following fields.	
	`x`	Ordered nodes of the initial mesh. Boundary conditions are imposed at a = `solinit.x(1)` and b = `solinit.x(end)`.

	`y`	Initial guess for the solution such that `solinit.y(:,i)` is a guess for the solution at the node `solinit.x(i)`.
	`parameters`	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named `x`, `y`, and `parameters`. You can form `solinit` with the helper function `bvpinit`. See `bvpinit` for details.	
`options`	Optional integration argument. A structure you create using the `bvpset` function. See `bvpset` for details.	

Description

`sol = bvp5c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form
$y' = f(x,y)$

on the interval [a,b] subject to two-point boundary value conditions
$bc(y(a),y(b)) = 0$

`odefun` and `bcfun` are function handles. See the `function_handle` reference page for more information.

"Parameterizing Functions" explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`.

The `bvp5c` solver can also find unknown parameters p for problems of the form
$y' = f(x,y,p)$
$0 = bc(y(a),y(b),p)$

where p corresponds to `parameters`. You provide `bvp5c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp5c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp5c` produces a solution that is continuous on `[a,b]` and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp5c` to evaluate the solution at specific points `xint` in the interval `[a,b]`.

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp5c` has the following fields:

`sol.x`	Mesh selected by `bvp5c`
`sol.y`	Approximation to $y(x)$ at the mesh points of `sol.x`
`sol.parameters`	Values returned by `bvp5c` for the unknown parameters, if any
`sol.solver`	`'bvp5c'`
`sol.stats`	Computational cost statistics (also displayed when the `stats` option is set with `bvpset`).

The structure `sol` can have any name, and `bvp5c` creates the fields `x`, `y`, `parameters`, and `solver`.

`sol = bvp5c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Singular Boundary Value Problems

`bvp5c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form
$y' = S \cdot y/x + f(x,y,p)$
$0 = bc(y(0),y(b),p)$

The interval is required to be $[0, b]$ with b > 0. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the `'SingularTerm'` option of `bvpset`, and `odefun` evaluates only $f(x,y,p)$. The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Multipoint Boundary Value Problems

`bvp5c` can solve multipoint boundary value problems where $a = a_0 < a_1 < a_2 < ... < a_n = b$ are boundary points in the interval $[a,b]$. The points $a_1,a_2, ... ,a_{n-1}$ represent interfaces

that divide [a,b] into regions. `bvp5c` enumerates the regions from left to right (from a to b), with indices starting from 1. In region k, [a_{k-1},a_k], `bvp5c` evaluates the derivative as

```
yp = odefun(x,y,k)
```

In the boundary conditions function

```
bcfun(yleft,yright)
```

yleft(:, k) is the solution at the left boundary of [a_{k-1},a_k]. Similarly, `yright(:,k)` is the solution at the right boundary of region k. In particular,

```
yleft(:,1) = y(a)
```

and

```
yright(:,end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit,yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x, k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bvp5c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

To see an example of that solves a three-point boundary value problem, type `threebvp` at the MATLAB command prompt.

More About

Algorithms

`bvp5c` is a finite difference code that implements the four-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1-continuous solution that is fifth-order accurate uniformly in `[a,b]`. The formula is implemented as an implicit Runge-Kutta formula. `bvp5c` solves the algebraic equations directly; `bvp4c`

uses analytical condensation. `bvp4c` handles unknown parameters directly; while `bvp5c` augments the system with trivial differential equations for unknown parameters.

bvpget

Extract properties from options structure created with bvpset

Syntax

```
val = bvpget(options,'name')
val = bvpget(options,'name',default)
```

Description

`val = bvpget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = bvpget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = bvpget(options,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `options`.

Introduced before R2006a

bvpinit

Form initial guess for BVP solvers

Syntax

```
solinit = bvpinit(x,yinit)
solinit = bvpinit(x,yinit,parameters)
solinit = bvpinit(sol,[anew bnew])
solinit = bvpinit(sol,[anew bnew],parameters)
```

Description

`solinit = bvpinit(x,yinit)` forms the initial guess for a boundary value problem solver.

`x` is a vector that specifies an initial mesh. If you want to solve the BVP on $[a,b]$, then specify `x(1)` as a and `x(end)` as b. The solver adapts this mesh to the solution, so a guess like `xb=nlinspace(a,b,10)` often suffices. However, in difficult cases, you should place mesh points where the solution changes rapidly. The entries of `x` must be in

- Increasing order if $a<b$
- Decreasing order if $a>b$

For two-point boundary value problems, the entries of `x` must be distinct. That is, if $a<b$, the entries must satisfy `x(1)` < `x(2)` < ... < `x(end)`. If $a>b$, the entries must satisfy `x(1)` > `x(2)` > ... > `x(end)`

For multipoint boundary value problem, you can specify the points in $[a,b]$ at which the boundary conditions apply, other than the endpoints a and b, by repeating their entries in `x`. For example, if you set

```
x = [0, 0.5, 1, 1,  1.5, 2];
```

the boundary conditions apply at three points: the endpoints `0` and `2`, and the repeated entry 1. In general, repeated entries represent boundary points between regions in $[a,b]$. In the preceding example, the repeated entry 1 divides the interval `[0,2]` into two regions: `[0,1]` and `[1,2]`.

`yinit` is a guess for the solution. It can be either a vector, or a function:

- Vector – For each component of the solution, `bvpinit` replicates the corresponding element of the vector as a constant guess across all mesh points. That is, `yinit(i)` is a constant guess for the `i`th component `yinit(i,:)` of the solution at all the mesh points in `x`.
- Function – For a given mesh point, the guess function must return a vector whose elements are guesses for the corresponding components of the solution. The function must be of the form

  ```
  y = guess(x)
  ```

  where `x` is a mesh point and `y` is a vector whose length is the same as the number of components in the solution. For example, if the guess function is a function, `bvpinit` calls

  ```
  y(:,j) = guess(x(j))
  ```

  at each mesh point.

  For multipoint boundary value problems, the guess function must be of the form

  ```
  y = guess(x, k)
  ```

  where `y` an initial guess for the solution at `x` in region `k`. The function must accept the input argument `k`, which is provided for flexibility in writing the guess function. However, the function is not required to use `k`.

`solinit = bvpinit(x,yinit,parameters)` indicates that the boundary value problem involves unknown parameters. Use the vector `parameters` to provide a guess for all unknown parameters.

`solinit` is a structure with the following fields. The structure can have any name, but the fields must be named `x`, `y`, and `parameters`.

`x`	Ordered nodes of the initial mesh.
`y`	Initial guess for the solution with `solinit.y(:,i)` a guess for the solution at the node `solinit.x(i)`.
`parameters`	Optional. A vector that provides an initial guess for unknown parameters.

`solinit = bvpinit(sol,[anew bnew])` forms an initial guess on the interval `[anew bnew]` from a solution `sol` on an interval $[a,b]$. The new interval must be larger than the previous one, so either `anew <=` a < b `<= bnew` or `anew >=` a > b `>= bnew`. The solution `sol` is extrapolated to the new interval. If `sol` contains `parameters`, they are copied to `solinit`.

`solinit = bvpinit(sol,[anew bnew],parameters)` forms `solinit` as described above, but uses `parameters` as a guess for unknown parameters in `solinit`.

`@` | `bvp4c` | `bvp5c` | `bvpget` | `bvpset` | `bvpxtend` | `deval`

Introduced before R2006a

bvpset

Create or alter options structure of boundary value problem

Syntax

```
options = bvpset('name1',value1,'name2',value2,...)
options = bvpset(oldopts,'name1',value1,...)
options = bvpset(oldopts,newopts)
bvpset
```

Description

`options = bvpset('name1',value1,'name2',value2,...)` creates a structure `options` that you can supply to the boundary value problem solver `bvp4c`, in which the named properties have the specified values. Any unspecified properties retain their default values. For all properties, it is sufficient to type only the leading characters that uniquely identify the property. `bvpset` ignores case for property names.

`options = bvpset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This overwrites any values in `oldopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = bvpset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `oldopts`.

`bvpset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `bvpget` to query the `options` structure for the value of a specific property.

BVP Properties

`bvpset` enables you to specify properties for the boundary value problem solver `bvp4c`. There are several categories of properties that you can set:

Error Tolerance Properties

Because `bvp4c` uses a collocation formula, the numerical solution is based on a mesh of points at which the collocation equations are satisfied. Mesh selection and error control are based on the residual of this solution, such that the computed solution $S(x)$ is the exact solution of a perturbed problem $S'(x) = f(x,S(x)) + res(x)$. On each subinterval of the mesh, a norm of the residual in the `i`th component of the solution, `res(i)`, is estimated and is required to be less than or equal to a tolerance. This tolerance is a function of the relative and absolute tolerances, `RelTol` and `AbsTol`, defined by the user.

$$|| \left(\text{res}(i) / \max\left(\text{abs}\left(f(i) \right), \text{AbsTol}(i) / \text{RelTol} \right) \right) || \le \text{RelTol}$$

The following table describes the error tolerance properties.

BVP Error Tolerance Properties

Property	Value	Description
`RelTol`	Positive scalar {`1e-3`}	A relative error tolerance that applies to all components of the residual vector. It is a measure of the residual relative to the size of $f(x,y)$. The default, `1e-3`, corresponds to 0.1% accuracy. The computed solution $S(x)$ is the exact solution of $S'(x) = F(x,S(x)) + \text{res}(x)$. On each subinterval of the mesh, the residual $\text{res}(x)$ satisfies $$|| \left(\text{res}(i) / \max\left(\text{abs}\left(F(i) \right), \text{AbsTol}(i) / \text{RelTol} \right) \right) || \le \text{RelTol}$$
`AbsTol`	Positive scalar or vector {`1e-6`}	Absolute error tolerances that apply to the corresponding components of the residual vector. `AbsTol(i)` is a threshold below which the values of the corresponding components are

Property	Value	Description
		unimportant. If a scalar value is specified, it applies to all components.

Vectorization

The following table describes the BVP vectorization property. Vectorization of the ODE function used by `bvp4c` differs from the vectorization used by the ODE solvers:

- For `bvp4c`, the ODE function must be vectorized with respect to the first argument as well as the second one, so that `F([x1 x2 ...],[y1 y2 ...])` returns `[F(x1,y1) F(x2,y2)...]`.
- `bvp4c` benefits from vectorization even when analytical Jacobians are provided. For stiff ODE solvers, vectorization is ignored when analytical Jacobians are used.

Vectorization Properties

Property	Value	Description

`Vectorized`	`on | {off}`	Set on to inform `bvp4c` that you have coded the ODE function F so that `F([x1 x2 ...],[y1 y2 ...])` returns `[F(x1,y1) F(x2,y2) ...]`. That is, your ODE function can pass to the solver a whole array of column vectors at once. This enables the solver to reduce the number of function evaluations and may significantly reduce solution time.
		
		With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. In the `shockbvp` example shown previously, the shockODE function has been vectorized using colon notation into the subscripts and by using the array multiplication (`.*`) operator.
		
		`function dydx = shockODE(x,y,e)`
		`pix = pi*x;`
		`dydx = [ y(2,:)...`
		`-x/e.*y(2,:)-pi^2*cos(pix)-`
		`pix/e.*sin(pix)];`

Analytical Partial Derivatives

By default, the `bvp4c` solver approximates all partial derivatives with finite differences. `bvp4c` can be more efficient if you provide analytical partial derivatives $\partial f/\partial y$ of the differential equations, and analytical partial derivatives, $\partial bc/\partial ya$ and $\partial bc/\partial yb$, of the boundary conditions. If the problem involves unknown parameters, you must also provide partial derivatives, $\partial f/\partial p$ and $\partial bc/\partial p$, with respect to the parameters.

The following table describes the analytical partial derivatives properties.

BVP Analytical Partial Derivative Properties

Property	Value	Description
`FJacobian`	Function handle	A function handle that computes the analytical partial derivatives of $f(x,y)$. When solving $y' = f(x,y)$, set this property to `@fjac` if `dfdy = fjac(x,y)` evaluates the Jacobian $\partial f/\partial y$. If the problem involves unknown parameters p, `[dfdy,dfdp] = fjac(x,y,p)` must also return the partial derivative $\partial f/\partial p$. For problems with constant partial derivatives, set this property to the value of `dfdy` or to a cell array `{dfdy,dfdp}`.
`BCJacobian`	Function handle	A function handle that computes the analytical partial derivatives of $bc(ya,yb)$. For boundary conditions $bc(ya,yb)$, set this property to `@bcjac` if `[dbcdya,dbcdyb] = bcjac(ya,yb)` evaluates the partial derivatives $\partial bc/\partial ya$, and $\partial bc/\partial yb$. If the problem involves unknown parameters p, `[dbcdya,dbcdyb,dbcdp] = bcjac(ya,yb,p)` must also return the partial derivative $\partial bc/\partial p$. For problems with constant partial derivatives, set this property to a cell array `{dbcdya,dbcdyb}` or `{dbcdya,dbcdyb,dbcdp}`.

Singular BVPs

`bvp4c` can solve singular problems of the form

$$y' = S\frac{y}{x} + f(x, y, p)$$

posed on the interval [0,*b*] where $b > 0$. For such problems, specify the constant matrix S as the value of `SingularTerm`. For equations of this form, `odefun` evaluates only the $f(x,y,p)$ term, where p represents unknown parameters, if any.

Singular BVP Property

Property	Value	Description
`SingularTerm`	Constant matrix	Singular term of singular BVPs. Set to the constant matrix S for equations of the form $$y' = S\frac{y}{x} + f(x, y, p)$$ posed on the interval [0,*b*] where $b > 0$.

Mesh Size Property

`bvp4c` solves a system of algebraic equations to determine the numerical solution to a BVP at each of the mesh points. The size of the algebraic system depends on the number of differential equations (`n`) and the number of mesh points in the current mesh (`N`). When the allowed number of mesh points is exhausted, the computation stops, `bvp4c` displays a warning message and returns the solution it found so far. This solution does not satisfy the error tolerance, but it may provide an excellent initial guess for computations restarted with relaxed error tolerances or an increased value of `NMax`.

The following table describes the mesh size property.

BVP Mesh Size Property

Property	Value	Description
`NMax`	positive integer {`floor(1000/n)`}	Maximum number of mesh points allowed when solving the BVP, where `n` is the

Property	Value	Description
		number of differential equations in the problem. The default value of `NMax` limits the size of the algebraic system to about 1000 equations. For systems of a few differential equations, the default value of `NMax` should be sufficient to obtain an accurate solution.

Solution Statistic Property

The `Stats` property lets you view solution statistics.

The following table describes the solution statistics property.

BVP Solution Statistic Property

Property	Value	Description
`Stats`	`on` | {`off`}	Specifies whether statistics about the computations are displayed. If the `stats` property is `on`, after solving the problem, `bvp4c` displays: • The number of points in the mesh • The maximum residual of the solution • The number of times it called the differential equation function `odefun` to evaluate $f(x,y)$ • The number of times it called the boundary condition function `bcfun` to evaluate $bc(y(a),y(b))$

Examples

To create an options structure that changes the relative error tolerance of `bvp4c` from the default value of `1e-3` to `1e-4`, enter

```
options = bvpset('RelTol',1e-4);
```

To recover the value of `'RelTol'` from `options`, enter

```
bvpget(options,'RelTol')

ans =

  1.0000e-004
```

See Also

`function_handle` | `deval` | `bvp4c` | `bvp5c` | `bvpget` | `bvpinit`

Introduced before R2006a

bvpxtend

Form guess structure for extending boundary value solutions

Syntax

```
solinit = bvpxtend(sol,xnew,ynew)
solinit = bvpxtend(sol,xnew,extrap)
solinit = bvpxtend(sol,xnew)
solinit = bvpxtend(sol,xnew,ynew,pnew)
solinit = bvpxtend(sol,xnew,extrap,pnew)
```

Description

`solinit = bvpxtend(sol,xnew,ynew)` uses solution `sol` computed on `[a,b]` to form a solution guess for the interval extended to `xnew`. The extension point `xnew` must be outside the interval `[a,b]`, but on either side. The vector `ynew` provides an initial guess for the solution at `xnew`.

`solinit = bvpxtend(sol,xnew,extrap)` forms the guess at `xnew` by extrapolating the solution `sol`. `extrap` is a string that determines the extrapolation method. `extrap` has three possible values:

- `'constant'` — `ynew` is a value nearer to end point of solution in `sol`.
- `'linear'` — `ynew` is a value at `xnew` of linear interpolant to the value and slope at the nearer end point of solution in `sol`.
- `'solution'` — `ynew` is the value of (cubic) solution in `sol` at `xnew`.

The value of `extrap` is case-insensitive and only the leading, unique portion needs to be specified.

`solinit = bvpxtend(sol,xnew)` uses the extrapolating solution where `extrap` is `'constant'`. If there are unknown parameters, values present in `sol` are used as the initial guess for parameters in `solinit`.

`solinit = bvpxtend(sol,xnew,ynew,pnew)` specifies a different guess `pnew`. `pnew` can be used with extrapolation, using the syntax `solinit =`

`bvpxtend(sol,xnew,extrap,pnew)`. To modify parameters without changing the interval, use `[]` as place holder for `xnew` and `ynew`.

See Also

`bvp4c` | `bvp5c` | `bvpinit`

caldays

Calendar duration in days

Syntax

```
D = caldays(X)
```

Description

`D = caldays(X)` returns an array representing calendar days equivalent to the values in array `X`.

- If `X` is a numeric array, then `D` is a `calendarDuration` array with each element equal to the number of calendar days in the corresponding element of `X`. Calendar days account for Daylight Saving Time shifts when used in calendar calculations.
- If `X` is a `calendarDuration` array, then `D` is a `double` array with each element equal to the number of whole calendar days in the corresponding element of `X`.

Examples

Create Array of Calendar Days

```
X = magic(5);
D = caldays(X)
```

```
D =

   17d   24d    1d    8d   15d
   23d    5d    7d   14d   16d
    4d    6d   13d   20d   22d
   10d   12d   19d   21d    3d
   11d   18d   25d    2d    9d
```

Convert Calendar Durations to Calendar Days

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar days.

```
X = caldays(8:10) + hours(1.2345)
```

```
X =

    8d 1h 14m 4.2s    9d 1h 14m 4.2s   10d 1h 14m 4.2s
```

```
D = caldays(X)
```

```
D =

     8     9    10
```

`caldays` returns a numeric array.

Current Time at Future Date

Add two calendar days to the current date and time.

```
t = datetime('now') + caldays(2)
```

```
t =

   25-Feb-2015 10:05:24
```

Create Sequence of Dates

Create a sequence of consecutive dates beginning on March 18, 2014.

```
T = datetime([2014,03,18]) + caldays(0:4)
```

```
T =
```

```
   18-Mar-2014   19-Mar-2014   20-Mar-2014   21-Mar-2014   22-Mar-2014
```

Create a sequence of dates beginning on March 18, 2014, spaced 2 days apart.

```
T = datetime([2014,03,18]) + caldays(0:2:8)
```

```
T =

   18-Mar-2014   20-Mar-2014   22-Mar-2014   24-Mar-2014   26-Mar-2014
```

Input Arguments

X — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If `X` is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

More About

Tips

- `caldays` creates days that account for Daylight Saving Time shifts when used in calendar calculations. To create exact fixed-length (24 hour) days, use the `days` function.

See Also

`calendarDuration` | `days` | `hours`

Introduced in R2014b

caldiff

Calendar math successive differences

Syntax

```
dt = caldiff(t)
dt = caldiff(t,components)
dt = caldiff(t,components,dim)
```

Description

`dt = caldiff(t)` calculates time differences between adjacent datetime values in `t` in terms of the calendar components years, months, days, and time. `caldiff` calculates differences along the first array dimension whose size does not equal 1.

- If `t` is a vector of length `m`, then `dt = caldiff(t)` returns a vector of length `m-1`. The elements of `dt` are the differences between adjacent elements of `t`.

  ```
  dt = [between(t(1),t(2)), between(t(2),t(3)),..., between(t(m-1),t(m))]
  ```

- If `t` is a nonvector `p`-by-`m` matrix, then `dt = caldiff(t)` returns a matrix of size `(p-1)`-by-`m`, whose elements are the differences between the rows of `t`.

  ```
  dt(:,I) = [between(t(1,I),t(2,I), between(t(2,I),t(3,I)), ...,
       between(t(p-1,I),t(p,I))]
  ```

`dt = caldiff(t,components)` finds the differences between successive datetimes in `t` in terms of the specified calendar or time components.

`dt = caldiff(t,components,dim)` finds the differences between successive datetimes along the dimension specified by `dim`.

Examples

Calendar Differences Between Datetime Values

Create a `datetime` array and then compute the differences between the values in terms of calendar components.

```
t = [datetime('yesterday');datetime('today');datetime('tomorrow')]

t =

   22-Feb-2015
   23-Feb-2015
   24-Feb-2015

D = caldiff(t)

D =

   1d
   1d
```

Differences Using Specific Calendar Components

Create a `datetime` array and then compute the differences between the values in terms of days.

```
t = datetime('now') + calmonths(0:3)

t =

Columns 1 through 3

   23-Feb-2015 09:54:57   23-Mar-2015 09:54:57   23-Apr-2015 09:54:57

Columns 4 through 4

   23-May-2015 09:54:57

D = caldiff(t,'days')

D =

   28d   31d   30d
```

Computer the differences between the datetime values in terms of weeks and days.

```
D = caldiff(t,{'weeks','days'})
```

```
D =

       4w    4w 3d    4w 2d
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`components` — Calendar or time components

`'years'` | `'quarters'` | `'months'` | `'weeks'` | `'days'` | `'time'` | cell array of strings

Calendar or time components, specified as one of the following strings, or a cell array containing one ore more of these strings.

- `'years'`
- `'quarters'`
- `'months'`
- `'weeks'`
- `'days'`
- `'time'`

Except for `'time'`, the above components are flexible lengths of time. For example, one month represents a different length of time when added to a datetime in January than when added to a datetime in February.

`caldiff` operates on the calendar or time components in decreasing order, starting with the largest component.

In general, `t(2:m)` is not equal to `t(1:m-1) + dt`, unless you include `'time'` in `components`.

Example: `{'years','quarters'}`

Data Types: `char` | `cell`

`dim` — Dimension to operate along

positive integer

Dimension to operate along, specified as a positive integer. If no value is specified, the default is the first array dimension whose size does not equal 1.

Output Arguments

`dt` — Difference array

scalar | vector | matrix | multidimensional array

Difference array, returned as a scalar, vector, matrix, or multidimensional `calendarDuration` array.

More About

Tips

- To compute successive differences between datetimes in `t1` and `t2` as exact, fixed-length units of hours, minutes, and seconds, use `diff(t)`.

See Also

`between` | `calendarDuration` | `diff` | `minus`

Introduced in R2014b

calendar

Calendar for specified month

Syntax

```
c = calendar
c = calendar(d)
c = calendar(y, m)
```

Description

`c = calendar` returns a 6-by-7 matrix containing a calendar for the current month. The calendar runs Sunday (first column) to Saturday.

`c = calendar(d)`, where `d` is a serial date number or a date string, returns a calendar for the specified month.

`c = calendar(y, m)`, where `y` and `m` are integers, returns a calendar for the specified month of the specified year.

If you do not specify an output argument, then `calendar` displays a calendar in the Command Window but does not return a value.

Examples

The command

```
calendar(1957,10)
```

reveals that the Space Age began on a Friday (on October 4, 1957, when Sputnik 1 was launched).

```
                Oct 1957
    S     M     Tu    W     Th    F     S
    0     0     1     2     3     4     5
    6     7     8     9     10    11    12
```

```
    13    14    15    16    17    18    19
    20    21    22    23    24    25    26
    27    28    29    30    31     0     0
     0     0     0     0     0     0     0
```

See Also

`datenum`

Introduced before R2006a

calendarDuration

Create calendar duration array from numeric values

The `calendarDuration` function creates an array that represents elapsed time in calendar units of variable length. For example, the number of days in 1 month depend on the particular month of the year. Calculations with calendar durations account for daylight saving time changes and leap years.

Syntax

```
L = calendarDuration(Y,M,D)
L = calendarDuration(Y,M,D,H,MI,S)
L = calendarDuration(Y,M,D,T)

L = calendarDuration( ___ ,'Format',displayFormat)
```

Description

`L = calendarDuration(Y,M,D)` creates an array of calendar durations from numeric arrays containing the number of years, months, and days specified by `Y`, `M`, and `D`, respectively. Alternatively, you can specify the input arguments as a matrix with three columns, `[Y,M,D]`.

`L = calendarDuration(Y,M,D,H,MI,S)` also includes the hours, minutes, and seconds specified by `H`, `MI`, and `S`, respectively. Alternatively, you can specify the input arguments as a matrix with six columns, `[Y,M,D,H,MI,S]`.

`L = calendarDuration(Y,M,D,T)` creates an array of calendar durations from numeric arrays containing the number of years, months, and days, and a duration array `T` containing elapsed times.

`L = calendarDuration( ___ ,'Format',displayFormat)` additionally specifies the format in which `L` displays, using any of the input arguments from the previous syntaxes.

Examples

Create Calendar Duration from Numeric Scalars

```
L = calendarDuration(1,3,15)
```

```
L =

   1y 3mo 15d
```

Create Calendar Duration from Year, Month, Day, and Duration Arrays

Create a 2-by-2 array representing numbers of days.

```
D = magic(2)
```

```
D =

     1     3
     4     2
```

Create a 2-by-2 `duration` array of hours.

```
T = hours([1 2; 25 12])
```

```
T =

     1 hr    2 hrs
   25 hrs   12 hrs
```

Create a `calendarDuration` array using scalar values for the year and month inputs.

```
L = calendarDuration(1,13,D,T)
```

```
L =

    2y 1mo 1d 1h 0m 0s    2y 1mo 3d 2h 0m 0s
   2y 1mo 4d 25h 0m 0s   2y 1mo 2d 12h 0m 0s
```

Month values greater than 12 carry over to years in the display. Hour values greater than 24 do not carry over to days in the display, because the number of hours in a calendar day is not necessarily 24 hours.

Specify Display Format of Calendar Duration

Create a `calendarDuration` array and specify a format that displays the values in terms of months, weeks, days, and time.

```
L = calendarDuration(1,1,5:9,12,0,0,'Format','mwdt')
```

```
L =

Columns 1 through 3

      13mo 5d 12h 0m 0s      13mo 6d 12h 0m 0s      13mo 1w 12h 0m 0s

Columns 4 through 5

   13mo 1w 1d 12h 0m 0s   13mo 1w 2d 12h 0m 0s
```

Input Arguments

`Y,M,D` — Year, month, and day values

scalar | vector | matrix | multidimensional array

Year, month, and day values, specified as scalars, vectors, matrices, or multidimensional arrays. These values must be the same size, or any can be a scalar. `Y,M,D` should contain only integer values.

If `Y,M,D` are all scalars or all column vectors, you can specify the input arguments as a matrix with three columns, `[Y,M,D]`.

Specifying month values greater than 12 is equivalent to a number of years plus a number of months. For example, 25 months are equal to 2 years and 1 month. However, day values are not equivalent to a number of months, because the number of days in a month is not fixed, and cannot be determined until you add the calendar duration to a specific datetime.

Example: `2,10,24`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Y,M,D,H,MI,S` — Year, month, day, hour, minute, and second values

scalar | vector | matrix | multidimensional array

Year, month, day, hour, minute and second values, specified as scalars, vectors, matrices, or multidimensional arrays. These values must be the same size, or any can be a scalar. Specify fractional seconds as part of the seconds input, `S`. The `Y,M,D,H,MI` inputs should contain only integer values.

If `Y,M,D,H,MI,S` are all scalars or all column vectors, you can specify the input arguments as a matrix with six columns, `[Y,M,D,H,MI,S]`.

Specifying month values greater than 12 is equivalent to a number of years plus a number of months. For example, 25 months are equal to 2 years and 1 month. Minute values greater than 60 carry over to a number of hours, and second values greater than 60 carry over to a number of minutes. However, day values are not equivalent to a number of months because the number of days in a month is not fixed and cannot be determined until you add the calendar duration to a specific datetime. Similarly, hour values are not equivalent to a number of calendar days.

Example: `2,10,24,12,45,07.451`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Y,M,D,T` — Year, month, day, and duration values

scalar | vector | matrix | multidimensional array

Year, month, day and duration values, specified as scalars, vectors, matrices, or multidimensional arrays. These values must be the same size, or any can be a scalar. `Y`, `M`, and `D` are numeric arrays, and `T` is a `duration` array containing elapsed times.

Specifying month values greater than 12 is equivalent to a number of years plus a number of months. For example, 25 months are equal to 2 years and 1 month. However, day values are not equivalent to a number of months and duration values are not equivalent to a number of days. The number of days in a month and the number of hours in a day are not fixed and cannot be determined until you add the calendar duration to a specific datetime.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`displayFormat` — Display format

`'ymdt'` (default) | string

Display format of the values in `L`, specified as a string that can include the characters `y`, `q`, `m`, `w`, `d`, and `t`, in this order. The string must include `m` to display the number of months, `d` to display the number of days, and `t` to display the number of hours, minutes, and seconds. The `y` (year), `q` (quarter), and `w` (week) characters are optional.

This table describes the date and time components that the characters represent.

Character	Date or Time Unit	Details
`y`	Years	Multiples of 12 months display as a number of years
`q`	Quarters	Multiples of 3 months display as a number of quarters
`m`	Months	Must be included in `displayFormat`
`w`	Weeks	Multiples of 7 days display as a number of weeks
`d`	Days	Must be included in `displayFormat`
`t`	Time (hours, minutes, and seconds)	Must be included in `displayFormat`

If the value of a date or time component is zero, it is not displayed.

Changing the display format of a `calendarDuration` array does not change the values in the array.

Example: `'yqmdt'`

Output Arguments

`L` — Calendar duration

`calendarDuration` array

Calendar duration, returned as a `calendarDuration` array.

You can change the display format of a calendar duration by modifying the `Format` property. For example, to display the calendar duration, `L`, as a number of months, type:

```
L.Format = 'm'
```

More About

Tips

- When you add a `calendarDuration` array that contains more than one unit to a datetime, MATLAB always adds the larger units first. If `t` is a datetime, then this command:

  ```
  t + calendarDuration(1,2,3)
  ```
  is the same as:

  ```
  t + calyears(1) + calmonths(2) + caldays(3)
  ```

- "Represent Dates and Times in MATLAB"

See Also

`duration`

Introduced in R2014b

calllib

Call function in shared library

Syntax

```
[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)
```

Description

`[x1,...,xN] = calllib(libname,funcname,arg1,...,argN)` calls function, funcname, in library, libname, passing input arguments, arg1,...,argN, and returns output values obtained from funcname in x1,...,xN.

Examples

Call `addStructByRef` Function

Load the library.

```
if ~libisloaded('shrlibsample')
   addpath(fullfile(matlabroot,'extern','examples','shrlib'))
   loadlibrary('shrlibsample')
end
```

Display function signature.

```
libfunctionsview shrlibsample
```

```
[double, c_structPtr] addStructByRef(c_structPtr)
```

The input argument is a pointer to a `c_struct` data type.

Create a MATLAB structure, `struct`:

```
struct.p1 = 4; struct.p2 = 7.3; struct.p3 = -290;
```

Call the function.

```
[res,st] = calllib('shrlibsample','addStructByRef',struct);
```

Display the results.

```
res
```

```
res =
          -279
```

Cleanup.

```
unloadlibrary shrlibsample
```

Input Arguments

`libname` — Name of shared library

string

Name of shared library, specified as a string. Do not include the path or file extension in `libname`.

If you call `loadlibrary` using the `alias` option, then you must use the alias name for the `libname` argument.

Data Types: `char`

`funcname` — Name of function in library

string

Name of function in library, specified as a string.

Data Types: `char`

`arg1,...,argN` — Input arguments

any type

Input arguments, 1 through N, required by `funcname` (if any), specified by any type. The `funcname` argument list specifies the argument type.

Output Arguments

`x1,...,xN` — Output arguments

any type

Output arguments, 1 through N, from `funcname` (if any), returned as any type. The `funcname` argument list specifies the argument type.

Limitations

- Use with libraries that are loaded using the `loadlibrary` function.

More About

- Passing Arguments
- "MATLAB Crashes Calling Function in Shared Library"

Introduced before R2006a

callSoapService

Send SOAP (Simple Object Access Protocol) message to endpoint

Compatibility

`callSoapService` will be removed in a future release. Use `matlab.wsdl.createWSDLClient` instead.

Syntax

```
response = callSoapService(endpoint,soapAction,message)
```

Description

`response = callSoapService(endpoint,soapAction,message)` sends message to the soapAction service at endpoint.

Examples

Retrieve Book Information from Library Database

This example assumes the library is on a local intranet and does not use an actual endpoint; therefore, you cannot run it.

Retrieve the name of the author of a book titled “In the Fall.” The relative path of the library service is `urn:LibraryCatalog`. To get the author's name, use the `getAuthor` function, which takes the book name as the input value. The `getAuthor` parameter is `nameToLookUp`. The XML data type for title is `{http://www.w3.org/2001/XMLSchema}string`. The SOAP message style is `rpc` by default.

Create the SOAP message.

```
message = createSoapMessage(...
```

```
  'urn:LibraryCatalog',...
  'getAuthor',...
  {'In the Fall'},...
  {'nameToLookUp'},...
  {'{http://www.w3.org/2001/XMLSchema}string'})

message =

[#document: null]
```

This response does not necessarily indicate that the message is valid, although certain input problems produce error messages.

Send the message to the server for processing, and get the author's name back. The server endpoint is `http://test/soap/services/LibraryCatalog`. The server method is `urn:LibraryCatalog#getAuthor`.

```
response = callSoapService(...
  'http://test/soap/services/LibraryCatalog',...
  'urn:LibraryCatalog#getAuthor',...
  message)

<?xml version="1.0" encoding="utf-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<getAuthorResponse xmlns="urn:LibraryCatalog">
<ns1:getAuthorReturn xmlns:ns1="http://latestversion.soap.test">
Kate Alvin
</ns1:getAuthorReturn>
</getAuthorResponse>
</soapenv:Body>
</soapenv:Envelope>
```

MATLAB returns the message in a single line, displayed here on separate lines for legibility.

Extract the author's name.

```
author = parseSoapResponse(response)

author = Kate Alvin
```

MATLAB automatically converted the XML string data type to `char`.

Input Arguments

`endpoint` — URL identifying a built-in HTTP service

string

URL identifying a built-in HTTP service, specified as a string.

Example: `'http://test/soap/services/LibraryCatalog'`

`soapAction` — Name of service

string

Name of service, specified as a string.

Example: `'urn:LibraryCatalog#getAuthor'`

`message` — Java® document object model (DOM)

string

Java document object model (DOM), specified as a string. Use `createSoapMessage` to create message.

Output Arguments

`response` — Result of `soapAction`

string

Result of `soapAction`, returned as a string. To read information in response, use the `parseSoapResponse` function.

See Also

`createSoapMessage` | `matlab.wsdl.createWSDLClient` | `parseSoapResponse` | `urlread` | `xmlread`

Introduced before R2006a

calmonths

Calendar duration in months

Syntax

```
M = calmonths(X)
```

Description

`M = calmonths(X)` returns an array representing calendar months equivalent to the values in `X`.

- If `X` is a numeric array, then `M` is a `calendarDuration` array with each element equal to the number of calendar months in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `M` is a `double` array with each element equal to the number of whole calendar months in the corresponding element of `X`.

Examples

Create Array of Calendar Months

```
X = magic(4);
M = calmonths(X)
```

```
M =

   1y 4mo      2mo      3mo   1y 1mo
      5mo     11mo     10mo      8mo
      9mo      7mo      6mo       1y
      4mo   1y 2mo   1y 3mo      1mo
```

Convert Calendar Durations to Calendar Months

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar months.

```
X = calmonths(15:17) + caldays(8) + hours(1.2345)

X =

   1y 3mo 8d 1h 14m 4.2s   1y 4mo 8d 1h 14m 4.2s   1y 5mo 8d 1h 14m 4.2s

M = calmonths(X)

M =

    15    16    17
```

Input Arguments

X — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If `X` is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

See Also

`calendarDuration` | `calweeks`

Introduced in R2014b

calquarters

Calendar duration in quarters

Syntax

```
Q = calquarters(X)
```

Description

`Q = calquarters(X)` returns an array representing calendar quarters equivalent to the values in array `X`.

- If `X` is a numeric array, then `Q` is a `calendarDuration` array with each element equal to the number of calendar quarters in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `Q` is a `double` array with each element equal to the number of whole calendar quarters in the corresponding element of `X`.

  ```
  Q = fix(calmonths(t)/3)
  ```

Examples

Create Array of Calendar Quarters

```
X = magic(4);
Q = calquarters(X)
```

```
Q =

   16q    2q    3q   13q
    5q   11q   10q    8q
    9q    7q    6q   12q
    4q   14q   15q    1q
```

Convert Calendar Durations to Quarters

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar quarters.

```
X = calmonths(2:2:6) + caldays(8)
```

```
X =

   2mo 8d   4mo 8d   6mo 8d
```

```
Q = calquarters(X)
```

```
Q =

     0     1     2
```

Input Arguments

X — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If `X` is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

See Also

`calendarDuration` | `calmonths`

Introduced in R2014b

calweeks

Calendar duration in weeks

Syntax

```
W = calweeks(X)
```

Description

`W = calweeks(X)` returns an array representing calendar weeks equivalent to the values in `X`.

- If `X` is a numeric array, then `W` is a `calendarDuration` array with each element equal to the number of calendar weeks in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `calweeks` returns the number of whole weeks equivalent to each calendar duration in `X`.

Examples

Create Array of Calendar Weeks

```
X = magic(4);
W = calweeks(X)
```

```
W =

   16w    2w    3w   13w
    5w   11w   10w    8w
    9w    7w    6w   12w
    4w   14w   15w    1w
```

Convert Calendar Durations to Calendar Weeks

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar weeks.

```
X = caldays(15:17) + hours(1.2345)

X =

   15d 1h 14m 4.2s   16d 1h 14m 4.2s   17d 1h 14m 4.2s

W = calweeks(X)

W =

     2     2     2
```

Input Arguments

X — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If `X` is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

Output Arguments

W — Calendar weeks

scalar | vector | matrix | multidimensional array

Calendar weeks, returned as a scalar, vector, matrix, or multidimensional array. `W` is the same size as `X`. The data type of `W` depends on `X`.

- If `X` is a numeric array, then `W` is an array of calendar durations in units of equivalent flexible-length calendar weeks.
- If `X` is a `calendarDuration` array, then `W` is a `double` array of integer values representing whole calendar weeks.

See Also

`caldays` | `calendarDuration`

Introduced in R2014b

calyears

Calendar duration in years

Syntax

```
Y = calyears(X)
```

Description

`Y = calyears(X)` returns an array representing calendar years equivalent to the values in `X`. Calendar years account for leap days when used in calendar calculations.

- If `X` is a numeric array, then `Y` is a `calendarDuration` array with each element equal to the number of calendar years in the corresponding element of `X`.
- If `X` is a `calendarDuration` array, then `calyears` returns the number of whole years equivalent to each calendar duration in `X`.

Examples

Create Array of Calendar Years

```
X = magic(4);
Y = calyears(X)
```

```
Y =

   16y    2y    3y   13y
    5y   11y   10y    8y
    9y    7y    6y   12y
    4y   14y   15y    1y
```

Convert Calendar Durations to Calendar Years

Create an array of calendar durations. Then, convert each value to the equivalent number of whole calendar years.

```
X = calmonths(21:25) + caldays(8)

X =

    1y 9mo 8d   1y 10mo 8d   1y 11mo 8d        2y 8d    2y 1mo 8d

Y = calyears(X)

Y =

     1     1     1     2     2
```

Input Arguments

X — Input array

numeric array | calendar duration array | logical array

Input array, specified as a numeric array, calendar duration array, or logical array. If `X` is a numeric array, it must contain only integer values. That is, you cannot create fractional calendar units.

Output Arguments

Y — Calendar years

scalar | vector | matrix | multidimensional array

Calendar years, returned as a scalar, vector, matrix, or multidimensional array. `Y` is the same size as `X`. The data type of `Y` depends on `X`.

- If `X` is a numeric array, then `Y` is an array of calendar durations in units of equivalent flexible-length calendar years.
- If `X` is a `calendarDuration` array, then `Y` is a `double` array of integer values representing whole calendar years.

More About

Tips

- `calyears` creates years that account for leap days when used in calendar calculations. To create exact fixed-length (365.2425 day) years, use the `years` function.

See Also

`calendarDuration` | `calmonths` | `years`

Introduced in R2014b

camdolly

Move camera position and target

Syntax

```
camdolly(dx,dy,dz)
camdolly(dx,dy,dz,'targetmode')
camdolly(dx,dy,dz,'targetmode','coordsys')
camdolly(axes_handle,...)
```

Description

`camdolly(dx,dy,dz)` moves the camera position and the camera target by the specified amounts `dx`, `dy`, and `dz`.

`camdolly(dx,dy,dz,'targetmode')` uses the `targetmode` argument to determine how the camera moves:

- `movetarget` (default) — Move both the camera and the target.
- `fixtarget` — Move only the camera.

`camdolly(dx,dy,dz,'targetmode','coordsys')` uses the `coordsys` argument to determine how MATLAB interprets `dx`, `dy`, and `dz`:

- `camera` (default) — Move in the coordinate system of the camera. `dx` moves left/right, `dy` moves down/up, and `dz` moves along the viewing axis. MATLAB normalizes the units to the scene.

  For example, setting `dx` to 1 moves the camera to the right, which pushes the scene to the left edge of the box formed by the axes position rectangle. A negative value moves the scene in the other direction. Setting `dz` to 0.5 moves the camera to a position halfway between the camera position and the camera target.
- `pixels` — Interpret `dx` and `dy` as pixel offsets and ignore `dz`.
- `data` — Interpret `dx`, `dy`, and `dz` as offsets in axes data coordinates.

`camdolly(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camdolly` operates on the current axes.

`camdolly` sets the axes `CameraPosition` and `CameraTarget` properties, which in turn sets the `CameraPositionMode` and `CameraTargetMode` properties to `manual`.

Examples

Move the camera along the *x*- and *y*-axes in a series of steps:

```
surf(peaks)
axis vis3d
t = 0:pi/20:4*pi;
dx = sin(t)./40;
dy = cos(t)./40;
for i = 1:length(t);
    camdolly(dx(i),dy(i),0)
    drawnow
end
```

Introduced before R2006a

cameratoolbar

Control camera toolbar programmatically

Syntax

```
cameratoolbar
cameratoolbar('NoReset')
cameratoolbar('SetMode',mode)
cameratoolbar('SetCoordSys',coordsys)
cameratoolbar('Show')
cameratoolbar('Hide')
cameratoolbar('Toggle')
cameratoolbar('ResetCameraAndSceneLight')
cameratoolbar('ResetCamera')
cameratoolbar('ResetSceneLight')
cameratoolbar('ResetTarget')
h = cameratoolbar(...)
mode = cameratoolbar('GetMode')
paxis = cameratoolbar('GetCoordsys')
tf = cameratoolbar('GetVisible')
cameratoolbar('Close')
cameratoolbar(fig,...)
```

Description

`cameratoolbar` creates a toolbar that enables interactive manipulation of the axes camera and light when you drag the mouse on the figure window. Several axes camera properties are set when the toolbar is initialized.

`cameratoolbar('NoReset')` creates the toolbar without setting any camera properties.

`cameratoolbar('SetMode',mode)` sets the toolbar mode (depressed button). `mode` can be `'orbit'`, `'orbitscenelight'`, `'pan'`, `'dollyhv'`, `'dollyfb'`, `'zoom'`, `'roll'`, `'nomode'`. For descriptions of the various modes, see “Camera Toolbar”. You can also set these modes using the toolbar, by clicking the respective buttons.

`cameratoolbar('SetCoordSys',coordsys)` sets the principal axis of the camera motion. `coordsys` can be: `'x'`, `'y'`, `'z'`, `'none'`.

`cameratoolbar('Show')` shows the toolbar on the current figure.

`cameratoolbar('Hide')` hides the toolbar on the current figure.

`cameratoolbar('Toggle')` toggles the visibility of the toolbar.

`cameratoolbar('ResetCameraAndSceneLight')` resets the current camera and scenelight.

`cameratoolbar('ResetCamera')` resets the current camera.

`cameratoolbar('ResetSceneLight')` resets the current scenelight.

`cameratoolbar('ResetTarget')` resets the current camera target.

`h = cameratoolbar(...)` returns the handle to the toolbar.

`mode = cameratoolbar('GetMode')` returns the current mode.

`paxis = cameratoolbar('GetCoordsys')` returns the current principal axis.

`tf = cameratoolbar('GetVisible')` returns the visibility of the toolbar (`1` if visible, `0` if not visible).

`cameratoolbar('Close')` removes the toolbar from the current figure.

`cameratoolbar(fig,...)` specifies the figure to operate on by passing the figure handle as the first argument.

In general, the use of OpenGL hardware improves rendering performance.

Alternatives

Display the toolbar by selecting **Camera Toolbar** from the figure window's **View** menu.

`rotate3d` | `zoom`

Introduced before R2006a

camlight

Create or move light object in camera coordinates

Syntax

```
camlight('headlight')
camlight('right')
camlight('left')
camlight
camlight(az,el)
camlight(...,'style')
camlight(light_handle,...)
light_handle = camlight(...)
```

Description

`camlight('headlight')` creates a light at the camera position.

`camlight('right')` creates a light right and up from camera.

`camlight('left')` creates a light left and up from camera.

`camlight` with no arguments is the same as `camlight('right')`.

`camlight(az,el)` creates a light at the specified azimuth (`az`) and elevation (`el`) with respect to the camera position. The camera target is the center of rotation and `az` and `el` are in degrees.

`camlight(...,'style')` defines the style argument using one of two values:

- `local` (default) — The light is a point source that radiates from the location in all directions.
- `infinite` — The light shines in parallel rays.

`camlight(light_handle,...)` uses the light specified in `light_handle`.

`light_handle = camlight(...)` returns the light object handle.

`camlight` sets the light object `Position` and `Style` properties. A light created with `camlight` does not track the camera. In order for the light to stay in a constant position relative to the camera, call `camlight` whenever you move the camera.

Examples

Create a light positioned to the left of the camera and then reposition the light each time the camera moves:

```
surf(peaks)
axis vis3d
h = camlight('left');
for i = 1:20;
   camorbit(10,0)
   camlight(h,'left')
   pause(.1)
end
```

`lightangle` | `light`

Introduced before R2006a

camlookat

Position camera to view object or group of objects

Syntax

```
camlookat(object_handles)
camlookat(axes_handle)
camlookat
```

Description

`camlookat(object_handles)` views the objects identified in the vector `object_handles`. The vector can contain the handles of axes `Children`.

`camlookat(axes_handle)` views the objects that are children of the axes identified by `axes_handle`.

`camlookat` views the objects that are in the current axes by moving the camera position and camera target while preserving the relative view direction and camera view angle. The viewed object (or objects) roughly fill the axes position rectangle. To change the view, `camlookat` sets the axes `CameraPosition` and `CameraTarget` properties.

Examples

Create three spheres at different locations and then progressively position the camera so that the scene composes around each sphere individually:

```
% Create three spheres using the sphere function:
[x y z] = sphere;
s1 = surf(x,y,z);
hold on
s2 = surf(x+3,y,z+3);
s3 = surf(x,y,z+6);
% Set the data aspect ratio using daspect:
daspect([1 1 1])
% Set the view:
```

```
view(30,10)
% Set the projection type using camproj:
camproj perspective
% Compose the scene around the current axes
camlookat(gca)
pause(2)
% Compose the scene around sphere s1
camlookat(s1)
pause(2)
% Compose the scene around sphere s2
camlookat(s2)
pause(2)
% Compose the scene around sphere s3
camlookat(s3)
pause(2)
camlookat(gca)
```

`campos` | `camtarget`

Introduced before R2006a

camorbit

Rotate camera position around camera target

Syntax

```
camorbit(dtheta,dphi)
camorbit(dtheta,dphi,'coordsys')
camorbit(dtheta,dphi,'coordsys','direction')
camorbit(axes_handle,...)
```

Description

`camorbit(dtheta,dphi)` rotates the camera position around the camera target by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`camorbit(dtheta,dphi,'coordsys')` rotates the camera position around the camera target, using the *`coordsys`* argument to determine the center of rotation. *`coordsys`* can take on two values:

- `data` (default) — Rotate the camera around an axis defined by the camera target and the `direction` (default is the positive *z* direction).
- `camera` — Rotate the camera about the point defined by the camera target.

`camorbit(dtheta,dphi,'coordsys','direction')` defines the axis of rotation for the data coordinate system using the `direction` argument in conjunction with the camera target. Specify `direction` as a three-element vector containing the *x*-, *y*-, and *z*-components of the direction or one of the characters, `x`, `y`, or `z`, to indicate `[1 0 0]`, `[0 1 0]`, or `[0 0 1]` respectively.

`camorbit(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camorbit` operates on the current axes.

The behavior of `camorbit` differs from the `rotate3d` function in that while the `rotate3d` tool modifies the `View` property of the axes, the `camorbit` function fixes the

aspect ratio and modifies the `CameraTarget`, `CameraPosition`, and `CameraUpVector` properties of the axes. See Axes Properties for more information on all axes properties.

Examples

Rotate the camera horizontally about a line defined by the camera target point and a direction that is parallel to the *y*-axis. Visualize this rotation as a cone formed with the camera target at the apex and the camera position forming the base:

```
surf(peaks)
axis vis3d
for i=1:36
   camorbit(10,0,'data',[0 1 0])
   drawnow
end
```

Rotate in the `camera` coordinate system to orbit the camera around the axes along a circle while keeping the center of a circle at the camera target:

```
surf(peaks)
axis vis3d
for i=1:36
   camorbit(10,0,'camera')
   drawnow
end
```

Alternatives

Enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

`axes` | `axis` | `camdolly` | `campan` | `camzoom` | `camroll`

Introduced before R2006a

campan

Rotate camera target around camera position

Syntax

```
campan(dtheta,dphi)
campan(dtheta,dphi,coordsys)
campan(dtheta,dphi,coordsys,direction)
campan(axes_handle,...)
```

Description

`campan(dtheta,dphi)` rotates the camera target of the current axes around the camera position by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`campan(dtheta,dphi,coordsys)` determine the center of rotation using the `coordsys` argument. It can take on two values:

- `'data'` (default) — Rotate the camera target around an axis defined by the camera position and the `direction` (default is the positive *z* direction)
- `'camera'` — Rotate the camera about the point defined by the camera target.

`campan(dtheta,dphi,coordsys,direction)` defines the axis of rotation for the data coordinate system using the `direction` argument with the camera position. Specify `direction` as a three-element vector containing the *x*-, *y*-, and *z*-components of the direction or one of the characters, `'x'`, `'y'`, or `'z'`, to indicate `[1 0 0]`, `[0 1 0]`, or `[0 0 1]` respectively.

`campan(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campan` operates on the current axes.

Examples

Move the camera target to pan the object in a circular motion.

```
sphere;
axis vis3d
hPan = sin(-pi:1:pi);
vPan = cos(-pi:1:pi);
for k=1:length(hPan)
   campan(hPan(k),vPan(k))
   pause(.1)
end
```

axes | camdolly | camorbit | camtarget | camzoom | camroll

Introduced before R2006a

campos

Set or query camera position

Syntax

```
campos
campos([camera_position])
campos('mode')
campos('auto')
campos('manual')
campos(axes_handle,...)
```

Description

`campos` returns the camera position in the current axes.

`campos([camera_position])` sets the position of the camera in the current axes to the specified value. Specify the position as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

`campos('mode')` returns the value of the camera position mode, which can be either `auto` (the default) or `manual`.

`campos('auto')` sets the camera position mode to `auto`.

`campos('manual')` sets the camera position mode to `manual`.

`campos(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campos` operates on the current axes.

`campos` sets or queries values of the axes `CameraPosition` and `CameraPositionMode` properties. The camera position is the point in the Cartesian coordinate system of the axes from which you view the scene.

Examples

Move the camera along the *x*-axis in a series of steps:

```
surf(peaks)
axis vis3d off
for x = -200:5:200
    campos([x,5,10])
    drawnow
end
```

More About

- "Camera Graphics Terminology"

See Also

`axis` | `camproj` | `camup` | `camva` | `camtarget`

Introduced before R2006a

camproj

Set or query projection type

Syntax

```
camproj
camproj('projection_type')
camproj(axes_handle,...)
```

Description

`camproj` returns the projection type setting in the current axes. The projection type determines whether MATLAB 3-D views use a perspective or orthographic projection.

`camproj('projection_type')` sets the projection type in the current axes to the specified value. Possible values for *`projection_type`* are `orthographic` and `perspective`.

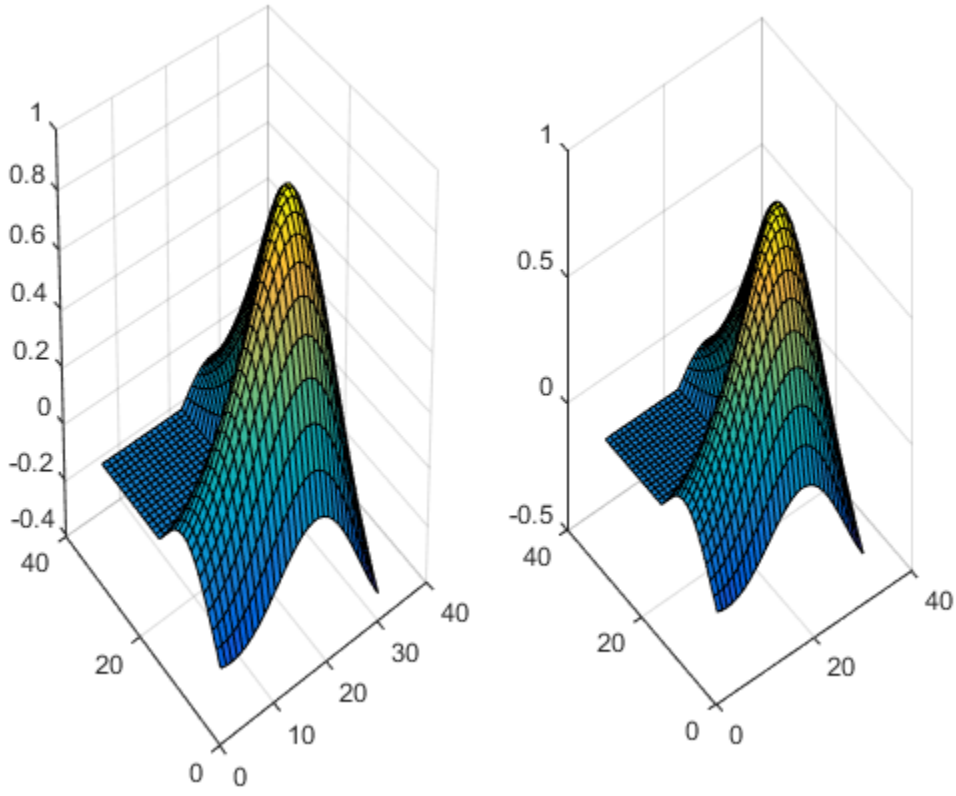
`camproj(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camproj` operates on the current axes.

`camproj` sets or queries values of the axes object `Projection` property.

Examples

Compare the different `camproj` settings using `subplot`:

```
subplot(1,2,1); surf(membrane); camproj('perspective')
subplot(1,2,2); surf(membrane); camproj('orthographic')
```



More About

- "Camera Graphics Terminology"

`axis` | `campos` | `camtarget` | `camup` | `camva`

Introduced before R2006a

camroll

Rotate camera about view axis

Syntax

```
camroll(dtheta)
camroll(axes_handle,dtheta)
```

Description

`camroll(dtheta)` rotates the camera around the camera viewing axis by the amounts specified in `dtheta` (in degrees). The viewing axis is the line passing through the camera position and the camera target.

`camroll(axes_handle,dtheta)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camroll` operates on the current axes.

`camroll` sets the axes `CameraUpVector` property and also sets the `CameraUpVectorMode` property to `manual`.

Examples

Rotate the camera around the viewing axis:

```
surf(peaks)
axis vis3d
for i=1:36
 camroll(10)
 drawnow
end
```

More About

- "Camera Graphics Terminology"

See Also

`axes` | `axis` | `camdolly` | `camorbit` | `camzoom` | `campan`

Introduced before R2006a

camtarget

Set or query location of camera target

Syntax

```
camtarget
camtarget([camera_target])
camtarget('mode')
camtarget('auto')
camtarget('manual')
camtarget(axes_handle,...)
```

Description

`camtarget` returns the location of the camera target in the current axes. The camera target is the location in the axes that the camera points to. The camera remains oriented toward this point regardless of its position.

`camtarget([camera_target])` sets the camera target in the current axes to the specified value. Specify the target as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

`camtarget('mode')` returns the value of the camera target mode, which can be either `auto` (default) or `manual`.

`camtarget('auto')` sets the camera target mode to `auto`. When the camera target mode is `auto`, the camera target is the center of the axes plot box.

`camtarget('manual')` sets the camera target mode to `manual`.

`camtarget(axes_handle,...)` performs the set or query on the axes identified by `axes_handle`. When you do not specify an axes handle, `camtarget` operates on the current axes.

`camtarget` sets or queries values of the axes object `CameraTarget` and `CameraTargetMode` properties.

Examples

Move the camera position and the camera target along the *x*-axis in a series of steps:

```
surf(peaks);
axis vis3d
xp = linspace(-150,40,50);
xt = linspace(25,50,50);
for i=1:50
     campos([xp(i),25,5]);
     camtarget([xt(i),30,0])
     drawnow
end
```

More About

- "Camera Graphics Terminology"

See Also

`axis` | `campos` | `camup` | `camva`

Introduced before R2006a

camup

Set or query camera up vector

Syntax

```
camup
camup([up_vector])
camup('mode')
camup('auto')
camup('manual')
camup(axes_handle,...)
```

Description

`camup` returns the camera up vector setting in the current axes. The camera up vector specifies the direction that is oriented up in the scene.

`camup([up_vector])` sets the up vector in the current axes to the specified value. Specify the up vector as *x*, *y*, and *z* components.

`camup('mode')` returns the current value of the camera up vector mode, which can be either `auto` (default) or `manual`.

`camup('auto')` sets the camera up vector mode to `auto`. In `auto` mode, `[0 1 0]` is the up vector of for 2-D views. This means the *y*-axis points up. For 3-D views, the up vector is `[0 0 1]`, meaning the *z*-axis points up.

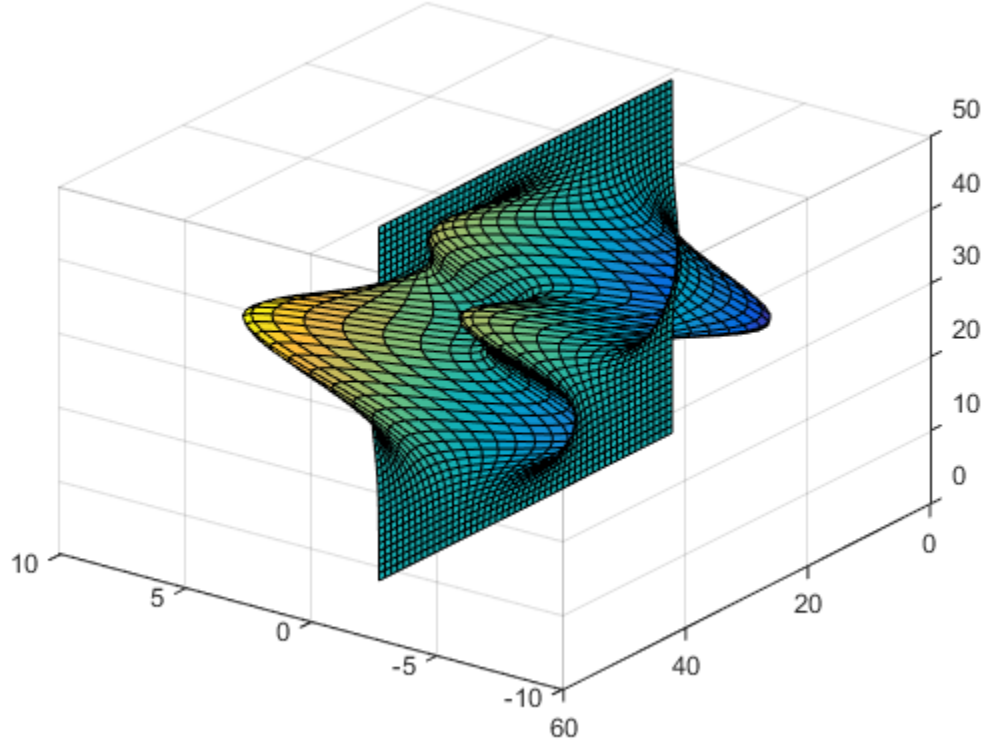
`camup('manual')` sets the camera up vector mode to `manual`. In `manual` mode, the value of the camera up vector does not change unless you set it.

`camup(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camup` operates on the current axes.

Examples

Set the *x*-axis to be the up axis:

```
surf(peaks)
camup([1 0 0]);
```



More About

- "Camera Graphics Terminology"

`axis` | `campos` | `camup` | `camtarget`

Introduced before R2006a

camva

Set or query camera view angle

Syntax

```
camva
camva(view_angle)
camva('mode')
camva('auto')
camva('manual')
camva(axes_handle,...)
```

Description

`camva` returns the camera view angle setting in the current axes. The camera view angle determines the field of view of the camera. Larger angles produce a smaller view of the scene. Implement zooming by changing the camera view angle.

`camva(view_angle)` sets the view angle in the current axes to the specified value. Specify the view angle in degrees.

`camva('mode')` returns the current value of the camera view angle mode, which can be either `auto` (the default) or `manual`.

`camva('auto')` sets the camera view angle mode to `auto`.

`camva('manual')` sets the camera view angle mode to `manual`.

`camva(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camva` operates on the current axes.

Tips

The `camva` function sets or queries values of the axes object `CameraViewAngle` and `CameraViewAngleMode` properties.

When the camera view angle mode is `auto`, the camera view angle adjusts so that the scene fills the available space in the window. If you move the camera to a different position, the camera view angle changes to maintain a view of the scene that fills the available area in the window.

Setting a camera view angle or setting the camera view angle to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the camera view angle to its current value,

```
camva(camva)
```

can cause a change in the way the graph looks. See `axes` for more information.

Examples

Create two pushbuttons, one that zooms in and another that zooms out:

```
% Set the range checking in the callback statements to keep
% the values for the camera view angle in the range greater
% than zero and less than 180.
uicontrol('Style','pushbutton',...
  'String','Zoom In',...
  'Position',[20 20 60 20],...
  'Callback','if camva <= 1;return;else;camva(camva-1);end');
uicontrol('Style','pushbutton',...
  'String','Zoom Out',...
  'Position',[100 20 60 20],...
  'Callback',...
  'if camva >= 179;return;else;camva(camva+1);end');
% Now create a graph to zoom in and out on:
surf(peaks);
```

`axis` | `campos` | `camup` | `camtarget`

Introduced before R2006a

camzoom

Zoom in and out on scene

Syntax

```
camzoom(zoom_factor)
camzoom(axes_handle,...)
```

Description

`camzoom(zoom_factor)` zooms in or out on the scene depending on the value specified by `zoom_factor`. If `zoom_factor` is greater than 1, the scene appears larger; if `zoom_factor` is greater than zero and less than 1, the scene appears smaller.

`camzoom(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camzoom` operates on the current axes.

More About

Tips

`camzoom` sets the axes `CameraViewAngle` property, which in turn causes the `CameraViewAngleMode` property to be set to `manual`. Note that setting the `CameraViewAngle` property disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This may result in a change to the aspect ratio of your graph. See the `axes` function for more information on this behavior.

cartToBary

Class: TriRep

(Will be removed) Convert point coordinates from cartesian to barycentric

---

Note: `cartToBary(TriRep)` will be removed in a future release. Use `cartesianToBarycentric(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
B = cartToBary(TR, SI, XC)
```

Description

`B = cartToBary(TR, SI, XC)` returns the barycentric coordinates of each point in `XC` with respect to its associated simplex `SI`.

Input Arguments

`TR`	Triangulation representation.
`SI`	Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`.
`XC`	Matrix that represents the Cartesian coordinates of the points to be converted. `XC` is of size `m`-by-`n`, where `m` is of `length(SI)`, the number of points to convert, and `n` is the dimension of the space where the triangulation resides.

Output Arguments

`B`	Matrix of dimension `m`-by-`k` where `k` is the number of vertices per simplex.

Definitions

A simplex is a triangle/tetrahedron or higher dimensional equivalent.

Examples

Compute the Delaunay triangulation of a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
dt = DelaunayTri(x,y)
```

Compute the barycentric coordinates of the incenters.

```
cc = incenters(dt);
tri = dt(:,:);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(dt); hold on;
plot(cc(:,1), cc(:,2), '*r');
hold off;
axis equal;
```

Stretch the triangulation and compute the mapped locations of the incenters on the deformed triangulation.

```
b = cartToBary(dt,[1:length(tri)]',cc);
y = [0 0 0 0 16 16 16 16]';
tr = TriRep(tri,x,y)
xc = baryToCart(tr, [1:length(tri)]', b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(tr);
hold on;
plot(xc(:,1), xc(:,2), '*r');
hold off;
axis equal;
```

cart2pol

Transform Cartesian coordinates to polar or cylindrical

Syntax

```
[THETA,RHO,Z] = cart2pol(X,Y,Z)
[THETA,RHO] = cart2pol(X,Y)
```

Description

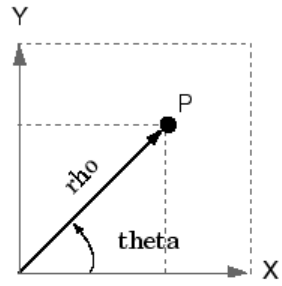
`[THETA,RHO,Z] = cart2pol(X,Y,Z)` transforms three-dimensional Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z`, into cylindrical coordinates. `THETA` is a counterclockwise angular displacement in radians from the positive *x*-axis, `RHO` is the distance from the origin to a point in the *x*-*y* plane, and `Z` is the height above the *x*-*y* plane. Arrays `X`, `Y`, and `Z` must be the same size (or any can be scalar).

`[THETA,RHO] = cart2pol(X,Y)` transforms two-dimensional Cartesian coordinates stored in corresponding elements of arrays `X` and `Y` into polar coordinates.

More About

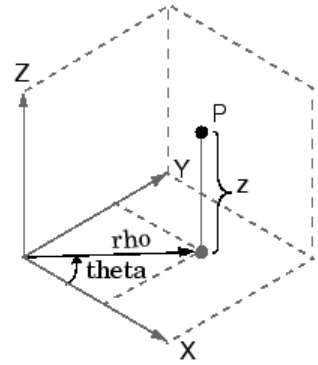
Algorithms

The mapping from two-dimensional Cartesian coordinates to polar coordinates, and from three-dimensional Cartesian coordinates to cylindrical coordinates is



Two-Dimensional Mapping

```
theta = atan2(y,x)
rho = sqrt(x.^2 + y.^2)
```



Three-Dimensional Mapping

```
theta = atan2(y,x)
rho = sqrt(x.^2 + y.^2)
z = z
```

See Also

`cart2sph` | `pol2cart` | `sph2cart`

Introduced before R2006a

cart2sph

Transform Cartesian coordinates to spherical

Syntax

```
[azimuth,elevation,r] = cart2sph(X,Y,Z)
```

Description

`[azimuth,elevation,r] = cart2sph(X,Y,Z)` transforms Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z` into spherical coordinates. `azimuth` and `elevation` are angular displacements in radians. `azimuth` is the counterclockwise angle in the *x*-*y* plane measured from the positive *x*-axis. `elevation` is the elevation angle from the *x*-*y* plane. `r` is the distance from the origin to a point.

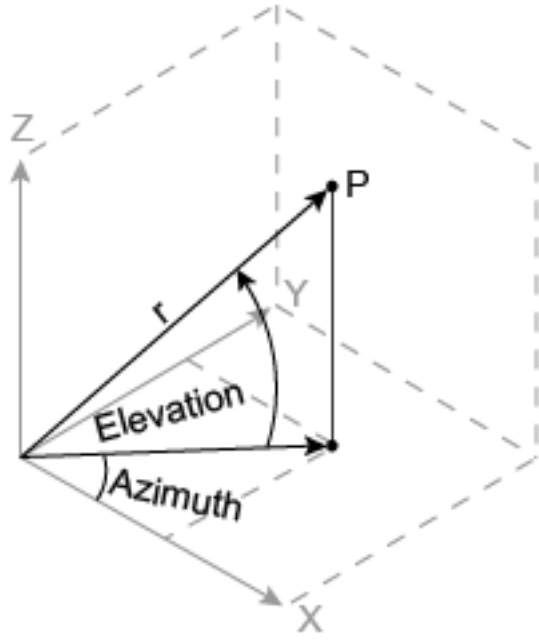
Arrays `X`, `Y`, and `Z` must be the same size (or any of them can be scalar).

More About

Algorithms

The mapping from three-dimensional Cartesian coordinates to spherical coordinates is

```
azimuth = atan2(y,x)
elevation = atan2(z,sqrt(x.^2 + y.^2))
r = sqrt(x.^2 + y.^2 + z.^2)
```



The notation for spherical coordinates is not standard. For the `cart2sph` function, `elevation` is measured from the *x*-*y* plane. Notice that if `elevation = 0`, the point is in the *x*-*y* plane. If `elevation = pi/2`, then the point is on the positive *z*-axis.

`cart2pol` | `pol2cart` | `sph2cart`

Introduced before R2006a

cast

Cast variable to different data type

Syntax

```
B = cast(A,newclass)
B = cast(A,'like',p)
```

Description

`B = cast(A,newclass)` converts `A` to class `newclass`, where `newclass` is the name of a built-in data type compatible with `A`. The `cast` function truncates any values in `A` that are too large to map into `newclass`.

`B = cast(A,'like',p)` converts `A` to the same data type and sparsity as the variable `p`. If `A` and `p` are both real, then `B` is also real. Otherwise, `B` is complex.

Examples

Convert Numeric Data Type

Convert an `int8` value to `uint8`.

Define a scalar 8-bit integer.

```
a = int8(5);
```

Convert `a` to an unsigned 8-bit integer.

```
b = cast(a,'uint8');
class(b)
```

```
ans =
uint8
```

Match Data Type and Complex Nature of p

Define a single precision vector `p` that is complex valued.

```
p = single([1+i 2]);
```

Define a 2-by-3 matrix of ones.

```
A = ones(2,3);
```

Convert A to the same data type and complexity (real or complex) as p.

```
B = cast(A,'like',p)
```

```
B =

   1.0000 + 0.0000i   1.0000 + 0.0000i   1.0000 + 0.0000i
   1.0000 + 0.0000i   1.0000 + 0.0000i   1.0000 + 0.0000i
```

Check the class of B.

```
class(B)
```

```
ans =

single
```

- "Class Support for Array-Creation Functions"

See Also

`class` | `typecast`

Introduced before R2006a

cat

Concatenate arrays along specified dimension

Syntax

```
C = cat(dim, A, B)
C = cat(dim, A1, A2, A3, A4, ...)
```

Description

`C = cat(dim, A, B)` concatenates the arrays `A` and `B` along array the dimension specified by `dim`. The `dim` argument must be a real, positive, integer value.

`C = cat(dim, A1, A2, A3, A4, ...)` concatenates all the input arrays (`A1`, `A2`, `A3`, `A4`, and so on) along array dimension `dim`.

For nonempty arrays, `cat(2, A, B)` is the same as `[A, B]`, and `cat(1, A, B)` is the same as `[A; B]`.

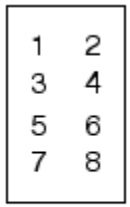
If your input arrays are tables, `dim` must be either 1 or 2. `cat` then concatenates by calling `horzcat` or `vertcat` respectively.

Examples

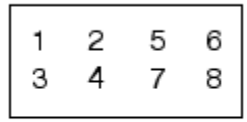
Given

```
A =                 B =
     1     2                 5     6
     3     4                 7     8
```

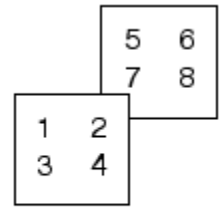
concatenating along different dimensions produces



C = cat(1,A,B)



C = cat(2,A,B)



C = cat(3,A,B)

The commands

```
A = magic(3); B = pascal(3);
C = cat(4, A, B);
```

produce a 3-by-3-by-1-by-2 array.

More About

Tips

When used with comma-separated list syntax, `cat(dim, C{:})` or `cat(dim, C.field)` is a convenient way to concatenate a cell or structure array containing numeric matrices into a single matrix.

You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

You can concatenate datetime arrays with cell arrays of strings.

You can concatenate duration arrays and calendar duration arrays. The result is a calendar duration array.

You can concatenate duration or calendar duration arrays with numeric arrays. Prior to concatenation, MATLAB converts the numeric array to an array of equivalent days using the `days` function.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”

`vertcat` | `strcat` | `char` | `special character` | `horzcat` | `num2cell` | `reshape` | `squeeze` | `strjoin` | `shiftdim`

Introduced before R2006a

categorical

Create categorical array

Use `categorical` to create a categorical array from data with values from a finite set of discrete categories. To group numeric data into categories, use `discretize`.

Syntax

```
B = categorical(A)
B = categorical(A,valueset)
B = categorical(A,valueset,catnames)
B = categorical(A, ___ ,Name,Value)
```

Description

`B = categorical(A)` creates a categorical array from the array, `A`. The categories of `B` are the sorted unique values from `A`.

For more information on creating and using categorical arrays, see “Categorical Arrays”.

`B = categorical(A,valueset)` creates one category for each value in valueset. The categories of `B` are in the same order as the values of valueset.

You can use valueset to include categories for values not present in `A`. Conversely, if `A` contains any values not present in `valueset`, the corresponding elements of `B` are undefined.

`B = categorical(A,valueset,catnames)` names the categories in `B` by matching the category values in valueset with the names in catnames.

`B = categorical(A, ___ ,Name,Value)` creates a categorical array with additional options specified by one or more Name,Value pair arguments. You can include any of the input arguments in previous syntaxes.

For example, you can specify that the categories have a mathematical ordering.

Examples

Create Categorical Array from Strings

Convert a cell array of strings to a categorical array.

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
A =

    'r'    'b'    'g'
    'g'    'r'    'b'
    'b'    'r'    'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B.

```
B = categorical(A)
```

```
B =

     r      b      g
     g      r      b
     b      r      g
```

The contents of B match the contents of A.

Display the categories of B.

```
categories(B)
```

```
ans =

    'b'
    'g'
    'r'
```

The categories of B are the unique values from A in alphabetical order.

Create Categorical Array and Specify Possible Unique Values

Convert a cell array of strings, A, to a categorical array. Specify a list of categories that includes values that are not present in A.

Create a cell array of strings.

```
A = {'republican' 'democrat'; 'democrat' 'democrat'; 'democrat' 'republican'}
```

```
A =

    'republican'    'democrat'
    'democrat'      'democrat'
    'democrat'      'republican'
```

A is a 3-by-2 cell array containing two unique values.

Convert the cell array of strings, A, to a categorical array, B and include a category for `independent`.

```
valueset = {'democrat' 'republican' 'independent'}
B = categorical(A,valueset)
```

```
B =

     republican      democrat
     democrat        democrat
     democrat        republican
```

The contents of B match the contents of A.

Display the categories of B.

```
categories(B)
```

```
ans =

    'democrat'
    'republican'
    'independent'
```

The categories of B are in the same order as the values specified in `valueset`.

Create Categorical Array and Specify Category Names

Create a cell array of strings.

```
A = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
A =
```

```
    'r'    'b'    'g'
    'g'    'r'    'b'
    'b'    'r'    'g'
```

A is a 3-by-3 cell array containing three unique values.

Convert the cell array of strings, A, to a categorical array, B, and specify category names.

```
B = categorical(A,{'r' 'g' 'b'},{'red' 'green' 'blue'})
```

```
B =

     red        blue       green
     green      red        blue
     blue       red        green
```

B uses the specified category names for the contents from A.

Display the categories of B.

```
categories(B)
```

```
ans =

    'red'
    'green'
    'blue'
```

The categories of B are in the order they were specified.

Create Categorical Array from Integers

Create a 2-by-3 numeric array.

```
A = gallery('integerdata',3,[2,3],3)
```

```
A =

     2     1     2
     1     1     3
```

A contains the values 1, 2, and 3.

Convert the numeric array, A, to a categorical array. Use the values 1, 2, and 3 to define the categories `car`, `bus`, and `bike`, respectively.

```
valueset = 1:3;
catnames = {'car' 'bus' 'bike'};

B = categorical(A,valueset,catnames)

B =

     bus      car      bus
     car      car      bike
```

`categorical` maps the numeric values in `valueset` to the category names in `catnames`.

The 2-by-3 categorical array, `B`, is not ordinal. Therefore, you can only compare the values in `B` for equality. To compare the values in `B` using relational operators, such as less than and greater than, you must include the `'Ordinal',true` name-value pair argument.

Create Ordinal Categorical Array from Integers

Create a 5-by-2 numeric array.

```
A = gallery('integerdata',3,[5,2],1)

A =

     3     2
     3     3
     3     2
     2     1
     3     2
```

`A` contains the values `1`, `2`, and `3`.

Convert the numeric array, `A`, to an ordinal categorical array where 1, 2, and 3 represent child, adult, and senior respectively.

```
valueset = [1:3];
catnames = {'child' 'adult' 'senior'};

B = categorical(A,valueset,catnames,'Ordinal',true)

B =
```

```
     senior      adult
     senior      senior
     senior      adult
     adult       child
     senior      adult
```

Since B is ordinal, the categories of B have a mathematical ordering, `child < adult < senior`.

Create Categorical Array by Binning Numeric Data

Use the `discretize` function (instead of `categorical`) to bin 100 random numbers into three categories.

```
x = rand(100,1);
y = discretize(x,[0 .25 .75 1],'categorical',{'small','medium','large'});
summary(y)
```

```
     small       22
     medium      46
     large       32
```

Input Arguments

A — Input array

numeric array | logical array | categorical array | cell array of strings | ...

Input array, specified as a numeric array, logical array, categorical array, or cell array of strings.

If A contains missing values, the corresponding element of B is `<undefined>`. Missing values are `NaN` for numeric arrays, the empty string (`''`) for cell arrays of strings, and `<undefined>` for categorical arrays. B does not have a category for undefined values. To create an explicit category for missing or undefined values, you must include the desired category name in `catnames`, and `NaN`, the empty string, or `<undefined>` in `valueset`.

In addition to an array, A can be an object with the following class methods:

- `unique`
- `eq`

`valueset` — Values to define categories

`unique(A)` (default) | vector of unique values

Values to define categories, specified as a vector of unique values. The data type of `valueset` and the data type of `A` must be the same.

`catnames` — Category names

cell array of strings

Category names, specified as a cell array of strings. If you do not specify the `catnames` input argument, `categorical` uses the values in `valueset` as category names.

To merge multiple distinct values in `A` into a single category in `B`, include duplicate names corresponding to those values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Ordinal',true` specifies that the categories have a mathematical ordering

`'Ordinal'` — Mathematical ordering indicator

`false` (default) | `true` | `0` | `1`

Mathematical ordering indicator, specified as the comma-separated pair consisting of `'Ordinal'` and either `false`, `true`, `0`, or `1`.

`false`	`categorical` creates a categorical array that is not ordinal. This is the default behavior. The categories of `B` have no mathematical ordering. Therefore, you can only compare the values in `B` for equality.
`true`	`categorical` creates an ordinal categorical array. The categories of `B` have a mathematical ordering, such that the first category specified is the smallest and the last category is the largest. You can compare the values in `B` using relational operators, such as less than and greater than, in addition to comparing the values for equality.

'Protected' — Category protection indicator

false | true | 0 | 1

Category protection indicator specified as the comma-separated pair consisting of 'Protected' and either false, true, 0, or 1. The categories of ordinal categorical arrays are always protected. The default value is true when you specify 'Ordinal',true and false otherwise.

false	When you assign new values to B, the categories update automatically. Therefore, you can combine (nonordinal) categorical arrays that have different categories. The categories can update accordingly to include the categories from both arrays.
true	When you assign new values to B, the values must belong to one of the existing categories. Therefore, you can only combine arrays that have the same categories. To add new categories to B, you must use the function addcats.

More About

- "Advantages of Using Categorical Arrays"

See Also

categories | discretize

categories

Categories of categorical array

Syntax

```
C = categories(A)
```

Description

`C = categories(A)` returns a cell array of strings containing the categories of the categorical array, `A`.

Examples

List Categories in Categorical Array

Create a categorical array, `A`.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =

     plane      car      train      car      plane
```

`A` is a 1-by-5 categorical array.

Display the categories of `A`.

```
C = categories(A)
```

```
C =

    'car'
    'plane'
    'train'
```

Since you created A by specifying only an input array, the categories appear in alphabetical order.

List Categories in Ordinal Categorical Array

Create an ordinal categorical array.

```
A = categorical({'medium' 'large'; 'small' 'xlarge'; 'large' 'medium'},...
    {'small' 'medium' 'large' 'xlarge'},'Ordinal',true)
```

```
A =

     medium      large
     small       xlarge
     large       medium
```

A is a 3-by-2 ordinal categorical array.

Display the categories of A.

```
C = categories(A)
```

```
C =

    'small'
    'medium'
    'large'
    'xlarge'
```

The categories appear in the order in which you specified them. Since A is ordinal, the categories have the mathematical ordering `small < medium < large < xlarge`.

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

More About

Tips

- `C` includes all categories in `A`, even if `A` does not contain any data from a category. To see the unique values in `A`, use `unique(A)`.
- The order of the categories listed in `C` is the same order used by functions, such as `summary` and `hist`. To change the order of the categories, use `reordercats`.

See Also

`addcats` | `categorical` | `hist` | `iscategory` | `mergecats` | `removecats` | `renamecats` | `reordercats` | `setcats` | `unique`

caxis

Color axis scaling

Syntax

```
caxis([cmin cmax])
caxis auto
caxis manual
caxis(caxis)
v = caxis
caxis(axes_handle,...)
```

Description

`caxis` controls the mapping of data values to the colormap. It affects any `surface`, `patch`, or `image` with indexed `CData` and `CDataMapping` set to scaled. It does not affect surfaces, patches, or images with true color `CData` or with `CDataMapping` set to `direct`.

`caxis([cmin cmax])` sets the color limits to specified minimum and maximum values. Data values less than `cmin` or greater than `cmax` map to `cmin` and `cmax`, respectively. Values between `cmin` and `cmax` linearly map to the current colormap.

`caxis auto` computes the color limits automatically using the minimum and maximum data values. This is the default behavior. Color values set to `Inf` map to the maximum color, and values set to `-Inf` map to the minimum color. Faces or edges with color values set to `NaN` are not drawn.

`caxis manual` and `caxis(caxis)`freeze the color axis scaling at the current limits. This enables subsequent plots to use the same limits when `hold` is `on`.

`v = caxis` returns a two-element row vector containing the `[cmin cmax]` currently in use.

`caxis(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

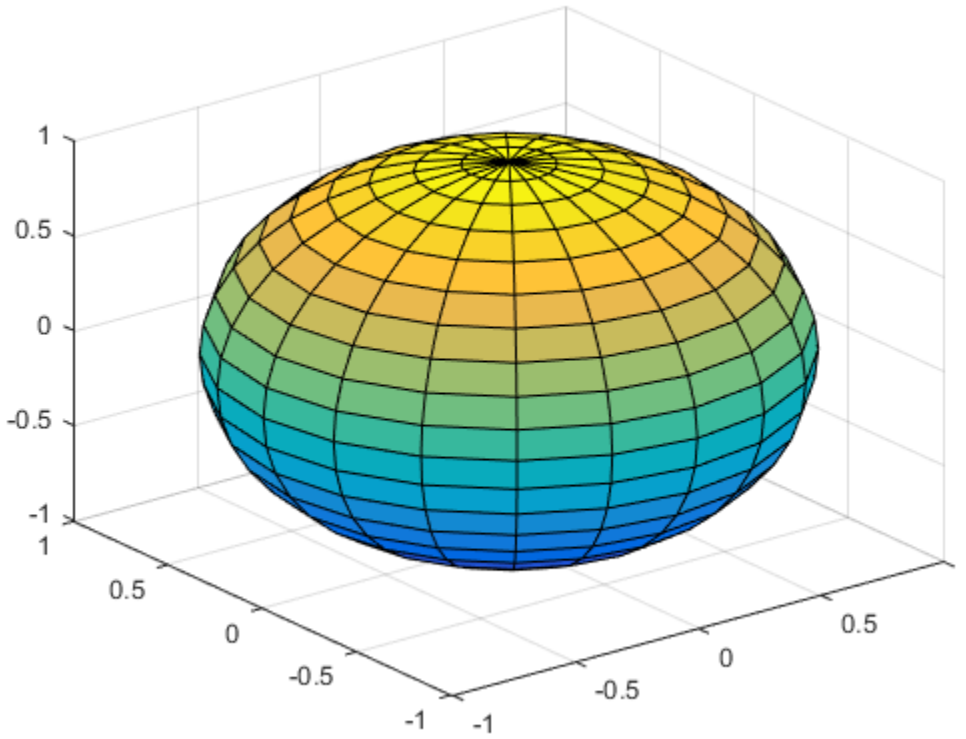
`caxis` changes the `CLim` and `CLimMode` properties of axes graphics objects.

Examples

Change Color Axis Scaling

Define `X`, `Y`, and `Z` as data for a sphere and view the data as a surface. Define the colors for the surface, `C`.

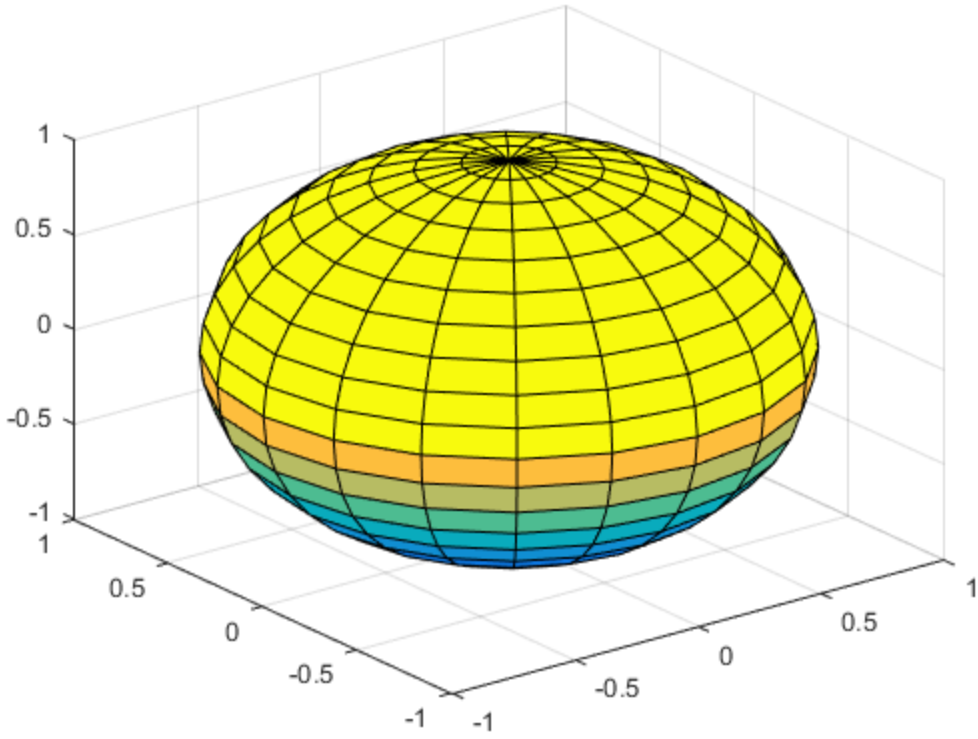
```
[X,Y,Z] = sphere;
C = Z;
surf(X,Y,Z,C)
```



Values of `C` are in the range `[-1,1]`. Values of `C` near -1 are assigned the lowest values in the colormap. Values of `C` near 1 are assigned the highest values in the colormap.

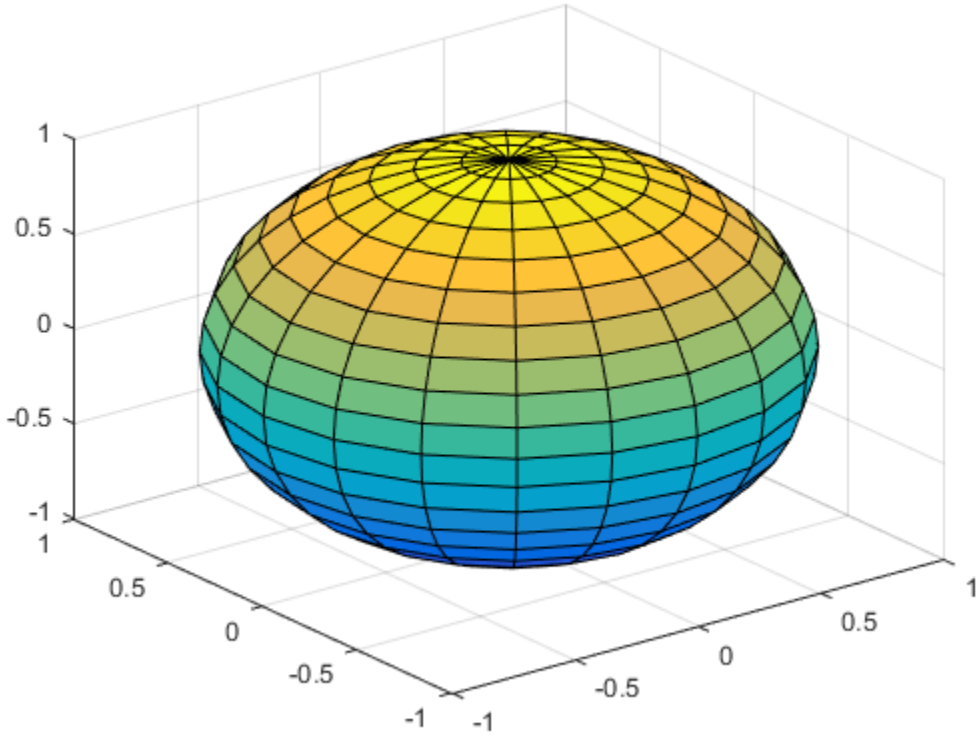
Map the top half of the surface to the highest value in the color table by setting the maximum color limit to 0.

```
caxis([-1,0])
```



Reset the axis scaling back to its default range.

```
caxis auto
```



Return the values of the current color limits.

```
v = caxis
```

```
v =

    -1     1
```

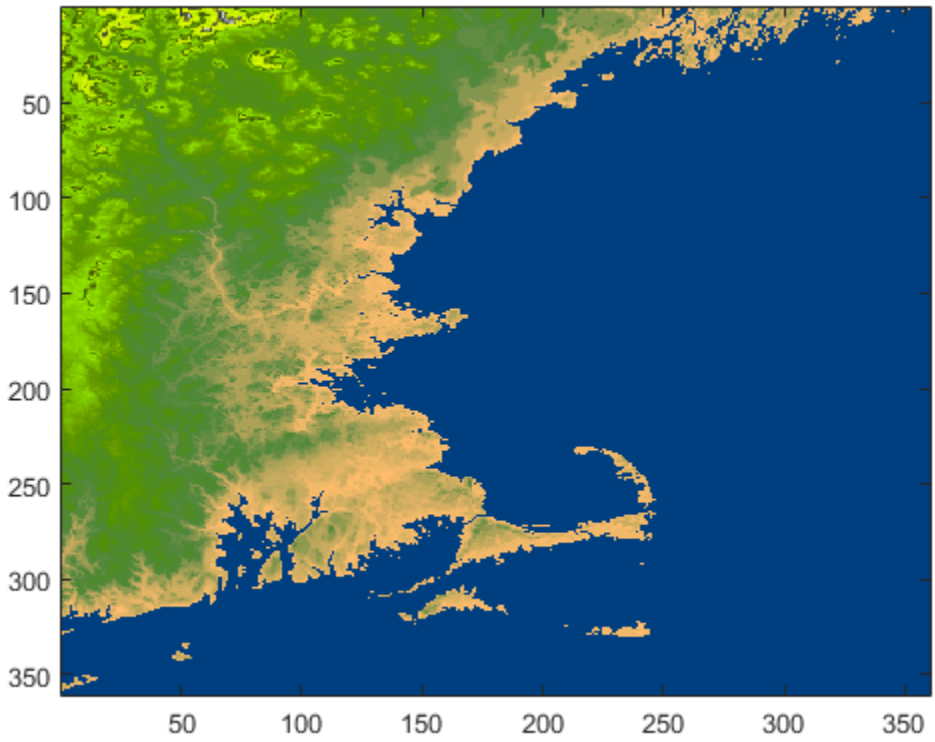
Set Color Axis Scaling for Image Data

Load the `cape` file which contains the image data, `X`, and the colormap, `map`, for Cape Cod, Massachusetts.

```
load cape
```

Display the image with `CDataMapping` set to `scaled`, and use the `map` colormap.

```
figure
image(X,'CDataMapping','scaled')
colormap(map)
```



The color limits span the range of the image data, which is 1 to 192. The blue color of the ocean is the first color in the colormap and is mapped to the lowest data value, 1. You can effectively move sea level by changing the lower color limit value using `caxis`.

Display the image data using four different color limit values.

```
load cape
```

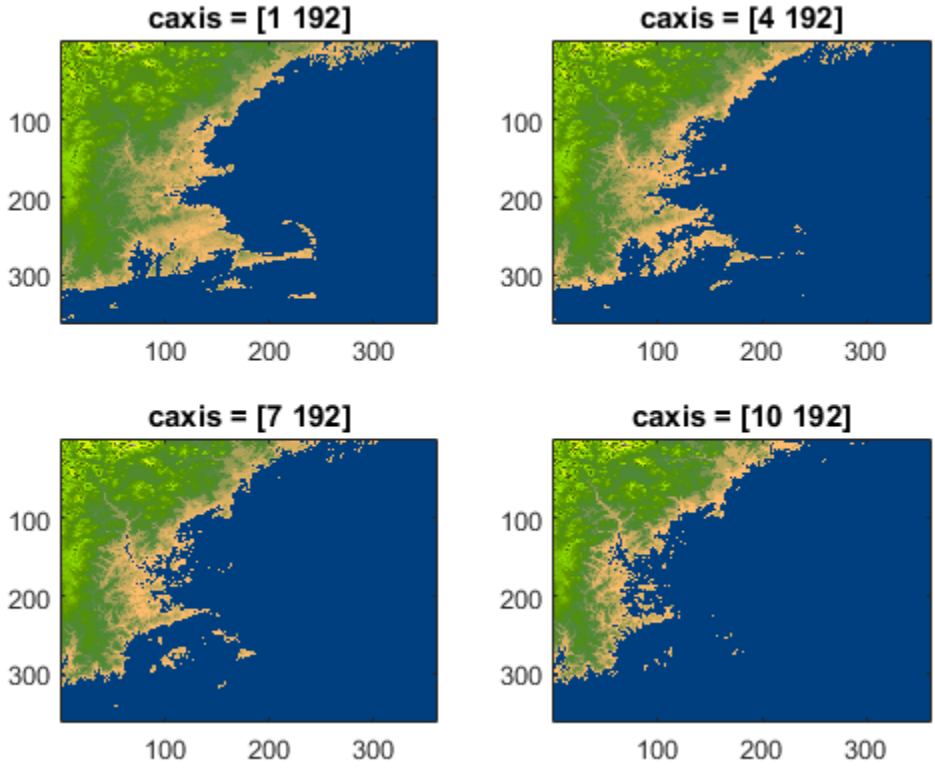
```
figure
colormap(map)

subplot(2,2,1)
image(X,'CDataMapping','scaled')
title('caxis = [1 192]')

subplot(2,2,2)
image(X,'CDataMapping','scaled')
caxis([4,192]) % change caxis
title('caxis = [4 192]')

subplot(2,2,3)
image(X,'CDataMapping','scaled')
caxis([7,192]) % change caxis
title('caxis = [7 192]')

subplot(2,2,4)
image(X,'CDataMapping','scaled')
caxis([10,192]) % change caxis
title('caxis = [10 192]')
```



More About

Tips

How Color Axis Scaling Works

Surface, patch, and image graphics objects having indexed `CData` and `CDataMapping` set to `scaled` map `CData` values to colors in the figure colormap each time they render. `CData` values equal to or less than `cmin` map to the first color value in the colormap, and `CData` values equal to or greater than `cmax` map to the last color value in the colormap. The following linear transformation is performed on the intermediate values (referred to

as `C` below) to map them to an entry in the colormap (whose length is `m`, and whose row index is referred to as `index` below).

```
index = fix((C-cmin)/(cmax-cmin)*m)+1;
%Clamp values outside the range [1 m]
index(index<1) = 1;
index(index>m) = m;
```

Introduced before R2006a

cd

Change current folder

Syntax

```
cd(newFolder)
oldFolder = cd(newFolder)
cd
```

Description

`cd(newFolder)` changes the current folder to newFolder.

`oldFolder = cd(newFolder)` returns the existing current folder as a string to oldFolder, and then changes the current folder to newFolder.

`cd` displays the current folder.

Input Arguments

`newFolder`

A string specifying the folder to which you want to change the current folder. Valid values can be any one of the following:

- A full or relative path.
- `../`, which indicates one level up from the current folder.
- Multiple strings of `../`, which indicates multiple levels up from the current folder.
- `./`, which indicates a path relative to the current folder, although without the `./`, `cd` assumes that the path is relative to the current folder.

Output Arguments

`oldFolder`

A string specifying the current folder that was in place when you issued the `cd` command.

Definitions

The current folder is a reference location that MATLAB uses to find files. This folder is sometimes referred to as the *current directory*, *current working folder*, or *present working directory*.

Examples

Use `cd` with the `matlabroot` function to change the current folder to the examples directory for the currently running version of MATLAB:

```
cd(fullfile(matlabroot, '/help/techdoc/matlab_env/examples'))
```

On a Microsoft Windows platform, specify the full path to change the current folder from any location to the examples directory for MATLAB Version 7.11 (R2010b), assuming that version is installed on your `C:` drive:

```
cd('C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples')

% Change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples to
% C:/Program Files/MATLAB/R2010b/help/techdoc:

cd ../..

% Use a relative path to change the current folder from
% C:/Program Files/MATLAB/R2010b/help/techdoc back to
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples:

cd matlab_env/examples

% Change the current folder from its current location to a new
% location,but save its previous location. Later, change the
```

```
% current folder to the previous location.

% This returns
% C:/Program Files/MATLAB/R2010b/help/techdoc/matlab_env/examples
% to oldFolder, and then changes the current folder to
% C:/Program Files:

oldFolder = cd('C:/Program Files')

% Display current folder:

pwd

% Change the current folder to the previous location:
cd(oldFolder)

pwd
```

On a UNIX platform, change the current folder to the examples directory for the currently running version of MATLAB, assuming it is installed in your home location:

```
cd('~/help/techdoc/matlab_env/examples')
```

More About

Tips

- When using the command syntax (`cd newfolder`), if the `newFolder` string contains spaces, enclose the string in single quotation marks.
- On UNIX platforms, use the ~ (tilde) character to represent the user home directory.
- If you use `cd` within a local function, the folder change persists after program control returns from the function. That is, the scope of the folder change is global.

- "Specify File Names"
- "Files and Folders that MATLAB Accesses"

convexHull

Class: DelaunayTri

(Will be removed) Convex hull

Note: `convexHull(DelaunayTri)` will be removed in a future release. Use `convexHull(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
K = convexHull(DT)
[K AV] = convexHull(DT)
```

Description

`K = convexHull(DT)` returns the indices into the array of points `DT.X` that correspond to the vertices of the convex hull.

`[K AV] = convexHull(DT)` returns the convex hull and the area or volume bounded by the convex hull.

Input Arguments

`DT`	Delaunay triangulation.

Output Arguments

`K`	If the points lie in 2-D space, `K` is a column vector of length `numf`. Otherwise `K` is a matrix of size `numf`-by-`ndim`, `numf` being the number of

	facets in the convex hull, and `ndim` the dimension of the space where the points reside.
`AV`	The area or volume of the convex hull.

Definitions

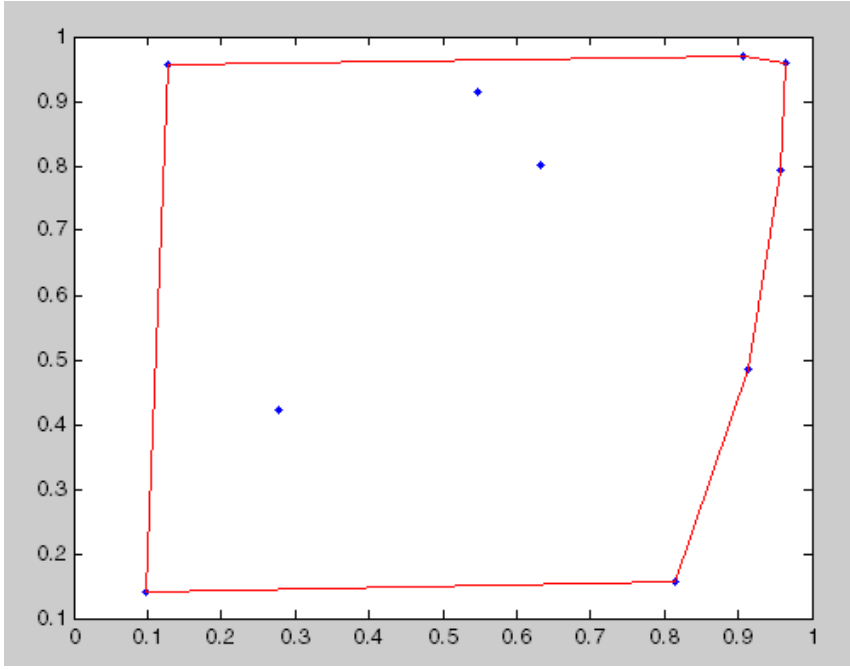
The convex hull of a set of points `X` is the smallest convex region containing all of the points of `X`.

Examples

Example 1

Compute the convex hull of a set of random points located within a unit square in 2-D space.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
k = convexHull(dt)
plot(dt.X(:,1),dt.X(:,2), '.', 'markersize',10); hold on;
plot(dt.X(k,1),dt.X(k,2), 'r'); hold off;
```



Example 2

Compute the convex hull of a set of random points located within a unit cube in 3-D space, and the volume bounded by the convex hull.

```
X = rand(25,3)
dt = DelaunayTri(X)
[ch v] = convexHull(dt)
trisurf(ch, dt.X(:,1),dt.X(:,2),dt.X(:,3), 'FaceColor', 'cyan')
```

cd

Class: FTP

Change or view current folder on FTP server

Syntax

```
cd(ftpobj,folder)
cd(ftpobj)
```

Description

`cd(ftpobj,folder)` changes the current folder on the FTP server.

`cd(ftpobj)` displays the current folder on the server.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`folder`

String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

Examples

Connect to the MathWorks FTP server, change to the `pub` folder, and view its contents:

```
mw=ftp('ftp.mathworks.com');
cd(mw,'pub');
dir(mw)
```

See Also

`dir` | `ftp`

Introduced before R2006a

cdf2rdf

Convert complex diagonal form to real block diagonal form

Syntax

```
[V,D] = cdf2rdf(V,D)
```

Description

If the eigensystem `[V,D] = eig(X)` has complex eigenvalues appearing in complex-conjugate pairs, `cdf2rdf` transforms the system so `D` is in real diagonal form, with 2-by-2 real blocks along the diagonal replacing the complex pairs originally there. The eigenvectors are transformed so that

```
X = V*D/V
```

continues to hold. The individual columns of `V` are no longer eigenvectors, but each pair of vectors associated with a 2-by-2 block in `D` spans the corresponding invariant vectors.

Examples

The matrix

```
X =
    1     2     3
    0     4     5
    0    -5     4
```

has a pair of complex eigenvalues.

```
[V,D] = eig(X)

V =

    1.0000      -0.0191 - 0.4002i     -0.0191 + 0.4002i
         0            0 - 0.6479i           0 + 0.6479i
         0       0.6479                 0.6479
```

```
D =

    1.0000            0                       0
         0       4.0000 + 5.0000i             0
         0            0                 4.0000 - 5.0000i
```

Converting this to real block diagonal form produces

```
[V,D] = cdf2rdf(V,D)

V =

    1.0000    -0.0191     -0.4002
         0          0     -0.6479
         0     0.6479           0

D =

    1.0000          0          0
         0     4.0000     5.0000
         0    -5.0000     4.0000
```

More About

Algorithms

The real diagonal form for the eigenvalues is obtained from the complex form using a specially constructed similarity transformation.

`eig` | `rsf2csf`

Introduced before R2006a

cdfepoch

Convert date string or serial date number to CDF formatted dates

Syntax

```
E = cdfepoch(date)
```

Description

`E = cdfepoch(date)` converts the date, specified by `date`, into a `cdfepoch` object. `date` must be a valid date string, returned by `datestr`, or a serial date number, returned by `datenum`. `date` can also be a `cdfepoch` object.

When writing data to a CDF file using `cdfwrite`, use `cdfepoch` to convert MATLAB date strings or serial date numbers to CDF formatted dates. The MATLAB `cdfepoch` object simulates the `CDFEPOCH` data type in CDF files.

To convert a `cdfepoch` object into a MATLAB serial date number, use the `todatenum` function.

Definitions

The MATLAB serial date number calculates dates differently than CDF epochs.

A MATLAB serial date number represents the whole and fractional number of days from 0-Jan-0000 to a specific date. The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.

A CDF epoch is the number of milliseconds since 1-Jan-0000.

Examples

Convert the current time in serial date number format into a CDF epoch object.

```
% NOW function returns current time as serial date number
```

```
dateobj = cdfepoch(now)

dateobj =

     cdfepoch object:
     11-Mar-2009 15:09:25
```

Convert the current time in date string format into a CDF epoch object.

```
% DATESTR function returns date as string
dateobj2 = cdfepoch(datestr(now))

dateobj2 =

     cdfepoch object:
     11-Mar-2009 15:09:25
```

Convert the CDF epoch object into a serial date number.

```
dateobj = cdfepoch(now);
mydatenum = todatenum(dateobj)

mydatenum =

     7.3384e+005
```

Introduced before R2006a

cdfinfo

Information about Common Data Format (CDF) file

Syntax

```
info = cdfinfo(filename)
```

Description

`info = cdfinfo(filename)` returns information about the Common Data Format (CDF) file specified in the string `filename`.

Note Because `cdfinfo` creates temporary files, the current working directory must be writeable.

The following table lists the fields returned in the structure, `info`. The table lists the fields in the order that they appear in the structure.

Field	Description
`Filename`	Text string specifying the name of the file
`FileModDate`	Text string indicating the date the file was last modified
`FileSize`	Double scalar specifying the size of the file, in bytes
`Format`	Text string specifying the file format
`FormatVersion`	Text string specifying the version of the CDF library used to create the file
`FileSettings`	Structure array containing library settings used to create the file
`Subfiles`	Filenames containing the CDF file's data, if it is a multi-file format CDF
`Variables`	N-by-6 cell array, where N is the number of variables, containing information about the variables in the file. The columns present the following information:

Field	Description	
	Column 1	Text string specifying name of variable
	Column 2	Double array specifying the dimensions of the variable, as returned by the `size` function
	Column 3	Double scalar specifying the number of records assigned for the variable
	Column 4	Text string specifying the data type of the variable, as stored in the CDF file

	Column 5	Text string specifying the record and dimension variance settings for the variable. The single `T` or `F` to the left of the slash designates whether values vary by record. The zero or more `T` or `F` letters to the right of the slash designate whether values vary at each dimension. Here are some examples.
		`T/  (scalar variable`
		`F/T (one-dimensional variable)`
		T/TFF (three-dimensional variable)

`GlobalAttributes`	Structure array that contains one field for each global attribute. The name of each field corresponds to the name of an attribute. The data in each field, contained in a cell array, represents the entry values for that attribute.	
`VariableAttributes`	Structure array that contains one field for each variable attribute. The name of each field corresponds to the name of an attribute. The data in each field is contained in a *n*-by-2 cell array, where *n* is the number of variables. The first column of this cell array contains the variable names associated with the entries. The second column contains the entry values.	

Note Attribute names returned by `cdfinfo` might not match the names of the attributes in the CDF file exactly. Attribute names can contain characters that are illegal in MATLAB field names. `cdfinfo` removes illegal characters that appear at the beginning of attributes and replaces other illegal characters with underscores ('_'). When `cdfinfo` modifies an attribute name, it appends the attribute's internal number to the end

of the field name. For example, the attribute name `Variable%Attribute` becomes `Variable_Attribute_013`.

Note: To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see `cdflib.setValidate`.

Examples

Get Information About CDF File

Get information about the sample file, `example.cdf`.

```
info = cdfinfo('example.cdf')
```

```
info =

             Filename: 'example.cdf'
          FileModDate: '10-May-2010 21:35:00'
             FileSize: 1310
               Format: 'CDF'
        FormatVersion: '2.7.0'
         FileSettings: [1x1 struct]
             Subfiles: {}
            Variables: {6x6 cell}
      GlobalAttributes: [1x1 struct]
    VariableAttributes: [1x1 struct]
```

View information about the variables in the file.

```
info.Variables
```

```
ans =

  Columns 1 through 5

    'Time'                [1x2 double]    [24]    'epoch'     'T/'
    'Longitude'           [1x2 double]    [ 1]    'int8'      'F/FT'
    'Latitude'            [1x2 double]    [ 1]    'int8'      'F/TF'
    'Data'                [1x3 double]    [ 1]    'double'    'T/TTT'
```

```
    'multidimensional'    [1x4 double]    [ 1]    'uint8'     'T/TTTT'
    'Temperature'         [1x2 double]    [10]    'int16'     'T/TT'

  Column 6

    'Full'
    'Full'
    'Full'
    'Full'
    'Full'
    'Full'
```

Introduced before R2006a

cdflib

Interact directly with CDF library

Description

MATLAB provides direct access to dozens of functions in the CDF library. Using these functions, you can read and write data, create variables, attributes, and entries, and take advantage of other features of the CDF library. To use these functions, you must be familiar with the CDF C interface. Documentation about CDF is available at the CDF website.

The MATLAB functions correspond to functions in the CDF library new Standard Interface. In most cases, the syntax of a MATLAB function is similar to the syntax of the corresponding CDF library function. To use these functions, you must prefix the function name with the package name, `cdflib`. For example, to use the CDF library function to open an existing CDF file, use this syntax:

```
cdfid = cdflib.open('example.cdf');
```

MATLAB supports CDF version 3.3.0. For copyright information, see the `cdfcopyright.txt` file.

The following tables list all of the functions in the MATLAB CDF library package, grouped by category.

Note: For information about MATLAB support for the Network Common Data Form (netCDF), which is a completely separate, incompatible format, see `netcdf`.

Library Information

cdflib.getConstantNames	Names of Common Data Format (CDF) library constants
cdflib.getConstantValue	Numeric value corresponding to Common Data Format (CDF) library constant

cdflib.getFileBackward	Return current backward compatibility mode setting
cdflib.getLibraryCopyright	Copyright notice of Common Data Format (CDF) library
cdflib.getLibraryVersion	Library version and release information
cdflib.getValidate	Library validation mode
cdflib.setFileBackward	Set backward compatibility mode
cdflib.setValidate	Specify library validation mode

File Operations

cdflib.close	Close Common Data Format (CDF) file
cdflib.create	Create Common Data Format (CDF) file
cdflib.delete	Delete existing Common Data Format (CDF) file
cdflib.getCacheSize	Number of cache buffers used
cdflib.getChecksum	Checksum mode
cdflib.getCompression	Compression settings
cdflib.getCompressionCacheSize	Number of compression cache buffers
cdflib.getCopyright	Copyright notice in Common Data Format (CDF) file

cdflib.getFormat	Format of Common Data Format (CDF) file
cdflib.getMajority	Majority of variables
cdflib.getName	Name of Common Data Format (CDF) file
cdflib.getReadOnlyMode	Read-only mode
cdflib.getStageCacheSize	Number of cache buffers for staging
cdflib.getVersion	Common Data Format (CDF) library version and release information
cdflib.inquire	Basic characteristics of Common Data Format (CDF) file
cdflib.open	Open existing Common Data Format (CDF) file
cdflib.setCacheSize	Specify number of dotCDF cache buffers
cdflib.setChecksum	Specify checksum mode
cdflib.setCompression	Specify compression settings
cdflib.setCompressionCacheSize	Specify number of compression cache buffers
cdflib.setFormat	Specify format of Common Data Format (CDF) file
cdflib.setMajority	Specify majority of variables
cdflib.setReadOnlyMode	Specify read-only mode

cdflib.setStageCacheSize	Specify number of staging cache buffers for Common Data Format (CDF) file

Variables

cdflib.closeVar	Close specified variable from multifile format Common Data Format (CDF) file
cdflib.createVar	Create new variable
cdflib.deleteVar	Delete variable
cdflib.deleteVarRecords	Delete range of records from variable
cdflib.getVarAllocRecords	Number of records allocated for variable
cdflib.getVarBlockingFactor	Blocking factor for variable
cdflib.getVarCacheSize	Number of multifile cache buffers
cdflib.getVarCompression	Information about compression used by variable
cdflib.getVarData	Single value from record in variable
cdflib.getVarMaxAllocRecNum	Maximum allocated record number for variable
cdflib.getVarMaxWrittenRecNum	Maximum written record number for variable
cdflib.getVarsMaxWrittenRecNum	Maximum written record number for CDF file

cdflib.getVarName	Variable name, given variable number
cdflib.getVarNum	Variable number, given variable name
cdflib.getVarNumRecsWritten	Number of records written to variable
cdflib.getVarPadValue	Pad value for variable
cdflib.getVarRecordData	Entire record for variable
cdflib.getVarReservePercent	Compression reserve percentage for variable
cdflib.getVarSparseRecords	Information about how variable handles sparse records
cdflib.hyperGetVarData	Read hyperslab of data from variable
cdflib.hyperPutVarData	Write hyperslab of data to variable
cdflib.inquireVar	Information about variable
cdflib.putVarData	Write single value to variable
cdflib.putVarRecordData	Write entire record to variable
cdflib.renameVar	Rename existing variable
cdflib.setVarAllocBlockRecords	Specify range of records to be allocated for variable
cdflib.setVarBlockingFactor	Specify blocking factor for variable

cdflib.setVarCacheSize	Specify number of multi-file cache buffers for variable
cdflib.setVarCompression	Specify compression settings used with variable
cdflib.setVarInitialRecs	Specify initial number of records written to variable
cdflib.setVarPadValue	Specify pad value used with variable
cdflib.SetVarReservePercent	Specify reserve percentage for variable
cdflib.setVarsCacheSize	Specify number of cache buffers used for all variables
cdflib.setVarSparseRecords	Specify how variable handles sparse records

Attributes

cdflib.createAttr	Create attribute
cdflib.deleteAttr	Delete attribute
cdflib.deleteAttrEntry	Delete attribute entry
cdflib.deleteAttrgEntry	Delete entry in global attribute
cdflib.getAttrEntry	Value of entry in attribute with variable scope
cdflib.getAttrgEntry	Value of entry in global attribute

cdflib.getAttrMaxEntry	Number of last entry for variable attribute
cdflib.getAttrMaxgEntry	Number of last entry for global attribute
cdflib.getAttrName	Name of attribute, given attribute number
cdflib.getAttrNum	Attribute number, given attribute name
cdflib.getAttrScope	Scope of attribute
cdflib.getNumAttrEntries	Number of entries for attribute with variable scope
cdflib.getNumAttrgEntries	Number of entries for attribute with global scope
cdflib.getNumAttributes	Number of attributes with variable scope
cdflib.getNumgAttributes	Number of attributes with global scope
cdflib.inquireAttr	Information about attribute
cdflib.inquireAttrEntry	Information about entry in attribute with variable scope
cdflib.inquireAttrgEntry	Information about entry in attribute with global scope
cdflib.putAttrEntry	Write value to entry in attribute with variable scope
cdflib.putAttrgEntry	Write value to entry in attribute with global scope

cdflib.renameAttr	Rename existing attribute

Utility Functions

cdflib.computeEpoch	Convert time value to `CDF_EPOCH` value
cdflib.computeEpoch16	Convert time value to `CDF_EPOCH16` value
cdflib.epoch16Breakdown	Convert `CDF_EPOCH16` value to time value
cdflib.epochBreakdown	Convert `CDF_EPOCH` value into time value

- “Export to CDF Files”

cdflib.close

Close Common Data Format (CDF) file

Syntax

```
cdflib.close(cdfId)
```

Description

`cdflib.close(cdfId)` closes the specified CDF file. `cdfId` identifies the CDF file.

You must close a CDF to guarantee that all modifications you made since opening the CDF are actually written to the file.

Examples

Open the example CDF file and then close it.

```
cdfid = cdflib.open('example.cdf');
cdflib.close(cdfid)
```

References

This function corresponds to the CDF library C API routine `CDFcloseCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.open` | `cdflib.create`

cdflib.closeVar

Close specified variable from multifile format Common Data Format (CDF) file

Syntax

```
cdflib.closeVar(cdfId,varNum)
```

Description

`cdflib.closeVar(cdfId,varNum)` closes a variable in a multifile format CDF.

`cdfId` identifies the CDF file and `varNum` is a numeric value that specifies the variable. Variable identifiers (variable numbers) are zero-based.

For multifile CDFs, you must close all open variable files to guarantee that all modifications you have made are actually written to the CDF file(s). You do not need to call this function for variables in a single-file format CDF.

Examples

Create a multifile CDF, create a variable, and then close the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_multifile.cdf');

% Make it a multifile format CDF
cdflib.setFormat(cdfid,'MULTI_FILE')

% Create a variable in the CDF.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

%  Close the variable.
cdflib.closeVar(cdfid, varnum)

% Clean up
cdflib.delete(cdfid)
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFclosezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getVarNum` | `cdflib.setFormat` | `cdflib.getFormat`

cdflib.computeEpoch

Convert time value to CDF_EPOCH value

Syntax

```
epoch = cdflib.computeEpoch(timeval)
```

Description

`epoch = cdflib.computeEpoch(timeval)` converts the time value specified by `timeval` into a CDF_EPOCH value.

Input Arguments

`timeval`

7-by-1 time vector. The following table describes the time components.

Component	Description
year	AD e.g. 1994
month	1–12
day	1–31
hour	0–23
minute	0–59
second	0–59
millisecond	0–999

Output Arguments

`epoch`

MATLAB `double` representing a CDF_EPOCH time value.

Examples

Convert a time value into a `CDF_EPOCH` value.

```
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);
```

References

This function corresponds to the CDF library C API routine `computeEPOCH`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.computeEpoch16` | `cdflib.epochBreakdown` | `cdflib.epoch16Breakdown`

cdflib.computeEpoch16

Convert time value to CDF_EPOCH16 value

Syntax

```
epoch16 = cdflib.computeEpoch16(timeval)
```

Description

`epoch16 = cdflib.computeEpoch16(timeval)` converts the time value specified by `timeval` into a CDF_EPOCH16 value.

Input Arguments

`timeval`

10-by-1 time vector. The following table describes the time components. To specify multiple time values, use additional columns.

Component	Description
year	AD e.g. 1994
month	1–12
day	1–31
hour	0–23
minute	0–59
second	0–59
millisecond	0–999
microsecond	0–999
nanosecond	0–999
picosecond	0–999

Output Arguments

`epoch16`

CDF Epoch16 time value. If the input argument `timeval` has `m-by-10` elements, the return value `epoch16` will have size `2-by-m`

Examples

Convert the time value into an `CDF_EPOCH16` value:

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
epoch16 = cdflib.computeEpoch16(timeval);
```

References

This function corresponds to the CDF library C API routine `computeEPOCH16`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.computeEpoch` | `cdflib.epochBreakdown` | `cdflib.epoch16Breakdown`

cdflib.create

Create Common Data Format (CDF) file

Syntax

```
cdfId = cdflib.create(filename)
```

Description

`cdfId = cdflib.create(filename)` creates a new CDF file with the name specified by the text string *`filename`*. Returns the CDF file identifier `cdfId`.

Examples

Create a CDF file. To run this example, you must have write permission in your current directory.

```
cdfId = cdflib.create('myfile.cdf');

% Clean up
cdflib.delete(cdfId);

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFcreateCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.open` | `cdflib.close`

cdflib.createAttr

Create attribute

Syntax

```
attrnum = cdflib.createAttr(cdfId,attrName,scope)
```

Description

`attrnum = cdflib.createAttr(cdfId,attrName,scope)` creates an attribute in a CDF file with the specified scope.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrName`

Text string that specifies the name you want to assign to the attribute.

`scope`

One of the following text strings, or its numeric equivalent, that specifies the scope of the attribute.

Text String	Description
`'global_scope'`	Attribute applies to the CDF as a whole.
`'variable_scope'`	Attribute applies only to the variable

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Output Arguments

attrNum

Numeric value identifying the attribute. Attribute numbers are zero-based.

Examples

Create a CDF, and then create an attribute in the CDF. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute
attrNum = cdflib.createAttr(cdfId,'Purpose','global_scope');

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFcreateAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getAttrNum` | `cdflib.deleteAttr` | `cdflib.getConstantValue` | `cdflib.getConstantNames`

cdflib.createVar

Create new variable

Syntax

```
varnum = cdflib.createVar(cdfId, varname, datatype, numElements,
dims, recVariance, dimVariance)
```

Description

`varnum = cdflib.createVar(cdfId, varname, datatype, numElements, dims, recVariance, dimVariance)` creates a new variable in the Common Data Format (CDF) file with the specified characteristics.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varname`

Text string that specifies the name you want to assign to the variable.

`datatype`

Data type of the variable. One of the following text strings, or its numeric equivalent, that specifies a valid CDF data type.

CDF Data Type	Description
`CDF_BYTE`	1-byte, signed integer
`CDF_CHAR`	1 byte, signed character data type that maps to the MATLAB `char` class
`CDF_INT1`	1-byte, signed integer
`CDF_UCHAR`	1 byte, unsigned character data type that maps to the MATLAB `uint8` class

CDF Data Type	Description
CDF_UINT1	1-byte, unsigned integer
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

numElements

Number of elements per datum. Value should be 1 for all data types, except CDF_CHAR and CDF_UCHAR.

dims

A vector of the dimensions extents; empty if there are no dimension extents.

recVariance

Specifies record variance: true or false.

dimVariance

A vector of logicals; empty if there are no dimensions.

Output Arguments

varNum

The numeric identifier for the variable. Variable numbers are zero-based.

Examples

Create a CDF file and then create a variable named `'Time'` in the CDF. The variable has no dimensions and varies across records. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Retrieve info about the file again to verify variable was created.
% Note value of numVars field is now 1.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 1
    numvAttrs: 0
    numgAttrs: 0

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFcreatezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

See Also

`cdflib.deleteVar` | `cdflib.closeVar`

cdflib.delete

Delete existing Common Data Format (CDF) file

Syntax

```
cdflib.delete(cdfId)
```

Description

`cdflib.delete(cdfId)` deletes the existing CDF file specified by the identifier `cdfId`. If the CDF file is a multi-file format CDF, the `cdflib.delete` function also deletes the variable files (having file extensions of `.z0`, `.z1`, etc.).

Examples

Create a CDF file, and then delete it. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('mytempfile.cdf');

% Verify that the file was created.
ls *.cdf

mytempfile.cdf

% Delete the file.
cdflib.delete(cdfId)

% Verify that the file no longer exists.
ls *.cdf
```

References

This function corresponds to the CDF library C API routine `CDFdeleteCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.create` | `cdflib.setFormat`

cdflib.deleteAttr

Delete attribute

Syntax

```
cdflib.deleteAttr(cdfId,attrNum)
```

Description

`cdflib.deleteAttr(cdfId,attrNum)` deletes the specified attribute from the CDF file.

`cdfId` identifies the Common Data Format (CDF) file.`attrNum` is a numeric identifier that specifies the attribute. Attribute numbers are zero-based.

Examples

Create a CDF file, and then create an attribute in the file. Then delete the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create attribute.
attrNum = cdflib.createAttr(cdfId,'Purpose','global_scope');

% Prove it exists.
anum = cdflib.getAttrNum(cdfid,'Purpose')

anum =

     0

% Delete the attribute.
cdflib.deleteAttr(cdfid,attrNum);

% Clean up
```

```
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFdeleteAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.createAttr` | `cdflib.getAttrNum`

cdflib.deleteAttrEntry

Delete attribute entry

Syntax

```
cdflib.deleteAttrEntry(cdfId,attrNum,entryNum)
```

Description

`cdflib.deleteAttrEntry(cdfId,attrNum,entryNum)` deletes an entry from an attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

`entryNum`

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Examples

Create a CDF, and then create an attribute in the file. Write a value to an entry for the attribute, and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create an attribute with variable scope in the file.
attrNum = cdflib.createAttr(cdfid,'my_var_scope_attr','variable_scope');

% Write a value to an entry for the attribute
cdflib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My attr value');

% Get the value of the attribute entry
value = cdflib.getAttrEntry(cdfid,attrNum,0)

value =

My attr value

% Delete the entry
cdflib.deleteAttrEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdflib.getAttrEntry(cdfid,attrNum,0)  % Should fail

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFdeleteAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.deleteAttrgEntry

Delete entry in global attribute

Syntax

```
cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)
```

Description

`cdflib.deleteAttrgEntry(cdfId,attrNum,entryNum)` deletes an entry from a global attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

`entryNum`

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Examples

Create a CDF and create a global attribute in the file. Write a value to an entry for the attribute and then delete the entry. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create an attribute with global scope in the file.
attrNum = cdflib.createAttr(cdfid,'my_global_attr','global_scope');

% Write a value to an entry for the attribute
cdflib.putAttrgEntry(cdfid,attrNum,0,'CDF_CHAR','My global attr');

% Get the value of the global attribute entry
value = cdflib.getAttrgEntry(cdfid,attrNum,0)

value =

My global attr

% Delete the entry
cdflib.deleteAttrgEntry(cdfid,attrNum,0);

% Now try to view the value of the entry
% Should return NO_SUCH_ENTRY failure.
value = cdflib.getAttrgEntry(cdfid,attrNum,0)  % Should fail

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFdeleteAttrgEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

`cdflib.deleteAttr` | `cdflib.deleteAttrEntry`

cdflib.deleteVar

Delete variable

Syntax

```
cdflib.deleteVar(cdfId,varNum)
```

Description

`cdflib.deleteVar(cdfId,varNum)` deletes a variable from a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that specifies the variable. Variable numbers are zero-based.

Examples

Create a CDF, create a variable in the CDF, and then delete it.

```
cdfid = cdflib.create('mycdf.cdf');

% Initially the file contains no variables.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create a variable in the CDF.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);
```

```
% Retrieve info about the variable in the CDF.

info = cdflib.inquireVar(cdfid, 0)

info =

           name: 'Time'
       datatype: 'cdf_int1'
    numElements: 1
           dims: []
    recVariance: 1
    dimVariance: []

% Delete the variable from the CDF

cdflib.deleteVar(cdfid,0);

% Check to see if the variable was deleted from the CDF.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

See Also

`cdflib.createVar`

cdflib.deleteVarRecords

Delete range of records from variable

Syntax

```
cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)
```

Description

`cdflib.deleteVarRecords(cdfId,varNum,startRec,endRec)` deletes a range of records from a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value that identifies the variable. Variable numbers are zero-based.

`startRec`

Numeric value that specifies the record at which to start deleting records. Record numbers are zero-based.

`endRec`

Numeric value that specifies the record at which to stop deleting records. Record numbers are zero-based.

Examples

Make a writable copy of the example CDF, get the number of a variable in the CDF, and delete specific records in the variable. To run this example, you must be in a writable folder.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.cdf');
copyfile(srcFile,'myfile.cdf');
fileattrib('myfile.cdf','+w');
cdfid = cdflib.open('myfile.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
cdflib.deleteVarRecords(cdfid,varnum,1,2);
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFdeletezVarRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.epoch16Breakdown

Convert CDF_EPOCH16 value to time value

Syntax

```
timeVec = cdflib.epoch16Breakdown(epoch16Time)
```

Description

`timeVec = cdflib.epoch16Breakdown(epoch16Time)` convert a CDF_EPOCH16 value into a time vector. `timeVec` will have 10-by-n elements, where n is the number of CDF_EPOCH16 values.

The following table describes the time value components.

timeVec Element	Description	Valid Values
`timeVec(1,:)`	Year AD	e.g. 1994
`timeVec(2,:)`	Month	1–12
`timeVec(3,:)`	Day	1–31
`timeVec(4,:)`	Hour	0–23
`timeVec(5,:)`	Minute	0–59
`timeVec(6,:)`	Second	0–59
`timeVec(7,:)`	Millisecond	0–999
`timeVec(8,:)`	Microsecond	0–999
`timeVec(9,:)`	Nanosecond	0–999
`timeVec(10,:)`	Picosecond	0–999

Examples

Convert CDF_EPOCH16 value into time value.

```
timeval = [1999; 12; 31; 23; 59; 59; 50; 100; 500; 999];
epoch16 = cdflib.computeEpoch16(timeval);

timevec = cdflib.epoch16Breakdown(epoch16)

timevec =

        1999
          12
          31
          23
          59
          59
          50
         100
         500
         999
```

References

This function corresponds to the CDF library C API routine `EPOCH16breakdown`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.computeEpoch16`

cdflib.epochBreakdown

Convert CDF_EPOCH value into time value

Syntax

```
timeVec = cdflib.epochBreakdown(epochTime)
```

Description

`timeVec = cdflib.epochBreakdown(epochTime)` decomposes the CDF_EPOCH value, `epochTime` value into individual time components. `timeVec` will have 7-by-*n* elements, where *n* is the number of CDF_EPOCH values in `epochTime`.

The return value `timeVec` has the following elements:

timeVec Element	Description	Valid Values
`timeVec(1,:)`	Year AD	e.g. 1994
`timeVec(2,:)`	Month	1–12
`timeVec(3,:)`	Day	1–31
`timeVec(4,:)`	Hour	0–23
`timeVec(5,:)`	Minute	0–59
`timeVec(6,:)`	Second	0–59
`timeVec(7,:)`	Millisecond	0–999

Examples

Convert a CDP_EPOCH value into a time vector.

```
% First convert a time vector into a CDF_EPOCH value
timeval = [1999 12 31 23 59 59 0];
epoch = cdflib.computeEpoch(timeval);
```

```
% Convert the CDF_EPOCH value into a time vector
timevec = cdflib.epochBreakdown(epoch)

timevec =

        1999
          12
          31
          23
          59
          59
           0
```

References

This function corresponds to the CDF library C API routine `EPOCHbreakdown`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

cdflib.getAttrEntry

Value of entry in attribute with variable scope

Syntax

```
value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)
```

Description

`value = cdflib.getAttrEntry(cdfId,attrNum,entryNum)` returns the value of an attribute entry in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

`entryNum`

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Output Arguments

`Value`

Value of the entry.

Examples

Open the example CDF and get the value of an entry associated with an attribute with variable scope in the file.

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,3,0)

dtype =

cdf_char

numel =

    10

% Get the value of the entry for this attribute.
% Note that it's a character string, 10 characters in length
value = cdflib.getAttrEntry(cdfid,3,0)

value =

Time value

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.putAttrEntry` | `cdflib.getAttrgEntry` | `cdflib.putAttrgEntry`

cdflib.getAttrgEntry

Value of entry in global attribute

Syntax

```
value = cdflib.getAttrgEntry(cdfId,attrNum,entryNum)
```

Description

`value = cdflib.getAttrgEntry(cdfId,attrNum,entryNum)` returns the value of a global attribute entry in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

`entryNum`

Numeric value that specifies the entry in the attribute. Entry numbers are zero-based.

Output Arguments

`Value`

Value of the entry.

Examples

Open the example CDF, and then get the value of an entry associated with a global attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attributes have global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get information about the first entry for global attribute
[dtype numel] = cdflib.inquireAttrgEntry(cdfid,0,0)

dtype =

cdf_char

numel =

    23

% Get the value of the first entry for this global attribute.
value = cdflib.getAttrgEntry(cdfid,0,0)

value =

This is a sample entry.

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrgEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getAttrMaxEntry

Number of last entry for variable attribute

Syntax

```
maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)
```

Description

`maxEntry = cdflib.getAttrMaxEntry(cdfId,attrNum)` returns the number of the last entry for an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Output Arguments

`maxEntry`

Entry number of the last entry in the attribute. Entry numbers are zero-based.

Examples

Open the example CDF and get the number of the last entry associated with an attribute with variable scope in the file:

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE

% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxEntry(cdfid,3)

entrynum =

    3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrMaxzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

Description

`maxEntry = cdflib.getAttrMaxgEntry(cdfId,attrNum)` returns the last entry number of a global attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

Output Arguments

`maxEntry`

Entry number of the last entry in the attribute. Entry numbers are zero-based.

Examples

Open the example CDF and get the number of the last entry associated with a global attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attribute are of global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get the number of the last entry for this attribute.
entrynum = cdflib.getAttrMaxgEntry(cdfid,0)

entrynum =

cdflib.getAttrName

Name of attribute, given attribute number

Syntax

```
name = cdflib.getAttrName(cdfId,attrNum)
```

Description

`name = cdflib.getAttrName(cdfId,attrNum)` returns the name of an attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based.

Output Arguments

`name`

Text string specifying the name of the attribute.

Examples

Open the example CDF and get name of an attribute.

```
cdfid = cdflib.open('example.cdf');
```

```
% Get name of the first attribute in the file.
attrName = cdflib.getAttrName(cdfId,0)

attrName =

SampleAttribute

% Clean up

`cdflib.createAttr`

cdflib.getAttrNum

Attribute number, given attribute name

Syntax

```
attrNum = cdflib.getAttrNum(cdfId,attrName)
```

Description

`attrNum = cdflib.getAttrNum(cdfId,attrName)` returns the number of an attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrName`

Text string specifying the name of an attribute.

Output Arguments

`attrNum`

Numeric value that identifies the attribute. Attribute numbers are zero-based.

Examples

Open the example CDF and get the attribute number associated with the `SampleAttribute` attribute.

```
cdfid = cdflib.open('example.cdf');

attrNum = cdflib.getAttrNum(cdfid,'SampleAttribute')

attrNum =

    0

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.createAttr` | `cdflib.getAttrName`

cdflib.getAttrScope

Scope of attribute

Syntax

```
scope = cdflib.getAttrScope(cdfId,attrNum)
```

Description

`scope = cdflib.getAttrScope(cdfId,attrNum)` returns the scope of an attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that specifies the attribute. Attribute numbers are zero-based.

Output Arguments

`scope`

Either of the following text strings, or its numeric equivalent.

Text String	Description
`'GLOBAL_SCOPE'`	Attribute applies to the CDF as a whole.
`'VARIABLE_SCOPE'`	Attribute applies only to the variable.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Examples

Open example CDF and get the scope of the first attribute in the file:

```
cdfid = cdflib.open('example.cdf');

attrScope = cdflib.getAttrScope(cdfid,0)

attrScope =

GLOBAL_SCOPE

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetAttrScope`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getCacheSize

Number of cache buffers used

Syntax

```
numBuffers = cdflib.getCacheSize(cdfId)
```

Description

`numBuffers = cdflib.getCacheSize(cdfId)` returns the number of cache buffers used for the Common Data Format (CDF) file identified by `cdfId`. For a discussion of cache schemes, see the *CDF User's Guide*.

Examples

Open the example CDF file and get the cache size:

```
cdfid = cdflib.open('example.cdf');

numBuf = cdflib.getCacheSize(cdfid)

numBuf =

   300

% Clean up
cdflib.close(cdfid)
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

Checksum mode

Syntax

```
mode = cdflib.getChecksum(cdfId)
```

Description

`mode = cdflib.getChecksum(cdfId)` returns the checksum mode of the Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`mode`

Either of the following text strings or its numeric equivalent.

`'MD5_CHECKSUM'`	File uses MD5 checksum.
`'NO_CHECKSUM'`	File does not use a checksum.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF file, and then get the checksum mode of the file:

```
cdfid = cdflib.open('example.cdf');

checksummode = cdflib.getChecksum(cdfid)

checksummode =

NO_CHECKSUM

% Clean up
cdflib.close(cdfid);
clear cdfid;
```

References

This function corresponds to the CDF library C API routine `CDFgetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setChecksum` | `cdflib.getConstantValue`

cdflib.getCompression

Compression settings

Syntax

```
[ctype,cparms,cpercentage] = cdflib.getCompression(cdfId)
```

Description

`[ctype,cparms,cpercentage] = cdflib.getCompression(cdfId)` returns information about the compression settings of a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`ctype`

Text string specifying compression type, such as `'HUFF_COMPRESSION'`. If the CDF does not use compression, the function returns the string `'NO_COMPRESSION'`. For a list of supported compression types, see `cdflib.setCompression`.

`cparms`

The value of the parameter associated with the type of compression. For example, for the `'RLE_COMPRESSION'` compression type, the parameter specifies the style of run-length encoding. For a list of parameters supported by each compression type, see `cdflib.setCompression`.

`cpercentage`

The rate of compression, expressed as a percentage.

Examples

Open the example CDF file and check the compression settings in the file.

```
cdfId = cdflib.open('example.cdf');

[ctype, cparms, cpercentage] = cdflib.getCompression(cdfId)

ctype =

GZIP_COMPRESSION

cparms =

     7

cper =

    26

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.setCompression` | `cdflib.getVarCompression` | `cdflib.setVarCompression`

cdflib.getCompressionCacheSize

Number of compression cache buffers

Syntax

```
numBuffers = cdflib.getCompressionCacheSize(cdfId)
```

Description

`numBuffers = cdflib.getCompressionCacheSize(cdfId)` returns the number of cache buffers used for the compression scratch Common Data Format (CDF) file. `cdfId` identifies the CDF file. For a discussion of cache schemes, see the *CDF User's Guide*.

Examples

Open the example CDF file and check the compression cache size of the file:

```
cdfId = cdflib.open('example.cdf');

numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    80

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetCompressionCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

See Also

`cdflib.setCompressionCacheSize`

cdflib.getConstantNames

Names of Common Data Format (CDF) library constants

Syntax

```
names = cdflib.getConstantNames()
```

Description

`names = cdflib.getConstantNames()` returns a cell array of text strings, where each text string is the name of a constant known to the Common Data Format (CDF) library.

Examples

Get a list of the names of CDF library constants.

```
names  = cdflib.getConstantNames()

names =

    'AHUFF_COMPRESSION'
    'ALPHAMVSD_ENCODING'
    'ALPHAMVSG_ENCODING'
    'ALPHAMVSI_ENCODING'
    'ALPHAOSF1_ENCODING'
    'CDF_BYTE'
    'CDF_CHAR'
     .
     .
     .
```

See Also

`cdflib.getConstantValue`

cdflib.getConstantValue

Numeric value corresponding to Common Data Format (CDF) library constant

Syntax

```
value = cdflib.getConstantValue(constantName)
```

Description

`value = cdflib.getConstantValue(constantName)` returns the numeric value of the CDF library constant specified by the text string *`constantName`*. To see a list of constant names, use `cdflib.getConstantNames`.

Examples

View the list of CDF library constants and get the numeric value corresponding to one of the constants.

```
% Retrieve a list of library constants
names = cdflib.getConstantNames();

value  = cdflib.getConstantValue(names{1})

value =

   3
```

References

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getConstantNames`

cdflib.getCopyright

Copyright notice in Common Data Format (CDF) file

Syntax

```
copyright = cdflib.getCopyright(cdfId)
```

Description

`copyright = cdflib.getCopyright(cdfId)` returns the copyright notice in the CDF file identified by `cdfId`.

Examples

Create a CDF file, and then get the copyright notice in the file. To run this example, you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');

copyright  = cdflib.getCopyright(cdfId)

copyright =

Common Data Format (CDF)
(C) Copyright 1990-2009 NASA/GSFC
Space Physics Data Facility
NASA/Goddard Space Flight Center
Greenbelt, Maryland 20771 USA
(Internet -- CDFSUPPORT@LISTSERV.GSFC.NASA.GOV)

% Clean up.
cdflib.delete(cdfId)
clear cdfId
```

References

`cdflib.getLibraryCopyright`

cdflib.getFileBackward

Return current backward compatibility mode setting

Syntax

```
mode = cdflib.getFileBackward()
```

Description

`mode = cdflib.getFileBackward()` returns the backward compatibility mode.

Output Arguments

`mode`

One of the following text strings:

`BACKWARDFILEon`	Backward compatibility mode is on.
`BACKWARDFILEoff`	Backward compatibility mode is off.

For more information about backward compatibility mode, see `cdflib.setFileBackward`.

Examples

```
mode = cdflib.getFileBackward

mode =

BACKWARDFILEoff
```

References

This function corresponds to the CDF library C API routine `CDFgetFileBackward`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.setFileBackward` | `cdflib.getConstantValue`

cdflib.getFormat

Format of Common Data Format (CDF) file

Syntax

```
format = cdflib.setFormat(cdfId)
```

Description

`format = cdflib.setFormat(cdfId)` returns the format of the CDF file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`format`

Either of the following text strings, or its numeric equivalent.

`'SINGLE_FILE'`	The CDF is stored in a single file.
`'MULTI_FILE'`	The CDF is made up of multiple files.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF file and determine its file format:

```
cdfId = cdflib.open('example.cdf');
```

```
format = cdflib.getFormat(cdfId)

format =

   'SINGLE_FILE'

% Clean up.
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetFormat`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.setFormat` | `cdflib.getConstantValue`

cdflib.getLibraryCopyright

Copyright notice of Common Data Format (CDF) library

Syntax

```
copyright = cdflib.getLibraryCopyright()
```

Description

`copyright = cdflib.getLibraryCopyright()` returns a text string containing the copyright notice of the CDF library.

Examples

Get the copyright of the CDF library.

```
copyright  = cdflib.getLibraryCopyright()

copyright =

Common Data Format (CDF)
(C) Copyright 1990-2008 NASA/GSFC
Space Physics Data Facility
NASA/Goddard Space Flight Center
Greenbelt, Maryland 20771 USA
(Internet -- CDFSUPPORT@LISTSERV.GSFC.NASA.GOV)
```

References

This function corresponds to the CDF library C API routine `CDFgetLibraryCopyright`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

`cdflib.getCopyright`

cdflib.getLibraryVersion

Library version and release information

Syntax

```
[version,release,increment] = cdflib.getLibraryVersion()
```

Description

`[version,release,increment] = cdflib.getLibraryVersion()` returns information about the Common Data Format (CDF) library.

Output Arguments

`version`

Numeric value indicating the version number of the CDF library.

`release`

Numeric value indicating the release number of the CDF library.

`increment`

Numeric value indicating the increment number of the CDF library.

Examples

Get the version information of the CDF library:

```
[version, release, increment] = cdflib.getLibraryVersion()

version =

     3
```

```
release =

     3

increment =

     0
```

References

This function corresponds to the CDF library C API routine `CDFgetLibraryVersion`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getVersion`

cdflib.getMajority

Majority of variables

Syntax

```
majority = cdflib.getMajority(cdfId)
```

Description

`majority = cdflib.getMajority(cdfId)` returns the majority of variables in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`majority`

Either of the following text strings, or its numeric equivalent.

`'ROW_MAJOR'`	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
`'COLUMN_MAJOR'`	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Open the example CDF file, and then determine the majority of variables in the file:

```
cdfId = cdflib.open('example.cdf');

majority = cdflib.getMajority(cdfId)

majority =

ROW_MAJOR

% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetMajority`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setMajority` | `cdflib.getConstantValue`

cdflib.getName

Name of Common Data Format (CDF) file

Syntax

```
name = cdflib.getName(cdfId)
```

Description

`name = cdflib.getName(cdfId)` returns the name of the CDF file identified by `cdfId`.

Examples

Open the example CDF file and get the name of the file. The path name returned for your installation will be different.

```
cdfId = cdflib.open('example.cdf');

name = cdflib.getName(cdfId)

name =

yourinstallation\matlab\toolbox\matlab\demos\example

% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.open` | `cdflib.create`

cdflib.getNumAttrEntries

Number of entries for attribute with variable scope

Syntax

```
nentries = cdflib.getNumAttrEntries(cdfId,attrNum)
```

Description

`nentries = cdflib.getNumAttrEntries(cdfId,attrNum)` returns the number of entries for the specified attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file.

`attrNum` is a numeric value that specifies the attribute. Attribute numbers are zero-based. The attribute must have variable scope.

Examples

Open the example CDF, find an attribute with variable scope, and determine how many entries are associated with the attribute:

```
cdfid = cdflib.open('example.cdf');

% Get the number of an attribute
% with variable scope
attrNum = cdflib.getAttrNum(cdfid,'Description');

% Check that scope of attribute is variable
attrScope = cdflib.getAttrScope(cdfid,attrNum)

VARIABLE_SCOPE

% Detemine the number of entries for the attribute
attrEntries = cdflib.getNumAttrEntries(cdfid,attrNum)

attrEntries =
```

```
    4

% Clean up
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFgetNumAttrzEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getAttrScope`

cdflib.getNumAttrgEntries

Number of entries for attribute with global scope

Syntax

```
nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)
```

Description

`nentries = cdflib.getNumAttrgEntries(cdfId,attrNum)` returns the number of entries written for the specified global attribute in the Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. The attribute must have global scope.

Examples

Open the example CDF and find out how many entries are associated with a global attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% The first attribute is a global attribute.
attrgEntries = cdflib.getNumAttrgEntries(cdfid,0)

attrgEntries =

    3

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetNumAttrgEntries`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getNumAttrEntries`

cdflib.getNumAttributes

Number of attributes with variable scope

Syntax

```
numAtts = cdflib.getNumAttributes(cdfId)
```

Description

`numAtts = cdflib.getNumAttributes(cdfId)` returns the total number of attributes with variable scope in a Common Data Format (CDF) file. `cdfId` identifies the CDF file.

Examples

Open the example CDF and find out how many attributes in the file have variable scope:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of attributes with variable scope
numAttrs = cdflib.getNumAttributes(cdfid)

numAttrs =

    1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetNumvAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getNumgAttributes`

cdflib.getNumgAttributes

Number of attributes with global scope

Syntax

```
ngatts = cdflib.getNumgAttributes(cdfId)
```

Description

`ngatts = cdflib.getNumgAttributes(cdfId)` returns the total number of global attributes in a Common Data Format (CDF) file. `cdfId` identifies the CDF file.

Examples

Open the example CDF and find out how many global attributes are in the file:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of global attributes in the file.
numgAttrs = cdflib.getNumgAttributes(cdfid)

numgAttrs =

    3

% Clean up
cdflib.close(cdfid);
```

References

This function corresponds to the CDF library C API routine `CDFgetNumgAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getNumAttributes`

cdflib.getReadOnlyMode

Read-only mode

Syntax

```
mode = cdflib.getReadOnlyMode(cdfId)
```

Description

`mode = cdflib.getReadOnlyMode(cdfId)` returns the read-only mode of a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`mode`

Either of the following text strings or its numeric equivalent.

`'READONLYon'`	CDF is in read-only mode
`'READONLYoff'`	CDF can be modified.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF file and determine its current read-only status:

```
cdfId = cdflib.open('example.cdf');

mode = cdflib.getReadOnlyMode(cdfId)

mode =

READONLYoff

% Clean up.
cdflib.close(cdfId);
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setReadOnlyMode` | `cdflib.getConstantValue`

cdflib.getStageCacheSize

Number of cache buffers for staging

Syntax

```
numBuffers = cdflib.getStageCacheSize(cdfId)
```

Description

`numBuffers = cdflib.getStageCacheSize(cdfId)` returns the number of cache buffers used for the staging scratch file of the Common Data Format (CDF) file. For more information about cache buffers, see the *CDF User's Guide*.

`cdfId` identifies the CDF file.

Examples

Open the example CDF file and determine the number of cache buffers used for staging:

```
cdfId = cdflib.open('example.cdf');

numBuf = cdflib.getStageCacheSize(cdfId)

numBuf =

   125

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetStageCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setStageCacheSize`

cdflib.getValidate

Library validation mode

Syntax

```
mode = cdflib.getValidate()
```

Description

`mode = cdflib.getValidate()` returns the validation mode of the Common Data Format (CDF) library.

Output Arguments

`mode`

Either of the following text strings or its numeric equivalent.

`'VALIDATEFILEon'`	Validation mode is on. For information about validation mode, see `cdflib.setValidate`.
`'VALIDATEFILEoff'`	Validation mode is off.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Determine the current validation mode of the CDF library.

```
mode = cdflib.getValidate()
```

```
mode =
```

```
'VALIDATEFILEon'
```

References

This function corresponds to the CDF library C API routine `CDFgetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setValidate` | `cdflib.getConstantValue`

cdflib.getVarAllocRecords

Number of records allocated for variable

Syntax

```
numrecs = cdflib.getVarAllocRecords(cdfId, varNum)
```

Description

`numrecs = cdflib.getVarAllocRecords(cdfId, varNum)` returns the number of records allocated for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Examples

Open example CDF and get the number of records allocated for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records allocated for the
% first variable in the file.
numrecs = cdflib.getVarAllocRecords(cdfid,0)

numrecs =

    64

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarAllocRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setVarAllocBlockRecords`

cdflib.getVarBlockingFactor

Blocking factor for variable

Syntax

```
blockingFactor = cdflib.getVarBlockingFactor(cdfId,varNum)
```

Description

`blockingFactor = cdflib.getVarBlockingFactor(cdfId,varNum)` returns the blocking factor for a variable in a Common Data Format (CDF) file. A variable's *blocking factor* specifies the minimum number of records the library allocates when you write to an unallocated record.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Examples

Open the example CDF and determine the blocking factor of a variable.

```
cdfid = cdflib.open('example.cdf');

cdflib.getVarBlockingFactor(cdfid,0)

ans =

     0

%  Clean up
cdflib.close(cdfid)
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarBlockingFactor`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setVarBlockingFactor`

cdflib.getVarCacheSize

Number of multifile cache buffers

Syntax

```
numBuffers = cdflib.getVarCacheSize(cdfId,varNum)
```

Description

`numBuffers = cdflib.getVarCacheSize(cdfId,varNum)` returns the number of cache buffers used for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable identifiers are zero-based.

This function applies only to multifile format CDFs. For more information about caching, see the *CDF User's Guide*.

Examples

Create a multifile CDF and retrieve the number of buffers being used for a variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
```

```
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

%  Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setVarCacheSize`

cdflib.getVarCompression

Information about compression used by variable

Syntax

```
[ctype,cparams,percent] = cdflib.getVarCompression(cdfId, varNum)
```

Description

`[ctype,cparams,percent] = cdflib.getVarCompression(cdfId, varNum)` returns information about the compression used for a variable in a Common Data Format (CDF) File.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`ctype`

Text string identifying the type of compression. For a list of compression types, see `cdflib.setCompression`.

`cparams`

Any additional parameter required by the compression type.

`percent`

Numeric value indicating the level of compression, expressed as a percentage.

Examples

Open the example CDF file and check the compression settings of any variable.

```
cdfid = cdflib.open('example.cdf');

% Check the compression setting of any variable in the file
% The example checks the first variable (variable numbers are zero-based).
[ctype params percent] = cdflib.getVarCompression(cdfid,0)

ctype =

NO_COMPRESSION

params =

     []

percent =

   100

% Clean up
cdflib.close(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.setCompression` | `cdflib.setVarCompression`

cdflib.getVarData

Single value from record in variable

Syntax

```
datum = cdflib.getVarData(cdfId,varNum,recNum,indices)
datum = cdflib.getVarData(cdfId,varNum,recNum)
```

Description

`datum = cdflib.getVarData(cdfId,varNum,recNum,indices)` returns a single value from a variable in a Common Data Format (CDF) file.

`datum = cdflib.getVarData(cdfId,varNum,recNum)` returns a single value from a variable with no dimensions in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying the variable containing the datum. Variable numbers are zero-based.

`recNum`

Numeric value identifying the location of the datum in the variable. In CDF terminology, this is called the *record number*. Record numbers are zero-based.

`indices`

Array of dimension indices within the record. Dimension indices are zero-based. If the variable has no dimensions, you can omit this parameter.

Output Arguments

datum

Value of the specified record.

Examples

Open the example CDF file and retrieve data associated with a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine how many variables are in the file.
info = cdflib.inquire(cdfid);

info.numVars

ans =

  5

% Determine if the first variable has dimensions.
varinfo = cdflib.inquireVar(cdfid,0);
vardims = varinfo.dims
vardims =

  []

% Get data from variable, without specifying dimensions.
datum = cdflib.getVarData(cdfid, varnum, recnum)

datum =

  6.3146e+013

% Get dimensions of another variable in file.
varinfo = cdflib.inquireVar(cdfid,3);
vardims = varinfo.dims
vardims =

  [4 2 2]
```

```
% Retrieve the first datum in the record. Indices are zero-based.
datum = cdflib.getVarData(cdfId,3,0,[0 0 0])

info =

    30

% Clean up.
cdflib.close(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.putVarData` | `cdflib.getVarRecordData` | `cdflib.hyperGetVarData`

cdflib.getVarMaxAllocRecNum

Maximum allocated record number for variable

Syntax

```
maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)
```

Description

`maxrec = cdflib.getVarMaxAllocRecNum(cdfId,varNum)` returns the record number of the maximum allocated record for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

Examples

Open example CDF and get the maximum allocated record number for a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine maximum record number for variable in file.
maxRecNum = cdflib.getVarMaxAllocRecNum(cdfid,0)

maxRecNum =

    63

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarMaxAllocRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getVarMaxWrittenRecNum`

cdflib.getVarMaxWrittenRecNum

Maximum written record number for variable

Syntax

```
maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)
```

Description

`maxrec = cdflib.getVarMaxwrittenRecNum(cdfId,varNum)` returns the record number of the maximum record written for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers and record numbers are zero-based.

Examples

Open the example CDF, and then determine the maximum number of records written to a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number records written to variable.
numRecs = cdflib.getVarNumRecsWritten(cdfid,0)

numRecs =

    24

% Determine the maximum record number of the records written
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0)

maxRecNum =

    23
```

```
%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarMaxWrittenRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.getVarMaxAllocRecNum` | `cdflib.getVarNumRecsWritten`

cdflib.getVarsMaxWrittenRecNum

Maximum written record number for CDF file

Syntax

```
maxrec = cdflib.getVarsMaxwrittenRecNum(cdfId)
```

Description

`maxrec = cdflib.getVarsMaxwrittenRecNum(cdfId)` returns the maximum record number written for all variables in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. Record numbers are zero-based.

Examples

Open the example CDF, and then determine the maximum number of records written to the file:

```
cdfid = cdflib.open('example.cdf');

% Determine the maximum record number of the records written
maxRecNum = cdflib.getVarsMaxWrittenRecNum(cdfid)

maxRecNum =

    23

%  Clean up
cdflib.close(cdfid)
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarsMaxWrittenRecNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getVarMaxWrittenRecNum`

cdflib.getVarName

Variable name, given variable number

Syntax

```
name = cdflib.getVarName(cdfId,varNum)
```

Description

`name = cdflib.getVarName(cdfId,varNum)` returns the name of the variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.`name` is a text string specifying the name.

Examples

Open the example CDF, and then get the name of a variable in the file:

```
cdfid = cdflib.open('example.cdf');

name = cdflib.getVarName(cdfid,1)

name =

Longitude

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarName`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.inquireVar`

cdflib.getVarNum

Variable number, given variable name

Syntax

```
varNum = cdflib.getVarNum(cdfId,varname)
```

Description

`varNum = cdflib.getVarNum(cdfId,varname)` returns the identifier (variable number) for a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. *`varname`* is a text string that identifies the variable. Variable names are case-sensitive.

Examples

Open example CDF, and then get the number of a variable named `Longitude`:

```
cdfid = cdflib.open('example.cdf');

varNum = cdflib.getVarNum(cdfid,'Longitude')

varNum =

     1

%  Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarNum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getVarName`

cdflib.getVarNumRecsWritten

Number of records written to variable

Syntax

```
numrecs = cdflib.getVarNumRecsWritten(cdfId,varNum)
```

Description

`numrecs = cdflib.getVarNumRecsWritten(cdfId,varNum)` returns the total number of records written to a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Examples

Open the example CDF, and then determine the number of records written to a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records written to the variable.
numRecs = cdflib.getVarNumRecsWritten(cdfid,0)

numRecs =

    24

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarNumRecsWritten`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

See Also

`cdflib.getVarMaxWrittenRecNum`

cdflib.getVarPadValue

Pad value for variable

Syntax

```
padvalue = cdflib.getVarPadValue(cdfId,varNum)
```

Description

`padvalue = cdflib.getVarPadValue(cdfId,varNum)` returns the pad value used with a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Examples

Open the example CDF, and then determine the pad value for a variable:

```
cdfid = cdflib.open('example.cdf');

% Check pad value of variable in the file.
padval = cdflib.getVarPadValue(cdfid,0)

padval =

     0

%  Clean up.
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarPadValue`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setVarPadValue`

cdflib.getVarRecordData

Entire record for variable

Syntax

```
data = cdflib.getVarRecordData(cdfId,varNum,recNum)
```

Description

`data = cdflib.getVarRecordData(cdfId,varNum,recNum)` returns the data in a record associated with a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value that identifies the variable in the CDF file. Variable numbers are zero-based.

`recNum`

Numeric value that identifies the record in the variable. Record numbers are zero-based.

Output Arguments

`data`

Data in the record.

Examples

Open the example CDF, and then get the data associated with a record in a variable:

```
cdfid = cdflib.open('example.cdf');

% Get data in first record in first variable in file.
recData = cdflib.getVarRecordData(cdfid,0,0)

recData =

    6.3146e+013

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarRecordData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.getVarReservePercent

Compression reserve percentage for variable

Syntax

```
percent = cdflib.getVarReservePercent(cdfId,varNum)
```

Description

`percent = cdflib.getVarReservePercent(cdfId,varNum)` returns the compression reserve percentage for a variable in a Common Data Format (CDF) file. This operation only applies to compressed variables.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based.

Examples

Open the example CDF file, get the number of a compressed variable, and then determine the reserve percent for the variable.

```
cdfid = cdflib.open('example.cdf');
varnum = cdflib.getVarNum(cdfid,'Temperature');
percent = cdflib.getVarReservePercent(cdfid,varnum);
cdflib.close(cdfid);
```

More About

reserve percentage

Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.

By default, the reserve percent is `0` (no extra space is reserved). You can specify any percentage between `1` and `100` and values greater than `100`. The value specifies the percentage of the uncompressed size of the variable.

References

This function corresponds to the CDF library C API routine `CDFgetzVarReservePercent`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setVarReservePercent`

cdflib.getVarSparseRecords

Information about how variable handles sparse records

Syntax

```
stype = cdflib.getVarSparseRecords(cdfId,varNum)
```

Description

`stype = cdflib.getVarSparseRecords(cdfId,varNum)` returns information about how a variable in the Common Data Format (CDF) file handles sparse records.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value that identifies the variable. Variable numbers are zero-based.

Output Arguments

`stype`

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
`'NO_SPARSERECORDS'`	No sparse records.
`'PAD_SPARSERECORDS'`	For sparse records, the library uses the variable's pad value when reading values from a missing record.

Text String	Description
'PREV_SPARSERECORDS'	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

To get the numeric equivalent of these text strings, use `cdflib.getConstantValue`.

Examples

Open the example CDF, and then get the sparse record type of a variable in the file:

```
cdfid = cdflib.open('example.cdf');

stype = cdflib.getVarSparseRecords(cdfid,0)

stype =

NO_SPARSERECORDS

%Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFgetzVarSparseRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.setVarSparseRecords`

cdflib.getVersion

Common Data Format (CDF) library version and release information

Syntax

```
[version,release,increment] = cdflib.getVersion(cdfId)
```

Description

`[version,release,increment] = cdflib.getVersion(cdfId)` returns information about the version of the Common Data Format (CDF) library used to create a CDF file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`version`

Numeric value indicating the version number of the CDF library.

`release`

Numeric value indicating the release number of the CDF library.

`increment`

Numeric value indicating the increment number of the CDF library.

Examples

Open the example CDF file, and then find out the version of the CDF library used to create it:

```
cdfId = cdflib.open('example.cdf');

[version, release, increment] = cdflib.getVersion(cdfId)

version =

     2

release =

     7

increment =

     8

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFgetVersion`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.getLibraryVersion`

cdflib.hyperGetVarData

Read hyperslab of data from variable

Syntax

```
data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec)
data = cdflib.hyperGetVarData(cdfId,varNum,recSpec)
```

Description

`data = cdflib.hyperGetVarData(cdfId,varNum,recSpec,dimSpec)` reads a hyperslab of data from a variable in the Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.

`data = cdflib.hyperGetVarData(cdfId,varNum,recSpec)` reads a hyperslab of data for a zero-dimensional variable in the Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Number identifying the variable containing the datum.

`recSpec`

Three-element array, `[RSTART RCOUNT RSTRIDE]`, where `RSTART`, `RCOUNT`, and `RSTRIDE` are scalar values specifying the starting record, number of records to read, and the sampling interval or stride between records. Record numbers are zero-based.

`dimSpec`

Three-element cell array, `{DSTART DCOUNT DSTRIDE}`, where `DSTART`, `DCOUNT`, and `DSTRIDE` are *n*-element vectors that describe the start, number of values along each

dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.

Examples

Open the example CDF file, and then get all the data associated with a variable:

```
cdfid = cdflib.open('example.cdf');

% Determine the number of records allocated for the first variable in the file.
maxRecNum = cdflib.getVarMaxWrittenRecNum(cdfid,0);

% Retrieve all data in records for variable.
data = cdflib.hyperGetVarData(cdfid,0,[0 maxRecNum 1]);

%  Clean up
cdflib.close(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFhyperGetzVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.hyperPutVarData`

cdflib.hyperPutVarData

Write hyperslab of data to variable

Syntax

```
cdflib.hyperPutVarData(cdfId,varNum,recSpec,dimSpec,data)
```

Description

`cdflib.hyperPutVarData(cdfId,varNum,recSpec,dimSpec,data)` writes a hyperslab of data to a variable in a Common Data Format (CDF) file. Hyper access allows more than one value to be read from or written to a variable with a single call to the CDF library.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Specifies the variable containing the datum.

`recSpec`

Three-element array described by `[RSTART RCOUNT RSTRIDE]`, where `RSTART`, `RCOUNT`, and `RSTRIDE` are scalar values giving the start, number of records, and sampling interval (or stride) between records. Record indices are zero-based.

`dimSpec`

Three-element cell array described by `{DSTART DCOUNT DSTRIDE}`, where `DSTART`, `DCOUNT`, and `DSTRIDE` are n-element vectors that describe the start, number of values along each dimension, and sampling interval along each dimension. If the hyperslab has zero dimensions, you can omit this parameter. Dimension indices are zero-based.

`data`

Data to write to the variable.

Examples

Create a CDF, create a variable, and then write a slab of data to the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Write data to the variable
cdflib.hyperPutVarData(cdfid,varNum,0,[],int8(98))

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFhyperzPutVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.hyperGetVarData`

cdflib.inquire

Basic characteristics of Common Data Format (CDF) file

Syntax

```
info = cdflib.inquire(cdfId)
```

Description

`info = cdflib.inquire(cdfId)` returns basic information about a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

Output Arguments

`info`

A structure containing the following fields:

Field	Description
`encoding`	Encoding of the variable data and attribute entry data
`majority`	Majority of the variable data
`maxRec`	Maximum record number written to a CDF variable
`numVars`	Number of CDF variables
`numvAttrs`	Number of attributes with variable scope
`numgAttrs`	Number of attributes with global scope

Examples

Open the example CDF file, and then get basic information about the file:

```
cdfId = cdflib.open('example.cdf');

info = cdflib.inquire(cdfId)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: 23
      numVars: 5
    numvAttrs: 1
    numgAttrs: 3
```

References

This function corresponds to the CDF library C API routines `CDFinquireCDF` and `CDFgetNumgAttributes`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.inquireVar`

cdflib.inquireAttr

Information about attribute

Syntax

```
info = cdflib.inquireAttr(cdfId,attrNum)
```

Description

`info = cdflib.inquireAttr(cdfId,attrNum)` returns information about an attribute in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value that identifies the attribute in the file. Attribute numbers are zero-based.

Output Arguments

`info`

Structure containing the following fields.

Field	Description
`name`	Attribute's name
`scope`	Either `'GLOBAL_SCOPE'` or `'VARIABLE_SCOPE'`
`maxgEntry`	The maximum entry number used for global attributes.

Field	Description
`maxEntry`	The maximum entry number used for attributes with variable scope.

Examples

Open the example CDF, and then get information about the first attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% Get information about an attribute
info = cdflib.inquireAttr(cdfid,0)

info =

         name: 'SampleAttribute'
        scope: 'GLOBAL_SCOPE'
    maxgEntry: 4
     maxEntry: -1

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFinquireAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.inquireAttrgEntry` | `cdflib.inquireAttrEntry`

cdflib.inquireAttrEntry

Information about entry in attribute with variable scope

Syntax

```
[datatype,numElements] =
cdflib.inquireAttrEntry(cdfId,attrNum,entryNum)
```

Description

`[datatype,numElements] = cdflib.inquireAttrEntry(cdfId,attrNum,entryNum)` returns the data type and the number of elements for an attribute entry in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value identifying an attribute in the file. Attribute numbers are zero-based. The attribute must have variable scope.

`entryNum`

Numeric value identifying the entry in the attribute. Entry number are zero-based.

Output Arguments

`datatype`

Text string identifying a CDF data type. For a list of CDF data types, see `cdflib.putAttrEntry`

`numElements`

Numeric value indicating the number of elements in the entry.

Examples

Open example CDF, and then get information about entries associated with an attribute in the file:

```
cdfid = cdflib.open('example.cdf');

% The fourth attribute is of variable scope.
attrscope = cdflib.getAttrScope(cdfid,3)

attrscope =

VARIABLE_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrEntry(cdfid,3,0)

dtype =

cdf_char

numel =

    10

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFinquireAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.inquireAttr` | `cdflib.getAttrScope`

cdflib.inquireAttrgEntry

Information about entry in attribute with global scope

Syntax

```
[datatype,numElements] =
cdflib.inquireAttrgEntry(cdfId,attrNum,entryNum)
```

Description

`[datatype,numElements] = cdflib.inquireAttrgEntry(cdfId,attrNum,entryNum)` returns the data type and the number of elements for a global attribute entry in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Numeric value identifying an attribute in the file. Attribute numbers are zero-based. The attribute must have global scope.

`entryNum`

Numeric value identifying the entry in the attribute. Entry number are zero-based.

Output Arguments

`datatype`

Text string identifying a CDF data type. For a list of CDF data types, see `cdflib.putAttrgEntry`

numElements

Numeric value indicating the number of elements in the entry.

Examples

Open the example CDF, and then get information about entries associated with a global attribute in the file.

```
cdfid = cdflib.open('example.cdf');

% Any of the first three attributes have global scope.
attrscope = cdflib.getAttrScope(cdfid,0)

attrscope =

GLOBAL_SCOPE

% Get information about the first entry for this attribute
[dtype numel] = cdflib.inquireAttrgEntry(cdfid,0,0)

dtype =

cdf_char

numel =

    23

% Clean up
cdflib.close(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFinquireAttrgEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

See Also

`cdflib.inquireAttr` | `cdflib.inquireAttrEntry`

cdflib.inquireVar

Information about variable

Syntax

```
info = cdflib.inquireVar(cdfId,varNum)
```

Description

`info = cdflib.inquireVar(cdfId,varNum)` returns information about a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value that identifies the variable. Variable numbers are zero-based.

Output Arguments

`info`

Structure containing the following fields.

Field	Description
`name`	Name of the variable
`datatype`	Data type
`numElements`	Number of elements of the datatype
`dims`	Sizes of the dimensions

Field	Description
recVariance	Record variance
dimVariance	Dimension variances

Record and dimension variances affect how the library physically stores variable data. For example, if a variable has a record variance of VARY, the library physically stores each record. If the record variance is NOVARY, the library only stores one record.

Examples

Open the example CDF file and get information about a variable.

```
cdfid = cdflib.open('example.cdf');

% Determine if the file contains variables
info  = cdflib.inquireVar(cdfid,1)

info =

           name: 'Longitude'
       datatype: 'cdf_int1'
    numElements: 1
           dims: [2 2]
    recVariance: 0
    dimVariance: [1 0]
```

References

This function corresponds to the CDF library C API routine CDFinquirezVar.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the cdfcopyright.txt file.

See Also

cdflib.inquire

cdflib.open

Open existing Common Data Format (CDF) file

Syntax

```
cdfId = cdflib.open(filename)
```

Description

`cdfId = cdflib.open(filename)` opens an existing Common Data Format (CDF) file. *`filename`* is a text string that identifies the file.

This function returns a CDF file identifier, `cdfId`.

All CDF files opened this way have the `zMode` set to `zModeon2`. Refer to the *CDF User's Guide* for information about `zModes`.

Examples

Open the example CDF file:

```
cdfId = cdflib.open('example.cdf');

% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFopenCDF`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.close` | `cdflib.create`

cdflib.putAttrEntry

Write value to entry in attribute with variable scope

Syntax

```
cdflib.putAttrEntry(cdfId,attrNum,entryNum,CDFDataType,entryVal)
```

Description

`cdflib.putAttrEntry(cdfId,attrNum,entryNum,CDFDataType,entryVal)` writes a value to an attribute entry in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Number identifying attribute. The attribute must have variable scope. Attribute numbers are zero-based.

`entryNum`

Number identifying entry. Entry numbers are zero-based.

`CDFdatatype`

One of the following text strings, or its numeric equivalent, that specify the data type of the attribute entry.

CDF Data Type	MATLAB Equivalent
`CDF_BYTE`	1-byte, signed integer
`CDF_CHAR`	1 byte, signed character data type that maps to the MATLAB `char` class

CDF Data Type	MATLAB Equivalent
CDF_INT1	1-byte, signed integer.
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB `uint8` class
CDF_UINT1	1-byte, unsigned integer
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

`entryVal`

Data to be written to attribute entry.

Examples

Create a CDF and create an attribute with variable scope in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
```

```
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create an attribute of variable scope in the file.
attrNum = cdflib.createAttr(cdfid,'Another Attribute','variable_scope');

% Write a value to an entry for the attribute
cdflib.putAttrEntry(cdfid,attrNum,0,'CDF_CHAR','My Variable Attribute Test');

% Get the value of the global attribute entry
value = cdflib.getAttrEntry(cdfid,attrNum,0)

value =

My Variable Attribute Test

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFputAttrzEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

`cdflib.getAttrEntry` | `cdflib.putAttrgEntry` | `cdflib.getAttrgEntry` | `cdflib.getConstantValue`

cdflib.putAttrgEntry

Write value to entry in attribute with global scope

Syntax

```
cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)
```

Description

`cdflib.putAttrgEntry(cdfId,attrNum,entryNum,cdfDataType,entryVal)` writes a value to a global attribute entry in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`attrNum`

Number identifying attribute. Attribute numbers are zero-based. The attribute must have global scope.

`entryNum`

Number identifying entry. Entry numbers are zero-based.

`CDFdatatype`

One of the following text strings that specify the data type of the attribute entry, or its numeric equivalent.

CDF Data Type	MATLAB Equivalent
`CDF_BYTE`	1-byte, signed integer
`CDF_CHAR`	1 byte, signed character data type that maps to the MATLAB `char` class

CDF Data Type	MATLAB Equivalent
CDF_INT1	1-byte, signed integer.
CDF_UCHAR	1 byte, unsigned character data type that maps to the MATLAB `uint8` class
CDF_UINT1	1-byte, unsigned integer
CDF_INT2	2-byte, signed integer
CDF_UINT2	2-byte, unsigned integer.
CDF_INT4	4-byte, signed integer
CDF_UINT4	4-byte, unsigned integer
CDF_FLOAT	4-byte, floating point
CDF_REAL4	4-byte, floating point
CDF_REAL8	8-byte, floating point.
CDF_DOUBLE	8-byte, floating point
CDF_EPOCH	8-byte, floating point
CDF_EPOCH16	two 8-byte, floating point

`entryVal`

Data to be written to global attribute entry.

Examples

Create a CDF and create a global attribute in the file. Write a value to an entry in the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Initially the file contains no attributes, global or variable.
info = cdflib.inquire(cdfid)

info =

     encoding: 'IBMPC_ENCODING'
     majority: 'ROW_MAJOR'
       maxRec: -1
```

```
      numVars: 0
    numvAttrs: 0
    numgAttrs: 0

% Create a global attribute in the file.
attrNum = cdflib.createAttr(cdfid,'Purpose','global_scope');

% Write a value to an entry for the global attribute
cdflib.putAttrgEntry(cdfid,attrNum,0,'CDF_CHAR','My Test');

% Get the value of the global attribute entry
value = cdflib.getAttrgEntry(cdfid,attrNum,0)

value =

My Test

% Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFputAttrgEntry`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.putVarData

Write single value to variable

Syntax

```
cdflib.putVarData(cdfId,varNum,recNum,indices,datum)
```

Description

`cdflib.putVarData(cdfId,varNum,recNum,indices,datum)` writes a single value to a variable in a Common Data File (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

`recNum`

Numeric value that identifies the record to which you want to write the datum. Record numbers are zero-based.

`dims`

Dimension indices within the record. Dimension indices are zero-based.

`datum`

Data to be written to the variable.

Examples

Create a CDF, create a variable in the CDF and write data to the variable. To run this example, you must have write permission in the current folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Write some data to the variable
cdflib.putVarData(cdfid,varNum,0,[],int8(98))

% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

   98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFputzVarData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

cdflib.putVarRecordData

Write entire record to variable

Syntax

```
cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)
```

Description

`cdflib.putVarRecordData(cdfId,varNum,recNum,recordData)` writes data to a record in a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value that identifies the variable to which you want to write the datum. Variable numbers are zero-based.

`recNum`

Numeric value identifying the location of the datum in the variable. Record numbers are zero-based.

`recordData`

Data to be written to the variable.

Examples

Create a CDF, create a variable, and write an entire record of data to the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Write some data to the variable
cdflib.putVarRecordData(cdfid,varNum,0,int8(98))

% Read the value from the variable.
datum = cdflib.getVarData(cdfid,varNum,0)

datum =

   98

%Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFputzVarRecordData`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

cdflib.renameAttr

Rename existing attribute

Syntax

```
cdflib.renameAttr(cdfId,attrNum,newName)
```

Description

`cdflib.renameAttr(cdfId,attrNum,newName)` renames an attribute in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `attrNum` is a numeric value that identifies the attribute. Attribute numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the attribute.

Examples

Create a CDF, create an attribute in the CDF, and then rename the attribute. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create an attribute
attrNum = cdflib.createAttr(cdfid,'Purpose','global_scope');

% Rename the attribute
cdflib.renameAttr(cdfid, attrNum, 'NewPurpose');

% Check the name of the attribute
attrName = cdflib.getAttrName(cdfid,anum)

attrName =

NewPurpose

% Clean up
```

```
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFrenameAttr`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.createAttr`

cdflib.renameVar

Rename existing variable

Syntax

```
cdflib.renameVar(cdfId,varNum,newName)
```

Description

`cdflib.renameVar(cdfId,varNum,newName)` renames a variable in a Common Data Format (CDF) file.

`cdfId` identifies the CDF file. `varNum` is a numeric value that identifies the variable. Variable numbers are zero-based. `newName` is a text string that specifies the name you want to assign to the variable.

Examples

Create a CDF, create a variable in the CDF, and then rename the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Get the name of the variable.
name = cdflib.getVarName(cdfid,varNum)

name =

Time

% Rename the variable
cdflib.renameVar(cdfid,varNum,'NewName');

% Check the new name.
```

```
name = cdflib.getVarName(cdfid,varNum)

name =

NewName

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFrenamezVar`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.createVar`

cdflib.setCacheSize

Specify number of dotCDF cache buffers

Syntax

```
cdflib.setCacheSize(cdfId,numBuffers)
```

Description

`cdflib.setCacheSize(cdfId,numBuffers)` specifies the number of cache buffers the CDF library uses for an open dotCDF file. A *dotCDF* file is a file with the `.cdf` file extension.

`cdfId` identifies an open CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

For information about cache schemes, see the *CDF User's Guide*.

Examples

Create a CDF file and set the cache size. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the default cache size
numBuf = cdflib.getCacheSize(cdfid)

numBuf =

   300

% Specify a cache size
cdflib.setCacheSize(cdfid,150)

% Check the cache size again
numBuf =  cdflib.getCacheSize(cdfid)
```

```
numBuf =

   150

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getCacheSize`

cdflib.setChecksum

Specify checksum mode

Syntax

```
cdflib.setChecksum(cdfId,mode)
```

Description

`cdflib.setChecksum(cdfId,mode)` specifies the checksum mode of a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`mode`

Either of the following text strings, or its numeric equivalent. To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

`'MD5_CHECKSUM'`	Sets file checksum to MD5 checksum.
`'NO_CHECKSUM'`	File does not use a checksum.

Examples

Create a CDF file and set the checksum mode. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('mycdf.cdf');

% Check initial value of checksum.
```

```
mode = cdflib.getChecksum(cdfid)

NO_CHECKSUM

cdflib.setChecksum(cdfid,'MD5_CHECKSUM')

% Verify the setting
mode = cdflib.getChecksum(cdfid)

MD5_CHECKSUM
```

References

This function corresponds to the CDF library C API routine `CDFsetChecksum`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getChecksum` | `cdflib.getConstantValue`

cdflib.setCompression

Specify compression settings

Syntax

```
cdflib.setCompression(cdfId,ctype,cparms)
```

Description

`cdflib.setCompression(cdfId,ctype,cparms)` specifies compression settings of a Common Data Format (CDF) file.

This function sets the compression for the CDF file itself, not that of any variables in the file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`ctype`

One of the following text strings, or its numeric equivalent, specifying compression type.

Text String	Compression Type
`'NO_COMPRESSION'`	No compression
`'RLE_COMPRESSION'`	Run-length encoding compression
`'HUFF_COMPRESSION'`	Huffman compression
`'AHUFF_COMPRESSION'`	Adaptive Huffman compression
`'GZIP_COMPRESSION'`	GNU's zip compression

To get the numeric equivalent, use `cdflib.getConstantValue`.

`cparms`

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is `'GZIP_COMPRESSION'`. For this compression type, use `cparms` to specify the level of compression as a numeric value between 1 and 9.

Examples

Create a CDF file and set the compression setting of the file. To run this example, your current folder must be writable.

```
cdfId = cdflib.create('your_file.cdf');

% Determine the file's default compression setting
[ctype, cparms, cpercent ] = cdflib.getCompression(cdfId)

ctype =

NO_COMPRESSION

cparms =

     []

cpercent =

   100

% Specify new compression setting
cdflib.setCompression(cdfId,'HUFF_COMPRESSION');

% Check the file's compression setting.
[ctype, cparms, cpercent ] = cdflib.getCompression(cdfId)

ctype =

HUFF_COMPRESSION

cparms =

OPTIMAL_ENCODING_TREES
```

```
cpercent =

     0

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getCompression` | `cdflib.getConstantValue`

cdflib.setCompressionCacheSize

Specify number of compression cache buffers

Syntax

```
cdflib.setCompressionCacheSize(cdfId,numBuffers)
```

Description

`cdflib.setCompressionCacheSize(cdfId,numBuffers)` specifies the number of cache buffers used for the compression scratch CDF file. For more information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` specifies the number of buffers.

Examples

Create a CDF file and specify the number of compression cache buffers used. To run this example you must be in a writable folder.

```
cdfId = cdflib.create('your_file.cdf');

% Get the current number of compression cache buffers
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =

    80

% Set a new value
cdflib.setCompressionCacheSize(cdfId,100)

% Check the new value
numBuf = cdflib.getCompressionCacheSize(cdfId)

numBuf =
```

```
   100

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetCompressionCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getCompressionCacheSize`

cdflib.setFileBackward

Set backward compatibility mode

Syntax

```
cdflib.setFileBackward(mode)
```

Description

`cdflib.setFileBackward(mode)` sets the backward compatibility mode to the value specified by `mode`.

Input Arguments

`mode`

One of the following text strings:

`BACKWARDFILEon`	Set backward compatibility mode on.
`BACKWARDFILEoff`	Set backward compatibility mode off.

Default: `BACKWARDFILEoff`

Examples

Set backward compatibility mode and then check the value.

```
cdflib.setFileBackward('BACKWARDFILEon');

mode = cdflib.getFileBackward

mode =

BACKWARDFILEon
```

More About

backward compatibility mode

When specified, ensures that any new CDF file created using CDF V3.0 (or later) will be readable by clients using version 2.7 of the CDF library. CDF 3.0 and later releases use a 64-bit file offset to allow for files greater than 2G bytes in size. CDF library versions released before CDF 3.0 use a 32-bit file offset.

Tips

- Setting backward compatibility mode affects only your current MATLAB session, or until you call `cdflib.setFileBackward` again.

References

This function corresponds to the CDF library C API routine `CDFsetFileBackward`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getFileBackward` | `cdflib.getConstantValue`

cdflib.setFormat

Specify format of Common Data Format (CDF) file

Syntax

```
cdflib.setFormat(cdfId,format)
```

Description

`cdflib.setFormat(cdfId,format)` specifies the format of a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`format`

Either of the following text strings, or its numeric equivalent.

`'SINGLE_FILE'`	The CDF consists of only one file. This is the default file format
`'MULTI_FILE'`	The CDF consists of one header file for control and attribute data and one additional file for each variable in the CDF.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Create a CDF file and specify its format. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('mycdffile.cdf');
```

```
% Specify multifile format.
cdflib.setFormat(cdfId, 'MULTI_FILE');

% Check format.
 format = cdflib.getFormat(cdfId)

format =

MULTI_FILE

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetFormat`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getFormat` | `cdflib.getConstantValue`

cdflib.setMajority

Specify majority of variables

Syntax

```
cdflib.setMajority(cdfId,majority)
```

Description

`cdflib.setMajority(cdfId,majority)` specifies the majority of variables in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`majority`

Either of the following text strings, or its numeric equivalent.

`'ROW_MAJOR'`	C-like array ordering for variable storage. The first dimension in each variable array varies the slowest. This is the default.
`'COLUMN_MAJOR'`	Fortran-like array ordering for variable storage. The first dimension in each variable array varies the fastest.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Create a CDF file and specify the majority used by variables in the file. To run this example, you must have write permission in your current folder.

```
cdfId = cdflib.create('your_file.cdf')

% Specify the majority used by variables in the file
cdflib.setMajority(cdfId,'COLUMN_MAJOR');

% Check the majority value
majority = cdflib.getMajority(cdfId)

majority =

COLUMN_MAJOR

% Clean up
cdflib.delete(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetMajority`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getMajority`

cdflib.setReadOnlyMode

Specify read-only mode

Syntax

```
cdflib.setReadOnlyMode(cdfId,mode)
```

Description

`cdflib.setReadOnlyMode(cdfId,mode)` specifies the read-only mode of a Common Data Format (CDF) file.

After you open a CDF file, you can put the file into read-only mode to prevent accidental modification.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`mode`

Either of the following text strings or its numeric equivalent.

`'READONLYon'`	CDF file is read-only
`'READONLYoff'`	CDF file is modifiable.

To get the numeric equivalent of these mode values, use `cdflib.getConstantValue`.

Examples

Open the example CDF file and set the file to read-only mode.

```
cdfId = cdflib.open('example.cdf');

% Set the  file to READONLY mode
cdflib.setReadOnlyMode(cdfId,'READONLYon')

% Check read-only status of file again.
mode = cdflib.getReadOnlyMode(cdfId)

mode =

READONLYon

% Clean up
cdflib.close(cdfId)
clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetReadOnlyMode`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getReadOnlyMode` | `cdflib.getConstantValue`

cdflib.setStageCacheSize

Specify number of staging cache buffers for Common Data Format (CDF) file

Syntax

```
cdflib.setStageCacheSize(cdfId,numBuffers)
```

Description

`cdflib.setStageCacheSize(cdfId,numBuffers)` specifies the number of staging cache buffers for a Common Data Format (CDF) file. For information about CDF cache schemes, see the *CDF User's Guide*.

`cdfId` identifies the CDF file. `numBuffers` is a numeric value that specifies the number of buffers.

Examples

Open the example CDF file and specify the number of cache buffers used.

```
cdfId = cdflib.open('example.cdf');

% Get current number of staging cache buffers
size = cdflib.getStageCacheSize(cdfId)

size =

   125

% Specify new cache size value.
cdflib.setStageCacheSize(cdfId, 200)

% Get size again.
size = cdflib.getStageCacheSize(cdfId)

size =
```

```
   200

% Clean up
cdflib.close(cdfId)

clear cdfId
```

References

This function corresponds to the CDF library C API routine `CDFsetStageCacheSize`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getStageCacheSize`

cdflib.setValidate

Specify library validation mode

Syntax

```
cdflib.setValidate(mode)
```

Description

`cdflib.setValidate(mode)` specifies the validation mode of the Common Data Format (CDF) library. Specify the validation mode before opening any files.

Input Arguments

`mode`

Either of the following text strings, or its numeric equivalent:

`'VALIDATEFILEon'`	Turns validation mode on. With validation mode on, the library performs sanity checks on the data fields in the CDF' file's internal data structures to make sure that the values are within valid ranges and consistent with the defined values/types/entries. This mode also ensures that variable and attribute associations within the file are valid. Note, however, that enabling this mode will, in most cases, slow down the file opening process, especially for large or very fragmented files.
`'VALIDATEFILEoff`	Turns validation mode off.

To get the numeric equivalent of these values, use `cdflib.getConstantValue`.

Examples

Set the validation mode of the CDF library.

```
cdflib.setValidate('VALIDATEFILEon');
```

References

This function corresponds to the CDF library C API routine `CDFsetValidate`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getValidate` | `cdflib.getConstantValue`

cdflib.setVarAllocBlockRecords

Specify range of records to be allocated for variable

Syntax

```
cdflib.setVarAllocBlockRecords(cdfId,varNum,firstrec,lastrec)
```

Description

`cdflib.setVarAllocBlockRecords(cdfId,varNum,firstrec,lastrec)` specifies a range of records you want to allocate (but not write) for a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

`firstRec`

Numeric value identifying the record at which to start allocating. Record numbers are zero-based.

`lastRec`

Numeric value identifying the record at which to stop allocating. Record numbers are zero-based.

Examples

Create a CDF, create a variable in the CDF, and then specify the number of records to allocate for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);

% Specify the number of records to allocate.
cdflib.setVarAllocBlockRecords(cdfid,varNum,1,10);

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarAllocBlockRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

See Also

`cdflib.getVarAllocRecords`

cdflib.setVarBlockingFactor

Specify blocking factor for variable

Syntax

```
cdflib.setVarBlockingFactor(cdfId,varNum,blockingFactor)
```

Description

`cdflib.setVarBlockingFactor(cdfId,varNum,blockingFactor)` specifies the blocking factor for a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable numbers are zero-based.

`blockingFactor`

Numeric value that specifies the number of records to allocate when writing to an unallocated record.

Examples

Create a CDF, create a variable in the CDF, and then set the blocking factor used with the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');
```

```
% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Get the current blocking factor used with the variable
bFactor = cdflib.getVarBlockingFactor(cdfid,varNum)

bFactor =

    0

% Change the blocking factor for the variable
cdflib.setVarBlockingFactor(cdfid,varNum,10);

% Check the new blocking factor .
bFactor = cdflib.getVarBlockingFactor(cdfid,varNum)

bFactor =

    10

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

More About

blocking factor

A variable's *blocking factor* specifies the minimum number of records the library allocates when you write to an unallocated record. If you specify a fractional blocking factor, the library rounds the value down.

References

This function corresponds to the CDF library C API routine `CDFsetzVarBlockingFactor`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

See Also

`cdflib.getVarBlockingFactor`

cdflib.setVarCacheSize

Specify number of multi-file cache buffers for variable

Syntax

```
cdflib.setVarCacheSize(cdfId,varNum,numBuffers)
```

Description

`cdflib.setVarCacheSize(cdfId,varNum,numBuffers)` specifies the number of cache buffers the CDF library uses for a variable in a Common Data Format (CDF) file.

This function is only used with multifile format CDF files. It does not apply to single-file format CDFs. For more information about caching, see the *CDF User's Guide*.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

`numBuffers`

Numeric value identifying the number of cache buffers to use.

Examples

Create a multifile CDF, and then retrieve the number of buffers being used for a variable:

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

% Increase the number of cache buffers used.
cdflib.setVarCacheSize(cdfid,varNum,5)

% Check the number of cache buffers used with the variable.
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     5

%  Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

See Also

`cdflib.getVarCacheSize` | `cdflib.setVarsCacheSize`

cdflib.setVarCompression

Specify compression settings used with variable

Syntax

```
cdflib.setVarCompression(cdfId,varNum,ctype,cparams)
```

Description

`cdflib.setVarCompression(cdfId,varNum,ctype,cparams)` configures the compression setting for a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

`ctype`

One of the following text strings, or its numeric equivalent, specifying the compression type.

Text String	Compression Type
`'NO_COMPRESSION'`	No compression.
`'RLE_COMPRESSION'`	Run-length encoding compression
`'HUFF_COMPRESSION'`	Huffman compression
`'AHUFF_COMPRESSION'`	Adaptive Huffman compression

Text String	Compression Type
'GZIP_COMPRESSION'	GNU's zip compression

cparams

Optional parameter specifying any additional parameters required by the compression type. Currently, the only compression type that uses this parameter is 'GZIP_COMPRESSION'. For this compression type, you use cparms to specify the level of compression as a numeric value between 1 and 9.

Examples

Create a CDF, create a variable, and then set the compression used by the variable. To run this example, you must be in a folder with execute permission.

```
cdfid = cdflib.create('mycdf.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Specify the compression used by the variable.
cdflib.setVarCompression(cdfid,0,'GZIP_COMPRESSION',8)

% Check the compression setting of the variable
[ctype params percent] = cdflib.getVarCompression(cdfid,0)

ctype =

GZIP_COMPRESSION

params =

     8

percent =

     0

% Clean up
cdflib.delete(cdfid);
clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarCompression`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

`cdflib.setCompression` | `cdflib.getVarCompression`

cdflib.setVarInitialRecs

Specify initial number of records written to variable

Syntax

```
cdflib.setVarInitialRecs(cdfId,varNum,numrecs)
```

Description

`cdflib.setVarInitialRecs(cdfId,varNum,numrecs)` specifies the initial number of records to write to a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable numbers are zero-based.

`numRecs`

Numeric value specifying the number of records to write.

Examples

Create a CDF, create a variable, and then specify the number of records to write for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Grades','cdf_int1',1,[],true,[]);
```

```
% Specify the number of records to write for the variable
cdflib.setVarInitialRecs(cdfid,varNum,100);

recsWritten = cdflib.getVarNumRecsWritten(cdfid,varNum)

recsWritten =

   100

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarInitialRecs`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.createVar`

cdflib.setVarPadValue

Specify pad value used with variable

Syntax

```
cdflib.setVarPadValue(cdfId,varNum,padvalue)
```

Description

`cdflib.setVarPadValue(cdfId,varNum,padvalue)` specifies the pad value used with a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable numbers are zero-based.

`padValue`

Value to use a pad value for the variable. The data type of the pad value must match the data type of the variable.

Examples

Create a CDF, create a variable in the CDF, and then set the pad value used with the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
```

```
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Get the current pad value used with the variable
padval = cdflib.getVarPadValue(cdfid,varNum)

padval =

    0

% Change the pad value for the variable
cdflib.setVarPadValue(cdfid,varNum,int8(1));

% Check the new pad value.
padval = cdflib.getVarPadValue(cdfid,varNum)

padval =

    1

%  Clean up
cdflib.delete(cdfid)

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarPadValue`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

See Also

`cdflib.getVarPadValue`

cdflib.SetVarReservePercent

Specify reserve percentage for variable

Syntax

```
cdflib.setVarReservePercent(cdfId,varNum,percent)
```

Description

`cdflib.setVarReservePercent(cdfId,varNum,percent)` specifies the compression reserve percentage for a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

`percent`

Numeric value specifying the amount of extra space to allocate for a compressed variable, experssed as a percentage. You can specify values between`0` (no extra space is reserved) and `100`, or values greater than `100`. The value specifies the percentage of the uncompressed size of the variable. If you specify a fractional reserve percentages, the library rounds the value down.

Examples

Create a CDF, create a variable, set the compression of the variable, and then set the reserve percent for the variable. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Set the compression of the variable.
cdflib.setVarCompression(cdfid,varNum,'GZIP_COMPRESSION',8);

% Set the compression reserver percentage
cdflib.setVarReservePercent(cdfid,varNum, 80);

cdflib.close(cdfid);
```

More About

reserve percentage

Specifies how much extra space to allocate for a compressed variable. This extra space allows the variable to expand when you write additional records to the variable. If you do not specify this room for growth, the library has to move the variable to the end of the file when the size expands and the space at the original location of the variable becomes wasted space.

References

This function corresponds to the CDF library C API routine `CDFsetzVarReservePercent`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

For copyright information, see the `cdfcopyright.txt` file.

`cdflib.getVarReservePercent` | `cdflib.setVarCompression` | `cdflib.getVarCompression`

cdflib.setVarsCacheSize

Specify number of cache buffers used for all variables

Syntax

```
cdflib.setVarsCacheSize(cdfId,varNum,numBuffers)
```

Description

`cdflib.setVarsCacheSize(cdfId,varNum,numBuffers)` specifies the number of cache buffers the CDF library uses for all the variables in the multifile format Common Data Format (CDF) file.

This function is not applicable to single-file CDFs. For more information about caching, see the *CDF User's Guide*.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Numeric value identifying a variable in the file. Variable identifiers (variable numbers) are zero-based.

`numBuffers`

Numeric value specifying the cache buffers.

Examples

Create a multifile CDF and specify the number of buffers used for all variables. To run this example, you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf')

% Set the format of the file to be multi-file
cdflib.setFormat(cdfid,'MULTI_FILE');

% Create a variable in the file
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Note how the library creates a separate file for the variable
ls your_file.*

your_file.cdf  your_file.z0

% Determine the number of cache buffers used with the variable
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     1

% Specify the number of cache buffers used by all variables in CDF.
cdflib.setVarsCacheSize(cdfid,6)

% Check the number of cache buffers used with the variable.
numBuf = cdflib.getVarCacheSize(cdfid,varNum)

numBuf =

     6

%  Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

`cdflib.getVarCacheSize` | `cdflib.setVarCacheSize`

cdflib.setVarSparseRecords

Specify how variable handles sparse records

Syntax

```
cdflib.getVarSparseRecords(cdfId,varNum,stype)
```

Description

`cdflib.getVarSparseRecords(cdfId,varNum,stype)` specifies the sparse records type of a variable in a Common Data Format (CDF) file.

Input Arguments

`cdfId`

Identifier of a CDF file, returned by a call to `cdflib.create` or `cdflib.open`.

`varNum`

Number that identifies the variable to be set. Variable numbers are zero-based.

`stype`

One of the following text strings, or its numeric equivalent, that specifies how the variable handles sparse records.

Text String	Description
`'NO_SPARSERECORDS'`	No sparse records
`'PAD_SPARSERECORDS'`	For sparse records, the library uses the variable's pad value when reading values from a missing record.
`'PREV_SPARSERECORDS'`	For sparse records, the library uses values from the previous existing record when reading values from a missing record. If there is no previous existing record, the library uses the variable's pad value.

To get the numeric equivalent of these text string constants, use the `cdflib.getConstantValue` function.

Examples

Open a multifile CDF and close a variable.

Create a CDF, create a variable, and set the sparse records type of the variable. To run this example you must be in a writable folder.

```
cdfid = cdflib.create('your_file.cdf');

% Create a variable in the file.
varNum = cdflib.createVar(cdfid,'Time','cdf_int1',1,[],true,[]);

% Set the sparse records type of the variable
cdflib.setVarSparseRecords(cdfid,varNum,'PAD_SPARSERECORDS');

% Check the sparse records type of the variable
stype = cdflib.getVarSparseRecords(cdfid,varNum)

stype =

PAD_SPARSERECORDS

%Clean up
cdflib.delete(cdfid);

clear cdfid
```

References

This function corresponds to the CDF library C API routine `CDFsetzVarSparseRecords`.

To use this function, you must be familiar with the CDF C interface. Read the CDF documentation at the CDF website.

`cdflib.getVarSparseRecords` | `cdflib.getConstantValue`

cdfread

Read data from Common Data Format (CDF) file

Syntax

```
data = cdfread(filename)
data = cdfread(filename, param1, val1, param2, val2, ...)
[data, info] = cdfread(filename, ...)
```

Description

`data = cdfread(filename)` reads all the data from the Common Data Format (CDF) file specified in the string `filename`. CDF data sets typically contain a set of variables, of a specific data type, each with an associated set of records. The variable might represent time values with each record representing a specific time that an observation was recorded. `cdfread` returns all the data in a cell array where each column represents a variable and each row represents a record associated with a variable. If the variables have varying numbers of associated records, `cdfread` pads the rows to create a rectangular cell array, using pad values defined in the CDF file.

Note Because `cdfread` creates temporary files, the current working directory must be writeable.

`data = cdfread(filename, param1, val1, param2, val2, ...)` reads data from the file, where *`param1`*, *`param2`*, and so on, can be any of the parameters listed in the following table.

`[data, info] = cdfread(filename, ...)` returns details about the CDF file in the `info` structure.

Parameter	Value
`'Records'`	A vector specifying which records to read. Record numbers are zero-based. `cdfread` returns a cell array with the same number of rows as the number of records read and as many columns as there are variables.

Parameter	Value
`'Variables'`	A 1-by-*n* or *n*-by-1 cell array specifying the names of the variables to read from the file. *n* must be less than or equal to the total number of variables in the file. `cdfread` returns a cell array with the same number of columns as the number of variables read, and a row for each record read.
`'Slices'`	An *m*-by-3 array, where each row specifies where to start reading along a particular dimension of a variable, the skip interval to use on that dimension (every item, every other item, etc.), and the total number of values to read on that dimension. *m* must be less than or equal to the number of dimensions of the variable. If *m* is less than the total number of dimensions, `cdfread` reads every value from the unspecified dimensions (`[0 1 n]`, where *n* is the total number of elements in the dimension. Note: Because the `'Slices'` parameter describes how to process a single variable, it must be used in conjunction with the `'Variables'` parameter.
`'ConvertEpochToDatenum'`	A Boolean value that determines whether `cdfread` automatically converts CDF epoch data types to MATLAB serial date numbers. If set to `false` (the default), `cdfread` wraps epoch values in MATLAB `cdfepoch` objects. Note: For better performance when reading large data sets, set this parameter to `true`.

Parameter	Value
'CombineRecords'	A Boolean value that determines how cdfread returns the CDF data sets read from the file. If set to false (the default), cdfread stores the data in an *m*-by-*n* cell array, where *m* is the number of records and *n* is the number of variables requested. If set to true, cdfread combines all records for a particular variable into one cell in the output cell array. In this cell, cdfread stores scalar data as a column array. cdfread extends the dimensionality of nonscalar and string data. For example, instead of creating 1000 elements containing 20-by-30 arrays for each record, cdfread stores all the records in one cell as a 1000-by-20-by-30 array Note: If you use the 'Records' parameter to specify which records to read, you cannot use the 'CombineRecords' parameter. Note: When using the 'Variable' parameter to read one variable, if the 'CombineRecords' parameter is true, cdfread returns the data as an M-by-N numeric or character array; it does not put the data into a cell array.

Note: To improve performance when working with large data files, use the 'ConvertEpochToDatenum' and 'CombineRecords' options.

Note: To improve performance, turn off the file validation which the CDF library does by default when opening files. For more information, see cdflib.setValidate.

Examples

Read all the data from a CDF file.

```
data = cdfread('example.cdf');
```

Read the data from the variable 'Time'.

```
data = cdfread('example.cdf', 'Variable', {'Time'});
```

Read the first value in the first dimension, the second value in the second dimension, the first and third values in the third dimension, and all values in the remaining dimension of the variable `'multidimensional'`.

```
data = cdfread('example.cdf', ...
               'Variable', {'multidimensional'}, ...
               'Slices', [0 1 1; 1 1 1; 0 2 2]);
```

This is similar to reading the whole variable into `data` and then using matrix indexing, as in the following.

```
data{1}(1, 2, [1 3], :)
```

Collapse the records from a data set and convert CDF epoch data types to MATLAB serial date numbers.

```
data = cdfread('example.cdf', ...
               'CombineRecords', true, ...
               'ConvertEpochToDatenum', true);
```

- "Import CDF Files Using Low-Level Functions"

See Also

`cdfepoch` | `cdfinfo` | `cdflib.setValidate`

Introduced before R2006a

cdfwrite

Write data to Common Data Format (CDF) file

Note: `cdfwrite` is not recommended. Use the `cdflib` low-level functions instead.

Syntax

```
cdfwrite(filename,variablelist)
cdfwrite(...,'PadValues',padvals)
cdfwrite(...,'GlobalAttributes',gattrib)
cdfwrite(..., 'VariableAttributes', vattrib)
cdfwrite(...,'WriteMode',mode)
cdfwrite(...,'Format',format)
```

Description

`cdfwrite(filename,variablelist)` writes out a Common Data Format (CDF) file, specified in `filename`. The `filename` input is a string enclosed in single quotes. The `variablelist` argument is a cell array of ordered pairs, each of which comprises a CDF variable name (a string) and the corresponding CDF variable value. To write out multiple records for a variable, put the values in a cell array where each element in the cell array represents a record.

Note Because `cdfwrite` creates temporary files, both the destination directory for the file and the current working directory must be writeable.

`cdfwrite(...,'PadValues',padvals)` writes out pad values for given variable names. `padvals` is a cell array of ordered pairs, each of which comprises a variable name (a string) and a corresponding pad value. Pad values are the default values associated with the variable when an out-of-bounds record is accessed. Variable names that appear in `padvals` must appear in `variablelist`.

`cdfwrite(...,'GlobalAttributes',gattrib)` writes the structure `gattrib` as global metadata for the CDF file. Each field of the structure is the name of a global attribute. The value of each field contains the value of the attribute. To write out multiple values for an attribute, put the values in a cell array where each element in the cell array represents a record.

Note To specify a global attribute name that is invalid in your MATLAB application, create a field called `'CDFAttributeRename'` in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `GlobalAttributes` structure, and the corresponding name of the attribute to be written to the CDF file.

`cdfwrite(..., 'VariableAttributes', vattrib)` writes the structure `vattrib` as variable metadata for the CDF. Each field of the struct is the name of a variable attribute. The value of each field should be an M-by-2 cell array where M is the number of variables with attributes. The first element in the cell array should be the name of the variable and the second element should be the value of the attribute for that variable.

Note To specify a variable attribute name that is illegal in MATLAB, create a field called `'CDFAttributeRename'` in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `VariableAttributes` struct, and the corresponding name of the attribute to be written to the CDF file. If you are specifying a variable attribute of a CDF variable that you are renaming, the name of the variable in the `VariableAttributes` structure must be the same as the renamed variable.

`cdfwrite(...,'WriteMode',`*`mode`*`)`, where *`mode`* is either `'overwrite'` or `'append'`, indicates whether or not the specified variables should be appended to the CDF file if the file already exists. By default, `cdfwrite` overwrites existing variables and attributes.

`cdfwrite(...,'Format',`*`format`*`)`, where *`format`* is either `'multifile'` or `'singlefile'`, indicates whether or not the data is written out as a multifile CDF. In a multifile CDF, each variable is stored in a separate file with the name `*.vN`, where `N` is the number of the variable that is written out to the CDF. By default, `cdfwrite` writes out a single file CDF. When `'WriteMode'` is set to `'Append'`, the `'Format'` option is ignored, and the format of the preexisting CDF is used.

Examples

Write out a file `'example.cdf'` containing a variable `'Longitude'` with the value `[0:360]`.

```
cdfwrite('example', {'Longitude', 0:360});
```

Write out a file `'example.cdf'` containing variables `'Longitude'` and `'Latitude'` with the variable `'Latitude'` having a pad value of 10 for all out-of-bounds records that are accessed.

```
cdfwrite('example', {'Longitude', 0:360, 'Latitude', 10:20}, ...
         'PadValues', {'Latitude', 10});
```

Write out a file `'example.cdf'`, containing a variable `'Longitude'` with the value `[0:360]`, and with a variable attribute of `'validmin'` with the value 10.

```
varAttribStruct.validmin = {'Longitude' [10]};
cdfwrite('example', {'Longitude' 0:360}, 'VariableAttributes', ...
         varAttribStruct);
```

Introduced before R2006a

ceil

Round toward positive infinity

Syntax

```
Y = ceil(X)
```

```
Y = ceil(t)
Y = ceil(t,unit)
```

Description

`Y = ceil(X)` rounds each element of `X` to the nearest integer greater than or equal to that element.

`Y = ceil(t)` rounds each element of the `duration` array `t` to the nearest number of seconds greater than or equal to that element.

`Y = ceil(t,unit)` rounds each element of `t` to the nearest number of the specified unit of time greater than or equal to that element.

Examples

Round Matrix Elements Toward Positive Infinity

```
X = [-1.9 -0.2 3.4; 5.6 7 2.4+3.6i];
Y = ceil(X)
```

```
Y =

  -1.0000 + 0.0000i   0.0000 + 0.0000i   4.0000 + 0.0000i
   6.0000 + 0.0000i   7.0000 + 0.0000i   3.0000 + 4.0000i
```

Round Duration Values Toward Positive Infinity

Round each value in a duration array to the nearest number of seconds greater than or equal to that value.

```
t = hours(8) + minutes(29:31) + seconds(1.23);
t.Format = 'hh:mm:ss.SS'
```

```
t =

   08:29:01.23   08:30:01.23   08:31:01.23
```

```
Y1 = ceil(t)
```

```
Y1 =

   08:29:02.00   08:30:02.00   08:31:02.00
```

Round each value in t to the nearest number of hours greater than or equal to that value.

```
Y2 = ceil(t,'hours')
```

```
Y2 =

   09:00:00.00   09:00:00.00   09:00:00.00
```

Input Arguments

X — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. For complex `X`, `ceil` treats the real and imaginary parts independently.

`ceil` converts logical and `char` elements of `X` into `double` values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char` | `logical`
Complex Number Support: Yes

t — Input duration

`duration` array

Input duration, specified as a `duration` array.

`unit` — Unit of time

`'seconds'` (default) | `'minutes'` | `'hours'` | `'days'`

Unit of time, specified as `'seconds'`, `'minutes'`, `'hours'`, or `'days'`.

Introduced before R2006a

cell

Create cell array

Syntax

```
C = cell(n)
C = cell(sz1,...,szN)
C = cell(sz)

D = cell(obj)
```

Description

`C = cell(n)` returns an `n`-by-`n` cell array of empty matrices.

`C = cell(sz1,...,szN)` returns a `sz1`-by-...-by-`szN` cell array of empty matrices where `sz1,...,szN` indicate the size of each dimension. For example, `cell(2,3)` returns a 2-by-3 cell array.

`C = cell(sz)` returns a cell array of empty matrices where size vector `sz` defines `size(C)`. For example, `cell([2 3])` returns a 2-by-3 cell array.

`D = cell(obj)` converts a Java array or .NET `System.String` or `System.Object` array into a MATLAB cell array.

Examples

Square Cell Array

Create a 3-by-3 cell array of empty matrices.

```
C = cell(3)
```

```
C =

    []    []    []
```

```
    []    []    []
    []    []    []
```

3-D Cell Array

Create a 3-by-4-by-2 cell array of empty matrices.

```
C = cell(3,4,2);
size(C)
```

```
ans =

     3     4     2
```

Clone Size from Existing Array

Create a cell array of empty matrices that is the same size as an existing array.

```
A = [7 9; 2 1; 8 3];
sz = size(A);
C = cell(sz)
```

```
C =

    []    []
    []    []
    []    []
```

It is a common pattern to combine the previous two lines of code into a single line.

```
C = cell(size(A));
```

Cell Array from Java Array

Convert an array of `java.lang.String` objects into a cell array.

```
X = java_array('java.lang.String', 3);
X(1) = java.lang.String('one');
X(2) = java.lang.String('two');
X(3) = java.lang.String('three');
```

```
D = cell(X)

D =

    'one'
    'two'
    'three'
```

Cell Array from .NET Array

Convert a .NET array of `System.Double` objects into a cell array.

```
N = NET.createArray('System.Double[]',2);
N(1) = [13 7 30];
N(2) = 42;
D = cell(N)

D =

    [1x3 double]    [42]
```

- "Create a Cell Array"
- "Access Data in a Cell Array"
- "Use Python list Type in MATLAB"

Input Arguments

n — Size of square cell array

integer value

Size of a square cell array, specified as an integer value.

- If `n` is `0`, then `C` is an empty cell array.
- If `n` is negative, then it is treated as `0`.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

sz1,...,szN — Size of each dimension (as separate arguments)

integer values

Size of each dimension, specified as separate arguments of integer values.

- If the size of any dimension is `0`, then `C` is an empty cell array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `cell` ignores trailing dimensions with a size of 1. For example, `cell([3,1,1,1])` produces a 3-by-1 cell array of empty matrices.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`sz` — Size of each dimension (as a row vector)

integer values

Size of each dimension, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is `0`, then `C` is an empty cell array.
- If the size of any dimension is negative, then it is treated as `0`.
- Beyond the second dimension, `cell` ignores trailing dimensions with a size of 1. For example, `cell([3,1,1,1])` produces a 3-by-1 cell array of empty matrices.

Example: `sz = [2, 3, 4]` creates a 2-by-3-by-4 cell array of empty matrices.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`obj` — Input array

Java array or object | .NET array of type `System.String` or `System.Object` | Python® sequence type

Input array, specified as:

- Java array or object
- .NET array of type `System.String` or `System.Object`
- Python sequence type

Output Arguments

`C` — Output array

cell array

Output array, returned as a cell array. Each cell contains an empty, 0-by-0 array of type `double`.

`D` — Converted array

cell array

Converted array, returned as a cell array.

Each cell contains a MATLAB type closest to the Java or .NET type. For more information, see:

- "Conversion of Java Return Types"
- ".NET Type to MATLAB Type Mapping"

More About

Tips

- Creating an empty array with the `cell` function, such as

  ```
  C = cell(3,4,2);
  ```

  is equivalent to assigning an empty array to the last index of a new cell array:

  ```
  C{3,4,2} = [];
  ```

See Also

`num2cell` | `table2cell`

Introduced before R2006a

cell2mat

Convert cell array to ordinary array of the underlying data type

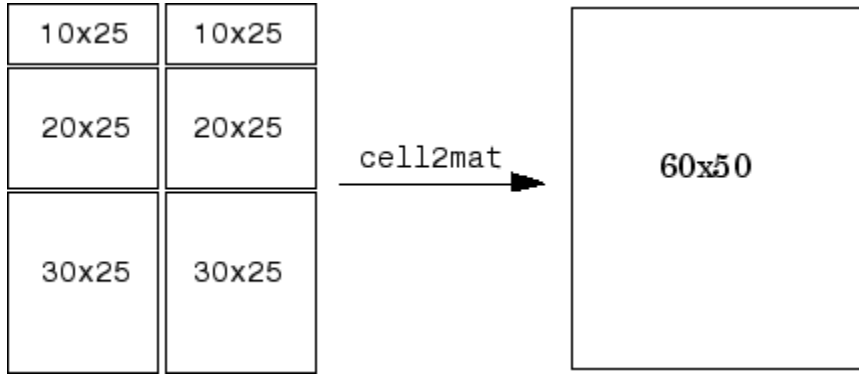
Syntax

```
A = cell2mat(C)
```

Description

`A = cell2mat(C)` converts a cell array into an ordinary array. The elements of the cell array must all contain the same data type, and the resulting array is of that data type.

The contents of `C` must support concatenation into an N-dimensional rectangle. Otherwise, the results are undefined. For example, the contents of cells in the same column must have the same number of columns, although they need not have the same number of rows (see figure).



Examples

Convert Cell Array to Numeric Array

Convert numeric arrays in four cells of a cell array into one numeric array.

```
C = {[1],    [2 3 4];
     [5; 9], [6 7 8; 10 11 12]}

C =

    [         1]    [1x3 double]
    [2x1 double]    [2x3 double]

A = cell2mat(C)

A =

     1     2     3     4
     5     6     7     8
     9    10    11    12
```

Convert Cell Array of Structures to Array

Convert structures in a cell array into one structure array. The structures must have the same fields.

```
s1.a = [1 2 3 4];
s1.b = 'Good';
s2.a = [5 6; 7 8];
s2.b = 'Morning';
c = {s1,s2};
d = cell2mat(c)

d =

1x2 struct array with fields:

    a
    b
```

Display the first field of structure `d(1)`.

```
d(1).a

ans =

     1     2     3     4
```

Display the second field of `d(2)`.

```
d(2).b
```

```
ans =

Morning
```

Input Arguments

C — Input cell array

cell array

Input cell array, in which all cells contain the same data type. `cell2mat` accepts numeric or character data within cells of `C`, or structures with the same field names and data types. `cell2mat` does not accept objects or nested cells within `C`.

See Also

`cell` | `cell2struct` | `cell2table` | `iscell` | `mat2cell` | `num2cell` | `struct2cell` | `table2cell`

Introduced before R2006a

cell2struct

Convert cell array to structure array

Syntax

```
structArray = cell2struct(cellArray, fields, dim)
```

Description

`structArray = cell2struct(cellArray, fields, dim)` creates a structure array, *`structArray`*, from the information contained within cell array *`cellArray`*.

The *`fields`* argument specifies field names for the structure array. This argument is an array of strings or a cell array of strings.

The *`dim`* argument tells MATLAB which axis of the cell array to use in creating the structure array. Use a numeric `double` to specify *`dim`*.

To create a structure array with fields derived from `N` rows of a cell array, specify `N` field names in the *`fields`* argument, and the number 1 in the *`dim`* argument. To create a structure array with fields derived from `M` columns of a cell array, specify `M` field names in the *`fields`* argument and the number 2 in the *`dim`* argument.

The *`structArray`* output is a structure array with `N` fields, where `N` is equal to the number of fields in the *`fields`* input argument. The number of fields in the resulting structure must equal the number of cells along dimension *`dim`* that you want to convert.

Examples

Create the following table for use with the examples in this section. The table lists information about the employees of a small Engineering company. Reading the table by rows shows the names of employees by department. Reading the table by columns shows the number of years each employee has worked at the company.

	5 Years	10 Years	15 Years
Development	Lee, Reed, Hill	Dean, Frye	Lane, Fox, King

	5 Years	10 Years	15 Years
Sales	Howe, Burns	Kirby, Ford	Hall
Management	Price	Clark, Shea	Sims
Quality	Bates, Gray	Nash	Kay, Chase
Documentation	Lloyd, Young	Ryan, Hart, Roy	Marsh

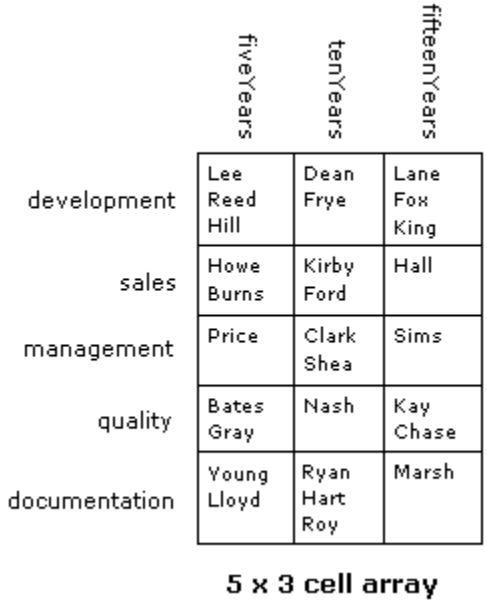
Enter the following commands to create the initial cell array `employees`:

```
devel = {{'Lee','Reed','Hill'}, {'Dean','Frye'}, ...
   {'Lane','Fox','King'}};
sales = {{'Howe','Burns'}, {'Kirby','Ford'}, {'Hall'}};
mgmt = {{'Price'}, {'Clark','Shea'}, {'Sims'}};
qual = {{'Bates','Gray'}, {'Nash'}, {'Kay','Chase'}};
docu = {{'Lloyd','Young'}, {'Ryan','Hart','Roy'}, {'Marsh'}};

employees = [devel; sales; mgmt; qual; docu]
employees =

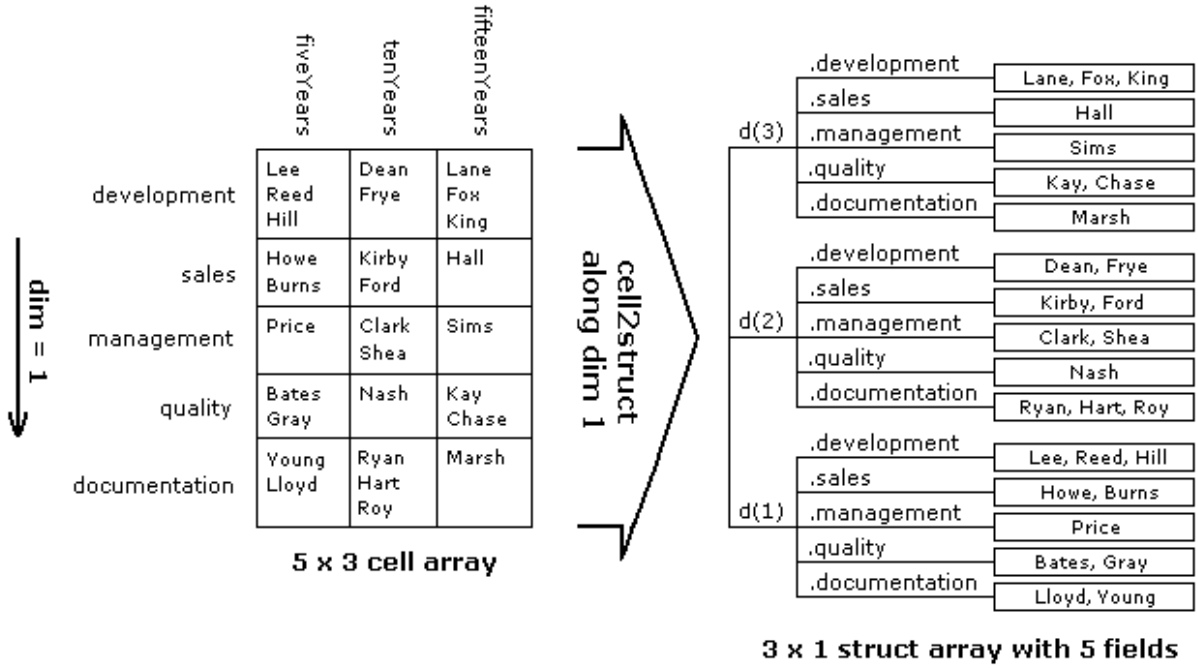
    {1x3 cell}    {1x2 cell}    {1x3 cell}
    {1x2 cell}    {1x2 cell}    {1x1 cell}
    {1x1 cell}    {1x2 cell}    {1x1 cell}
    {1x2 cell}    {1x1 cell}    {1x2 cell}
    {1x2 cell}    {1x3 cell}    {1x1 cell}
```

This is the resulting cell array:



Convert the cell array to a struct along dimension 1:

1 Convert the 5-by-3 cell array along its first dimension to construct a 3-by-1 struct array with 5 fields. Each of the rows along dimension 1 of the cell array becomes a field in the struct array:



Traversing the first (i.e., vertical) dimension, there are 5 rows with row headings that read as follows:

```
rowHeadings = {'development', 'sales', 'management', ...
   'quality', 'documentation'};
```

2 Convert the cell array to a struct array, `depts`, in reference to this dimension:

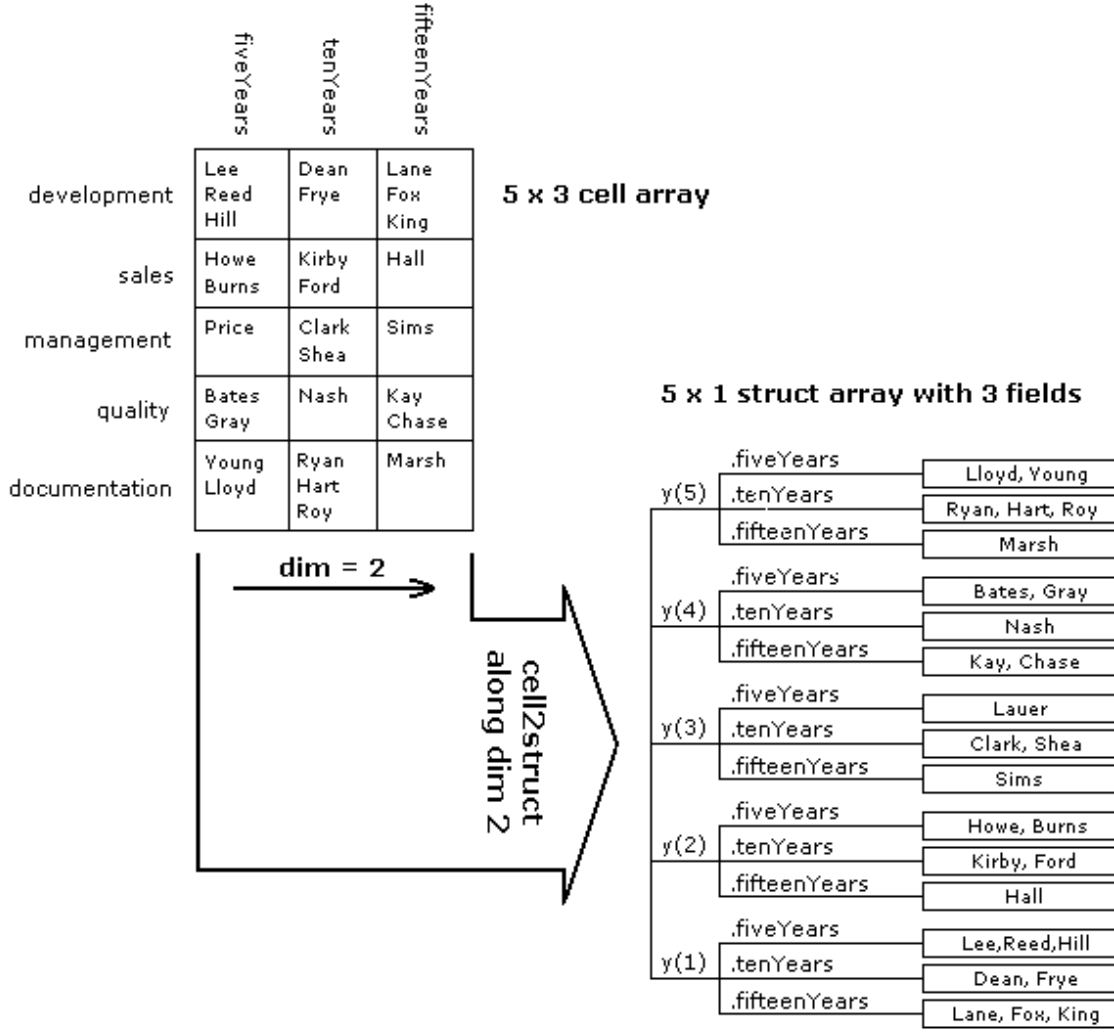
```
depts = cell2struct(employees, rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    sales
    management
    quality
    documentation
```

3 Use this row-oriented structure to find the names of the Development staff who have been with the company for up to 10 years:

```
depts(1:2).development
ans =
    'Lee'    'Reed'    'Hill'
ans =
    'Dean'    'Frye'
```

Convert the same cell array to a struct along dimension 2:

1. Convert the 5-by-3 cell array along its second dimension to construct a 5-by-1 struct array with 3 fields. Each of the columns along dimension 2 of the cell array becomes a field in the struct array:



2 Traverse the cell array along the second (or horizontal) dimension. The column headings become fields of the resulting structure:

```
colHeadings = {'fiveYears' 'tenYears' 'fifteenYears'};
```

```
years = cell2struct(employees, colHeadings, 2)
years =
5x1 struct array with fields:
    fiveYears
    tenYears
    fifteenYears
```

3 Using the column-oriented structure, show how many employees from the Sales and Documentation departments have worked for the company for at least 5 years:

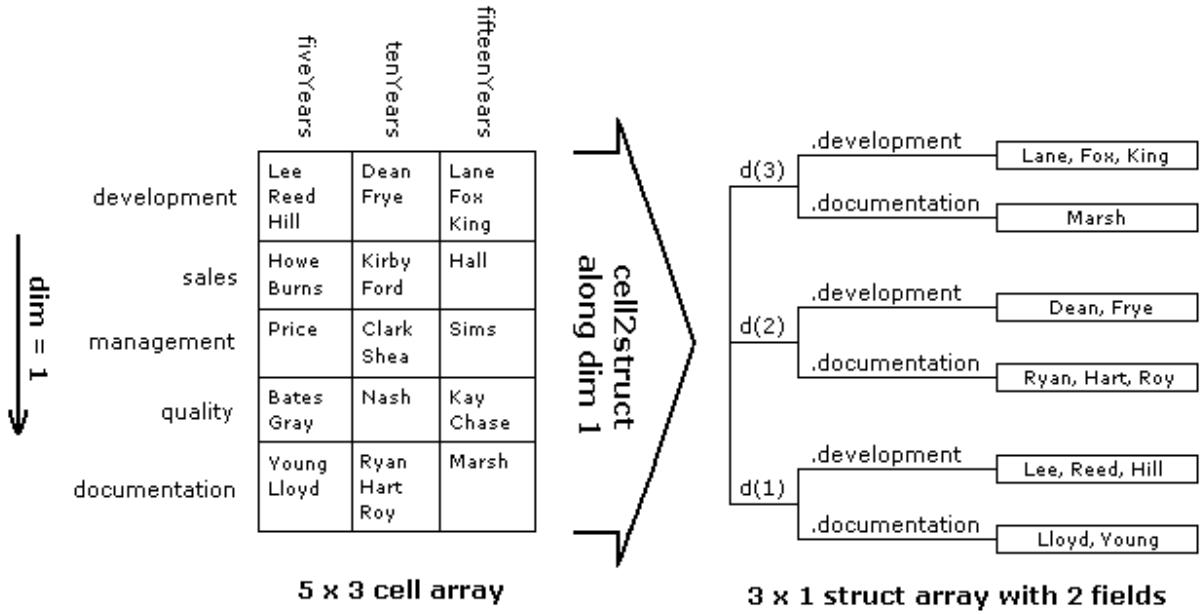
```
[~, sales_5years, ~, ~, docu_5years] = years.fiveYears
sales_5years =
    'Howe'    'Burns'
docu_5years =
    'Lloyd'    'Young'
```

Convert only part of the cell array to a struct:

1 Convert only the first and last rows of the cell array. This results in a 3-by-1 struct array with 2 fields:

```
rowHeadings = {'development', 'documentation'};

depts = cell2struct(employees([1,5],:), rowHeadings, 1)
depts =
3x1 struct array with fields:
    development
    documentation
```



2 Display those employees who belong to these departments for all three periods of time:

```
for k=1:3
   depts(k,:)
end

ans =
      development: {'Lee'  'Reed'  'Hill'}
    documentation: {'Lloyd'  'Young'}
ans =
      development: {'Dean'  'Frye'}
    documentation: {'Ryan'  'Hart'  'Roy'}
ans =
      development: {'Lane'  'Fox'  'King'}
    documentation: {'Marsh'}
```

`struct2cell` | `cell2table` | `table2struct` | `cell` | `iscell` | `struct` | `isstruct` | `fieldnames`

Introduced before R2006a

cell2table

Convert cell array to table

Syntax

```
T = cell2table(C)
T = cell2table(C,Name,Value)
```

Description

`T = cell2table(C)` converts the contents of an `m`-by-`n` cell array, `C`, to an `m`-by-`n` table, `T`. Each variable in the table, `T`, is numeric, with a data type `double`, or a cell array of strings.

`cell2table` uses the input array name appended with the column number for the variable names in the table. If these names are not valid MATLAB identifiers, `cell2table` uses strings of the form `'Var1',...,'VarN'` where *N* is the number of columns in `C`.

`T = cell2table(C,Name,Value)` creates a table from a cell array, `C`, with additional options specified by one or more Name,Value pair arguments.

For example, you can specify row names or variable names to include in the table.

Examples

Convert Cell Array to Table

Create a cell array containing strings and numeric data.

```
C = {5 'cereal' 110 'C+'; 12 'pizza' 140 'B';...
    23 'salmon' 367 'A'; 2 'cookies' 160 'D'}
```

```
C =

    [ 5]    'cereal'    [110]    'C+'
```

```
    [12]    'pizza'      [140]    'B'
    [23]    'salmon'     [367]    'A'
    [ 2]    'cookies'    [160]    'D'
```

Convert the cell array, `C`, to a table and specify variable names.

```
T = cell2table(C,...
    'VariableNames',{'Age' 'FavoriteFood' 'Calories' 'NutritionGrade'})
```

```
T =

    Age    FavoriteFood    Calories    NutritionGrade
    ___    ____________    ________    ______________

     5     'cereal'        110         'C+'
    12     'pizza'         140         'B'
    23     'salmon'        367         'A'
     2     'cookies'       160         'D'
```

The variables `T.Age` and `T.Calories` are numeric while the variables `T.FavoriteFood` and `T.NutritionGrade` are cell arrays of strings.

Convert Column Headings to Variable Names

Convert a cell array to a table, and then include the first row from the cell array as variable names for the table.

Create a cell array where the first row contains strings to identify column headings.

```
Patients = {'Gender' 'Age' 'Height' 'Weight' 'Smoker';...
    'M' 38 71 176 true;...
    'M' 43 69 163 false;...
    'M' 38 64 131 false;...
    'F' 38 64 131 false;...
    'F' 40 67 133 false;...
    'F' 49 64 119 false}
```

```
Patients =

    'Gender'    'Age'    'Height'    'Weight'    'Smoker'
    'M'         [ 38]    [    71]    [   176]    [     1]
    'M'         [ 43]    [    69]    [   163]    [     0]
    'M'         [ 38]    [    64]    [   131]    [     0]
    'F'         [ 38]    [    64]    [   131]    [     0]
    'F'         [ 40]    [    67]    [   133]    [     0]
```

```
    'F'         [ 49]    [    64]    [   119]    [     0]
```

Exclude the columns headings and convert the contents of the cell array to a table.

```
C = Patients(2:end,:);
T = cell2table(C)
```

```
T =

    C1     C2    C3    C4      C5
    ___    __    __    ___    _____

    'M'    38    71    176    true
    'M'    43    69    163    false
    'M'    38    64    131    false
    'F'    38    64    131    false
    'F'    40    67    133    false
    'F'    49    64    119    false
```

The table, `T`, has variable names `C1,...,C5`.

Change the variable names by setting the table property, `T.Properties.VariableNames`, to the first row of the cell array.

```
T.Properties.VariableNames = Patients(1,:)
```

```
T =

    Gender    Age    Height    Weight    Smoker
    ______    ___    ______    ______    ______

    'M'       38     71        176       true
    'M'       43     69        163       false
    'M'       38     64        131       false
    'F'       38     64        131       false
    'F'       40     67        133       false
    'F'       49     64        119       false
```

- “Access Data in a Table”

Input Arguments

`C` — Input cell array

2-D cell array

Input cell array, specified as a 2-D cell array.

If the cell contents have compatible sizes and types, then `cell2table` vertically concatenates the contents of the cells in each column of `C` to create each variable in `T`. If the cell contents have different sizes or incompatible types, then the corresponding variable in the table, `T`, is a column of cells.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `RowNames',{'row1','row2','row3'}` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

`'RowNames'` — Row names for `T`
`{}` (default) | cell array of nonempty, distinct strings

Row names for `T`, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows, `size(C,1)`.

`'VariableNames'` — Variable names for `T`
cell array of nonempty, distinct strings

Variable names for `T`, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables, `size(C,2)`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of `N` strings of the form `{'Var1' ... 'VarN'}`, where *N* is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

Output Arguments

`T` — Output table
table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see `Table Properties`.

See Also

`array2table` | `isvarname` | `struct2table` | `table` | `table2cell`

celldisp

Display cell array contents

Syntax

```
celldisp(C)
celldisp(C, name)
```

Description

`celldisp(C)` recursively displays the contents of a cell array.

`celldisp(C, name)` uses the string *`name`* for the display instead of the name of the first input (or `ans`).

Examples

Use `celldisp` to display the contents of a 2-by-3 cell array:

```
C = {[1 2] 'Tony' 3+4i; [1 2;3 4] -5 'abc'};
celldisp(C)

C{1,1} =
     1     2

C{2,1} =
     1     2
     3     4

C{1,2} =
Tony

C{2,2} =
    -5

C{1,3} =
   3.0000+ 4.0000i
```

```
C{2,3} =
abc
```

- “Export Cell Array to Text File”

See Also

`cellplot`

Introduced before R2006a

cellfun

Apply function to each cell in cell array

Syntax

```
[A1,...,Am] = cellfun(func,C1,...,Cn)
[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)
```

Description

`[A1,...,Am] = cellfun(func,C1,...,Cn)` calls the function specified by function handle `func` and passes elements from cell arrays `C1,...,Cn`, where `n` is the number of inputs to function `func`. Output arrays `A1,...,Am`, where `m` is the number of outputs from function `func`, contain the combined outputs from the function calls. The `i`th iteration corresponds to the syntax `[A1(i),...,Am(i)] = func(C1{i},...,Cn{i})`. The `cellfun` function does not perform the calls to function `func` in a specific order.

`[A1,...,Am] = cellfun(func,C1,...,Cn,Name,Value)` calls function `func` with additional options specified by one or more Name,Value pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

Input Arguments

`func`

Handle to a function that accepts `n` input arguments and returns `m` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

Backward Compatibility

`cellfun` accepts function name strings for function `func`, rather than a function handle, for these function names: `isempty`, `islogical`, `isreal`, `length`, `ndims`, `prodofsize`, `size`, `isclass`. Enclose the function name in single quotes.

If you specify a function name string rather than a function handle:

- `cellfun` does not call any overloaded versions of the function.
- The `size` and `isclass` functions require additional inputs to the `cellfun` function:

  `A = cellfun('size', C, k)` returns the size along the `k`th dimension of each element of `C`.

  `A = cellfun('isclass', C, classname)` returns logical `1` (`true`) for each element of `C` that matches the `classname` string. This syntax returns logical 0 (`false`) for objects that are a subclass of `classname`.

`C1,...,Cn`

Cell arrays that contain the `n` inputs required for function `func`. Each cell array must have the same dimensions.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'UniformOutput'`

Logical value, as follows:

`true (1)`	Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type and size. The `cellfun` function combines the outputs in arrays `A1,...,Am`, where `m` is the number of function outputs. Each output array is of the same type as the individual function outputs.
`false (0)`	Requests that the `cellfun` function combine the outputs into cell arrays `A1,...,Am`. The outputs of function `func` can be of any size or type.

Default: `true`

`'ErrorHandler'`

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

`identifier`	Error identifier.
`message`	Error message text.
`index`	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

Output Arguments

`A1,...,Am`

Arrays that collect the `m` outputs from function `func`. Each array `A` is the same size as each of the inputs `C1,...,Cn`.

Function `func` can return output arguments of different classes. However, if `UniformOutput` is `true` (the default):

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each set of inputs. The class of the corresponding output array is the same as the class of the outputs from function `func`.

Examples

Compute the mean of each vector in cell array `C`.

```
C = {1:10, [2; 4; 6], []};
```

```
averages = cellfun(@mean, C)
```

This code returns

```
averages =
    5.5000    4.0000       NaN
```

Compute the size of each array in `C`, created in the previous example.

```
[nrows, ncols] = cellfun(@size, C)
```

This code returns

```
nrows =
     1     3     0
ncols =
    10     1     0
```

Create a cell array that contains strings, and abbreviate those strings to the first three characters. Because the output strings are nonscalar, set `UniformOutput` to `false`.

```
days = {'Monday', 'Tuesday', 'Wednesday', 'Thursday', 'Friday'};

abbrev = cellfun(@(x) x(1:3), days, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function. This code returns

```
abbrev =
    'Mon'    'Tue'    'Wed'    'Thu'    'Fri'
```

Compute the covariance between arrays in two cell arrays `C` and `D`. Because the covariance output is nonscalar, set `UniformOutput` to `false`.

```
c1 = rand(5,1);  c2 = rand(10,1);  c3 = rand(15,1);
d1 = rand(5,1);  d2 = rand(10,1);  d3 = rand(15,1);
C = {c1, c2, c3};
D = {d1, d2, d3};

covCD = cellfun(@cov, C, D, 'UniformOutput', false)
```

This code returns

```
covCD =
    [2x2 double]    [2x2 double]    [2x2 double]
```

Define and call a custom error handling function.

```
function result = errorfun(S, varargin)
   warning(S.identifier, S.message);
   result = NaN;
end

A = {rand(3)};
B = {rand(5)};
AgtB = cellfun(@(x,y) x > y, A, B, 'ErrorHandler', @errorfun, ...
               'UniformOutput', false)
```

Introduced before R2006a

cellplot

Graphically display structure of cell array

Syntax

```
cellplot(c)
cellplot(c, 'legend')
handles = cellplot(c)
```

Description

`cellplot(c)` displays a figure window that graphically represents the contents of `c`. Filled rectangles represent elements of vectors and arrays, while scalars and short text strings are displayed as text.

`cellplot(c, 'legend')` places a colorbar next to the plot labelled to identify the data types in `c`.

`handles = cellplot(c)` displays a figure window and returns a vector of surface handles.

Limitations

The `cellplot` function can display only two-dimensional cell arrays.

Examples

Consider a 2-by-2 cell array containing a matrix, a vector, and two text strings:

```
c{1,1} = '2-by-2';
c{1,2} = 'eigenvalues of eye(2)';
c{2,1} = eye(2);
c{2,2} = eig(eye(2));
```

The command `cellplot(c)` produces

`celldisp`

Introduced before R2006a

cellstr

Convert to cell array of strings

Syntax

```
C = cellstr(S)

S = cellstr(D)
S = cellstr(D,fmt)
S = cellstr(D,fmt,locale)
```

Description

`C = cellstr(S)` converts array `S` to a cell array.

- If `S` is a character array, then each row of `S` is a cell of `C`. Any trailing spaces in the rows of `S` are removed. Use the `char` function to convert back into a character array.
- If `S` is a cell array of strings, then `cellstr` returns `S` unaltered.
- If `S` is a categorical array, then `cellstr` returns a cell array of the same size.

`S = cellstr(D)` converts a datetime, duration, or calendar duration array into a cell array of strings in the format specified by the `Format` property of `D`. The output has the same dimensions as `D`.

`S = cellstr(D,fmt)` represents dates or durations in the specified format, such as `'HH:mm:ss'`.

`S = cellstr(D,fmt,locale)` represents dates or durations in the specified locale, such as `'en_US'`. The locale affects the language used to represent character strings such as month and day names.

Examples

Convert Character Array to Cell Array of Strings

Create a character array. Include trailing spaces so that each row has the same length, resulting in a 3-by-4 array.

```
S = ['abc ';'defg';'hi  ']
```

```
S =

abc
defg
hi
```

```
whos S
```

```
 Name      Size            Bytes  Class    Attributes

  S         3x4                24  char
```

Convert the character array to a 3-by-1 cell array of strings.

```
C = cellstr(S)
```

```
C =

    'abc'
    'defg'
    'hi'
```

```
whos C
```

```
 Name      Size            Bytes  Class    Attributes

  C         3x1               354  cell
```

Convert Calendar Duration Array to Cell Array of Strings

Create a `calendarDuration` array.

```
D = calmonths(15:17) + caldays(8) + hours(1.2345)
```

```
D =

   1y 3mo 8d 1h 14m 4.2s   1y 4mo 8d 1h 14m 4.2s   1y 5mo 8d 1h 14m 4.2s
```

Convert the array to a cell array of strings.

```
C = cellstr(D)
```

```
C =

    '1y 3mo 8d 1h 14m ...'    '1y 4mo 8d 1h 14m ...'    '1y 5mo 8d 1h 14m ...'
```

```
whos C
```

```
  Name      Size            Bytes  Class    Attributes

  C         1x3               462  cell
```

Input Arguments

`S` — Input array

character array | cell array of strings | categorical array

Input array, specified as a character array, a cell array of strings, or a categorical array.

If `S` is a character array, then each row of `S` becomes a separate cell of `C`, with trailing spaces removed.

If `S` is a cell array of strings, then `cellstr` returns `S` unaltered.

Data Types: `char` | `cell`

`D` — Input date and time

date or duration array

Input date and time, specified as a date or duration array.

Data Types: `datetime` | `duration` | `calendarDuration`

`fmt` — Date format

string

Date format, specified as a string. The supported formats depend on the data type of input `D`.

- `datetime` formats can include combinations of units and delimiters, such as `'yyyy-MMM-dd HH:mm:ss.SSS'`. For details, see the `Format` property for datetime arrays.
- `duration` formats are either single characters (`'y'`, `'d'`, `'h'`, `'m'`, or `'s'`) or one of these combinations:

- `'dd:hh:mm:ss'`
- `'hh:mm:ss'`
- `'mm:ss'`
- `'hh:mm'`
- Any of the above, with up to nine `S` characters to indicate fractional second digits, such as `'hh:mm:ss.SSSS'`

- `calendarDuration` formats can include combinations of the characters `'y'`, `'q'`, `'m'`, `'w'`, `'d'`, and `'t'` in order from largest to smallest unit of time, such as `'ym'`.

For more information on the `duration` and `calendarDuration` formats, see "Set Date and Time Display Format".

`locale` — Locale of the character strings to create

string

Locale of the character strings to create, specified as a string.

`locale` can be:

- `'system'`, to specify your system locale.
- a string in the form *`xx`*`_`*`YY`*, where *`xx`* is a lowercase ISO 639-1 two-letter code that specifies a language, and *`YY`* is an uppercase ISO 3166-1 alpha-2 code that specifies a country.

These are the same strings accepted by the `'Locale'` name-value pair argument for the `datetime` function. The locale affects the language used in the output array.

Example: `'en_US'`

Example: `'ja_JP'`

Introduced before R2006a

cgs

Conjugate gradients squared method

Syntax

```
x = cgs(A,b)
cgs(A,b,tol)
cgs(A,b,tol,maxit)
cgs(A,b,tol,maxit,M)
cgs(A,b,tol,maxit,M1,M2)
cgs(A,b,tol,maxit,M1,M2,x0)
[x,flag] = cgs(A,b,...)
[x,flag,relres] = cgs(A,b,...)
[x,flag,relres,iter] = cgs(A,b,...)
[x,flag,relres,iter,resvec] = cgs(A,b,...)
```

Description

`x = cgs(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. You can specify `A` as a function handle, `afun`, such that `afun(x)` returns `A*x`.

"Parameterizing Functions" explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `cgs` converges, a message to that effect is displayed. If `cgs` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`cgs(A,b,tol)` specifies the tolerance of the method, `tol`. If `tol` is `[]`, then `cgs` uses the default, `1e-6`.

`cgs(A,b,tol,maxit)` specifies the maximum number of iterations, `maxit`. If `maxit` is `[]` then `cgs` uses the default, `min(n,20)`.

`cgs(A,b,tol,maxit,M)` and `cgs(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `cgs` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`cgs(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess `x0`. If `x0` is `[]`, then `cgs` uses the default, an all-zero vector.

`[x,flag] = cgs(A,b,...)` returns a solution `x` and a flag that describes the convergence of `cgs`.

Flag	Convergence
0	`cgs` converged to the desired tolerance `tol` within `maxit`iterations.
1	`cgs` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`cgs` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `cgs` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = cgs(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, then `relres <= tol`.

`[x,flag,relres,iter] = cgs(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = cgs(A,b,...)` also returns a vector of the residual norms at each iteration, including `norm(b-A*x0)`.

Examples

Using cgs with a Matrix Input

```
A = gallery('wilk',21);
```

```
b = sum(A,2);
tol = 1e-12;  maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x = cgs(A,b,tol,maxit,M1);
```

displays the message

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

Using cgs with a Function Handle

This example replaces the matrix `A` in the previous example with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in the file `run_cgs` that

- Calls `cgs` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_cgs` are available to `afun` and `myfun`.

The following shows the code for `run_cgs`:

```
function x1 = run_cgs
n = 21;
b = afun(ones(n,1));
tol = 1e-12;  maxit = 15;
x1 = cgs(@afun,b,tol,maxit,@mfun);

    function y = afun(x)
        y = [0; x(1:n-1)] + ...
              [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
              [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_cgs
```

MATLAB software returns

```
cgs converged at iteration 13 to a solution with
relative residual 2.4e-016.
```

Using cgs with a Preconditioner.

This example demonstrates the use of a preconditioner.

Load `west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12;
maxit = 20;
```

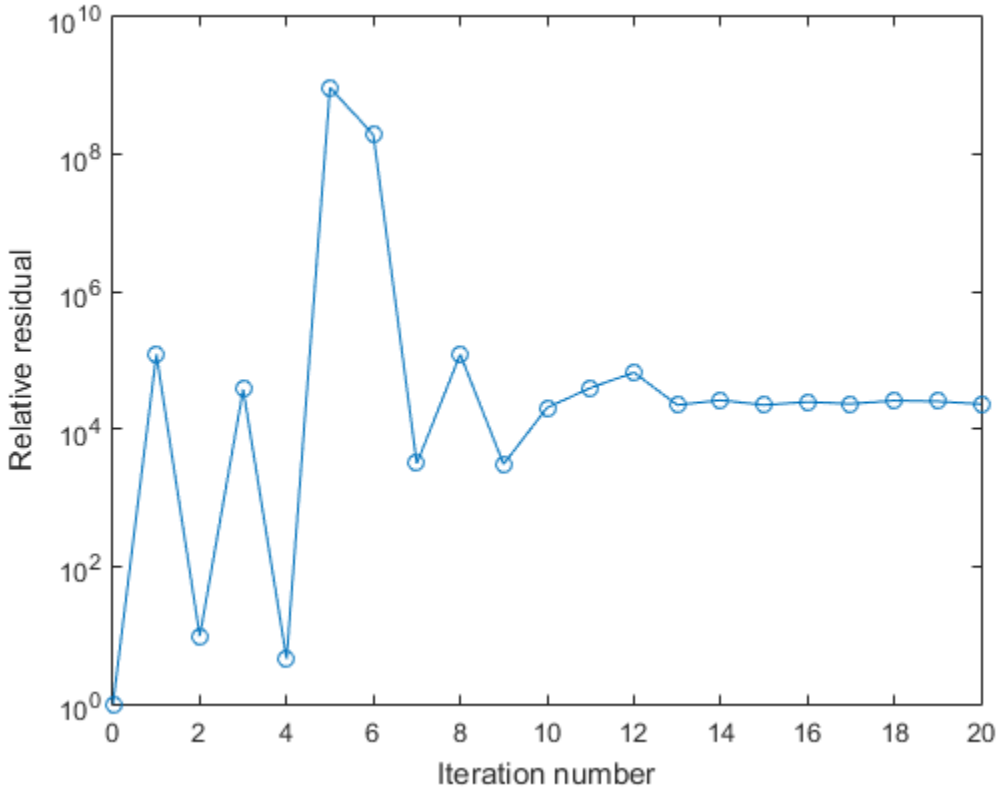
Use `cgs` to find a solution at the requested tolerance and number of iterations.

```
[x0,fl0,rr0,it0,rv0] = cgs(A,b,tol,maxit);
```

`fl0` is 1 because `cgs` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. In fact, the behavior of `cgs` is so poor that the initial guess (`x0 = zeros(size(A,2),1)`) is the best solution and is returned as indicated by `it0 = 0`. MATLAB stores the residual history in `rv0`.

Plot the behavior of `cgs`.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```



The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create a preconditioner with `ilu`, since `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

```
Error using ilu
There is a pivot equal to zero.  Consider decreasing the
drop tolerance or consider using the 'udiag' option.
```

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,fl1,rr1,it1,rv1] = cgs(A,b,tol,maxit,L,U);
```

`fl1` is 0 because `cgs` drives the relative residual to `4.3851e-014` (the value of `rr1`). The relative residual is less than the prescribed tolerance of `1e-12` at the third iteration (the value of `it1`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. The output `rv1(1)` is `norm(b)` and the output `rv1(14)` is `norm(b-A*x2)`.

You can follow the progress of `cgs` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

Introduced before R2006a

char

Convert to character array (string)

Syntax

```
S = char(A)
S = char(A1,...,AN)

S = char(D)
S = char(D,fmt)
S = char(D,fmt,locale)
```

Description

`S = char(A)` converts array `A` into a character array.

- If `A` is a numeric array, then `char` converts numbers into characters. Valid numeric values range from 0 to 65535, with 0 to 127 corresponding to 7-bit ASCII characters. Values from 128 to 65535 produce characters that depend upon your locale setting.
- If `A` is a character array, then `char` returns `A` unaltered.

  To convert characters into a numeric array, use a function that converts to a numeric type (for example, `double`, `int32`, or `cast`).
- If `A` is a cell array of strings, then `char` converts the cell array into a character array. The strings from the cell array become rows in `S` (automatically padded with blanks as needed).

  To convert `S` back into a cell array, use the `cellstr` function.
- If `A` is a categorical array, then `char` converts each element of `A` into a row of a character array, in column order.

`S = char(A1,...,AN)` converts the arrays `A1,...,AN` into a single character array. After conversion to characters, the input arrays become rows in `S`. Each row is automatically padded with blanks as needed. An empty string becomes a row of blanks.

The input arrays `A1,...,AN` cannot be cell arrays or categorical arrays.

`A1,...,AN` can be of different sizes and shapes.

`S = char(D)` converts a datetime, duration, or calendar duration array into a character array in the format specified by the `Format` property of `D`. The output contains one date or duration in each row.

`S = char(D,fmt)` represents dates or durations in the specified format, such as `'HH:mm:ss'`.

`S = char(D,fmt,locale)` represents dates or durations in the specified locale, such as `'en_US'`. The locale affects the language used to represent character strings such as month and day names.

Examples

Convert Integers to Printable ASCII Character Array

Convert the integers 32–127 into a 3-by-32 array of the printable ASCII characters.

```
A = reshape(32:127,32,3)';
S = char(A)
```

```
S =

 !"#$%&'()*+,-./0123456789:;<=>?
@ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_
`abcdefghijklmnopqrstuvwxyz{|}~#
```

Convert Multiple Arrays to Character Array

Convert multiple arrays into a single character array. The input arrays need not have the same shape.

```
A1 = [65 66; 67 68];
A2 = 'abcd';
S = char(A1,A2)
```

```
S =

AB
CD
abcd
```

Because the input arrays do not have the same number of columns, `char` pads the rows from `A1` with blanks.

```
whos S
```

```
  Name      Size            Bytes  Class    Attributes

  S         3x4                24  char
```

Convert Cell Array of Strings to Character Array

Convert a cell array of strings into a character array.

```
A = {'ABCD','efghijk','','LM'};
S = char(A)
```

```
S =

ABCD
efghijk

LM
```

Because the input strings from cell array `A` have different lengths, `char` pads the strings with blanks. `char` pads the third row with seven blanks, because the third cell of `A` contains an empty string.

```
whos S
```

```
  Name      Size            Bytes  Class    Attributes

  S         4x7                56  char
```

Convert Duration Array to Character Array

Create a `duration` array.

```
D = hours(23:25) + minutes(8) + seconds(1.2345)
```

```
D =

   23.134 hrs   24.134 hrs   25.134 hrs
```

Convert `D` to a character array.

```
S = char(D)
```

```
S =

23.134 hrs
24.134 hrs
25.134 hrs
```

S is a character array with one duration value per row.

Specify the format of the duration values in S.

```
S = char(D,'hh:mm')
```

```
S =

23:08
24:08
25:08
```

Input Arguments

A — Input array

numeric array | character array | cell array of strings | categorical array

Input array, specified as an array of real numbers or characters, a cell array of strings, or a categorical array.

If A is a numeric array, then:

- Nonintegers are rounded towards zero.
- Values less than 0 are treated as 0.
- Values greater than 65535 are treated as 65535.

Example: `char(65)` converts the integer 65 into the character A.

D — Input date and time

date or duration array

Input date and time, specified as a date or duration array.

Data Types: `datetime` | `duration` | `calendarDuration`

`fmt` — Date format

string

Date format, specified as a string. The supported formats depend on the data type of input `D`.

- `datetime` formats can include combinations of units and delimiters, such as `'yyyy-MMM-dd HH:mm:ss.SSS'`. For details, see the `Format` property for datetime arrays.
- `duration` formats are either single characters (`'y'`, `'d'`, `'h'`, `'m'`, or `'s'`) or one of these combinations:
  - `'dd:hh:mm:ss'`
  - `'hh:mm:ss'`
  - `'mm:ss'`
  - `'hh:mm'`
  - Any of the above, with up to nine `S` characters to indicate fractional second digits, such as `'hh:mm:ss.SSSS'`
- `calendarDuration` formats can include combinations of the characters `'y'`, `'q'`, `'m'`, `'w'`, `'d'`, and `'t'` in order from largest to smallest unit of time, such as `'ym'`.

For more information on the `duration` and `calendarDuration` formats, see "Set Date and Time Display Format".

`locale` — Locale of the character strings to create

string

Locale of the character strings to create, specified as a string.

`locale` can be:

- `'system'`, to specify your system locale.
- a string in the form *`xx_YY`*, where *`xx`* is a lowercase ISO 639-1 two-letter code that specifies a language, and *`YY`* is an uppercase ISO 3166-1 alpha-2 code that specifies a country.

These are the same strings accepted by the `'Locale'` name-value pair argument for the `datetime` function. The locale affects the language used in the output array.

Example: `'en_US'`

Example: `'ja_JP'`

Introduced before R2006a

checkcode

Check MATLAB code files for possible problems

Alternatives

For information on using the graphical user interface for checking code, see “Check Code for Errors and Warnings”.

Syntax

```
checkcode('filename')
checkcode('filename','-config=settings.txt')
checkcode('filename','-config=factory')
inform=checkcode('filename','-struct')
msg=checkcode('filename','-string')
[inform,filepaths]=checkcode('filename')
inform=checkcode('filename','-id')
inform=checkcode('filename','-fullpath')
inform=checkcode('filename','-notok')
checkcode('filename','-cyc')
checkcode('filename','-codegen')
checkcode('filename','-eml')
```

Description

`checkcode('filename')` displays messages, sometimes referred to as Code Analyzer messages, about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `checkcode(F1,F2,F3,...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `checkcode` messages is subject to some change between versions.

`checkcode('filename','-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

Note: If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

For information about creating a `settings.txt` file, see "Save and Reuse Code Analyzer Message Settings". If you specify an invalid file, `checkcode` returns a message indicating that it cannot open or read the file you specified. In that case, `checkcode` uses the factory default settings.

`checkcode('filename','-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=checkcode('filename','-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
`message`	Message describing the suspicious construct that code analysis caught.
`line`	Vector of file line numbers to which the message refers.
`column`	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=checkcode('filename','-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **-struct** or **-string** argument and you specify an output argument, the default behavior is **-struct**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepaths]=checkcode('filename')` additionally returns `filepaths`, the absolute paths to the file names, in the same order as you specified them.

`inform=checkcode('filename','-id')` requests the message ID, where ID is a string of the form `ABC...`. When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=checkcode('filename','-fullpath')` assumes that the input file names are absolute paths, so that `checkcode` does not try to locate them.

`inform=checkcode('filename','-notok')` runs `checkcode` for all lines in `filename`, even those lines that end with the `checkcode` suppression directive, `%#ok`.

`checkcode('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`checkcode('filename','-codegen')` enables code generation messages for display in the Command Window.

`checkcode('filename','-eml')` `'-eml'` is not recommended. Use `'-codegen'` instead.

Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in *`matlabroot`*`/help/techdoc/matlab_env/examples`. If you want to run the examples, save a copy of `lengthofline.m` to a location on your MATLAB path.

Running checkcode on a File with No Options

To run `checkcode` on the example file, `lengthofline.m`, run

```
checkcode('lengthofline')
```

MATLAB displays the Code Analyzer messages for `lengthofline.m` in the Command Window:

```
L 21 (C 1-9): The value assigned to variable 'nothandle' might be unused.
L 22 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 23 (C 5-11): The variable 'notline' appears to change size on every loop iteration. Consider preallocating for speed.
L 23 (C 44-49): Use STRCMPI(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 27 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 33 (C 13-16): The variable 'data' appears to change size on every loop iteration. Consider preallocating for speed.
L 33 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
L 37 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 38 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 44 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 47 (C 52): Invalid syntax at ';'. Possibly, a ), }, or ] is missing.
L 47 (C 53): Invalid syntax at ')'. Possibly, a ), }, or ] is missing.
L 47 (C 54): Parse error at ']': usage might be invalid MATLAB syntax.
L 48 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 48 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

Running checkcode with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=checkcode('lengthofline','-id')
```

MATLAB returns

```
inform =

17x1 struct array with fields:

    id
    message
    fix
    line
    column
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =

         id: 'NASGU'
    message: 'The value assigned to variable 'nothandle' might be unused.'
        fix: 0
       line: 21
     column: [1 9]
```

Here, the message is for the value that appears on line 21 that extends from column 1–9 in the file.NASGU is the ID for the message `'The value assigned to variable 'nothandle' might be unused.'`.

Displaying McCabe Complexity with checkcode

To display the McCabe complexity of a MATLAB code file, run `checkcode` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
checkcode lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the Code Analyzer messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 21 (C 1-9): The value assigned to variable 'nothandle' might be unused.
L 22 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 23 (C 5-11): The variable 'notline' appears to change size on every loop iteration. Consider preallocating for speed.
L 23 (C 44-49): Use STRCMPI(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 27 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 33 (C 13-16): The variable 'data' appears to change size on every loop iteration. Consider preallocating for speed.
L 33 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
L 37 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 38 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 44 (C 13-15): The variable 'dim' appears to change size on every loop iteration. Consider preallocating for speed.
L 47 (C 52): Invalid syntax at ';'. Possibly, a ), }, or ] is missing.
L 47 (C 53): Invalid syntax at ')'. Possibly, a ), }, or ] is missing.
L 47 (C 54): Parse error at ']': usage might be invalid MATLAB syntax.
L 48 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 48 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages ”.

checkin

(To be removed) Check files into source control system (UNIX platforms)

Note: `checkin` will be removed in a future release.

Syntax

```
checkin('filename','comments','comment_text')
checkin({'filename1','filename2'},'comments','comment_text')
checkin('filename','comments', 'comment_text','option','value')
```

Description

`checkin('filename','comments','comment_text')` checks in the file named `filename` to the source control system. Use the full path for `filename` and include the file extension. You must save the file before checking it in, but the file can be open or closed. The `comment_text` is a MATLAB string containing checkin comments for the source control system. You must supply **`comments`** and `comment_text`.

`checkin({'filename1','filename2'},'comments','comment_text')` checks in the files `filename1` through `filenamen` to the source control system. Use the full paths for the files and include file extensions. Comments apply to all files checked in.

`checkin('filename','comments', 'comment_text','option','value')` provides additional `checkin` options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1','filename2',...}`. Options apply to all file names. The *`option`* and *`value`* arguments are shown in the following table.

option Argument	value Argument	Purpose
`'force'`	`'on'`	`filename` is checked in even if the file has not changed since it was checked out.
`'force'`	`'off'` (default)	`filename` is not checked in if there were no changes since checkout.

option Argument	value Argument	Purpose
`'lock'`	`'on'`	`filename` is checked in with comments, and is automatically checked out.
`'lock'`	`'off'` (default)	`filename` is checked in with comments but does not remain checked out.

Examples

Check In a File

Check the file `/myserver/myfiles/clock.m` into the source control system, with the comment `Adjustment for leapyear`:

```
checkin('/myserver/myfiles/clock.m','comments',...
'Adjustment for leapyear')
```

Check In Multiple Files

Check two files into the source control system, using the same comment for each:

```
checkin({'/myserver/myfiles/clock.m', ...
'/myserver/myfiles/calendar.m'},'comments',...
'Adjustment for leapyear')
```

Check In a File and Keep It Checked Out

Check the file `/myserver/myfiles/clock.m` into the source control system and keep the file checked out:

```
checkin('/myserver/myfiles/clock.m','comments',...
'Adjustment for leapyear','lock','on')
```

Introduced before R2006a

checkout

(To be removed) Check files out of source control system (UNIX platforms)

Note: `checkout` will be removed in a future release.

Syntax

```
checkout('filename')
checkout({'filename1','filename2', ...})
checkout('filename','option','value',...)
```

Description

`checkout('filename')` checks out the file named `filename` from the source control system. Use the full path for `filename` and include the file extension. The file can be open or closed when you use `checkout`.

`checkout({'filename1','filename2', ...})` checks out the files named `filename1` through `filenamen` from the source control system. Use the full paths for the files and include the file extensions.

`checkout('filename','option','value',...)` provides additional `checkout` options. For multiple file names, use an array of strings instead of `filename`, that is, `{'filename1','filename2', ...}`. Options apply to all file names. The *`option`* and *`value`* arguments are shown in the following table.

option Argument	value Argument	Purpose
`'force'`	`'on'`	The checkout is forced, even if you already have the file checked out. This is effectively an `undocheckout` followed by a `checkout`.

option Argument	value Argument	Purpose
`'force'`	`'off'` (default)	Prevents you from checking out the file if you already have it checked out.
`'lock'`	`'on'` (default)	The checkout gets the file, allows you to write to it, and locks the file so that access to the file for others is read only.
`'lock'`	`'off'`	The checkout gets a read-only version of the file, allowing another user to check out the file for updating. You do not have to check the file in after checking it out with this option.
`'revision'`	`'version_num'`	Checks out the specified revision of the file.

If you end the MATLAB session, the file remains checked out. You can check in the file from within the MATLAB desktop during a later session, or directly from your source control system.

Examples

Check Out a File

Check out the file `/myserver/myfiles/clock.m` from the source control system:

```
checkout('/myserver/myfiles/clock.m')
```

Check Out Multiple Files

Check out `/matlab/myfiles/clock.m` and `/matlab/myfiles/calendar.m` from the source control system:

```
checkout({'/myserver/myfiles/clock.m',...
'/myserver/myfiles/calendar.m'})
```

Force a Checkout, Even If File Is Already Checked Out

Check out `/matlab/myfiles/clock.m` even if `clock.m` is already checked out to you:

```
checkout('/myserver/myfiles/clock.m','force','on')
```

Check Out Specified Revision of File

Check out revision `1.1` of `clock.m`:

```
checkout('/matlab/myfiles/clock.m','revision','1.1')
```

Introduced before R2006a

chol

Cholesky factorization

Syntax

```
R = chol(A)
L = chol(A,'lower')
R = chol(A,'upper')
[R,p] = chol(A)
[L,p] = chol(A,'lower')
[R,p] = chol(A,'upper')
[R,p,S] = chol(A)
[R,p,s] = chol(A,'vector')
[L,p,s] = chol(A,'lower','vector')
[R,p,s] = chol(A,'upper','vector')
```

Description

`R = chol(A)` produces an upper triangular matrix `R` from the diagonal and upper triangle of matrix `A`, satisfying the equation `R'*R=A`. The `chol` function assumes that `A` is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the upper triangle as the lower triangle. Matrix `A` must be positive definite.

`L = chol(A,'lower')` produces a lower triangular matrix `L` from the diagonal and lower triangle of matrix `A`, satisfying the equation `L*L'=A`. The `chol` function assumes that `A` is (complex Hermitian) symmetric. If it is not, `chol` uses the (complex conjugate) transpose of the lower triangle as the upper triangle. When `A` is sparse, this syntax of `chol` is typically faster. Matrix `A` must be positive definite. `R = chol(A,'upper')` is the same as `R = chol(A)`.

`[R,p] = chol(A)` for positive definite `A`, produces an upper triangular matrix `R` from the diagonal and upper triangle of matrix `A`, satisfying the equation `R'*R=A` and `p` is zero. If `A` is not positive definite, then `p` is a positive integer and MATLAB does not generate an error. When `A` is full, `R` is an upper triangular matrix of order `q=p-1` such that `R'*R=A(1:q,1:q)`. When `A` is sparse, `R` is an upper triangular matrix of size `q`-by-`n`

so that the L-shaped region of the first q rows and first q columns of R'*R agree with those of A.

[L,p] = chol(A,'lower') for positive definite A, produces a lower triangular matrix L from the diagonal and lower triangle of matrix A, satisfying the equation L*L'=A and p is zero. If A is not positive definite, then p is a positive integer and MATLAB does not generate an error. When A is full, L is a lower triangular matrix of order q=p-1 such that L*L'=A(1:q,1:q). When A is sparse, L is a lower triangular matrix of size q-by-n so that the L-shaped region of the first q rows and first q columns of L*L' agree with those of A. [R,p] = chol(A,'upper') is the same as [R,p] = chol(A).

The following three-output syntaxes require sparse input A.

[R,p,S] = chol(A), when A is sparse, returns a permutation matrix S. Note that the preordering S may differ from that obtained from amd since chol will slightly change the ordering for increased performance. When p=0, R is an upper triangular matrix such that R'*R=S'*A*S. When p is not zero, R is an upper triangular matrix of size q-by-n so that the L-shaped region of the first q rows and first q columns of R'*R agree with those of S'*A*S. The factor of S'*A*S tends to be sparser than the factor of A.

[R,p,s] = chol(A,'vector'), when A is sparse, returns the permutation information as a vector s such that A(s,s)=R'*R, when p=0. You can use the 'matrix' option in place of 'vector' to obtain the default behavior.

[L,p,s] = chol(A,'lower','vector'), when A is sparse, uses only the diagonal and the lower triangle of A and returns a lower triangular matrix L and a permutation vector s such that A(s,s)=L*L', when p=0. As above, you can use the 'matrix' option in place of 'vector' to obtain a permutation matrix. [R,p,s] = chol(A,'upper','vector') is the same as [R,p,s] = chol(A,'vector').

Note Using chol is preferable to using eig for determining positive definiteness.

Examples

Example 1

The gallery function provides several symmetric, positive, definite matrices.

```
A=gallery('moler',5)
```

```
A =

     1    -1    -1    -1    -1
    -1     2     0     0     0
    -1     0     3     1     1
    -1     0     1     4     2
    -1     0     1     2     5

C=chol(A)

ans =

     1    -1    -1    -1    -1
     0     1    -1    -1    -1
     0     0     1    -1    -1
     0     0     0     1    -1
     0     0     0     0     1
isequal(C'*C,A)

ans =

     1
```

For sparse input matrices, `chol` returns the Cholesky factor.

```
N = 100;
A = gallery('poisson', N);
```

`N` represents the number of grid points in one direction of a square `N`-by-`N` grid. Therefore, `A` is N^2 by N^2.

```
L = chol(A, 'lower');
D = norm(A - L*L', 'fro');
```

The value of `D` will vary somewhat among different versions of MATLAB but will be on order of 10^{-14}.

Example 2

The binomial coefficients arranged in a symmetric array create a positive definite matrix.

```
n = 5;
```

```
X = pascal(n)
X =
     1     1     1     1     1
     1     2     3     4     5
     1     3     6    10    15
     1     4    10    20    35
     1     5    15    35    70
```

This matrix is interesting because its Cholesky factor consists of the same coefficients, arranged in an upper triangular matrix.

```
R = chol(X)
R =
     1     1     1     1     1
     0     1     2     3     4
     0     0     1     3     6
     0     0     0     1     4
     0     0     0     0     1
```

Destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element.

```
X(n,n) = X(n,n)-1

X =
     1     1     1     1     1
     1     2     3     4     5
     1     3     6    10    15
     1     4    10    20    35
     1     5    15    35    69
```

Now an attempt to find the Cholesky factorization of `X` fails.

```
chol(X)
Error using chol
Matrix must be positive definite.
```

See Also

`ichol` | `cholupdate`

Introduced before R2006a

cholupdate

Rank 1 update to Cholesky factorization

Syntax

```
R1 = cholupdate(R,x)
R1 = cholupdate(R,x,'+')
R1 = cholupdate(R,x,'-')
[R1,p] = cholupdate(R,x,'-')
```

Description

`R1 = cholupdate(R,x)` where `R = chol(A)` is the original Cholesky factorization of `A`, returns the upper triangular Cholesky factor of `A + x*x'`, where `x` is a column vector of appropriate length. `cholupdate` uses only the diagonal and upper triangle of `R`. The lower triangle of `R` is ignored.

`R1 = cholupdate(R,x,'+')` is the same as `R1 = cholupdate(R,x)`.

`R1 = cholupdate(R,x,'-')` returns the Cholesky factor of `A - x*x'`. An error message reports when R is not a valid Cholesky factor or when the downdated matrix is not positive definite and so does not have a Cholesky factorization.

`[R1,p] = cholupdate(R,x,'-')` will not return an error message. If `p` is `0`, `R1` is the Cholesky factor of `A - x*x'`. If `p` is greater than `0`, `R1` is the Cholesky factor of the original `A`. If `p` is `1`, `cholupdate` failed because the downdated matrix is not positive definite. If `p` is `2`, `cholupdate` failed because the upper triangle of `R` was not a valid Cholesky factor.

Examples

```
A = pascal(4)
A =

     1     1     1     1
     1     2     3     4
```

```
     1     3     6    10
     1     4    10    20

R = chol(A)
R =

     1     1     1     1
     0     1     2     3
     0     0     1     3
     0     0     0     1
x = [0 0 0 1]';
```

This is called a rank one update to `A` since `rank(x*x')` is `1`:

```
A + x*x'
ans =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    21
```

Instead of computing the Cholesky factor with `R1 = chol(A + x*x')`, we can use `cholupdate`:

```
R1 = cholupdate(R,x)
R1 =

    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    1.4142
```

Next destroy the positive definiteness (and actually make the matrix singular) by subtracting `1` from the last element of `A`. The downdated matrix is:

```
A - x*x'
ans =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    19
```

Compare `chol` with `cholupdate`:

```
R1 = chol(A-x*x')
Error using chol
Matrix must be positive definite.
R1 = cholupdate(R,x,'-')
Error using cholupdate
Downdated matrix must be positive definite.
```

However, subtracting `0.5` from the last element of `A` produces a positive definite matrix, and we can use `cholupdate` to compute its Cholesky factor:

```
x = [0 0 0 1/sqrt(2)]';
R1 = cholupdate(R,x,'-')
R1 =
    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    0.7071
```

More About

Tips

`cholupdate` works only for full matrices.

Algorithms

`cholupdate` uses the algorithms from the LINPACK subroutines `ZCHUD` and `ZCHDD`. `cholupdate` is useful since computing the new Cholesky factor from scratch is an $O(N^3)$ algorithm, while simply updating the existing factor in this way is an $O(N^2)$ algorithm.

`chol` | `qrupdate`

Introduced before R2006a

circshift

Shift array circularly

Compatibility

The default behavior of `circshift(A,K)`, where `K` is a scalar, will change in a future release. The new default behavior will be to operate along the first array dimension of `A` whose size does not equal 1. Use `circshift(A,[K 0])` to retain current behavior.

Syntax

```
Y = circshift(A,K)
Y = circshift(A,K,dim)
```

Description

`Y = circshift(A,K)` circularly shifts the elements in array `A` by `K` positions. Specify `K` as an integer to shift the rows of `A`, or as a vector of integers to specify the shift amount in each dimension.

`Y = circshift(A,K,dim)` circularly shifts the values in array `A` by `K` positions along dimension `dim`. Inputs `K` and `dim` must be scalars.

Examples

Shift Column Vector Elements

Create a numeric column vector.

```
A = (1:10)'
```

```
A =

     1
     2
```

```
     3
     4
     5
     6
     7
     8
     9
    10
```

Use `circshift` to shift the elements by three positions.

```
Y = circshift(A,3)
```

```
Y =

     8
     9
    10
     1
     2
     3
     4
     5
     6
     7
```

The result, `Y`, has the same elements as `A` but they are in a different order.

Move Characters in Array

Create an array of characters.

```
A = 'racecar'
```

```
A =

racecar
```

Use `circshift` to shift the characters by three positions in the second dimension.

```
Y = circshift(A,3,2)
```

```
Y =

carrace
```

The characters are in a different order in Y.

Move Matrix Elements

Create a numeric array with a cluster of ones in the top left.

```
A = [1 1 0 0; 1 1 0 0; 0 0 0 0; 0 0 0 0]
```

```
A =

     1     1     0     0
     1     1     0     0
     0     0     0     0
     0     0     0     0
```

Use `circshift` to shift the elements of A by one position in each dimension.

```
Y = circshift(A,[1 1])
```

```
Y =

     0     0     0     0
     0     1     1     0
     0     1     1     0
     0     0     0     0
```

The cluster of ones is now in the center of the matrix.

To move the cluster back to its original position, use `circshift` on Y with negative shift values.

```
X = circshift(Y,[-1 -1])
```

```
X =

     1     1     0     0
     1     1     0     0
     0     0     0     0
     0     0     0     0
```

The matrix X is equivalent to A.

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`
Complex Number Support: Yes

K — Shift amount

integer scalar | vector of integers

Shift amount, specified as an integer scalar or vector of integers. If the shift amount is larger than the length of the corresponding dimension in A, then the shift circularly wraps to the beginning of that dimension. For example, shifting a 3-element vector by +3 positions will bring its elements back to their original positions.

- If you specify K as an integer and do not specify `dim`, then `circshift` shifts the rows of A down (positive integer) or up (negative integer).
- If you specify K as a vector of integers, each element specifies the shift amount for the *N*th dimension in A. If the *N*th element in K is positive, then the values of A are shifted towards the end (positive integer) or beginning (negative integer) of the *N*th dimension.

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is `dim = 1`. If you specify `dim`, then K must be an integer scalar. Specify `dim = 1` to exchange rows, `dim = 2` to exchange columns, and so on.

`fftshift` | `permute` | `reshape` | `shiftdim`

Introduced before R2006a

circumcenters

Class: TriRep

(Will be removed) Circumcenters of specified simplices

Note: `circumcenters(TriRep)` will be removed in a future release. Use `circumcenter(triangulation)` instead.

`TriRep` will be removed in a future release. Use `triangulation` instead.

Syntax

```
CC = circumcenters(TR, SI)
[CC RCC] = circumcenters(TR, SI)
```

Description

`CC = circumcenters(TR, SI)` returns the coordinates of the circumcenter of each specified simplex `SI`. `CC` is an `m`-by-`n` matrix, where `m` is of length `length(SI)`, the number of specified simplices, and `n` is the dimension of the space where the triangulation resides.

`[CC RCC] = circumcenters(TR, SI)` returns the circumcenters and the corresponding radii of the circumscribed circles or spheres.

Input Arguments

`TR`	Triangulation object.
`SI`	Column vector of simplex indices that index into the triangulation matrix `TR.Triangulation`. If `SI` is not specified the circumcenter information

for the entire triangulation is returned, where the circumcenter associated with simplex `i` is the `i`'th row of `CC`.

Output Arguments

`CC`	`m`-by-`n` matrix. `m` is the number of specified simplices and `n` is the dimension of the space where the triangulation resides. Each row `CC(i,:)` represents the coordinates of the circumcenter of simplex `SI(i)`.
`RCC`	Vector of length `length(SI)`, the number of specified simplices containing radii of the circumscribed circles or spheres.

Definitions

A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

Examples

Example 1

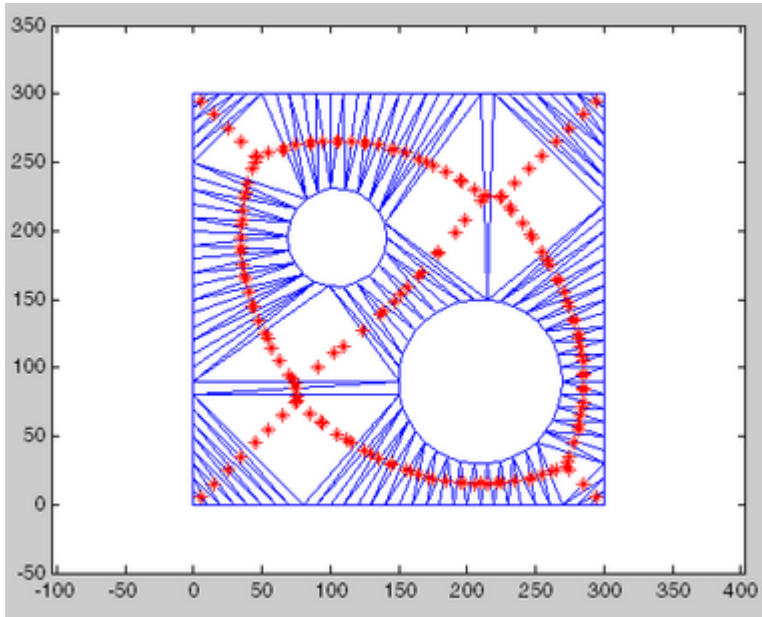
Load a 2-D triangulation.

```
load trimesh2d
trep = TriRep(tri, x,y)
```

Compute the circumcenters.

```
cc = circumcenters(trep);
triplot(trep);
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
```

The circumcenters represent points on the medial axis of the polygon.



Example 2

Query a 3-D triangulation created with `DelaunayTri`. Compute the circumcenters of the first five tetrahedra.

```
X = rand(10,3);
dt = DelaunayTri(X);
cc = circumcenters(dt, [1:5]')
```

See Also

`delaunayTriangulation` | `incenter` | `triangulation`

cla

Clear axes

Syntax

```
cla
cla reset

cla(ax)
cla(ax,'reset')
```

Description

`cla` deletes all graphics objects that have visible handles from the current axes. The handle is visible if the `HandleVisibility` property of the object is set to `'on'`. The next plot added to the axes uses the first color and line style based on the `ColorOrder` and `LineStyleOrder` properties of the axes.

`cla reset` deletes graphics objects from the current axes regardless of their handle visibility. It also resets axes properties to their default values, with the exception of the `Position` and `Units` properties.

`cla(ax)` deletes graphics objects from the axes specified by `ax` instead of the current axes.

`cla(ax,'reset')` resets properties for the specified axes.

Examples

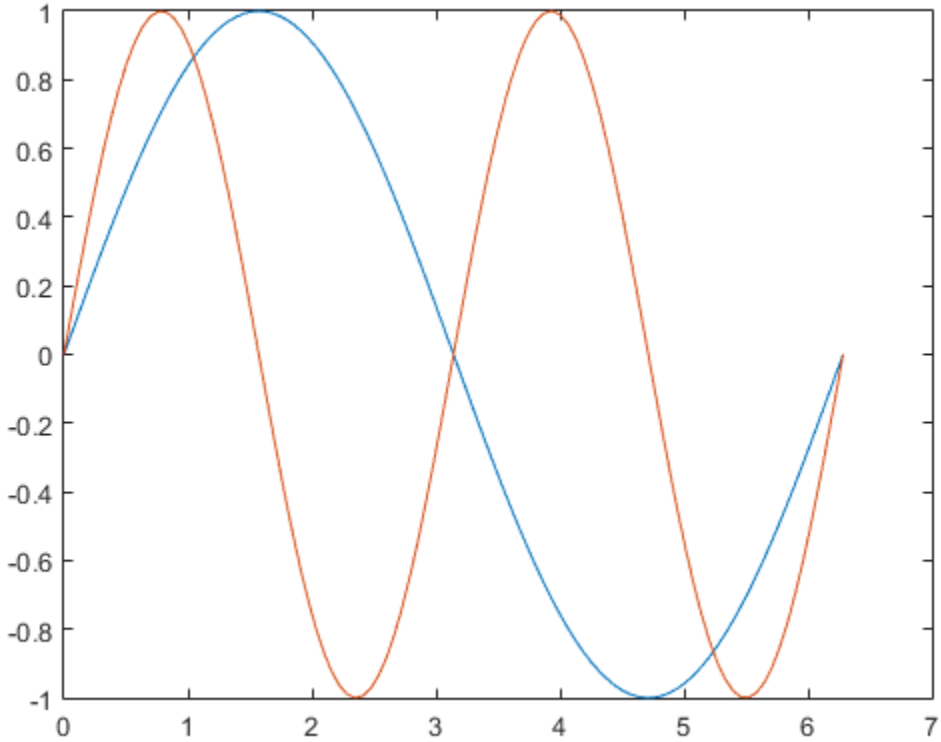
Clear Current Axes

Plot two sine waves. Then, clear the line plots from the axes.

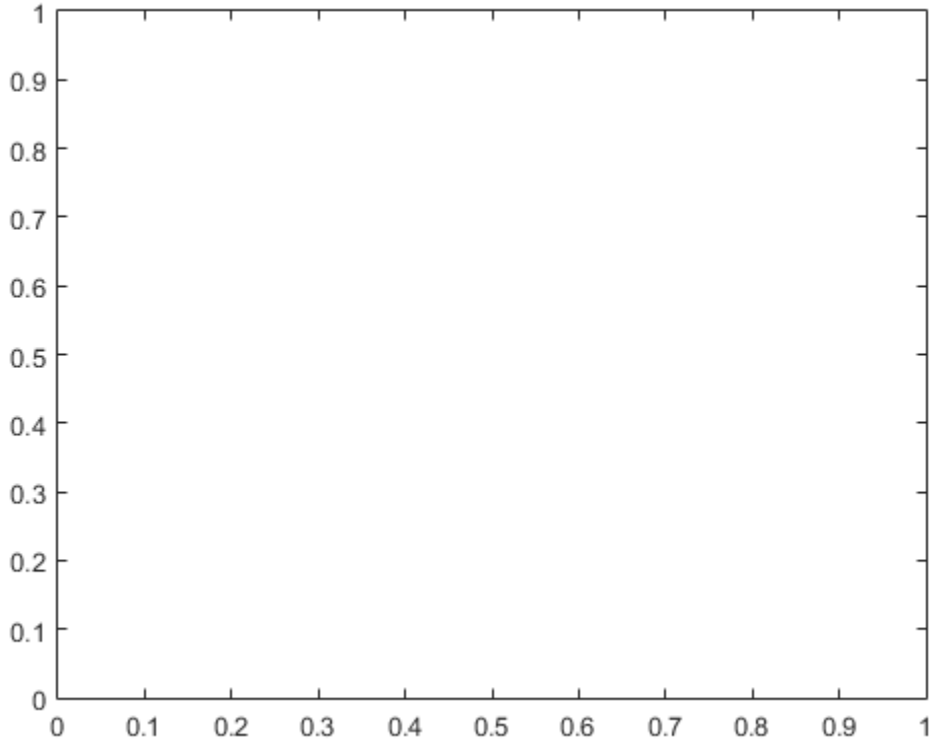
```
x = linspace(0,2*pi);
```

```
y1 = sin(x);
y2 = sin(2*x);

plot(x,y1)
hold on
plot(x,y2)
```

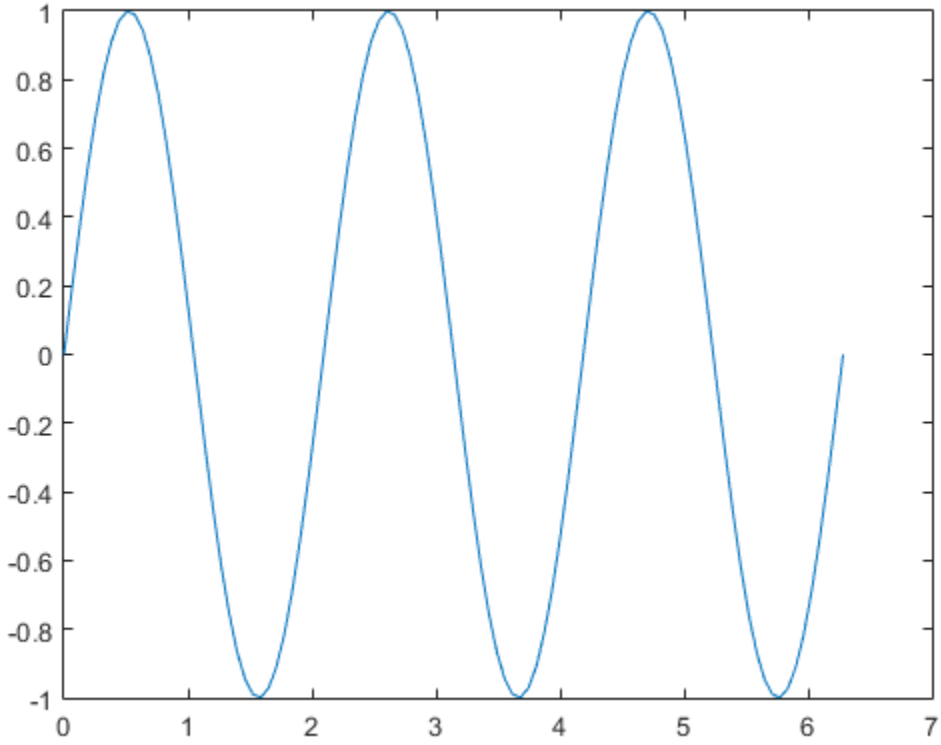


```
cla
```



`cla` clears the line plots and resets the `ColorIndex` and `LineStyleIndex` properties of the axes to 1. Subsequent plots start from the beginning of the color order and line style order. For example, plot another sine wave.

```
y3 = sin(3*x);
plot(x,y3)
hold off
```

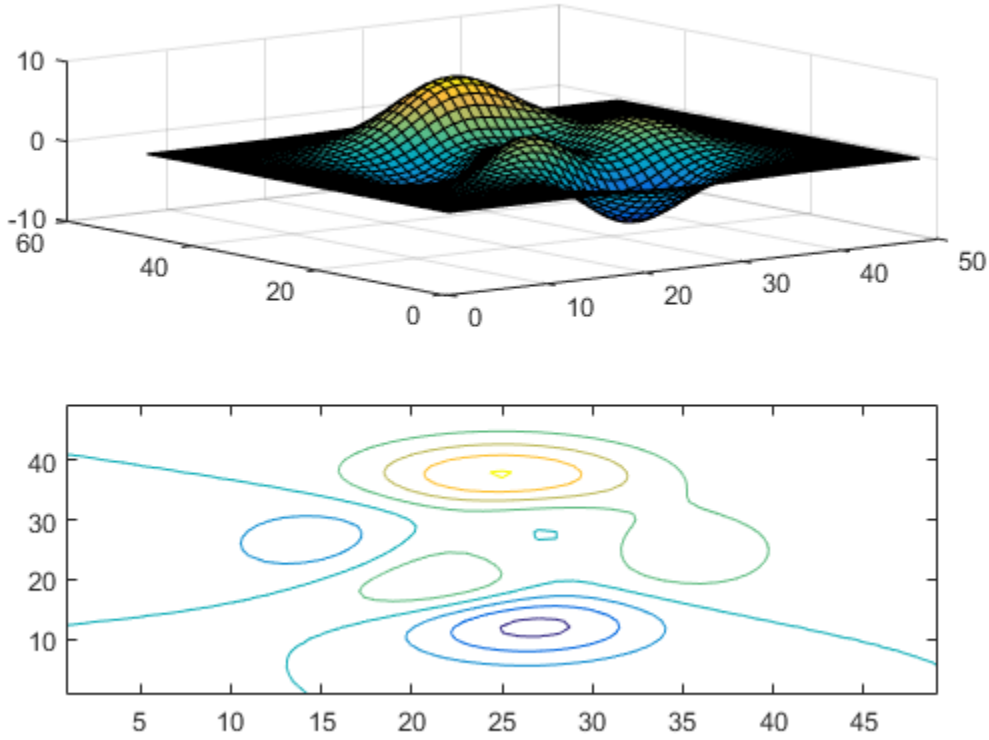


Clear Objects from Specific Axes

Create a figure with two subplots and add plots to both axes.

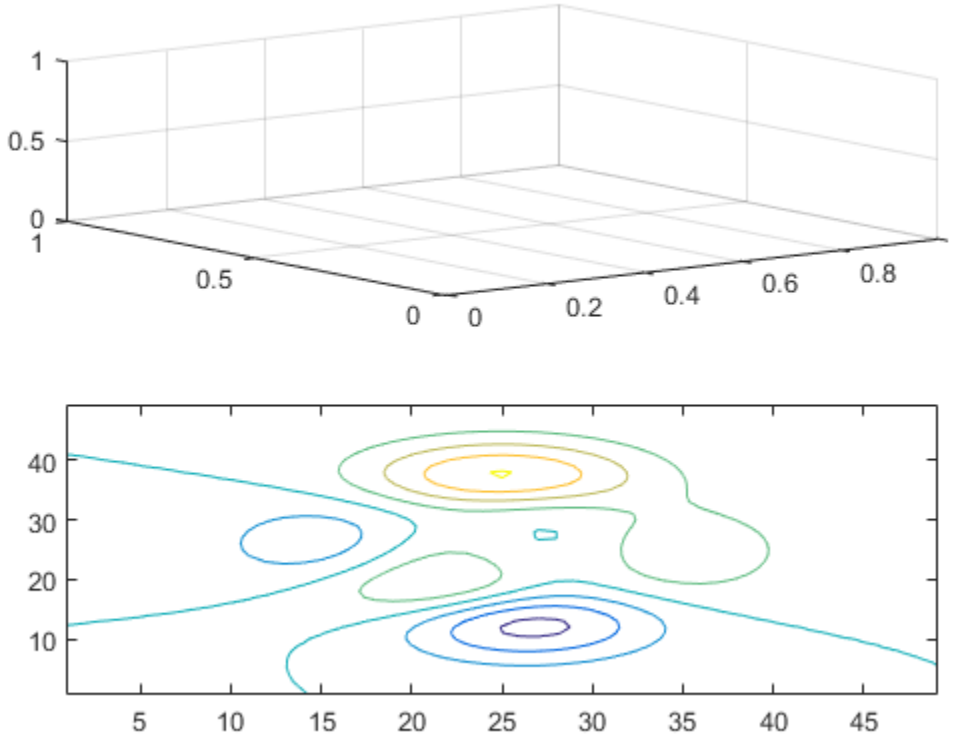
```
ax1 = subplot(2,1,1);
surf(peaks)

ax2 = subplot(2,1,2);
contour(peaks)
```



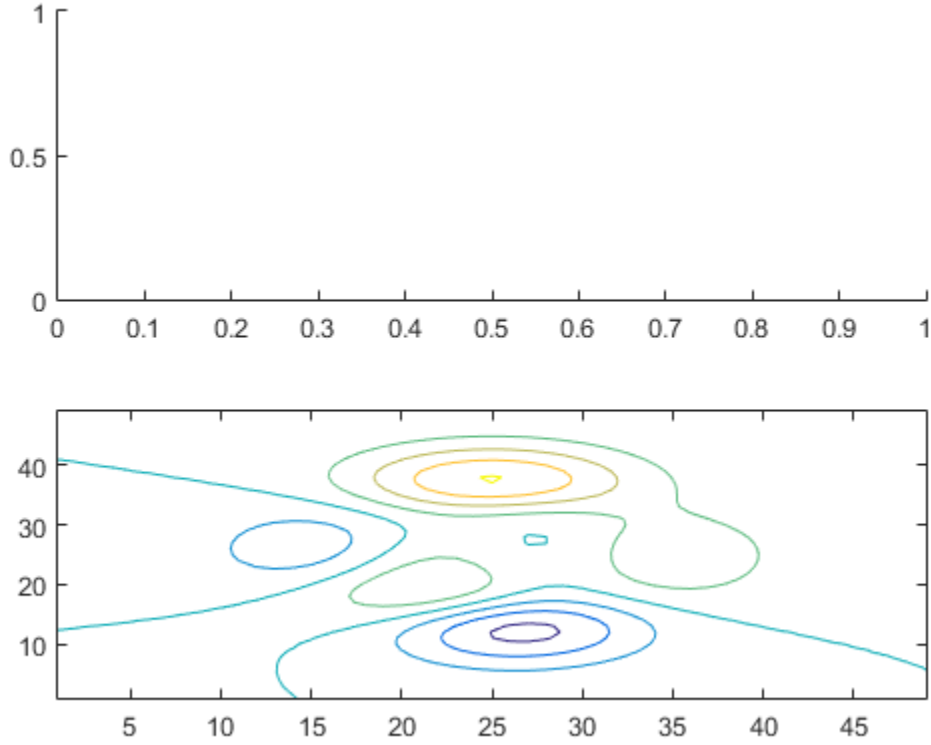
Clear the surface plot from the upper subplot.

```
cla(ax1)
```



Now, reset all axes properties for the upper subplot, including the camera properties that control the view, by using the optional input argument `'reset'`.

```
cla(ax1,'reset')
```

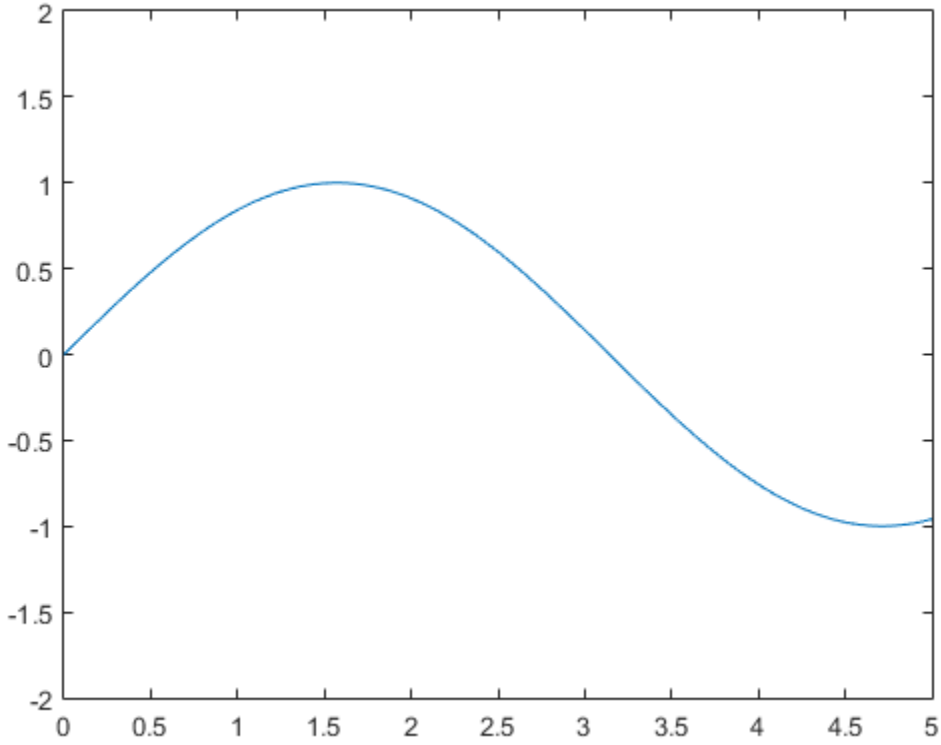


Clear Axes and Reset All Axes Properties

Create a line plot and set the axis limits.

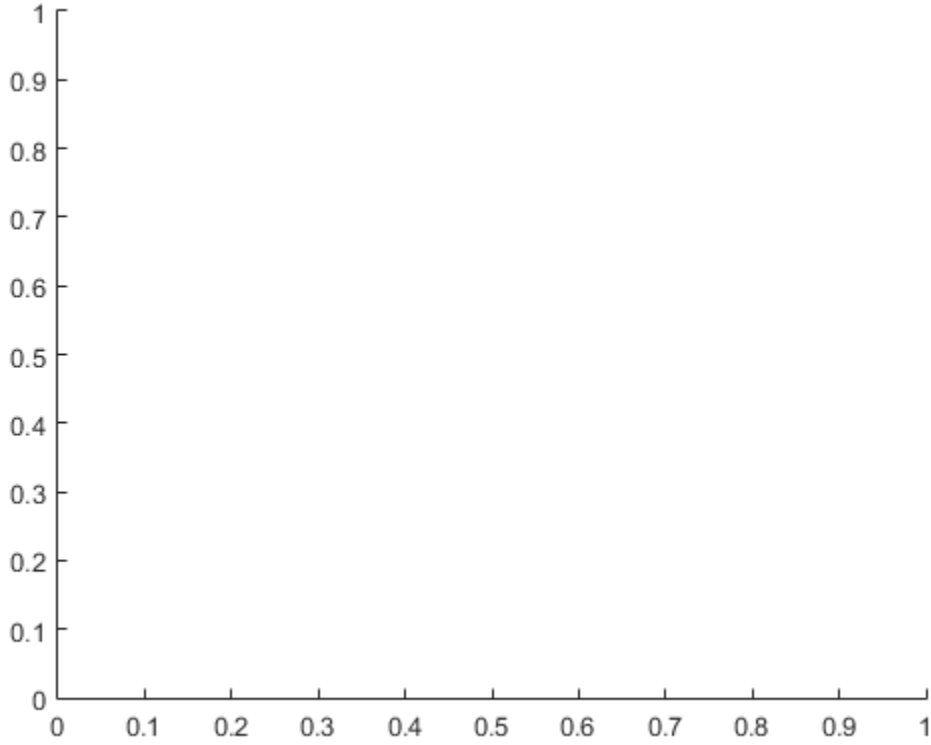
```
x = linspace(0,2*pi);
y = sin(x);

plot(x,y)
axis([0,5,-2,2])
```



Clear the line plot from the axes and reset all the axes properties to their default values. `cla reset` resets all properties of the current axes, except for the `Position` and `Units` properties.

```
cla reset
```



Input Arguments

ax — Axes object

axes object

Axes object. Use `ax` to clear a specific axes, instead of the current axes.

More About

Tips

- If an axes does not exist, then `cla` creates one.
- The `cla` command resets the `ColorOrderIndex` and `LineStyleOrderIndex` properties of the current axes to `1`.
- `cla` only deletes objects with a `HandleVisibility` property set to `'on'`. Therefore, if the `HandleVisibility` of an object is set to `'callback'` and you are in a callback, then `cla` does not delete it.

Properties
Axes Properties

Introduced before R2006a

clabel

Contour plot elevation labels

Syntax

```
clabel(C)
clabel(C,v)
clabel(C,'manual')
clabel( ___ ,Name,Value)
tl = clabel( ___ )

clabel(C,h)
clabel(C,h,v)
clabel(C,h,'manual')
clabel( ___ ,'LabelSpacing',space)
```

Description

`clabel(C)` labels all contours displayed in the current contour plot. Labels are upright and displayed with `'+'` symbols. `clabel` randomly selects label positions.

`clabel(C,v)` labels only the contour levels specified by the vector, `v`.

`clabel(C,'manual')` places contour labels at locations you select with a mouse. Click the mouse or press the space bar to label the contour closest to the center of the crosshair. Press the **Return** key while the cursor is within the figure window to terminate labeling.

`clabel( ___ ,Name,Value)` specifies text properties using one or more `Name,Value` pair arguments. Use this option with any of the input argument combinations in the previous syntaxes. For example, `'FontSize',14` sets the font size to 14 points.

`tl = clabel( ___ )` returns the text and line objects created.

`clabel(C,h)` inserts rotated labels into each contour line. The contour line must be long enough to fit the label, otherwise `clabel` does not insert a label. If you do not have the contour matrix `C`, then replace `C` with `[]`.

`clabel(C,h,v)` labels only the contour levels specified by vector `v`.

`clabel(C,h,'manual')` places contour labels at locations you select with a mouse. Press the **Return** key while the cursor is within the figure window to terminate labeling.

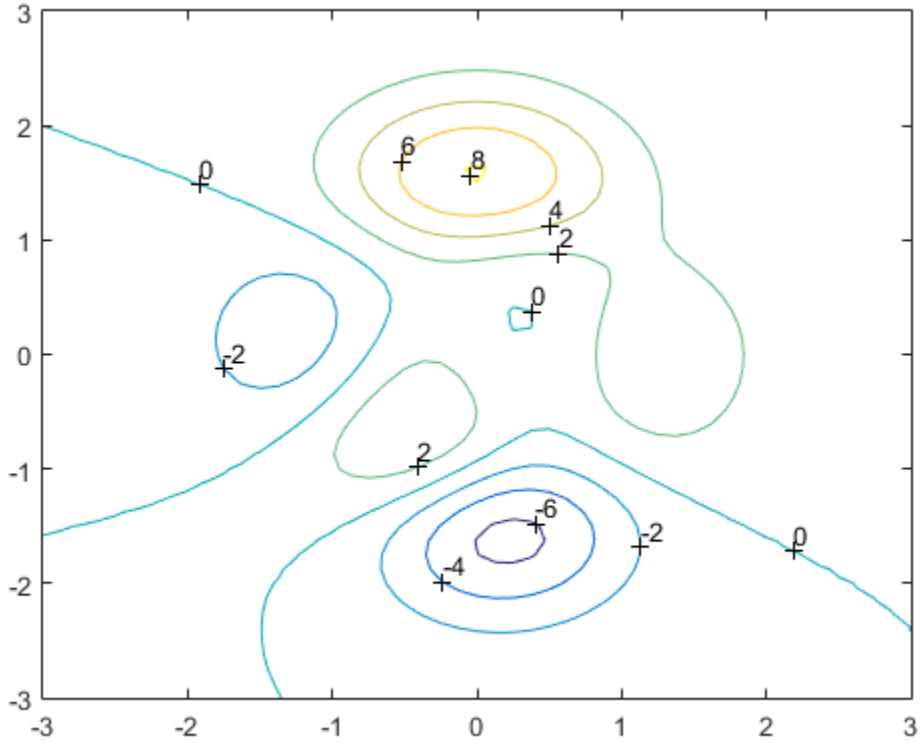
`clabel( ___ ,'LabelSpacing',space)` specifies the spacing between labels as a scalar value. Use this option with any of the input argument combinations that use both the contour matrix `C` and the contour object `h`. For example, `clabel(C,h,'LabelSpacing',72)` spaces the labels 72 points apart (1 inch).

Examples

Label Contour Plot with Vertical Text

Create a contour plot and return the contour matrix, `C`. Then, label the contours.

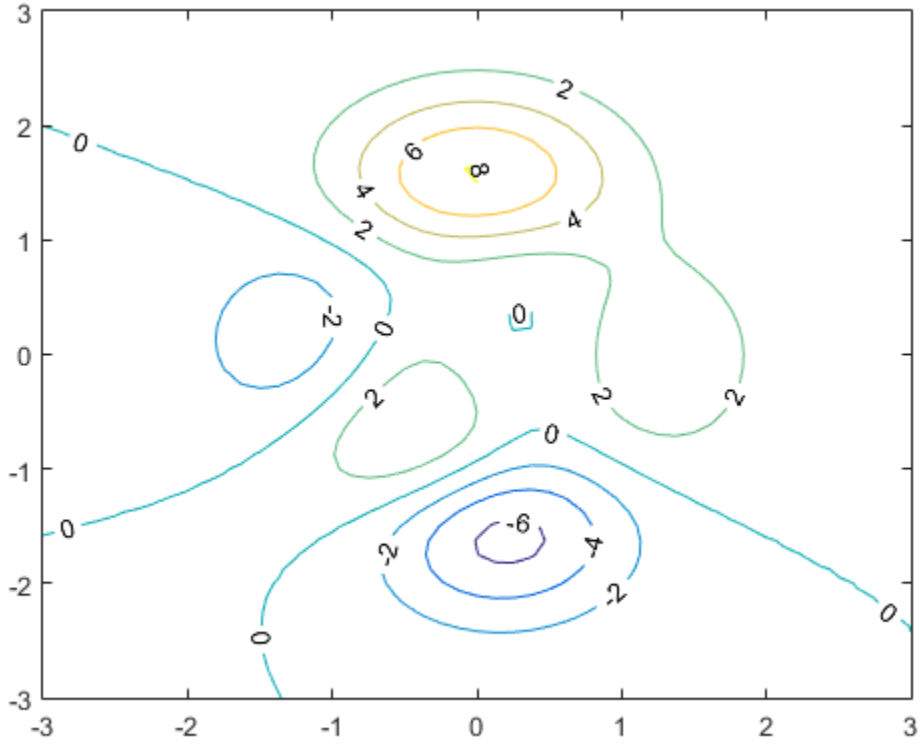
```
[x,y,z] = peaks;
C = contour(x,y,z);
clabel(C)
```



Label Contour Plot with Rotated Text

Create a contour plot and obtain the contour matrix, `C`, and the contour object, `h`. Then, label the contour plot.

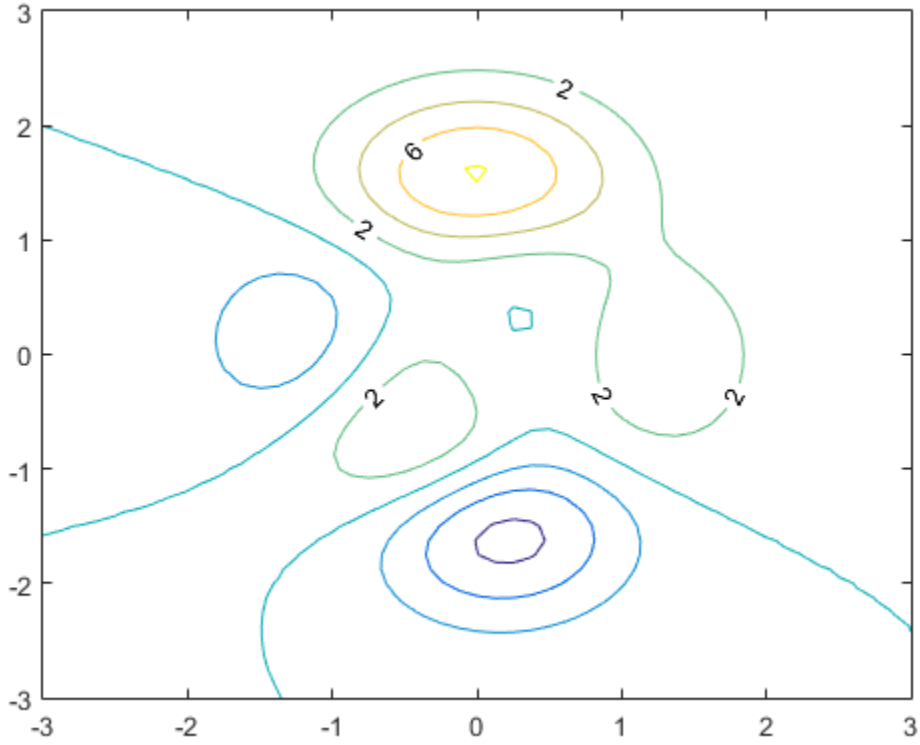
```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
clabel(C,h)
```



Label Specific Contour Levels

Label only the contours with contour levels 2 or 6.

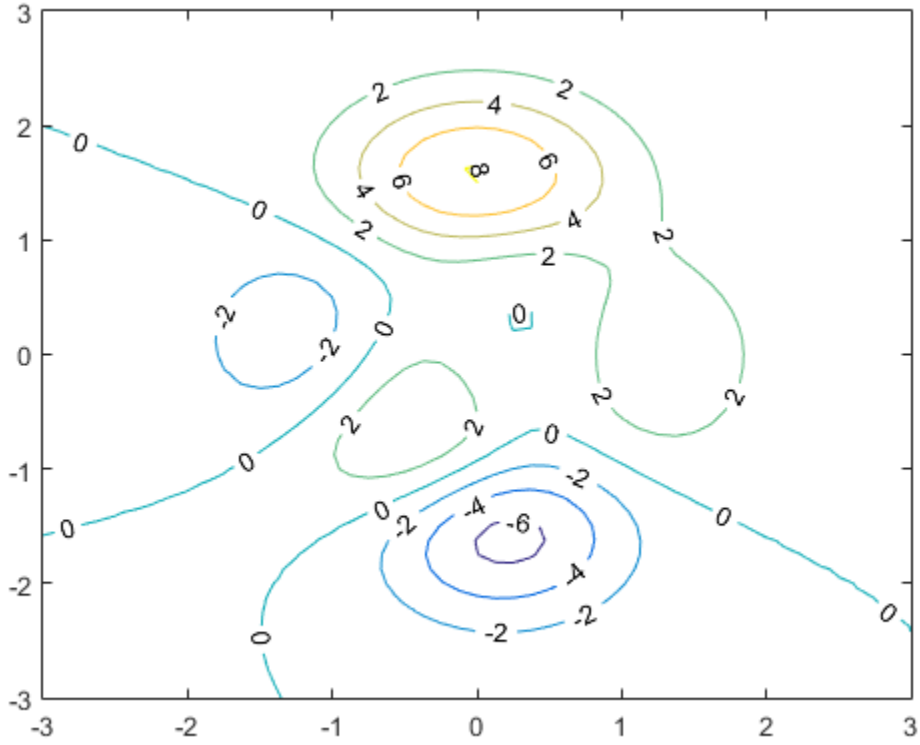
```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
v = [2,6];
clabel(C,h,v)
```



Set Contour Label Spacing

Set the label spacing to 72 points (1 inch).

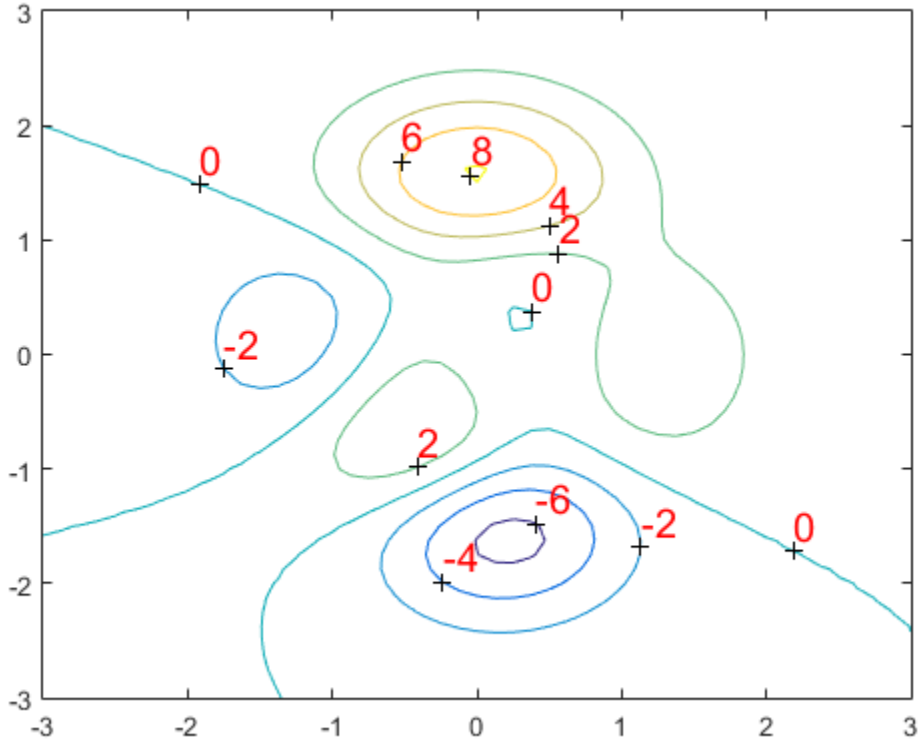
```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
clabel(C,h,'LabelSpacing',72)
```



Set Contour Label Text Properties

Use `Name,Value` arguments to set the font size, font color, and text orientation of the labels.

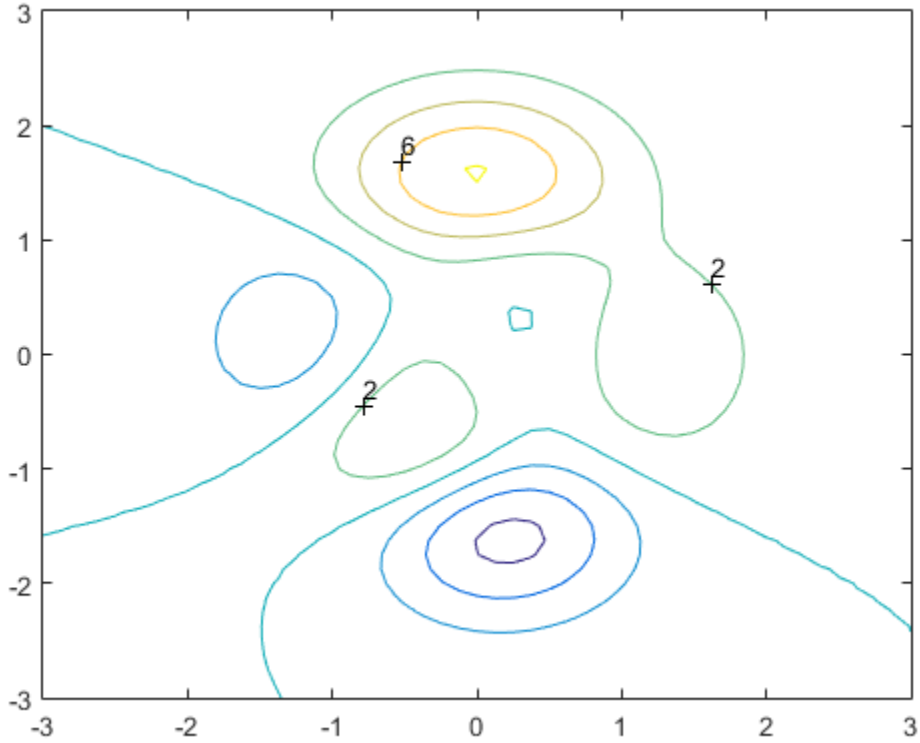
```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
clabel(C,'FontSize',15,'Color','r','Rotation',0)
```



Set Contour Label Text Properties After Creation

Label the contour lines at level 2 and 6. Return the text and line objects created.

```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
tl = clabel(C,[2,6]);
```



The output `tl` is a vector that contains one text object and one line object for each contour label.

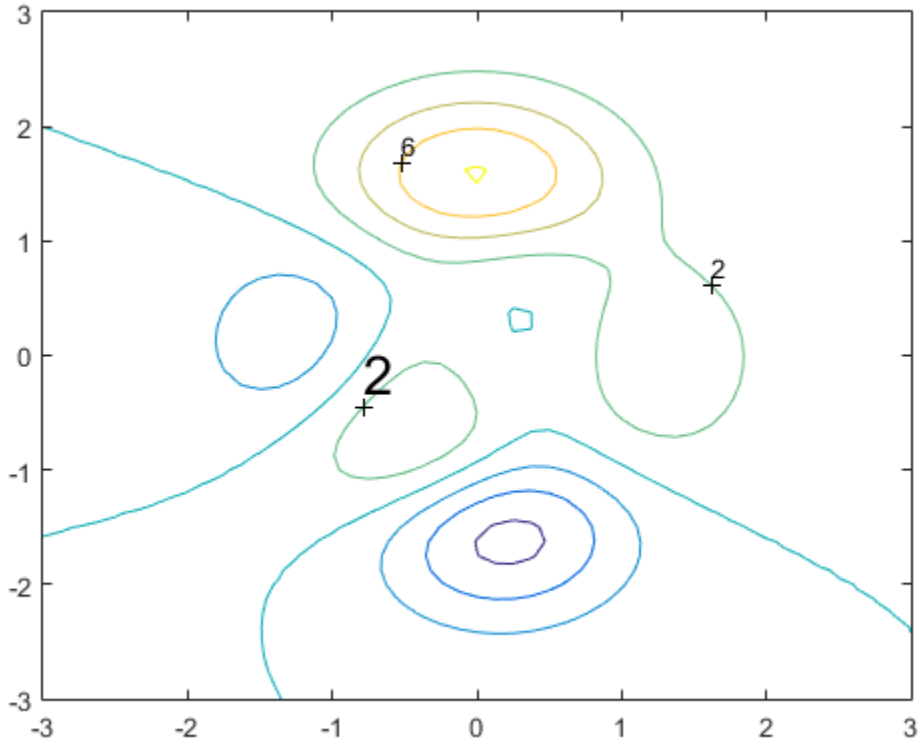
```
disp(tl)
```

```
  6x1 graphics array:

  Line
  Text    (2)
  Line
  Text    (2)
  Line
  Text    (6)
```

Change the font size for one of the labels. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
tl(2).FontSize = 20;
```



Input Arguments

C — Contour matrix

two-row matrix

Contour matrix returned by the `contour`, `contour3`, or `contourf` function. `C` contains the data that defines the contour lines.

Note: If you pass the contour object h to the `clabel` function, then you can replace `C` with `[]`. For example, use `clabel([],h)`.

h — Contour object
contour object

Contour object returned by the `contour`, `contour3`, or `contourf` function.

v — Contour level values
vector

Contour level values, specified as a row or column vector of individual values.

Example: `[0 10 20]`

space — Space between labels
scalar

Space between labels, specified as a scalar in point units.

Example: `72`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Color','red','Rotation',45` specifies red labels rotated 45 degrees.

Note: Starting in R2014b, you can no longer set text properties if you pass the contour object `h` as an input argument to the function. For example, `clabel(C,h,'Fontsize',14)` does not set the font size. Use `clabel(C,'FontSize',14)` instead.

The text properties listed here are only a subset, for a complete list, see Text Properties.

'FontSize' — Font size
10 (default) | scalar value greater than 0

Font size, specified as a scalar value greater than 0 in point units. One point equals 1/72 inch. To change the font units, use the FontUnits property.

Example: `12`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`'FontName'` — Font name

`'Helvetica'` (default) | `'FixedWidth'` | system supported font name

Font name, specified as the name of the font to use or the string `'FixedWidth'`. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string `'FixedWidth'`. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The `'FixedWidth'` value relies on the root `FixedWidthFontName` property. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Example: `'Cambria'`

`'FontWeight'` — Thickness of text characters

`'normal'` (default) | `'bold'`

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

`'Color'` — Text color

`[0 0 0]` (default) | RGB triplet | color string | `'none'`

Text color, specified as a three-element RGB triplet, a color string, or `'none'`. The default color is black with an RGB triplet value of `[0 0 0]`. If you set the color to `'none'`, then the text is invisible.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `'blue'`

Example: `[0 0 1]`

Output Arguments

`tl` — Text and line objects

vector

Text and line objects, returned as a vector. The `String` properties of the text objects contain the contour values displayed. The line objects correspond to the `'+'` symbols.

Note: Starting in R2014b, you can no longer return the output argument `tl` if you pass the contour object `h` as an input argument to the function. For example, `tl = clabel(C,h)` warns and returns empty. Use `tl = clabel(C)` instead.

Properties
Text Properties

Introduced before R2006a

class

Determine class of object

Syntax

```
ClassName = class(object)
obj = class(s,'class_name')
obj = class(s,'class_name',parent1,parent2,...)
obj = class(struct([]),'class_name',parent1,parent2,...)
obj_struct = class(struct_array,'class_name',parent_array)
```

Description

`ClassName = class(object)` returns a string specifying the class of `object`. See "Fundamental MATLAB Classes" for more information on MATLAB classes.

Note: Before MATLAB 7.6 (classes defined without a `classdef` statement), class constructors called the `class` function to create the object. The following `class` function syntaxes apply only within classes defined before Version 7.6.

`obj = class(s,'class_name')` creates an array of class `class_name` objects using the `struct` `s` as a pattern to determine the size of `obj`.

`obj = class(s,'class_name',parent1,parent2,...)` inherits the methods and fields of the parent objects `parent1`, `parent2`, and so on. The size of the parent objects must match the size of `s` or be a scalar (1–by-1), in which case, MATLAB performs scalar expansion.

`obj = class(struct([]),'class_name',parent1,parent2,...)` constructs object containing only fields that it inherits from the parent objects. All parents must have the same, nonzero size, which determines the size of the returned object `obj`.

`obj_struct = class(struct_array,'class_name',parent_array)` maps every element of the `parent_array` to a corresponding element in the `struct_array` to produce the output array of objects, `obj_struct`.

All arrays must be of the same size. If either the `struct_array` or the `parent_array` is of size 1–by–1, then MATLAB performs scalar expansion to match the array sizes.

To create an object array of size 0–by-0, set the size of the `struct_array` and `parent_array` to 0–by-0.

Examples

Return the class of Java object `obj`:

```
import java.lang.*;
obj = String('mystring');
class(obj)

ans =

java.lang.String
```

Return class of any MATLAB variable:

```
h = @sin;
class(h)

ans =

function_handle
```

`isa` | `isobject` | `metaclass`

Introduced before R2006a

classdef

Class definition keywords

Syntax

```
classdef classname
   properties
      PropName
   end
   methods
      methodName
   end
   events
      EventName
   end
   enumeration
      EnumName
   end
end
```

Description

`classdef` *`classname`* begins the class definition and an `end` keyword terminates the `classdef` block. Only blank lines and comments can precede `classdef`. Enter a class definition in a file having the same name as the class, with a filename extension of `.m`.

Class definition files can be in folders on the MATLAB path or in class folders whose parent folder is on the MATLAB path. Class folder names begin with the `'@'` character followed by the class name (for example, `@MyClass`). For more information on class folders, see “Class Files and Folders” .

For more information on classes, see “Classdef Block” and “Class Definition” .

`properties` begins a property definition block, an `end` keyword terminates the `properties` block. Class definitions can contain multiple property definition blocks, each specifying different attribute settings that apply to the properties in that particular block.

For more information on properties, see “Defining Properties”.

Note: Properties cannot have the same name as the class.

`methods` begins a methods definition block, an `end` keyword terminates the `methods` block. This block contains functions that implement class methods. Class definitions can contain multiple method blocks, each specifying different attribute settings that apply to the methods in that particular block. It is possible to define method functions in separate files.

For more information on methods, see “How to Use Methods”.

`events` begins an events definition block, an `end` keyword terminates the `events` block. This block contains event names defined by the class. Class definitions can contain multiple event blocks, each specifying different attribute settings that apply to the events in that particular block.

For more information on events, see “Events and Listeners — Syntax and Techniques”.

`enumeration` begins an enumeration definition block, an `end` keyword terminates the `enumeration` block.

For more information on enumerations, see “Enumerations”.

`properties`, `methods`, `events`, and `enumeration` are also the names of MATLAB functions used to query the respective class members for a given object or class name.

To see the attributes of all class components in a popup window, click this link: Attribute Tables

Examples

Use these keywords to define classes.

```
classdef (Attributes) ClassName
   properties (Attributes)
      PropertyName
   end
   methods (Attributes)
```

```
      function obj = methodName(obj,arg2,...)
         ...
      end
   end
   events (Attributes)
      EventName
   end
   enumeration
      EnumName
   end
end
```

See Also

properties | methods | events

clc

Clear Command Window

Syntax

```
clc
```

Description

`clc` clears all input and output from the Command Window display, giving you a "clean screen."

After using `clc`, you cannot use the scroll bar to see the history of functions, but you still can use the up arrow key, ↑, to recall statements from the command history.

Examples

Use `clc` in a MATLAB code file to always display output in the same starting position on the screen.

`clear` | `clf` | `close` | `home`

Introduced before R2006a

clear

Remove items from workspace, freeing up system memory

Syntax

```
clear
clear name1 ... nameN
clear -regexp expr1 ... exprN
clear ItemType
```

Description

`clear` removes all variables from the current workspace, releasing them from system memory.

`clear name1 ... nameN` removes the variables, scripts, functions, or MEX-functions `name1 ... nameN` from memory.

- If `name` is a function name, then `clear name` reinitializes any persistent variables in the function.
- If function `name` is locked by `mlock`, then it remains in memory.
- If variable `name` is global, then `clear` removes it from the current workspace, but it remains in the global workspace.

`clear -regexp expr1 ... exprN` clears all variables that match any of the regular expressions listed. This option only clears variables.

`clear ItemType` clears the types of items indicated by `ItemType`, such as `all`, `functions`, or `classes`.

Examples

Clear a Single Variable

Define two variables `a` and `b`, and then clear `a`.

```
a = 1;
```

```
b = 2;
clear a
whos
```

```
Name      Size            Bytes  Class     Attributes

b         1x1                 8  double
```

Only variable `b` remains in the workspace.

Clear Specific Variables by Name

Using regular expressions, clear those variables with names that begin with `Mon`, `Tue`, or `Wed`.

```
clear -regexp ^Mon ^Tue ^Wed;
```

Clear List of Variables

Create a cell array, `varlist`, that contains the names of variables to clear. Then, clear those variables.

```
varlist = {'v1','v2','time'};
clear(varlist{:})
```

Clear All Compiled Scripts, Functions, and MEX-functions

```
clear functions
```

If a function is locked, it will not be cleared from memory.

Input Arguments

`name1 ... nameN` — Names of variables, scripts, functions, or MEX-functions to clear

string

Names of variables, scripts, functions, or MEX-functions to clear, specified as strings.

Use a partial path to distinguish between different overloaded versions of a function. For example, `clear polynom/display` clears only the `display` method for `polynom` objects, leaving any other implementations in memory.

`expr1 ... exprN` — Regular expressions matching names of variables to clear

string

Regular expressions matching names of variables to clear, specified as strings.

`ItemType` — Type of items to clear
`all` | `classes` | `functions` | `global` | `import` | `java` | `mex` | `variables`

Type of items to clear, specified as one of the following strings. Click the linked strings below for additional information.

Value of `ItemTyp`	Items Cleared								
	Variables in scope	Scripts and function	Class definition	Persistent variables	Debuggir breakpoi	MEX functions	Global variable	Import list	Java classes on the dynamic path
`all`	✓	✓		✓	✓	✓	✓	From comman prompt only	
`classes`	✓	✓	✓	✓	✓	✓	✓		
`functio`		✓		✓	✓	✓			
`global`							✓		
`import`								✓	
`java`	✓	✓		✓	✓	✓	✓		✓
`mex`						✓			
`variabl`	✓								

The following applies to clearing types of items.

`all`:

- `clear all` also removes the import list when issued from the command prompt.

`classes`:

- `clear classes` issues a warning and does not clear a class of objects if any of those objects still exists after the workspace is cleared. For example, objects can still exist in persistent variables of functions or figure windows.

- `clear classes` does not clear a class if its file is locked using the `mlock` command. No warning is issued in this case.

`global`:

- `clear global` removes all global variables in the base and global workspaces. If called from a function, `clear global` also removes all global variables in the function workspace.
- Use `clear global name1 ... nameN` to clear the global variables with the specified names.
- Use `clear global –regexp expr1 ... exprN` to clear all global variables that match any of the regular expressions listed.

`import`:

- Call `clear import` only from the command prompt. Calling `clear import` in a function returns an error.

`java`:

- `clear java` issues a warning and does not remove the Java class definition if any Java objects exist outside the workspace (for example, in user data or persistent variables in a locked code file).
- Issue a `clear java` command after modifying any files on the dynamic Java path.

`mex`:

- `clear mex` does not clear locked MEX functions or functions that are currently in use.

If the name of a variable is a value of `ItemType`, then calling `clear` followed by that name deletes the variable with that name. `clear` does not interpret the name as a keyword in this context. For example, if the workspace contains variables `a`, `all`, `b`, and `ball`, `clear all` removes the variable `all` only.

More About

Tips

- The `clear` function can remove variables that you specify. To remove all but some specified variables, use `clearvars` instead.

- You can clear the handle of a figure or graphics object, but the object itself is not removed. Use `delete` to remove objects. Deleting an object does not delete the variable (if any) used for storing its handle.
- The `clear` function does not clear Simulink® models. Use `bdclose` instead.
- On UNIX systems, `clear` does not affect the amount of memory allocated to the MATLAB process.

- "Base and Function Workspaces"
- "Strategies for Efficient Use of Memory"
- "Automatic Updates for Modified Classes"
- "Java Class Path"
- "Regular Expressions"

Introduced before R2006a

clearpoints

Clear points from animated line

To use this function, you must first create an animated line with the `animatedline` function. For more information on line animations, see Using Animated Line Objects.

Syntax

```
clearpoints(h)
```

Description

`clearpoints(h)` clears all points from the animated line specified by `h`. If you want to display the update on the screen, use `drawnow` after using `clearpoints`.

Examples

Clear Points from Animated Line

Create an animated line with 10 points. Then, clear the points stored in the animated line.

```
h = animatedline(1:10,1:10);
clearpoints(h)
```

The animated line still exists, but has no data.

Input Arguments

h — Animated line object

animated line object

Animated line object. Create an animated line object using the `animatedline` function.

See Also

Functions
`addpoints` | `animatedline` | `getpoints`

Using Objects
Using Animated Line Objects

clearvars

Clear variables from memory

Syntax

```
clearvars
clearvars variables
clearvars -except keepVariables
clearvars variables -except keepVariables

clearvars -global ___
```

Description

`clearvars` removes all variables from the currently active workspace.

`clearvars variables` removes the variables specified by `variables`. If any of the variables are global, `clearvars` removes these variables from the current workspace only, leaving them accessible to any functions that declare them as global.

`clearvars -except keepVariables` removes all variables, except for those specified by `keepVariables`. Use this syntax to keep specific variables and remove all others.

`clearvars variables -except keepVariables` removes the variables specified by `variables`, and does not remove the variables specified by `keepVariables`. This syntax allows you to use a combination of variable names, wild card characters, or regular expressions to specify variables to remove or keep.

`clearvars -global ___` removes the specified global variables from the workspace, including those made global within functions, using any of the input arguments in the preceding syntaxes. The `-global` flag must be first in the argument list.

Examples

Clear Named Variables

Define three variables, `a`, `b`, and `c`. Then, clear `a` and `c`.

```
a = 1;
b = 2;
c = 3;
clearvars a c
whos
```

```
  Name      Size            Bytes  Class     Attributes

  b         1x1                 8  double
```

Only variable `b` remains in the workspace.

Clear All Variables Except Specified

Remove all variables from the workspace except for the variables `C` and `D`.

```
clearvars -except C D
```

Clear Variables Using Regular Expressions and Name Variables to Exclude

Clear variables with names that start with `b` and are followed by 3 digits, except for the variable `b106`.

```
clearvars -regexp ^b\d{3}$ -except b106
```

Name Variables to Clear and Preserve Variables Using Regular Expressions

Clear variables with names that start with `a` and do not end with `a`.

```
clearvars a* -except -regexp a$
```

Clear Global Variables Except Specified

Clear all global variables, except those with names that start with `x`.

```
clearvars -global -except x*
```

Clear List of Variables

Clear a list of variables used for intermediate calculations.

Create two variables in the workspace.

```
cashOnHand = 20;
cost = 12.99;
```

Store a list of the names of all the variables currently in the workspace.

```
initialVars = who;
```

Specify or calculate additional variables, `taxRate` and `tax`.

```
taxRate = 0.0625;
tax = round(100*cost*taxRate)/100;
```

Update the initial variables, `cost` and `cashOnHand`.

```
cost = cost + tax;
cashOnHand = cashOnHand - cost;
```

Clear all variables except the initial variables, using the function form of `clearvars`. When using the function form of a syntax, enclose input strings in single quotes, and separate them with commas.

```
clearvars('-except',initialVars{:})
```

`clearvars` clears the variables, `initialVars`, `taxRate`, and `tax`.

Input Arguments

`variables` — Names of variables to remove

strings

Names of variables to remove, specified as one or more strings in one of the following forms.

Form of `Variables` Input	Variables to Remove
`var1 ... varN`	Named variables, specified as individual strings. Use the `'*'` wildcard to match patterns. For example, `clearvars A*` clears all variables in the workspace with names that start with `A`.
`-regexp` *`expr1 ... exprN`*	Variables with names that match the regular expressions, specified as strings. For example, `clearvars -regexp ^Mon ^Tues` clears only the variables in the workspace with names that begin with `Mon` or `Tues`.

`keepVariables` — Names of variables to keep
strings

Names of variables to keep, specified as one or more strings in one of the following forms.

Form of `Variables` Input	Variables to Keep
`var1 ... varN`	Named variables, specified as individual strings. Use the `'*'` wildcard to match patterns. For example, `clearvars -except A*` clears all variables in the workspace, except those with names that start with `A`.
`-regexp` *`expr1 ... exprN`*	Variables with names that match the regular expressions, specified as strings. For example, `clearvars -except -regexp ^Mon ^Tues` clears all the variables in the workspace, except those with names that begin with `Mon` or `Tues`.

See Also

`clear` | `exist` | `global` | `persistent` | `save` | `who` | `whos`

clear (serial)

Remove serial port object from MATLAB workspace

Syntax

```
clear obj
```

Description

`clear obj` removes `obj` from the MATLAB workspace, where `obj` is a serial port object or an array of serial port objects.

Examples

This example creates the serial port object `s` on a Windows platform, copies `s` to a new variable `scopy`, and clears `s` from the MATLAB workspace. `s` is then restored to the workspace with `instrfind` and is shown to be identical to `scopy`.

```
s = serial('COM1');
scopy = s;
clear s
s = instrfind;
isequal(scopy,s)
ans =
     1
```

More About

Tips

If `obj` is connected to the device and it is cleared from the workspace, then `obj` remains connected to the device. You can restore `obj` to the workspace with the `instrfind` function. A serial port object connected to the device has a `Status` property value of `open`.

To disconnect `obj` from the device, use the `fclose` function. To remove `obj` from memory, use the `delete` function. You should remove invalid serial port objects from the workspace with `clear`.

See Also

`delete` | `isvalid` | `fclose` | `instrfind` | `Status`

Introduced before R2006a

clf

Clear current figure window

Syntax

```
clf
clf('reset')
clf(fig)
clf(fig,'reset')
figure_handle = clf(...)
```

Description

`clf` deletes from the current figure all graphics objects whose handles are not hidden (i.e., their `HandleVisibility` property is set to `on`).

`clf('reset')` deletes from the current figure all graphics objects regardless of the setting of their `HandleVisibility` property and resets all figure properties except `Position`, `Units`, `PaperPosition`, and `PaperUnits` to their default values.

`clf(fig)` or `clf(fig,'reset')` clears the single figure with handle `fig`.

`figure_handle = clf(...)` returns the handle of the figure. This is useful when the figure `IntegerHandle` property is `off` because the noninteger handle becomes invalid when the reset option is used (i.e., `IntegerHandle` is reset to `on`, which is the default).

Alternatives

Use **Clear Figure** from the figure window's **Edit** menu to clear the contents of a figure. You can also create a *desktop shortcut* to clear the current figure with one mouse click. See “Create Shortcuts to Rerun Commands”.

More About

Tips

The `clf` command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the `HandleVisibility` setting of `callback`. This means that when issued from within a callback routine, `clf` deletes only those objects whose `HandleVisibility` property is set to `on`.

`cla` | `clc` | `hold` | `reset`

Introduced before R2006a

clipboard

Copy and paste strings to and from system clipboard

Syntax

```
clipboard('copy', data)
str = clipboard('paste')
data = clipboard('pastespecial')
```

Description

`clipboard('copy', data)` sets the clipboard contents to *`data`*. If *`data`* is not a character array, the clipboard uses `mat2str` to convert *`data`* to a string.

`str` `= clipboard('paste')` returns the current contents of the clipboard as a string or, if MATLAB cannot convert the current clipboard contents to a string, as an empty string (`''`).

`data` `= clipboard('pastespecial')` returns the current contents of the clipboard as an array by using `uiimport`.

Definitions

The `clipboard` function requires Oracle® Java software.

See Also

`load` | `mat2str` | `uiimport`

Introduced before R2006a

clock

Current date and time as date vector

Syntax

```
c = clock
```

Description

`c = clock` returns a six-element date vector containing the current date and time in decimal form:

```
[year month day hour minute seconds]
```

Examples

Round clock Output to Integer Display

Use `clock` to return the current date and time.

```
format shortg
c = clock
```

```
c =

        2015           2          23           9          55      59.151
```

The sixth element of the date vector output (seconds) is accurate to several digits beyond the decimal point.

Use the `fix` function to round to integer display format.

```
fix(c)
```

```
ans =

        2015           2          23           9          55          59
```

More About

Tips

- To time the duration of an event, use the `timeit` or `tic` and `toc` functions instead of `clock` and `etime`. The `clock` function is based on the system time, which can be adjusted periodically by the operating system, and thus might not be reliable in time comparison operations.
- To return a datetime scalar representing the current date and time, type:

  ```
  t = datetime('now')
  ```

See Also

`cputime` | `date` | `datetime` | `etime` | `fix` | `now` | `tic` | `timeit` | `toc`

Introduced before R2006a

close

Remove specified figure

Syntax

```
close
close(h)
close name
close all
close all hidden
close all force
status = close(...)
```

Description

`close` deletes the current figure or the specified figure(s). It optionally returns the status of the close operation.

`close` deletes the current figure (equivalent to `close(gcf)`).

`close(h)` deletes the figure identified by `h`. If `h` is an array, `close` deletes all figures identified by `h`. `h` can also be the figure `Number`.

`close name` deletes the figure with the specified name.

`close all` deletes all figures whose handles are not hidden.

`close all hidden` deletes all figures including those with hidden handles.

`close all force` deletes all figures, including GUIs for which `CloseRequestFcn` has been altered to not close the window.

`status = close(...)` returns `1` if the specified windows have been deleted and `0` otherwise.

More About

Algorithms

The `close` function works by evaluating the specified figure's `CloseRequestFcn` property with the statement

```
eval(get(h,'CloseRequestFcn'))
```

The default `CloseRequestFcn`, `closereq`, deletes the current figure using `delete(get(groot,'CurrentFigure'))`. If you specify an array of figure handles, `close` executes each figure's `CloseRequestFcn` in turn. If an error that terminates the execution of a `CloseRequestFcn` occurs, the figure is not deleted. Note that using your computer's window manager (i.e., the **Close** menu item) also calls the figure's `CloseRequestFcn`.

If a figure's handle is hidden (i.e., the figure's `HandleVisibility` property is set to `callback` or `off` and the root `ShowHiddenHandles` property is set to `on`), you must specify the `hidden` option when trying to access a figure using the `all` option.

To delete all figures unconditionally, use the statements

```
set(groot,'ShowHiddenHandles','on')
c = get(groot,'Children');
delete(c)
```

The figure `CloseRequestFcn` allows you to either delay or abort the closing of a figure once the `close` function has been issued. For example, you can display a dialog box to see if the user really wants to delete the figure or save and clean up before closing.

When coding a `CloseRequestFcn` callback, make sure that it does not call `close`, because this sets up a recursion that results in a MATLAB warning. Instead, the callback should destroy the figure with `delete`. The `delete` function does not execute the figure's `CloseRequestFcn`; it deletes the specified figure.

See Also

`delete` | `figure` | `gcf`

Introduced before R2006a

close

Class: Tiff

Close Tiff object

Syntax

```
close(tiffobj)
```

Description

`close(tiffobj)` closes a Tiff object.

Examples

Close Tiff Object

Open a Tiff object and then close it.

```
t = Tiff('example.tif','r');
close(t)
```

- "Exporting Image Data and Metadata to TIFF Files"
- "Reading Image Data and Metadata from TIFF Files"

References

This method corresponds to the `TIFFClose` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTiff - TIFF Library and Utilities.

close (avifile)

Close Audio/Video Interleaved (AVI) file

Note: `avifile` has been removed. Use `VideoWriter` instead.

Syntax

```
aviobj = close(aviobj)
```

Description

`aviobj = close(aviobj)` finishes writing and closes the AVI file associated with *`aviobj`*, which is an AVI file object created using the `avifile` function.

To close all open AVI files, use the `clear mex` command.

See Also

`avifile` | `addframe (avifile)`

Introduced before R2006a

close

Class: FTP

Close connection to FTP server

Syntax

```
close(ftpobj)
```

Description

`close(ftpobj)` closes the connection to the FTP server.

Tips

- If you do not run `close` at the end of your session, the connection either times out automatically or terminates when you exit MATLAB.
- After calling `close`, calling any other FTP method on the same object automatically reopens the connection.
- `close` does not return any output to indicate success or failure.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

Examples

Connect to the MathWorks FTP server, and then disconnect:

```
mw=ftp('ftp.mathworks.com');
```

```
close(mw)
```

See Also

`ftp`

Introduced before R2006a

close

Class: VideoWriter

Close file after writing video data

Syntax

```
close(writerObj)
```

Description

`close(writerObj)` closes the file associated with object writerObj. The object remains in the workspace. If you call the `open` method after closing, `open` discards any existing contents of the file.

Input Arguments

`writerObj`

`VideoWriter` object created by the `VideoWriter` function.

Examples

AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
```

```
axis tight
set(gca,'nextplot','replacechildren');
set(gcf,'Renderer','zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
   surf(sin(2*pi*k/20)*Z,Z)
   frame = getframe;
   writeVideo(writerObj,frame);
end

close(writerObj);
```

See Also

`open` | `writeVideo` | `VideoWriter`

closereq

Default figure close request function

Syntax

```
closereq
```

Description

`closereq` deletes the current figure. For more information, see the `CloseRequestFcn` figure property.

Introduced before R2006a

cmopts

(To be removed) Name of source control system

Note: `cmopts` will be removed in a future release. View the currently selected source control system through **Preferences** instead.

Syntax

```
cmopts
```

Description

`cmopts` returns the name of your version control system.

Output Arguments

Value Returned by cmopts	Description	Platform Supported On
`clearcase`	ClearCase® software from IBM® Rational®	UNIX platforms
`customverctrl`	Custom interface created using `customverctrl` function	UNIX platforms
`cvs`	Concurrent Version System (CVS)	UNIX platforms
`none`	No source control system selected	
`pvcs`	PVCS® and ChangeMan® software	UNIX platforms
`rcs`	Revision Control System (RCS)	UNIX platforms

Value Returned by cmopts	Description	Platform Supported On
Any SCC-compliant source control system, for example, `Microsoft Visual SourceSafe`	Varies	Windows platforms

Alternatives

To view the currently selected source control system, click the **Preferences** button on the **Home** tab, and select **General > Source Control**.

Introduced before R2006a

cmpermute

Rearrange colors in colormap

Syntax

```
[Y,newmap] = cmpermute(X,map)
[Y,newmap] = cmpermute(X,map,index)
```

Description

`[Y,newmap] = cmpermute(X,map)` randomly reorders the colors in `map` to produce a new colormap, `newmap`. The `cmpermute` function also modifies the values in `X` to maintain correspondence between the indices and the colormap, and returns the result in `Y`. The image `Y` and associated colormap, `newmap`, produce the same image as `X` and `map`.

`[Y,newmap] = cmpermute(X,map,index)` uses an ordering matrix (such as the second output of `sort`) to define the order of colors in the new colormap.

Class Support

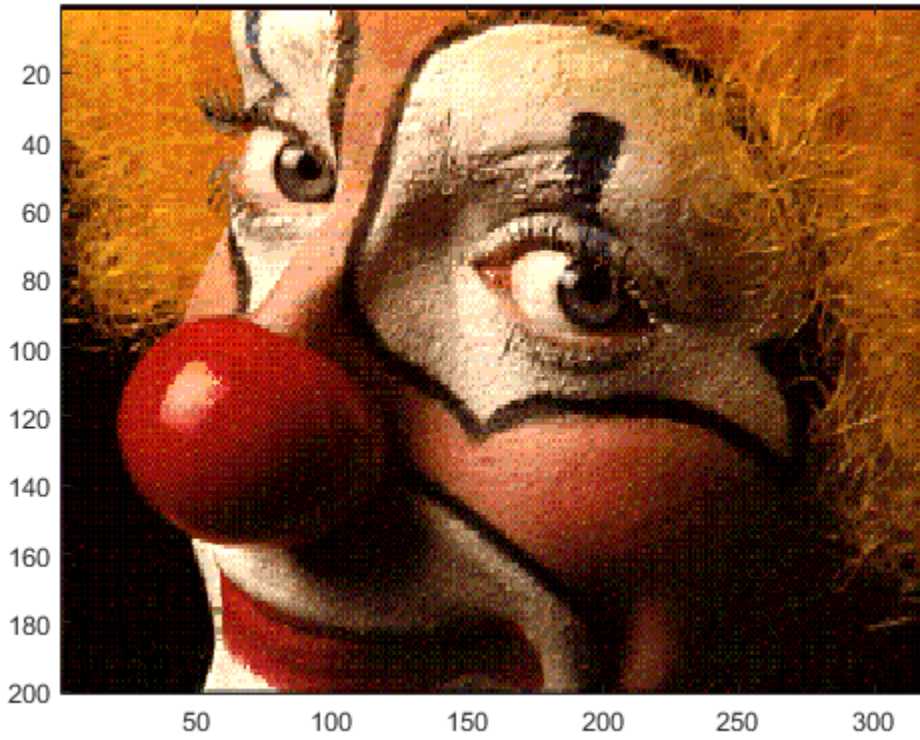
The input image `X` can be of class `uint8` or `double`. `Y` is returned as an array of the same class as `X`.

Examples

Randomly Reorder Colormap and Display Image

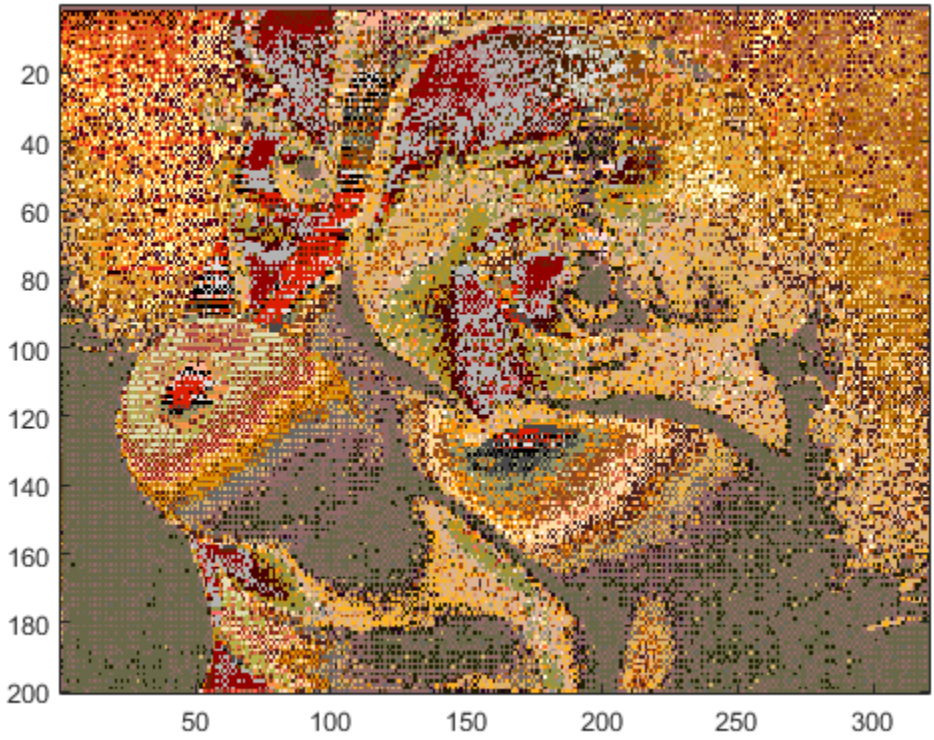
Load the `clown` data set to get image `X` and its associated colormap, `map`. Display the image.

```
load clown
figure
image(X)
colormap(map)
```



Randomly reorder the colormap to get the new colormap, `newmap`. Display image `X` with the new colormap.

```
[Y, newmap] = cmpermute(X,map);
colormap(newmap)
```



See Also

`randperm` | `sort`

cmunique

Eliminate duplicate colors in colormap; convert grayscale or truecolor image to indexed image

Syntax

```
[Y,newmap] = cmunique(X,map)
[Y,newmap] = cmunique(RGB)
[Y,newmap] = cmunique(I)
```

Description

`[Y,newmap] = cmunique(X,map)` returns the indexed image `Y` and associated colormap, `newmap`, that produce the same image as `(X,map)` but with the smallest possible colormap. The `cmunique` function removes duplicate rows from the colormap and adjusts the indices in the image matrix accordingly.

`[Y,newmap] = cmunique(RGB)` converts the truecolor image `RGB` to the indexed image `Y` and its associated colormap, `newmap`. The return value `newmap` is the smallest possible colormap for the image, containing one entry for each unique color in `RGB`.

Note: `newmap` might be very large, because the number of entries can be as many as the number of pixels in `RGB`.

`[Y,newmap] = cmunique(I)` converts the grayscale image `I` to an indexed image `Y` and its associated colormap, `newmap`. The return value, `newmap`, is the smallest possible colormap for the image, containing one entry for each unique intensity level in `I`.

Class Support

The input image can be of class `uint8`, `uint16`, or `double`. The class of the output image `Y` is `uint8` if the length of `newmap` is less than or equal to 256. If the length of `newmap` is greater than 256, `Y` is of class `double`.

Examples

Eliminate Duplicate Entries in Colormap

Use the `magic` function to define `X` as a 4-by-4 array that uses every value in the range between 1 and 16.

```
X = magic(4);
```

Use the `gray` function to create an eight-entry colormap. Then, concatenate the two eight-entry colormaps to create a colormap with 16 entries, `map`. In `map`, entries 9 through 16 are duplicates of entries 1 through 8.

```
map = [gray(8); gray(8)];
size(map)
```

```
ans =

    16     3
```

Use `cmunique` to eliminate duplicate entries in the colormap.

```
[Y, newmap] = cmunique(X, map);
size(newmap)
```

```
ans =

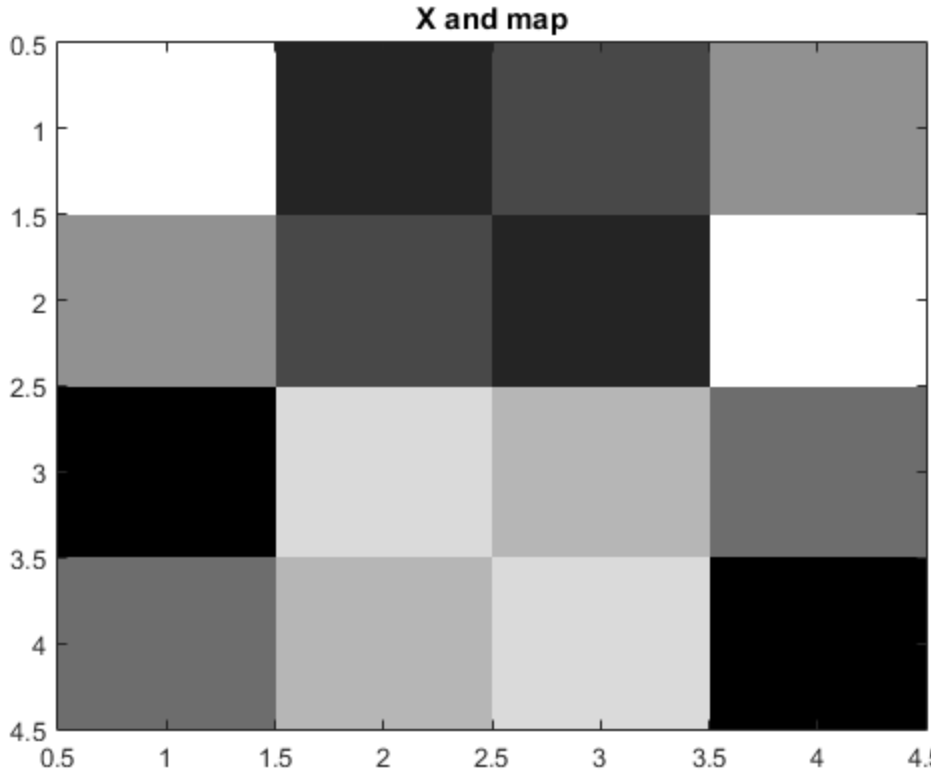
     8     3
```

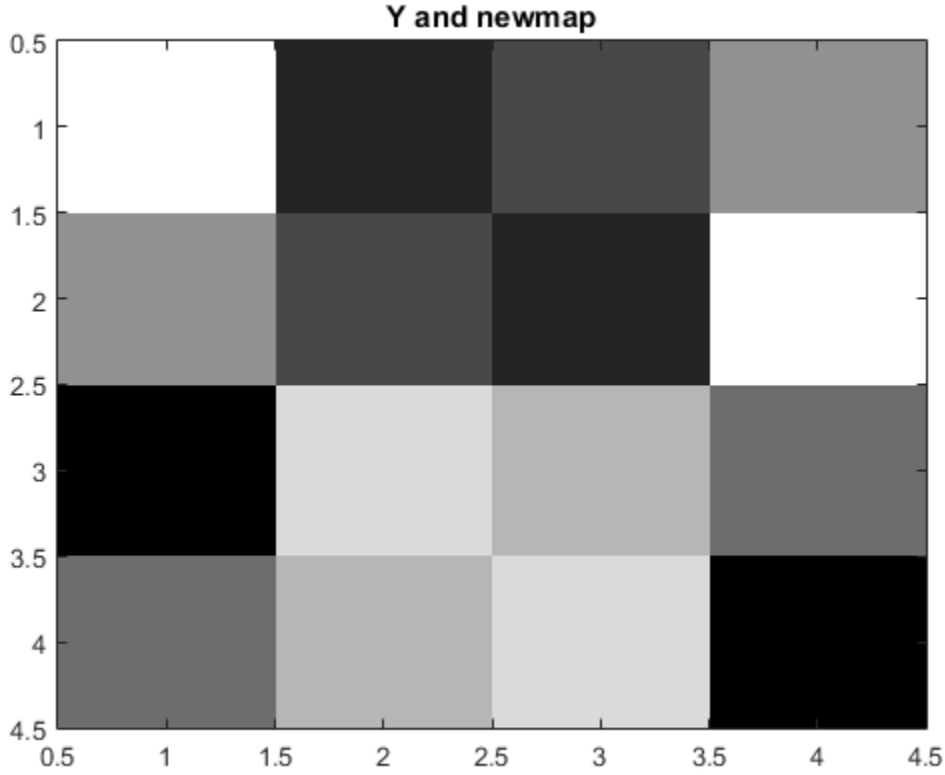
`cmunique` adjusts the values in the original image `X` so that `Y` and `newmap` produce the same image as `X` and `map`.

```
figure
image(X)
colormap(map)
title('X and map')

figure
image(Y)
```

```
colormap(newmap)
title('Y and newmap')
```





See Also

`rgb2ind`

colamd

Column approximate minimum degree permutation

Syntax

```
p = colamd(S)
```

Description

`p = colamd(S)` returns the column approximate minimum degree permutation vector for the sparse matrix `S`. For a non-symmetric matrix `S`, `S(:,p)` tends to have sparser LU factors than `S`. The Cholesky factorization of `S(:,p)' * S(:,p)` also tends to be sparser than that of `S'*S`.

`knobs` is a two-element vector. If S is `m`-by-`n`, then rows with more than `(knobs(1))*n` entries are ignored. Columns with more than `(knobs(2))*m` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs(1)` = `knobs(2) = spparms('wh_frac')`.

`stats` is an optional vector that provides data about the ordering and the validity of the matrix `S`.

`stats(1)`	Number of dense or empty rows ignored by `colamd`
`stats(2)`	Number of dense or empty columns ignored by `colamd`
`stats(3)`	Number of garbage collections performed on the internal data structure used by `colamd` (roughly of size `2.2*nnz(S) + 4*m + 7*n` integers)
`stats(4)`	`0` if the matrix is valid, or `1` if invalid
`stats(5)`	Rightmost column index that is unsorted or contains duplicate entries, or `0` if no such column exists
`stats(6)`	Last seen duplicate or out-of-order row index in the column index given by `stats(5)`, or `0` if no such row index exists
`stats(7)`	Number of duplicate and out-of-order row indices

Although MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `colamd`. For this reason, `colamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `colamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `colamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `colamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`) .

The ordering is followed by a column elimination tree post-ordering.

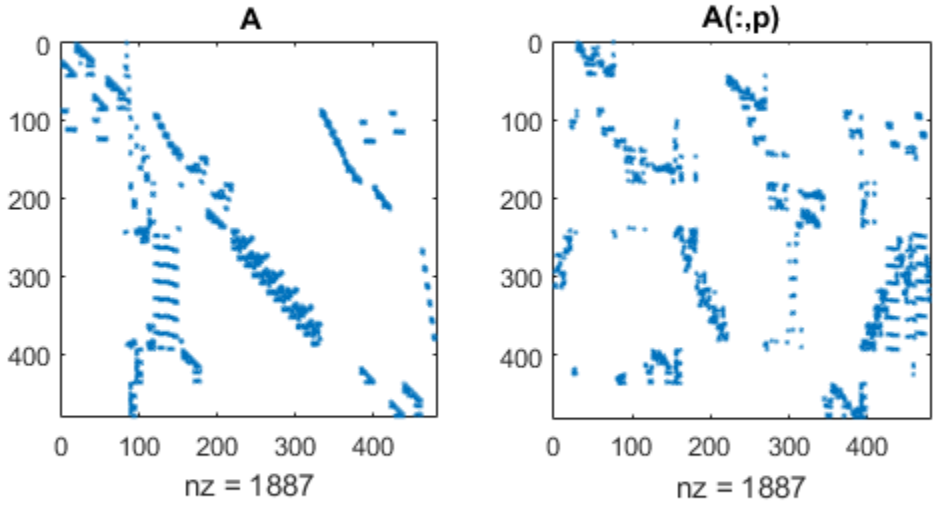
Examples

Compare Sparse Matrix and LU Factorization

The Harwell-Boeing collection of sparse matrices and the MATLAB® demos directory include a test matrix `west0479`. It is a matrix of order 479 resulting from a model due to Westerberg of an eight-stage chemical distillation column. The spy plot shows evidence of the eight stages. The `colamd` ordering scrambles this structure.

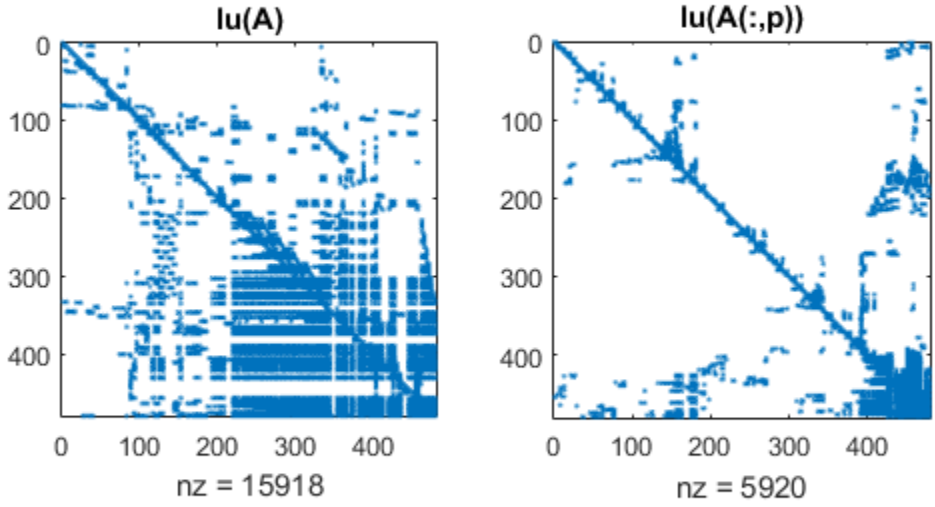
```
load west0479
A = west0479;
p = colamd(A);

figure()
subplot(1,2,1), spy(A,4), title('A')
subplot(1,2,2), spy(A(:,p),4), title('A(:,p)')
```



Comparing the spy plot of the LU factorization of the original matrix with that of the reordered matrix shows that minimum degree reduces the time and storage requirements by better than a factor of 2.8. The nonzero counts are 15918 and 5920, respectively.

```
figure()
subplot(1,2,1), spy(lu(A),4), title('lu(A)')
subplot(1,2,2), spy(lu(A(:,p)),4), title('lu(A(:,p))')
```



References

[1] The authors of the code for “colamd” are Stefan I. Larimore and Timothy A. Davis (davis@cise.ufl.edu), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National Laboratory. `colperm` | `symamd` | `symrcm` | `spparms`

Introduced before R2006a

colorbar

Colorbar showing color scale

Syntax

```
colorbar
colorbar(placement)
colorbar(Name,Value)
colorbar(placement,Name,Value)

colorbar(ax, ___ )
colorbar('peer',ax ___ )
h = colorbar( ___ )

colorbar('off')
colorbar(h,'off')
colorbar(ax,'off')
```

Description

`colorbar` displays a vertical colorbar to the right of the current axes. Colorbars display the current colormap and indicate the mapping of data values into the colormap.

`colorbar(placement)` displays a colorbar in the location specified by `placement`, which is a location string such as `'northoutside'`.

`colorbar(Name,Value)` specifies colorbar properties using one or more `Name,Value` pair arguments. For example, `'Direction','reverse'` reveres the color scale.

`colorbar(placement,Name,Value)` specifies both the colorbar location and other colorbar properties.

`colorbar(ax, ___ )` adds a colorbar to the axes specified by `ax` instead of the current axes (`gca`). The option, `ax`, can precede any of the input argument combinations in the previous syntaxes.

`colorbar('peer',ax___)` adds a colorbar to the axes specified by `ax` instead of the current axes. This syntax is not recommended and might be removed in a future release. Use `colorbar(ax,__)` instead.

`h = colorbar(___)` returns the colorbar object. Use `h` to set properties of the colorbar after it is created.

Note: Starting in R2014b, the `colorbar` function returns a colorbar object. In previous releases it returns an axes object.

`colorbar('off')` deletes all colorbars associated with the current axes.

`colorbar(h,'off')` deletes the colorbar specified by `h`.

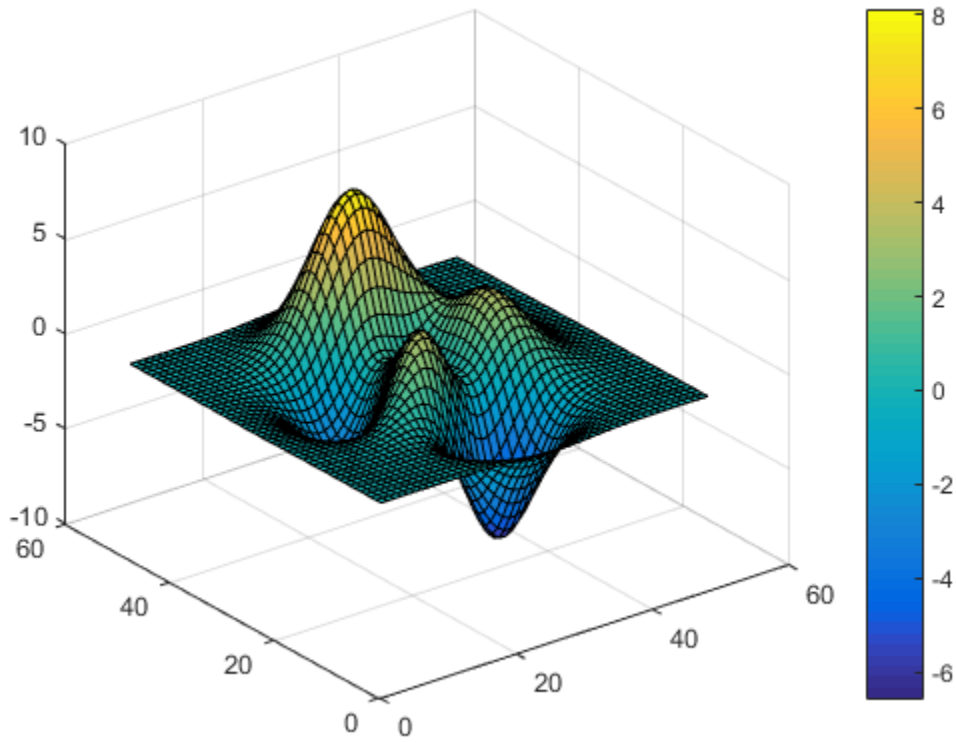
`colorbar(ax,'off')` deletes all colorbars associated with the axes specified by `ax` instead of the current axes (`gca`).

Examples

Add Colorbar to Graph

Add a colorbar to a surface plot indicating the color scale.

```
figure
surf(peaks)
colorbar
```

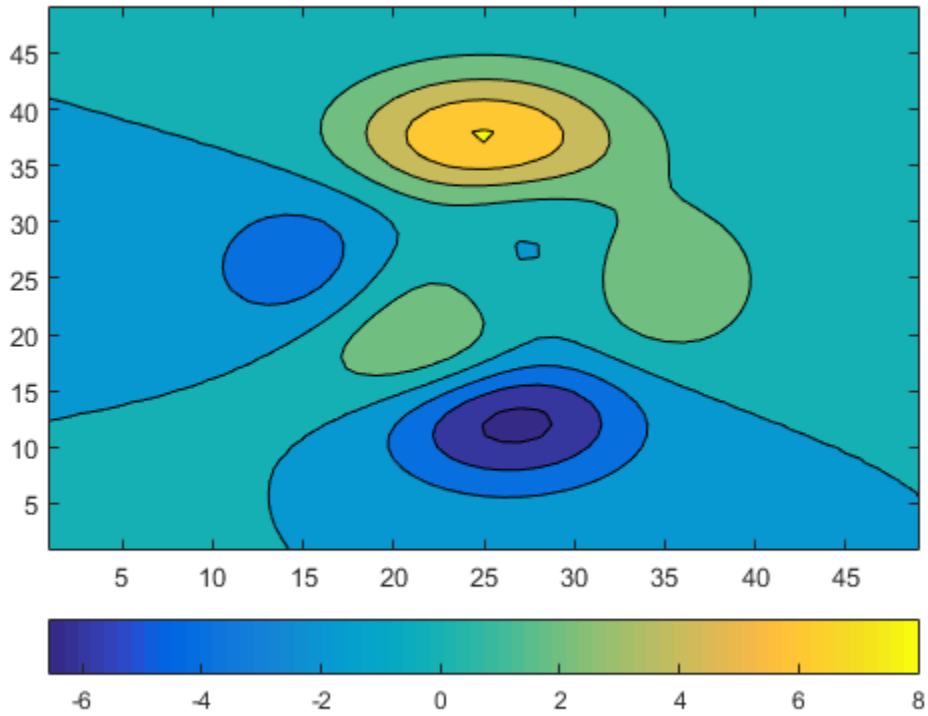


By default, the `colorbar` function adds a vertical colorbar to the right side of the graph.

Add Horizontal Colorbar to Graph

Add a horizontal colorbar below a plot by specifying the colorbar location as `'southoutside'`.

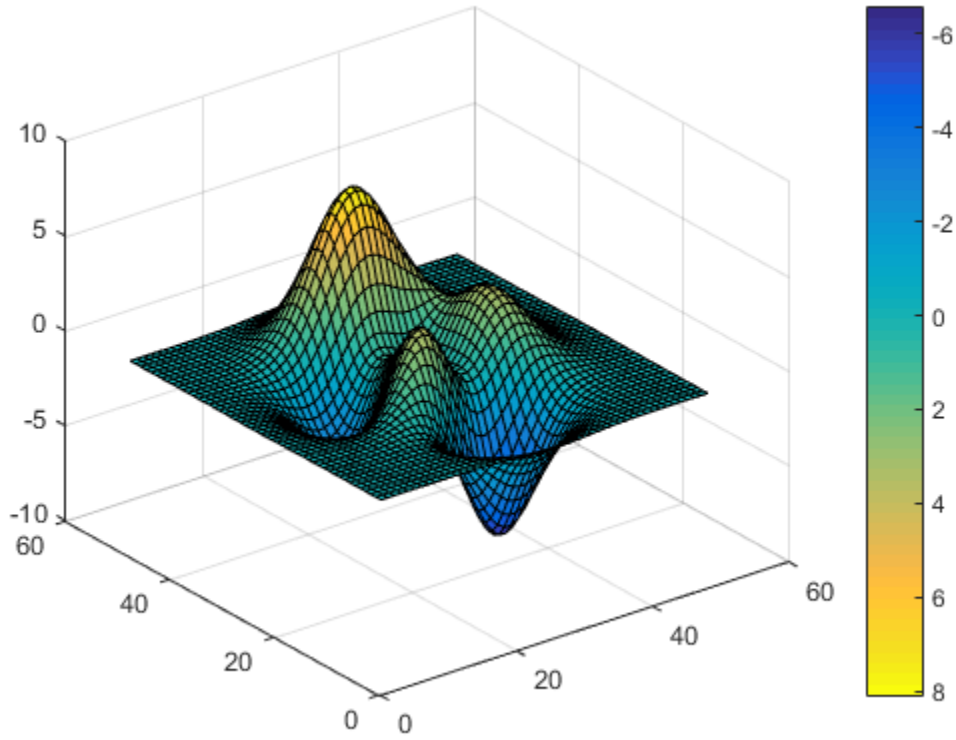
```
figure
contourf(peaks)
colorbar('southoutside')
```



Reverse Colorbar Direction

Reverse the direction of values in a colorbar on a graph by setting the `'Direction'` property of the colorbar to `'reverse'`.

```
figure
surf(peaks)
colorbar('Direction','reverse')
```

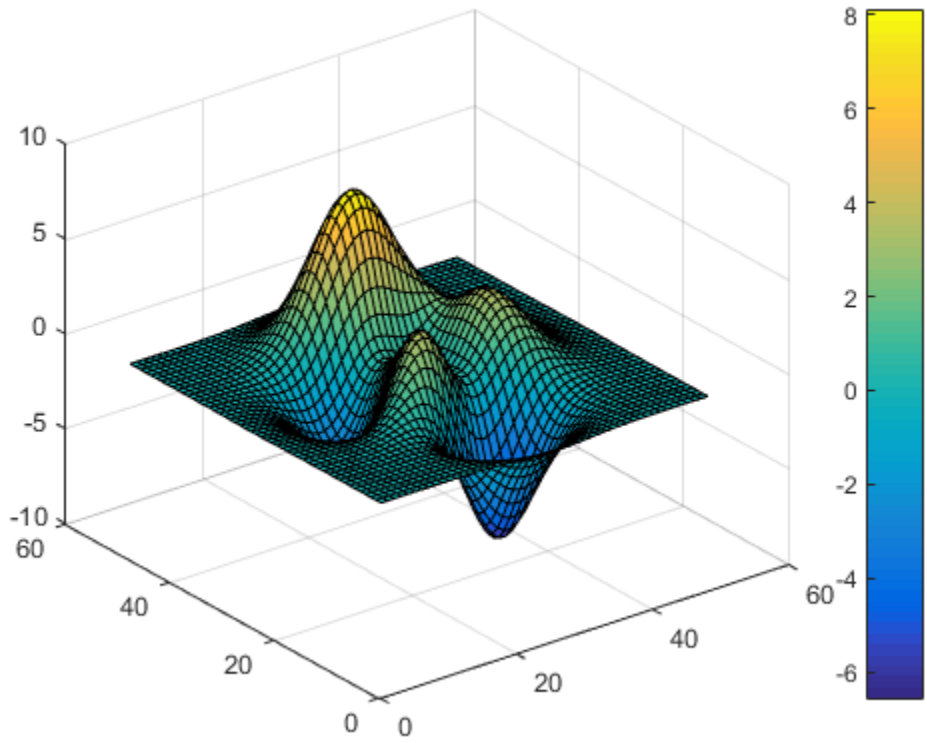


The colorbar values ascend from top to bottom instead of ascending from bottom to top.

Display Colorbar Ticks on Opposite Side

Display the colorbar tick marks and tick labels on the side of a colorbar facing the surface plot.

```
surf(peaks)
colorbar('AxisLocation','in')
```

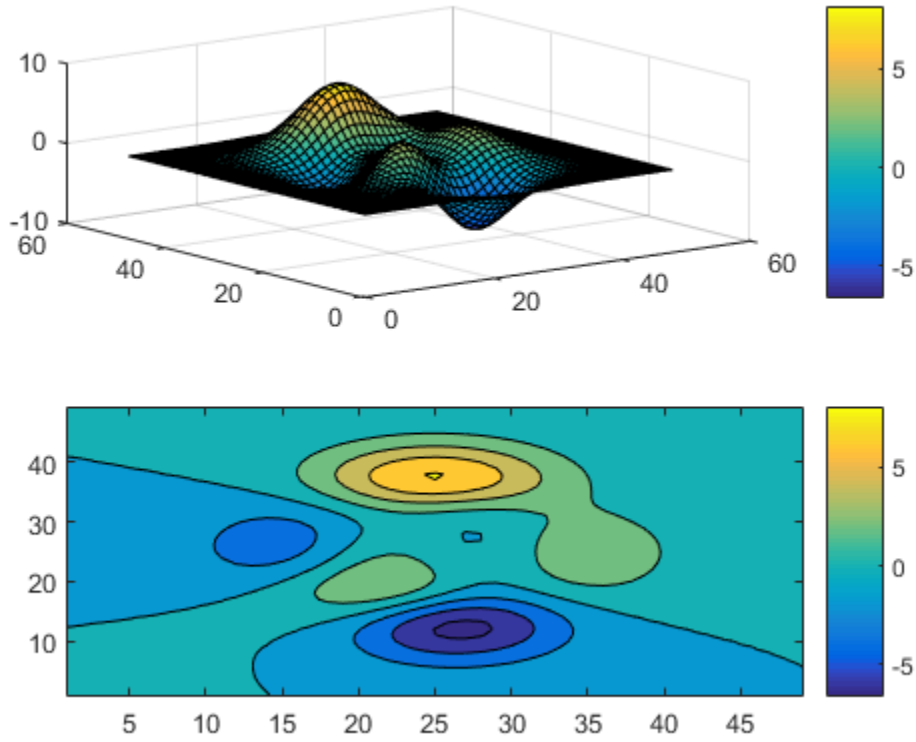


Add Colorbars to Subplots

Create a figure with two subplots. Add colorbars to both subplots.

```
figure
subplot(2,1,1) % upper subplot
surf(peaks)
colorbar

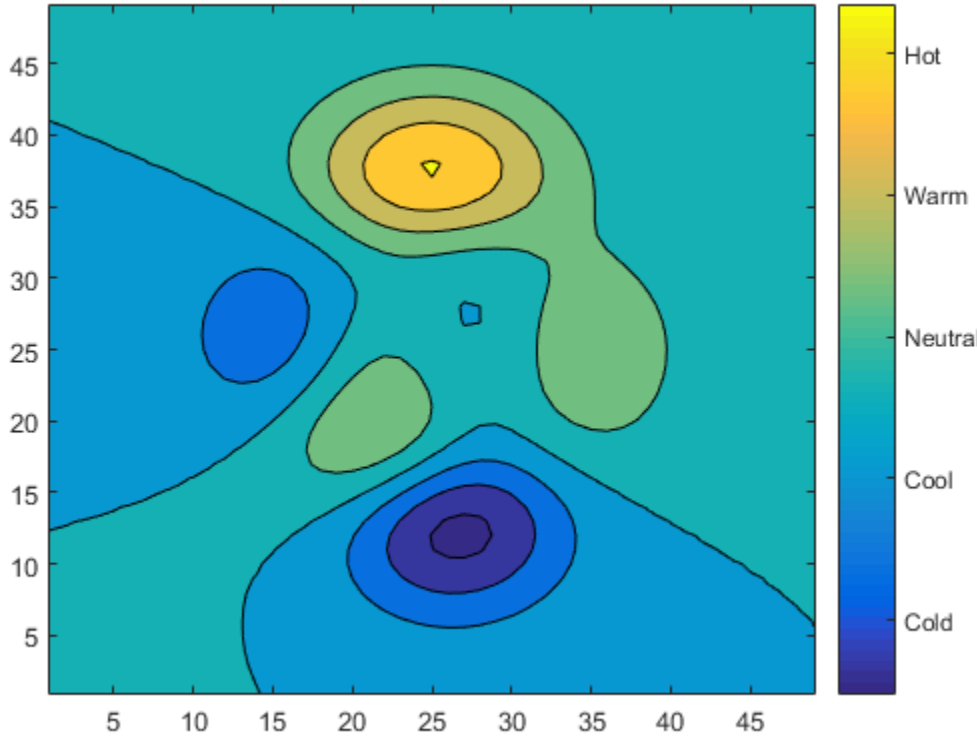
subplot(2,1,2) % lower subplot
contourf(peaks)
colorbar
```



Specify Colorbar Ticks and Tick Labels

Add a colorbar to a plot and specify the colorbar tick marks and tick labels. Specify the same number of tick labels as tick marks. If you do not specify enough tick labels, then the `colorbar` function repeats the labels.

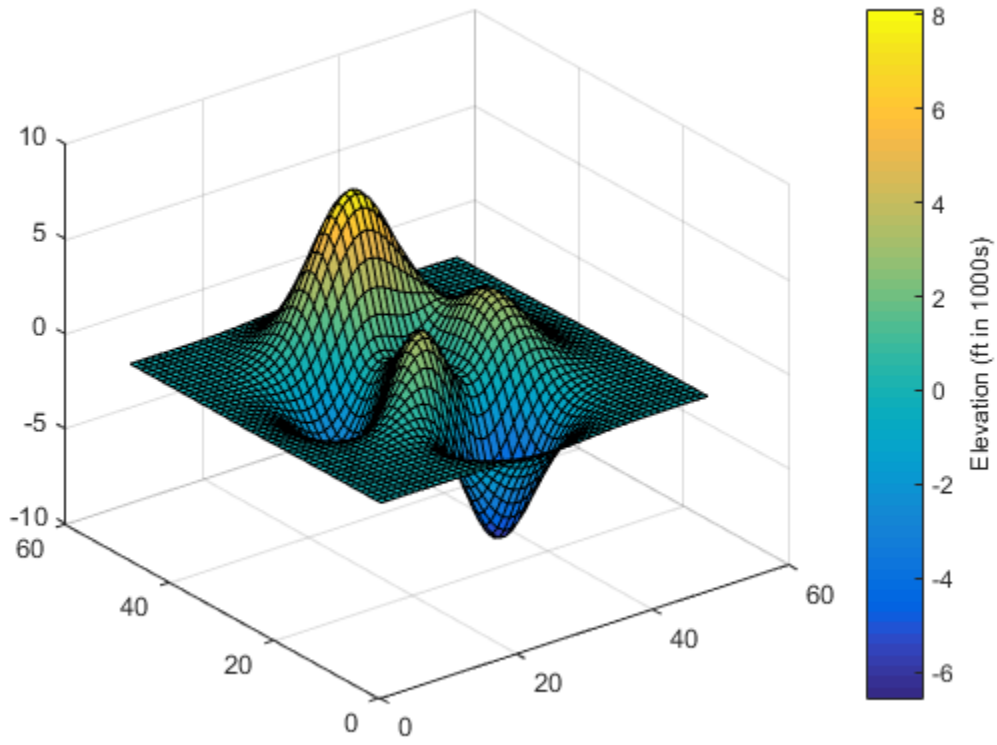
```
contourf(peaks)
colorbar('Ticks',[-5,-2,1,4,7],...
         'TickLabels',{'Cold','Cool','Neutral','Warm','Hot'})
```



Label Colorbar

Add a text label along a colorbar. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

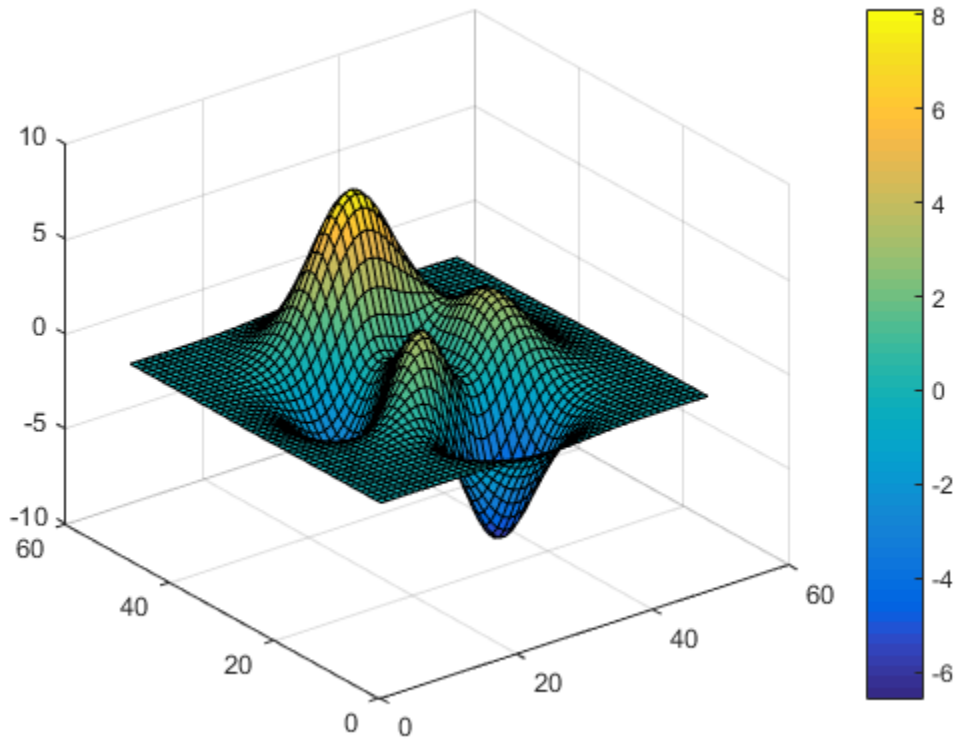
```
surf(peaks)
c = colorbar;
c.Label.String = 'Elevation (ft in 1000s)';
```



Delete Colorbar

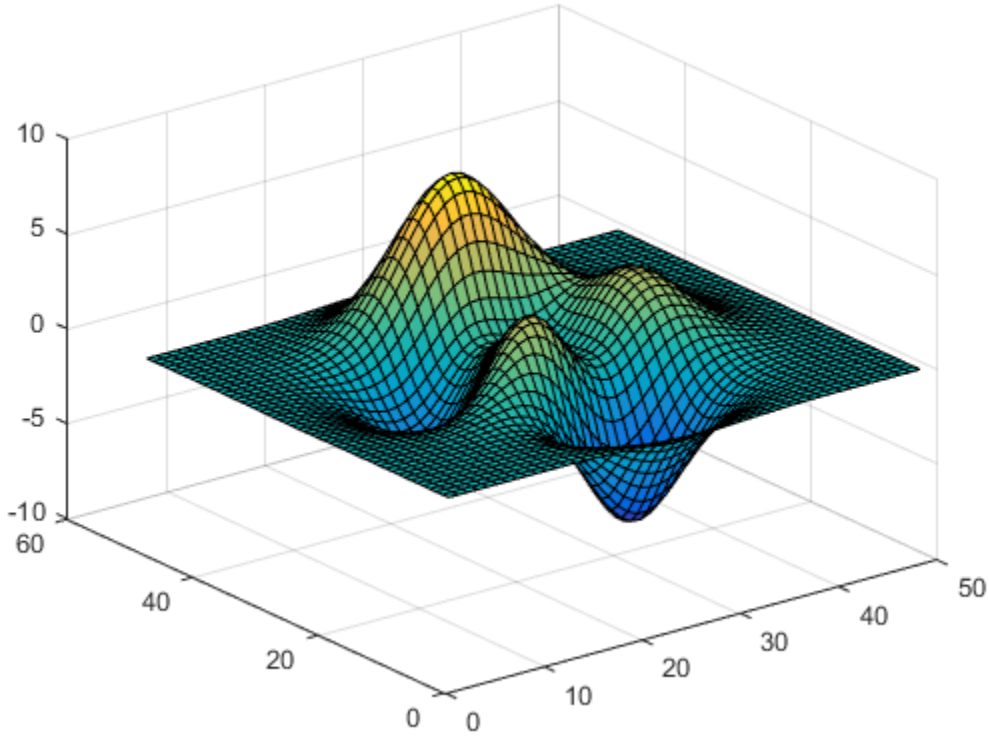
Add a colorbar to a surface plot.

```
figure
surf(peaks)
colorbar
```



Delete the colorbar from the surface plot.

```
colorbar('off')
```



- “Change Colorbar Width”
- “Change Mapping of Data Values into the Colormap”

Input Arguments

`placement` — Colorbar location and orientation

`'eastoutside'` (default) | location string

Colorbar location and orientation with respect to the axes, specified as a location string. This table lists the location strings.

String	Resulting Location	Resulting Orientation
`'north'`	Top of axes	Horizontal
`'south'`	Bottom of axes	Horizontal
`'east'`	Right side of axes	Vertical
`'west'`	Left side of axes	Vertical
`'northoutside'`	Top outside of axes	Horizontal
`'southoutside'`	Bottom outside of axes	Horizontal
`'eastoutside'`	Right outside of axes (default)	Vertical
`'westoutside'`	Left outside of axes	Vertical

If a colorbar already exists in the specified location, then an updated colorbar replaces the existing one. To ensure that the colorbar does not overlap the graph, specify a location with the suffix, `outside`.

You also can set the colorbar location using its `Location` property. For example, `colorbar('Location','northoutside')` is the same as `colorbar('northoutside')`. If you use the shorthand syntax, `colorbar('northoutside')`, then MATLAB sets the colorbar `Location` property value to `'northoutside'`.

Example: `colorbar('westoutside')`

ax — Axes object

axes object

Axes object. If you do not specify an axes, then the `colorbar` function adds a colorbar for the current axes.

Name-Value Pair Arguments

The colorbar properties listed here are only a subset. For a complete list see Colorbar Properties.

Example: `colorbar('FontSize',12,'Direction','reverse')` sets the font size of the colorbar to 12 points and reverses the orientation of the colorbar.

'Location' — Location with respect to the axes

`'eastoutside'` (default) | tring

Location with respect to the axes, specified as one of the strings listed in this table.

String	Resulting Location	Resulting Orientation
`'north'`	Top of axes	Horizontal
`'south'`	Bottom of axes	Horizontal
`'east'`	Right side of axes	Vertical
`'west'`	Left side of axes	Vertical
`'northoutside'`	Top outside of axes	Horizontal
`'southoutside'`	Bottom outside of axes	Horizontal
`'eastoutside'`	Right outside of axes (default)	Vertical
`'westoutside'`	Left outside of axes	Vertical
`'manual'`	Determined by `Position` property	Vertical

To display the colorbar in a location that does not appear in the table, use the Position property to specify a custom location. If you set the Position property, then MATLAB sets the Location property to `'manual'`. The associated axes does not resize to accommodate the colorbar when the Location property is set to `'manual'`.

`'Label'` — Label that displays along colorbar

text object (default)

Label that displays along the colorbar, returned as a text object. This text object contains properties that control the label appearance and the text that displays. Use the `Label` property to access the text object, for example:

```
c = colorbar;
c.Label

ans =

  Text with properties:

               String: ''
             FontSize: 10
           FontWeight: 'normal'
             FontName: 'Helvetica'
```

```
                Color: [0.1500 0.1500 0.1500]
   HorizontalAlignment: 'left'
              Position: [0 0 0]
                 Units: 'data'

  Show all properties
```

By default, there is no text displayed. To display text or change existing text, set the String property for the text object, for example:

```
c.Label.String = 'Label Text Goes Here';
```

To change the label appearance, such as the font style or color, set other text properties. For example, this code changes the font size.

```
c.Label.FontSize = 12;
```

For a full list of options, see Text Properties.

Note: The `Label` property is different from other colorbar properties. You cannot set the `Label` property as a name-value pair when creating the colorbar. Instead, use dot notation (demonstrated above) or the `set` function.

`'TickLabels'` — Tick mark labels

cell array of strings | numeric array | string

Tick mark labels, specified as a cell array of strings, a numeric array, or a string. By default, the colorbar labels the tick marks with numeric values. If you specify labels and do not specify enough labels for all the tick marks, then MATLAB cycles through the labels.

Example: `{'cold','warm','hot'}`

`'TickLabelInterpreter'` — Interpretation of characters in tick labels

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of tick label characters, specified as one of these values:

- `'tex'` — Interpret strings using a subset of the TeX markup.
- `'latex'` — Interpret strings using a subset of LaTeX markup.
- `'none'` — Display literal characters

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to `'tex'`, which is the default value. Modifiers remain in effect until the end of the string, except for superscripts and subscripts which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`
`\sl`	Oblique font (rarely available)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Set `specifier` as the name of a font family to change the font style. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Set `specifier` as a scalar numeric value to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Set `specifier` as a three-element RGB triplet to change the font color.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\alpha	α	\upsilon	υ	\sim	~
\angle	∠	\phi	Φ	\leq	≤
\ast	*	\chi	χ	\infty	∞
\beta	ß	\psi	ψ	\clubsuit	♣
\gamma	γ	\omega	ω	\diamondsuit	♦
\delta	δ	\Gamma	Γ	\heartsuit	♥
\epsilon	ε	\Delta	Δ	\spadesuit	♠
\zeta	ζ	\Theta	Θ	\leftrightarrow	↔
\eta	η	\Lambda	Λ	\leftarrow	←
\theta	Θ	\Xi	Ξ	\Leftarrow	⇐
\vartheta	ϑ	\Pi	Π	\uparrow	↑
\iota	ι	\Sigma	Σ	\rightarrow	→
\kappa	κ	\Upsilon	ϒ	\Rightarrow	⇒
\lambda	λ	\Phi	Φ	\downarrow	↓
\mu	µ	\Psi	Ψ	\circ	º
\nu	ν	\Omega	Ω	\pm	±
\xi	ξ	\forall	∀	\geq	≥
\pi	π	\exists	∃	\propto	∝
\rho	ρ	\ni	∋	\partial	∂
\sigma	σ	\cong	≅	\bullet	•
\varsigma	ς	\approx	≈	\div	÷
\tau	τ	\Re	ℜ	\neq	≠
\equiv	≡	\oplus	⊕	\aleph	ℵ

LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The FontName, FontWeight, and FontAngle properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

`'Ticks'` — Tick mark locations

vector of monotonically increasing numeric values

Tick mark locations, specified as a vector of monotonically increasing numeric values. The values do not need to be equally spaced. If you do not want tick marks displayed, then set the property to the empty vector, `[]`.

Example: `[-1,0,1,2,3,4,5]`

Data Types: `single` | `double`

`'Direction'` — Direction of color scale

`'normal'` (default) | `'reverse'`

Direction of color scale, specified as one of these values:

- `'normal'` — Display the colormap and labels ascending from bottom to top for a vertical colorbar, and ascending from left to right for a horizontal colorbar. This is the default value.
- `'reverse'` — Display the colormap and labels descending from bottom to top for a vertical colorbar, and descending from left to right for a horizontal colorbar.

`'FontSize'` — Font size
9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the colorbar font size to 90% of the axes font size. If you manually set the colorbar font size, then changing the axes font size does not affect the colorbar.

Example: `12`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

Output Arguments

`h` — Colorbar object
colorbar object

Colorbar object. Use `h` to set properties of the colorbar after it is created.

More About

Tips

- Adding a colorbar might resize the axes to accommodate the colorbar.
- If an axes does not exist, then the `colorbar` function creates a blank axes and displays a colorbar with the default colormap.
- You can use `colorbar('delete')` or `colorbar('hide')` instead of `colorbar('off')` to delete all colorbars in the current axes.

Properties
Colorbar Properties

Introduced before R2006a

Colorbar Properties

Control colorbar appearance and behavior

Colorbar properties control the appearance and behavior of a colorbar object. By changing property values, you can modify certain aspects of the colorbar. Use dot notation to refer to a particular object and property:

```
c = colorbar;
w = c.LineWidth;
c.LineWidth = 1.5;
```

Appearance

`Color` — Color of tick marks, text, and box outline

`[0 0 0]` (default) | RGB triplet | color string

Color of the tick marks, text, and box outline, specified as an RGB triplet or a color string.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`
`'red'`	`'r'`	`[1 0 0]`
`'green'`	`'g'`	`[0 1 0]`
`'blue'`	`'b'`	`[0 0 1]`
`'white'`	`'w'`	`[1 1 1]`
`'black`	`'k'`	`[0 0 0]`

Example: `[0 1 0]`

Example: `'green'`

`Box` — Box outline

`'on'` (default) | `'off'`

Box outline, specified as one of these values:

- `'on'` — Display the box outline around the colorbar.
- `'off'` — Do not display the box outline around the colorbar.

`LineWidth` — Width of box outline

`0.5` (default) | positive value

Width of box outline, specified as a positive value in point units. One point equals 1/72 inches.

Example: `1.5`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Label` — Label that displays along colorbar

text object (default)

Label that displays along the colorbar, returned as a text object. This text object contains properties that control the label appearance and the text that displays. Use the `Label` property to access the text object, for example:

```
c = colorbar;
c.Label
```

```
ans =

  Text with properties:

               String: ''
             FontSize: 10
           FontWeight: 'normal'
             FontName: 'Helvetica'
                Color: [0.1500 0.1500 0.1500]
    HorizontalAlignment: 'left'
             Position: [0 0 0]
                Units: 'data'

  Show all properties
```

By default, there is no text displayed. To display text or change existing text, set the String property for the text object, for example:

```
c.Label.String = 'Label Text Goes Here';
```

To change the label appearance, such as the font style or color, set other text properties. For example, this code changes the font size.

```
c.Label.FontSize = 12;
```

For a full list of options, see Text Properties.

Note: The `Label` property is different from other colorbar properties. You cannot set the `Label` property as a name-value pair when creating the colorbar. Instead, use dot notation (demonstrated above) or the `set` function.

Location and Size

`Location` — Location with respect to the axes

`'eastoutside'` (default) | tring

Location with respect to the axes, specified as one of the strings listed in this table.

String	Resulting Location	Resulting Orientation
`'north'`	Top of axes	Horizontal
`'south'`	Bottom of axes	Horizontal
`'east'`	Right side of axes	Vertical
`'west'`	Left side of axes	Vertical
`'northoutside'`	Top outside of axes	Horizontal
`'southoutside'`	Bottom outside of axes	Horizontal
`'eastoutside'`	Right outside of axes (default)	Vertical
`'westoutside'`	Left outside of axes	Vertical
`'manual'`	Determined by `Position` property	Vertical

To display the colorbar in a location that does not appear in the table, use the Position property to specify a custom location. If you set the Position property, then MATLAB sets the Location property to `'manual'`. The associated axes does not resize to accommodate the colorbar when the Location property is set to `'manual'`.

`Position` — Custom location and size

four-element vector

Custom location and size, specified as a four-element vector of the form `[left, bottom, width, height]`. The `left` and `bottom` elements specify the distance from the lower-left corner of the figure or to the lower-left corner of the colorbar. The `width` and `height` elements specify the dimensions of the colorbar. The Units property determines the position units.

If you specify the Position property, then MATLAB changes the Location property to `'manual'`. The associated axes does not resize to accommodate the colorbar when the `Location` property is `'manual'`.

Example: `[0.1 0.1 0.3 0.7]`

`Units` — Position units

`'normalized'` (default) | `'inches'` | `'centimeters'` | `'characters'` | `'points'` | `'pixels'`

Position units, specified as one of the values in this table.

`Units`	Description
`'normalized'` (default)	Normalized with respect to the container, which is usually the figure. The lower-left corner of the figure maps to `(0,0)` and the upper-right corner maps to `(1,1)`.
`'inches'`	Inches.
`'centimeters'`	Centimeters.
`'characters'`	Based on the size of characters in the default system font. The width of one character unit is the width of the letter `x`. The height of one character unit is the distance between the baselines of two lines of text.
`'points'`	Points. One point equals 1/72 inch.

Units	Description
'pixels'	Pixels. Pixel size depends on the screen resolution.

All units are measured from the lower-left corner of the container window.

This property affects the Position property. If you change the units, then it is good practice to return it to its default value after completing your computation to prevent affecting other functions that assume Units is the default value.

If you specify the Position and Units properties as `Name,Value` pairs when creating the colorbar, then the order of specification matters. If you want to define the position with particular units, then you must set the Units property before the Position property.

Tick Marks and Tick Labels

`Ticks` — Tick mark locations

vector of monotonically increasing numeric values

Tick mark locations, specified as a vector of monotonically increasing numeric values. The values do not need to be equally spaced. If you do not want tick marks displayed, then set the property to the empty vector, `[]`.

Example: `[-1,0,1,2,3,4,5]`

Data Types: `single` | `double`

`TicksMode` — Selection mode for `Ticks`

`'auto'` (default) | `'manual'`

Selection mode for `Ticks`, specified as one of these values:

- `'auto'` — Automatically choose the values.
- `'manual'` — Use manually specified values. To specify the values, set the Ticks property.

`TickLabels` — Tick mark labels

cell array of strings | numeric array | string

Tick mark labels, specified as a cell array of strings, a numeric array, or a string. By default, the colorbar labels the tick marks with numeric values. If you specify labels and

do not specify enough labels for all the tick marks, then MATLAB cycles through the labels.

Example: `{'cold','warm','hot'}`

`TickLabelsMode` — Selection mode for `TickLabels`

`'auto'` (default) | `'manual'`

Selection mode for `TickLabels`, specified as one of these values:

- `'auto'` — Automatically choose the tick mark labels.
- `'manual'` — Use manually specified values. To specify the values, set the TickLabels property.

`TickLabelInterpreter` — Interpretation of characters in tick labels

`'tex'` (default) | `'latex'` | `'none'`

Interpretation of tick label characters, specified as one of these values:

- `'tex'` — Interpret strings using a subset of the TeX markup.
- `'latex'` — Interpret strings using a subset of LaTeX markup.
- `'none'` — Display literal characters

TeX Markup

By default, MATLAB supports a subset of TeX markup. Use TeX markup to add superscripts and subscripts, modify the text type and color, and include special characters in the text string.

This table lists the supported modifiers when the `TickLabelInterpreter` property is set to `'tex'`, which is the default value. Modifiers remain in effect until the end of the string, except for superscripts and subscripts which only modify the next character or the text within the curly braces `{}`.

Modifier	Description	Example of String
`^{ }`	Superscript	`'text^{superscript}'`
`_{ }`	Subscript	`'text_{subscript}'`
`\bf`	Bold font	`'\bf text'`
`\it`	Italic font	`'\it text'`

Modifier	Description	Example of String
`\sl`	Oblique font (rarely available)	`'\sl text'`
`\rm`	Normal font	`'\rm text'`
`\fontname{specifier}`	Set `specifier` as the name of a font family to change the font style. You can use this in combination with other modifiers.	`'\fontname{Courier} text'`
`\fontsize{specifier}`	Set `specifier` as a scalar numeric value to change the font size.	`'\fontsize{15} text'`
`\color{specifier}`	Set `specifer` as one of these colors: `red`, `green`, `yellow`, `magenta`, `blue`, `black`, `white`, `gray`, `darkGreen`, `orange`, or `lightBlue`.	`'\color{magenta} text'`
`\color[rgb] {specifier}`	Set `specifier` as a three-element RGB triplet to change the font color.	`'\color[rgb] {0,0.5,0.5} text'`

This table lists the supported special characters when the interpreter is set to `'tex'`.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol

LaTeX Markup

To use LaTeX markup, set the `TickLabelInterpreter` property to `'latex'`. The displayed text uses the default LaTeX font style. The FontName, FontWeight, and FontAngle properties do not have an effect. To change the font style, use LaTeX markup within the text string.

The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, this reduces by about 10 characters per line.

For more information about the LaTeX system, see The LaTeX Project Web site at http://www.latex-project.org/.

`Direction` — Direction of color scale

`'normal'` (default) | `'reverse'`

Direction of color scale, specified as one of these values:

- `'normal'` — Display the colormap and labels ascending from bottom to top for a vertical colorbar, and ascending from left to right for a horizontal colorbar. This is the default value.
- `'reverse'` — Display the colormap and labels descending from bottom to top for a vertical colorbar, and descending from left to right for a horizontal colorbar.

`AxisLocation` — Location of tick marks, tick labels, and colorbar label

`'out'` (default) | `'in'`

Location of tick marks, tick labels, and colorbar label, specified as one of these values:

- `'out'` — Display the tick marks and labels on the side of the colorbar towards the outside of the figure. This is the default value.
- `'in'` — Display the tick marks and labels on the side of the colorbar towards the inside of the figure.

`AxisLocationMode` — Selection mode for `AxisLocation`

`'auto'` (default) | `'manual'`

Selection mode for `AxisLocation`, specified as one of these values:

- `'auto'` — Automatically choose the location.
- `'manual'` — Use a manually specified location. To specify the location, set the AxisLocation property.

`TickDirection` — Tick mark direction

`'in'` (default) | `'out'`

Tick mark direction, specified as one of these values:

- `'in'` — Display the tick marks facing inward from the colorbar box.
- `'out'` — Display the tick marks facing outward from the colorbar box.

`TickLength` — Tick mark length

`0.01` (default) | scalar

Tick mark length, specified as a scalar. Specify the tick length in units normalized to the length of the colorbar axis.

Example: `0.05`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Limits` — Minimum and maximum tick mark values

two-element vector

The minimum and maximum tick mark values, specified as a two-element vector. The second vector element must be greater than the first element.

Example: `[0 1]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LimitsMode` — Selection mode for limits

`'auto'` (default) | `'manual'`

Selection mode for limits, specified as one of these values:

- `'auto'` — Automatically chooses the limits.
- `'manual'` — Use manually specified limits. To specify the limits, set the Limits property.

Font Style

FontAngle — Character slant

'normal' (default) | 'italic'

Character slant, specified as 'normal' or 'italic'. Not all fonts have both font styles. Therefore, the italic font might look the same as the normal font.

Note: The 'oblique' value has been removed. Use 'italic' instead.

FontName — Font name

'Helvetica' (default) | 'FixedWidth' | system supported font name

Font name, specified as the name of the font to use or the string 'FixedWidth'. To display and print properly, the font name must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding. The 'FixedWidth' value relies on the root FixedWidthFontName property. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

Example: 'Cambria'

FontSize — Font size

9 (default) | scalar value greater than zero

Font size, specified as a scalar value greater than zero in point units. The default value is 9 points. If you change the axes font size, then MATLAB automatically sets the colorbar font size to 90% of the axes font size. If you manually set the colorbar font size, then changing the axes font size does not affect the colorbar.

Example: 12

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

FontWeight — Thickness of text characters

'normal' (default) | 'bold'

Thickness of the text characters, specified as one of these values:

- `'normal'` — Default weight as defined by the particular font
- `'bold'` — Thicker characters outlines than normal

MATLAB uses the FontWeight property to select a font from those available on your system. Not all fonts have a bold font weight. Therefore, specifying a bold font weight could still result in the normal font weight.

Note: The `'light'` and `'demi'` font weight values have been removed. Use `'normal'` instead.

Visibility

`Visible` — Visibility of colorbar

`'on'` (default) | `'off'`

Visibility of colorbar, specified as one of these values:

- `'on'` — Display the colorbar.
- `'off'` — Hide the colorbar without deleting it. You still can access the properties of an invisible colorbar object.

Identifiers

`Type` — Type of graphics object

`'colorbar'`

Type of graphics object, returned as `'colorbar'`. Use this property to find all objects of a given type within a plotting hierarchy, such as searching for the type using `findobj`.

`Tag` — Tag to associate with colorbar

`'colorbar'` (default) | string

Tag to associate with the colorbar, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with colorbar

`[ ]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the colorbar object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

Parent/Child

`Parent` — Parent of colorbar

figure object | uipanel object | uitab object

Parent of the colorbar, specified as a figure object, uipanel object, or a uitab object.

The colorbar must have the same parent as the associated axes. If you change the parent of the associated axes, then the colorbar automatically updates to use the same parent.

`Children` — Children of colorbar

empty `GraphicsPlaceholder` array

The colorbar has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of colorbar object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The colorbar object handle is always visible.
- `'off'` — The colorbar object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.

- `'callback'` — The colorbar object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the colorbar at the command-line, but allows callback functions to access it.

If the colorbar object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the colorbar. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The colorbar object — You can access properties of the colorbar object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the colorbar. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the colorbar when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the colorbar.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The Visible property must be set to `'on'`. The HitTest property determines if the colorbar responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the colorbar passes the click to the object below it in the current view of the figure window. The HitTest property of the colorbar has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the colorbar. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the colorbar that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the colorbar object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`Interruptible` — Callback interruption

`'off'` (default) | `'on'`

Callback interruption, specified as `'off'` or `'on'`. The `Interruptible` property determines if a running callback can be interrupted.

If the `ButtonDownFcn` callback of the colorbar is the running callback, then the `Interruptible` property determines if it can be interrupted by another callback. The `Interruptible` property has two possible values:

- `'off'` — The running callback cannot be interrupted. MATLAB finishes executing the running callback without any interruptions. This is the default behavior.
- `'on'` — The running callback can be interrupted. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback.

MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see “Interrupt Callback Execution”.

- If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

Example: `'off'`

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the colorbar tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the colorbar. Setting the `CreateFcn` property on an existing colorbar has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during colorbar creation. MATLAB executes the callback after creating the colorbar and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The colorbar object — You can access properties of the colorbar object from within the callback function. You also can access the colorbar object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the colorbar. MATLAB executes the callback before destroying the colorbar so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The colorbar object — You can access properties of the colorbar object from within the callback function. You also can access the colorbar object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of colorbar

`'off'` (default) | `'on'`

Deletion status of colorbar, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the colorbar begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the colorbar no longer exists.

Check the value of the BeingDeleted property to verify that the colorbar is not about to be deleted before querying or modifying it.

colordef

Set default property values to display different color schemes

Syntax

```
colordef white
colordef black
colordef none
colordef(fig,color_option)
h = colordef('new',color_option)
```

Description

`colordef` enables you to select either a white or black background for graphics display. It sets axis lines and labels so that they contrast with the background color.

`colordef white` sets the axis background, axis lines and labels, and the figure background to the default system colors.

`colordef black` sets the axis background color to black, the axis lines and labels to white, and the figure background color to dark gray.

`colordef none` sets the figure coloring to that used by MATLAB Version 4. The most noticeable difference is that the axis background is set to `'none'`, making the axis background and figure background colors the same. The figure background color is set to black.

`colordef(fig,color_option)` sets the color scheme of the figure identified by the handle `fig` to one of the color options `'white'`, `'black'`, or `'none'`. When you use this syntax to apply `colordef` to an existing figure, the figure must have no graphic content. If it does, you should first clear it (via `clf`) before using this form of the command.

`h = colordef('new',color_option)` returns the handle to a new figure created with the specified color options (i.e., `'white'`, `'black'`, or `'none'`). This form of the command is useful for creating GUIs when you may want to control the default environment. The figure is created with `'visible','off'` to prevent flashing.

More About

Tips

`colordef` affects only subsequently drawn figures, not those currently on the display. This is because `colordef` works by setting default property values (on the root or figure level). You can list the currently set default values on the root level with the statement

```
get(groot,'Default')
```

You can remove all default values using the `reset` command:

```
reset(groot)
```

See the `get` and `reset` references pages for more information.

`whitebg` | `clf`

Introduced before R2006a

colormap

View and set current colormap

Syntax

```
colormap name
colormap default

colormap(map)
colormap(fig,map)
colormap(ax,map)

colormap(fig,'default')
colormap(ax,'default')

cmap = colormap
cmap = colormap(fig)
cmap = colormap(ax)
```

Description

`colormap name` sets the colormap for the current figure to the built-in colormap specified by name. The new colormap uses the same number of colors as the current colormap. The figure colormap affects all axes in the figure, unless you set an axes colormap separately. For more information, see “What Is a Colormap?” on page 1-1354.

`colormap default` uses the default colormap, which is the `parula` colormap with 64 colors. Versions of MATLAB prior to R2014b use `jet` as the default.

`colormap(map)` sets the colormap for the current figure to the colormap specified by `map`. The figure colormap affects all axes in the figure, unless you set an axes colormap separately. Use this syntax if you want to use a built-in colormap with a specific number of colors or if you want to use a custom colormap.

- For a built-in colormap with a specific number of colors, specify `map` as one of the built-in colormap functions and pass it an integer value as an input argument. For

example, `colormap(summer(10))` uses 10 colors from the `summer` colormap. If you do not specify the number of colors, such as `colormap(summer)`, then the colormap contains the same number of colors as the current colormap.

- For a custom colormap, specify `map` as a three-column matrix of values in the range `[0,1]` where each row is an RGB triplet that defines one color of the colormap. An RGB triplet is a three-element row vector specifying the red, green, and blue intensities for a color.

`colormap(fig,map)` sets the colormap for the figure specified by `fig`.

`colormap(ax,map)` sets the colormap for the axes specified by `ax`. Each axes within a figure can have a unique colormap. After you set an axes colormap, changing the figure colormap does not affect the axes.

`colormap(fig,'default')` sets the colormap for the figure specified by `fig` to the default colormap.

`colormap(ax,'default')` sets the colormap for the axes specified by `ax` to the default colormap.

`cmap = colormap` returns the three-column matrix of RGB triplets defining the colormap for the current figure.

`cmap = colormap(fig)` returns the colormap for the figure specified by `fig`.

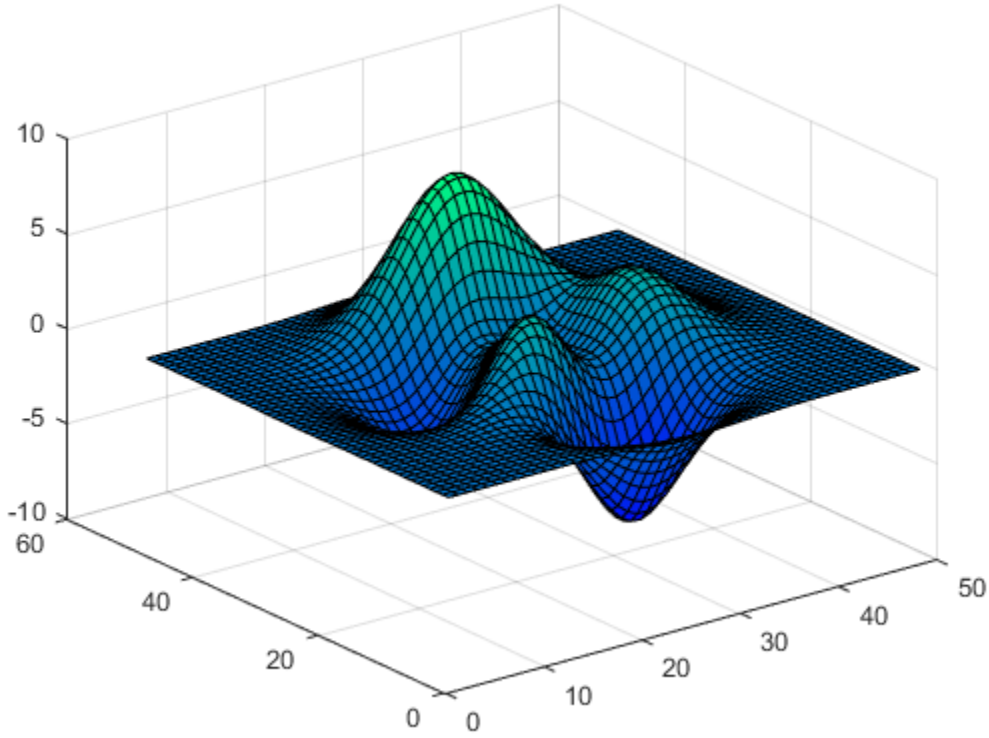
`cmap = colormap(ax)` returns the colormap for the axes specified by `ax`.

Examples

Change Colormap for Figure

Create a surface plot and set the colormap to `winter`.

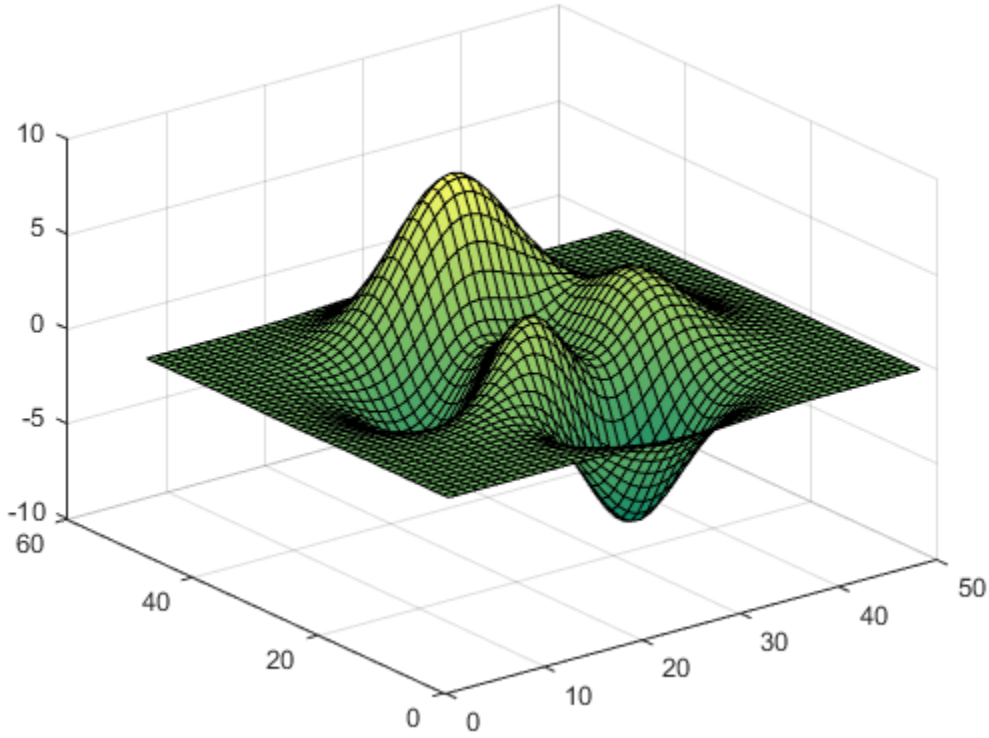
```
figure
surf(peaks)
colormap winter
```



Set Colormap Back to Default

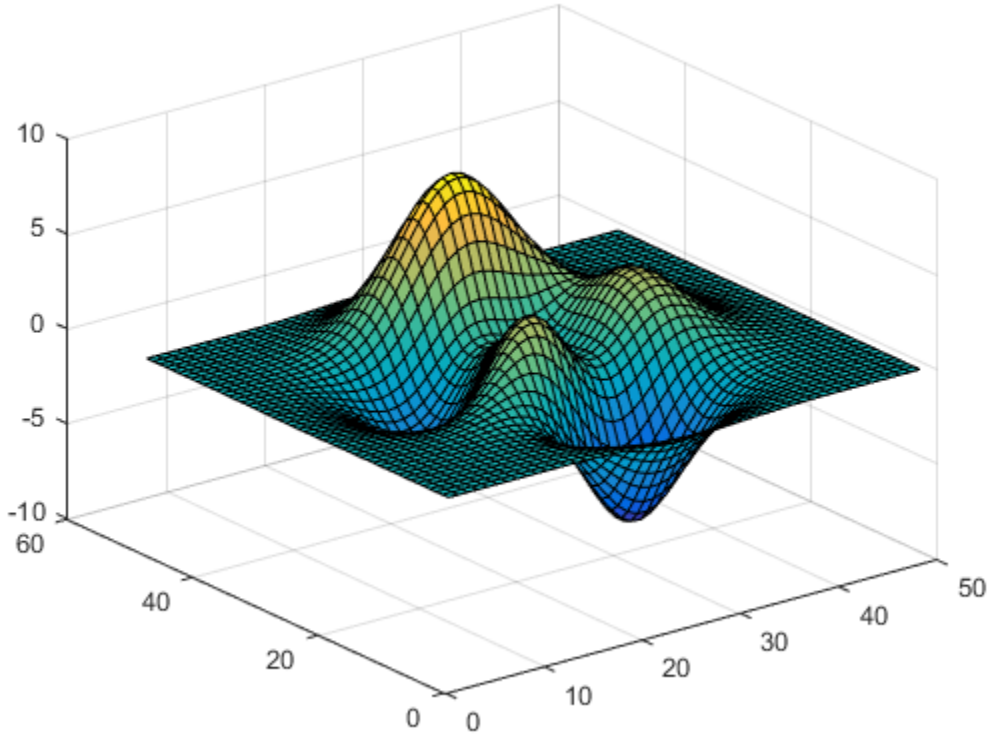
First, change the colormap for the current figure to `summer`.

```
figure
surf(peaks)
colormap summer
```



Now set the colormap back to your system's default value. If you have not specified a different default value, then the default colormap is `parula`.

```
colormap default
```



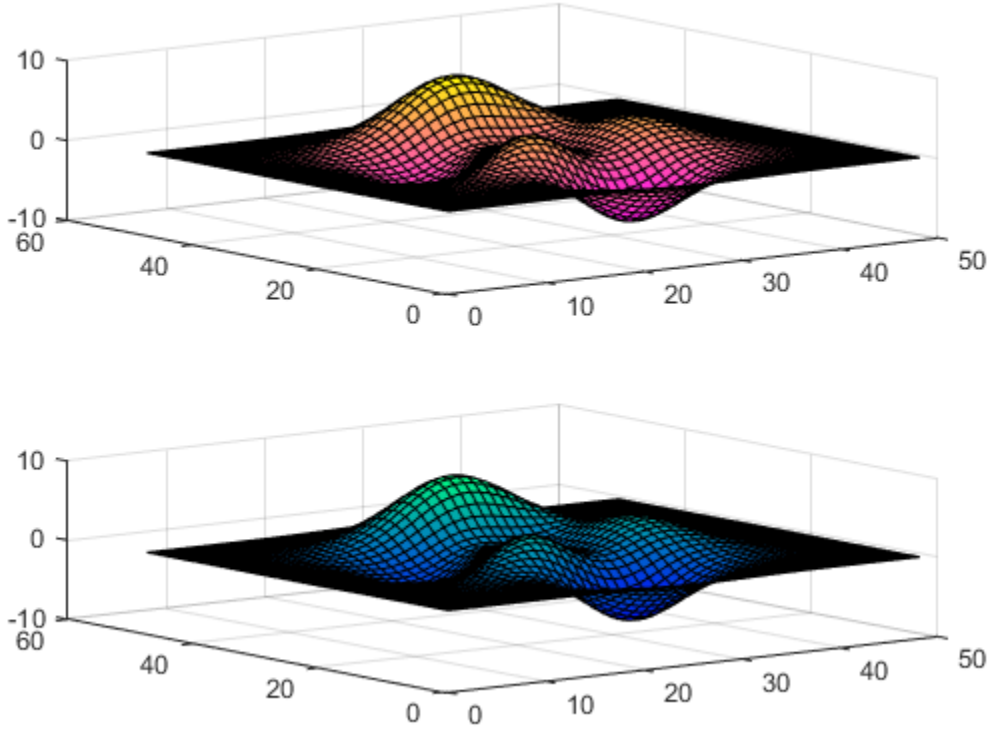
Use Different Colormaps for Each Axes in Figure

Create a figure with two subplots and store the axes handles, `ax1` and `ax2`. Use a different colormap for each axes by passing the axes handles to the `colormap` function. In the upper subplot, create a surface plot using the `spring` colormap. In the lower subplot, create a surface plot using the `winter` colormap.

```
figure
ax1 = subplot(2,1,1);
surf(peaks)
colormap(ax1,spring)

ax2 = subplot(2,1,2);
surf(peaks)
```

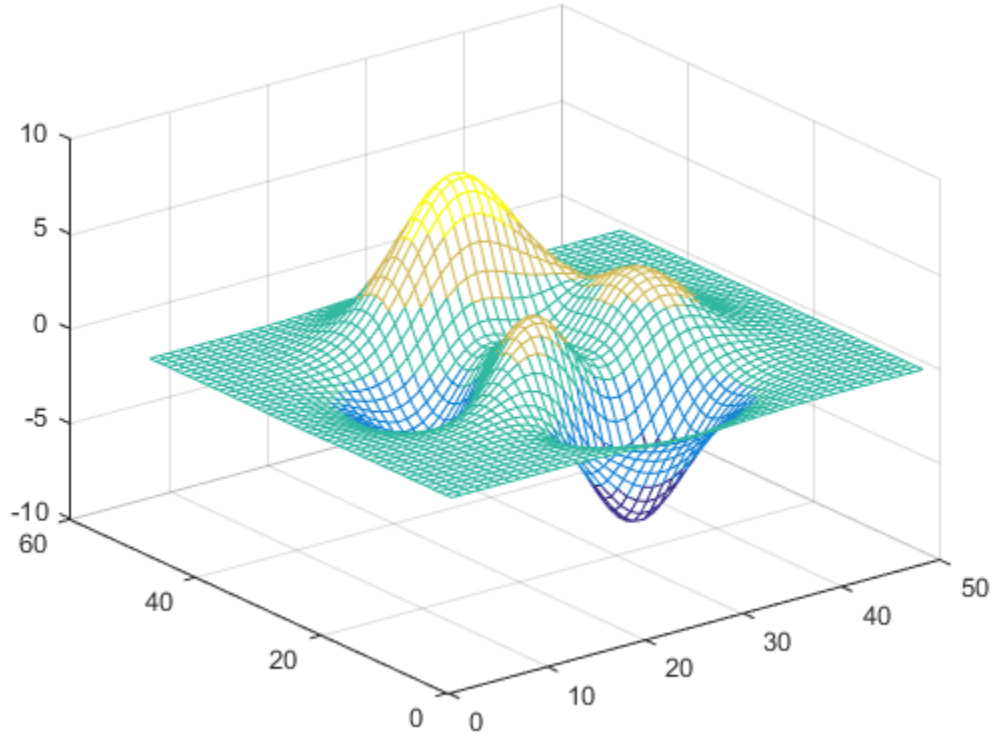
```
colormap(ax2,winter)
```



Specify Number of Colors for Colormap

Specify the number of colors used in a colormap by passing an integer as an input argument to the built-in colormap. Use five colors from the parula colormap.

```
figure
mesh(peaks)
colormap(parula(5))
```



Create Custom Colormap

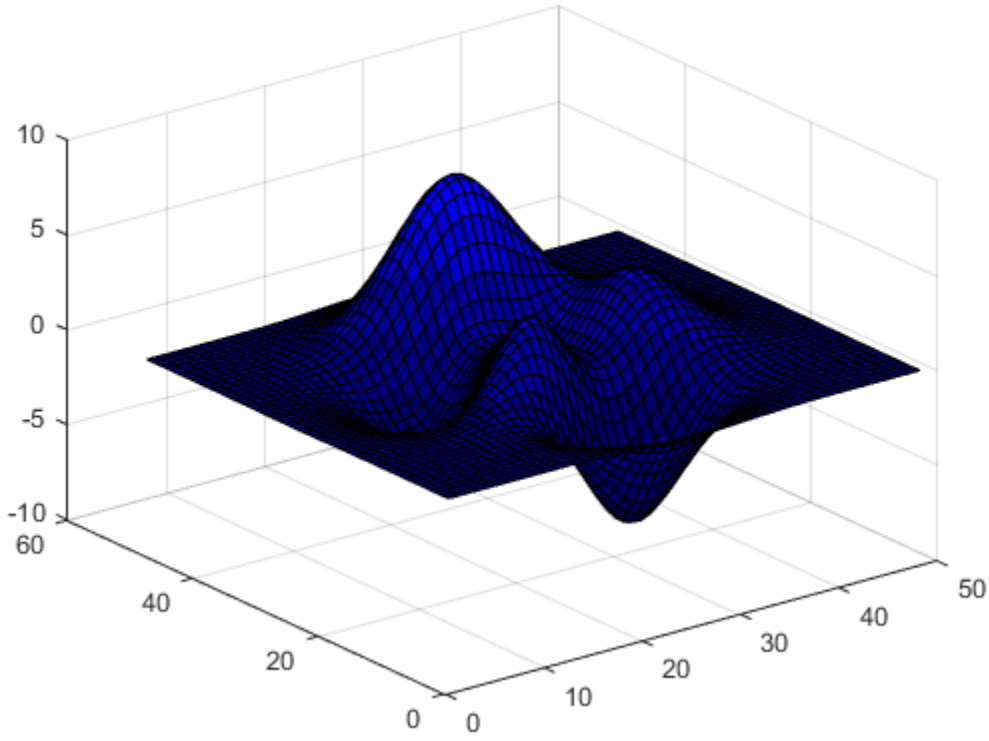
Create a custom colormap by defining a three-column matrix of values between 0.0 and 1.0. Each row defines a three-element RGB triplet. The first column specifies the red intensities. The second column specifies the green intensities. The third column specifies the blue intensities.

Use a colormap of blue values by setting the first two columns to zeros.

```
map = [0, 0, 0.3
    0, 0, 0.4
    0, 0, 0.5
    0, 0, 0.6
    0, 0, 0.8
```

```
    0, 0, 1.0];

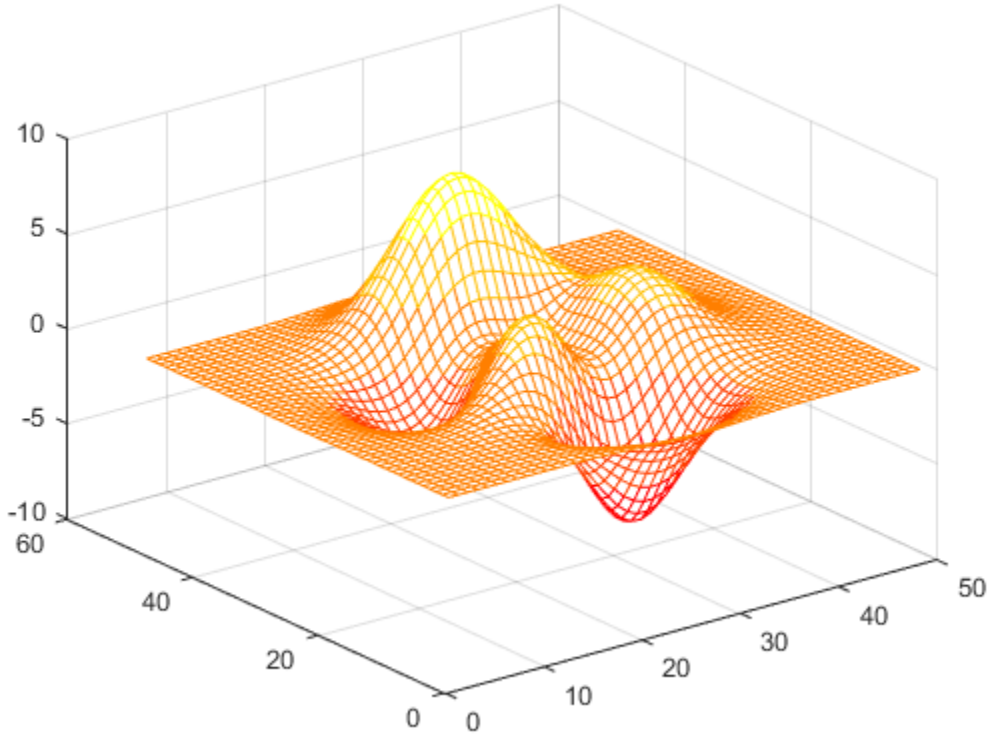
figure
surf(peaks)
colormap(map)
```



Return Colormap Values Used in Plot

Create a surface plot of the `peaks` function and specify a colormap.

```
figure
mesh(peaks)
colormap(autumn(5))
```



Return the three-column matrix of values that define the colors used in the plot. Each row is an RGB triplet color value that specifies one color of the colormap.

```
cmap = colormap
```

```
cmap =

    1.0000         0         0
    1.0000    0.2500         0
    1.0000    0.5000         0
    1.0000    0.7500         0
    1.0000    1.0000         0
```

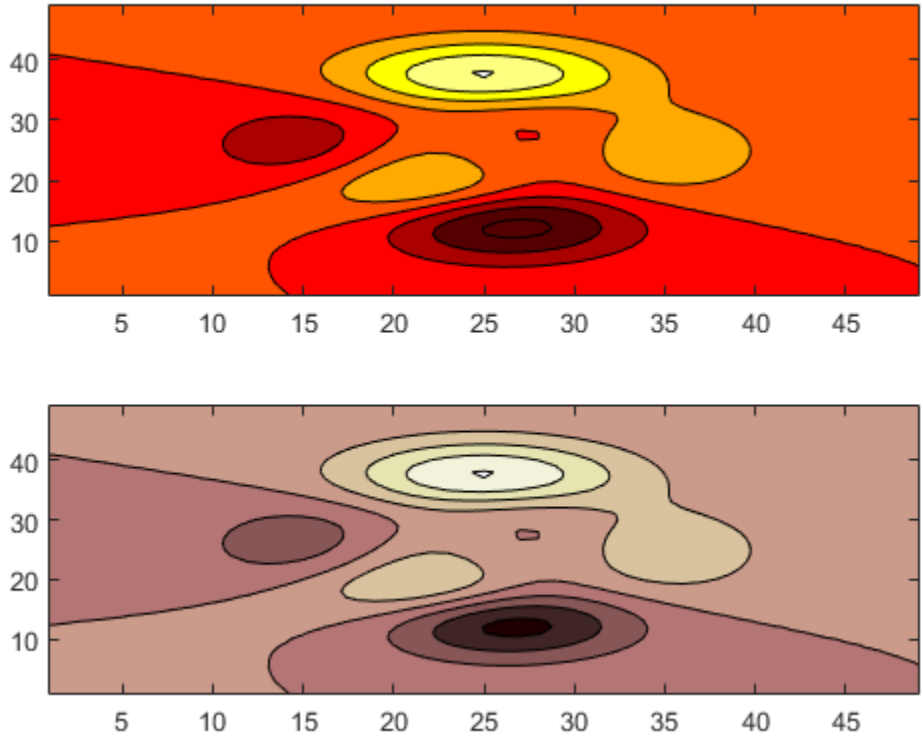
Return Colormap Values for Specific Axes

Return the colormap values for a specific axes by passing its axes handle to the `colormap` function.

Create a figure with two subplots and return the axes handles, `ax1` and `ax2`. Add a filled contour plot to each axes and use a different colormap for each axes.

```
figure
ax1 = subplot(2,1,1);
contourf(peaks)
colormap(ax1,hot(8));

ax2 = subplot(2,1,2);
contourf(peaks)
colormap(ax2,pink);
```



Return the colormap values used in the upper subplot by passing its axes handle, `ax1`, to the `colormap` function. Each row is an RGB triplet color value that specifies one color of the colormap.

```
cmap = colormap(ax1)
```

```
cmap =

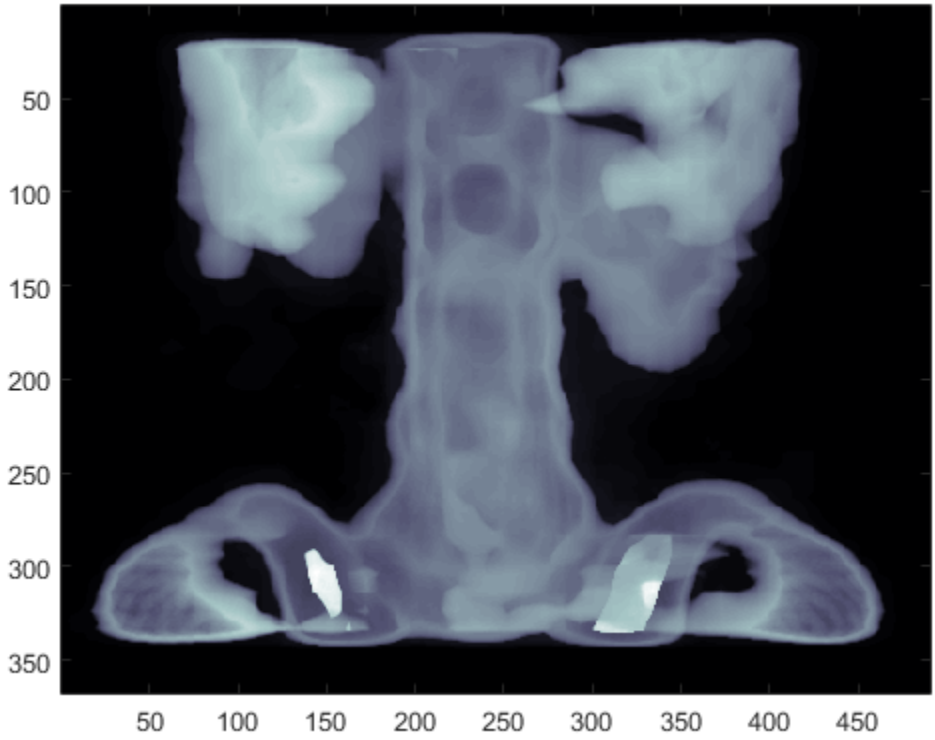
    0.3333         0         0
    0.6667         0         0
    1.0000         0         0
    1.0000    0.3333         0
    1.0000    0.6667         0
```

```
    1.0000    1.0000         0
    1.0000    1.0000    0.5000
    1.0000    1.0000    1.0000
```

Change Colormap for Figure with Image

Load the `spine` data set that returns the image `X` and its associated colormap `map`. Display `X` using the `image` function and set the colormap to `map`.

```
load spine
figure
image(X)
colormap(map)
```



- “Change Mapping of Data Values into the Colormap”

Input Arguments

`name` — Built-in colormap

`parula` (default) | built-in colormap

Built-in colormap, specified as a one of the colormaps listed in the table. The default colormap is `parula`. Versions of MATLAB prior to R2014b use `jet` as the default.

The `colormap` function applies the new colormap with the same number of colors as the current colormap. To change the number of colors, use the map input argument.

This table lists the built-in colormaps.

Colormap Name	Color Scale
`parula`	
`jet`	
`hsv`	`hot`	
`cool`	`spring`	`summer`	
`autumn`	
`winter`	
`gray`	
`bone`	
`copper`	
`pink`	`lines`	
`colorcube`	
`prism`	
`flag`	
`white`	
`map` — Built-in or custom colormap

`parula` (default) | built-in colormap function | three-column matrix of RGB triplets

Built-in or custom colormap, specified as one of the built-in colormap functions or a three-column matrix of RGB triplets. The default colormap is `parula`. Versions of MATLAB prior to R2014b use `jet` as the default.

Built-In Colormap Functions

To use a built-in colormap with a specific number of colors, specify `map` as one of the built-in colormaps functions and pass it an integer value as an input argument. For example, `colormap(parula(12))` uses a map with 12 colors from the `parula` colormap. If you do not specify the number of colors, such as `colormap(parula)`, then MATLAB uses the same number of colors as the current colormap.

Note: Both the `name` and the `map` input arguments provide the same built-in colormap options. However, if you use the input argument `name`, then the `colormap` function processes `name` as a string and you cannot control the number of colors. If you use the input argument `map`, then the `colormap` function processes `map` as a function, which means that you can pass the built-in colormap an integer value to control the number of colors.

This table lists the built-in colormaps functions.

Colormap Name	Color Scale
`parula`	
`jet`	`hsv`	
`hot`	
`cool`	`spring`	`summer`	
`autumn`	
`winter`	
`gray`	
`bone`	
`copper`	

Colormap Name	Color Scale
`pink`	`lines`	
`colorcube`	`prism`	
`flag`	
`white`	

Custom Colormap

To create a custom colormap, specify `map` as a three-column matrix of RGB triplets where each row defines one color. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`. For example, this matrix defines a colormap containing five colors.

```
map = [0.2, 0.1, 0.5
    0.1, 0.5, 0.8
    0.2, 0.7, 0.6
    0.8, 0.7, 0.3
    0.9, 1, 0];
```

This table lists the RGB triplet values for common colors.

Color	RGB Triplet
yellow	`[1,1,0]`
magenta	`[1,0,1]`
cyan	`[0,1,1]`
red	`[1,0,0]`
green	`[0,1,0]`
blue	`[0,0,1]`
white	`[1,1,1]`
black	`[0,0,0]`

`fig` — Figure object

figure object

Figure object. The figure colormap affects plots for all axes within the figure, unless you specify an axes colormap separately.

Each figure has a `Colormap` property. When you change the figure colormap using the `colormap` function, MATLAB updates the `Colormap` property of the figure.

`ax` — Axes object

axes object

Axes object. You can define a unique colormap for each axes. After you set an axes colormap, changing the figure colormap does not affect the axes.

Output Arguments

`cmap` — Colormap values

three-column matrix of RGB triplets

Colormap values, returned as a three-column matrix of RGB triplets. Each row of the matrix defines one RGB triplet that specifies one color of the colormap. The values are in the range `[0,1]`.

More About

What Is a Colormap?

A colormap is matrix of values between `0` and `1` that define the colors for graphics objects such as surface, image, and patch objects. MATLAB draws the objects by mapping data values to colors in the colormap.

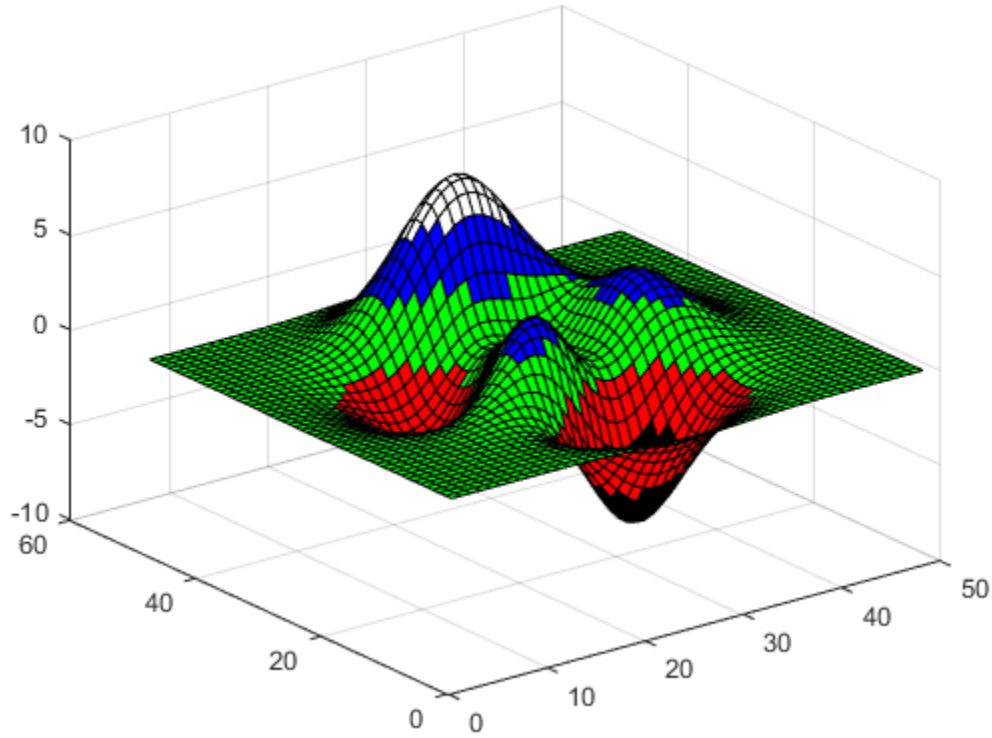
Colormaps can be any length, but must be three columns wide. Each row in the matrix defines one color using an RGB triplet. An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`. A value of `0` indicates no color and a value of `1` indicates full intensity. For example, this is a colormap with five colors: black, red, green, blue, and white.

```
mymap = [0 0 0
    1 0 0
```

```
    0 1 0
    0 0 1
    1 1 1];
```

Colormaps are associated with axes and figures. Use the `colormap` function to change the colormap for a particular axes or figure. For example, create a surface plot and use `mymap` as the colormap for the figure.

```
surf(peaks)
colormap(mymap)
```



Tips

- To control the mapping of data values into the colormap, use the `caxis` function.

Introduced before R2006a

colormapeditor

Open colormap editor

Syntax

```
colormapeditor
```

Description

`colormapeditor` displays the colormap for the current axes as a strip of rectangular cells in the colormap editor. Node pointers are colored cells below the colormap strip that indicate points in the colormap where the rate of the variation of R, G, and B values changes. You can also work in the HSV colorspace by setting the **Interpolating Colorspace** selector to HSV.

You can also start the colormap editor by selecting **Colormap** from the **Edit** menu.

Node Pointer Operations

You can select and move node pointers to change a range of colors in the colormap. The color of a node pointer remains constant as you move it, but the colormap changes by linearly interpolating the RGB values between nodes.

Change the color at a node by double-clicking the node pointer. A color picker box appears, from which you can select a new color. After you select a new color at a node, the colors between nodes are reinterpolated.

You can select a different color map using the **Standard Colormaps** submenu of the **Tools** menu. The Plotting Tools Property Editor has a dropdown menu that also lets you select from standard colormaps, but does not help you to modify a colormap.

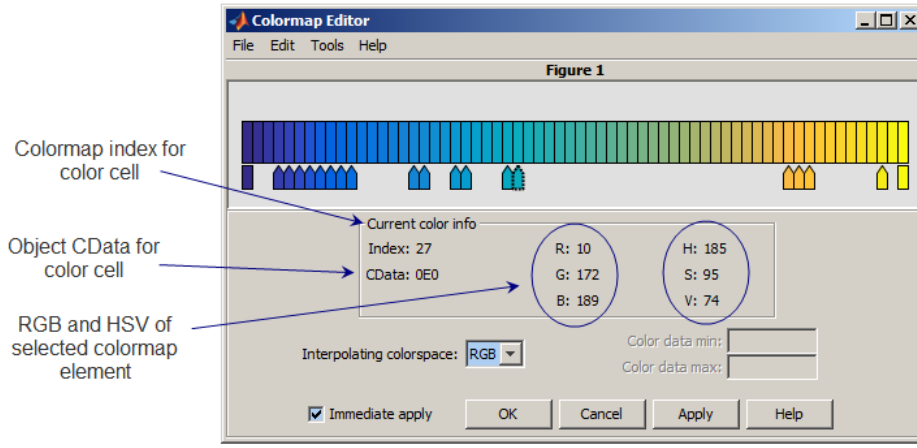
Operation	How to Perform
Select a built-in colormap	**Tools > Standard Colormaps**

Operation	How to Perform
Add a node	Click below the corresponding cell in the colormap strip.
Select a node	Left-click the node.
Select multiple nodes	Adjacent: left-click first node, **Shift+click** the last node. Nonadjacent: left-click first node, **Ctrl+click** subsequent nodes.
Move a node	Select and drag with the mouse or select and use the left and right arrow keys.
Move multiple nodes	Select multiple nodes and use the left and right arrow keys to move nodes as a group. Movement stops when one of the selected nodes hits an unselected node or an end node.
Delete a node	Select the node and then press the **Delete** key, or select **Delete** from the **Edit** menu, or type **Ctrl+x**.
Delete multiple nodes	Select the nodes and then press the **Delete** key, or select **Delete** from the **Edit** menu, or type **Ctrl+x**.
Display color picker for a node	Double-click the node pointer.

Current Color Info

When you put the mouse over a color cell or node pointer, the colormap editor displays the following information about that colormap element:

- The element's index in the colormap
- The value from the graphics object color data that is mapped to the node's color (i.e., data from the `CData` property of any image, patch, or surface objects in the figure)
- The color's RGB and HSV color value



Interpolating Colorspace

The colorspace determines what values are used to calculate the colors of cells between nodes. For example, in the RGB colorspace, internode colors are calculated by linearly interpolating the red, green, and blue intensity values from one node to the next. Switching to the HSV colorspace causes the colormap editor to recalculate the colors between nodes using the hue, saturation, and value components of the color definition.

Note that when you switch from one colorspace to another, the color editor preserves the number, color, and location of the node pointers, which can cause the colormap to change.

Interpolating in HSV. Since hue is conceptually mapped about a color circle, the interpolation between hue values can be ambiguous. To minimize this ambiguity, the interpolation uses the shortest distance around the circle. For example, interpolating between two nodes, one with hue of 2 (slightly orange red) and another with a hue of 356 (slightly magenta red), does not result in hues 3,4,5...353,354,355 (orange/red-yellow-green-cyan-blue-magenta/red). Taking the shortest distance around the circle gives 357,358,1,2 (orange/red-red-magenta/red).

Color Data Min and Max

The **Color Data Min** and **Color Data Max** text fields enable you to specify values for the axes `CLim` property. These values change the mapping of object color data (the `CData` property of images, patches, and surfaces) to the colormap.

Examples

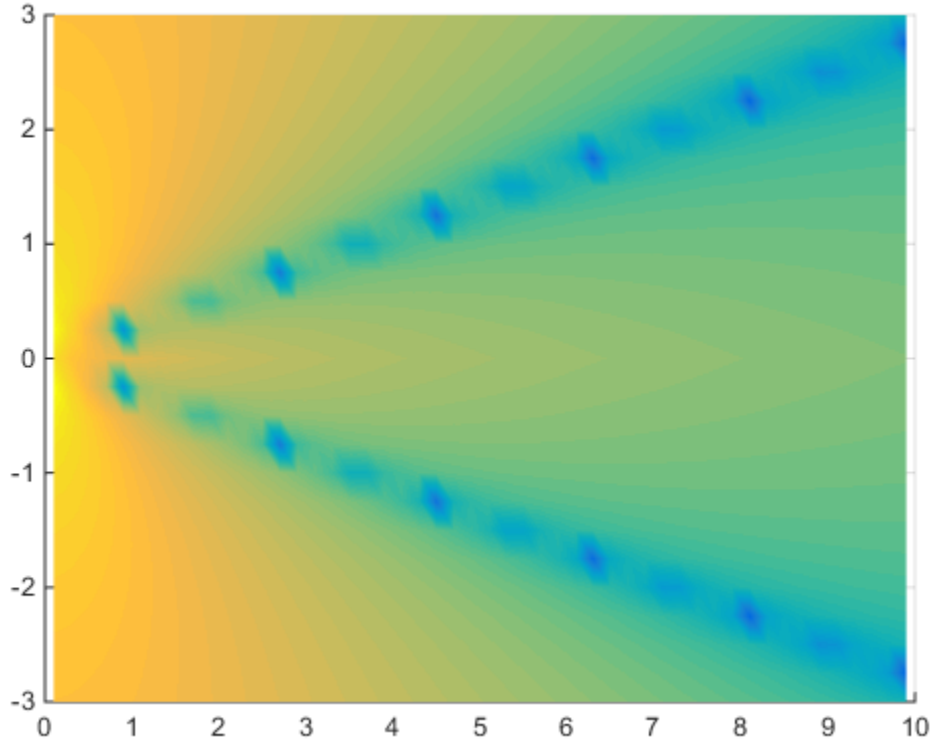
This example modifies a default MATLAB colormap so that ranges of data values are displayed in specific ranges of color. The graph is a slice plane illustrating a cross section of fluid flow through a jet nozzle. See the `slice` reference page for more information on this type of graph.

Enhance Colormap

This example modifies a default MATLAB colormap so that ranges of data values are displayed more prominently.

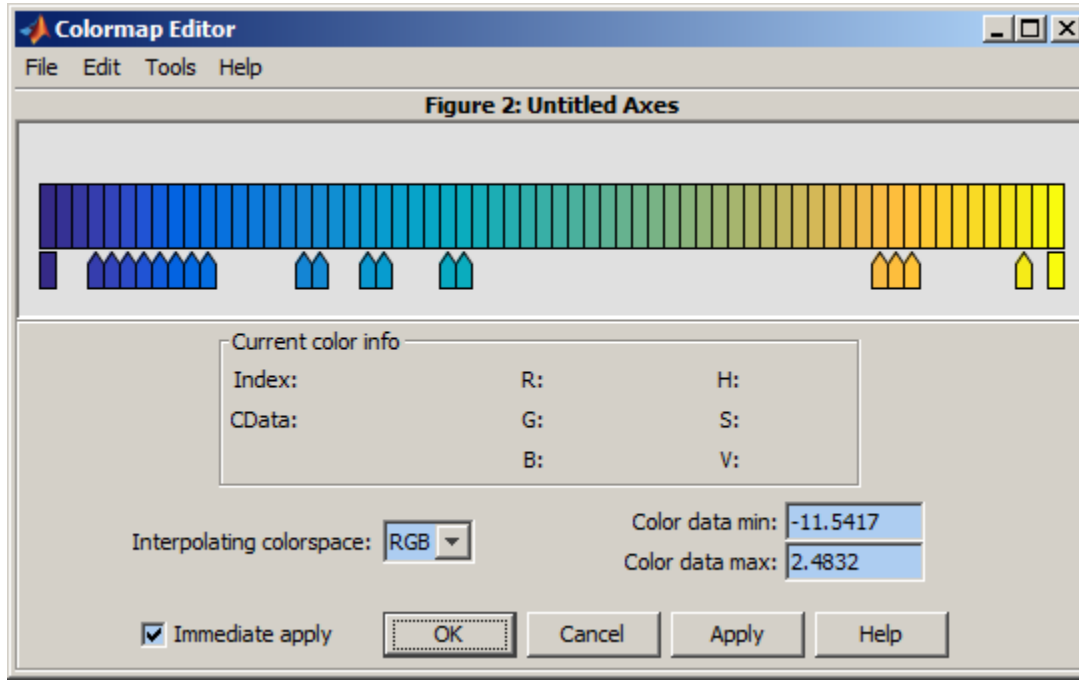
Create a slice plane for the flow dataset:

```
[x,y,z,v] = flow;
hz = slice(x,y,z,v,[],[],0);
hz.EdgeColor = 'none';
hz.FaceColor = 'interp';
view(2)
```

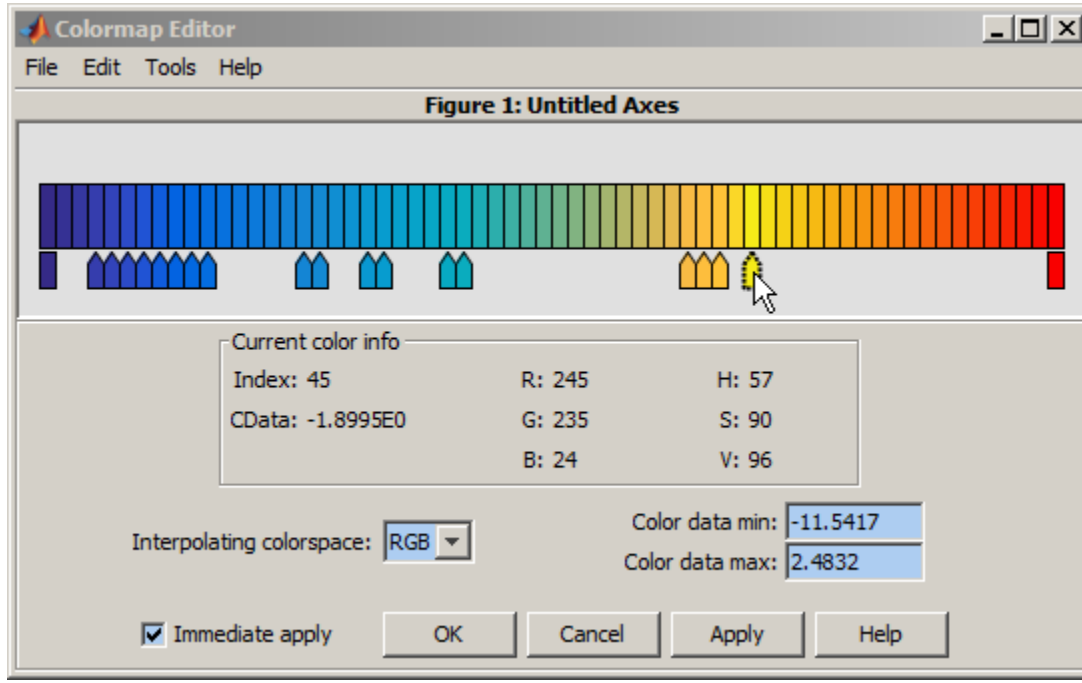


Start the colormap editor:

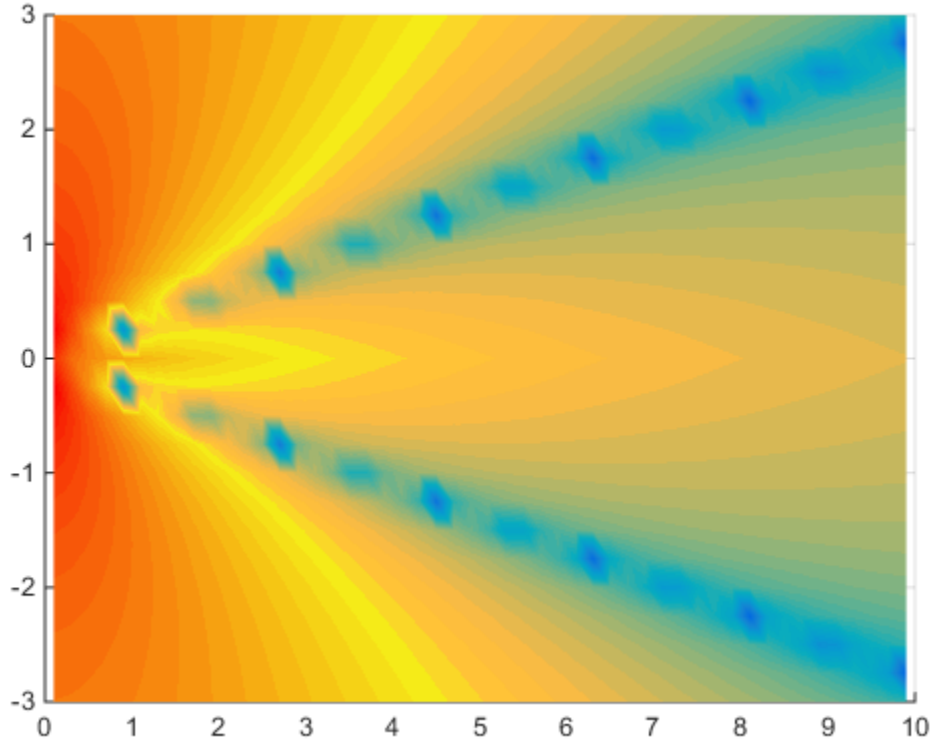
```
colormapeditor
```



To reveal more information about the flow data, create more color variation in the region of interest. Add the color red for the largest color data value and blend it with the yellow and orange colors:



The new colormap reveals more of the flow data variation in the higher data values:



Saving the Modified Colormap

You can save the modified colormap using the `colormap` function.

After you have applied your changes, save the current axes colormap in a variable:

```
mycmap = colormap(ax);
```

To use this colormap in another axes, set the colormap for the axes to `mycmap`:

```
colormap(ax_new,mycmap)
```

To save your modified colormap in a MAT-file, use the `save` command to save the `mycmap` workspace variable:

```
save('MyColormaps','mycmap')
```

To use your saved colormap in another MATLAB session, `load` the variable into the workspace and assign the colormap to the axes:

```
load('MyColormaps','mycmap')
colormap(ax,mycmap)
```

See Also

`colormap` | `save` | `set` | `get` | `load` | `propertyeditor`

Introduced before R2006a

ColorSpec (Color Specification)

Color specification

Description

`ColorSpec` is not a function; it refers to the three ways in which you specify color for MATLAB graphics:

- RGB triple
- Short name
- Long name

The short names and long names are MATLAB strings that specify one of eight predefined colors. The RGB triple is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color; the intensities must be in the range [0 1]. The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
`[1 1 0]`	`y`	`yellow`
`[1 0 1]`	`m`	`magenta`
`[0 1 1]`	`c`	`cyan`
`[1 0 0]`	`r`	`red`
`[0 1 0]`	`g`	`green`
`[0 0 1]`	`b`	`blue`
`[1 1 1]`	`w`	`white`
`[0 0 0]`	`k`	`black`

Examples

To change the background color of a figure to green, specify the color with a short name, a long name, or an RGB triple. These statements generate equivalent results:

```
whitebg('g')
whitebg('green')
whitebg([0 1 0]);
```

You can use `ColorSpec` anywhere you need to define a color. For example, this statement changes the figure background color to pink:

```
set(gcf,'Color',[1,0.4,0.6])
```

More About

Tips

The eight predefined colors and any colors you specify as RGB values are not part of a figure's colormap, nor are they affected by changes to the figure's colormap. They are referred to as *fixed* colors, as opposed to *colormap* colors.

Some high-level functions (for example, `scatter`) accept a colorspec as an input argument and use it to set the `CData` of graphic objects they create. When using such functions, take care not to specify a colorspec in a property/value pair that sets `CData`; values for `CData` are always n-length vectors or n-by-3 matrices, where n is the length of `XData` and `YData`, never strings.

colperm

Sparse column permutation based on nonzero count

Syntax

```
j = colperm(S)
```

Description

`j = colperm(S)` generates a permutation vector `j` such that the columns of `S(:,j)` are ordered according to increasing count of nonzero entries. This is sometimes useful as a preordering for LU factorization; in this case use `lu(S(:,j))`.

If `S` is symmetric, then `j = colperm(S)` generates a permutation `j` so that both the rows and columns of `S(j,j)` are ordered according to increasing count of nonzero entries. If `S` is positive definite, this is sometimes useful as a preordering for Cholesky factorization; in this case use `chol(S(j,j))`.

Examples

The `n`-by-`n` *arrowhead* matrix

```
A = [ones(1,n); ones(n-1,1) speye(n-1,n-1)]
```

has a full first row and column. Its LU factorization, `lu(A)`, is almost completely full. The statement

```
j = colperm(A)
```

returns `j = [2:n 1]`. So `A(j,j)` sends the full row and column to the bottom and the rear, and `lu(A(j,j))` has the same nonzero structure as `A` itself.

On the other hand, the Bucky ball example,

```
B = bucky
```

has exactly three nonzero elements in each row and column, so `j = colperm(B)` is the identity permutation and is no help at all for reducing fill-in with subsequent factorizations.

More About

Algorithms

The algorithm involves a sort on the counts of nonzeros in each column.

`chol` | `colamd` | `lu` | `spparms` | `symamd` | `symrcm`

Introduced before R2006a

Combine

Convenience function for static .NET System.Delegate Combine method

Syntax

```
result = Combine(delegateA,delegateB)
```

Description

`result = Combine(delegateA,delegateB)` combines two delegates into a new delegate.

Input Arguments

`delegateA`

.NET `System.Delegate` object. The first delegate in the new delegate.

Default:

`delegateB`

.NET `System.Delegate` object. The last delegate in the new delegate.

Default:

Output Arguments

`result`

.NET `System.Delegate` object. A new delegate that delegates to the input delegate `delegateA`, then `delegateB`

Alternatives

Use the static `Combine` method of the `System.Delegate` class.

`Remove` | `RemoveAll`

Introduced in R2011a

comet

2-D comet plot

Syntax

```
comet(y)
comet(x,y)
comet(x,y,p)
comet(axes_handle,...)
```

Description

`comet(y)` displays a comet graph of the vector `y`. A comet graph is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

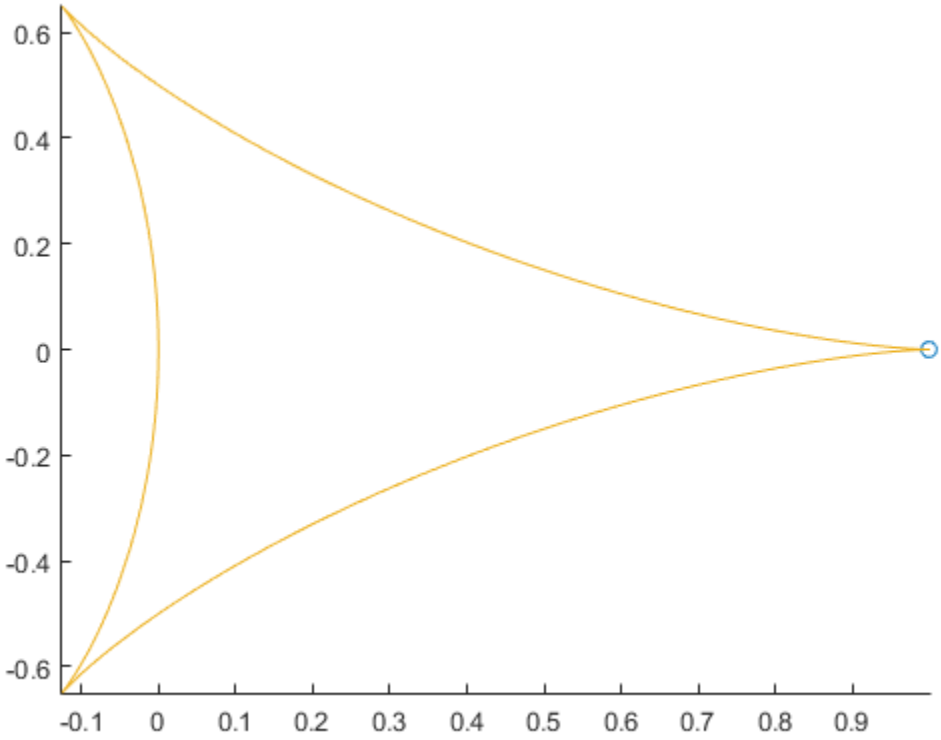
`comet(x,y)` displays a comet graph of vector `y` versus vector `x`.

`comet(x,y,p)` specifies a comet body of length `p*length(y)`. `p` defaults to `0.1`.

`comet(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Create Comet Graph

```
t = 0:.01:2*pi;
x = cos(2*t).*(cos(t).^2);
y = sin(2*t).*(sin(t).^2);
comet(x,y);
```



More About

Tips

- Comet graphs do not support data tips.

See Also

`comet3` | `animatedline`

Introduced before R2006a

comet3

3-D comet plot

Syntax

```
comet3(z)
comet3(x,y,z)
comet3(x,y,z,p)
comet3(axes_handle,...)
```

Description

A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet3(z)` displays a 3-D comet graph of the vector `z`.

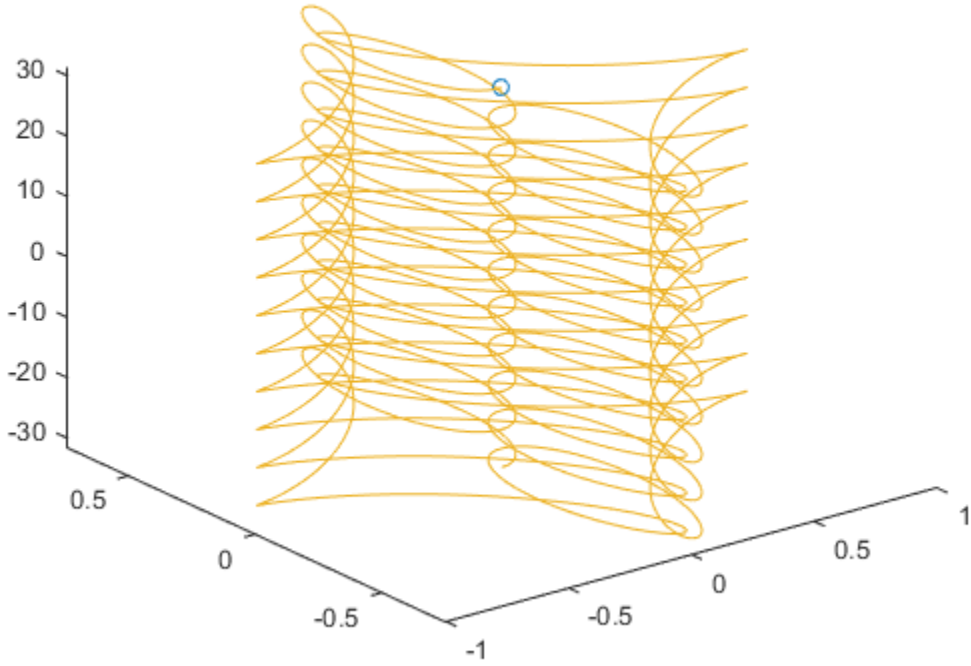
`comet3(x,y,z)` displays a comet graph of the curve through the points `[x(i),y(i),z(i)]`.

`comet3(x,y,z,p)` specifies a comet body of length `p*length(y)`. `p` must be between `0` and `1`.

`comet3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Create 3-D Comet Graph

```
t = -10*pi:pi/250:10*pi;
x = (cos(2*t).^2).*sin(t);
y = (sin(2*t).^2).*cos(t);
comet3(x,y,t);
```



See Also

`comet` | `animatedline`

Introduced before R2006a

commandhistory

Open Command History window, or select it if already open

Syntax

```
commandhistory
```

Description

`commandhistory` opens the MATLAB Command History window when it is closed, and selects the Command History window when it is open. The Command History window presents a log of the statements most recently run in the Command Window.

More About

- "Command History"

See Also

`diary` | `prefdir` | `startup`

Introduced before R2006a

commandwindow

Open Command Window, or select it if already open

Syntax

```
commandwindow
```

Description

`commandwindow` opens the MATLAB Command Window when it is closed, and selects the Command Window when it is open.

More About

Tips

To determine the number of columns and rows that display in the Command Window, given its current size, use

```
matlab.desktop.commandwindow.size
```

The number of columns is based on the width of the Command Window. With the matrix display width preference set to 80 columns, the number of columns is always 80.

- "Optimize Desktop Layout for Limited Screen Space"
- "Set Command Window Preferences"

`commandhistory` | `input` | `inputdlg`

Introduced before R2006a

compan

Companion matrix

Syntax

```
A = compan(u)
```

Description

`A = compan(u)` returns the corresponding companion matrix whose first row is `-u(2:n)/u(1)`, where `u` is a vector of polynomial coefficients. The eigenvalues of `compan(u)` are the roots of the polynomial.

Examples

The polynomial $(x-1)(x-2)(x+3) = x^3 - 7x + 6$ has a companion matrix given by

```
u = [1  0  -7  6]
A = compan(u)
A =
    0    7   -6
    1    0    0
    0    1    0
```

The eigenvalues are the polynomial roots:

```
eig(compan(u))

ans =
   -3.0000
    2.0000
    1.0000
```

This is also `roots(u)`.

See Also

`eig` | `poly` | `polyval` | `roots`

Introduced before R2006a

compass

Plot arrows emanating from origin

Syntax

```
compass(U,V)
compass(Z)
compass(...,LineSpec)
compass(axes_handle,...)
h = compass(...)
```

Description

A compass graph displays the vectors with components `(U,V)` as arrows emanating from the origin. `U`, `V`, and `Z` are in Cartesian coordinates and plotted on a circular grid.

`compass(U,V)` displays a compass graph having *n* arrows, where *n* is the number of elements in `U` or `V`. The location of the base of each arrow is the origin. The location of the tip of each arrow is a point relative to the base and determined by `[U(i),V(i)]`.

`compass(Z)` displays a compass graph having *n* arrows, where *n* is the number of elements in `Z`. The location of the base of each arrow is the origin. The location of the tip of each arrow is relative to the base as determined by the real and imaginary components of `Z`. This syntax is equivalent to `compass(real(Z),imag(Z))`.

`compass(...,LineSpec)` draws a compass graph using the line type, marker symbol, and color specified by `LineSpec`.

`compass(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = compass(...)` returns handles to line objects.

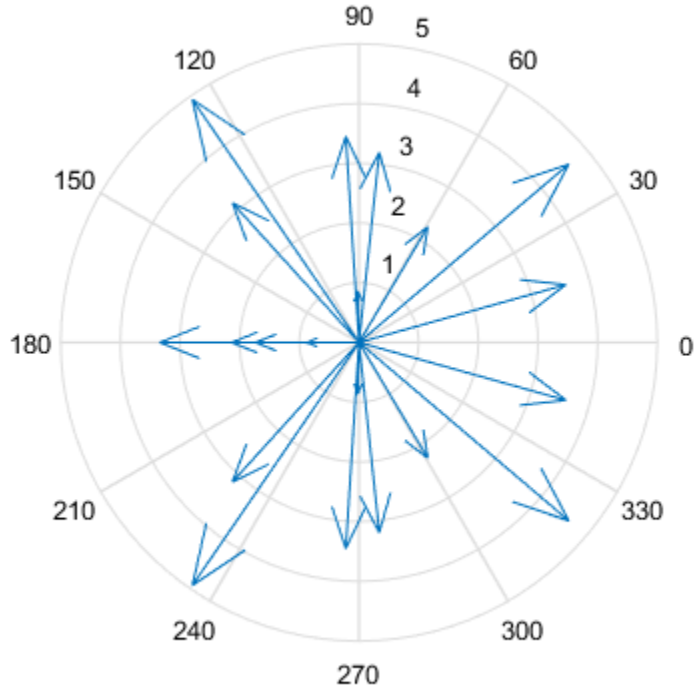
Examples

Create Compass Graph

Create a compass graph of the eigenvalues of a random matrix.

```
rng(0,'twister') % initialize random number generator
M = randn(20,20);
Z = eig(M);

figure
compass(Z)
```



See Also

`feather` | `quiver` | `rose` | `polar` | `LineSpec`

Introduced before R2006a

complex

Create complex array

Syntax

```
z = complex(a,b)
z = complex(x)
```

Description

`z = complex(a,b)` creates a complex output, `z`, from two real inputs, such that `z = a + bi`.

The `complex` function provides a useful substitute for expressions, such as `a + 1i*b` or `a + 1j*b`, when

- `a` and `b` are not `double` or `single`
- `b` is all zeros

`z = complex(x)` returns the complex equivalent of `x`, such that `isreal(z)` returns logical `0` (`false`).

- If `x` is real, then `z` is `x + 0i`.
- If `x` is complex, then `z` is identical to `x`.

Examples

Complex Scalar from Two Real Scalars

Use the `complex` function to create the complex scalar, `3 + 4i`.

```
z = complex(3,4)
```

```
z =
```

```
   3.0000 + 4.0000i
```

Complex Vector from Two Complex Vectors

Create a complex `uint8` vector from two real `uint8` vectors.

```
a = uint8([1;2;3;4]);
b = uint8([2;2;7;7]);

z = complex(a,b)

z =

    1 +    2i
    2 +    2i
    3 +    7i
    4 +    7i
```

The size of `z`, 4-by-1, is the same as the size of the input arguments.

Complex Scalar from One Real Scalar

Create a complex scalar with zero imaginary part.

```
z = complex(12)

z =

  12.0000 + 0.0000i
```

Verify that `z` is complex.

```
isreal(z)

ans =

     0
```

Input Arguments

a — Real component

scalar | vector | matrix | multidimensional array

Real component, specified as a scalar, vector, matrix, or multidimensional array.

The size of `a` must match the size of `b`, unless one is a scalar. If either `a` or `b` is a scalar, MATLAB expands the scalar to match the size of the other input.

`a` and `b` must be the same data type with the following exceptions:

- `single` can combine with `double`.
- scalar `double` can combine with an integer data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

b — Imaginary component

scalar | vector | matrix | multidimensional array

Imaginary component, specified as a scalar, vector, matrix, or multidimensional array.

The size of `b` must match the size of `a`, unless one is a scalar. If either `a` or `b` is a scalar, MATLAB expands the scalar to match the size of the other input.

`a` and `b` must be the same data type with the following exceptions:

- `single` can combine with `double`.
- scalar `double` can combine with an integer data type.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

x — Input array

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

Output Arguments

z — Complex array

scalar | vector | matrix | multidimensional array

Complex array, returned as a scalar, vector, matrix, or multidimensional array.

The size of `z` is the same as the input arguments.

The following describes the data type of `z`, when `a` and `b` have different data types.

- If either `a` or `b` is `single`, then `z` is `single`.
- If either `a` or `b` is an integer data type, then `z` is the same integer data type.

More About

Tips

- If `b` contains only zeros, then `z` is complex and the value of all its imaginary components is `0`. In contrast, the addition `a + 0i` returns a strictly real result.
- "Complex Numbers"

Introduced before R2006a

computeStrip

Class: Tiff

Index number of strip containing specified coordinate

Syntax

```
stripNumber = computeStrip(tiffobj,row)
stripNumber = computeStrip(tiffobj,row,plane)
```

Description

`stripNumber = computeStrip(tiffobj,row)` returns the index number of the strip containing the given row. The value of `row` must be one-based.

`stripNumber = computeStrip(tiffobj,row,plane)` returns the index number of the strip containing the given row in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The values of row and plane must be one-based.

`computeStrip` clamps out-of-range coordinate values to the bounds of the image.

Examples

Determine Index Number of Strip

Determine the index number of the strip containing a row in the second image of a file.

Create a `Tiff` object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');
setDirectory(t,2)
```

Get the number of rows in the image. Then, get the index of the strip containing the middle row.

```
numRows = getTag(t,'ImageLength');
stripNumber = computeStrip(t,numRows/2)
```

```
stripNumber =

     4
```

Close the `Tiff` object.

```
close(t)
```

`Tiff.computeTile`

computeTile

Class: Tiff

Index number of tile containing specified coordinates

Syntax

```
tileNumber = computeTile(tiffobj,[row col])
tileNumber = computeTile(tiffobj,[row col],plane)
```

Description

`tileNumber = computeTile(tiffobj,[row col])` returns the index number of the tile containing the pixel specified by the one-based indices, `row` and `col`.

`tileNumber = computeTile(tiffobj,[row col],plane)` returns the index number of the tile containing the pixel specified by the indices in the specified plane, if the value of the `PlanarConfiguration` tag is `Tiff.PlanarConfiguration.Separate`. The row, column, and plane coordinate values are one-based.

`computeTile` clamps out-of-range coordinate values to the bounds of the image.

Examples

Get Index Number of Tile Containing Last Pixel

Open a `Tiff` object and get the dimensions of the image to calculate coordinates.

```
t = Tiff('example.tif','r');
numRows = getTag(t,'ImageLength');
numCols = getTag(t,'ImageWidth');
```

Get the ID number of the tile containing the coordinates.

```
tileNum = computeTile(t,[numRows numCols])
```

```
tileNum =

   110
```

Close the `Tiff` object.

```
close(t)
```

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

References

This method corresponds to the `TIFFComputeTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at LibTiff - TIFF Library and Utilities.

`Tiff.computeStrip`

computer

Information about computer on which MATLAB software is running

Syntax

```
str = computer
archstr = computer('arch')
[str,maxsize] = computer
[str,maxsize,endian] = computer
```

Description

`str = computer` returns the string `str` with the computer type on which MATLAB is running.

`archstr = computer('arch')` returns the string `archstr` which is used by the `mex` command and standalone applications to locate MATLAB library files.

`[str,maxsize] = computer` returns the integer `maxsize`, the maximum number of elements allowed in an array with this version of MATLAB.

`[str,maxsize,endian] = computer` returns either `'L'` for little-endian byte ordering or `'B'` for big-endian byte ordering.

Platform	Word Size	str	archstr	maxsize	endian	ispc	isunix	ismac
Microsoft Windows	32-bit	PCWIN	win32	2^31 - 1	L	1	0	0
	64-bit	PCWIN64	win64	2^48 - 1	L	1	0	0
Linux	64-bit	GLNXA64	glnxa64	2^48 - 1	L	0	1	0
Apple Mac	64-bit	MACI64	maci64	2^48 - 1	L	0	1	1

More About

Tips

In some cases, both 32-bit and 64-bit versions of MATLAB can run on the same platform. In this case, the value returned by `computer` reflects which of these are running. For example, if you run a 32-bit version of MATLAB on a Windows x64 platform, `computer` returns `PCWIN`, indicating that the 32-bit version is running. You can get this information and the value of `archstr` from the **Help** menu, as described in "Information About Your Installation".

`getenv` | `setenv` | `ispc` | `isunix` | `ismac`

Introduced before R2006a

cond

Condition number with respect to inversion

Syntax

```
c = cond(X)
c = cond(X,p)
```

Description

The *condition number* of a matrix measures the sensitivity of the solution of a system of linear equations to errors in the data. It gives an indication of the accuracy of the results from matrix inversion and the linear equation solution. Values of `cond(X)` and `cond(X,p)` near 1 indicate a well-conditioned matrix.

`c = cond(X)` returns the 2-norm condition number, the ratio of the largest singular value of `X` to the smallest.

`c = cond(X,p)` returns the matrix condition number in `p`-norm:

```
norm(X,p) * norm(inv(X),p)
```

If p is...	Then cond(X,p) returns the...
1	1-norm condition number
2	2-norm condition number
'fro'	Frobenius norm condition number
inf	Infinity norm condition number

More About

Algorithms

The algorithm for `cond` (when `p = 2`) uses the singular value decomposition, `svd`. When the input matrix is sparse, `cond` ignores any specified `p` value and calls `condest`.

See Also

`condeig` | `norm` | `condest` | `normest` | `rank` | `rcond` | `svd`

Introduced before R2006a

condeig

Condition number with respect to eigenvalues

Syntax

```
c = condeig(A)
[V,D,s] = condeig(A)
```

Description

`c = condeig(A)` returns a vector of condition numbers for the eigenvalues of `A`. These condition numbers are the reciprocals of the cosines of the angles between the left and right eigenvectors.

`[V,D,s] = condeig(A)` is equivalent to

```
[V,D] = eig(A);
s = condeig(A);
```

Large condition numbers imply that `A` is near a matrix with multiple eigenvalues.

See Also

`balance` | `cond` | `eig`

Introduced before R2006a

condest

1-norm condition number estimate

Syntax

```
c = condest(A)
c = condest(A,t)
[c,v] = condest(A)
```

Description

`c = condest(A)` computes a lower bound `c` for the 1-norm condition number of a square matrix `A`.

`c = condest(A,t)` changes `t`, a positive integer parameter equal to the number of columns in an underlying iteration matrix. Increasing the number of columns usually gives a better condition estimate but increases the cost. The default is `t = 2`, which almost always gives an estimate correct to within a factor 2.

`[c,v] = condest(A)` also computes a vector `v` which is an approximate null vector if `c` is large. `v` satisfies `norm(A*v,1) = norm(A,1)*norm(v,1)/c`.

Note: `condest` invokes `rand`. If repeatable results are required then use `rng` to set the random number generator to its startup settings before using `condest`.

```
rng('default')
```

More About

Tips

This function is particularly useful for sparse matrices.

Algorithms

`condest` is based on the 1-norm condition estimator of Hager [1] and a block-oriented generalization of Hager's estimator given by Higham and Tisseur [2]. The heart of the

algorithm involves an iterative search to estimate $\left\|A^{-1}\right\|_1$ without computing A^{-1}. This is posed as the convex but nondifferentiable optimization problem $\max\left\|A^{-1}\mathbf{x}\right\|_1$ subject to $\left\|\mathbf{x}\right\|_1 = 1$

`cond` | `norm` | `normest`

Introduced before R2006a

coneplot

Plot velocity vectors as cones in 3-D vector field

Syntax

```
coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)
coneplot(U,V,W,Cx,Cy,Cz)
coneplot(...,s)
coneplot(...,color)
coneplot(...,'quiver')
coneplot(...,'method')
coneplot(X,Y,Z,U,V,W,'nointerp')
coneplot(axes_handle,...)
h = coneplot(...)
```

Description

`coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)` plots velocity vectors as cones pointing in the direction of the velocity vector and having a length proportional to the magnitude of the velocity vector. `X`, `Y`, `Z` define the coordinates for the vector field. `U`, `V`, `W` define the vector field. These arrays must be the same size, monotonic, and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). `Cx`, `Cy`, `Cz` define the location of the cones in the vector field. The section "Specifying Starting Points for Stream Plots" in Visualization Techniques provides more information on defining starting points.

`coneplot(U,V,W,Cx,Cy,Cz)` (omitting the `X`, `Y`, and `Z` arguments) assumes `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p]= size(U)`.

`coneplot(...,s)` automatically scales the cones to fit the graph and then stretches them by the scale factor `s`. If you do not specify a value for `s`, `coneplot` uses a value of 1. Use `s = 0` to plot the cones without automatic scaling.

`coneplot(...,color)` interpolates the array `color` onto the vector field and then colors the cones according to the interpolated values. The size of the `color` array must be the same size as the `U`, `V`, `W` arrays. This option works only with cones (that is, not with the `quiver` option).

`coneplot(...,'quiver')` draws arrows instead of cones (see `quiver3` for an illustration of a quiver plot).

`coneplot(...,'method')` specifies the interpolation method to use. *`method`* can be `linear`, `cubic`, or `nearest`. `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`coneplot(X,Y,Z,U,V,W,'nointerp')` does not interpolate the positions of the cones into the volume. The cones are drawn at positions defined by `X`, `Y`, `Z` and are oriented according to `U`, `V`, `W`. Arrays `X`, `Y`, `Z`, `U`, `V`, `W` must all be the same size.

`coneplot(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = coneplot(...)` returns the handle to the `patch` object used to draw the cones.

`coneplot` automatically scales the cones to fit the graph, while keeping them in proportion to the respective velocity vectors.

Examples

3-D Cone Plot

Plot velocity vector cones for vector volume data representing motion of air through a rectangular region of space.

Load the data. The `wind` data set contains the arrays `u`, `v`, and `w` that specify the vector components and the arrays `x`, `y`, and `z` that specify the coordinates.

```
load wind
```

Establish the range of the data to place the slice planes and to specify where you want the cone plots.

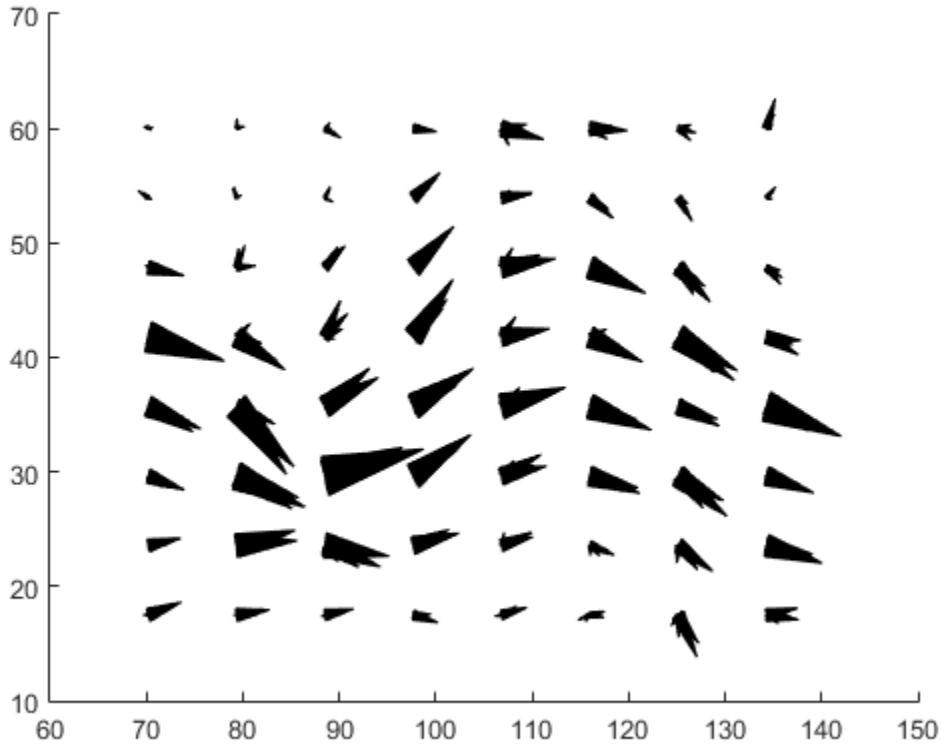
```
xmin = min(x(:));
xmax = max(x(:));
ymin = min(y(:));
ymax = max(y(:));
zmin = min(z(:));
```

Define where to plot the cones. Select the full range in `x` and `y` and select the range 3 to 15 in `z`.

```
xrange = linspace(xmin,xmax,8);
yrange = linspace(ymin,ymax,8);
zrange = 3:4:15;
[cx,cy,cz] = meshgrid(xrange,yrange,zrange);
```

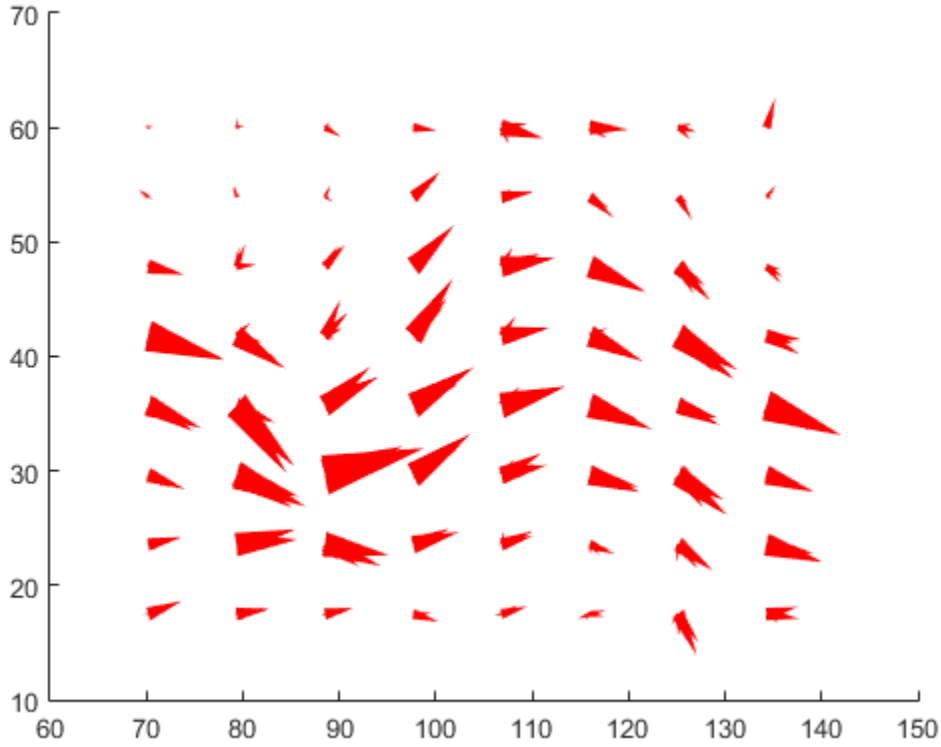
Plot the cones and set the scale factor to 5 to make the cones larger than the default size.

```
figure
hcone = coneplot(x,y,z,u,v,w,cx,cy,cz,5);
```



Set the cone colors.

```
hcone.FaceColor = 'red';
hcone.EdgeColor = 'none';
```

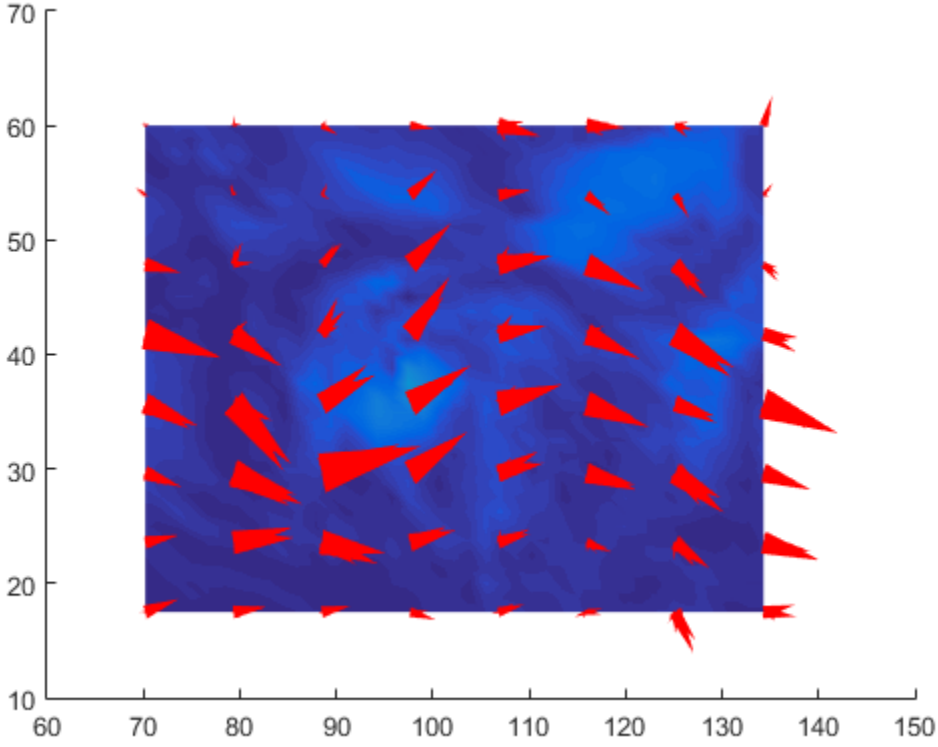


Calculate the magnitude of the vector field (which represents wind speed) to generate scalar data for the `slice` command.

```
hold on
wind_speed = sqrt(u.^2 + v.^2 + w.^2);
```

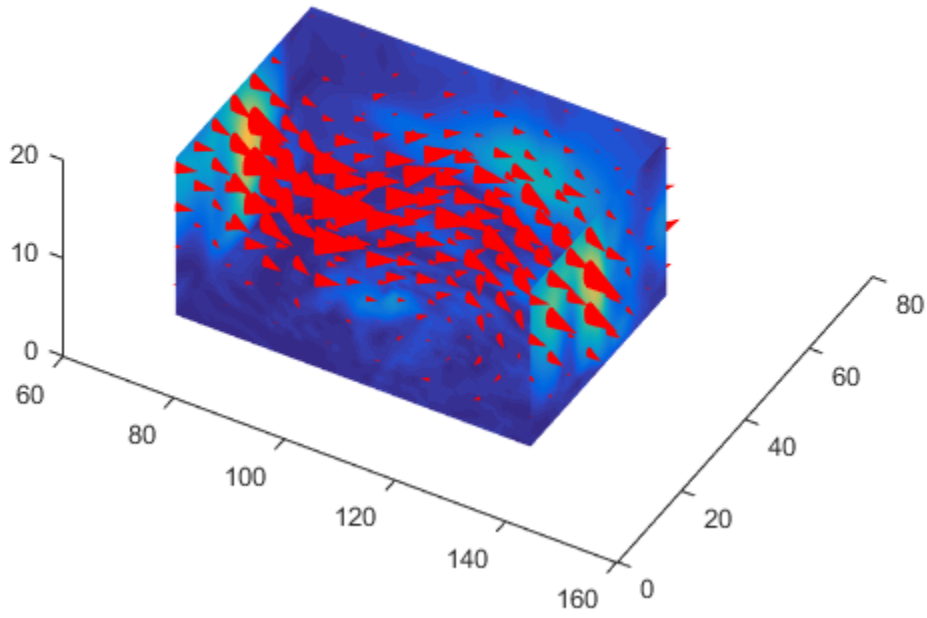
Create slice planes along the *x*-axis at `xmin` and `xmax`, along the *y*-axis at `ymax`, and along the *z*-axis at `zmin`. Specify interpolated face color so the slice coloring indicates wind speed, and do not draw edges.

```
hsurfaces = slice(x,y,z,wind_speed,[xmin,xmax],ymax,zmin);
set(hsurfaces,'FaceColor','interp','EdgeColor','none')
hold off
```



Change the axes view and set the data aspect ratio.

```
view(30,40)
daspect([2,2,1])
```



Add a light source to the right of the camera and use Gouraud lighting to give the cones and slice planes a smooth, three-dimensional appearance.

```
camlight right
lighting gouraud
set(hsurfaces,'AmbientStrength',0.6)
hcone.DiffuseStrength = 0.8;
```

conj

Complex conjugate

Syntax

```
ZC = conj(Z)
```

Description

`ZC = conj(Z)` returns the complex conjugate of the elements of `Z`.

More About

Algorithms

If `Z` is a complex array:

```
conj(Z) = real(Z) - i*imag(Z)
```

See Also

`i` | `j` | `imag` | `real`

Introduced before R2006a

continue

Pass control to next iteration of `for` or `while` loop

Syntax

```
continue
```

Description

`continue` passes control to the next iteration of a `for` or `while` loop. It skips any remaining statements in the body of the loop for the current iteration. The program continues execution from the next iteration.

`continue` applies only to the body of the loop where it is called. In nested loops, `continue` skips remaining statements only in the body of the loop in which it occurs.

Examples

Selectively Display Values in Loop

Display the multiples of 7 from 1 through 50. If a number is not divisible by 7, use `continue` to skip the `disp` statement and pass control to the next iteration of the `for` loop.

```
for n = 1:50
    if mod(n,7)
        continue
    end
    disp(['Divisible by 7: ' num2str(n)])
end
```

```
Divisible by 7: 7
Divisible by 7: 14
Divisible by 7: 21
Divisible by 7: 28
Divisible by 7: 35
Divisible by 7: 42
```

```
Divisible by 7: 49
```

Skip to Next Loop Iteration

Count the number of lines of code in the file `magic.m`. Skip blank lines and comments using a `continue` statement. `continue` skips the remaining instructions in the `while` loop and begins the next iteration.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) || strncmp(line,'%',1) || ~ischar(line)
        continue
    end
    count = count + 1;
end
count
fclose(fid);
```

```
count =

    31
```

More About

Tips

- The `continue` statement skips the rest of the instructions in a `for` or `while` loop and begins the next iteration. To exit the loop completely, use a `break` statement.
- `continue` is not defined outside a `for` or `while` loop. To exit a function, use `return`.

Introduced before R2006a

contour

Contour plot of matrix

Syntax

```
contour(Z)
contour(Z,n)
contour(Z,v)
contour(X,Y,Z)
contour(X,Y,Z,n)
contour(X,Y,Z,v)
contour(...,LineSpec)
contour(...,Name,Value)
contour(ax,...)
[C,h] = contour(...)
```

Description

A contour plot displays isolines of matrix `Z`. Label the contour lines using `clabel`.

`contour(Z)` draws a contour plot of matrix `Z`, where `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The *x* values correspond to the column indices of `Z` and the *y* values correspond to the row indices of `Z`. The contour levels are chosen automatically.

`contour(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels where `n` is a scalar. The contour levels are chosen automatically.

`contour(Z,v)` draws a contour plot of matrix `Z` with contour lines at the data values specified in the monotonically increasing vector `v`. To display a single contour line at a particular value, define `v` as a two-element vector with both elements equal to the desired contour level. For example, to draw contour lines at level `k`, use `contour(Z,[k k])`. Specifying the vector `v` sets the `LevelListMode` property to manual.

`contour(X,Y,Z)`, `contour(X,Y,Z,n)`, and `contour(X,Y,Z,v)` draw contour plots of `Z` using `X` and `Y` to determine the *x* and *y* values.

- If `X` and `Y` are vectors, then `length(X)` must equal `size(Z,2)` and `length(Y)` must equal `size(Z,1)`. The vectors must be strictly increasing or strictly decreasing and cannot contain any repeated values.
- If `X` and `Y` are matrices, then their sizes must equal the size of `Z`. Typically, you should set `X` and `Y` so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

If `X` or `Y` is irregularly spaced, then `contour` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

`contour(...,LineSpec)` draws the contours using the line type and color specified by `LineSpec`. `contour` ignores marker symbols.

`contour(...,Name,Value)` specifies contour properties using one or more property name, property value pairs. `Name` is the property name and must appear inside single quotes (`''`). `Value` is the corresponding value. For example, `'LineWidth',2` sets the contour line width to 2. For a list of contour property names and values, see Contour Properties.

`contour(ax,...)` plots into the axes specified by `ax` instead of the current axes (`gca`).

`[C,h] = contour(...)` returns the contour matrix `C` containing the data that defines the contour lines, and the contour object `h`. The `ContourMatrix` property for the contour object also contains the contour matrix. The `clabel` function uses the contour matrix to label the contour lines.

Use contour object properties to control the contour plot appearance. For a list, see Contour Properties.

Examples

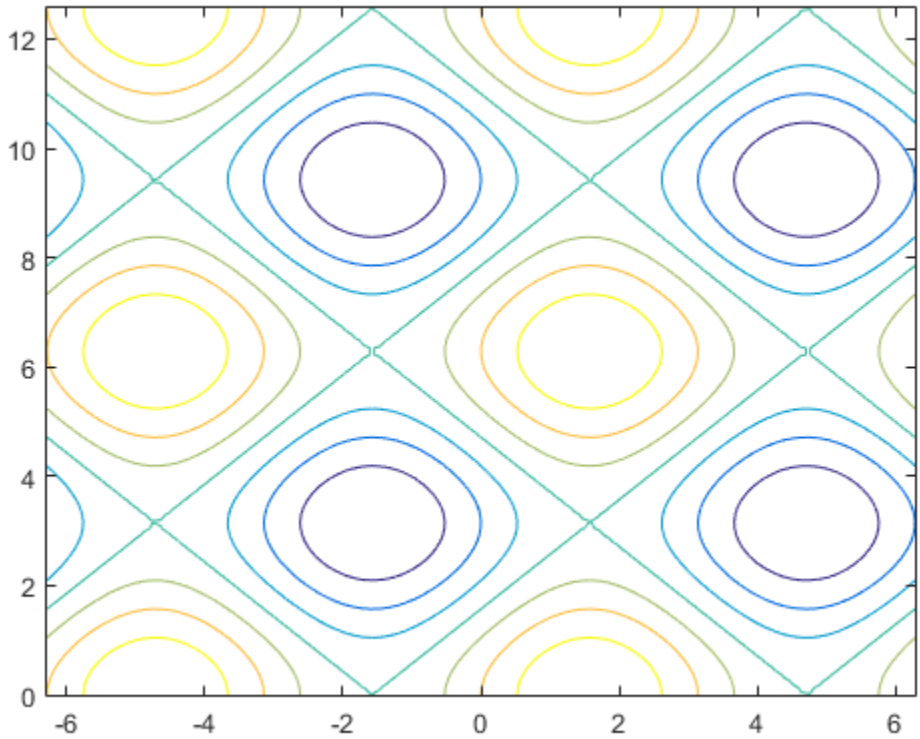
Create Contour Plot

Use the `meshgrid` function to generate matrices `X` and `Y`. Create a third matrix, `Z`, and plot its contours.

```
x = linspace(-2*pi,2*pi);
y = linspace(0,4*pi);
```

```
[X,Y] = meshgrid(x,y);
Z = sin(X)+cos(Y);

figure
contour(X,Y,Z)
```

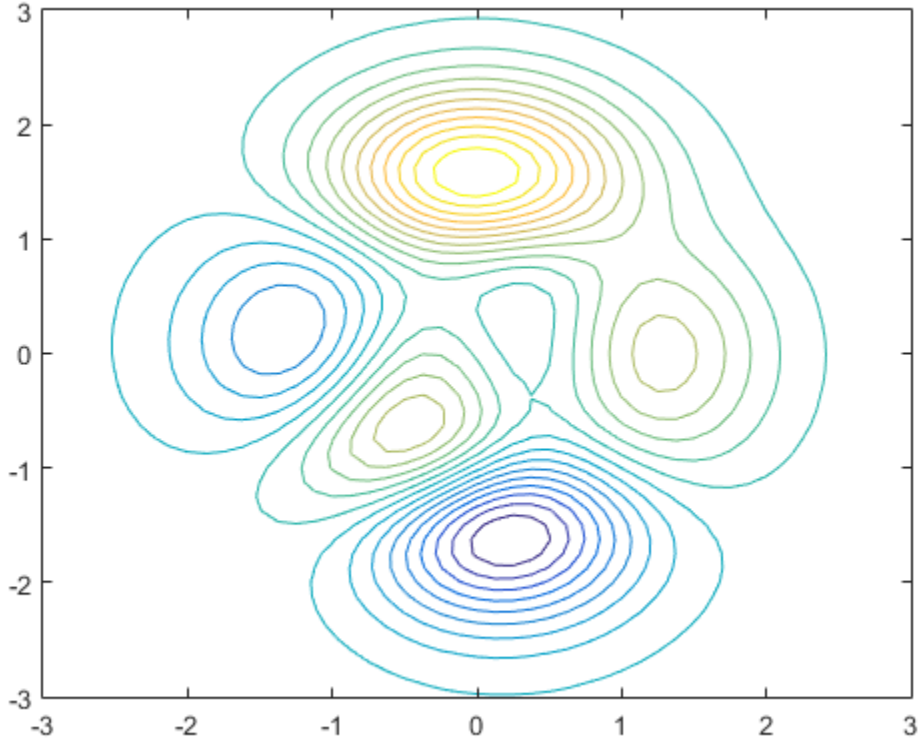


Specify Number of Contour Lines

Store the data from the `peaks` function in matrices `X`, `Y`, and `Z`. Plot 20 contours of the data in `Z`.

```
[X,Y,Z] = peaks;
figure
```

```
contour(X,Y,Z,20)
```



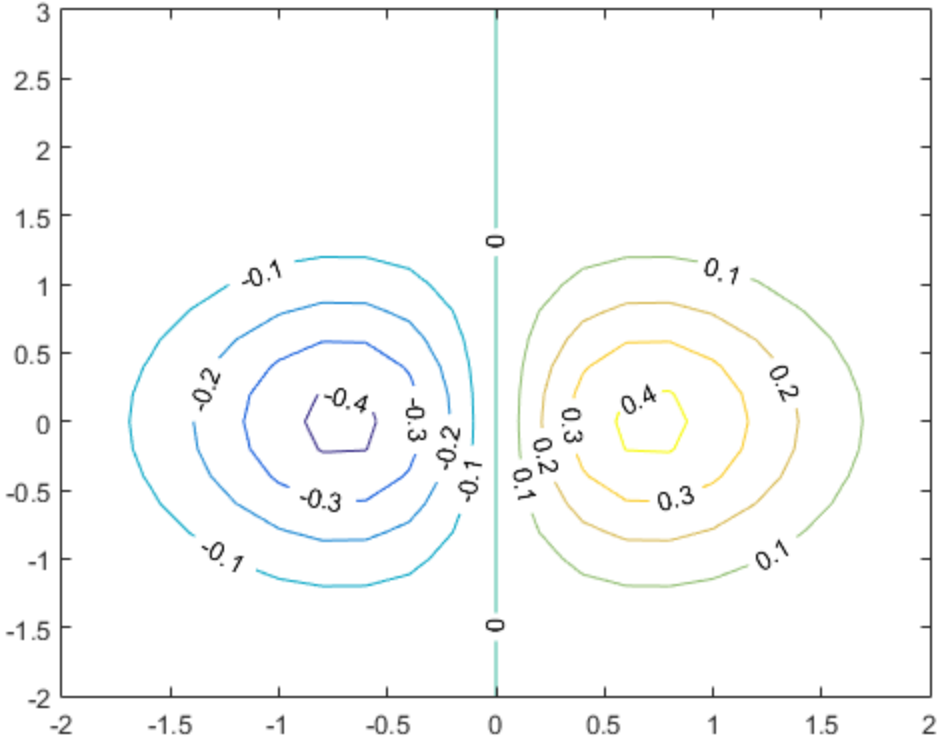
Display Contour Labels

Set up matrices `X`, `Y`, and `Z`. Create a contour plot and display the contour labels by setting the `ShowText` property to `on`.

```
x = -2:0.2:2;
y = -2:0.2:3;
[X,Y] = meshgrid(x,y);
Z = X.*exp(-X.^2-Y.^2);

figure
```

```
contour(X,Y,Z,'ShowText','on')
```



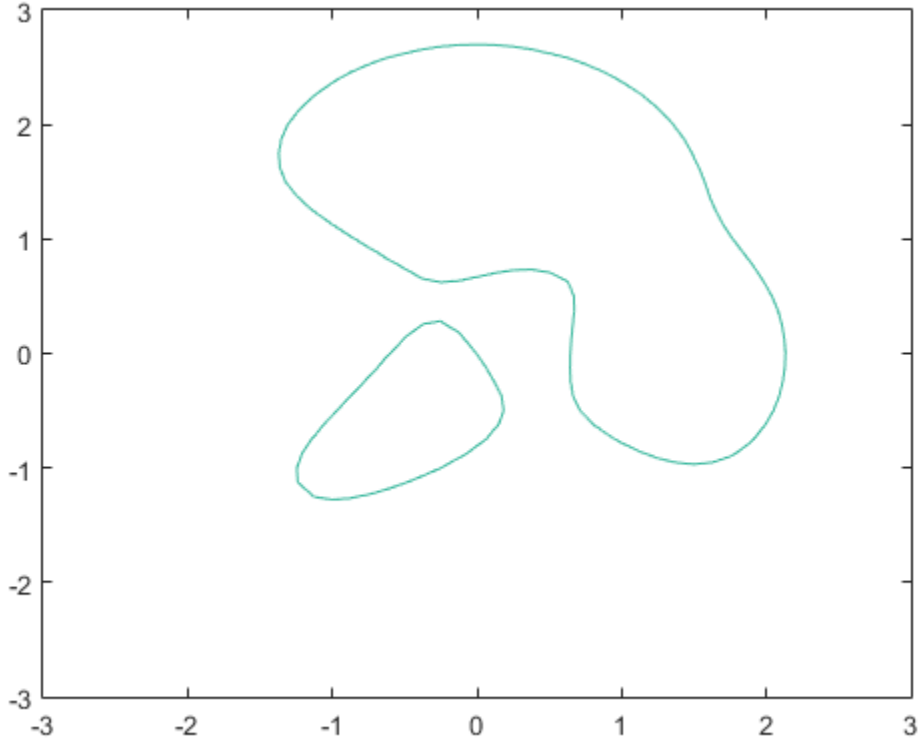
Display Single Contour Line

Create a contour plot of the `peaks` function and display only one contour level at `Z = 1`.

```
x = -3:0.125:3;
y = -3:0.125:3;
[X,Y] = meshgrid(x,y);
Z = peaks(X,Y);
v = [1,1];

figure
```

```
contour(X,Y,Z,v)
```



More About

Tips

- The `contour` function cannot determine if there are discontinuities in the input data. Add `NaN` values to the data to prevent drawing the contour lines in those regions.

- "Label Contour Plot Levels"
- "Highlight Specific Contour Levels"

Introduced before R2006a

contour3

3-D contour plot

Syntax

```
contour3(Z)
contour3(Z,n)
contour3(Z,v)
contour3(X,Y,Z)
contour3(X,Y,Z,n)
contour3(X,Y,Z,v)
contour3(...,LineSpec)
contour3(...,Name,Value)
contour3(ax,...)
[C,h] = contour3(...)
```

Description

`contour3` creates a 3-D contour plot of a surface defined on a rectangular grid.

`contour3(Z)` draws a contour plot of matrix `Z` in a 3-D view. `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The *x* values correspond to the column indices of `Z` and the *y* values correspond to the row indices of `Z`. The contour levels are chosen automatically.

`contour3(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels in a 3-D view.

`contour3(Z,v)` draws a contour plot of matrix `Z` with contour lines at the values specified in vector `v`. The number of contour levels is equal to `length(v)`. Specifying the vector `v` sets the `LevelListMode` property to manual. To display a single contour line at a particular value, define `v` as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level `k`, use `contour3(Z,[k k])`.

`contour3(X,Y,Z)`, `contour3(X,Y,Z,n)`, and `contour3(X,Y,Z,v)` draw contour plots of `Z` using `X` and `Y` to determine the *x* and *y* values.

- If `X` and `Y` are vectors, then `length(X)` must equal `size(Z,2)` and `length(Y)` must equal `size(Z,1)`. The vectors must be strictly increasing or strictly decreasing and cannot contain any repeated values.
- If `X` and `Y` are matrices, then their sizes must equal the size of `Z`. Typically, you should set `X` and `Y` so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

If `X` or `Y` is irregularly spaced, then `contour3` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

`contour3(...,LineSpec)` draws the contour lines using the line type and color specified by `LineSpec`. `contour3` ignores marker symbols.

`contour3(...,Name,Value)` specifies contour properties using one or more property name, property value pairs. `Name` is the property name and must appear inside single quotes (`''`). `Value` is the corresponding value. For example, `'LineWidth',2` sets the contour line width to 2. For a list of contour property names and values, see Contour Properties.

`contour3(ax,...)` plots into the axes specified by `ax` instead of into the current axes (`gca`).

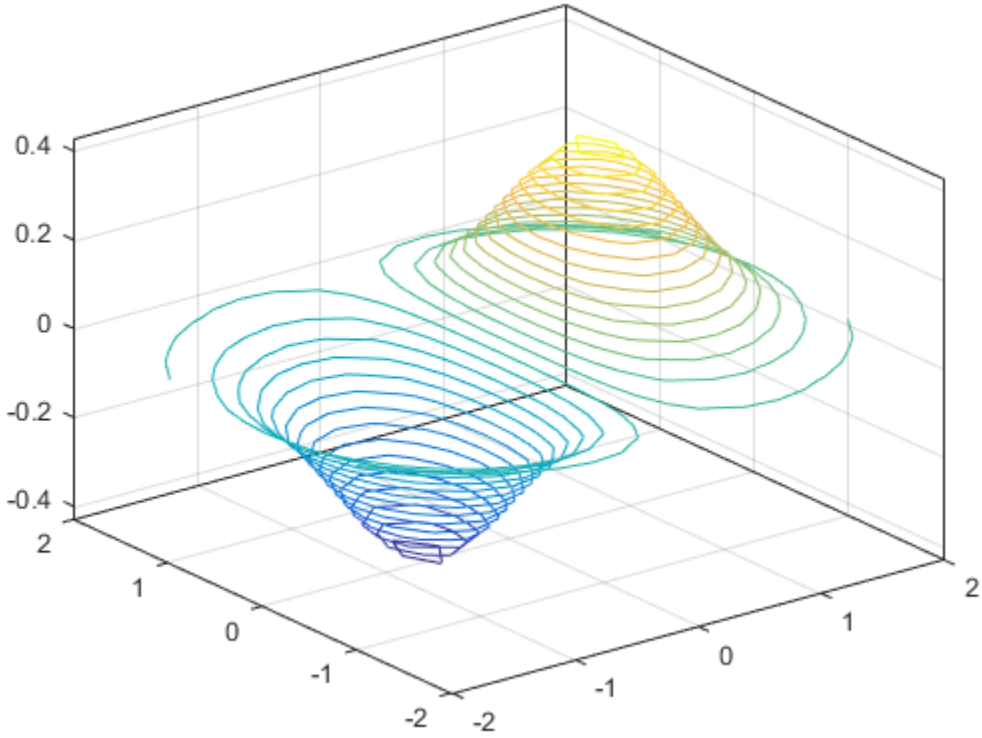
`[C,h] = contour3(...)` returns the contour matrix `C` containing the data that defines the contour lines and the contour object `h`. The `clabel` function uses the contour matrix to label the contour lines.

Examples

Create 3-D Contour Plot

Set up matrices `X` and `Y` using the `meshgrid` function. Plot 30 contours of matrix `Z`.

```
x = -2:0.25:2;
[X,Y] = meshgrid(x);
Z = X.*exp(-X.^2-Y.^2);
contour3(X,Y,Z,30)
```



More About

Tips

If you do not specify `LineSpec`, the functions `colormap` and `caxis` control the color.

Label the contour lines using `clabel`.

`contour3(...)` works the same as `contour(...)` except that the contours are drawn at their corresponding *z* values.

Properties
Contour Properties

Introduced before R2006a

contourc

Low-level contour plot computation

Syntax

```
C = contourc(Z)
C = contourc(Z,n)
C = contourc(Z,v)
C = contourc(x,y,Z)
C = contourc(x,y,Z,n)
C = contourc(x,y,Z,v)
```

Description

`contourc` calculates the contour matrix `C` used by `contour`, `contour3`, and `contourf`. The values in `Z` determine the heights of the contour lines with respect to a plane. The contour calculations use a regularly spaced grid determined by the dimensions of `Z`.

`C = contourc(Z)` computes the contour matrix from data in matrix `Z`, where `Z` must be at least a 2-by-2 matrix. The contours are isolines in the units of `Z`. The number of contour lines and the corresponding values of the contour lines are chosen automatically.

`C = contourc(Z,n)` computes contours of matrix `Z` with `n` contour levels.

`C = contourc(Z,v)` computes contours of matrix `Z` with contour lines at the values specified in vector `v`. The length of `v` determines the number of contour levels. To compute a single contour of level `k`, use `contourc(Z,[k k])`.

`C = contourc(x,y,Z)`, `C = contourc(x,y,Z,n)`, and `C = contourc(x,y,Z,v)` compute contours of `Z` using vectors `x` and `y` to determine the *x* and *y* values. `x` and `y` must be monotonically increasing.

More About

Tips

For more information on the contour matrix, see the `ContourMatrix` property for contour objects.

Specifying irregularly spaced `x` and `y` vectors is not the same as contouring irregularly spaced data. If `x` or `y` is irregularly spaced, `contourc` calculates contours using a regularly spaced contour grid, then transforms the data to `x` or `y`.

`clabel` | `contour` | `contour3` | `contourf`

Introduced before R2006a

contourf

Filled 2-D contour plot

Syntax

```
contourf(Z)
contourf(Z,n)
contourf(Z,v)
contourf(X,Y,Z)
contourf(X,Y,Z,n)
contourf(X,Y,Z,v)
contourf(...,LineSpec)
contourf(...,Name,Value)
contourf(ax,...)
[C,h] = contourf(...)
```

Description

A filled contour plot displays isolines calculated from matrix `Z` and fills the areas between the isolines using constant colors corresponding to the current figure's colormap.

`contourf(Z)` draws a filled contour plot of matrix `Z`, where `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The *x* values correspond to the column indices of `Z` and the *y* values correspond to the row indices of `Z`. The contour levels are chosen automatically.

`contourf(Z,n)` draws a filled contour plot of matrix `Z` with `n` contour levels.

`contourf(Z,v)` draws a filled contour plot of matrix `Z` with contour lines at the data values specified in the monotonically increasing vector `v`. To display a single contour line at a particular value, define `v` as a two-element vector with both elements equal to the desired contour level. For example, to draw a single contour of level `k`, use `contourf(Z, [k k])`. Specifying the vector `v` sets the `LevelListMode` property to manual.

`contourf(X,Y,Z)`, `contourf(X,Y,Z,n)`, and `contourf(X,Y,Z,v)` draw filled contour plots of `Z` using `X` and `Y` to determine the *x* and *y* values.

- If `X` and `Y` are vectors, then `length(X)` must equal `size(Z,2)` and `length(Y)` must equal the number of rows in `size(Z,1)`. The vectors must be strictly increasing or strictly decreasing and cannot contain any repeated values.
- If `X` and `Y` are matrices, then their sizes must equal the size of `Z`. Typically, you should set `X` and `Y` so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

If `X` or `Y` is irregularly spaced, then `contourf` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

`contourf(...,LineSpec)` draws the contour lines using the line type and color specified by `LineSpec`. `contourf` ignores marker symbols.

`contourf(...,Name,Value)` specifies contour properties using one or more property name, property value pairs. `Name` is the property name and must appear inside single quotes (`''`). `Value` is the corresponding value. For example, `'LineWidth',2` sets the contour line width to 2. For a list of contour property names and values, see Contour Properties.

`contourf(ax,...)` plots into the axes specified by `ax` instead of into the current axes (`gca`).

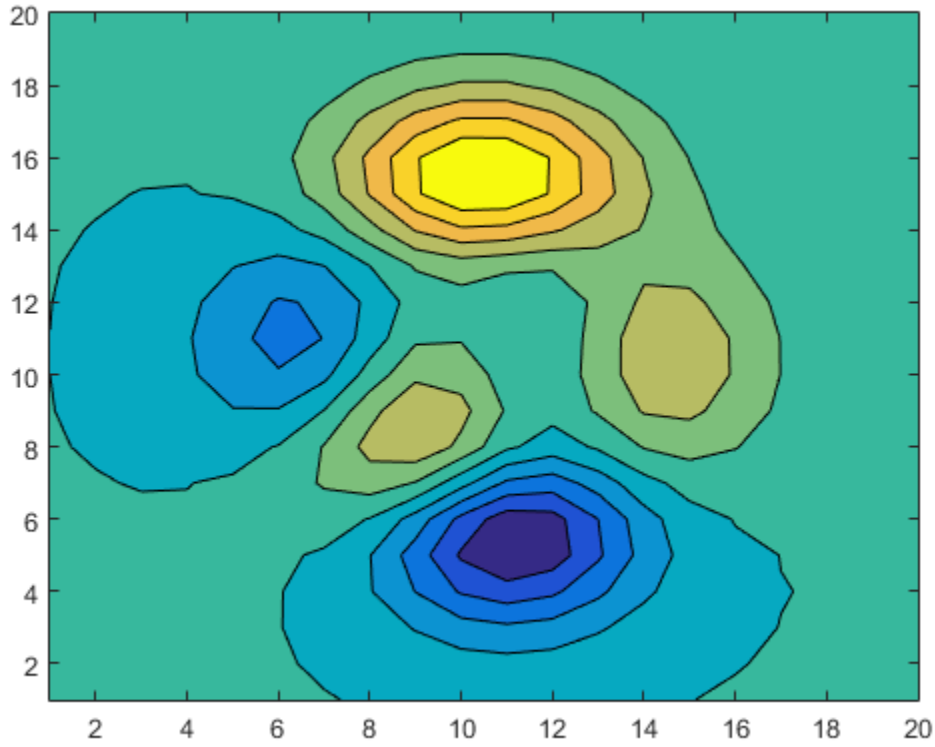
`[C,h] = contourf(...)` returns the contour matrix `C` containing the data that defines the contour lines and a contour object `h`. The `ContourMatrix` property for the contour object also contains the contour matrix. The `clabel` function uses the contour matrix to label the contour lines.

Examples

Create Filled Contour Plot

Use the `peaks` function to define `z` as a 20-by-20 matrix. Create a filled contour plot of `z` with 10 contour lines.

```
Z = peaks(20);
contourf(Z,10)
```



More About

Tips

`NaN` values in `Z` leave white holes with black borders in the contour plot.

- "Change Fill Colors for Contour Plot"

Properties
Contour Properties

Introduced before R2006a

Contour Properties

Control contour appearance and behavior

Contour properties control the appearance and behavior of contour objects. By changing property values, you can modify certain aspects of the contour.

Starting in R2014b, you can use dot notation to query and set properties.

```
[C,h] = contour(...);
w = h.LineWidth;
h.LineWidth = 2;
```

If you are using an earlier release, use the `get` and `set` functions instead.

Lines

`LineColor` — Color of contour lines

`'flat'` (default) | `'none'` | RGB triplet | color string

Color of contour lines, specified as one of these values:

- `'flat'` — Use a different color for each contour line, determined by its contour value, the colormap, and the scaling of data values into the colormap. For more information on color scaling, see `caxis`.
- `'none'` — Do not draw the contour lines.
- RGB triplet or color string — Use the same color for all contour lines. Specify the color using an RGB triplet or a color string.

An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`, for example, `[0.4 0.6 0.7]`. This table lists RGB triplet values that have equivalent color strings.

Long Name	Short Name	RGB Triplet
`'yellow'`	`'y'`	`[1 1 0]`
`'magenta'`	`'m'`	`[1 0 1]`
`'cyan'`	`'c'`	`[0 1 1]`

Long Name	Short Name	RGB Triplet
'red'	'r'	[1 0 0]
'green'	'g'	[0 1 0]
'blue'	'b'	[0 0 1]
'white'	'w'	[1 1 1]
'black	'k'	[0 0 0]

`LineStyle` — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as one of the line style strings listed in this table.

String	Line Style	Resulting Line
'-'	Solid line	'--'	Dashed line	
':'	Dotted line	'-.'	Dash-dotted line	
'none'	No line	No line

`LineWidth` — Width of contour lines

0.5 (default) | positive value

Width of contour lines, specified as a positive value in points. One point equals 1/72 inch.

Example: 2

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Contour Levels

`LevelList` — Contour levels

empty matrix (default) | vector of z values

Contour levels, specified as a vector of z values. By default, the `contour` function chooses values that span the range of values in the `ZData` property.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LevelListMode` — Selection mode for `LevelList`

`'auto'` (default) | `'manual'`

Selection mode for the LevelList, specified as one of these values:

- `'auto'` — Determine the values based on the `ZData` values.
- `'manual'` — Use manually specified values. To specify the values, set the LevelList property. When the mode is manual, the `contour` function does not change the values as you change ZData.

`LevelStep` — Spacing between contour lines

`0` (default) | scalar numeric value

Spacing between contour lines, specified as a scalar numeric value. For example, specify a value of 2 to draw contour lines at increments of 2. The `contour` function determines the contour interval based on the `ZData` values.

Setting this property sets the associated mode property to manual.

Example: `3.4`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`LevelStepMode` — Selection mode for `LevelStep`

`'auto'` (default) | `'manual'`

Selection mode for the LevelStep, specified as one of these values:

- `'auto'` — Determine the value based on the `ZData` values.
- `'manual'` — Use a manually specified value. To specify the value, set the LevelStep property. When the mode is manual, the `contour` function does not change the value as you change `ZData`.

Contour Labels

`ShowText` — Contour line labels

`'off'` (default) | `'on'`

Contour line labels, specified as one of these values:

- `'off'` — Do not label the contour lines.
- `'on'` — Display text labels on each contour line indicating the contour value.

`LabelSpacing` — Spacing between contour line labels

144 (default) | numeric scalar

Spacing between contour line labels, specified as a numeric scalar in point units. One point equals 1/72 inch. You must set the `ShowText` property to `'on'` for the `LabelSpacing` property to have an effect.

If you use the `clabel` function to display the labels, then the `LabelSpacing` property has no effect. The contour plot contains a single label per line instead.

Example: `36`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TextList` — Contour lines to label

empty matrix (default) | vector of real values

Contour lines to label, specified as a vector of real values.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TextListMode` — Selection mode for `TextList`

`'auto'` (default) | `'manual'`

Selection mode for the TextList, specified as one of these values:

- `'auto'` — Use values equal to the values of the LevelList property. The contour plot includes a text label for each line.
- `'manual'` — Use manually specified values. Specify the values by setting the TextList property.

`TextStep` — Interval between labeled contour lines

0 (default) | scalar numeric value

Interval between labeled contour lines, specified as a scalar numeric value. By default, the contour plot includes a label for every contour line when the `ShowText` property is set to `'on'`.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`TextStepMode` — Selection mode for `TextStep`

`'auto'` (default) | `'manual'`

Selection mode for the TextStep, specified as one of these values:

- `'auto'` — Determine value based on the `ZData` values. If the `ShowText` property is set to `'on'`, then the `contour` function labels every contour line.
- `'manual'` — Use a manually specified value. To specify the value, set the TextStep property.

Filled Contours

`Fill` — Fill between contour lines

`'off'` (default) | `'on'`

Fill between contour lines, specified as one of these values:

- `'off'` — Do not fill the spaces between contour lines with a color. This is the default value when you create the contour chart using the `contour` or `contour3` functions.
- `'on'` — Fill the spaces between contour lines with color. This is the default value when you create the contour chart using the `contourf` function.

Contour Matrix

`ContourMatrix` — Contour line definitions

[ ] (default) | two-row matrix

Contour line definitions, returned as a two-row matrix. Each contour line in the plot has an associated definition. If there are a total of `N` contour lines in the plot, then the contour matrix consists of `N` definitions:

```
C = [C(1) C(2)...C(k)...C(N)]
```

Each contour line definition follows this pattern:

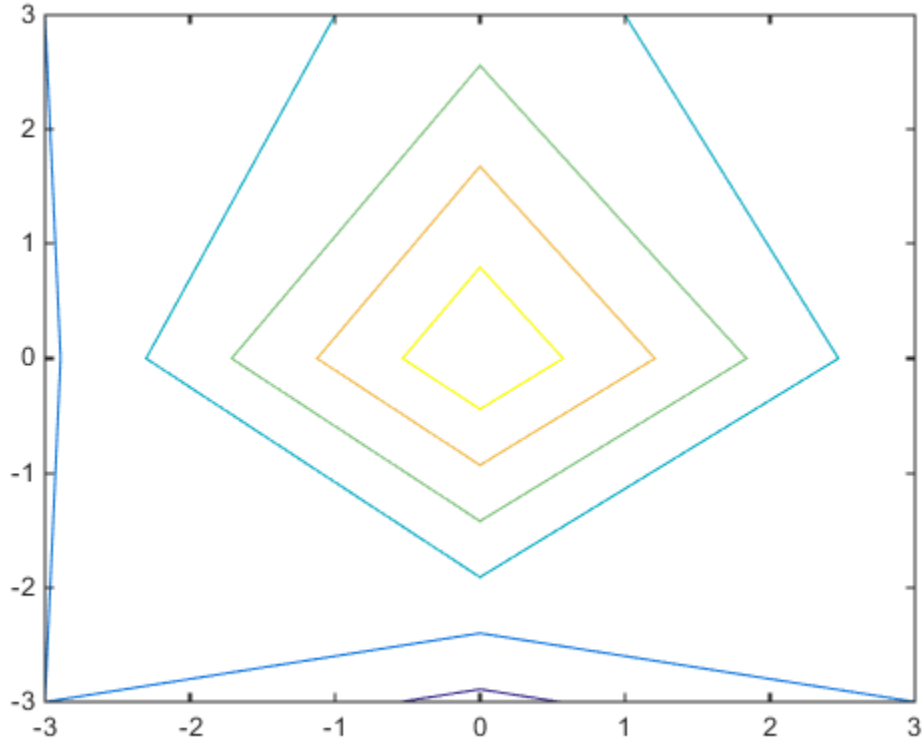
```
C(k) = [level   x(1) x(2)...
        numxy   y(1) y(2)... ]
```

The first entry, `level`, indicates the contour level where the contour line is drawn. Beneath the contour level is the number of (*x*,*y*) vertices that define the contour line. The remaining columns contain the data for each of the vertices. If the first and last vertices are the same, then the contour line is a closed loop. If a particular contour level has multiple contour lines in the graph, then the matrix contains a separate definition for each line.

Example

Create a contour plot of values from the `peaks` function.

```
[x,y,z] = peaks(3);
[C,h] = contour(x,y,z);
```



Access the contour matrix using either the output argument `C` or the `ContourMatrix` property of the contour object (`h.ContourMatrix`). The contour matrix contains definitions for each of the seven contour lines. The circles in this matrix show the beginnings of the contour line definitions.

```
C =

  Columns 1 through 8

   -0.2000    1.8165    2.0000    2.1835         0    1.0003    2.0000    3.0000
    3.0000    1.0000    1.0367    1.0000    3.0000    1.0000    1.1998    1.0002

  Columns 9 through 16

         0    1.0000    1.0359    1.0000    0.2000    1.6669    1.2324    2.0000
    3.0000    2.9991    2.0000    1.0018    5.0000    3.0000    2.0000    1.3629

  Columns 17 through 24

    2.8240    2.3331    0.4000    1.4290    2.0000    2.6130    2.0000    1.4290
    2.0000    3.0000    5.0000    2.0000    1.5261    2.0000    2.8530    2.0000

  Columns 25 through 32

    0.6000    1.6255    2.0000    2.4020    2.0000    1.6255    0.8000    1.8221
    5.0000    2.0000    1.6892    2.0000    2.5594    2.0000    5.0000    2.0000

  Columns 33 through 36

    2.0000    2.1910    2.0000    1.8221
    1.8524    2.0000    2.2657    2.0000
```

The first definition in the matrix indicates that there is a contour line drawn at the -0.2 level , consisting of the three vertices `(1.8165,1)`, `(2,1.0367)`, and `(2.1835,1)`. Since the first and last vertices are not the same, the contour line is not a closed loop. The second and third definitions indicate that there are two closed loops at the 0 level.

Data

`XData` — x values

[ ] (default) | vector or matrix

x values, specified as a vector or matrix.

- If `XData` is a vector, then `length(XData)` must equal `size(ZData,2)` and YData must also be a vector. The `XData` values must be strictly increasing or strictly decreasing and cannot contain any duplicates.
- If `XData` is a matrix, then `size(XData)` and `size(YData)` must equal `size(ZData)`. Typically, you should set the `XData` values so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`YData` — y values

[ ] (default) | vector or matrix

y values, specified as a vector or matrix.

- If `YData` is a vector, then `length(YData)` must equal `size(ZData,1)` and XData must also be a vector. The `XData` values must be strictly increasing or strictly decreasing and cannot contain any duplicates.
- If `YData` is a matrix, then `size(XData)` and `size(YData)` must equal `size(ZData)`. Typically, you should set the `YData` values so that the columns are strictly increasing or strictly decreasing and the rows are uniform (or the rows are strictly increasing or strictly decreasing and the columns are uniform).

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`ZData` — Data that defines surface to contour

[ ] (default) | matrix

Data that defines the surface to contour, specified as a matrix. `ZData` must be at least a 2-by-2 matrix.

Setting this property sets the associated mode property to manual.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`XDataSource` — Variable linked to `XData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `XData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `XData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `XData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'x'`

`YDataSource` — Variable linked to `YData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `YData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `YData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `YData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'y'`

`ZDataSource` — Variable linked to `ZData`

`''` (default) | string containing MATLAB workspace variable name

Variable linked to `ZData`, specified as a string containing a MATLAB workspace variable name. MATLAB evaluates the variable in the base workspace to generate the `ZData`.

By default, there is no linked variable so the value is an empty string, `''`. If you link a variable, then MATLAB does not update the `ZData` values immediately. To force an update of the data values, use the `refreshdata` function.

Note: If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Example: `'z'`

`XDataMode` — Selection mode for `XData`

`'auto'` (default) | `'manual'`

Selection mode for the `XData`, specified as one of these values:

- `'auto'` — Set the `XData` using the column indices of `ZData`.
- `'manual'` — Use manually specified values. To specify the values, set the `XData` property directly, or specify the input argument `X` to the `contour`, `contourf`, or `contour3` function.

`YDataMode` — Selection mode for `XData`

`'auto'` (default) | `'manual'`

Selection mode for the `YData`, specified as one of these values:

- `'auto'` — Set the `YData` using the row indices of `ZData`.
- `'manual'` — Use manually specified values. To specify the values, set the `YData` property directly, or specify the input argument `Y` to the `contour`, `contourf`, or `contour3` function.

Visibility

`Visible` — Visibility of contour

`'on'` (default) | `'off'`

Visibility of contour, specified as one of these values:

- `'on'` — Display the contour.

- `'off'` — Hide the contour without deleting it. You still can access the properties of an invisible contour object.

`Clipping` — Clipping of contour to axes limits

`'on'` (default) | `'off'`

Clipping of contour to the axes limits, specified as one of these values:

- `'on'` — Do not display parts of the contour that are outside the axes limits.
- `'off'` — Display the entire contour, even if parts of it appear outside the axes limits. Parts of the contour might appear outside the axes limits if you create a plot, set `hold on`, freeze the axis scaling, and then create the contour that is larger than the original plot.

`EraseMode` — (removed) Technique to draw and erase objects

`'normal'` (default) | `'none'` | `'xor'` | `'background'`

Note: `EraseMode` has been removed. You can delete code that accesses the `EraseMode` property with minimal impact. If you were using `EraseMode` to create line animations, use the `animatedline` function instead.

Technique to draw and erase objects, specified as one of these values:

- `'normal'` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and, therefore, are less accurate.
- `'none'` — Do not erase the object when it is moved or destroyed. After you erase the object with `EraseMode,'none'`, it is still visible on the screen. However, you cannot print the object because MATLAB does not store any information on its former location.
- `'xor'` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object color depends on the color of whatever is beneath it on the display.
- `'background'` — Erase the object by redrawing it in the axes background color, or the figure background color if the axes `Color` property is `'none'`. This damages objects that are behind the erased object, but properly colors the erased object.

MATLAB always prints figures as if the `EraseMode` property of all objects is set to `'normal'`. This means graphics objects created with `EraseMode` set to `'none'`, `'xor'`, or `'background'` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors and ignores three-dimensional sorting to obtain greater rendering speed. However, MATLAB does not apply these techniques to the printed output. Use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

Identifiers

`Type` — Type of graphics object

`'contour'`

Type of graphics object, returned as the string `'contour'`.

`Tag` — User-specified tag

`''` (default) | any string

Tag to associate with the contour, specified as a string. Tags provide a way to identify graphics objects. Use this property to find all objects with a specific tag within a plotting hierarchy, for example, searching for the tag using `findobj`.

Example: `'January Data'`

`UserData` — Data to associate with contour

`[]` (default) | scalar, vector, or matrix | cell array | character array | table | structure

Data to associate with the contour object, specified as a scalar, vector, matrix, cell array, character array, table, or structure. MATLAB does not use this data.

To associate multiple sets of data or to attach a field name to the data, use the `getappdata` and `setappdata` functions.

Example: `1:100`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `table` | `cell`

`DisplayName` — Text used by legend

`''` (default) | string

Text used by the legend, specified as a string. The text appears next to an icon of the contour.

Example: `'Text Description'`

For multiline text, create the string using `sprintf` with the new line character `\n`.

Example: `sprintf('line one\nline two')`

Alternatively, you can specify the legend text using the `legend` function.

- If you specify the text as an input argument to the `legend` function, then the legend uses the specified text and sets the `DisplayName` property to the same value.
- If you do not specify the text as an input argument to the `legend` function, then the legend uses the text in the `DisplayName` property. If the `DisplayName` property does not contain any text, then the legend generates a string. The string has the form `'dataN'`, where `N` is the number assigned to the contour object based on its location in the list of legend entries.

If you edit interactively the string in an existing legend, then MATLAB updates the `DisplayName` property to the edited string.

`Annotation` — Legend icon display style

`Annotation` object

Legend icon display style, returned as an `Annotation` object. Use this object to include or exclude the contour from a legend.

1. Query the `Annotation` property to get the `Annotation` object.
2. Query the `LegendInformation` property of the `Annotation` object to get the `LegendEntry` object.
3. Specify the `IconDisplayStyle` property of the `LegendEntry` object to one of these values:
   - `'on'` — Include the contour object in the legend as one entry (default).
   - `'off'` — Do not include the contour object in the legend.
   - `'children'` — Include only children of the contour object as separate entries in the legend.

If a legend already exists and you change the `IconDisplayStyle` setting, then you must call `legend` to update the display.

Parent/Child

`Parent` — Parent of contour

axes object | group object | transform object

Parent of contour, specified as an axes, group, or transform object.

`Children` — Children of contour

empty `GraphicsPlaceholder` array

The contour has no children. You cannot set this property.

`HandleVisibility` — Visibility of object handle

`'on'` (default) | `'off'` | `'callback'`

Visibility of contour object handle in the `Children` property of the parent, specified as one of these values:

- `'on'` — The contour object handle is always visible.
- `'off'` — The contour object handle is invisible at all times. This option is useful for preventing unintended changes to the UI by another function. Set the HandleVisibility to `'off'` to temporarily hide the handle during the execution of that function.
- `'callback'` — The contour object handle is visible from within callbacks or functions invoked by callbacks, but not from within functions invoked from the command line. This option blocks access to the contour at the command-line, but allows callback functions to access it.

If the contour object is not listed in the `Children` property of the parent, then functions that obtain object handles by searching the object hierarchy or querying handle properties cannot return it. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Hidden object handles are still valid. Set the root ShowHiddenHandles property to `'on'` to list all object handles regardless of their HandleVisibility property setting.

Interactive Control

`ButtonDownFcn` — Mouse-click callback

`''` (default) | function handle | cell array | string

Mouse-click callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you click the contour. If you specify this property using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The contour object — You can access properties of the contour object from within the callback function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then this callback does not execute.

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`UIContextMenu` — Context menu

uicontextmenu object

Context menu, specified as a uicontextmenu object. Use this property to display a context menu when you right-click the contour. Create the context menu using the `uicontextmenu` function.

Note: If the PickableParts property is set to `'none'` or if the HitTest property is set to `'off'`, then the context menu does not appear.

`Selected` — Selection state

`'off'` (default) | `'on'`

Selection state, specified as one of these values:

- `'on'` — Selected. If you click the contour when in plot edit mode, then MATLAB sets its `Selected` property to `'on'`. If the SelectionHighlight property also is set to `'on'`, then MATLAB displays selection handles around the contour.
- `'off'` — Not selected.

`SelectionHighlight` — Display of selection handles when selected

`'on'` (default) | `'off'`

Display of selection handles when selected, specified as one of these values:

- `'on'` — Display selection handles when the Selected property is set to `'on'`.
- `'off'` — Never display selection handles, even when the Selected property is set to `'on'`.

Callback Execution Control

`PickableParts` — Ability to capture mouse clicks

`'visible'` (default) | `'none'`

Ability to capture mouse clicks, specified as one of these values:

- `'visible'` — Can capture mouse clicks only when visible. The Visible property must be set to `'on'`. The HitTest property determines if the contour responds to the click or if an ancestor does.
- `'none'` — Cannot capture mouse clicks. Clicking the contour passes the click to the object below it in the current view of the figure window. The HitTest property of the contour has no effect.

`HitTest` — Response to captured mouse clicks

`'on'` (default) | `'off'`

Response to captured mouse clicks, specified as one of these values:

- `'on'` — Trigger the ButtonDownFcn callback of the contour. If you have defined the UIContextMenu property, then invoke the context menu.
- `'off'` — Trigger the callbacks for the nearest ancestor of the contour that has a HitTest property set to `'on'` and a `PickableParts` property value that enables the ancestor to capture mouse clicks.

Note: The PickableParts property determines if the contour object can capture mouse clicks. If it cannot, then the `HitTest` property has no effect.

`HitTestArea` — (removed) Extents of clickable area for contour

`'off'` (default) | `'on'`

Note: `HitTestArea` has been removed. Use PickableParts instead.

Extents of clickable area for contour, specified as one of these values:

- `'off'` — Click the contour plot to select it. This is the default value.
- `'on'` — Click anywhere within the extent of the contour plot to select it, that is, anywhere within the rectangle that encloses the contour plot.

Example: `'off'`

`Interruptible` — Callback interruption

`'on'` (default) | `'off'`

Callback interruption, specified as `'on'` or `'off'`. The `Interruptible` property determines if a running callback can be interrupted.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.

- The *interrupting* callback is a callback that tries to interrupt the running callback. Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the contour is the running callback, then the `Interruptible` property determines if it another callback can interrupt it:

- `'on'` — Interruptible. Interruption occurs at the next point where MATLAB processes the queue, such as when there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command.
  - If the running callback contains one of these commands, then MATLAB stops the execution of the callback at this point and executes the interrupting callback. MATLAB resumes executing the running callback when the interrupting callback completes. For more information, see "Interrupt Callback Execution".
  - If the running callback does not contain one of these commands, then MATLAB finishes executing the callback without interruption.
- `'off'` — Not interruptible. MATLAB finishes executing the running callback without any interruptions.

`BusyAction` — Callback queuing

`'queue'` (default) | `'cancel'`

Callback queuing specified as `'queue'` or `'cancel'`. The `BusyAction` property determines how MATLAB handles the execution of interrupting callbacks.

Note: There are two callback states to consider:

- The *running* callback is the currently executing callback.
- The *interrupting* callback is a callback that tries to interrupt the running callback.

Whenever MATLAB invokes a callback, that callback attempts to interrupt a running callback. The Interruptible property of the object owning the running callback determines if interruption is allowed. If interruption is not allowed, then the `BusyAction` property of the object owning the interrupting callback determines if it is discarded or put in the queue.

If the `ButtonDownFcn` callback of the contour tries to interrupt a running callback that cannot be interrupted, then the `BusyAction` property determines if it is discarded or put in the queue. Specify the `BusyAction` property as one of these values:

- `'queue'` — Put the interrupting callback in a queue to be processed after the running callback finishes execution. This is the default behavior.
- `'cancel'` — Discard the interrupting callback.

Creation and Deletion Control

`CreateFcn` — Creation callback

`''` (default) | function handle | cell array | string

Creation callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you create the contour. Setting the `CreateFcn` property on an existing contour has no effect. You must define a default value for this property, or define this property using a `Name,Value` pair during contour creation. MATLAB executes the callback after creating the contour and setting all of its properties.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The contour object — You can access properties of the contour object from within the callback function. You also can access the contour object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`DeleteFcn` — Deletion callback

`''` (default) | function handle | cell array | string

Deletion callback, specified as one of these values:

- Function handle
- Cell array containing a function handle and additional arguments
- String that is a valid MATLAB command or function, which is evaluated in the base workspace (not recommended)

Use this property to execute code when you delete the contour. MATLAB executes the callback before destroying the contour so that the callback can access its property values.

If you specify this callback using a function handle, then MATLAB passes two arguments to the callback function when executing the callback:

- The contour object — You can access properties of the contour object from within the callback function. You also can access the contour object through the `CallbackObject` property of the root, which can be queried using the `gcbo` function.
- Event data — This argument is empty for this property. Replace it with the tilde character (~) in the function definition to indicate that this argument is not used.

For more information on how to use function handles to define callback functions, see "Callback Definition".

Example: `@myCallback`

Example: `{@myCallback,arg3}`

`BeingDeleted` — Deletion status of contour

`'off'` (default) | `'on'`

Deletion status of contour, returned as `'on'` or `'off'`. MATLAB sets the BeingDeleted property to `'on'` when the delete function of the contour begins execution (see the DeleteFcn property). The BeingDeleted property remains set to `'on'` until the contour no longer exists.

Check the value of the BeingDeleted property to verify that the contour is not about to be deleted before querying or modifying it.

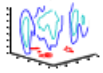
contourslice

Draw contours in volume slice planes



Syntax

```
contourslice(X,Y,Z,V,Sx,Sy,Sz)
contourslice(X,Y,Z,V,Xi,Yi,Zi)
contourslice(V,Sx,Sy,Sz)
contourslice(V,Xi,Yi,Zi)
contourslice(...,n)
contourslice(...,cvals)
contourslice(...,[cv cv])
contourslice(...,'method')
contourslice(axes_handle,...)
h = contourslice(...)
```

Description

`contourslice(X,Y,Z,V,Sx,Sy,Sz)` draws contours in the *x*-, *y*-, and *z*-axis aligned planes at the points in the vectors `Sx`, `Sy`, `Sz`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V` and must be monotonic and represent a Cartesian, axis-aligned grid (such as the data produced by `meshgrid`). The color at each contour is determined by the volume `V`, which must be an m-by-n-by-p volume array.

`contourslice(X,Y,Z,V,Xi,Yi,Zi)` draws contours through the volume `V` along the surface defined by the 2-D arrays `Xi,Yi,Zi`. The surface should lie within the bounds of the volume.

`contourslice(V,Sx,Sy,Sz)` and `contourslice(V,Xi,Yi,Zi)` (omitting the `X`, `Y`, and `Z` arguments) assume `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p]= size(v)`.

`contourslice(...,n)` draws `n` contour lines per plane, overriding the automatic value.

`contourslice(...,cvals)` draws `length(cval)` contour lines per plane at the values specified in vector `cvals`.

`contourslice(...,[cv cv])` computes a single contour per plane at the level `cv`.

`contourslice(...,'method')` specifies the interpolation method to use. *`method`* can be `linear`, `cubic`, or `nearest`. `nearest` is the default except when the contours are being drawn along the surface defined by `Xi`, `Yi`, `Zi`, in which case `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`contourslice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = contourslice(...)` returns a vector of handles to `patch` objects that are used to implement the contour lines.

Examples

Contour Slices of Fluid Flow

Store the matrices `X`, `Y`, `Z`, and `V` from the `flow` data set.

```
[X,Y,Z,V] = flow;
```

Create nine contour plots in the y-z plane, no plots in the x-z plane, and one plot in the x-y plane by specifying `Sx` as a vector of nine elements, `Sy` as an empty vector, and `Sz` as a scalar.

```
Sx = 1:9;
Sy = [];
Sz = 0;
```

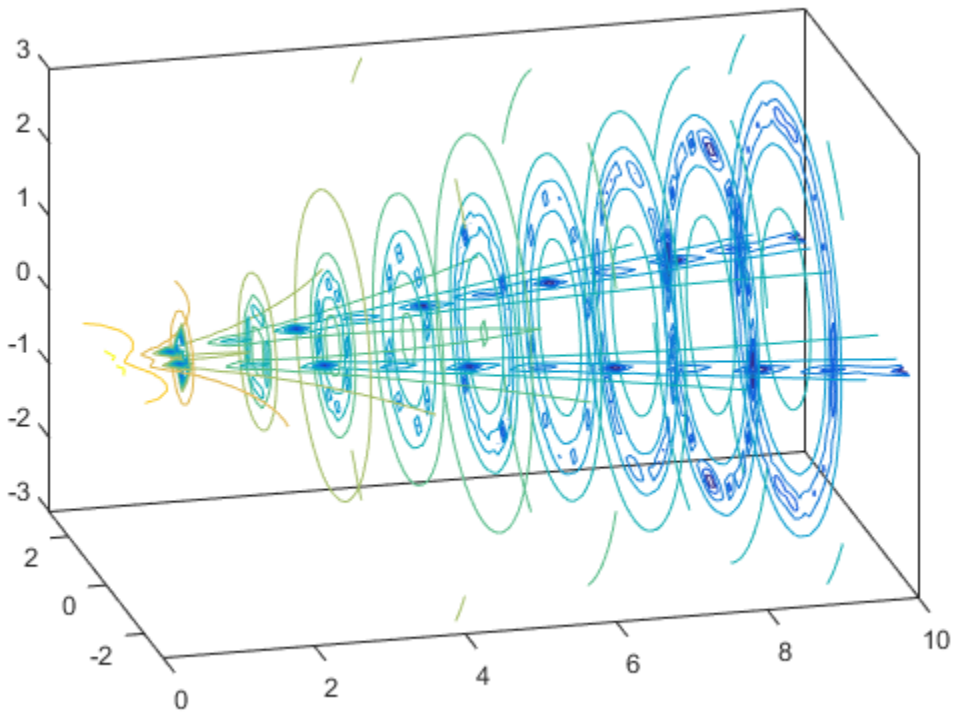
Draw 10 contour lines between -8 and 2 by specifying `cvals` as a 10-element vector of linearly spaced values between -8 and 2.

```
cvals = linspace(-8,2,10);
```

Create the contour slice plots and set the axis limits. Set the data aspect ratio, change the camera position, and display the black box outline.

```
figure
contourslice(X,Y,Z,V,Sx,Sy,Sz,cvals)
```

```
axis([0,10,-3,3,-3,3])
daspect([1,1,1])
campos([0,-20,7])
box on
```



Contour Slices Along Spherical Surface

Set up matrices `X`, `Y`, and `Z` using the `meshgrid` function.

```
x = -2:0.2:2;
y = -2:0.25:2;
z = -2:0.16:2;
[X,Y,Z] = meshgrid(x,y,z);
```

Use `X`, `Y`, and `Z` to define `V` as a matrix of volume data.

```
V = X.*exp(-X.^2-Y.^2-Z.^2);
```

Return matrices `Xi`, `Yi`, and `Zi` from the `sphere` function.

```
[Xi,Yi,Zi] = sphere;
```

Draw contours through the volume `V` along the surface defined by `Xi`, `Yi`, and `Zi`. Change the plot view to a 3-D view.

```
contourslice(X,Y,Z,V,Xi,Yi,Zi)
view(3)
```

Introduced before R2006a

matlab.unittest.constraints

Summary of classes in MATLAB Constraints Interface

Description

Constraints specify business rules against which to qualify a calculated value. Use constraints in conjunction with the `matlab.unittest.qualifications` qualification methods `assertThat`, `assumeThat`, `fatalAssertThat`, or `verifyThat`. Constraints determine whether or not a calculated (actual) value satisfies the constraint. Constraints also provide diagnostics. The `matlab.unittest.constraints` package consists of the following classes.

Constraint Implementations

Fundamental Constraint-Related Interfaces

matlab.unittest.constraints.BooleanConstraint	Interface class for boolean combinations of constraints
matlab.unittest.constraints.Constraint	Fundamental interface class for comparisons

General Purpose

matlab.unittest.constraints.Eventually	Poll for value to asynchronously satisfy constraint
matlab.unittest.constraints.HasField	Constraint specifying structure containing particular field

matlab.unittest.constraints.IsAnything
: Constraint specifying any value

matlab.unittest.constraints.IsFalse
: Constraint specifying false value

matlab.unittest.constraints.IsEqualTo
: General constraint to compare for equality

matlab.unittest.constraints.IsSameHandleAs
: Constraint specifying handle instance same as another

matlab.unittest.constraints.IsTrue
: Constraint specifying true value

matlab.unittest.constraints.ReturnsTrue
: Constraint specifying function handle that returns true

Errors and Warnings

matlab.unittest.constraints.IssuesNoWarnings
: Constraint specifying function that issues no warnings

matlab.unittest.constraints.IssuesWarnings
: Constraint specifying function that issues expected warning profile

matlab.unittest.constraints.Throws
: Constraint specifying function handle that throws MException

Inequalities

matlab.unittest.constraints.IsGreaterThan
: Constraint specifying value greater than another value

matlab.unittest.constraints.IsGreaterThanOrEqualTo
: Constraint specifying value greater than or equal to another value

matlab.unittest.constraints.IsLessThan
: Constraint specifying value less than another value

matlab.unittest.constraints.IsLessThanOrEqualTo
: Constraint specifying value less than or equal to another value

Array Size

matlab.unittest.constraints.HasElementCount
: Constraint specifying expected number of elements

matlab.unittest.constraints.HasLength
: Constraint specifying expected length of array

matlab.unittest.constraints.HasSize
: Constraint specifying expected size of array

matlab.unittest.constraints.IsEmpty
: Constraint specifying empty value

matlab.unittest.constraints.IsScalar
: Constraint specifying scalar value

Type

matlab.unittest.constraints.IsInstanceOf
: Constraint specifying inclusion in given class hierarchy

matlab.unittest.constraints.IsOfClass
: Constraint specifying class type

Strings

matlab.unittest.constraints.ContainsSubstring
: Constraint specifying string containing substring

matlab.unittest.constraints.EndsWithSubstring
: Constraint specifying string ending with substring

matlab.unittest.constraints.IsSubstringOf
: Constraint specifying substring of another string

matlab.unittest.constraints.Matches
: Constraint specifying string matches regular expression

matlab.unittest.constraints.StartsWithSubstring
: Constraint specifying string starting with substring

Finiteness

matlab.unittest.constraints.HasInf
: Constraint specifying array containing any infinite value

matlab.unittest.constraints.HasNaN
: Constraint specifying array containing NaN value

matlab.unittest.constraints.IsFinite
: Constraint specifying finite value

Numeric Attributes

matlab.unittest.constraints.IsReal
: Constraint specifying real valued array

matlab.unittest.constraints.IsSparse
: Constraint specifying sparse array

Actual Value Proxies

matlab.unittest.constraints.AnyCellOf
: Test if any element of cell array meets constraint

matlab.unittest.constraints.AnyElementOf
: Test if any element of array meets constraint

matlab.unittest.constraints.EveryCellOf
: Test if all elements of cell array meet constraint

matlab.unittest.constraints.EveryElementOf
: Test if all elements of array meet constraint

Tolerances

matlab.unittest.constraints.AbsoluteTolerance
: Absolute numeric tolerance

matlab.unittest.constraints.RelativeTolerance
: Relative numeric tolerance

matlab.unittest.constraints.Tolerance
: Abstract interface class for tolerances

Comparators

matlab.unittest.constraints.CellComparator
: Comparator for cell arrays

matlab.unittest.constraints.LogicalComparator
: Comparator for two logical values

matlab.unittest.constraints.NumericComparator
: Comparator for numeric data types

matlab.unittest.constraints.ObjectComparator
: Comparator for MATLAB or Java objects

matlab.unittest.constraints.PublicPropertyComparator
: Comparator for public properties of MATLAB objects

matlab.unittest.constraints.StringComparator
: Comparator for two strings

matlab.unittest.constraints.StructComparator

Comparator for MATLAB structure arrays

matlab.unittest.constraints.AbsoluteTolerance class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Tolerance

Absolute numeric tolerance

Description

This numeric `Tolerance` assesses the magnitude of the difference between actual and expected values. For the tolerance to be satisfied, `abs(expVal - actVal) <= absTol` must be true.

Construction

`AbsoluteTolerance(tolVals)` creates an absolute tolerance object that assesses the magnitude of the difference between the actual and expected values.

The data types of the inputs to the `AbsoluteTolerance` constructor determines which data types the tolerance supports. For example, `AbsoluteTolerance(10*eps)` constructs an `AbsoluteTolerance` for comparing double-precision numeric arrays, while `AbsoluteTolerance(int8(2))` constructs an `AbsoluteTolerance` for comparing numeric arrays of type `int8`. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.

To specify different tolerance values for different data types, you can pass multiple tolerance values to the constructor. For example, `AbsoluteTolerance(10*eps, 10*eps('single'), int8(1))` constructs an `AbsoluteTolerance` object applies the following absolute tolerances:

- `10*eps` applies an absolute tolerance of `10*eps` for double-precision numeric arrays.
- `10*eps('single')` applies an absolute tolerance of `10*eps` for single-precision numeric arrays.
- `int8(1)` applies an absolute tolerance of `1` for numeric arrays of type `int8`.

You can specify more than one tolerance for a particular data type by combining tolerances with the & and | operators. To combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

Input Arguments

`tolVals`

Numeric tolerances, specified as a comma-separated list of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array can be a scalar or array the same size as the actual and expected values.

Default:

Properties

`Values`

Numeric tolerances, specified by the `tolVals` input argument

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test with Absolute Tolerance

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance

testCase = TestCase.forInteractiveUse;
```

Assert that the difference between an actual value, `4.1`, and an expected value, `4.5`, is less than `0.5`.

```
testCase.assertThat(4.1, IsEqualTo(4.5, ...
    'Within', AbsoluteTolerance(0.5)))
```

```
Interactive assertion passed.
```

Specify Absolute Tolerance for Different Data Types

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance

testCase = TestCase.forInteractiveUse;
```

Create the following actual and expected cell arrays.

```
act = {'abc', 123, single(106), int8([1, 2, 3])};
exp = {'abc', 122, single(105), int8([2, 4, 6])};
```

Test whether the arrays satisfy the `AbsoluteTolerance` constraint within a value of `2`.

```
testCase.verifyThat(act, IsEqualTo(exp, ...
    'Within', AbsoluteTolerance(2)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    Path to failure: <Value>{3}
    --> The values are not equal using "isequaln".
    --> The tolerance does not support single values so it was not used.
    --> Failure table:
                Index    Actual    Expected    Error    RelativeError
                _____    ______    ________    _____    _____________

                1        106       105         1        0.00952381

    Actual Value:
```

```
           106
    Expected Value:
           105

Actual cell:
        'abc'    [123]    [106]    [1x3 int8]
Expected cell:
        'abc'    [122]    [105]    [1x3 int8]
```

The test fails because the tolerance is only applied to the `double` data type.

Create a tolerance object that specifies different tolerances for different data types.

```
tolObj = AbsoluteTolerance(2, single(3), int8([2, 3, 5]));
```

A tolerance of `2` is a applied to `double` valued data. A tolerance of `3` is applied to `single` valued data. A tolerance of `[2 3 5]` is applied to corresponding array elements of `int8` valued data.

Verify that the expected and actual values satisfy the `AbsoluteTolerance` constraint.

```
testCase.verifyThat(act, IsEqualTo(exp, 'Within', tolObj))
```

```
Interactive verification passed.
```

Combine Absolute and Relative Tolerances

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance

testCase = TestCase.forInteractiveUse;
```

Define an actual value approximation for `pi`.

```
act = 3.14;
```

Construct a tolerance object to test that the difference between the actual and expected values is within `0.001` and within `0.25%`.

```
tolObj = AbsoluteTolerance(0.001) & RelativeTolerance(0.0025);
```

Verify that the actual value is within the tolerance of the expected value of `pi`.

```
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> AndTolerance failed.
        --> AbsoluteTolerance failed.
            --> The error was not within absolute tolerance.
        --> RelativeTolerance passed.
        --> Failure table:
                    Index    Actual        Expected               Error
                    _____    ______    _________________    ____________________    ____

                    1        3.14      3.14159265358979    -0.00159265358979299    -0.0

Actual Value:
       3.140000000000000
Expected Value:
       3.141592653589793
```

The actual value does not satisfy the `AbsoluteTolerance` constraint.

Construct a constraint that is satisfied if the values are within `0.001` or `0.25%`, and then retest the actual value.

```
tolObj = AbsoluteTolerance(0.001) | RelativeTolerance(0.0025);
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))

Interactive verification passed.
```

Combine Absolute and Relative Tolerances to Test Small and Large Values

Combine tolerances so when you test the equality of values, an absolute (floor) tolerance dominates when the values are near zero, and a relative tolerance dominates for larger values.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
```

```
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance

testCase = TestCase.forInteractiveUse;
```

Define two structures containing electromagnetic properties of a vacuum. One structure, `approxVacuumProps`, contains approximate values for the permeability and speed of light in a vacuum.

```
approxVacuumProps.Permeability = 1.2566e-06; % Approximate
approxVacuumProps.Permitivity = 8.854187817*10^-12;
approxVacuumProps.LightSpeed = 2.9979e+08; % Approximate

baselineVacuumProps.Permeability = 4*pi*10^-7;
baselineVacuumProps.Permitivity = 8.854187817*10^-12;
baselineVacuumProps.LightSpeed = 1/sqrt(...
    baselineVacuumProps.Permeability*baselineVacuumProps.Permitivity);
```

Test that the relative difference between the approximate and baseline values is within `eps*1e11`.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', RelativeTolerance(eps*1e11)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    Path to failure: <Value>.Permeability
    --> The values are not equal using "isequaln".
    --> RelativeTolerance failed.
        --> The error was not within relative tolerance.
        --> Failure table:
                    Index      Actual            Expected                  Error
                    _____    __________    ______________________    ____________________

                    1        1.2566e-06    1.25663706143592e-06    -3.70614359173257e-

    Actual Value:
             1.256600000000000e-06
    Expected Value:
             1.256637061435917e-06
```

```
Actual struct:
        Permeability: 1.256600000000000e-06
         Permitivity: 8.854187816999999e-12
          LightSpeed: 299790000
Expected struct:
        Permeability: 1.256637061435917e-06
         Permitivity: 8.854187816999999e-12
          LightSpeed: 2.997924580105029e+08
```

The test fails because the relative difference in the permeabilities is not within the tolerance. The difference between the two values is small, but the numbers are close to zero, so the difference relative to their size is not small enough to satisfy the tolerance.

Construct a tolerance object to test that the absolute difference between the approximate and baseline values is within `1e-4`.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', AbsoluteTolerance(1e-4)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    Path to failure: <Value>.LightSpeed
    --> The values are not equal using "isequaln".
    --> AbsoluteTolerance failed.
        --> The error was not within absolute tolerance.
        --> Failure table:
                    Index     Actual          Expected              Error             R
                    _____    _________    _________________    _________________    ___

                    1        299790000    299792458.010503    -2458.01050287485    -8.1

    Actual Value:
           299790000
    Expected Value:
             2.997924580105029e+08

Actual struct:
        Permeability: 1.256600000000000e-06
         Permitivity: 8.854187816999999e-12
```

```
          LightSpeed: 299790000
Expected struct:
        Permeability: 1.256637061435917e-06
         Permitivity: 8.854187816999999e-12
          LightSpeed: 2.997924580105029e+08
```

The test fails because the absolute difference in the speed of light is not within the tolerance. The difference between the two values is small relative to their size, but too large to satisfy the tolerance.

Construct a logical disjunction of tolerance objects to test that the absolute difference between the approximate and baseline values is within `1e-4` or the relative difference is within `eps*1e11`. The test uses this tolerance so permeability values that are close to zero satisfy the absolute (floor) tolerance, and speed of light values that are large, satisfy the relative tolerance.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', RelativeTolerance(eps*1e11)| AbsoluteTolerance(1e-4)))
```

```
Interactive verification passed.
```

matlab.unittest.constraints.AnyCellOf class

Package: matlab.unittest.constraints

Test if any element of cell array meets constraint

Description

The `AnyCellOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of a cell array, which ensures that a passing result occurs if at least one element of the cell array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

Construction

`AnyCellOf(actVal)` creates a proxy instance that tests if any element of a provided cell array, `actVal`, meets a constraint. The test passes if at least one element individually satisfies the constraint.

Input Arguments

`actVal`

Actual value to test against constraint

Properties

`ActualValue`

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Any Cell Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.AnyCellOf

testCase = TestCase.forInteractiveUse;
```

Test that at least one cell of `actVal` is finite.

```
import matlab.unittest.constraints.IsFinite
actVal = {NaN, Inf, 5};
testCase.verifyThat(AnyCellOf(actVal), IsFinite)
```

```
Interactive verification passed.
```

Test that at least one cell of the actual value contains five elements.

```
import matlab.unittest.constraints.HasElementCount
testCase.verifyThat(AnyCellOf({42, [11 38], 1:5}), HasElementCount(5))
```

```
Interactive verification passed.
```

Test that at least one cell of the actual value matches the string `'tea'` regardless of case.

```
import matlab.unittest.constraints.Matches
testCase.verifyThat(AnyCellOf({'Coffee','Tea','Water'}), ...
    Matches('tea','IgnoringCase',true))
```

```
Interactive verification passed.
```

Test that at least one cell of the actual value is less than zero.

```
import matlab.unittest.constraints.IsLessThan
```

```
testCase.verifyThat(AnyCellOf({1, 5}), IsLessThan(0))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
All cells failed. The first cell failed because:
--> IsLessThan failed.
    --> The value must be less than the maximum value.

    Actual Value:
             1
    Maximum Value (Exclusive):
             0

Actual Value Cell Array:
       [1]    [5]
```

Neither actual value element is less than zero.

Test that neither cell of the actual value is empty.

```
import matlab.unittest.constraints.IsEmpty
testCase.verifyThat(AnyCellOf({inputParser.empty,''}), ~IsEmpty)

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
All cells failed. The first cell failed because:
--> Negated IsEmpty failed.
    --> The value must not be empty.
    --> The value has a size of [0  0].

    Actual Value:
          0x0 inputParser array with properties:

            FunctionName
            CaseSensitive
            KeepUnmatched
            PartialMatching
            StructExpand
            Parameters
```

```
            Results
            Unmatched
            UsingDefaults

Actual Value Cell Array:
        []    ''
```

Both actual value elements are empty.

AnyElementOf | EveryCellOf | EveryElementOf | matlab.unittest.qualifications

matlab.unittest.constraints.AnyElementOf class

Package: matlab.unittest.constraints

Test if any element of array meets constraint

Description

The `AnyElementOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of an array, which ensures that a passing result occurs when at least one element of the array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

Construction

`AnyElementOf(actVal)` creates a proxy instance that tests if any element of a provided array, `actVal`, meets a constraint. The test passes if at least one element individually satisfies the constraint.

Tips

- `AnyElementOf` checks if any element in the provided array satisfies an associated constraint. However, there are some constraints, such as `HasNaN` and `HasInf`, that natively validate if any of the elements satisfy a condition. In these situations, use of `AnyElementOf` is unnecessary and impedes qualification performance.

Input Arguments

`actVal`

Actual value to test against constraint

Properties

`ActualValue`

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Any Element Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.AnyElementOf

testCase = TestCase.forInteractiveUse;
```

Test that at least one element of `actVal` is finite.

```
import matlab.unittest.constraints.IsFinite
actVal = [NaN, Inf, 5];
testCase.verifyThat(AnyElementOf(actVal), IsFinite)
```

```
Interactive verification passed.
```

Test that at least one element of the actual value is complex.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(AnyElementOf([1+0i 4i]), ~IsReal)
```

```
Interactive verification passed.
```

Test that at least one element of the actual value array is less than zero.

```
import matlab.unittest.constraints.IsLessThan
```

```
testCase.verifyThat(AnyElementOf([1 5]), IsLessThan(0))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
All elements failed. The first element failed because:
--> IsLessThan failed.
    --> The value must be less than the maximum value.

    Actual Value:
             1
    Maximum Value (Exclusive):
             0

Actual Value Array:
         1     5
```

Neither actual value element is less than zero.

matlab.unittest.constraints.BooleanConstraint class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Interface class for boolean combinations of constraints

Description

The `BooleanConstraint` interface class provides an interface for boolean combinations of `Constraints`. Any constraint that derives from `BooleanConstraint` can be combined and negated using the `and` (`&`), `or` (`|`), and `not` (`~`) operators.

Classes that derive from the `BooleanConstraint` interface class must implement everything required by the standard `Constraint` interface. When a given constraint is negated, the diagnostics must be written in a different form than for a standard (non-negated) failure. Therefore, classes deriving from the `BooleanConstraint` class must implement a method to provide a `Diagnostic` object for the negated case, in addition to the non-negated case.

In exchange for meeting these requirements, all `BooleanConstraint` implementations inherit the appropriate MATLAB overloads for `and`, `or`, and `not` so that they can be combined with other `BooleanConstraint` objects or negated.

Methods

getNegativeDiagnosticFor	Produce negated diagnostic for value

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Boolean HasSameSizeAs Constraint

Create a custom constraint that determines if a given value is the same size as an expected value.

In a file in your working folder, create a file `HasSameSizeAs.m`. The constructor accepts a value to compare to the actual size. This value is stored within the `ValueWithExpectedSize` property. It is recommended that `BooleanConstraint` implementations be immutable, so set the property `SetAccess=immutable`.

```
classdef HasSameSizeAs < matlab.unittest.constraints.BooleanConstraint

    properties(SetAccess=immutable)
        ValueWithExpectedSize
    end

    methods
        function constraint = HasSameSizeAs(value)
            constraint.ValueWithExpectedSize = value;
        end
    end
end
```

Include these methods in the `methods` block in `HasSameSizeAs.m`. Since the `BooleanConstraint` class is a subclass of `Constraint`, classes that derive from it must implement the `satisfiedBy` and `getDiagnosticFor` methods. For more information about these methods, see `matlab.unittest.constraints.Constraint`.

```
    methods
        function bool = satisfiedBy(constraint, actual)
            bool = isequal(size(actual), size(constraint.ValueWithExpectedSize));
        end
        function diag = getDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic

            if constraint.satisfiedBy(actual)
                diag = StringDiagnostic('HasSameSizeAs passed.');
            else
                diag = StringDiagnostic(sprintf(...
                    'HasSameSizeAs failed.\nActual Size: [%s]\nExpectedSize: [%s]',...
                    int2str(size(actual)),...
                    int2str(size(constraint.ValueWithExpectedSize))));
            end
        end
    end
```

Include the `getNegativeDiagnosticFor` method in the a `methods` block with protected access in `HasSameSizeAs.m`. Classes that derive from `BooleanConstraint` must implement the `getNegativeDiagnosticFor` method. This method must provide a `Diagnostic` object that is expressed in the negative sense of the constraint.

```
    methods(Access=protected)
        function diag = getNegativeDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic

            if constraint.satisfiedBy(actual)
                diag = StringDiagnostic(sprintf(...
                    ['Negated HasSameSizeAs failed.\nSize [%s] of ' ...
                    'Actual Value and Expected Value were the same ' ...
                    'but should not have been.'], int2str(size(actual))));
            else
                diag = StringDiagnostic('Negated HasSameSizeAs passed.');
            end
        end
    end
```

In exchange for implementing the required methods, the constraint inherits the appropriate `and`, `or`, and `not` overloads so it can be combined with other `BooleanConstraint` objects or negated.

HasSameSizeAs Class Definition Summary

```
classdef HasSameSizeAs < matlab.unittest.constraints.BooleanConstraint
    properties(SetAccess=immutable)
        ValueWithExpectedSize
    end
    methods
        function constraint = HasSameSizeAs(value)
            constraint.ValueWithExpectedSize = value;
        end
        function bool = satisfiedBy(constraint, actual)
            bool = isequal(size(actual), size(constraint.ValueWithExpectedSize));
        end
        function diag = getDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic

            if constraint.satisfiedBy(actual)
                diag = StringDiagnostic('HasSameSizeAs passed.');
            else
                diag = StringDiagnostic(sprintf(...
                    'HasSameSizeAs failed.\nActual Size: [%s]\nExpectedSize: [%s]',...
                    int2str(size(actual)), ...
                    int2str(size(constraint.ValueWithExpectedSize))));
            end
        end
    end
    methods(Access=protected)
        function diag = getNegativeDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic
            if constraint.satisfiedBy(actual)
                diag = StringDiagnostic(sprintf(...
                    ['Negated HasSameSizeAs failed.\nSize [%s] of ' ...
                    'Actual Value and Expected Value were the same ' ...
                    'but should not have been.'], int2str(size(actual))));
            else
                diag = StringDiagnostic('Negated HasSameSizeAs passed.');
            end
        end
    end
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasLength

testCase = TestCase.forInteractiveUse;
```

Test a passing case.

```
testCase.verifyThat(zeros(5), HasLength(5) | ~HasSameSizeAs(repmat(1,5)))

Interactive verification passed.
```

The test passes because one of the `or` conditions, `HasLength(5)`, is true.

Test a failing case.

```
testCase.verifyThat(zeros(5), HasLength(5) & ~HasSameSizeAs(repmat(1,5)))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
AndConstraint failed.
--> + [First Condition]:
     |   HasLength passed.
--> AND
    + [Second Condition]:
     |   Negated HasSameSizeAs failed.
     |   Size [5  5] of Actual Value and Expected Value were the same but should not ha
    -+---------------------
```

The test fails because one of the `and` conditions, `~HasSameSizeAs(repmat(1,5))`, is false.

Boolean Combinations of Constraints

At the command prompt, create a test case for interactive testing and import several classes that subclass `BooleanConstraint`.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasElementCount
import matlab.unittest.constraints.HasLength
import matlab.unittest.constraints.HasInf
```

```
import matlab.unittest.constraints.HasNaN
import matlab.unittest.constraints.IsEmpty
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.IsGreaterThanOrEqualTo
import matlab.unittest.constraints.IsOfClass
import matlab.unittest.constraints.IsReal

testCase = TestCase.forInteractiveUse;
```

Test these passing cases.

```
testCase.verifyThat(3, IsReal & IsGreaterThanOrEqualTo(3))
testCase.verifyThat([1 2 3; 4 5 6], HasLength(3) & HasElementCount(6))
testCase.verifyThat([3 NaN 5], HasNaN | HasInf)
testCase.verifyThat(3, ~IsEqualTo(4))
testCase.verifyThat('Some char', IsOfClass(?char) & ~IsEmpty)
```

`Diagnostic` | `matlab.unittest.constraints`

getNegativeDiagnosticFor

Produce negated diagnostic for value

Syntax

```
diag = getNegativeDiagnosticFor(constObj, actVal)
```

Description

`diag = getNegativeDiagnosticFor(constObj, actVal)` produces a negated diagnostic for a value. The `getNegativeDiagnosticFor` method analyzes the provided value, `actVal`, against the constraint, `constObj`, and produces a `matlab.unittest.diagnostics.Diagnostic` object, `diag`, which corresponds to the negation of the constraint, `constObj`. This method is a protected method.

The diagnostics that this method produces are expressed in the negative sense of the constraint. For example, a hypothetical `IsTasty` constraint, when negated, should express that the actual value was "tasty", when it should not have been, and it should describe the details on why it was found to be tasty.

Like the `getDiagnosticFor` method of `Constraint`, the `getNegativeDiagnosticFor` is only called upon failures, and thus can afford a more detailed analysis than the `satisfiedBy` method.

Input Arguments

`constObj`

`BooleanConstraint` instance

`actVal`

Value for comparison

Examples

Implement `getNegativeDiagnosticFor` method

```
function diag = getNegativeDiagnosticFor(constraint, actual)
% getNegativeDiagnosticFor - produce a diagnostic when the constraint is
% incorrectly met
%
%   This method is called by the testing framework when the constraint has
%   been met but should not have been met because it was negated in a
%   boolean expression. It should produce a Diagnostic result that
%   describes the failure in the correct terms which express the
%   requirement that the constraint actually should not have been met.

import matlab.unittest.diagnostics.StringDiagnostic

if constraint.satisfiedBy(actual)
    % Create the negative diagnostic. This will show information such as the
    % constraint class name and display the raw actual and expected values.
    % Using the DiagnosticSense.NegativeDiagnostic enumeration also
    % produces language more appropriate for the negated case.
    diag = StringDiagnostic(sprintf(...
        ['Negated HasSameSizeAs failed.\nSize [%s] of ' ...
        'Actual Value and Expected Value were the same ' ...
        'but should not have been.', int2str(size(actual))));
else
    % Produce a passing diagnostic, with language appropriate for
    % the negated case.
    diag = StringDiagnostic('Negated HasSameSizeAs passed.');
end % if

end % function
```

`Diagnostic` | `getDiagnosticFor` | `satisfiedBy`

matlab.unittest.constraints.CellComparator class

Package: matlab.unittest.constraints

Comparator for cell arrays

Description

The `CellComparator` compares cell arrays.

Construction

`CellComparator` creates a comparator for cell arrays.

`CellComparator(compObj)` indicates a comparator, `compObj`, that defines the comparator used to compare values contained in the cell array. By default, a cell comparator supports only empty cell arrays.

`CellComparator(compObj,Name,Value)` provides a comparator with additional options specified by one or more Name,Value pair arguments.

`CellComparator(Name,Value)` provides a comparator for empty cell arrays with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`compObj`

Comparator object

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'IgnoringCase'

Indicator whether the comparator is insensitive to case, specified as `false` or `true` (`logical` `0` or `1`). When it is `false`, the comparator is sensitive to case. The comparator uses this name-value pair only if the contents being compared are strings.

Default: `false`

'IgnoringWhitespace'

Indicator whether the comparator is insensitive to whitespace characters, specified as `false` or `true` (`logical` `0` or `1`). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator uses this name-value pair only if the contents being compared are strings.

Default: `false`

'Recursively'

Indicator of whether comparator operates recursively, specified as `false` or `true` (`logical` `0` or `1`). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the cell comparator supports are fully supported in recursion. For example:

```
comp1 = CellComparator(StringComparator)
comp2 = CellComparator(StringComparator,'Recursively', true)
```

Both `comp1` and `comp2` support cell arrays of strings. However, only `comp2` supports cell arrays that recursively contain either cell arrays or strings as their elements.

Default: `false`

'Within'

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. The comparator uses this name-value pair only if the contents being compared are numeric types.

Default: (empty)

Properties

`IgnoreCase`

Indicator whether the comparator is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`

`IgnoreWhitespace`

Indicator whether the comparator is insensitive to whitespace characters, specified in the name-value pair argument, `'IgnoringWhitespace'`

`Recursive`

Indicator of whether comparator operates recursively, specified in the name-value pair argument, `'Recursively'`

`Tolerance`

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, `'Within'`

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare Cell Arrays

Create a test case for interactive testing.

```
import matlab.unittest.constraints.CellComparator
import matlab.unittest.constraints.StringComparator
import matlab.unittest.constraints.IsEqualTo

testCase = matlab.unittest.TestCase;
```

Use a `CellComparator` to test that two cell arrays are equal to each other.

```
actual = {'abc','def'};
expected = {'abc','def'};
testCase.verifyThat(actual, IsEqualTo(expected,...
    'Using', CellComparator(StringComparator)))
```

```
Interactive verification passed.
```

By default, the `CellComparator` supports only comparison of empty cell arrays. Therefore, it is necessary to pass it a `StringComparator`.

Change the actual value and compare it to the expected value. To satisfy the constraint, construct it to ignore case and whitespace characters.

```
actual = {'ABC','D E F'};
testCase.verifyThat(actual, IsEqualTo(expected, 'Using', ...
    CellComparator(StringComparator, ...
    'IgnoringWhitespace', true, 'IgnoringCase',true)))
```

```
Interactive verification passed.
```

Test nested cell arrays of strings by constructing the comparator to operate recursively.

```
actual = {'abc',{'def','ghi'}};
expected = {'abc',{'def','ghi'}};

testCase.verifyThat(actual, IsEqualTo(expected, 'Using', ...
    CellComparator(StringComparator, 'Recursively', true)))
```

```
Interactive verification passed.
```

Introduced in R2013a

matlab.unittest.constraints.Constraint class

Package: matlab.unittest.constraints

Fundamental interface class for comparisons

Description

The `Constraint` interface class is the means by which `matlab.unittest` constraints encode comparison logic and the corresponding diagnostic information. Every comparison that conditionally can produce a failure inherits from the `Constraint` interface class.

Classes deriving from the `Constraint` interface class must provide a means to determine if a given value satisfies the constraint. To do this, implement the `satisfiedBy` method, which includes the definition of the underlying comparison logic. Classes deriving from the `Constraint` class also must provide a diagnostic for any given actual value. The testing framework uses the diagnostic when it encounters a qualification failure. To do this, implement the `getDiagnosticFor` method.

In exchange for meeting these requirements, all `Constraint` implementations are easily used with all qualification types through the `verifyThat`, `assertThat`, `assumeThat`, or `fatalAssertThat` methods. The qualifications use the comparison and diagnostic knowledge contained within the constraints. Also, the constraints can be used in situations where a test failure is not wanted, but the testing framework needs to reuse the comparison logic. For example, a constraint implementation may want to use the logic defined inside of another constraint. Since the constraint can interact with the other constraint directly, it can use the logic without the potential of causing a qualification failure.

Methods

getDiagnosticFor	Produce diagnostic for compared value
satisfiedBy	Determine whether value satisfies constraint

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create HasSameSizeAs Constraint

Create a custom constraint that determines if a given value is the same size as an expected value.

In a file in your working folder, create a `HasSameSizeAs.m`. The constructor accepts a value to compare to the actual size. This value is stored within the `ValueWithExpectedSize` property. Since, it is recommended that `Constraint` implementations are immutable, set the property `SetAccess=immutable`.

```
classdef HasSameSizeAs < matlab.unittest.constraints.Constraint

    properties(SetAccess=immutable)
        ValueWithExpectedSize
    end

    methods
        function constraint = HasSameSizeAs(value)
            constraint.ValueWithExpectedSize = value;
        end
    end
end
```

Classes that derive from `Constraint` must implement the `satisfiedBy` method. This method must contain the comparison logic and return a `boolean` value.

Include the `satisfiedBy` method in the `methods` block in `HasSameSizeAs.m`.

```
        function bool = satisfiedBy(constraint, actual)
            bool = isequal(size(actual), size(constraint.ValueWithExpectedSize));
        end
```

This method returns `true` if the actual size and expected size are equal.

Classes deriving from `Constraint` must implement the `getDiagnosticFor` method. This method must evaluate the actual value against the constraint and

provide a `Diagnostic` object. In this example, `getDiagnosticFor` returns a `StringDiagnostic`. Include the `getDiagnosticFor` method in the `methods` block in `HasSameSizeAs.m`.

```
        function diag = getDiagnosticFor(constraint, actual)
            import matlab.unittest.diagnostics.StringDiagnostic

            if constraint.satisfiedBy(actual)
                diag = StringDiagnostic('HasSameSizeAs passed.');
            else
                diag = StringDiagnostic(sprintf(...
                    'HasSameSizeAs failed.\nActual Size: [%s]\nExpectedSize: [%s]',...
                    int2str(size(actual)),...
                    int2str(size(constraint.ValueWithExpectedSize))));
            end
        end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase

testCase = TestCase.forInteractiveUse;
```

Test a passing case.

```
testCase.verifyThat(zeros(5), HasSameSizeAs(repmat(1,5)))

Interactive verification passed.
```

Test a failing case.

```
testCase.verifyThat(zeros(5), HasSameSizeAs(ones(1,5)))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
HasSameSizeAs failed.
Actual Size: [5  5]
ExpectedSize: [1  5]
```

getDiagnosticFor

Class: matlab.unittest.constraints.Constraint
Package: matlab.unittest.constraints

Produce diagnostic for compared value

Syntax

```
diag = getDiagnosticFor(constObj,actVal)
```

Description

`diag = getDiagnosticFor(constObj,actVal)` produces a diagnostic, `diag`, for a compared value, `actVal`. When creating a custom constraint, the class author must implement the `getDiagnosticFor` method so that it analyzes the value, `actVal`, against the constraint, `constObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, the testing framework calls this method when it encounters a qualification failure. Therefore, the constraint author can afford to undertake a more detailed analysis in the `getDiagnosticFor` method than the `satisfiedBy` method.

Input Arguments

`actVal`

Value for comparison

`constObj`

`Constraint` instance

Output Arguments

`diag`

`Diagnostic` instance

Examples

See example for `matlab.unittest.constraints.Constraint`.

See Also

`ConstraintDiagnostic` | `Diagnostic` | `satisfiedBy`

satisfiedBy

Class: matlab.unittest.constraints.Constraint
Package: matlab.unittest.constraints

Determine whether value satisfies constraint

Syntax

```
TF = satisfiedBy(constObj,actVal)
```

Description

`TF = satisfiedBy(constObj,actVal)` determines whether a value, `actVal`, satisfies a constraint, `constObj`. The `satisfiedBy` method is used to determine qualification success or failure. It returns `true` or `false` (`logical` `0` or `1`). When creating a custom constraint, a class author must place comparison logic in this method.

Since the most common usage is for the passing case, the constraint author should optimize for speed in that case. It is only in the failing case that more expensive detailed analysis is helpful.

Input Arguments

`actVal`

Value to evaluate against the constraint

`constObj`

`Constraint` instance

Examples

See example for `matlab.unittest.constraints.Constraint`.

See Also

`getDiagnosticFor`

matlab.unittest.constraints.ContainsSubstring class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying string containing substring

Construction

`ContainsSubstring(substring)` creates a constraint that specifies a string containing a substring, `substring`. The constraint is satisfied only if the actual value contains an expected string.

`ContainsSubstring(substring,Name,Value)` provides a constraint with additional options specified by one or more Name,Value pair arguments. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`substring`

Text that must be contained within the actual value, specified as a string. `substring` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'IgnoringCase'`

Indicator if the constraint is insensitive to case, specified as `false` or `true` (`logical 0` or `1`)

Default: `false`

`'IgnoringWhitespace'`

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

Properties

`IgnoreCase`

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`. This property applies at all levels of recursion, such as nested structures.

`IgnoreWhitespace`

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

`Substring`

String that must be included in the actual value, specified in the input argument, `substring`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Contains Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
```

```
import matlab.unittest.constraints.ContainsSubstring

testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test the `actVal` contains the substring `'One'`.

```
testCase.verifyThat(actVal, ContainsSubstring('One'))

Interactive verification passed.
```

Test the `actVal` contains the substring `'long'`.

```
testCase.verifyThat(actVal, ContainsSubstring('long'))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
ContainsSubstring failed.
--> The string must contain the substring.

Actual String:
    This Is One Long String
Expected Substring:
    long
```

By default, the `ContainsSubstring` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat(actVal, ContainsSubstring('long',...
    'IgnoringCase', true))

Interactive verification passed.
```

Test `actVal` contains the substring `'thisisone'`. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, ContainsSubstring('thisisone', ...
    'IgnoringCase', true, 'IgnoringWhitespace', true))
```

```
Interactive verification passed.
```

Assert that `actVal` does not contain the substring `'longer'`.

```
testCase.assertThat(actVal, ~ContainsSubstring('longer',...
    'IgnoringCase', true))
```

```
Interactive verification passed.
```

See Also

`EndsWithSubstring` | `IsSubstringOf` | `Matches` | `StartsWithSubstring`

matlab.unittest.constraints.EndsWithSubstring class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying string ending with substring

Construction

`EndsWithSubstring(suffix)` creates a constraint specifying a string ending with a substring. The constraint is satisfied only if the actual value ends with an expected string, `suffix`.

`EndsWithSubstring(suffix,Name,Value)` provides a constraint with additional options specified by one or more Name,Value pair arguments. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`suffix`

Text that occurs at the end of the actual value, specified as a string. `suffix` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'IgnoringCase'`

Indicator if the constraint is insensitive to case, specified as `false` or `true` (`logical 0` or `1`)

Default: `false`

`'IgnoringWhitespace'`

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

Properties

`IgnoreCase`

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`. This property applies at all levels of recursion, such as nested structures.

`IgnoreWhitespace`

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

`Suffix`

Text that occurs at the end of the actual value, specified in the input argument, `suffix`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Ends with Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EndsWithSubstring
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test the `actVal` ends with the substring `'String'`.

```
testCase.verifyThat(actVal, EndsWithSubstring('String'))
```

```
Interactive verification passed.
```

Test the `actVal` ends with the substring `'InG'`.

```
testCase.verifyThat(actVal, EndsWithSubstring('InG'))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
EndsWithSubstring failed.
--> The string has an incorrect suffix.

Actual String:
    This Is One Long String
Expected Suffix:
    InG
```

By default, the `EndsWithSubstring` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat(actVal, EndsWithSubstring('InG',...
    'IgnoringCase', true))
```

```
Interactive verification passed
```

Test the `actVal` ends with the substring `'longstring'`. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, EndsWithSubstring('longstring', ...
    'IgnoringCase', true, 'IgnoringWhitespace', true))
```

```
Interactive verification passed.
```

Assert that `actVal` does not end with the substring `'long'`.

```
testCase.assertThat(actVal, ~EndsWithSubstring('long'))
```

```
Interactive verification passed.
```

See Also

`ContainsSubstring` | `IsSubstringOf` | `Matches` | `StartsWithSubstring`

matlab.unittest.constraints.Eventually class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Poll for value to asynchronously satisfy constraint

Construction

`outConstObj = Eventually(constObj)` creates a constraint, `outConstObj`, that polls for an actual value function handle to asynchronously satisfy the constraint specified in the `constObj` constraint. It is not satisfied if evaluation of the function handle does not produce a value that satisfies the constraint within 20 seconds. The testing framework invokes the `drawnow` function while the `Eventually` constraint waits for specified function to satisfy the constraint.

`outConstObj = Eventually(constObj,'WithTimeoutOf',timeOutVal)` creates a constraint that polls for the constraint to be satisfied within the timer period specified in `timeOutVal`.

Input Arguments

`constObj`

`Constraint` instance

`timeOutVal`

Maximum time to wait for passing behavior, specified in seconds

Default: `20` seconds

Properties

`TimeOut`

Maximum time to wait for passing behavior, specified by the `timeOutVal` input argument

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Verify Test Passes Eventually

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.Eventually
import matlab.unittest.constraints.IsGreaterThan
import matlab.unittest.constraints.IsLessThan

testCase = TestCase.forInteractiveUse;
```

Verify that, within the timeout period, a call to `toc` results in a value greater than 10 (seconds). The `Eventually` constraint repeatedly calls `toc` until either the constraint is satisfied or the elapsed time exceeds the timeout period. Repeated calls to `toc` result in the elapsed time since the last call to `tic`.

```
tic
testCase.verifyThat(@toc, Eventually(IsGreaterThan(10)))
```

```
Interactive verification passed.
```

The verification may take as long as 10 seconds for `toc` to reach a passing value. If you issue the call to `tic` and wait more than 10 seconds before issuing the `verifyThat` command, the verification returns immediately since `toc` already returns a value greater than 10.

Verify that, within the timeout period, `toc` does not return a negative value.

```
testCase.verifyThat(@toc, Eventually(IsLessThan(0)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
Eventually failed.
--> The function did not pass after 20 seconds.
```

```
--> IsLessThan failed.
    --> The value must be less than the maximum value.

    Actual Value:
          20.286452356691139
    Maximum Value (Exclusive):
             0

Evaluated Function:
        @toc
```

This failure is expected since elapsed time is not going to be less than zero. However, `Eventually` polls `toc` for the duration of the timeout period.

Adjust the timeout period so `Eventually` polls for 5 seconds.

```
tic
testCase.verifyThat(@toc, Eventually(IsGreaterThan(10), ...
    'WithTimeoutOf', 5))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
Eventually failed.
--> The function did not pass after 5 seconds.
--> IsGreaterThan failed.
    --> The value must be greater than the minimum value.

    Actual Value:
           5.076293030150061
    Minimum Value (Exclusive):
             10

Evaluated Function:
        @toc
```

If you didn't wait more than 5 seconds between calls to `tic` and `verifyThat`, the test fails because the elapsed time is not greater than 10 seconds within the modified timeout period.

See Also

`matlab.unittest.constraints.Constraint` | `drawnow`

matlab.unittest.constraints.EveryCellOf class

Package: matlab.unittest.constraints

Test if all elements of cell array meet constraint

Description

The `EveryCellOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of a cell array, which ensures that a passing result occurs when every element of the cell array satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

Construction

`EveryCellOf(actVal)` creates a proxy instance that tests if every element of a provided cell array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

Tips

- `EveryCellOf` checks if every element in the provided cell array satisfies an associated constraint. However, there are some constraints, a prominent one being `IsEqualTo`, that natively validate if all elements in cell arrays satisfy a condition. In these situations, use of `EveryCellOf` is unnecessary and impedes qualification performance.

Input Arguments

`actVal`

Actual value to test against constraint

Properties

`ActualValue`

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Every Cell Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EveryCellOf

testCase = TestCase.forInteractiveUse;
```

Test that every cell of `actVal` contains the substring `'ain'`.

```
import matlab.unittest.constraints.ContainsSubstring
actVal = {'Rain','Main','Plain'};
testCase.verifyThat(EveryCellOf(actVal), ContainsSubstring('ain'))
```

```
Interactive verification passed.
```

Test that every cell of the actual value array has two elements.

```
import matlab.unittest.constraints.HasElementCount
testCase.verifyThat(EveryCellOf({{'hello','world'}, {11 38}}), HasElementCount(2))
```

```
Interactive verification passed.
```

Test that every cell of the actual value array is empty.

```
import matlab.unittest.constraints.IsEmpty
```

```
testCase.verifyThat(EveryCellOf({inputParser.empty,''}), IsEmpty)

Interactive verification passed.
```

Test that every cell of the actual value array is finite.

```
import matlab.unittest.constraints.IsFinite
testCase.verifyThat(EveryCellOf({NaN, Inf, 5}), IsFinite)

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
At least one cell failed.

Failing indices:
         1     2
The first failing cell failed because:
--> IsFinite failed.
    --> The value must be finite.

    Actual Value:
           NaN

Actual Value Cell Array:
        [NaN]    [Inf]    [5]
```

Only the third element has a finite value.

Test that every cell of the actual value array is real.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(EveryCellOf({1 4i}), IsReal)

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
At least one cell failed.

Failing indices:
         2
The first failing cell failed because:
```

```
--> IsReal failed.
    --> The value must be real.

    Actual Value:
          0.000000000000000 + 4.000000000000000i

Actual Value Cell Array:
        [1]    [0.000000000000000 + 4.000000000000000i]
```

The second element has an imaginary value.

`AnyCellOf` | `AnyElementOf` | `EveryElementOf` | `matlab.unittest.qualifications`

matlab.unittest.constraints.EveryElementOf class

Package: matlab.unittest.constraints

Test if all elements of array meet constraint

Description

The `EveryElementOf` class creates a proxy of the actual value to the framework. The proxy enables a test writer to apply a constraint against each element of an array, which ensures that a passing result occurs when every element of the array that satisfies the constraint.

It is intended that you use this class through `matlab.unittest` qualifications as shown in the examples. The class does not modify the provided actual value, but serves as a wrapper to perform the constraint analysis. The testing framework analyzes the constraint on an element-by-element basis.

Construction

`EveryElementOf(actVal)` creates a proxy instance that tests if every element of a provided array, `actVal`, meets a constraint. The test passes if all elements satisfy the constraint.

Tips

- `EveryElementOf` checks if every element in the provided array satisfies an associated constraint. However, there are some constraints, such as `IsEqualTo` and `IsGreaterThan`, `IsLessThan`, that natively validate if all elements in the array satisfy a condition. In these situations, use of `EveryElementOf` is unnecessary and impedes qualification performance.

Input Arguments

`actVal`

Actual value to test against constraint

Properties

`ActualValue`

Actual value to test against constraint. Set this property through the constructor via the `actVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Every Element Satisfies Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.EveryElementOf

testCase = TestCase.forInteractiveUse;
```

Test that every element of `actVal` is less than 55.

```
import matlab.unittest.constraints.IsLessThan
actVal = [1 1 2 3 5 8 13 21 34];
testCase.verifyThat(EveryElementOf(actVal), IsLessThan(55))
```

```
Interactive verification passed.
```

Test that every element of the actual value array is complex.

```
import matlab.unittest.constraints.IsReal
testCase.verifyThat(EveryElementOf([1+2i 4i]), ~IsReal)
```

```
Interactive verification passed.
```

Test that every element of the actual value array is less than zero.

```
import matlab.unittest.constraints.IsLessThan
```

```
testCase.verifyThat(EveryElementOf([1 -5]), IsLessThan(0))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
At least one element failed.

Failing indices:
         1
The first failing element failed because:
--> IsLessThan failed.
    --> The value must be less than the maximum value.

    Actual Value:
             1
    Maximum Value (Exclusive):
             0

Actual Value Array:
         1    -5
```

Only the second element is less than zero.

Test that every element of the actual value array has a `NaN` value.

```
import matlab.unittest.constraints.HasNaN
testCase.verifyThat(EveryElementOf([NaN 0/0 5]), HasNaN)

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
At least one element failed.

Failing indices:
         3
The first failing element failed because:
--> HasNaN failed.
    --> The value must be NaN.

    Actual Value:
             5
```

```
Actual Value Array:
       NaN   NaN     5
```

Only the third element has a `NaN` value.

matlab.unittest.constraints.HasElementCount class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying expected number of elements

Construction

`HasElementCount(countVal)` provides a constraint that specifies an expected number of elements. The constraint is satisfied if the actual value array has the same number of elements specified as by `countVal`.

Input Arguments

`countVal`

Number of elements a value must have to satisfy the constraint.

Properties

`Count`

Number of elements a value must have to satisfy the constraint. Set this property through the constructor via the `countVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test for Expected Number of Elements

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasElementCount

testCase = TestCase.forInteractiveUse;
```

Verify a scalar has an element count of one.

```
testCase.verifyThat(3, HasElementCount(1))

Interactive verification passed.
```

Test the element count of the vector.

```
testCase.assertThat([42 7 13], HasElementCount(3))

Interactive assertion passed.
```

Test the element count of the matrix.

```
testCase.assertThat([1 2 3; 4 5 6], HasElementCount(5))

Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
HasElementCount failed.
--> The value did not have the correct number of elements.

    Actual Number of Elements:
             6
    Expected Number of Elements:
             5

Actual Value:
         1     2     3
         4     5     6
Assertion failed.
```

The matrix has six elements.

Test that a square identity matrix has the correct number of elements.

```
n = 7;
testCase.assumeThat(eye(n), HasElementCount(n^2))
```

```
Interactive assumption passed.
```

Verify the element count of a cell array of strings.

```
testCase.verifyThat({'aString', 'anotherString'}, HasElementCount(2))
```

```
Interactive verification passed.
```

Test the element count of a structure.

```
s.Field1 = 1;
s.Field2 = 2;
testCase.verifyThat(s, HasElementCount(2))
```

```
Interactive verification failed.

--------------------
Framework Diagnostic:
--------------------
HasElementCount failed.
--> The value did not have the correct number of elements.

    Actual Number of Elements:
             1
    Expected Number of Elements:
             2

Actual Value:
        Field1: 1
        Field2: 2
```

The structure has two fields, but it only has one element.

```
testCase.verifyThat(s, HasElementCount(1))
```

```
Interactive verification passed.
```

HasLength | HasSize | IsEmpty | numel

matlab.unittest.constraints.HasField class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying structure containing particular field

Construction

`HasField(fieldname)` provides a constraint specifying structure containing particular field, `fieldname`. The constraint is satisfied if the actual value is a structure and that structure contains a field named `fieldname`.

Input Arguments

`fieldname`

Name of the field that a structure must contain to satisfy the constraint, specified as a string.

Properties

`Field`

Name of the field that a structure must contain to satisfy the constraint. Set this property through the constructor via the `fieldname` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Structure Has Particular Field

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasField

testCase = TestCase.forInteractiveUse;
```

Define the following structure, `S`, with two fields.

```
S = struct('Tag', 123, 'Serial', 345);
```

Verify that the structure has a `'Tag'` field.

```
testCase.verifyThat(S, HasField('Tag'))
```

```
Interactive verification passed.
```

Verify that the structure has a `'tag'` field.

```
testCase.verifyThat(S, HasField('tag'))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
HasField failed.
--> The value did not have the expected field.

    Actual Fieldnames:
            'Tag'
            'Serial'
    Expected Fieldname:
            'tag'

Actual Value:
           Tag: 123
        Serial: 345
```

The verification fails because the field name comparison is case sensitive.

Verify that the structure has a `'Tag'` field.

```
testCase.verifyThat(S, HasField('Tag'))
```

```
Interactive verification passed.
```

Verify that the structure has both a `'Tag'` and a `'Serial'` field.

```
testCase.verifyThat(S, HasField('Tag') & HasField('Serial'))
```

```
Interactive verification passed.
```

Verify that the structure does not have a `'Name'` field.

```
testCase.verifyThat(S, ~HasField('Name'))
```

```
Interactive verification passed.
```

matlab.unittest.constraints.HasInf class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying array containing any infinite value

Construction

`HasInf` creates a constraint that is able to determine if any value of an actual value array is an infinite value. This constraint is satisfied only if the actual value array contains at least one infinite value.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Array Contains Infinite Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasInf

testCase = TestCase.forInteractiveUse;
```

Test that the value `Inf` satisfies the constraint.

```
testCase.verifyThat(Inf, HasInf)
```

```
Interactive verification passed.
```

Assert that an array contains an infinite value.

```
testCase.assertThat([0 1 1 2 3 5 8 13], HasInf)
```

```
Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
HasInf failed.
--> At least one element must be Inf or -Inf.

Actual Value:
         0     1     1     2     3     5     8    13
Assertion failed.
```

The array does not contain any infinite values.

Verify that an array contains an infinite value.

```
testCase.verifyThat([-Inf 5 NaN], HasInf)
```

```
Interactive verification passed.
```

Assert that a complex number that is infinite in the imaginary part satisfies the constraint.

```
testCase.assertThat(42+Inf*1i, HasInf)
```

```
Interactive verification passed.
```

Verify that an array does not contain any infinite values.

```
testCase.verifyThat([NaN -7+NaN*1i], ~HasInf)
```

```
Interactive verification passed.
```

Negating the `HasInf` constraint does not ensure the value is finite, only that it does not contain any infinite values.

See Also

`HasNaN` | `IsFinite` | `isinf`

matlab.unittest.constraints.HasLength class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying expected length of array

Construction

`HasLength(lengthVal)` provides a constraint that specifies an expected length of an array. The constraint is satisfied if the largest dimension length of the actual value array has the same number of elements specified as by `lengthVal`.

Input Arguments

`lengthVal`

Length a value must have to satisfy the constraint.

Properties

`Count`

Length a value must have to satisfy the constraint. Set this property through the constructor via the `lengthVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test for Expected Array Length

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasLength

testCase = TestCase.forInteractiveUse;
```

Assert that a 2x5x3 array has an expected length.

```
testCase.assertThat(rand(2, 5, 3), HasLength(5))
```

```
Interactive assertion passed.
```

Verify that a cell array of strings has an expected length.

```
testCase.verifyThat({'SomeString', 'SomeOtherString'}, HasLength(2))
```

```
Interactive verification passed.
```

Verify that an identity matrix has an expected length.

```
testCase.verifyThat(eye(2), HasLength(4))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
HasLength failed.
--> The array has an incorrect length.

    Actual Length:
             2
    Expected Length:
             4

Actual Array:
         1     0
         0     1
```

The matrix has a length of 2.

See Also

HasElementCount | HasSize | IsEmpty | length

matlab.unittest.constraints.HasNaN class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying array containing NaN value

Construction

`HasNaN` creates a constraint that is able to determine if any value of an actual value array is `NaN`. This constraint is satisfied only if the actual value array contains at least one `NaN` value.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Array Contains NaN Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasNaN

testCase = TestCase.forInteractiveUse;
```

Test that the value `NaN` satisfies the constraint.

```
testCase.verifyThat(NaN, HasNaN)
```

```
Interactive verification passed.
```

Assert that an array contains a NaN value.

```
testCase.assertThat([0 1 1 2 3 5 8 13], HasNaN)
```

```
Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
HasNaN failed.
--> At least one element must be NaN.

Actual Value:
         0     1     1     2     3     5     8    13
Assertion failed.
```

The array does not contain a NaN value.

Verify that an array contains a NaN value.

```
testCase.verifyThat([-Inf 5 NaN], HasNaN)
```

```
Interactive verification passed.
```

Assert that a complex number satisfies the constraint.

```
testCase.assertThat(42+NaN*1i, HasNaN)
```

```
Interactive assertion passed.
```

Verify that an array does not contain any `NaN` values.

```
testCase.verifyThat([Inf -7+Inf*1i], ~HasNaN)
```

```
Interactive verification passed.
```

Negating the `HasNaN` constraint does not ensure the value is finite, only that it does not contain any `NaN` values.

`HasInf` | `IsFinite` | `isnan`

matlab.unittest.constraints.HasSize class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying expected size of array

Construction

`HasSize(sizeVal)` provides a constraint that specifies an expected size of an array. The constraint is satisfied if the actual value array size is equal to the size specified by `sizeVal`.

Input Arguments

`sizeVal`

Size a value must have to satisfy the constraint.

Properties

`Count`

Size a value must have to satisfy the constraint. Set this property through the constructor via the `sizeVal` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test for Expected Array Size

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.HasSize

testCase = TestCase.forInteractiveUse;
```

Assert that a `2x5x3` array has an expected size.

```
testCase.assertThat(rand(2, 5, 3), HasSize([2 5 3]))
```

```
Interactive assertion passed.
```

Verify that a cell array of strings has an expected size.

```
testCase.verifyThat({'SomeString', 'SomeOtherString'}, HasSize([1 2]))
```

```
Interactive verification passed.
```

Verify that an identity matrix has an expected size.

```
testCase.verifyThat(eye(2), HasSize([4 1]))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
HasSize failed.
--> The value had an incorrect size.

    Actual Size:
             2     2
    Expected Size:
             4     1

Actual Value:
         1     0
         0     1
```

The matrix has a size of `2x2`.

`HasElementCount` | `HasLength` | `IsEmpty` | `size`

matlab.unittest.constraints.IsAnything class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying any value

Construction

`IsAnything` provides a constraint specifying any value. The constraint is satisfied by any value. It is the default constraint for selectors that do not require an input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate `IsAnything` Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsAnything

testCase = TestCase.forInteractiveUse;
```

Verify that the following values satisfy the `IsAnything` constraint: `NaN`, an `inputParser` object, a numeric array, and a complex number.

```
testCase.verifyThat(NaN, IsAnything)
testCase.verifyThat(inputParser, IsAnything)
testCase.verifyThat(1:10, IsAnything)
testCase.verifyThat(-Inf+5j, IsAnything)
```

```
Interactive verification passed.
Interactive verification passed.
```

```
Interactive verification passed.
Interactive verification passed.
```

Test that empty cells, arrays, and strings satisfy the `IsAnything` constraint.

```
testCase.verifyThat({}, IsAnything)
testCase.verifyThat([], IsAnything)
testCase.verifyThat('', IsAnything)
```

```
Interactive verification passed.
Interactive verification passed.
Interactive verification passed.
```

The constraint is satisfied even though the data are empty.

See Also

`matlab.unittest.selectors`

matlab.unittest.constraints.IsEmpty class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying empty value

Construction

`IsEmpty` provides a constraint that specifies an empty value. The constraint is satisfied if the actual value array is empty.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Empty

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEmpty

testCase = TestCase.forInteractiveUse;
```

Verify that an empty string satisfies the `IsEmpty` constraint.

```
testCase.verifyThat('', IsEmpty)
```

```
Interactive verification passed.
```

Assert that a vector is not empty.

```
testCase.assertThat([13 42], ~IsEmpty)
```

```
Interactive verification passed.
```

Verify that a matrix with a dimension of length zero is empty.

```
testCase.verifyThat(rand(2, 5, 0, 3), IsEmpty)
```

```
Interactive verification passed.
```

Assert that an empty object satisfies the `IsEmpty` constraint.

```
testCase.assertThat(MException.empty, IsEmpty)
```

```
Interactive assertion passed.
```

Verify that a cell array containing an empty numeric array is empty.

```
testCase.verifyThat({[]}, IsEmpty)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEmpty failed.
--> The value must be empty.
--> The value has a size of [1  1].

Actual Value:
        {[]}
```

The cell array is not empty, even though the only thing it contains is an empty array.

matlab.unittest.constraints.IsFalse class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying false value

Construction

`IsFalse` provides a constraint specifying a false value. This constraint is satisfied only by a scalar logical with a value of `false`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test Actual Value Is False

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsFalse

testCase = TestCase.forInteractiveUse;
```

Test that `false` satisfies the `IsFalse` constraint.

```
testCase.verifyThat(false, IsFalse)
```

```
Interactive verification passed.
```

Test that the `IsFalse` constraint is not satisfied by `true`.

```
testCase.verifyThat(true, IsFalse)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsFalse failed.
--> The value must evaluate to "false".

Actual Value:
         1
```

The test fails because `true` returns `logical(1)`.

Test that the `IsFalse` constraint is not satisfied by the double `0`.

```
testCase.verifyThat(0, IsFalse)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsFalse failed.
--> The value must be logical. It is of type "double".

Actual Value:
         0
```

The `IsFalse` constraint is satisfied only by `logical(0)`.

Test that the `IsFalse` constraint is not satisfied by a logical array of zeros.

```
testCase.verifyThat([false false false], IsFalse)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsFalse failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         0     0     0
```

The `IsFalse` constraint is only satisfied if the value is scalar and `logical(0)`.

See Also

matlab.unittest.constraints.IsFinite class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying finite value

Construction

`IsFinite` creates a constraint that is able to determine if all values of an actual value array are finite. This constraint is satisfied only if the actual value array does not contain any infinite or `NaN` values.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Array Contains Only Finite Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsFinite

testCase = TestCase.forInteractiveUse;
```

Test that the value `17` satisfies the constraint.

```
testCase.verifyThat(17, IsFinite)
```

```
Interactive verification passed.
```

Assert that an array is completely finite.

```
testCase.assertThat([0 1 1 2 3 5 8 13], IsFinite)
```

```
Interactive assertion passed.
```

Verify that an array is completely finite.

```
testCase.verifyThat([-Inf 5 NaN], IsFinite)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsFinite failed.
--> All elements must be finite-valued.
    Failing indices:
              1     3

Actual Value:
      -Inf     5   NaN
```

The array contains an infinite value.

Test if a complex number that is infinite in the imaginary part satisfies the constraint.

```
testCase.assertThat(42+Inf*1i, IsFinite)
```

```
Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
IsFinite failed.
--> The value must be finite.

Actual Value:
     42.000000000000000 +               Infi
Assertion failed.
```

Verify that an array does not contain all finite values.

```
testCase.verifyThat([NaN -7+NaN*1i], ~IsFinite)
```

```
Interactive verification passed.
```

matlab.unittest.constraints.IsGreaterThan class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying value greater than another value

Construction

`IsGreaterThan(floorVal)` creates a constraint specifying that an actual value is greater than another value. The constraint is satisfied if the actual value array is greater than the specified floor value, `floorVal`. The actual value is greater than `floorVal` only if the result of the expression `actual > floorVal` is nonempty and all values are true.

Input Arguments

`floorVal`

Largest value that fails the constraint.

Properties

`FloorValue`

Largest value that fails the constraint. Set this property through the constructor via the `floorVal` input argument.

Methods

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Greater Than Provided Floor Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsGreaterThan

testCase = TestCase.forInteractiveUse;
```

Test that the actual value is greater than two.

```
actVal = 3;
testCase.verifyThat(actVal, IsGreaterThan(2))
```

```
Interactive verification passed.
```

Test that the actual value is greater than three.

```
testCase.verifyThat(actVal, IsGreaterThan(3))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsGreaterThan failed.
--> The value must be greater than the minimum value.

Actual Value:
         3
Minimum Value (Exclusive):
         3
```

The actual value is equal to, not greater than, three.

Test that each element in the actual value array is greater than four.

```
actVal = [5 6 7];
testCase.verifyThat(actVal, IsGreaterThan(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is greater than four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsGreaterThan(4))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsGreaterThan failed.
--> Each element must be greater than the minimum value.

    Failing Indices:
              1     2     3     5

Actual Value:
         1     2     3
         4     5     6
Minimum Value (Exclusive):
         4
```

The matrix contains four elements with a value less than or equal to four.

Test that the actual value, 5, is greater than every element in an array.

```
testCase.verifyThat(5, IsGreaterThan([1 2 3]))

Interactive verification passed.
```

Test that elements in the actual value array are greater than the corresponding floor values.

```
testCase.verifyThat([5 -3 2], IsGreaterThan([4 -9 0]))

Interactive verification passed.
```

Repeat the test, this time negating the first actual value element.

```
testCase.verifyThat([-5 -3 2], IsGreaterThan([4 -9 0]))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsGreaterThan failed.
--> Each element must be greater than each corresponding element of the minimum value a
```

```
    Failing Indices:
              1

Actual Value:
        -5    -3     2
Minimum Value (Exclusive):
         4    -9     0
```

The negated element is less than four.

matlab.unittest.constraints.IsGreaterThanOrEqualTo class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying value greater than or equal to another value

Construction

`IsGreaterThanOrEqualTo(floorVal)` creates a constraint specifying that an actual value is greater than or equal to another value. The constraint is satisfied if the actual value array is greater than or equal to the specified floor value, `floorVal`. The actual value is greater than or equal to `floorVal` only if the result of the expression `actual >= floorVal` is nonempty and all values are true.

Input Arguments

`floorVal`

Minimum value to satisfy the constraint.

Properties

`FloorValue`

Minimum value to satisfy the constraint. Set this property through the constructor via the `floorVal` input argument.

Methods

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Greater Than or Equal to Provided Floor Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsGreaterThanOrEqualTo

testCase = TestCase.forInteractiveUse;
```

Test that the actual value is greater than or equal to two.

```
actVal = 3;
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(2))
```

Test that the actual value is greater than or equal to three.

```
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(3))
```

```
Interactive verification passed.
```

Test that each element in the actual value array is greater than or equal to four.

```
actVal = [5 6 7];
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is greater than or equal to four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsGreaterThanOrEqualTo(4))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsGreaterThanOrEqualTo failed.
--> Each element must be greater than or equal to the minimum value.

    Failing Indices:
              1     3     5
```

```
Actual Value:
         1     2     3
         4     5     6
Minimum Value (Inclusive):
         4
```

The matrix contains three elements that are greater than or equal to four.

Test that the actual value, 5, is greater than or equal to every element in an array.

```
testCase.verifyThat(5, IsGreaterThanOrEqualTo([1 2 3 5]))
```

```
Interactive verification passed.
```

Test that elements in the actual value array are greater than or equal to the corresponding floor values.

```
testCase.verifyThat([5 -3 0], IsGreaterThanOrEqualTo([4 -9 0]))
```

```
Interactive verification passed.
```

Repeat the test, this time negating the first actual value element.

```
testCase.verifyThat([-5 -3 0], IsGreaterThanOrEqualTo([4 -9 0]))
```

```
Interactive verification failed.

----------------------
Framework Diagnostic:
----------------------
IsGreaterThanOrEqualTo failed.
--> Each element must be greater than or equal to each corresponding element of the mi

    Failing Indices:
              1

Actual Value:
        -5    -3     0
Minimum Value (Inclusive):
         4    -9     0
```

The negated element is less than or equal to four.

matlab.unittest.constraints.IsEqualTo class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

General constraint to compare for equality

Description

The `IsEqualTo` class creates a constraint that compares data for equality. The type of comparison it uses is governed by the data type of the expected value. First, the testing framework checks if the expected value is an object. This check is performed first because it is possible for the object to have overridden methods that are used in subsequent checks (e.g. `islogical`). The following list categorizes and describes the various tests.

Data Type	Equality Comparison Method
MATLAB & Java Objects	If the expected value is a MATLAB or Java object, the `IsEqualTo` constraint calls the `isequaln` method if it is defined on the expected value object, otherwise it calls `isequal`. If the check returns false and a supported tolerance is specified, the `IsEqualTo` constraint checks the actual and expected values for equivalent class, size, and sparsity before determining if the values are within the tolerance.
Logicals	If the expected value is a `logical`, the constraint checks the actual and expected values for equivalent sparsity. If the sparsity matches, the constraint compares the values with the `isequal` method. Otherwise, the constraint is not satisfied.
Numerics	If the expected value is `numeric`, the constraint checks the actual and expected values for equivalent class, size, and sparsity. If the all these checks match, the constraint uses the `isequaln` method for comparison. If `isequaln` returns `true`, the constraint is satisfied. If the complexity does not match or `isequaln` returns `false`, and a supported tolerance is supplied, the constraint uses the tolerance in the comparison. Otherwise, the constraint is not satisfied.
Strings	If the expected value is a `string`, the constraint uses the `strcmp` function to check the actual and expected values for equality. However, if the `IgnoreCase` property is true, the strings are compared using `strcmpi`. If the `IgnoreWhitespace` is `true`, all whitespace characters

Data Type	Equality Comparison Method
	are removed from the actual and expected strings before passing them to `strcmp` or `strcmpi`.
Structures	If the expected value is a `struct`, the constraint compares the field count of the actual and expected values. If not equal, the constraint is not satisfied. Otherwise, each field of the expected value `struct` must exist on the actual value `struct`. If any field names are different, the constraint is not satisfied. Then, the constraint recursively compares the fields in a depth first examination. The recursion continues until a fundamental data type is encountered (i.e. logical, numeric, string, or object), and then the values are compared as described above.
Cell Arrays	If the expected value is a cell array, the constraint checks the actual and expected values for size equality. If they are not equal in size, the constraint is not satisfied. Otherwise, each element of the array is recursively compared in a manner identical to fields in a structure, described above.

Construction

`IsEqualTo(expVal)` provides a general constraint to compare for equality.

`IsEqualTo(expVal,Name,Value)` provides a constraint with additional options specified by one or more Name,Value pair arguments. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`expVal`

The expected value that will be compared to the actual value.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`''`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'IgnoringCase'`

Indicator if the constraint is insensitive to case, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

`'IgnoringWhitespace'`

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

`'Using'`

Particular comparator to use for constraint construction, specified as a `matlab.unittest.constraints.Comparator` object

Default: (empty)

`'Within'`

Tolerance to use in constraint construction, specified as a `matlab.unittest.constraints.Tolerance` object

Default: (empty)

Properties

`Comparator`

Specific comparator used in construction of the constraint, specified as a `matlab.unittest.constraints.Comparator` object in the name-value pair argument, `'Using'`.

`Expected`

The expected value that will be compared to the actual value specified in the `expVal` input argument.

`IgnoreCase`

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`. This property applies at all levels of recursion, such as nested structures.

`IgnoreWhitespace`

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

`Tolerance`

Specific tolerance used in construction of the constraint, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, `'Within'`. This property applies at all levels of recursion, such as nested structures.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test Numerics for Equality

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance

testCase = TestCase.forInteractiveUse;
```

Verify that an actual value of 5 is equal to the expected value.

```
expVal = 5;
testCase.verifyThat(expVal, IsEqualTo(5))
```

```
Interactive verification passed.
```

Assume that the actual value is 4.95. Verify that the difference between the actual value and expected value is less than 0.09.

```
testCase.verifyThat(expVal, IsEqualTo(4.95, 'Within', AbsoluteTolerance(0.09)))
```

```
Interactive verification passed.
```

Assume that the actual value is 4.9. Verify that the difference between the actual and expected value is less than 1%.

```
testCase.verifyThat(expVal, IsEqualTo(4.9, 'Within', RelativeTolerance(0.01)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> RelativeTolerance failed.
        --> The error was not within relative tolerance.
        --> Failure table:
                    Index    Actual    Expected          Error              RelativeErro
                    _____    ______    ________    __________________    ________________

                    1        5         4.9         0.0999999999999996    0.020408163265

Actual Value:
         5
Expected Value:
       4.900000000000000
```

The two values differ by more than 1%.

Test Floating Point Calculation with Tolerance

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Test that `0.1*3 = 0.3`.

```
act = 0.1*3;
exp = 0.3;
testCase.verifyThat(act, IsEqualTo(exp))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> Failure table:
                Index    Actual    Expected           Error                RelativeError
                _____    ______    ________    ____________________    _________________

                1        0.3       0.3         5.55111512312578e-17    1.85037170770859

Actual Value:
       0.300000000000000
Expected Value:
       0.300000000000000
```

This test fails due to round off error in floating point arithmetic.

Perform the comparison of floating point numbers using a tolerance. Test that `0.1*3 = 0.3` within a relative tolerance of `2*eps`.

```
testCase.verifyThat(act, IsEqualTo(exp, ...
    'Within', RelativeTolerance(2*eps)))
```

```
Interactive verification passed.
```

Test Strings for Equality

Create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo

testCase = TestCase.forInteractiveUse;
```

Verify that two strings are equal.

```
expVal = 'Hello';
testCase.verifyThat(expVal, IsEqualTo('Hello'))
```

```
Interactive verification passed.
```

Change the case of the actual string and test for equality.

```
testCase.verifyThat(expVal, IsEqualTo('hello'))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> StringComparator failed.
    --> The strings are not equal

Actual String:
    Hello
Expected String:
    hello
```

Ignore case and test again.

```
testCase.verifyThat(expVal, IsEqualTo('hello', 'IgnoringCase', true))
```

```
Interactive verification passed.
```

Ignore whitespace and test two strings.

```
expVal = 'a bc';
testCase.verifyThat(expVal, IsEqualTo('abc', 'IgnoringWhitespace', true))
testCase.verifyThat(expVal, IsEqualTo('ab c', 'IgnoringWhitespace', true))
```

```
Interactive verification passed.
Interactive verification passed.
```

Test Objects for Equality Using Comparator

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
```

```
import matlab.unittest.constraints.RelativeTolerance
import matlab.unittest.constraints.PublicPropertyComparator

testCase = TestCase.forInteractiveUse;
```

Define actual and expected `timeseries` objects. Perturb one of the actual data points by 1%.

```
expected = timeseries(1:10);
actual = expected;
actual.Data(7) = 1.01*actual.Data(7);
```

Test that the actual and expected values are equal within a relative tolerance of 2%.

```
testCase.verifyThat(actual, IsEqualTo(expected,...
    'Within', RelativeTolerance(.02)))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> ObjectComparator failed.
    --> The objects are not equal using "isequal".
    --> The tolerance does not support timeseries values so it was not used.

Actual Object:
      timeseries

      Common Properties:
                Name: 'unnamed'
                Time: [10x1 double]
            TimeInfo: [1x1 tsdata.timemetadata]
                Data: [1x1x10 double]
            DataInfo: [1x1 tsdata.datametadata]

      More properties, Methods
Expected Object:
      timeseries

      Common Properties:
                Name: 'unnamed'
                Time: [10x1 double]
            TimeInfo: [1x1 tsdata.timemetadata]
```

```
                Data: [1x1x10 double]
            DataInfo: [1x1 tsdata.datametadata]

      More properties, Methods
```

Use the `PublicPropertyComparator` in the construction of the constraint.

```
testCase.verifyThat(actual, IsEqualTo(expected,...
    'Within', RelativeTolerance(.02),...
    'Using', PublicPropertyComparator.supportingAllValues))
```

```
Interactive verification passed.
```

The test passes because the `PublicPropertyComparator` compares each public property individually instead of comparing the object all at once. In the former test, the `ObjectComparator` compares `timeseries` objects, and therefore relies on the `isequal` method of the `timeseries` class. Due to the perturbation in the actual `timeseries`, `isequal` returns `false`. The comparator does not apply the tolerance because the double-valued tolerance cannot apply directly to the `timeseries` object. In the latter test, the comparator applies the tolerance to each public property that contains double-valued data.

Introduced in R2013a

matlab.unittest.constraints.IsInstanceOf class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying inclusion in given class hierarchy

Construction

`IsInstanceOf(class)` provides a constraint specifying inclusion in a given class hierarchy. The constraint is satisfied if the actual value instance passes the "isa" relationship with `class` .

Input Arguments

`class`

Class name that the actual value must derive from or be an instance of to satisfy the constraint, specified as a fully qualified class name string or a `meta.class` instance.

Properties

`Class`

Class name that the actual value must derive from or be an instance of to satisfy the constraint. Set this property through the constructor via the `class` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Instance of Specified Class

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsInstanceOf

testCase = TestCase.forInteractiveUse;
```

Verify that the actual value, 5, is an instance of the double class.

```
testCase.verifyThat(5, IsInstanceOf('double'))
```

```
Interactive verification passed.
```

Repeat the test using an instance of `meta.class` instead of a string.

```
testCase.verifyThat(5, IsInstanceOf(?double))
```

```
Interactive verification passed.
```

Assert that zero is an instance of the logical class.

```
testCase.assertThat(0, IsInstanceOf('logical'))
```

```
Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
IsInstanceOf failed.
--> The value must be an instance of the expected type.

    Actual Class:
        double
    Expected Type:
        logical

Actual Value:
         0
Assertion failed.
```

Verify that `@sin` is a function handle.

```
testCase.verifyThat(@sin, IsInstanceOf(?function_handle))
```

```
Interactive verification passed.
```

Verify that `name` is an instance of the `char` class.

```
name = 42;
```

```
testCase.verifyThat(name, IsInstanceOf('char'))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsInstanceOf failed.
--> The value must be an instance of the expected type.

    Actual Class:
        double
    Expected Type:
        char

Actual Value:
        42
```

Test That Derived Class Is Instance of Specified Class

In a file in your working folder, create a class, `DerivedExample`, that inherits from the `handle` class.

```
classdef DerivedExample < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsInstanceOf

testCase = TestCase.forInteractiveUse;
```

Verify that an instance of the `DerivedExample` class is an instance of a `handle`.

```
exObj = DerivedExample;
testCase.verifyThat(exObj, IsInstanceOf(?handle))

Interactive verification passed.
```

Even though `exObj` is not an instance of the `handle` class, the verification passes because it derives from the `handle` class.

`isa` | `IsOfClass`

matlab.unittest.constraints.IsLessThan class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying value less than another value

Construction

`IsLessThan(ceilVal)` creates a constraint specifying that an actual value is less than another value. The constraint is satisfied if the actual value array is less than the specified ceiling value, `ceilVal`. The actual value is less than `ceilVal` only if the result of the expression `actual < ceilVal` is nonempty and all values are true.

Input Arguments

`ceilVal`

Smallest value that fails the constraint.

Properties

`CeilingValue`

Smallest value that fails the constraint. Set this property through the constructor via the `ceilVal` input argument.

Methods

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Less Than Provided Ceiling Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsLessThan

testCase = TestCase.forInteractiveUse;
```

Test that the actual value is less than four.

```
actVal = 3;
testCase.verifyThat(actVal, IsLessThan(4))
```

```
Interactive verification passed.
```

Test that the actual value is less than three.

```
testCase.verifyThat(actVal, IsLessThan(3))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsLessThan failed.
--> The value must be less than the maximum value.

Actual Value:
         3
Maximum Value (Exclusive):
         3
```

The actual value is equal to, not less than, three.

Test that each element in the actual value array is less than four.

```
actVal = [1 2 3];
testCase.verifyThat(actVal, IsLessThan(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is less than four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsLessThan(4))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsLessThan failed.
--> Each element must be less than the maximum value.

    Failing Indices:
              2     4     6

Actual Value:
         1     2     3
         4     5     6
Maximum Value (Exclusive):
         4
```

The matrix contains three elements that are greater than or equal to four.

Test that the actual value, 0, is less than every element in an array.

```
testCase.verifyThat(0, IsLessThan([1 2 3]))

Interactive verification passed.
```

Test that elements in the actual value array are less than the corresponding ceiling values.

```
testCase.verifyThat([4 -9 0], IsLessThan([5 -3 2]))

Interactive verification passed.
```

Repeat the test, this time negating the second actual value element.

```
testCase.verifyThat([4 9 0], IsLessThan([5 -3 2]))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsLessThan failed.
--> Each element must be less than each corresponding element of the maximum value arra
```

```
    Failing Indices:
              2

Actual Value:
         4     9     0
Maximum Value (Exclusive):
         5    -3     2
```

The negated element is greater than `-3`.

`IsGreaterThan` | `IsGreaterThanOrEqualTo` | `IsLessThanOrEqualTo` | `lt`

matlab.unittest.constraints.IsLessThanOrEqualTo class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying value less than or equal to another value

Construction

`IsLessThanOrEqualTo(ceilVal)` creates a constraint specifying that an actual value is less than or equal to another value. The constraint is satisfied if the actual value array is less than or equal to the specified ceiling value, `ceilVal`. The actual value is less than or equal to `ceilVal` only if the result of the expression `actual <= ceilVal` is nonempty and all values are true.

Input Arguments

`ceilVal`

Maximum value to satisfy the constraint.

Properties

`CeilingValue`

Maximum value to satisfy the constraint. Set this property through the constructor via the `ceilVal` input argument.

Methods

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Less Than or Equal to Provided Ceiling Value

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsLessThanOrEqualTo

testCase = TestCase.forInteractiveUse;
```

Test that the actual value is less than or equal to four.

```
actVal = 3;
testCase.verifyThat(actVal, IsLessThanOrEqualTo(4))
```

```
Interactive verification passed.
```

Test that the actual value is less than or equal to three.

```
testCase.verifyThat(actVal, IsLessThanOrEqualTo(3))
```

```
Interactive verification passed.
```

Test that each element in the actual value array is less than or equal to four.

```
actVal = [1 2 3 4];
testCase.verifyThat(actVal, IsLessThanOrEqualTo(4))
```

```
Interactive verification passed.
```

Test that each element in the actual value matrix is less than or equal to four.

```
actVal = [1 2 3; 4 5 6];
testCase.verifyThat(actVal, IsLessThanOrEqualTo(4))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsLessThanOrEqualTo failed.
--> Each element must be less than or equal to the maximum value.

    Failing Indices:

`IsGreaterThan` | `IsGreaterThanOrEqualTo` | `IsLessThan` | `le`

matlab.unittest.constraints.IsOfClass class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying class type

Construction

`IsOfClass(class)` provides a constraint specifying the class type. The constraint is satisfied if the actual value is the same class as `class` . The constraint is not satisfied if the actual value derives from `class`.

Input Arguments

`class`

Class name that must be matched by the actual value to satisfy the constraint, specified as a fully qualified class name string or a `meta.class` instance.

Properties

`Class`

Class name that must be matched by the actual value to satisfy the constraint. Set this property through the constructor via the `class` input argument.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Class Is Specified Class

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsOfClass

testCase = TestCase.forInteractiveUse;
```

Verify that the actual value, 5, is a double.

```
testCase.verifyThat(5, IsOfClass('double'))

Interactive verification passed.
```

Repeat the test using an instance of `meta.class` instead of a string.

```
testCase.verifyThat(5, IsOfClass(?double))

Interactive verification passed.
```

Assert that zero is an instance of the logical class.

```
testCase.assertThat(0, IsOfClass('logical'))

Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
IsOfClass failed.
--> The value's class is incorrect.

    Actual Class:
        double
    Expected Class:
        logical

Actual Value:
         0
Assertion failed.
```

Verify that `@sin` is a function handle.

```
testCase.verifyThat(@sin, IsOfClass(?function_handle))

Interactive verification passed.
```

Verify that `name` is an instance of the `char` class.

```
name = 42;
testCase.verifyThat(name, IsOfClass('char'))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsOfClass failed.
--> The value's class is incorrect.

    Actual Class:
        double
    Expected Class:
        char

Actual Value:
        42
```

Test That Derived Class Is Instance of Specified Class

In a file in your working folder, create a class, `DerivedExample`, that inherits from the `handle` class.

```
classdef DerivedExample < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsOfClass

testCase = TestCase.forInteractiveUse
```

Verify that an instance of the `DerivedExample` class is an instance of a `handle`.

```
exObj = DerivedExample;
testCase.verifyThat(exObj, IsOfClass(?handle))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsOfClass failed.
```

```
--> The value's class is incorrect.

    Actual Class:
        DerivedExample
    Expected Class:
        handle

Actual Value:
      DerivedExample with no properties.
```

Even though `exObj` derives from the `handle` class, it is not an instance of the `handle` class.

Verify that an instance of the `DerivedExample` class is an instance of a `DerivedExample`.

```
testCase.verifyThat(exObj, IsOfClass(?DerivedExample))
```

```
Interactive verification passed.
```

matlab.unittest.constraints.IsReal class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying real valued array

Construction

`IsReal` provides a constraint specifying a real valued array. This constraint is satisfied only if the actual value contains only real values.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Array Is Real Valued

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsReal

testCase = TestCase.forInteractiveUse;
```

Verify that the values `5` and `5+0i` are real.

```
testCase.verifyThat(5, IsReal)
testCase.verifyThat(5+0i, IsReal)
```

```
Interactive verification passed.
Interactive verification passed.
```

Test if the imaginary number is real.

```
testCase.verifyThat(sqrt(-1), IsReal)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsReal failed.
--> The value must be real.

Actual Value:
      0.000000000000000 + 1.000000000000000i
```

The actual value is imaginary.

Assert that an array contains only real values.

```
testCase.assertThat([0 1 1 2 3 5 8 13], IsReal)
```

```
Interactive assertion passed.
```

Test that the array, `arr`, is real.

```
arr = [NaN -Inf];
testCase.verifyThat(arr, IsReal)
```

```
Interactive verification passed.
```

Multiply the array by a complex number and test that the values are not real.

```
testCase.verifyThat(42i*arr, ~IsReal)
```

```
Interactive verification passed.
```

`isreal`

matlab.unittest.constraints.IsSameHandleAs class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying handle instance same as another

Construction

`IsSameHandle(h)` provides a constraint specifying a handle instance or group of instances is same as another.

The constraint is satisfied only if each element of the actual value is the same instance as each corresponding element of `h`.

Input Arguments

`h`

`handle` object or array of `handle` objects. The actual value array passed to the qualification must be the same size as `h`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test Handles for Equality

In a file in your working folder, create the following handle class for interactive testing.

```
classdef ExampleHandle < handle
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSameHandleAs

testCase = TestCase.forInteractiveUse;
```

Instantiate two handles.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Verify that the handle, `h1`, is the same as `h1`.

```
testCase.verifyThat(h1, IsSameHandleAs(h1))
```

```
Interactive verification passed.
```

Test that `h1` is the same handle instance as `h2`.

```
testCase.verifyThat(h1, IsSameHandleAs(h2))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsSameHandleAs failed.
--> Values do not refer to the same handle.

Actual Value:
      ExampleHandle with no properties.
Expected Handle Object:
      ExampleHandle with no properties.
```

Test that two arrays of handles are the same instances.

```
expArr = [h1 h2 h1];
actArr = [h1 h2 h1];

testCase.verifyThat(expArr, IsSameHandleAs(actArr))
```

```
Interactive verification passed.
```

The arrays satisfy the constraint even though the elements within a particular array are not the same instance as each other.

Verify that the constraint is not satisfied if it expects a single handle and the actual value is an array of the same instances.

```
testCase.verifyThat([h1 h1], IsSameHandleAs(h1))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsSameHandleAs failed.
--> Sizes do not match.
     Actual Value Size           : [1  2]
     Expected Handle Object Size : [1  1]

Actual Value:
      1x2 ExampleHandle array with no properties.
Expected Handle Object:
      ExampleHandle with no properties.
```

Similarly, the constraint is not satisfied a single handle instance if it expects an array of handles.

```
testCase.verifyThat(h2, IsSameHandleAs([h2 h2]))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsSameHandleAs failed.
--> Sizes do not match.
     Actual Value Size           : [1  1]
     Expected Handle Object Size : [1  2]

Actual Value:
      ExampleHandle with no properties.
Expected Handle Object:
      1x2 ExampleHandle array with no properties.
```

matlab.unittest.constraints.IsScalar class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying scalar value

Construction

`IsScalar` provides a constraint that specifies a scalar value. The constraint is satisfied if the actual value is a scalar.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Scalar

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsScalar

testCase = TestCase.forInteractiveUse;
```

Verify that a value of zero satisfies the `IsScalar` constraint.

```
testCase.verifyThat(0,IsScalar)
```

```
Interactive verification passed.
```

Assert that a single object is scalar.

```
testCase.assertThat(timeseries(1),IsScalar)
```

```
Interactive verification passed.
```

Verify that a vector is not scalar.

```
testCase.verifyThat([2 3],IsScalar)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsScalar failed.
--> The value must be a scalar.
--> The value has a size of [1  2].

Actual Value:
         2     3
```

Assert that an empty structure does not satisfy the `IsScalar` constraint.

```
testCase.assertThat(struct([]),IsScalar)
```

```
Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
IsScalar failed.
--> The value must be a scalar.
--> The value has a size of [0  0].

Actual Value:
    0x0 struct array with no fields.
Assertion failed.
```

Introduced in R2014b

matlab.unittest.constraints.IsSparse class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying sparse array

Construction

`IsSparse` creates a constraint specifying a sparse array. This constraint is satisfied only when the actual value is sparse.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Array Is Sparse

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSparse

testCase = TestCase.forInteractiveUse;
```

Create an identity matrix, and test if it is sparse.

```
F = eye(7);
testCase.verifyThat(F, IsSparse)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
```

```
IsSparse failed.
--> The value must be sparse.

Actual Value:
         1     0     0     0     0     0     0
         0     1     0     0     0     0     0
         0     0     1     0     0     0     0
         0     0     0     1     0     0     0
         0     0     0     0     1     0     0
         0     0     0     0     0     1     0
         0     0     0     0     0     0     1
```

The matrix, `F`, is a full matrix.

Convert `F` to a sparse matrix and retest for sparsity.

```
S = sparse(F);
testCase.verifyThat(S, IsSparse)
```

```
Interactive verification passed.
```

`issparse`

matlab.unittest.constraints.IsSubstringOf class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying substring of another string

Construction

`IsSubstringOf(superstring)` creates a constraint specifying a substring of another string. The constraint is satisfied only if the actual value is contained within an expected string, `superstring`.

`IsSubstringOf(superstring,Name,Value)` provides a constraint with additional options specified by one or more Name,Value pair arguments. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`superstring`

Text that contains the actual value, specified as a string. `superstring` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'IgnoringCase'`

Indicator if the constraint is insensitive to case, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

`'IgnoringWhitespace'`

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

Properties

`IgnoreCase`

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`. This property applies at all levels of recursion, such as nested structures.

`IgnoreWhitespace`

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

`Superstring`

String that includes the actual value, specified in the input argument, `superstring`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Is Substring of Specified String

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsSubstringOf
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
S = 'This Is One Long String';
```

Test that the actual value string, `'One'`, is contained in `S`.

```
testCase.verifyThat('One', IsSubstringOf(S))
```

```
Interactive verification passed.
```

Test that the actual value string, `'long'`, is contained in `S`.

```
testCase.verifyThat('long', IsSubstringOf(S))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsSubstringOf failed.
--> The string must be found within the superstring.

Actual String:
    long
Expected Superstring:
    This Is One Long String
```

By default, the `IsSubstringOf` constraint is case sensitive.

Repeat the test ignoring case.

```
testCase.verifyThat('long', IsSubstringOf(S,...
    'IgnoringCase', true))
```

```
Interactive verification passed.
```

Test that the actual value string, `'thisisone'`, is contained in `S`. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat('thisisone', IsSubstringOf(S, ...
    'IgnoringCase', true, 'IgnoringWhitespace', true))
```

```
Interactive verification passed.
```

Assert that the actual value string, `'longer'`, is not contained in S.

```
testCase.assertThat('Longer', ~IsSubstringOf(S))
```

```
Interactive assertion passed.
```

matlab.unittest.constraints.IssuesNoWarnings class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying function that issues no warnings

Construction

`outConstObj = IssuesNoWarnings` creates a constraint, `outConstObj`, specifying a function that issues no warnings when the testing framework invokes it. The constraint is satisfied if no warnings are issued when the testing framework invokes the function.

`outConstObj = IssuesNoWarnings('WhenNargoutIs', numOutputs)` creates a constraint that can determine if the actual value is a function handle that issues no warnings when the testing framework invokes it with a particular number of output arguments, `numOutputs`.

Input Arguments

`numOutputs`

Number of outputs the constraint requests when invoking the function handle, specified as a non-negative, real, scalar integer.

Default: `0`

Properties

`FunctionOutputs`

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and the testing framework sets it when it invokes the function handle. The number of outputs is determined by the `Nargout` property.

`Nargout`

Number of output arguments the instance uses when executing functions. Set this property through the constructor via the `numOutputs` input argument.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate `IssuesNoWarnings` Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IssuesNoWarnings

testCase = TestCase.forInteractiveUse;
```

Verify that a call to `true` does not result in any warning.

```
testCase.verifyThat(@true, IssuesNoWarnings)
```

```
Interactive verification passed.
```

Verify that a call to `size` with an empty array does not result in any warning. Examine the output arguments.

```
issuesNoWarningsConstraint = IssuesNoWarnings('WhenNargoutIs', 2);
testCase.verifyThat(@() size([]), issuesNoWarningsConstraint)
[actualOut1, actualOut2] = issuesNoWarningsConstraint.FunctionOutputs{:};
```

```
Interactive verification passed.
```

Verify that the constraint is not satisfied if the actual value is not a function handle.

```
testCase.verifyThat(5, IssuesNoWarnings)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IssuesNoWarnings failed.
--> The value must be an instance of the expected type.
```

```
    Actual Class:
        double
    Expected Type:
        function_handle

Actual Value:
         5
```

Verify that the constraint is not satisfied if the actual value results in a warning.

```
testCase.verifyThat(@() warning('some:id', 'Message'), IssuesNoWarnings)
```

```

matlab.unittest.constraints.IssuesWarnings class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying function that issues expected warning profile

Description

The `IssuesWarnings` class creates a constraint that issues an expected warning profile. The constraint is satisfied only if the actual value is a function handle that issues a specific set of warnings. You specify warnings using warning identifiers.

By default, the constraint only confirms that when the testing framework invokes the function handle, MATLAB issues the specified set of warnings. It ignores the number of times the warnings are issued, in what order they are issued, and whether or not any unspecified warnings are issued. However, you can set parameters to respect the order, the count, and the warning set. Alternatively, you can specify the exact warning profile for comparison.

Construction

`outConstObj = IssuesWarnings(warnArr)` creates a constraint, `outConstObj`, specifying a function that issues expected warnings, `warnArr`.

`outConstObj = IssuesWarnings(expVal,Name,Value)` creates a constraint with additional options specified by one or more Name,Value pair arguments. `Name` must appear inside single quotes (`''`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`warnArr`

Warning identifiers expected when the testing framework invokes the function handle, specified as a cell array of warning identifiers. If `warnArr` is empty, the constructor throws an `MException`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'Exactly'`

Indicator if the value is a function handle that must issue a warning profile that is an exact match, specified as `false` or `true` (`logical` `0` or `1`). When this value is `false`, the instance relies on specification of other parameters and default instance behavior to determine the strictness of its comparison. When set to `true`, the instance requires the warning profile to be exactly the same as the specified warning profile.

Default: `false`

`'RespectingCount'`

Indicator whether to respect element counts, specified as `false` or `true` (`logical` `0` or `1`). When this value is `false`, the instance is insensitive to the number of occurrences of members and ignores their frequency. When set to `true`, the instance is sensitive to the total number of set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if the number of times that a particular warning issues differs from the number of times that warning is specified in `warnArr`.

Default: `false`

`'RespectingOrder'`

Indicator whether to respect the order of elements, specified as `false` or `true` (`logical` `0` or `1`). When this value is `false`, the instance is insensitive to the order of the set members. When set to `true`, the instance is sensitive to the order of the set members. This means that this instance is not satisfied if the order of the issued warnings differs from the order the warnings are specified in `warnArr`.

The order of a given set of warnings is determined by trimming the warning profiles to a profile with no repeated adjacent warnings. For example, the warning profile `{id:A, id:A, id:B, id:C, id:C, id:C, id:A, id:A, id:A}` is trimmed to `{id:A, id:B, id:C, id:A}`.

When this constraint respects order, the order of the warnings that are issued and expected must match the order of the expected warning profile. Warnings issued that are not listed in `warnArr` are ignored when determining order.

Default: `false`

`'RespectingSet'`

Indicator whether to respect set elements, specified as `false` or `true` (`logical 0` or `1`). When this value is `false`, the instance ignores additional set members. When set to `true`, the instance is sensitive to additional set members. This means that, in addition to ensuring that all of the specified warnings are issued, this instance is not satisfied if any extra, unspecified warnings are issued.

Default: `false`

`'WhenNargoutIs'`

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

Default: `0`

Properties

`Exact`

Indicator of whether the constraint performs exact comparisons. Set this property through the constructor via the name-value pair argument, `'Exactly'`.

`ExpectedWarnings`

Expected warning identifiers. Set this read-only property through the constructor via the `warnArr` input argument.

`FunctionOutputs`

Output arguments produced at invocation of the supplied function handle, specified as a cell array. This property provides access to output arguments. It is read only and the testing framework sets it when it invokes the function handle. The number of outputs is determined by the `Nargout` property.

`Nargout`

Number of output arguments the instance uses when it executes functions. Set this property through the constructor via the name-value pair argument, `'WhenNargoutIs'`.

`RespectCount`

Indicator if the constraint respects the element counts, specified through the constructor via the name-value pair argument, `'RespectingCount'`.

`RespectOrder`

Indicator if the constraint respects the order of elements, specified through the constructor via the name-value pair argument, `'RespectingOrder'`.

`RespectSet`

Indicator if the constraint respects set elements, specified through the constructor via the name-value pair argument, `'RespectingSet'`.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate `IssuesWarnings` Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IssuesWarnings

testCase = TestCase.forInteractiveUse;
```

Create a helper anonymous function for use in this example. Create several warning identifiers.

```
issueWarnings = @(idCell) cellfun(@(id) warning(id,'Message'), idCell);
```

```
firstID =   'first:id';
secondID =  'second:id';
thirdID =   'third:id';
```

Verify that the helper function issues a particular warning.

```
testCase.verifyThat(@() issueWarnings({firstID}),...
    IssuesWarnings({firstID}))
```

```
Interactive verification passed.
```

Verify the function issues a warning ignoring count, warning set, and order.

```
testCase.verifyThat(@() issueWarnings({firstID, thirdID, secondID,...
    firstID}), IssuesWarnings({secondID, firstID}))
```

```
Interactive verification passed.
```

Verify the function issues a warning while respecting the warning set.

```
testCase.verifyThat(@() issueWarnings({firstID, thirdID, secondID,...
    firstID}), IssuesWarnings({firstID, secondID, thirdID}, ...
    'RespectingSet', true))
```

```
Interactive verification passed.
```

Verify the function issues a warning while respecting the warning count.

```
testCase.verifyThat(@() issueWarnings({secondID, firstID, thirdID,...
    secondID}), IssuesWarnings({firstID, secondID, secondID}, ...
    'RespectingCount', true))
```

```
Interactive verification passed.
```

Verify the function issues a warning while respecting the warning order.

```
testCase.verifyThat(@() issueWarnings({firstID, secondID, secondID,...
    thirdID}), IssuesWarnings({firstID, secondID}, 'RespectingOrder', true))
```

```
Interactive verification passed.
```

Verify the function issues an exact match to the expected warning profile.

```
testCase.verifyThat(@() issueWarnings({firstID, secondID, secondID,...
    thirdID}), IssuesWarnings({firstID, secondID, secondID, thirdID}, ...
```

```
    'Exactly', true))

Interactive verification passed.
```

Verify that the constraint is not satisfied if the actual value is not a function handle.

```
testCase.verifyThat(5, IssuesWarnings({firstID}))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IssuesWarnings failed.
--> The value must be an instance of the expected type.

    Actual Class:
        double
    Expected Type:
        function_handle

Actual Value:
         5
```

Verify that the constraint is not satisfied if the function does not issue a warning.

```
testCase.verifyThat(@rand, IssuesWarnings({firstID}))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IssuesWarnings failed.
--> The function handle did not issue a correct warning profile.
    The expected warning profile ignores:
      Set
      Count
      Order
    --> The function handle did not issue any warnings.

    Expected Warning Profile:
         first:id

Evaluated Function:
```

```
        @rand
```

Verify that the constraint is not satisfied if the function issues a non-specified warning identifier.

```
testCase.verifyThat(@() issueWarnings({firstID}), IssuesWarnings({secondID}))
```

```

--> The function handle did not issue a correct warning profile.
    The expected warning profile must match exactly.
    --> The function handle did not issue the exact warning profile expected.

    Actual Warning Profile:
         first:id
         first:id
         second:id
         first:id
    Expected Warning Profile:
         first:id
         second:id
         first:id
         first:id

Evaluated Function:
        @()issueWarnings({firstID,firstID,secondID,firstID})
```

Test whether the warning array is the same as the expected array when respecting set, order and count.

```
testCase.verifyThat(actVal, IssuesWarnings(warnArr,...
    'RespectingSet',true,'RespectingOrder',true,'RespectingCount',true))

Interactive verification passed.
```

In this example, a constraint that specifies a warning profile that respects set, order and count is not the same as one that specifies an exact warning profile.

More About

- "Message Identifiers"

matlab.unittest.constraints.IsTrue class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying true value

Construction

`IsTrue` provides a constraint specifying a true value. This constraint is satisfied only by a scalar logical with a value of `true`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Tips

- For faster test execution, use `verifyTrue`, `assertTrue`, `assumeTrue`, or `fatalAssertTrue` instead of `IsTrue`.
- To display custom comparisons in the form of a function handle, use `ReturnsTrue` instead of `IsTrue`.

Examples

Test Actual Value Is True

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsTrue

testCase = TestCase.forInteractiveUse;
```

Test that `true` satisfies the `IsTrue` constraint.

```
testCase.verifyThat(true, IsTrue)
```

```
Interactive verification passed.
```

Test that the `IsTrue` constraint is not satisfied by `false`.

```
testCase.verifyThat(false, IsTrue)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsTrue failed.
--> The value must evaluate to "true".

Actual Value:
         0
```

The test fails because `false` returns `logical(0)`.

Test that the `IsTrue` constraint is not satisfied by the double `1`.

```
testCase.verifyThat(1, IsTrue)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsTrue failed.
--> The value must be logical. It is of type "double".

Actual Value:
         1
```

The `IsTrue` constraint is satisfied only by `logical(1)`.

Test that the `IsTrue` constraint is not satisfied by a logical array of ones.

```
testCase.verifyThat([true true true], IsTrue)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
```

```
---------------------
IsTrue failed.
--> The value must be scalar. It has a size of [1  3].

Actual Value:
         1     1     1
```

The `IsTrue` constraint is satisfied only if the value is scalar and `logical(1)`.

See Also

`IsFalse` | `ReturnsTrue`

matlab.unittest.constraints.LogicalComparator class

Package: matlab.unittest.constraints

Comparator for two logical values

Construction

`LogicalComparator` creates a comparator for two logical values. The comparator is satisfied if the actual and expected values have the same sparsity and the logical values are equivalent.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare Logical Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.LogicalComparator
import matlab.unittest.constraints.IsEqualTo

testCase = TestCase.forInteractiveUse;
```

Test the value of `true`.

```
testCase.assertThat(true, IsEqualTo(true, ...
    'Using', LogicalComparator))
```

```
Interactive assertion passed.
```

Test an array of `true` values.

```
testCase.assertThat([true true true], IsEqualTo(true, ...
```

```
    'Using', LogicalComparator))

Interactive assertion failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> LogicalComparator failed.
    --> The logical values are not equal

Actual Logical Value:
         1     1     1
Expected Logical Value:
         1
Assertion failed.
```

The actual value must be a scalar logical to satisfy the constraint.

Compare the value of `1` to `true`.

```
testCase.verifyThat(1, IsEqualTo(true, 'Using', LogicalComparator))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> LogicalComparator failed.
    --> The logical values are not equal

Actual Logical Value:
         1
Expected Logical Value:
         1
```

Compare the value of `false` to `true`.

```
testCase.assertThat(false, IsEqualTo(true, 'Using', LogicalComparator))

Interactive assertion failed.

---------------------
Framework Diagnostic:
```

```
---------------------
IsEqualTo failed.
--> LogicalComparator failed.
    --> The logical values are not equal

Actual Logical Value:
        0
Expected Logical Value:
        1
Assertion failed.
```

`matlab.unittest.constraints.IsEqualTo`

Introduced in R2013a

matlab.unittest.constraints.Matches class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying string matches regular expression

Construction

`Matches(expr)` creates a constraint that specifies that a string matches a regular expression. The constraint is satisfied only if the actual value matches the given regular expression, `expr`.

`Matches(expr,'IgnoringCase',caseInsensitive)` creates a constraint indicating whether to ignore case difference.

Input Arguments

`expr`

Regular expression that the actual value must match to satisfy the constraint, specified as a string. `expr` can include newline characters.

`caseInsensitive`

Indicator if the constraint is insensitive to case, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

Properties

`Expression`

Regular expression that the actual value must match, specified in the input argument, `expr`.

`IgnoreCase`

Indicator if the constraint is insensitive to case, specified in the input argument, `ignoreCase`. This property applies at all levels of recursion, such as nested structures.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Matches Regular Expression

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.Matches

testCase = TestCase.forInteractiveUse;
```

Test that the actual value string, `'Epsilon Eridani'`, matches `'eps'`.

```
testCase.verifyThat('Epsilon Eridani', Matches('^eps'))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
Matches failed.
--> The string did not match the regular expression.

Actual String:
    Epsilon Eridani
Regular Expression:
    ^eps
```

To satisfy the constraint, configure it to be case insensitive.

```
testCase.verifyThat('Epsilon Eridani', Matches('^eps', ...
```

```
    'IgnoringCase', true))
```

```
Interactive verification passed.
```

Define the regular expression that the actual value must match.

```
expr = 'Some[Ss]?tring';
```

The `[Ss]?` contained in the regular expression indicates that either `'S'` or `'s'` matches at that location 0 or 1 times.

Test that the actual values, `'SomeString'` and `'Somestring'`, satisfy the constraint.

```
testCase.verifyThat('SomeString', Matches(expr))
testCase.verifyThat('Somestring', Matches(expr))
```

```
Interactive verification passed.
Interactive verification passed.
```

Test that the actual value `'Sometring'` satisfies the constraint.

```
testCase.verifyThat('Sometring', Matches(expr))
```

```
Interactive verification passed.
```

Test that the actual value `'somestring'` satisfies the constraint.

```
testCase.verifyThat('somestring', Matches(expr))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
Matches failed.
--> The string did not match the regular expression.

Actual String:
    somestring
Regular Expression:
    Some[Ss]?tring
```

More About

- "Regular Expressions"

matlab.unittest.constraints.NumericComparator class

Package: matlab.unittest.constraints

Comparator for numeric data types

Construction

`NumericComparator` creates a comparator for numeric data types. The comparator is satisfied if inputs are of the same class with equivalent size, complexity, and sparsity, and the built-in `isequaln` function returns `true`.

`NumericComparator('Within',tolObj)` creates a comparator using a specified tolerance. In this case, `NumericComparator` first checks for equivalent class, size, and sparsity of the actual and expected values. If these checks fail, the comparator is not satisfied. If these checks pass and the `isequaln` or complexity check fails, `NumericComparator` delegates comparison to the supplied tolerance, `tolObj`.

Input Arguments

`tolObj`

`matlab.unittest.constraints.Tolerance` instance

Properties

`Tolerance`

Specific tolerance used in construction of the comparator, specified as a `Tolerance` object in the `tolObj` input argument

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare Numeric Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.NumericComparator
import matlab.unittest.constraints.IsEqualTo

testCase = TestCase.forInteractiveUse;
```

Use a numeric comparator to test that `1.618` is equal to `1.618`.

```
testCase.verifyThat(1.618, IsEqualTo(1.618,...
    'Using', NumericComparator))
```

```
Interactive verification passed.
```

Verify that `(1+sqrt(5))/2` is equal to `1.618`.

```
testCase.verifyThat((1+sqrt(5))/2, IsEqualTo(1.618, ...
    'Using', NumericComparator))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> Failure table:
                Index       Actual           Expected         Error                  Rel
                _____    ________________    ________    ____________________    ______

                1        1.61803398874989    1.618       3.39887498947977e-05    2.1006

Actual Value:
       1.618033988749895
Expected Value:
       1.618000000000000
```

Retest using a relative tolerance of `0.25%`.

```
import matlab.unittest.constraints.RelativeTolerance

testCase.verifyThat((1+sqrt(5))/2, IsEqualTo(1.618, ...
    'Using', NumericComparator('Within', RelativeTolerance(0.0025))))

Interactive verification passed.
```

matlab.unittest.constraints.IsEqualTo | matlab.unittest.constraints.Tolerance | isequaln

Introduced in R2013a

matlab.unittest.constraints.ObjectComparator class

Package: matlab.unittest.constraints

Comparator for MATLAB or Java objects

Construction

`ObjectComparator` creates a comparator for MATLAB or Java objects. The comparator is satisfied if the built-in `isequal` function returns `true`. However, if the class of the expected value defines an `isequaln` method, the `ObjectComparator` uses that method for comparison instead of `isequal`.

`ObjectComparator('Within',tolObj)` creates a comparator using a specified tolerance. `ObjectComparator` first checks that a call to `isequal` or `isequaln` returns `true`. If the check fails, the `ObjectComparator` checks for equivalent class, size, and sparsity of the actual and expected values. If these checks pass, `ObjectComparator` delegates comparison to the supplied tolerance, `tolObj`. The value of this tolerance must be of the same class as the actual and expected values.

Input Arguments

`tolObj`

`Tolerance` instance

Properties

`Tolerance`

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the `tolObj` input argument

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare MATLAB Objects

In a file, `MyInt.m`, in your working folder, create a subclass of `int8`.

```
classdef MyInt < int8
    methods
        function i = MyInt(value)
            i@int8(value);
        end
    end
end
```

At the command prompt, create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.ObjectComparator
import matlab.unittest.constraints.IsEqualTo

testCase = TestCase.forInteractiveUse;
```

Use an `ObjectComparator` to test that two instances of `MyInt` are equal to each other.

```
testCase.verifyThat(MyInt(10), ...
    IsEqualTo(MyInt(10), 'Using', ObjectComparator))
```

```
Interactive verification passed.
```

Test the equality of two instances of `MyInt` that are constructed with different input values.

```
testCase.verifyThat(MyInt(11), ...
    IsEqualTo(MyInt(10), 'Using', ObjectComparator))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> ObjectComparator failed.
    --> The objects are not equal using "isequal".

Actual Object:
```

```
      MyInt:

      int8 data:
       11
Expected Object:
      MyInt:

      int8 data:
       10
```

One instance of `MyInt` has a value of `11`, and the other has a value of `10`.

Repeat the test and specify that values must be equal within an absolute tolerance of `1`.

```
import matlab.unittest.constraints.AbsoluteTolerance

testCase.verifyThat(MyInt(11), IsEqualTo(MyInt(10), ...
    'Using', ObjectComparator('Within', AbsoluteTolerance(MyInt(1)))))
```

```
Interactive verification passed.
```

`matlab.unittest.constraints.IsEqualTo` | `matlab.unittest.constraints.Tolerance` | `isequal`

Introduced in R2013a

matlab.unittest.constraints.PublicPropertyComparator class

Package: matlab.unittest.constraints

Comparator for public properties of MATLAB objects

Description

The `PublicPropertyComparator` compares public properties of MATLAB objects.

The `PublicPropertyComparator` supports MATLAB objects or arrays of objects and recursively compares data structures contained in the public properties. The `PublicPropertyComparator` is different from the `isequal` function because it examines only the public properties of the objects.

Construction

`PublicPropertyComparator` creates a comparator for public properties of MATLAB objects. This comparator supports only objects with no public properties.

`PublicPropertyComparator(compObj)` indicates a comparator, `compObj`, that defines the comparator used to compare public properties. This comparator supports recursion only in the data types supported by `compObj`.

`PublicPropertyComparator(compObj,Name,Value)` provides a comparator with additional options specified by one or more Name,Value pair arguments.

`PublicPropertyComparator(Name,Value)` provides a comparator for MATLAB objects with no public properties with additional options specified by one or more Name,Value pair arguments.

`PublicPropertyComparator.supportingAllValues` creates a comparator for public properties of MATLAB objects. This comparator supports any value in recursion. `supportingAllValues` is a `Static` method of the `PublicPropertyComparator` class.

You typically pass this comparator to another constraint, such as `IsEqualTo`. You can use the `Name,Value` pairs of the `IsEqualTo`

constraint in combination with a comparator constructed with the `PublicPropertyComparator.supportingAllValues` syntax.

Input Arguments

`compObj`

Comparator object

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'IgnoringCase'`

Indicator if the comparator is insensitive to case, specified as `false` or `true` (`logical` `0` or `1`). When it is `false`, the comparator is sensitive to case. The comparator uses this name-value pair only if the content being compared consists of strings.

Default: `false`

`'IgnoringWhitespace'`

Indicator if the comparator is insensitive to whitespace characters, specified as `false` or `true` (`logical` `0` or `1`). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator uses this name-value pair only if the contents being compared consists of strings.

Default: `false`

`'Recursively'`

Indicator of whether comparator operates recursively, specified as `false` or `true` (`logical` `0` or `1`). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types that the public property comparator supports are fully supported in recursion.

Default: `false`

`'Within'`

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. The comparator uses this name-value pair only if the contents being compared consist of numeric types.

Default: (empty)

Properties

`IgnoreCase`

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`

`IgnoreWhitespace`

Indicator if the comparator is insensitive to whitespace characters, specified in the name-value pair argument, `'IgnoringWhitespace'`

`Recursive`

Indicator of whether comparator operates recursively, specified in the name-value pair argument, `'Recursively'`

`Tolerance`

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, `'Within'`

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate `PublicPropertyComparator` Object

In a file in your working folder, construct this `Employee` class.

```
classdef Employee
    properties (SetAccess=immutable)
        Name
    end
    properties (Access=private)
        Location
    end
    methods
        function obj = Employee(name,location)
            obj.Name = name;
            obj.Location = location;
        end
    end
end
```

At the command prompt, create two instances of the `Employee` class.

```
e1 = Employee('sam','Building A');
e2 = Employee('Sam','Building B');
```

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.PublicPropertyComparator
import matlab.unittest.constraints.StringComparator

testCase = TestCase.forInteractiveUse;
```

Construct a comparator and verify that `e1` and `e2` are equal.

```
compObj = PublicPropertyComparator;
testCase.verifyThat(e1, IsEqualTo(e2,'Using',compObj))
```

```
Error using matlab.unittest.constraints.ComparatorList/throwUnsupportedType (line 148)
No comparator in list supports the char below:
    Sam
List contains the following comparators:
   <empty>
```

```
Error in matlab.unittest.constraints.ComparatorList/getAndPrepareComparatorFor (line 19
               list.throwUnsupportedType(expVal);

Error in matlab.unittest.constraints.ComparatorList/satisfiedBy (line 129)
            comp = list.getAndPrepareComparatorFor(expVal);

Error in matlab.unittest.internal.constraints.FieldComparator/findFirstDifferingField (
                  bool = comp.satisfiedBy(actField, expField);

Error in matlab.unittest.internal.constraints.FieldComparator/fieldsHaveSameContents (l
            bool = comparator.findFirstDifferingField(actVal, expVal);

Error in matlab.unittest.internal.constraints.FieldComparator/satisfiedBy (line 22)
            bool = haveSameClass(actVal, expVal) && ...

Error in matlab.unittest.constraints.IsEqualTo/satisfiedBy (line 165)
            bool = comp.supports(actual) && comp.satisfiedBy(actual, constraint.Expecte

Error in matlab.unittest.internal.qualifications.QualificationDelegate/qualifyThat (lin
               result = constraint.satisfiedBy(actual);

Error in matlab.unittest.qualifications.Verifiable/verifyThat (line 206)
            qualifyThat(verifiable.VerificationDelegate, actual, constraint, varargin{
```

The test fails because, by default, the `PublicPropertyComparator` does not support strings.

Construct a comparator that supports strings. Specify that the comparison is not case-sensitive.

```
compObj = PublicPropertyComparator(StringComparator, 'IgnoringCase',true);
testCase.verifyThat(e1, IsEqualTo(e2,'Using',compObj))
```

```
Interactive verification passed.
```

Note that the test passes even though `e1.Location` and `e2.Location` are not the same. Since `Location` is a private property, the comparator does not compare its contents.

Instantiate `PublicPropertyComparator` Object to Support All Values

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
```

```
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.PublicPropertyComparator

testCase = TestCase.forInteractiveUse;
```

Test a passing case.

```
m1 = MException('Msg:ID','MsgText');
m2 = MException('Msg:ID','MsgText');
testCase.verifyThat(m1, IsEqualTo(m2, 'Using', ...
    PublicPropertyComparator.supportingAllValues))

Interactive verification passed.
```

Test a failing case.

```
m1 = MException('Msg:ID','MsgText');
m2 = MException('Msg:ID','msgtext');
testCase.verifyThat(m1, IsEqualTo(m2, 'Using', ...
    PublicPropertyComparator.supportingAllValues))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> StringComparator failed.
    Path to failure: <Value>.message
    --> The strings are not equal

    Actual String:
        MsgText
    Expected String:
        msgtext

Actual MException:
      MException with properties:

        identifier: 'Msg:ID'
           message: 'MsgText'
             cause: {}
             stack: [0x1 struct]
Expected MException:
      MException with properties:
```

```
        identifier: 'Msg:ID'
           message: 'msgtext'
             cause: {}
             stack: [0x1 struct]
```

Test a case that passes when the comparator ignores differences in case.

```
m1 = MException('Msg:ID','MsgText');
m2 = MException('Msg:ID','msgtext');
testCase.verifyThat(m1, IsEqualTo(m2, 'IgnoringCase', true,...
    'Using', PublicPropertyComparator.supportingAllValues))
```

```
Interactive verification passed.
```

Instantiate `PublicPropertyComparator` Object with Tolerance

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance
import matlab.unittest.constraints.PublicPropertyComparator

testCase = TestCase.forInteractiveUse;
```

Define actual and expected `timeseries` objects. Perturb one of the actual data points by 1%.

```
expected = timeseries(1:10);
actual = expected;
actual.Data(7) = 1.01*actual.Data(7);
```

Test that the actual and expected values are equal within a relative tolerance of 2%.

```
testCase.verifyThat(actual, IsEqualTo(expected,...
    'Within', RelativeTolerance(.02)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> ObjectComparator failed.
    --> The objects are not equal using "isequal".
    --> The tolerance does not support timeseries values so it was not used.
```

```
Actual Object:
      timeseries

      Common Properties:
                Name: 'unnamed'
                Time: [10x1 double]
            TimeInfo: [1x1 tsdata.timemetadata]
                Data: [1x1x10 double]
            DataInfo: [1x1 tsdata.datametadata]

      More properties, Methods
Expected Object:
      timeseries

      Common Properties:
                Name: 'unnamed'
                Time: [10x1 double]
            TimeInfo: [1x1 tsdata.timemetadata]
                Data: [1x1x10 double]
            DataInfo: [1x1 tsdata.datametadata]

      More properties, Methods
```

Use the `PublicPropertyComparator` in the construction of the constraint.

```
testCase.verifyThat(actual, IsEqualTo(expected,...
    'Within', RelativeTolerance(.02),...
    'Using', PublicPropertyComparator.supportingAllValues))
```

```
Interactive verification passed.
```

The test passes because the `PublicPropertyComparator` compares each public property individually instead of comparing the object all at once. In the former test, the `ObjectComparator` compares `timeseries` objects, and therefore relies on the `isequal` method of the `timeseries` class. Due to the perturbation in the actual `timeseries`, `isequal` returns `false`. The comparator does not apply the tolerance because the double-valued tolerance cannot apply directly to the `timeseries` object. In the latter test, the comparator applies the tolerance to each public property that contains double-valued data.

`matlab.unittest.constraints.ObjectComparator`

Introduced in R2014a

matlab.unittest.constraints.RelativeTolerance class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Tolerance

Relative numeric tolerance

Description

This numeric `Tolerance` assesses the magnitude of the difference between actual and expected values, relative to the expected value. For the tolerance to be satisfied, `abs(expVal - actVal) <= relTol.*abs(expVal)` must be true.

Construction

`RelativeTolerance(tolVals)` creates a relative tolerance object that assesses the magnitude of the difference between actual and expected values, relative to the expected value.

The data types of the inputs to the `RelativeTolerance` constructor determine which data types the tolerance supports. For example, `RelativeTolerance(10*eps)` constructs a `RelativeTolerance` for comparing double-precision numeric arrays while `RelativeTolerance(int8(2))` constructs a `RelativeTolerance` for comparing numeric arrays of type `int8`. If the actual and expected values being compared contain more than one numeric data type, the tolerance only applies to the data types specified by the values passed into the constructor.

To specify different tolerance values for different data types, you can pass multiple tolerance values to the constructor. For example, `RelativeTolerance(10*eps, 10*eps('single'), int8(1))` constructs an `RelativeTolerance` that applies the following absolute tolerances:

- `10*eps` applies a relative tolerance of `10*eps` for double-precision numeric arrays.
- `10*eps('single')` applies a relative tolerance of `10*eps` for single-precision numeric arrays.
- `int8(1)` applies a relative tolerance of `1` for numeric arrays of type `int8`.

You can specify more than one tolerance for a particular data type by combining tolerances with the & and | operators. To combine two tolerances, the sizes of the tolerance values for each data type must be compatible.

Input Arguments

`tolVals`

Numeric tolerances, specified as a comma-separated list of numeric arrays. Each input argument contains the tolerance specification for a particular data type. Each numeric array can be a scalar or array the same size as the actual and expected values.

Default:

Properties

`Values`

Numeric tolerances, specified by the `tolVals` input argument

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test with Relative Tolerance

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance

testCase = TestCase.forInteractiveUse;
```

Assert that the difference between an actual value, `4.1`, and an expected value, `4.5`, is less than 10%.

```
testCase.assertThat(4.1, IsEqualTo(4.5, ...
    'Within', RelativeTolerance(0.1)))
```

```
Interactive assertion passed.
```

Specify Relative Tolerance for Different Data Types

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.RelativeTolerance

testCase = TestCase.forInteractiveUse;
```

Create the following actual and expected cell arrays.

```
act = {'abc', 123, single(106)};
exp = {'abc', 122, single(105)};
```

Test that the arrays satisfy the `RelativeTolerance` constraint within 2%.

```
testCase.verifyThat(act, IsEqualTo(exp, ...
    'Within', RelativeTolerance(0.02)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    Path to failure: <Value>{3}
    --> The values are not equal using "isequaln".
    --> The tolerance does not support single values so it was not used.
    --> Failure table:
                Index    Actual    Expected    Error    RelativeError
                _____    ______    ________    _____    _____________

                1        106       105         1        0.00952381

    Actual Value:
```

```
           106
    Expected Value:
           105

Actual cell:
        'abc'    [123]    [106]
Expected cell:
        'abc'    [122]    [105]
```

The test fails because the tolerance is only applied to the `double` data type.

Create a tolerance object that specifies different tolerances for different data types.

```
tolObj = RelativeTolerance(0.02, single(0.02));
```

A tolerance of `2%` is a applied to `double` and `single` valued data.

Verify that the expected and actual values satisfy the `RelativeTolerance` constraint.

```
testCase.verifyThat(act, IsEqualTo(exp, 'Within', tolObj))
```

```
Interactive verification passed.
```

Combine Relative and Absolute Tolerances

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance

testCase = TestCase.forInteractiveUse;
```

Define an actual value approximation for `pi`.

```
act = 3.14;
```

Construct a tolerance object to test that the difference between the actual and expected values is within `0.001` and within `0.25%`.

```
tolObj = AbsoluteTolerance(0.001) & RelativeTolerance(0.0025);
```

Verify that the actual value is within the tolerance of the expected value of `pi`.

```
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> AndTolerance failed.
        --> AbsoluteTolerance failed.
            --> The error was not within absolute tolerance.
        --> RelativeTolerance passed.
        --> Failure table:
                    Index    Actual        Expected               Error
                    _____    ______    _________________    ____________________

                    1        3.14      3.14159265358979     -0.00159265358979299

Actual Value:
       3.140000000000000
Expected Value:
       3.141592653589793
```

The actual value does not satisfy the `AbsoluteTolerance` constraint.

Construct a constraint that is satisfied if the values are within `0.001` or `0.25%`, and then retest the actual value.

```
tolObj = AbsoluteTolerance(0.001) | RelativeTolerance(0.0025);
testCase.verifyThat(act, IsEqualTo(pi, 'Within', tolObj))
```

```
Interactive verification passed.
```

Combine Absolute and Relative Tolerances to Test Small and Large Values

Combine tolerances so when you test the equality of values, an absolute (floor) tolerance dominates when the values are near zero, and a relative tolerance dominates for larger values.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.RelativeTolerance
```

```
testCase = TestCase.forInteractiveUse;
```

Define two structures containing electromagnetic properties of a vacuum. One structure, `approxVacuumProps`, contains approximate values for the permeability and speed of light in a vacuum.

```
approxVacuumProps.Permeability = 1.2566e-06; % Approximate
approxVacuumProps.Permitivity = 8.854187817*10^-12;
approxVacuumProps.LightSpeed = 2.9979e+08; % Approximate

baselineVacuumProps.Permeability = 4*pi*10^-7;
baselineVacuumProps.Permitivity = 8.854187817*10^-12;
baselineVacuumProps.LightSpeed = 1/sqrt(...
    baselineVacuumProps.Permeability*baselineVacuumProps.Permitivity);
```

Test that the relative difference between the approximate and baseline values is within `eps*1e11`.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', RelativeTolerance(eps*1e11)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    Path to failure: <Value>.Permeability
    --> The values are not equal using "isequaln".
    --> RelativeTolerance failed.
        --> The error was not within relative tolerance.
        --> Failure table:
                    Index      Actual            Expected                  Error
                    _____    __________    ____________________    ____________________

                    1        1.2566e-06    1.25663706143592e-06    -3.70614359173257e-

    Actual Value:
             1.256600000000000e-06
    Expected Value:
             1.256637061435917e-06

Actual struct:
```

```
        Permeability: 1.256600000000000e-06
         Permitivity: 8.854187816999999e-12
          LightSpeed: 299790000
Expected struct:
        Permeability: 1.256637061435917e-06
         Permitivity: 8.854187816999999e-12
          LightSpeed: 2.997924580105029e+08
```

The test fails because the relative difference in the permeabilities is not within the tolerance. The difference between the two values is small, but the numbers are close to zero, so the difference relative to their size is not small enough to satisfy the tolerance.

Construct a tolerance object to test that the absolute difference between the approximate and baseline values is within `1e-4`.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', AbsoluteTolerance(1e-4)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    Path to failure: <Value>.LightSpeed
    --> The values are not equal using "isequaln".
    --> AbsoluteTolerance failed.
        --> The error was not within absolute tolerance.
        --> Failure table:
                    Index     Actual          Expected              Error             R
                    _____    _________    _________________    _________________    ___

                    1        299790000    299792458.010503    -2458.01050287485    -8.1

    Actual Value:
           299790000
    Expected Value:
             2.997924580105029e+08

Actual struct:
        Permeability: 1.256600000000000e-06
         Permitivity: 8.854187816999999e-12
          LightSpeed: 299790000
Expected struct:
```

```
        Permeability: 1.256637061435917e-06
         Permitivity: 8.854187816999999e-12
          LightSpeed: 2.997924580105029e+08
```

The test fails because the absolute difference in the speed of light is not within the tolerance. The difference between the two values is small relative to their size, but too large to satisfy the tolerance.

Construct a logical disjunction of tolerance objects to test that the absolute difference between the approximate and baseline values is within `1e-4` or the relative difference is within `eps*1e11`. The test uses this tolerance so permeability values that are close to zero satisfy the absolute (floor) tolerance, and speed of light values that are large, satisfy the relative tolerance.

```
testCase.verifyThat(approxVacuumProps, IsEqualTo(baselineVacuumProps, ...
    'Within', RelativeTolerance(eps*1e11)| AbsoluteTolerance(1e-4)))
```

```
Interactive verification passed.
```

`matlab.unittest.constraints.AbsoluteTolerance` | `matlab.unittest.constraints.IsEqualTo`

matlab.unittest.constraints.ReturnsTrue class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying function handle that returns true

Construction

`ReturnsTrue` provides a constraint specifying that a function handle that returns true. The constraint is satisfied only by a function handle that returns a scalar logical with a value of `true`.

When negated using the tilde operator, `~`, this constraint not only passes when the function handle returns `false`, but also when the function handle returns any non-scalar value (such as `[true true]`) or any non-logical (such as integer valued1).

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Tips

- To display custom comparisons in the form of a function handle, use `ReturnsTrue` instead of `IsTrue`.

Examples

Test Actual Value Specified by Function Handle Returns True

These comparisons are shown for example only. There are other constraints that might better handle the particular comparisons.

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.ReturnsTrue

testCase = TestCase.forInteractiveUse;
```

Verify that the `ReturnsTrue` constraint is satisfied by the value returned by a handle to `true`.

```
testCase.verifyThat(@true, ReturnsTrue)
```

```
Interactive verification passed.
```

Verify that the `ReturnsTrue` constraint is not satisfied by a handle to `false`.

```
testCase.verifyThat(@false, ReturnsTrue)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
ReturnsTrue failed.
--> The function handle should have evaluated to "true".
--> Returned value:
             0

Actual Function Handle:
        @false
```

Verify that a call to `isequal` returns true.

```
testCase.verifyThat(@() isequal(1,1), ReturnsTrue)
```

```
Interactive verification passed.
```

Verify that a function that returns a double-valued 1 does not satisfy the `ReturnsTrue` constraint.

```
testCase.verifyThat(@() double(true), ReturnsTrue)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
ReturnsTrue failed.
```

```
--> The function handle should have returned a logical value. It was of type "double".
--> Returned value:
             1

Actual Function Handle:
        @()double(true)
```

Verify that the negation of a string comparison of `'a'` and `'b'` returns true.

```
testCase.verifyThat(@() ~strcmp('a','b'), ReturnsTrue)
```

```
Interactive verification passed.
```

Test if a comparison of `'a'` to the cell array `{'a','a'}` returns true.

```
testCase.verifyThat(@() strcmp('a',{'a','a'}), ReturnsTrue)
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
ReturnsTrue failed.
--> The function handle should have returned a scalar. The return value had a size of |
--> Returned value:
             1     1

Actual Function Handle:
        @()strcmp('a',{'a','a'})
```

The constraint is not satisfied because the call to `strcmp` results a logical array, not a logical scalar.

`Constraint` | `IsTrue`

matlab.unittest.constraints.StartsWithSubstring class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.BooleanConstraint

Constraint specifying string starting with substring

Construction

`StartsWithSubstring(prefix)` creates a constraint specifying a string starting with a substring. The constraint is satisfied only if the actual value starts with an expected string, `prefix`.

`StartsWithSubstring(prefix,Name,Value)` provides a constraint with additional options specified by one or more Name,Value pair arguments. `Name` must appear inside single quotes (`' '`). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`prefix`

Text at the start of the actual value, specified as a string. `prefix` can include newline characters.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'IgnoringCase'`

Indicator if the constraint is insensitive to case, specified as `false` or `true` (`logical 0` or `1`)

Default: `false`

`'IgnoringWhitespace'`

Indicator if the constraint is insensitive to whitespace, specified as `false` or `true` (`logical` `0` or `1`)

Default: `false`

Properties

`IgnoreCase`

Indicator if the constraint is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`. This property applies at all levels of recursion, such as nested structures.

`IgnoreWhitespace`

Indicator if the constraint is insensitive to whitespace, specified in the name-value pair argument, `'IgnoringWhitespace'`. This property applies at all levels of recursion, such as nested structures.

`Prefix`

Text at the start of the actual value, specified in the input argument, `prefix`.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Test That Actual Value Starts with Specified Substring

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.StartsWithSubstring
```

```
testCase = TestCase.forInteractiveUse;
```

Define the actual value string.

```
actVal = 'This Is One Long String';
```

Test that `actVal` starts with the substring `'This'`.

```
testCase.verifyThat(actVal, StartsWithSubstring('This'))
```

```
Interactive verification passed.
```

Test that `actVal` starts with the substring `'this is'`.

```
testCase.verifyThat(actVal, StartsWithSubstring('this is'))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
StartsWithSubstring failed.
--> The string has an incorrect prefix.

Actual String:
    This Is One Long String
Expected Prefix:
    this is
```

By default, the `StartsWithSubstring` constraint is case sensitive.

Repeat the test, this time ignoring case.

```
testCase.verifyThat(actVal, StartsWithSubstring('this is',...
    'IgnoringCase', true))
```

```
Interactive verification passed.
```

Test that `actVal` starts with the substring `'thisisone'`. For the test to pass, configure the constraint to ignore whitespace and case.

```
testCase.verifyThat(actVal, StartsWithSubstring('thisisone', ...
    'IgnoringCase', true, 'IgnoringWhitespace', true))
```

```
Interactive verification passed.
```

Assert that `actVal` does not start with the substring `'long'`.

```
testCase.assertThat(actVal, ~StartsWithSubstring('Long'))
```

```
Interactive assertion passed.
```

See Also

`ContainsSubstring` | `EndsWithSubstring` | `IsSubstringOf` | `Matches`

matlab.unittest.constraints.StringComparator class

Package: matlab.unittest.constraints

Comparator for two strings

Construction

`StringComparator` creates a comparator for two strings. The comparator is satisfied if the two strings are equal.

`StringComparator(Name,Value)` creates a comparator with additional options specified by one or more Name,Value pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'IgnoringCase'`

Indicator if the comparator is insensitive to case, specified as `false` or `true` (`logical 0` or `1`). When it is `false`, the comparator is sensitive to case.

Default: `false`

`'IgnoringWhitespace'`

Indicator if the comparator is insensitive to whitespace characters, specified as `false` or `true` (`logical 0` or `1`). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab.

Default: `false`

Properties

`IgnoreCase`

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`

`IgnoreWhitespace`

Indicator if the comparator is insensitive to whitespace characters, specified in the name-value pair argument, `'IgnoringWhitespace'`

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare Cell Arrays

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.StringComparator
import matlab.unittest.constraints.IsEqualTo

testCase = TestCase.forInteractiveUse;
```

Verify that the actual and expected strings are equal using a string comparator.

```
expected = 'coffee';
actual = 'coffee';
testCase.verifyThat(actual,IsEqualTo(expected, ...
    'Using', StringComparator))
```

```
Interactive verification passed.
```

Change the actual string and repeat the comparison.

```
expected = 'coF Fee';
```

```
testCase.verifyThat(actual,IsEqualTo(expected, ...
    'Using', StringComparator))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> StringComparator failed.
    --> The strings are not equal

Actual String:
    coffee
Expected String:
    coF Fee
```

For the test to pass, construct a comparator that ignores case and whitespace characters.

```
testCase.verifyThat(actual,IsEqualTo(expected, ...
    'Using', StringComparator('IgnoringCase', true, ...
    'IgnoringWhitespace', true)))

Interactive verification passed.
```

See Also

`matlab.unittest.constraints.IsEqualTo` | `strcmp`

Introduced in R2013a

matlab.unittest.constraints.StructComparator class

Package: matlab.unittest.constraints

Comparator for MATLAB structure arrays

Construction

`StructComparator` creates a comparator for MATLAB structure arrays.

`StructComparator(compObj)` indicates a comparator, `compObj`, that defines the comparator used to compare values contained in the structure. By default, a `StructComparator` supports only empty structure arrays.

`StructComparator(compObj,Name,Value)` provides a comparator with additional options specified by one or more Name,Value pair arguments.

`StructComparator(Name,Value)` provides a comparator for empty structure arrays with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`compObj`

Comparator object

A comparator is passed into the `StructComparator` to provide support for data types during recursion. By default, the `StructComparator` supports only empty structure arrays.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

'IgnoringCase'

Indicator if the comparator is insensitive to case, specified as `false` or `true` (`logical` `0` or `1`). When it is `false`, the comparator is sensitive to case. The comparator uses this name-value pair only if the contents being compared are strings.

Default: `false`

'IgnoringWhitespace'

Indicator if the comparator is insensitive to whitespace characters, specified as `false` or `true` (`logical` `0` or `1`). When it is `false`, the comparator is sensitive to whitespace characters. Whitespace characters consist of space, form feed, new line, carriage return, horizontal tab, and vertical tab. The comparator uses this name-value pair only if the contents being compared are strings.

Default: `false`

'Recursively'

Indicator of whether comparator operates recursively, specified as `false` or `true` (`logical` `0` or `1`). When this value is `false`, the comparator does not operate recursively on its data.

When the value is `true`, the data types the `StructComparator` supports are fully supported in recursion. For example:

```
comp1 = StructComparator(NumericComparator);
comp2 = StructComparator(NumericComparator, 'Recursively', true);
```

Both `comp1` and `comp2` support structures that contain numeric values as their fields. However, only `comp2` supports structures that recursively contain either structures or numeric values as their fields.

Default: `false`

'Within'

Tolerance to use for numerical comparison, specified as a `matlab.unittest.constraints.Tolerance` object. This name-value pair is applicable to contents that are numeric types.

Default: (empty)

Properties

`IgnoreCase`

Indicator if the comparator is insensitive to case, specified in the name-value pair argument, `'IgnoringCase'`

`IgnoreWhitespace`

Indicator if the comparator is insensitive to whitespace characters, specified in the name-value pair argument, `'IgnoringWhitespace'`

`Recursive`

Indicator of whether comparator operates recursively, specified in the name-value pair argument, `'Recursively'`

`Tolerance`

Specific tolerance used in construction of the comparator, specified as a `matlab.unittest.constraints.Tolerance` object in the name-value pair argument, `'Within'`

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Compare Numeric Structures

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.AbsoluteTolerance
import matlab.unittest.constraints.StructComparator
import matlab.unittest.constraints.NumericComparator
```

```
testCase = TestCase.forInteractiveUse;
```

Create two equal structures.

```
s1 = struct('id',7,'score',7.3);
s2 = s1;
```

Test that the structures are equal. By default, the `StructComparator` supports only empty structures, so you need to configure the comparator with a `NumericComparator`.

```
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...
    StructComparator(NumericComparator)))
```

```
Interactive verification passed.
```

Change the score of `s2` and compare the structures again.

```
s2.score = 7.6;
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...
    StructComparator(NumericComparator)))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    Path to failure: <Value>.score
    --> The values are not equal using "isequaln".
    --> Failure table:
                Index    Actual    Expected    Error       RelativeError
                _____    ______    ________    _____    __________________

                1        7.3       7.6         -0.3     -0.0394736842105263

    Actual Value:
           7.300000000000000
    Expected Value:
           7.600000000000000

Actual struct:
           id: 7
        score: 7.300000000000000
```

```
Expected struct:
           id: 7
        score: 7.600000000000000
```

Specify an absolute tolerance for the comparison.

```
testCase.verifyThat(s1, IsEqualTo(s2, 'Using', ...
    StructComparator(NumericComparator, 'Within', ...
    AbsoluteTolerance(0.5))))
```

```
Interactive verification passed.
```

Compare Character Structures

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.constraints.StructComparator
import matlab.unittest.constraints.StringComparator

testCase = TestCase.forInteractiveUse;
```

Create two structures. Make one of the fields a nested structure.

```
e1 = struct('name', struct('first','sam','last','smith'), ...
    'location','Building A');
e2 = e1;
```

Verify that the two structures are equal. Since the struct contains a nested structure, configure the constraint to operate recursively.

```
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...
    StructComparator(StringComparator, 'Recursively', true)))
```

```
Interactive verification passed.
```

Change the first name field of the `e2` structure and repeat the comparison.

```
e2.name.first = ' SAM';
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...
    StructComparator(StringComparator, 'Recursively', true)))
```

```
Interactive verification failed.

--------------------
```

```
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> StringComparator failed.
    Path to failure: <Value>.name.first
    --> The strings are not equal

    Actual String:
        sam
    Expected String:
         SAM

Actual struct:
            name: [1x1 struct]
        location: 'Building A'
Expected struct:
            name: [1x1 struct]
        location: 'Building A'
```

Configure the comparator to ignore case and whitespace characters.

```
testCase.verifyThat(e1, IsEqualTo(e2, 'Using', ...
    StructComparator(StringComparator, 'Recursively', true, ...
    'IgnoringCase', true, 'IgnoringWhitespace', true)))

Introduced in R2013a

matlab.unittest.constraints.Throws class

Package: matlab.unittest.constraints
Superclasses: matlab.unittest.constraints.Constraint

Constraint specifying function handle that throws MException

Description

The `Throws` class creates a constraint that is satisfied only if the actual value is a function handle that throws a specific exception.

If the function throws an `MException` and the `ExpectedException` property of the constraint is an error identifier, a qualification failure occurs if the actual `MException` thrown has a different identifier. Alternately, if the `ExpectedException` property is a `meta.class`, the constraint is not satisfied if the actual `MException` thrown does not derive from the `ExpectedException`.

Construction

`outConstObj = Throws(excep)` provides a constraint, `outConstObj`, specifying a function handle that throws a particular `MException`, `excep`.

`outConstObj = Throws(excep,Name,Value)` provides a constraint with additional options specified by one or more Name,Value pair arguments.

Input Arguments

`excep`

Error identifier or `meta.class` representing the specific type of expected exception. If `excep` is a `meta.class` but does not derive from `MException`, the `Throws` constructor throws an `MException`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single

quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`'CausedBy'`

Expected causes, specified as a cell array of strings or an array of `meta.class` instances.

The testing results in a qualification failure if any causes specified in `CausedBy` are not found within the cause tree.

Default: `{}`

`'WhenNargoutIs'`

Number of outputs the constraint should request when invoking the function handle, specified as a non-negative, real, scalar integer.

Default: `0`

Properties

`ExpectedException`

Expected `MException` identifier or class. Set this read-only property through the constructor via the `excep` input argument.

`Nargout`

Number of output arguments the instance uses when executing functions. Set this property through the constructor via the name-value pair argument, `'WhenNargoutIs'`.

`RequiredCauses`

Expected causes for the function handle throwing an `MException`. Set this property through the constructor via the name-value pair argument, `'CausedBy'`.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Instantiate Throws Constraint

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.Throws

testCase = TestCase.forInteractiveUse;
```

Verify that a function throws a specified error id.

```
testCase.verifyThat(@() error('SOME:error:id','Error!'), ...
    Throws('SOME:error:id'))
```

```
Interactive verification passed.
```

Verify that a function throws a specified exception class.

```
testCase.verifyThat(@() error('SOME:error:id','Error!'), ...
    Throws(?MException))
```

```
Interactive verification passed.
```

Verify that a function, when called with a specified number of outputs, throws a specified error.

```
testCase.verifyThat(@() disp('hi'), Throws('MATLAB:maxlhs', ...
    'WhenNargoutIs', 1))
```

```
Interactive verification passed.
```

Check causes by identifier.

```
me = MException('TOP:error:id','TopLevelError!');
causeBy = MException('causedBy:someOtherError:id','CausedByError!');
me  = me.addCause(causeBy);
testCase.verifyThat(@() me.throw, Throws('TOP:error:id','CausedBy', ...
    {'causedBy:someOtherError:id'}))
```

```
Interactive verification passed.
```

Check causes by class.

```
me = MException('TOP:error:id','TopLevelError!');
```

```
causeBy = MException('causedBy:someOtherError:id','CausedByError!');
me = me.addCause(causeBy);
testCase.verifyThat(@() me.throw, Throws('TOP:error:id','CausedBy', ...
    ?MException))

Interactive verification passed.
```

Verify that if the actual value is not a function handle, the constraint is not satisfied.

```
testCase.fatalAssertThat(5, Throws('some:id'))

Interactive fatal assertion failed.

----------------------
Framework Diagnostic:
----------------------
Throws failed.
--> The value must be an instance of the expected type.

    Actual Class:
        double
    Expected Type:
        function_handle

Actual Value:
         5
Fatal assertion failed.
```

Verify that if the function does not throw an exception, the constraint is not satisfied.

```
testCase.assumeThat(@rand, Throws(?MException))

Interactive assumption failed.

----------------------
Framework Diagnostic:
----------------------
Throws failed.
--> The function did not throw any exception.

    Expected Exception Type:
        MException

Evaluated Function:
        @rand
```

```
Assumption failed.
```

Verify that if the function issues a non-specified error identifier, the constraint is not satisfied.

```
testCase.verifyThat(@() error('SOME:id','Error!'), Throws('OTHER:id'))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
Throws failed.
--> The function threw the wrong exception.

    Actual Exception:
        SOME:id
    Expected Exception:
        OTHER:id

Evaluated Function:
        @()error('SOME:id','Error!')
```

Verify that if the function throws an exception and the cause does not match the specified identifier, the constraint is not satisfied.

```
testCase.verifyThat(@() error('TOP:error:id','TopLevelError!'), ...
    Throws('TOP:error:id','CausedBy',{'causedBy:someOtherError:id'}))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
Throws failed.
--> The following causes were not found in the exception tree:
    --> causedBy:someOtherError:id

Evaluated Function:
        @()error('TOP:error:id','TopLevelError!')
```

Introduced in R2013a

matlab.unittest.constraints.Tolerance class

Package: matlab.unittest.constraints

Abstract interface class for tolerances

Description

Tolerances define a notion of fuzzy equality for a set of data types and can be plugged in to the `IsEqualTo` constraint through the `'Within'` name-value pair argument.

Classes that derive from the `Tolerance` interface class must provide a tolerance definition. Use the `satisfiedBy` method to implement the tolerance definition. Classes that derive from the `Tolerance` class also must provide a diagnostic for two compared values. The testing framework uses the diagnostic when the compared values are outside of the allowable tolerance. Use the `getDiagnosticFor` method to implement this condition. Finally, classes that derive from the `Tolerance` class must provide a means to determine which data types the tolerance supports. Define the supported data types by implementing the `supports` method.

Methods

getDiagnosticFor	Produce diagnostic for two values specified to be within tolerance
satisfiedBy	Determine whether two values are within tolerance
supports	Determine whether tolerance supports specified data type

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create Custom Tolerance Class

Determine if two DNA sequences have a Hamming distance within a specified tolerance. For two DNA sequences (strings) of the same length, the Hamming distance is the number of positions in which the nucleotides (letters) of one sequence differ from the other.

In a file, `DNA.m`, in your working folder, create a simple class for a DNA sequence.

```
classdef DNA
    properties(SetAccess=immutable)
        Sequence
    end

    methods
        function dna = DNA(sequence)
            validLetters = ...
                sequence == 'A' | ...
                sequence == 'C' | ...
                sequence == 'T' | ...
                sequence == 'G';

            if ~all(validLetters(:))
                error('Sequence contained a letter not found in DNA.')
            end
            dna.Sequence = sequence;
        end
    end
end
```

In a file in your working folder, create a tolerance class so that you can test that DNA sequences are within a specified Hamming distance. The constructor requires a `Value` property that defines the maximum Hamming distance.

```
classdef HammingDistance < matlab.unittest.constraints.Tolerance
    properties
        Value
    end

    methods
        function tolerance = HammingDistance(value)
            tolerance.Value = value;
```

```
        end
    end
end
```

In a `methods` block with the `HammingDistance` class definition, include the following method so that the tolerance supports DNA objects. Tolerance classes must implement a `supports` method.

```
    methods
        function tf = supports(~, value)
            tf = isa(value, 'DNA');
        end
    end
```

In a `methods` block with the `HammingDistance` class definition, include the following method that returns `true` or `false`. Tolerance classes must implement a `satisfiedBy` method. The testing framework uses this method to determine if two values are within the tolerance.

```
    methods
        function tf = satisfiedBy(tolerance, actual, expected)
            if ~isSameSize(actual.Sequence, expected.Sequence)
                tf = false;
                return
            end
            tf = hammingDistance(actual.Sequence,expected.Sequence) <= tolerance.Value;
        end
    end
```

In the `HammingDistance.m` file, define the following helper functions outside of the `classdef` block. The `isSameSize` function returns `true` if two DNA sequences are the same size, and the `hammingDistance` function returns the Hamming distance between two sequences.

```
function tf = isSameSize(str1, str2)
tf = isequal(size(str1), size(str2));
end

function distance = hammingDistance(str1, str2)
distance = nnz(str1 ~= str2);
end
```

The function returns a `Diagnostic` object with information about the comparison. In a `methods` block with the `HammingDistance` class definition, include the following

method that returns a `StringDiagnostic`. Tolerance classes must implement a `getDiagosticFor` method.

```
    methods
        function diag = getDiagnosticFor(tolerance, actual, expected)
            import matlab.unittest.diagnostics.StringDiagnostic

            if ~isSameSize(actual.Sequence, expected.Sequence)
                str = 'The DNA sequences must be the same length.';
            else
                str = sprintf('%s%d.\n%s%d.', ...
                    'The DNA sequences have a Hamming distance of ', ...
                    hammingDistance(actual.Sequence, expected.Sequence), ...
                    'The allowable distance is ', ...
                    tolerance.Value);
            end
            diag = StringDiagnostic(str);
        end
    end
```

HammingDistance Class Definition Summary

```
classdef HammingDistance < matlab.unittest.constraints.Tolerance
    properties
        Value
    end

    methods
        function tolerance = HammingDistance(value)
            tolerance.Value = value;
        end

        function tf = supports(~, value)
            tf = isa(value, 'DNA');
        end

        function tf = satisfiedBy(tolerance, actual, expected)
            if ~isSameSize(actual.Sequence, expected.Sequence)
                tf = false;
                return
            end
            tf = hammingDistance(actual.Sequence,expected.Sequence) <= tolerance.Value;
        end

        function diag = getDiagnosticFor(tolerance, actual, expected)
```

```
            import matlab.unittest.diagnostics.StringDiagnostic

            if ~isSameSize(actual.Sequence, expected.Sequence)
                str = 'The DNA sequences must be the same length.';
            else
                str = sprintf('%s%d.\n%s%d.', ...
                    'The DNA sequences have a Hamming distance of ', ...
                    hammingDistance(actual.Sequence, expected.Sequence), ...
                    'The allowable distance is ', ...
                    tolerance.Value);
            end
            diag = StringDiagnostic(str);
        end
    end
end

function tf = isSameSize(str1, str2)
tf = isequal(size(str1), size(str2));
end

function distance = hammingDistance(str1, str2)
distance = nnz(str1 ~= str2);
end
```

At the command prompt, create a `TestCase` for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo

testCase = TestCase.forInteractiveUse;
```

Create two DNA objects.

```
sampleA = DNA('ACCTGAGTA');
sampleB = DNA('ACCACAGTA');
```

Verify that the DNA sequences are equal to each other.

```
testCase.verifyThat(sampleA, IsEqualTo(sampleB))
```

```
Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
```

```
IsEqualTo failed.
--> ObjectComparator failed.
    --> The objects are not equal using "isequal".

Actual Object:
      DNA with properties:

        Sequence: 'ACCTGAGTA'
Expected Object:
      DNA with properties:

        Sequence: 'ACCACAGTA'
```

Verify that the DNA sequences are equal to each other within a Hamming distance of 1.

```
testCase.verifyThat(sampleA, IsEqualTo(sampleB,...
    'Within', HammingDistance(1)))

Interactive verification failed.

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> ObjectComparator failed.
    --> The objects are not equal using "isequal".
    --> The DNA sequences have a Hamming distance of 2.
        The allowable distance is 1.

Actual Object:
      DNA with properties:

        Sequence: 'ACCTGAGTA'
Expected Object:
      DNA with properties:

        Sequence: 'ACCACAGTA'
```

The sequences are not equal to each other within a tolerance of 1. The testing framework displays additional diagnostics from the `getDiagnosticFor` method.

Verify that the DNA sequences are equal to each other within a Hamming distance of 2.

```
testCase.verifyThat(sampleA, IsEqualTo(sampleB,...
    'Within', HammingDistance(2)))
```

```
Interactive verification passed.
```

getDiagnosticFor

Class: matlab.unittest.constraints.Tolerance
Package: matlab.unittest.constraints

Produce diagnostic for two values specified to be within tolerance

Syntax

```
diag = getDiagnosticFor(tolObj,actVal,expVal)
```

Description

`diag = getDiagnosticFor(tolObj,actVal,expVal)` produces a diagnostic, `diag`, for a value, `actVal`, evaluated against another value, `expVal`, within the tolerance defined by `tolObj`. When creating a custom tolerance, the class author must implement the `getDiagnosticFor` method so that it analyzes the two values, `actVal` and `expVal`, against the tolerance, `tolObj`, and instantiates and returns a `matlab.unittest.diagnostics.Diagnostic` object.

Typically, this diagnostic is used when the `getDiagnosticFor` method of `IsEqualTo` is invoked, and the result is incorporated into the diagnostic output of the `IsEqualTo` constraint.

Input Arguments

`actVal`

Value to determine if is within tolerance of `expVal`

`tolObj`

`Tolerance` instance

`expVal`

Expected value

See Also

`ConstraintDiagnostic` | `Diagnostic` | `satisfiedBy` | `supports`

satisfiedBy

Class: matlab.unittest.constraints.Tolerance
Package: matlab.unittest.constraints

Determine whether two values are within tolerance

Syntax

```
TF = satisfiedBy(tolObj,actVal,expVal)
```

Description

`TF = satisfiedBy(tolObj,actVal,expVal)` determines whether two values, `actVal` and `expVal`, are within the tolerance defined by `tolObj`. The `satisfiedBy` method is used to determine whether the tolerance is met. It returns `true` or `false` (`logical` `0` or `1`). When creating a custom tolerance, a class author uses this method to contain the tolerance definition.

Input Arguments

`actVal`

Value to determine if is within tolerance of `expVal`

`tolObj`

`Tolerance` instance

`expVal`

Expected value

See Also

`getDiagnosticFor` | `supports`

supports

Class: matlab.unittest.constraints.Tolerance
Package: matlab.unittest.constraints

Determine whether tolerance supports specified data type

Syntax

```
TF = supports(tolObj,typeVal)
```

Description

`TF = supports(tolObj,typeVal)` determines whether the tolerance supports a specific data type. It returns `true` or `false` (`logical` `0` or `1`).

The `supports` method provides the ability for a tolerance author to specify support for data types. Generally, the method operates by examining the type of `typeVal` to determine whether it is supported.

Input Arguments

`tolObj`

`Tolerance` instance

`typeVal`

Value used to determine tolerance support

See Also

`getDiagnosticFor` | `satisfiedBy`

contrast

Grayscale colormap for contrast enhancement

Syntax

```
cmap = contrast(X)
cmap = contrast(X,m)
```

Description

The `contrast` function enhances the contrast of an `image`. It creates a new gray colormap, `cmap`, that has an approximately equal intensity distribution. All three elements in each row are identical.

`cmap = contrast(X)` returns a gray colormap that is the same length as the current colormap. If there are `NaN` or `Inf` elements in `X` the length of the colormap increases.

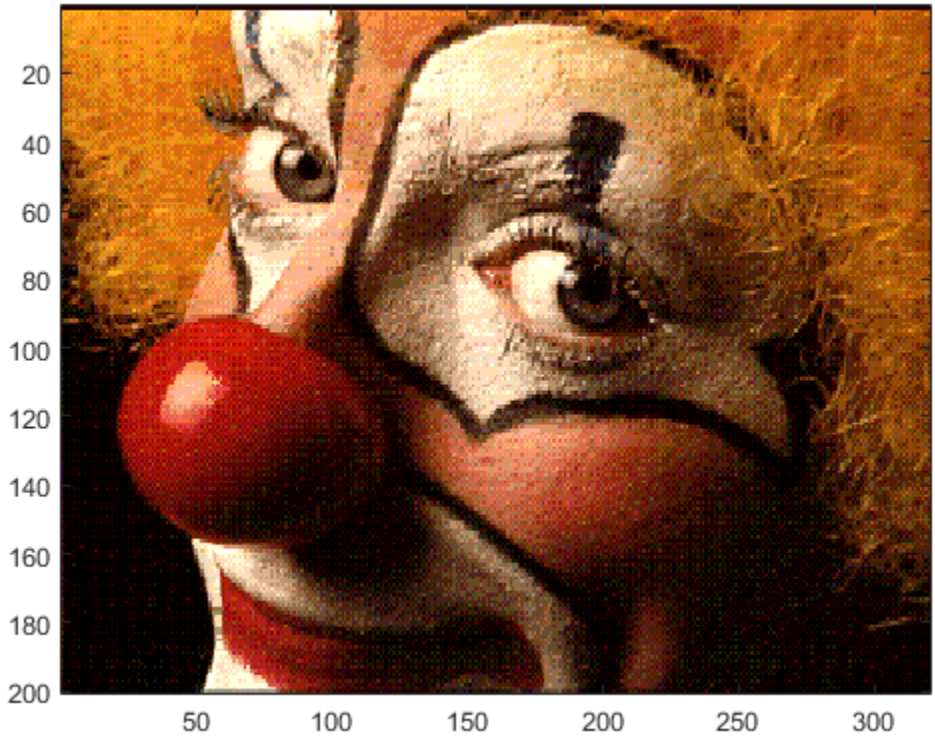
`cmap = contrast(X,m)` returns an `m`-by-3 gray colormap.

Examples

Display Image with Gray Colormap

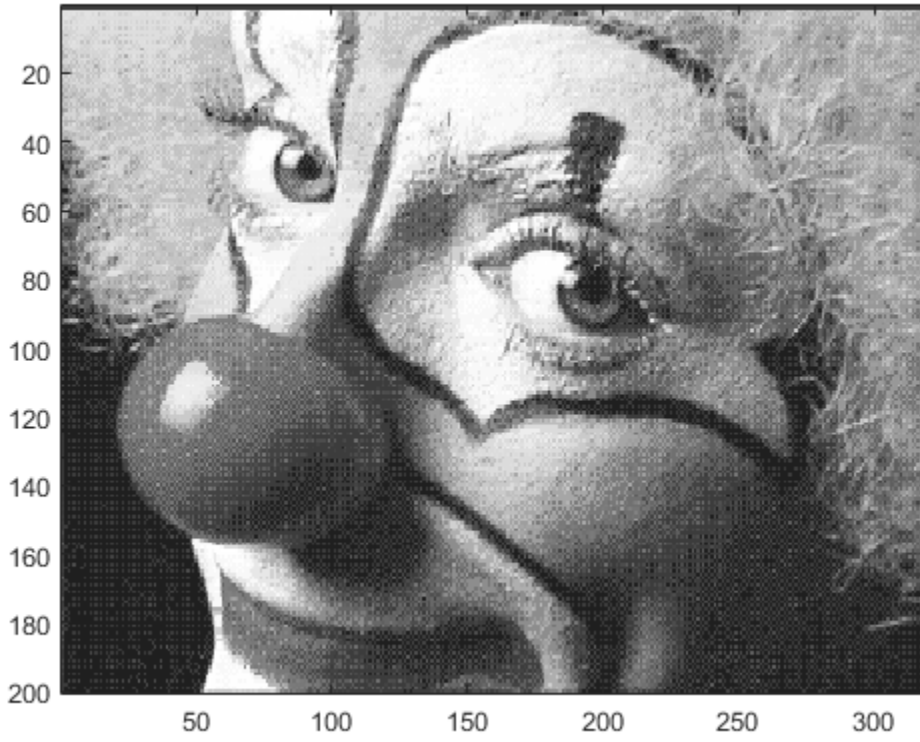
Load `clown` to get image `X` and its associated colormap, `map`. Display the image produced by `X` and `map`.

```
load clown
figure
image(X)
colormap(map)
```



Use `contrast` to return a gray colormap that is the same length as the current colormap, `map`. Display the image with the new colormap, `cmap`.

```
cmap = contrast(X);
colormap(cmap)
```



See Also

`brighten` | `image` | `colormap`

Introduced before R2006a

conv

Convolution and polynomial multiplication

Syntax

```
w = conv(u,v)
w = conv(u,v,shape)
```

Description

`w = conv(u,v)` returns the convolution of vectors `u` and `v`. If `u` and `v` are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials.

`w = conv(u,v,shape)` returns a subsection of the convolution, as specified by `shape`. For example, `conv(u,v,'same')` returns only the central part of the convolution, the same size as `u`, and `conv(u,v,'valid')` returns only the part of the convolution computed without the zero-padded edges.

Examples

Polynomial Multiplication via Convolution

Create vectors `u` and `v` containing the coefficients of the polynomials $x^2 + 1$ and $2x + 7$.

```
u = [1 0 1];
v = [2 7];
```

Use convolution to multiply the polynomials.

```
w = conv(u,v)
```

```
w =

     2     7     2     7
```

`w` contains the polynomial coefficients for $2x^3 + 7x^2 + 2x + 7$.

Vector Convolution

Create two vectors and convolve them.

```
u = [1 1 1];
v = [1 1 0 0 0 1 1];
w = conv(u,v)
```

```
w =

     1     2     2     1     0     1     2     2     1
```

The length of `w` is `length(u)+length(v)-1`, which in this example is `9`.

Central Part of Convolution

Create two vectors. Find the central part of the convolution of `u` and `v` that is the same size as `u`.

```
u = [-1 2 3 -2 0 1 2];
v = [2 4 -1 1];
w = conv(u,v,'same')
```

```
w =

    15     5    -9     7     6     7    -1
```

`w` has a length of `7`. The full convolution would be of length `length(u)+length(v)-1`, which in this example would be 10.

Input Arguments

`u,v` — Input vectors

vectors

Input vectors, specified as either row or column vectors. The output vector is the same orientation as the first input argument, `u`. The vectors `u` and `v` can be different lengths or data types.

Data Types: `double` | `single`
Complex Number Support: Yes

`shape` — Subsection of convolution

`'full'` (default) | `'same'` | `'valid'`

Subsection of the convolution, specified as `'full'`, `'same'`, or `'valid'`.

`'full'`	Full convolution (default).
`'same'`	Central part of the convolution of the same size as `u`.
`'valid'`	Only those parts of the convolution that are computed without the zero-padded edges. Using this option, `length(w)` is `max(length(u)-length(v)+1,0)`, except when `length(v)` is zero. If `length(v) = 0`, then `length(w) = length(u)`.

More About

Convolution

The convolution of two vectors, `u` and `v`, represents the area of overlap under the points as `v` slides across `u`. Algebraically, convolution is the same operation as multiplying polynomials whose coefficients are the elements of `u` and `v`.

Let `m = length(u)` and `n = length(v)` . Then `w` is the vector of length `m+n-1` whose `k`th element is

$$w(k) = \sum_j u(j)v(k-j+1).$$

The sum is over all the values of `j` that lead to legal subscripts for `u(j)` and `v(k-j+1)`, specifically `j = max(1,k+1-n):1:min(k,m)`. When `m = n`, this gives

```
w(1) = u(1)*v(1)
w(2) = u(1)*v(2)+u(2)*v(1)
w(3) = u(1)*v(3)+u(2)*v(2)+u(3)*v(1)
```

```
...
w(n) = u(1)*v(n)+u(2)*v(n-1)+ ... +u(n)*v(1)
...
w(2*n-1) = u(n)*v(n)
```

conv2 | convmtx | convn | deconv | filter | xcorr

Introduced before R2006a

conv2

2-D convolution

Syntax

```
C = conv2(A,B)
C = conv2(h1,h2,A)
C = conv2(...,shape)
```

Description

`C = conv2(A,B)` computes the two-dimensional convolution of matrices `A` and `B`. If one of these matrices describes a two-dimensional finite impulse response (FIR) filter, the other matrix is filtered in two dimensions. The size of `C` is determined as follows: if `[ma,na] = size(A)`, `[mb,nb] = size(B)`, and `[mc,nc] = size(C)`, then `mc = max([ma+mb-1,ma,mb])` and `nc = max([na+nb-1,na,nb])`.

`C = conv2(h1,h2,A)` first convolves each column of `A` with the vector `h1` and then convolves each row of the result with the vector `h2`. The size of `C` is determined as follows: if `n1 = length(h1)` and `n2 = length(h2)`, then `mc = max([ma +n1-1,ma,n1])` and `nc = max([na+n2-1,na,n2])`.

`C = conv2(...,shape)` returns a subsection of the two-dimensional convolution, as specified by the `shape` parameter:

`'full'`	Returns the full two-dimensional convolution (default).
`'same'`	Returns the central part of the convolution of the same size as `A`.
`'valid'`	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, `size(C) = max([ma-max(0,mb-1),na-max(0,nb-1)],0)`.

Note: All numeric inputs to `conv2` must be of type `double` or `single`.

Examples

Shape for Subsection of 2-D Convolution

For the `'same'` case, `conv2` returns the central part of the convolution. If there are an odd number of rows or columns, the "center" leaves one more at the beginning than the end.

This example first computes the convolution of A using the default (`'full'`) shape, then computes the convolution using the `'same'` shape. Note that the array returned using `'same'` corresponds to the red highlighted elements of the array returned using the default shape.

```
A = rand(3);
B = rand(4);
C = conv2(A,B)   % C is 6-by-6

C =
   0.1838  0.2374  0.9727  1.2644  0.7890  0.3750
   0.6929  1.2019  1.5499  2.1733  1.3325  0.3096
   0.5627  1.5150  2.3576  3.1553  2.5373  1.0602
   0.9986  2.3811  3.4302  3.5128  2.4489  0.8462
   0.3089  1.1419  1.8229  2.1561  1.6364  0.6841
   0.3287  0.9347  1.6464  1.7928  1.2422  0.5423

Cs = conv2(A,B,'same')   % Cs is the same size as A: 3-by-3
Cs =
   2.3576  3.1553  2.5373
   3.4302  3.5128  2.4489
   1.8229  2.1561  1.6364
```

Extract Edges from Raised Pedestal

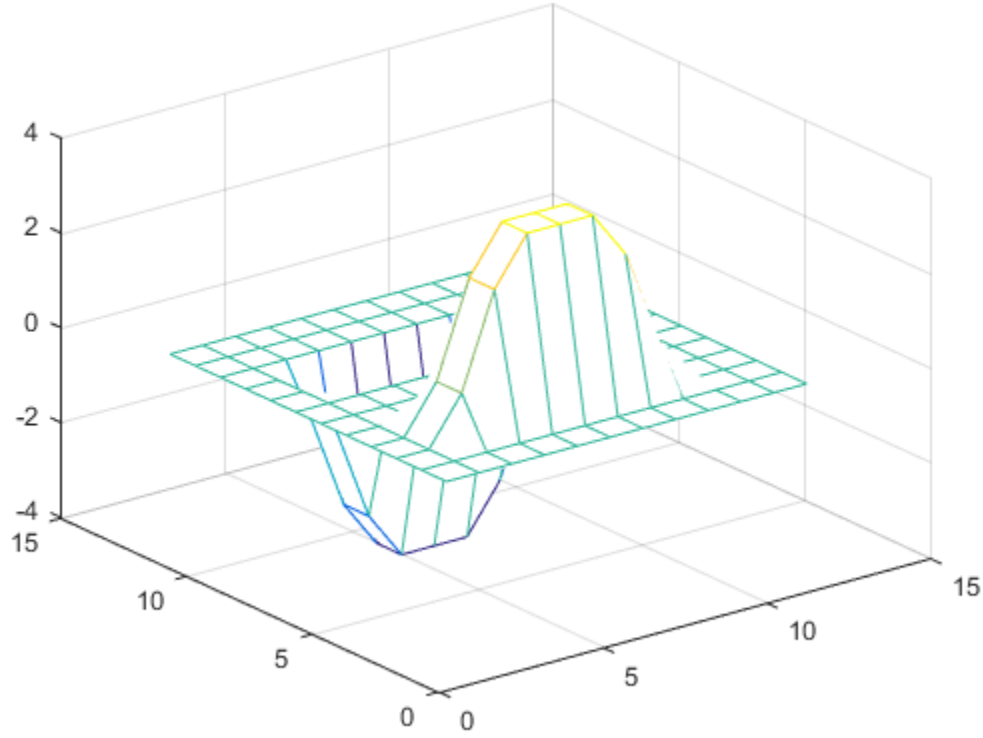
In image processing, the Sobel edge finding operation is a two-dimensional convolution of an input array with the special matrix:

```
s = [1 2 1; 0 0 0; -1 -2 -1];
```

These commands extract the horizontal edges from a raised pedestal.

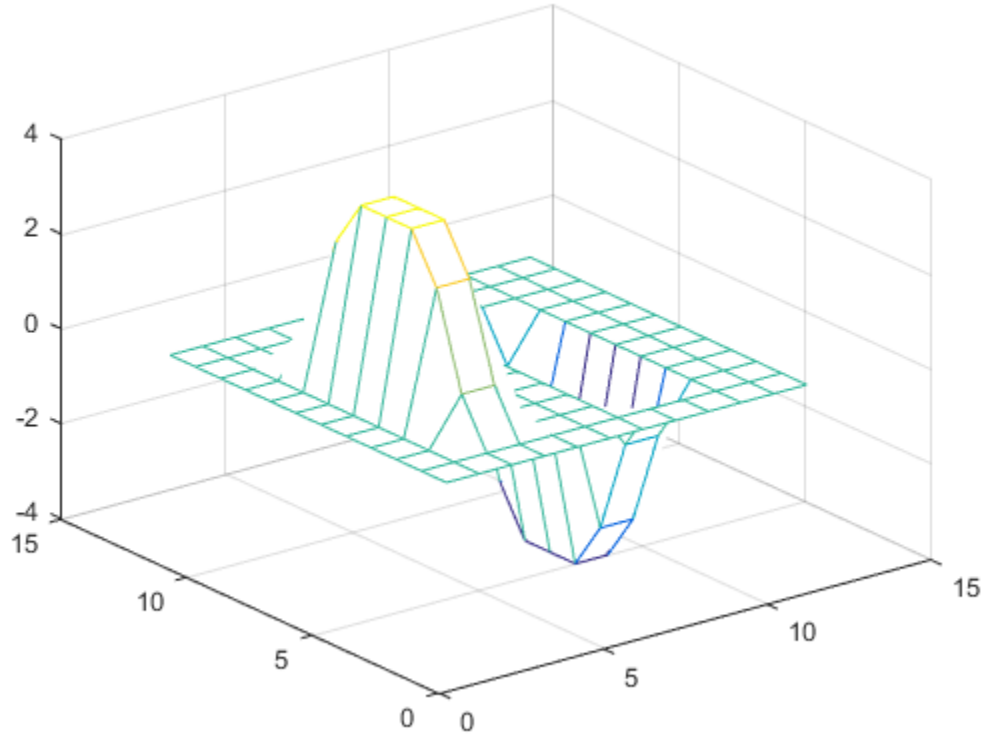
```
A = zeros(10);
```

```
A(3:7,3:7) = ones(5);
H = conv2(A,s);
figure, mesh(H)
```



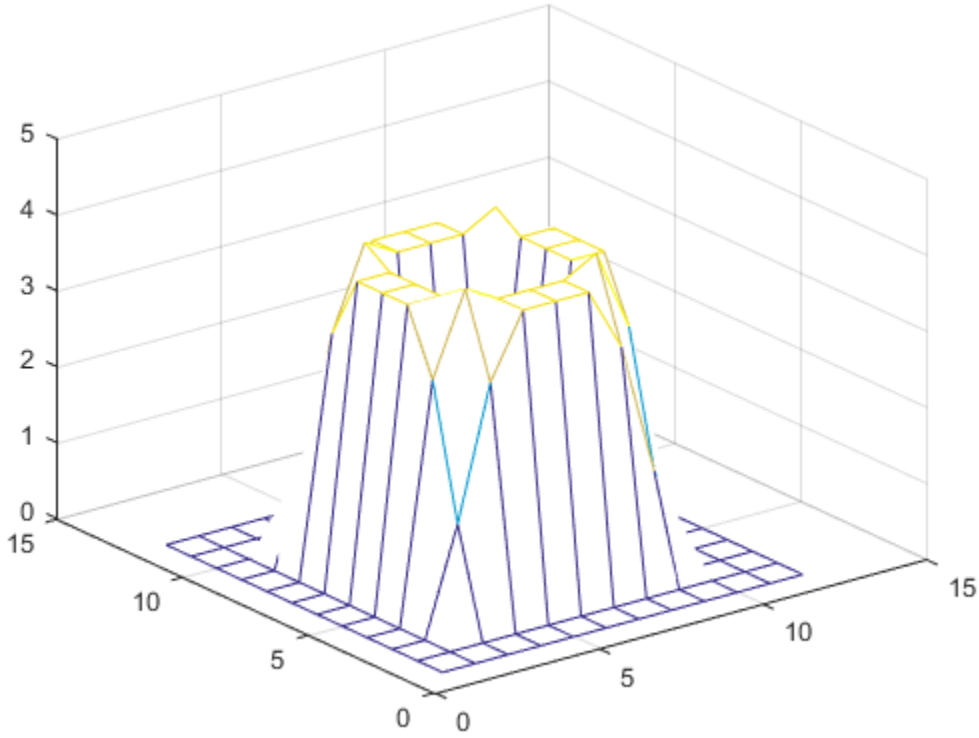
Transposing the filter `s` extracts the vertical edges of `A`.

```
V = conv2(A,s');
figure, mesh(V)
```



This figure combines both horizontal and vertical edges.

```
figure
mesh(sqrt(H.^2 + V.^2))
```



More About

Algorithms

`conv2` uses a straightforward formal implementation of the two-dimensional convolution equation in spatial form. If a and b are functions of two discrete variables, n_1 and n_2, then the formula for the two-dimensional convolution of a and b is

$$c(n_1,n_2) = \sum_{k_1=-\infty}^{\infty}\sum_{k_2=-\infty}^{\infty} a(k_1,k_2)b(n_1-k_1,n_2-k_2)$$

In practice however, `conv2` computes the convolution for finite intervals.

Note that matrix indices in MATLAB software always start at 1 rather than 0. Therefore, matrix elements `A(1,1)`, `B(1,1)`, and `C(1,1)` correspond to mathematical quantities $a(0,0)$, $b(0,0)$, and $c(0,0)$.

Introduced before R2006a

convhull

Convex hull

Note: Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `convhull`.

Syntax

```
K = convhull(X,Y)
K = convhull(X,Y,Z)
K = convhull(X)
K = convhull(...,'simplify', logicalvar)
[K,V] = convhull(...)
```

Definitions

`convhull` returns the convex hull of a set of points in 2-D or 3-D space.

Description

`K = convhull(X,Y)` returns the 2-D convex hull of the points (`X`,`Y`), where `X` and `Y` are column vectors. The convex hull `K` is expressed in terms of a vector of point indices arranged in a counterclockwise cycle around the hull.

`K = convhull(X,Y,Z)` returns the 3-D convex hull of the points (`X`,`Y`,`Z`), where `X`, `Y`, and `Z` are column vectors. `K` is a triangulation representing the boundary of the convex hull. `K` is of size `mtri`-by-3, where `mtri` is the number of triangular facets. That is, each row of `K` is a triangle defined in terms of the point indices.

`K = convhull(X)` returns the 2-D or 3-D convex hull of the points `X`. This variant supports the definition of points in matrix format. `X` is of size `mpts`-by-`ndim`, where `mpts`

is the number of points and `ndim` is the dimension of the space where the points reside, 2 ≦ `ndim` ≦ 3. The output facets are equivalent to those generated by the 2-input or 3-input calling syntax.

`K = convhull(...,'simplify', logicalvar)` provides the option of removing vertices that do not contribute to the area/volume of the convex hull, the default is false. Setting `'simplify'` to true returns the topology in a more concise form.

`[K,V] = convhull(...)` returns the convex hull `K` and the corresponding area/volume `V` bounded by `K`.

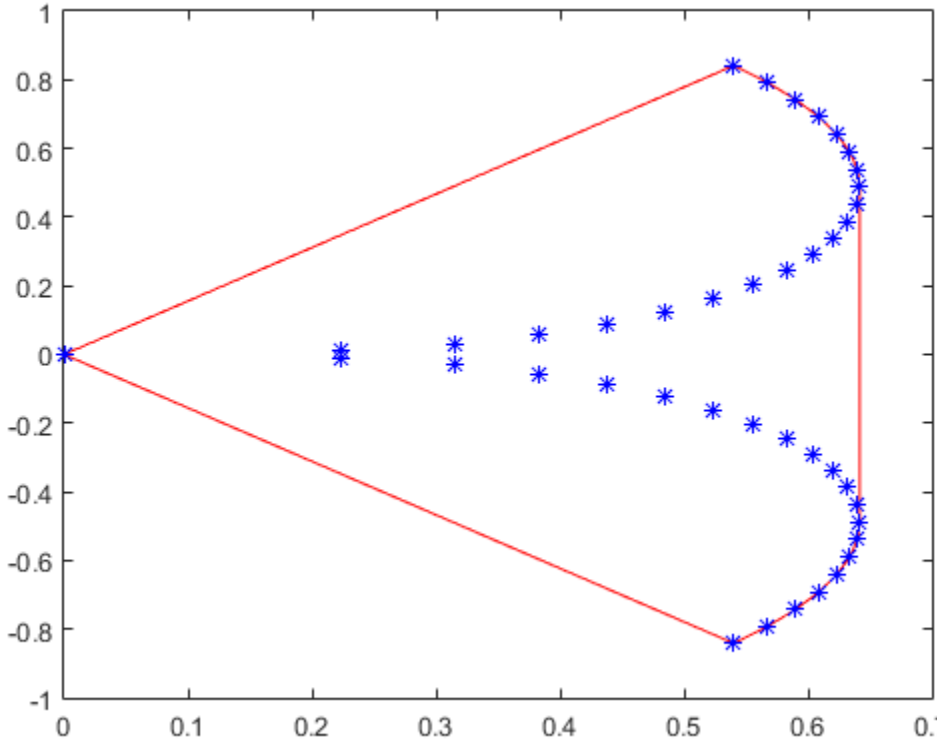
Visualization

Use `plot` to plot the output of `convhull` in 2-D. Use `trisurf` or `trimesh` to plot the output of convhull in 3-D.

Examples

Plot 2-D Convex Hull

```
xx = -1:.05:1;
yy = abs(sqrt(xx));
[x,y] = pol2cart(xx,yy);
k = convhull(x,y);
plot(x(k),y(k),'r-',x,y,'b*')
```



See Also

convexHull | voronoiDiagram | convhulln | delaunay | polyarea | voronoi

Introduced before R2006a

convhulln

N-D convex hull

Syntax

```
K = convhulln(X)
K = convhulln(X, options)
[K, v] = convhulln(...)
```

Description

`K = convhulln(X)` returns the indices `K` of the points in `X` that comprise the facets of the convex hull of `X`. `X` is an `m`-by-`n` array representing `m` points in N-dimensional space. If the convex hull has `p` facets then `K` is `p`-by-`n`.

`convhulln` uses Qhull.

`K = convhulln(X, options)` specifies a cell array of strings `options` to be used as options in Qhull. The default options are:

- `{'Qt'}` for 2-, 3-. and 4-dimensional input
- `{'Qt','Qx'}` for 5-dimensional input and higher.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see http://www.qhull.org/.

`[K, v] = convhulln(...)` also returns the volume `v` of the convex hull.

Visualization

Plotting the output of `convhulln` depends on the value of `n`:

- For `n = 2`, use `plot` as you would for `convhull`.
- For `n = 3`, you can use `trisurf` to plot the output. The calling sequence is

```
K = convhulln(X);
trisurf(K,X(:,1),X(:,2),X(:,3))
```

- You cannot plot `convhulln` output for `n > 3`.

Examples

The following example illustrates the `options` input for `convhulln`. The following commands

```
X = [0 0; 0 1e-10; 0 0; 1 1];
K = convhulln(X)
```

return a warning.

```
Warning: qhull precision warning:
The initial hull is narrow
(cosine of min. angle is 0.9999999999999998).
A coplanar point may lead to a wide facet.
Options 'QbB' (scale to unit box) or 'Qbb'
(scale last coordinate) may remove this warning.
Use 'Pp' to skip this warning.
```

To suppress the warning, use the option `'Pp'`. The following command passes the option `'Pp'`, along with the default `'Qt'`, to `convhulln`.

```
K = convhulln(X,{'Qt','Pp'})

K =

     1     4
     1     2
     4     2
```

More About

Algorithms

`convhulln` is based on Qhull [1]. For information about Qhull, see http://www.qhull.org/. For copyright information, see http://www.qhull.org/COPYING.txt.

Introduced before R2006a

convn

N-D convolution

Syntax

```
C = convn(A,B)
C = convn(A,B,'shape')
```

Description

`C = convn(A,B)` computes the N-dimensional convolution of the arrays `A` and `B`. The size of the result is `size(A)+size(B)-1`.

`C = convn(A,B,'shape')` returns a subsection of the N-dimensional convolution, as specified by the `shape` parameter:

`'full'`	Returns the full N-dimensional convolution (default).
`'same'`	Returns the central part of the result that is the same size as `A`.
`'valid'`	Returns only those parts of the convolution that can be computed without assuming that the array A is zero-padded. The size of the result is `max(size(A)-size(B) + 1, 0)`

matlab.mixin.CustomDisplay class

Package: matlab.mixin

Display customization interface class

Description

This class provides an interface for customizing the MATLAB display of objects. Derive your class from `matlab.mixin.CustomDisplay` to add the custom display functionality to your class.

`matlab.mixin.CustomDisplay` implements three public sealed methods. `disp` and `display` provide a simple object display. The `details` method provides a standard formal display of object information.

For customizing object display, `matlab.mixin.CustomDisplay` defines a number of protected methods that you can override in your subclass. By overriding specific methods, you can customize specific aspects of the object display.

Note: You cannot use `matlab.mixin.CustomDisplay` to derive a custom display for enumeration classes. For an alternative approach, see "Overload the disp Function"

Methods

convertDimensionsToString	Return array dimensions as string
details	Fully detailed formal object display
disp	Simple informal object display
display	Print variable name and display object
displayEmptyObject	Display for empty object arrays

displayNonScalarObject	Display format for non-scalar objects
displayPropertyGroups	Display titles and property groups as defined
displayScalarHandleToDeletedObject	Display format for deleted scalar handles
displayScalarObject	Display format for scalar objects
getClassNameForHeader	Return class name for display
getDeletedHandleText	Returns text for handle to deleted object display
getDetailedFooter	Returns default detailed footer for object display
getDetailedHeader	Returns default detailed header for object display
getFooter	Build and return display footer text
getHandleText	Return string `'handle'` with link to documentation
getHeader	Build and return display header text
getPropertyGroups	Construct array of property groups
getSimpleHeader	Return simple header for object display

Attributes

`Abstract`	This class defines an interface that subclasses inherit. You cannot instantiate this class.
`HandleCompatibile`	You can use this class to derive both handle and value classes.

Introduced in R2013b

matlab.mixin.CustomDisplay.convertDimensionsToString

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Return array dimensions as string

Syntax

```
dimstr = matlab.mixin.CustomDisplay.convertDimensionsToString(obj)
```

Description

`dimstr = matlab.mixin.CustomDisplay.convertDimensionsToString(obj)` converts a size vector into a properly formatted string of dimensions for the nonscalar header.

Input Arguments

`obj`

MATLAB object

Default:

Output Arguments

`dimstr`

String representing the object's dimensions as determined by calling `size`.

Attributes

`Static`	`true`

`Access`	`Protected`
`Sealed`	`true`
`Hidden`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`matlab.mixin.CustomDisplay.getHeader`

Related Examples

- "Custom Display Interface"

details

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Fully detailed formal object display

Syntax

```
details(obj)
```

Description

`details(obj)` displays the detailed state of obj. The detailed display is not affected by customizations made to classes derived from `matlab.mixin.CustomDisplay`.

Attributes

`Access = public`	You can call `details` on any object that is a class derived from `matlab.mixin.CustomDisplay`.
`Sealed`	You cannot override the `details` method in your sublcass of `matlab.mixin.CustomDisplay`

Input Arguments

`obj`

Instance of a class derived from `matlab.mixin.CustomDisplay`.

Default: none

Examples

Suppose `EmployeeInfo` is a subclass of `matlab.mixin.CustomDisplay`

```
details(e1)

  EmployeeInfo handle with properties:

          Name: 'Bill Tork'
      JobTitle: 'Software Engineer'
    Department: 'Product Development'
        Salary: 1000
      Password: 'bill123'

  Methods, Events, Superclasses
```

See Also

disp | display

disp

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Simple informal object display

Syntax

```
disp(obj)
```

Description

`disp(obj)` displays the contents of obj in one of four simple formats, based on the state of obj.

- Handle to deleted object
- Empty object array
- Scalar
- Nonscalar

To customize a display format, override one or more of the four handler methods.

Input Arguments

`obj`

Object of a class derived from `matlab.mixin.CustomDisplay`

Attributes

`Access`	`public`
`Sealed`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

Related Examples

- “Custom Display Interface”

display

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Print variable name and display object

Syntax

```
display(obj)
```

Description

`display(obj)` prints the name of input argument obj as it appears in the workspace of the caller. If there is no assignment to a variable, `display` uses, `ans`. `display` then calls the `disp` method to print the object.

Input Arguments

`obj`

Object array of a class derived from `matlab.mixin.CustomDisplay`

Attributes

`Access`	`public`
`Sealed`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`details` | `disp`

Related Examples

- “Custom Display Interface”

displayEmptyObject

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Display for empty object arrays

Syntax

```
displayEmptyObject(obj)
```

Description

`displayEmptyObject(obj)` is called by `disp` when the object, obj, is empty. An object array is empty if one or more of its dimensions are zero. An empty object array is never scalar.

The default display of an empty object consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayEmptyObject` shows only those properties with public `GetAccess` and `Hidden` set to `false`.

Override this method to customize the appearance of an empty object array.

Input Arguments

`obj`

Object of a class derived from `matlab.mixin.CustomDisplay`

Default:

Attributes

`Access`	`protected`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Related Examples

- “Custom Display Interface”

displayNonScalarObject

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Display format for non-scalar objects

Syntax

```
displayNonScalarObject(obj)
```

Description

`displayNonScalarObject(obj)` is called by the `disp` method when the object, obj, is nonscalar (`prod(size(obj)) > 1`)

The default display of a nonscalar object array consists of a header and a list of property names. The header consists of the object's dimensions and the properties are shown in the order defined in the class definition. `displayNonScalarObject` shows only those properties with public `GetAccess` and `Hidden` set to `false`.

Override this method to customize the display a nonscalar object array.

Input Arguments

`obj`

Object array of a class derived from `matlab.mixin.CustomDisplay`

Default:

Attributes

`Access`	`protected`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Display titles and property groups as defined

Syntax

```
matlab.mixin.CustomDisplay.displayPropertyGroups(obj,
propertyGroupArray)
```

Description

`matlab.mixin.CustomDisplay.displayPropertyGroups(obj, propertyGroupArray)` displays titles and custom property lists as defined by the property groups.

Input Arguments

`obj`

MATLAB object

Default:

`propertyGroupArray`

Array of `matlab.mixin.util.PropertyGroup` objects.

Default:

Attributes

`Static`	`true`

`Access`	`Protected`
`Sealed`	`true`
`Hidden`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

`PropertyGroup`

Related Examples

- “Custom Display Interface”

displayScalarHandleToDeletedObject

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Display format for deleted scalar handles

Syntax

```
displayScalarHandleToDeletedObject(obj)
```

Description

`displayScalarHandleToDeletedObject(obj)` is called by the `disp` method when `obj` is:

- An instance of a handle class
- Scalar
- A handle to a deleted object

That is, the following expression is `true`.

```
isa(obj,'handle') && isscalar(obj) && ~isvalid(obj)
```

Override this method to customize the appearance of your object's display when it is deleted.

Input Arguments

`obj`

Object of a class derived from `matlab.mixin.CustomDisplay`

Default:

Attributes

Access	protected

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`matlab.mixin.CustomDisplay.displayScalarObject` |
`matlab.mixin.CustomDisplay.displayNonScalarObject` |
`matlab.mixin.CustomDisplay.displayEmptyObject`

Related Examples

displayScalarObject

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Display format for scalar objects

Syntax

```
displayScalarObject(obj)
```

Description

`displayScalarObject(obj)` is called by the `disp` method when the object, obj, is scalar (`prod(size(obj)) == 1`).

The default display of a scalar object consists of a header and a list of properties and their values. Properties are shown in the order they are defined in the class definition. `displayScalarObject` shows only those properties with public `GetAccess` and `Hidden` set to `false`.

Override this method to customize the display of a scalar object.

Input Arguments

`obj`

Object of a class derived from `matlab.mixin.CustomDisplay`

Default:

Attributes

`Access`	`protected`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

matlab.mixin.CustomDisplay.getClassNameForHeader

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Return class name for display

Syntax

```
name = matlab.mixin.CustomDisplay.getClassNameForHeader(obj)
```

Description

`name = matlab.mixin.CustomDisplay.getClassNameForHeader(obj)` returns the class name of obj. If the display supports hypertext links, the text is linked to the help for the class of `obj`.

Use this method when building a custom display that includes the class name, but differs from the default header.

Input Arguments

`obj`

MATLAB object

Default:

Output Arguments

`name`

The simple class name, linked to the help for the class if the display supports hypertext links

Attributes

`Static`	`true`
`Access`	`Protected`
`Sealed`	`true`
`Hidden`	`true`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

Package: matlab.mixin

Returns text for handle to deleted object display

Syntax

```
handleText = matlab.mixin.CustomDisplay.getDeletedHandleText
```

Description

`handleText = matlab.mixin.CustomDisplay.getDeletedHandleText` returns the text:

```
'handle to deleted'
```

The text is linked to the documentation on deleted handle objects.

Output Arguments

`handleText`

String `'handle to deleted'`, linked if the display supports hypertext links

Attributes

Static	true
Access	Protected
Sealed	true
Hidden	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

matlab.mixin.CustomDisplay.getDetailedFooter

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Returns default detailed footer for object display

Syntax

```
headerText = matlab.mixin.CustomDisplay.getDetailedFooter(obj)
```

Description

`headerText = matlab.mixin.CustomDisplay.getDetailedFooter(obj)` returns the string containing:

```
Methods, Events, Superclass
```

Each link executes the respective command on `obj`.

Input Arguments

`obj`

MATLAB object

Default:

Output Arguments

`headerText`

String containing the linked phrase `'Methods, Events, Superclasses'` or the empty string if the display does not support hypertext links

Attributes

`Static`	`true`
`Access`	`Protected`
`Sealed`	`true`
`Hidden`	`true`

matlab.mixin.CustomDisplay.getDetailedHeader

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Returns default detailed header for object display

Syntax

```
header = matlab.mixin.CustomDisplay.getDetailedHeader(obj)
```

Description

`header = matlab.mixin.CustomDisplay.getDetailedHeader(obj)` returns a string containing:

- Linked class name of `obj`
- Link to handle documentation if `obj` is a handle class
- The string `'with properties:'`

Input Arguments

`obj`

MATLAB object

Default:

Output Arguments

`header`

String containing the full detailed header, with properly inserted links if the display supports hypertext linking

Attributes

`Static`	`true`
`Access`	`Protected`
`Sealed`	`true`
`Hidden`	`true`

getFooter

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Build and return display footer text

Syntax

```
s = getFooter(obj)
```

Description

`s = getFooter(obj)` returns the text used as the footer when displaying obj. This method is called once for the entire object array.

Override this method to create a custom footer. The overriding implementation must support all states of the object, including scalar, nonscalar, empty, and deleted (if obj is an instance of a handle class).

Input Arguments

`obj`

Object array of a class derived from `matlab.mixin.CustomDisplay`

Default:

Output Arguments

`s`

Footer text, returned as a string.

The default implementation returns an empty string

Attributes

`Access`	`protected`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

`getHeader`

Related Examples

- “Custom Display Interface”

getHeader

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Build and return display header text

Syntax

```
s = getHeader(obj)
```

Description

`s = getHeader(obj)` returns the text used as the header when displaying obj. This method is called once for the entire object array.

Override this method to create a custom header. The overriding implementation must support all states of the object, including scalar, nonscalar, empty, and deleted (if obj is an instance of a handle class).

Input Arguments

`obj`

Object array of a class derived from `matlab.mixin.CustomDisplay`

Output Arguments

`s`

Header string, returned as a `char` array

The default implementation returns the following:

- If obj is scalar, returns *`classname`*, which is the simple name of the class (the nonpackage-qualified name).
- If obj is nonscalar, returns *`classname`* and dimensions.

- If obj is empty, returns an empty string.
- If obj is a deleted handle, returns the string `deleted` *`classname`* `handle`

`classname` is linked to MATLAB documentation for the class. Selecting the link displays the `helpPopup` window.

If you override this method, you might need to terminate s with a newline (`\n`) character.

Examples

Append Text to Default Header

Append the string, `'with Customized Display'`, to the header text.

Write a `getHeader` method.

```
methods (Access = protected)
   function header = getHeader(obj)
      if ~isscalar(obj)
         header = getHeader@matlab.mixin.CustomDisplay(obj);
      else
         headerStr = matlab.mixin.CustomDisplay.getClassNameForHeader(obj);
         headerStr = [headerStr,' with Customized Display'];
         header = sprintf('%s\n',headerStr);
      end
   end
end
```

Add `getHeader` method to class definition.

- “Custom Display Interface”

Attributes

`Access`	`protected`

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

See Also

`matlab.mixin.CustomDisplay.getFooter` |
`matlab.mixin.CustomDisplay.getPropertyGroups`

getPropertyGroups

Class: matlab.mixin.CustomDisplay
Package: matlab.mixin

Construct array of property groups

Syntax

```
groups = getPropertyGroups(obj)
```

Description

`groups = getPropertyGroups(obj)` returns an array of `matlab.mixin.util.PropertyGroup` objects. MATLAB displays property groups separated by blank spaces.

Each default display state handler method calls this method once. The default implementation returns the properties in one group. These properties must have public `GetAccess` and not be defined as `Hidden`. If the object is scalar, MATLAB includes dynamic properties.

Override this method to construct one or more customized groups of properties to display.

Each group object array has the following fields:

- `Title` — String used as the header for the property group or an empty string if no title is used.
- `PropertyList` — The property list can be either:
  - A 1-by-1 `struct` of property name-property value pairs
  - A cell array of string property names.

Use the `struct` of name-value pairs if the object is scalar and you want to assign custom property values. Otherwise, use a cell array of string property names. If the object is scalar MATLAB adds the property values retrieved from the object.

Input Arguments

obj

Object array of a class derived from `matlab.mixin.CustomDisplay`

Default:

Output Arguments

groups

1xN array of `matlab.mixin.util.PropertyGroup` objects, where N is the number of groups

Examples

Custom Property Group

Customize the values returned by some properties.

Write a `getPropertyGroups` method.

```
methods (Access = protected)
   function propgrp = getPropertyGroups(obj)
      if ~isscalar(obj)
         propgrp = getPropertyGroups@matlab.mixin.CustomDisplay(obj);
      else
         pd(1:length(obj.Password)) = '*';
         propList = struct('Department',obj.Department,...
            'JobTitle',obj.JobTitle,...
            'Name',obj.Name,...
            'Salary','Not avalable',...
            'Password',pd);
         propgrp = matlab.mixin.util.PropertyGroup(propList);
      end
   end
end
```

Add function to class definition.

matlab.mixin.Copyable class

Package: matlab.mixin

Superclass providing copy functionality for handle objects

Description

The `matlab.mixin.Copyable` class is an abstract handle class that provides a `copy` method for copying handle objects. The `copy` method makes a shallow copy of the object (that is, it shallow copies all non-dependent properties from the source to the destination object). In making a shallow copy, MATLAB does not call `copy` recursively on any handles contained in property values.

Subclass `matlab.mixin.Copyable` when you want to define handles classes that inherit a `copy` method. The `copy` method:

- Copies data without calling class constructors or property set functions and therefore produces no side effects.
- Enables subclasses to customize the copy behavior

Customizing Subclass Copy Behavior

The `copy` method provides the public, non-overrideable interface to copy behavior. `copy` takes an array of objects as input and returns an array of the same shape and dimensions.

`copyElement` is a protected method that the `copy` method uses to perform the copy operation on each object in the input array. `copyElement` is not `Sealed` so you can override it in your subclass to customize the behavior of the inherited `copy` method.

Implementing a Selective Deep Copy

This example overrides the `copyElement` method in a subclass of `matlab.mixin.Copyable` to implement a deep copy of a specific class of `handle` objects.

Consider the following classes:

- `ContainsHandles` — subclass of `matlab.mixin.Copyable` that contains `handle` objects in two properties
- `DeepCp` — subclass of `matlab.mixin.Copyable`
- `ShallowCp` — subclass of `handle`

Here are the simplified class definitions:

```
classdef ContainsHandles < matlab.mixin.Copyable
   properties
      Prop1
      Prop2
      DeepObj     % Contains a DeepCp object
      ShallowObj  % Contains a ShallowCp object
   end
   methods
      function obj = ContainsHandles(val1,val2,deepobj,shallowobj)
         if nargin > 0
            obj.Prop1 = val1;
            obj.Prop2 = val2;
            obj.DeepObj = deepobj;
            obj.ShallowObj = shallowobj;
          end
      end
   end
      methods(Access = protected)
       % Override copyElement method:
      function cpObj = copyElement(obj)
         % Make a shallow copy of all four properties
         cpObj = copyElement@matlab.mixin.Copyable(obj);
         % Make a deep copy of the DeepCp object
         cpObj.DeepObj = copy(obj.DeepObj);
      end
   end
end
```

The `DeepCp` class derives from `matlab.mixin.Copyable`:

```
classdef DeepCp < matlab.mixin.Copyable
   properties
      DpProp
   end
   methods
      function obj = DeepCp(val)
      ...
```

```
      end
   end
end
```

The `handle` class `ShallowCp` does not derive from `matlab.mixin.Copyable` and, therefore, has no copy method:

```
classdef ShallowCp < handle
   properties
      ShProp
   end
   methods
      function obj = ShallowCp(val)
       ...
      end
   end
end
```

Create a `ContainsHandles` object, which contains the two handle objects in its `DpProp` and `ShProp` properties:

```
>> sc = ShallowCp(7);
>> dc = DeepCp(7);
>> a = ContainsHandles(4,5,dc,sc);
>> a.DeepObj
ans =

  DeepCp with properties:

    DpProp: 7
>> a.ShallowObj.ShProp
ans =

  ShallowCp with properties:

    ShProp: 7
```

Make a copy of the `ContainsHandles` object:

```
>> b = copy(a);
```

The returned copy `b` contains a shallow copy of object `sc`, and a deep copy of object `dc`. That is, the `dc` object passed to `ContainsHandles` constructor is now a new, independent objects as a result of the copy operation. You can now change the `dc` object without affecting the copy. This is not the case for the shallow copied object, `sc`:

```
% Change the property values of the handle objects:
>> sc.ShProp = 5;
>> dc.DpProp = 5;
% Note that the deep copied object is not affected:
>> b.DeepObj

ans =

  DeepCp with properties:

    DpProp: 7
% The shallow copied object is still referencing the same data:
>> b.ShallowObj

ans =

  ShallowCp with properties:

    ShProp: 5
```

Overriding Copy Behavior in Hierarchies

The `copyElement` method in a superclass cannot access the private data in a subclass.

If you override `copyElement` in a subclass of `matlab.mixin.Copyable`, and then use this subclass as a superclass, you need to override `copyElement` in all subclasses that contain private properties. The override of `copyElement` in subclasses should call the `copyElement` in the respective superclass, as in the previous example.

The following simplified code demonstrates this approach:

```
classdef SuperClass < matlab.mixin.Copyable
   properties(Access = private)
      super_prop
   end
   methods
        ...

      function cpObj = copyElement(obj)
            ...
         cpObj = copyElement@mixin.matlab.Copyable(obj);
            ...
      end
   end
```

```
end

classdef SubClass1 < SuperClass
   properties(Access=private)
      sub_prop1
   end
   methods
      function cpObj = copyElement(obj)
         % Copy super_prop
         cpObj = copyElement@SuperClass(obj);
         % Copy sub_prop1 in subclass
         % Assignment can introduce side effects
         cpObj.sub_prop1 = obj.sub_prop1;
      end
   end
end
```

The override of `copyElement` in `SubClass1` copies the private subclass property because the superclass cannot access private data in the subclass.

Note: The assignment of `sub_prop1` in the override of `copyElement` in `SubClass1` calls the property set method, if one exists, possibly introducing side effects to the copy operation.

Copy Behaviors for Specific Inputs

Given a call to the `matlab.mixin.Copyable` `copy` method of the form:

```
B = copy(A);
```

Under the following conditions, produces the described results:

- `A` has dynamic properties — `copy` does not copy dynamic properties. You can implement dynamic-property copying in the subclass if needed.
- `A` has no non-Dependent properties — `copy` creates a new object with no property values without calling the class constructor to avoid introducing side effects.
- `A` contains deleted handles — `copy` creates deleted handles of the same class in the output array.
- `A` has attached listeners — `copy` does not copy listeners.

- A contains objects of enumeration classes — Enumeration classes cannot subclass `matlab.mixin.Copyable`.
- A `delete` method calls `copy` — `copy` creates a legitimate copy, obeying all the behaviors that apply in any other usage.

Note: You cannot derive an enumeration class from `matlab.mixin.Copyable` because the number of instances you can create are limited to the ones defined inside the enumeration block. See "Working with Enumerations" for more information about enumeration classes.

Methods

copy	Copy array of handle objects

Definitions

Deep Copy

Copy each property value and assign it to the new (copied) property. Recursively copy property values that reference handle objects to copy all of the underlying data.

Shallow Copy

Copy each property value and assign it to the new (copied) property. If a property value is a handle, copy the handle but not the underlying data.

Attributes

`ConstructOnLoad`	`true`

To learn about attributes of classes, see Class Attributes in the MATLAB Object-Oriented Programming documentation.

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

`handle`

How To

- Class Attributes

Introduced in R2011a

copy

Class: matlab.mixin.Copyable
Package: matlab.mixin

Copy array of handle objects

Syntax

```
B = copy(A)
```

Description

`B = copy(A)` copies each element in the array of handles `A` to the new array of handles `B`.

The `copy` method performs a copy according to the following rules:

- The `copy` method does not copy `Dependent` properties
- MATLAB does not call the `copy` method recursively on any handles contained in property values
- MATLAB does not call the class constructor or property set methods during the copy operation.
- `B` has the same number of elements and same size as `A`.
- `B` is the same class as `A`.
- If `A` is empty, `B` is also empty.
- If `A` is heterogeneous, `B` is also heterogeneous.
- If `A` contains deleted handle objects, copy creates deleted handles of the same class in `B`.
- Dynamic properties and listeners associated with objects in `A` are not copied to objects in `B`.
- You can call `copy` inside your class `delete` method.

Input Arguments

A

Handle object array

Default:

Output Arguments

B

Handle object array containing copies of the objects in A.

Attributes

Sealed	true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

`matlab.mixin.Copyable` | `handle` | `copyElement`

copyfile

Copy file or folder

Syntax

```
copyfile('source','destination')
copyfile('source','destination','f')
status = copyfile( ___ )
[status,message] = copyfile( ___ )
[status,message,messageid] = copyfile( ___ )
```

Description

`copyfile('source','destination')` copies the file or folder named `source` to the file or folder `destination`. The values for `source` and `destination` are 1 x n strings. Use full path names or path names relative to the current folder. To copy multiple files or folders, use one or more wildcard characters (`*`) after the last file separator in `source`. You cannot use a wildcard character in `destination`.

`copyfile('source','destination','f')` copies `source` to `destination`, even when `destination` is not writable. The state of the read-write attribute for `destination` does not change. You can use `f` with any syntax for `copyfile`.

`status = copyfile( ___ )` reports the outcome as a logical scalar, `status`. The value is `1` for success and `0` for failure.

`[status,message] = copyfile( ___ )` returns any warning or error message as a string to `message`. When `copyfile` succeeds, `message` is an empty string.

`[status,message,messageid] = copyfile( ___ )` returns any warning or error identifier as a string to `messageId`. When `copyfile` succeeds, `messageId` is an empty string.

Examples

Copy File to Another Folder

Copy `myFun.m` from the current folder to `d:/work/Projects/`.

```
copyfile('myFun.m','d:/work/Projects/')
```

Copy File to Its Current Folder

Copy `myFun.m` in the current folder, assigning it the name `myFun2.m`.

```
copyfile('myFun.m','myFun2.m')
```

Copy Files and Folders to a New Folder Using Wildcards

Copy files and subfolders whose names begin with `my`, from the `Projects` subfolder within the current folder to the folder `newProjects`, which is at the same level as the current folder:

```
copyfile('Projects/my*','../newProjects/')
```

Copy Files to a New, Nonexistent Folder

Copy the contents of the `Projects` subfolder within the current folder to the `I:/work/newProjects` folder, where `newProjects` does not exist.

```
copyfile('Projects','I:/work/newProjects')
```

Copy File that Overwrites a Read-Only File

Copy the contents of `myFun.m` from the current folder to `d:/work/restricted/myFun2.m`, where `myFun2.m` is read-only.

```
[status,message,messageId] = copyfile('myFun.m', ...
'd:/work/restricted/myFun2.m','f')
```

```
status =
     1

message =
     ''

messageId =
```

```
' '
```

The `status` of 1 and empty `message` and `messageId` strings confirm the copy was successful.

More About

Tips

- The timestamp for `destination` is the same as the timestamp for `source`.
- When `source` is a folder, `destination` must be a folder.
  - When `source` is a folder and `destination` does not exist, `copyfile` creates `destination` and copies the contents of `source` into `destination`.
  - When `source` is a folder and `destination` is an existing folder, `copyfile` copies the contents of `source` into `destination`.
  - When `source` is multiple files and `destination` does not exist, `copyfile` creates `destination`.
- "Specify File Names"
- "Manage Files and Folders"

Introduced before R2006a

copyobj

Copy graphics objects and their descendants

Syntax

```
new_handle = copyobj(h,p)
copyobj(___,'legacy')
```

Description

`copyobj` creates copies of graphics objects and assigns the objects to the new parent.

The new parent must be appropriate for the copied object (for example, you can copy an axes only to figure or uipanel). `copyobj` copies children as well.

`new_handle = copyobj(h,p)` copies one or more graphics objects identified by `h` and returns the handle of the new object or an array of new objects. The new graphics objects are children of the graphics objects specified by `p`.

`copyobj(___,'legacy')` copies object callback properties and object application data. This behavior is consistent with versions of `copyobj` before MATLAB release R2014b.

What is Not Copied

`copyobj` does not copy properties or objects that depend on their original context to operate properly. Objects with default context menus (such as legends and colorbars) create new context menus for the new object. Figures create new toolbars and menus for the new figure.

`copyobj` does *not* copy:

- Callback properties (except when using the `legacy` option)
- Application data associated with the object (except when using the `legacy` option)
- Context menu of legends, colorbars, or other objects that define default context menus.

- Default Figure toolbar and menus
- You cannot copy the same object more than once to the same parent in a single call to `copyobj`.

MATLAB changes the `Parent` property to the new parent and assigns the new objects a new handle.

Examples

Copy a surface to a new axes that is in a different figure.

```
h = surf(peaks);
colormap hsv
```

Create the destination figure and axes:

```
fig = figure;
ax = axes;
```

Copy the surface to the new axes and set properties that are not surface properties:

```
new_handle = copyobj(h,ax);
colormap(fig,hsv)
view(ax,3)
grid(ax,'on')
```

Note that while the surface is copied, the `colormap`, `view`, and `grid` are not copied.

More About

Tips

`h` and `p` can be scalars or vectors. When both are vectors, they must be the same length, and the output argument, `new_handle`, is a vector of the same length. In this case, `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p(i)`.

When `h` is a scalar and `p` is a vector, `h` is copied once to each of the parents in `p`. Each `new_handle(i)` is a copy of `h` with its `Parent` property set to `p(i)`, and `length(new_handle)` equals `length(p)`.

When `h` is a vector and `p` is a scalar, each `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p`. The length of `new_handle` equals `length(h)`.

Note: You must copy the associated axes when copying a legend or a colorbar.

When programming a UI, do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the recursion limit.

Introduced before R2006a

corrcoef

Correlation coefficients

Syntax

```
R = corrcoef(X)
R = corrcoef(x,y)
[R,P]=corrcoef(...)
[R,P,RLO,RUP]=corrcoef(...)
[...]=corrcoef(...,'param1',val1,'param2',val2,...)
```

Description

`R = corrcoef(X)` returns a matrix `R` of correlation coefficients calculated from an input matrix `X` whose rows are observations and whose columns are variables. The matrix `R = corrcoef(X)` is related to the covariance matrix `C = cov(X)` by

$$R(i,j) = \frac{C(i,j)}{\sqrt{C(i,i)C(j,j)}}.$$

`corrcoef(X)` is the zeroth lag of the normalized covariance function, that is, the zeroth lag of `xcov(x,'coeff')` packed into a square array.

`R = corrcoef(x,y)` where `x` and `y` are column vectors is the same as `corrcoef([x y])`. If `x` and `y` are not column vectors, `corrcoef` converts them to column vectors. For example, in this case `R=corrcoef(x,y)` is equivalent to `R=corrcoef([x(:) y(:)])`.

`[R,P]=corrcoef(...)` also returns `P`, a matrix of p-values for testing the hypothesis of no correlation. Each p-value is the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero. If `P(i,j)` is small, say less than `0.05`, then the correlation `R(i,j)` is significant.

`[R,P,RLO,RUP]=corrcoef(...)` also returns matrices `RLO` and `RUP`, of the same size as `R`, containing lower and upper bounds for a 95% confidence interval for each coefficient.

`[...]=corrcoef(...,'param1',val1,'param2',val2,...)` specifies additional parameters and their values. Valid parameters are the following.

`'alpha'`	A number between 0 and 1 to specify a confidence level of 100*(1 – `alpha`)%. Default is 0.05 for 95% confidence intervals.
`'rows'`	Either `'all'` (default) to use all rows, `'complete'` to use rows with no `NaN` values, or `'pairwise'` to compute `R(i,j)` using rows with no `NaN` values in either column `i` or `j`.

The p-value is computed by transforming the correlation to create a t statistic having `n`-2 degrees of freedom, where `n` is the number of rows of `X`. The confidence bounds are based on an asymptotic normal distribution of `0.5*log((1+R)/(1-R))`, with an approximate variance equal to `1/(n-3)`. These bounds are accurate for large samples when `X` has a multivariate normal distribution. The `'pairwise'` option can produce an `R` matrix that is not positive definite.

Examples

Generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4);     % Uncorrelated data
x(:,4) = sum(x,2);   % Introduce correlation.
[r,p] = corrcoef(x)  % Compute sample correlation and p-values.
[i,j] = find(p<0.05);  % Find significant correlations.
[i,j]                % Display their (row,col) indices.

r =
    1.0000   -0.3566    0.1929    0.3457
   -0.3566    1.0000   -0.1429    0.4461
    0.1929   -0.1429    1.0000    0.5183
    0.3457    0.4461    0.5183    1.0000

p =
    1.0000    0.0531    0.3072    0.0613
    0.0531    1.0000    0.4511    0.0135
    0.3072    0.4511    1.0000    0.0033
    0.0613    0.0135    0.0033    1.0000

ans =
     4     2
```

```
     4     3
     2     4
     3     4
```

See Also

cov | mean | median | std | var | xcorr | xcov

cos

Cosine of argument in radians

Syntax

```
Y = cos(X)
```

Description

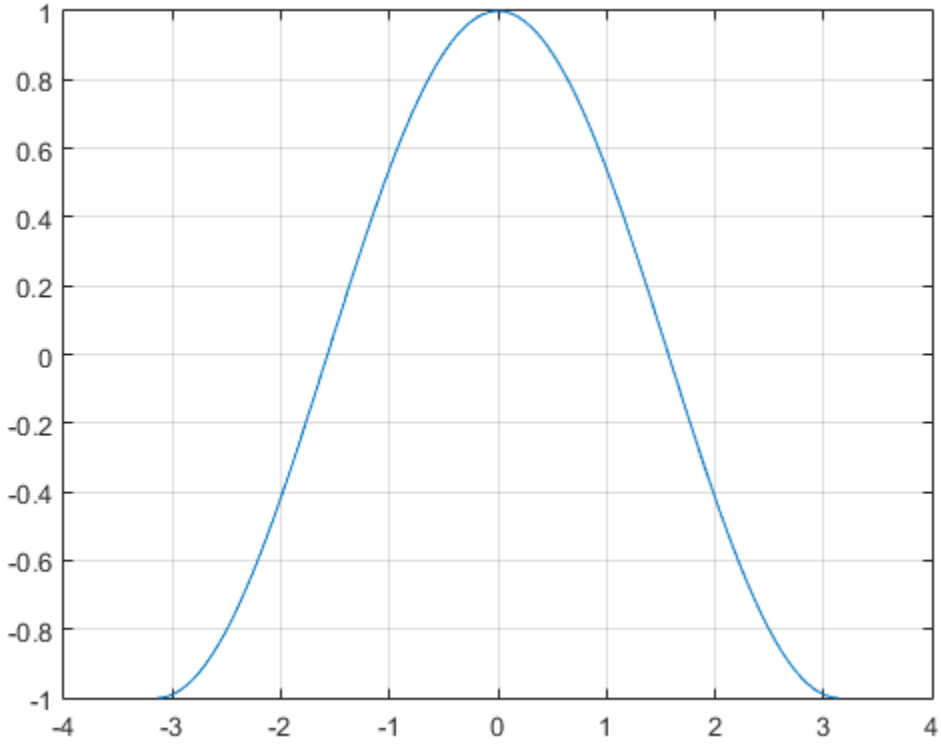
`Y = cos(X)` returns the cosine for each element of `X`. The `cos` function operates element-wise on arrays. The function accepts both real and complex inputs. For purely real values or imaginary values of X, `cos` returns real values in the interval [-1 ,1]. For complex values of X, `cos` returns complex values. All angles are in radians.

Examples

Plot Cosine Function

Plot the cosine function over the domain $-\pi \le x \le \pi$.

```
x = -pi:0.01:pi;
plot(x,cos(x))
grid on
```



Cosine of Vector of Complex Angles

Calculate the cosine of the complex angles in vector `x`.

```
x = [-i pi+i*pi/2 -1+i*4];
y = cos(x)
```

```
y =

   1.5431 + 0.0000i  -2.5092 - 0.0000i  14.7547 +22.9637i
```

Input Arguments

X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Cosine of input angle

scalar value | vector | matrix | N-D array

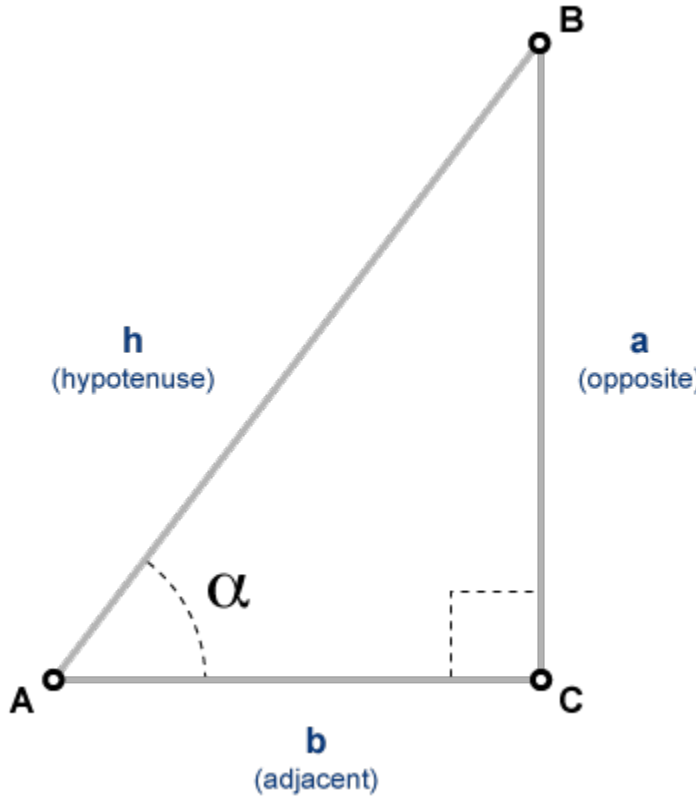
Cosine of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

More About

Cosine Function

The cosine of an angle, α, defined with reference to a right angled triangle is

$$\cos(\alpha) = \frac{\text{adjacent side}}{\text{hypotenuse}} = \frac{b}{h}.$$



The cosine of a complex angle, α, is

$$\cos(\alpha) = \frac{e^{i\alpha} + e^{-i\alpha}}{2}.$$

See Also

acos | acosd | cosd | cosh

Introduced before R2006a

cosd

Cosine of argument in degrees

Syntax

```
Y = cosd(X)
```

Description

`Y = cosd(X)` returns the cosine of the elements of `X`, which are expressed in degrees.

Examples

Cosine of 90 degrees compared to cosine of π/2 radians

```
cosd(90)
```

```
ans =

     0
```

```
cos(pi/2)
```

```
ans =

   6.1232e-17
```

Cosine of complex angles specified in degrees

Create an array of three complex angles and compute the cosine.

```
z = [180+i 45+2i 10+3i];
y = cosd(z)
```

```
y =
```

```
   -1.0002         0.7075 - 0.0247i   0.9862 - 0.0091i
```

Input Arguments

X — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cosd` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Cosine of angle

scalar value | vector | matrix | N-D array

Cosine of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

See Also

`acos` | `acosd` | `cos`

Introduced before R2006a

cosh

Hyperbolic cosine

Syntax

```
Y = cosh(X)
```

Description

The `cosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

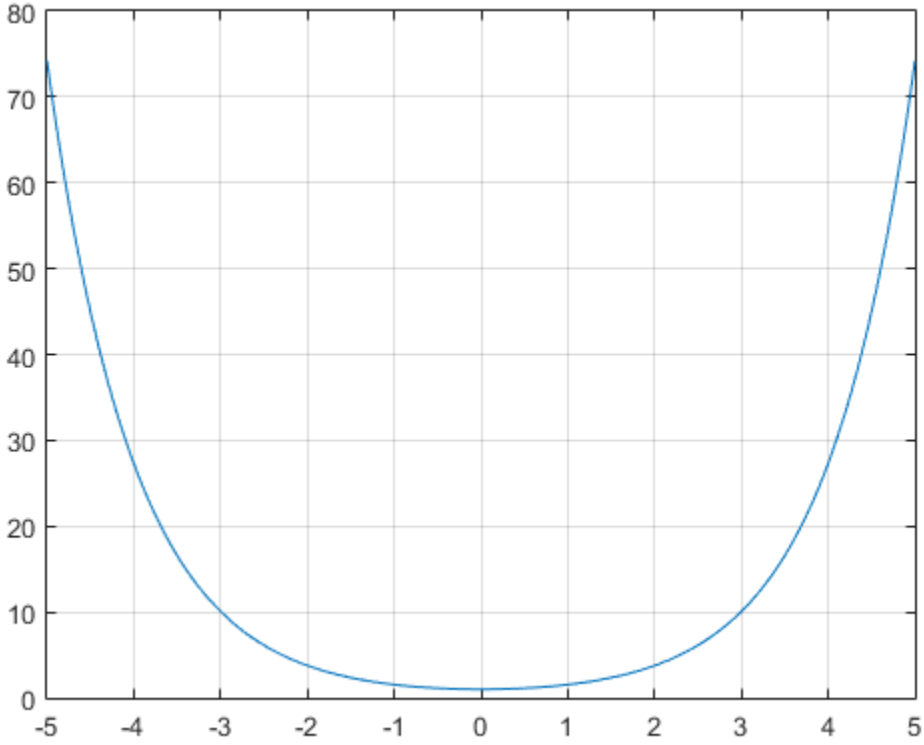
`Y = cosh(X)` returns the hyperbolic cosine for each element of `X`.

Examples

Graph of Hyperbolic Cosine

Graph the hyperbolic cosine function over the domain $-5 \le x \le 5$.

```
x = -5:0.01:5;
plot(x,cosh(x)), grid on
```



Hyperbolic Cosine

The hyperbolic cosine of z is

$$\cosh(z) = \frac{e^z + e^{-z}}{2}.$$

See Also

`acosh` | `cos` | `sinh` | `tanh`

Introduced before R2006a

cot

Cotangent of angle in radians

Syntax

```
Y = cot(X)
```

Description

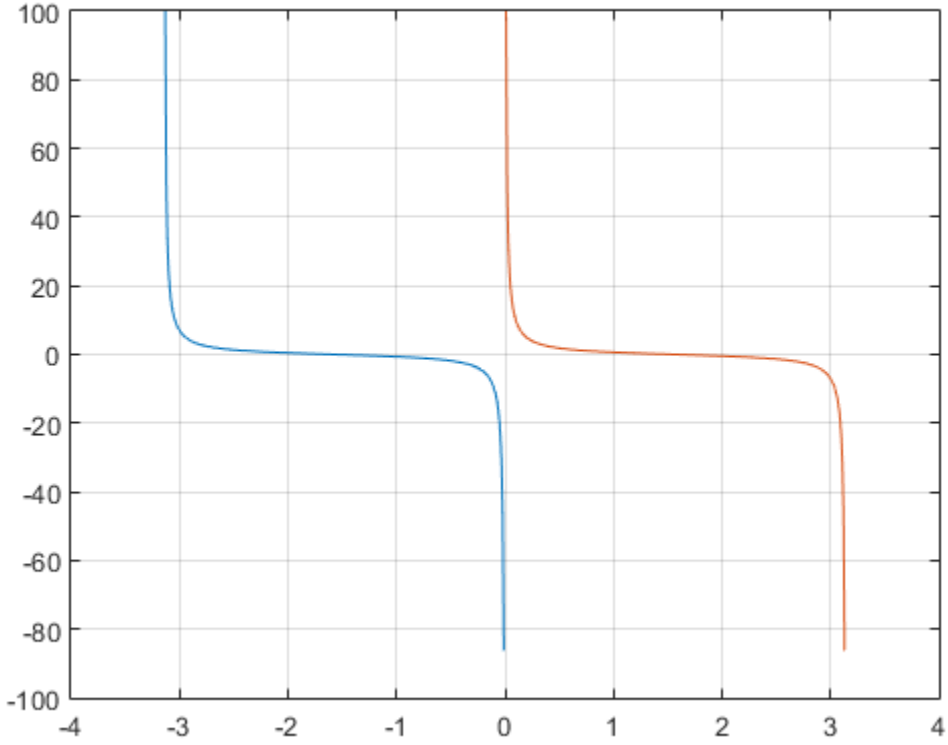
`Y = cot(X)` returns the cotangent of elements of X. The `cot` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of X in the interval [-Inf,Inf], `cot` returns real values in the interval [-Inf,Inf].. For complex values of X, `cot` returns complex values. All angles are in radians.

Examples

Plot Cotangent Function

Plot the cotangent function over the domain $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,cot(x1),x2,cot(x2)), grid on
```



Cotangent of Vector of Complex Angles

Calculate the cotangent of the complex angles in vector `x`.

```
x = [-i pi+i*pi/2 -1+i*4];
y = cot(x)
```

```
y =

   0.0000 + 1.3130i  -0.0000 - 1.0903i  -0.0006 - 0.9997i
```

Input Arguments

X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Cotangent of input angle

scalar value | vector | matrix | N-D array

Cotangent of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

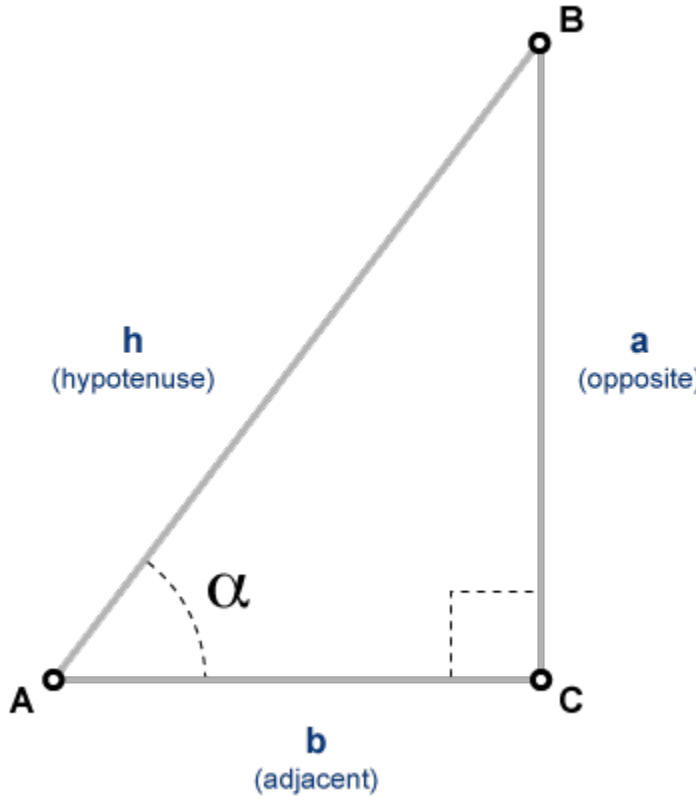
More About

Cotangent Function

The cotangent of an angle, α, defined with reference to a right angled triangle is

$$\cot(\alpha) = \frac{1}{\tan(\alpha)} = \frac{\text{adjacent side}}{\text{opposite side}} = \frac{b}{a}.$$

.



The cotangent of a complex angle α is

$$\cot(\alpha) = \frac{i\left(e^{i\alpha} + e^{-i\alpha}\right)}{\left(e^{i\alpha} - e^{-i\alpha}\right)}.$$

.

See Also

`acot` | `acotd` | `acoth` | `cotd` | `coth`

Introduced before R2006a

cotd

Cotangent of argument in degrees

Syntax

```
Y = cotd(X)
```

Description

`Y = cotd(X)` returns the cotangent of the elements of `X`, which are expressed in degrees.

Examples

Cotangent of angles approaching 90 and 180 degrees

Create a vector of input angles consisting of 90° and the next smaller and larger double precision numbers. Then compute the cotangent.

```
x1 = [90-eps(90) 90 90+eps(90)];
y1 = cotd(x1)
```

```
y1 =

   1.0e-15 *

    0.2480         0   -0.2480
```

`cotd` returns zero when the input angle is exactly 90°. Evaluation at the next smaller double-precision angle returns a slightly positive result. Likewise, the cotangent is slightly negative when the input angle is the next double-precision number larger than 90.

The behavior is similar for input angles near 180°.

```
x2 = [180-eps(180) 180 180+eps(180)];
y2 = cotd(x2)
```

```
y2 =

   1.0e+15 *

   -2.0159       Inf    2.0159
```

Cotangent of complex angle, specified in degrees

```
x = 35+5i;
y = cotd(x)

y =

   1.3958 - 0.2606i
```

Input Arguments

X — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cotd` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Cotangent of angle

scalar value | vector | matrix | N-D array

Cotangent of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

See Also

`acot` | `acotd` | `cot`

Introduced before R2006a

coth

Hyperbolic cotangent

Syntax

```
Y = coth(X)
```

Description

The `coth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

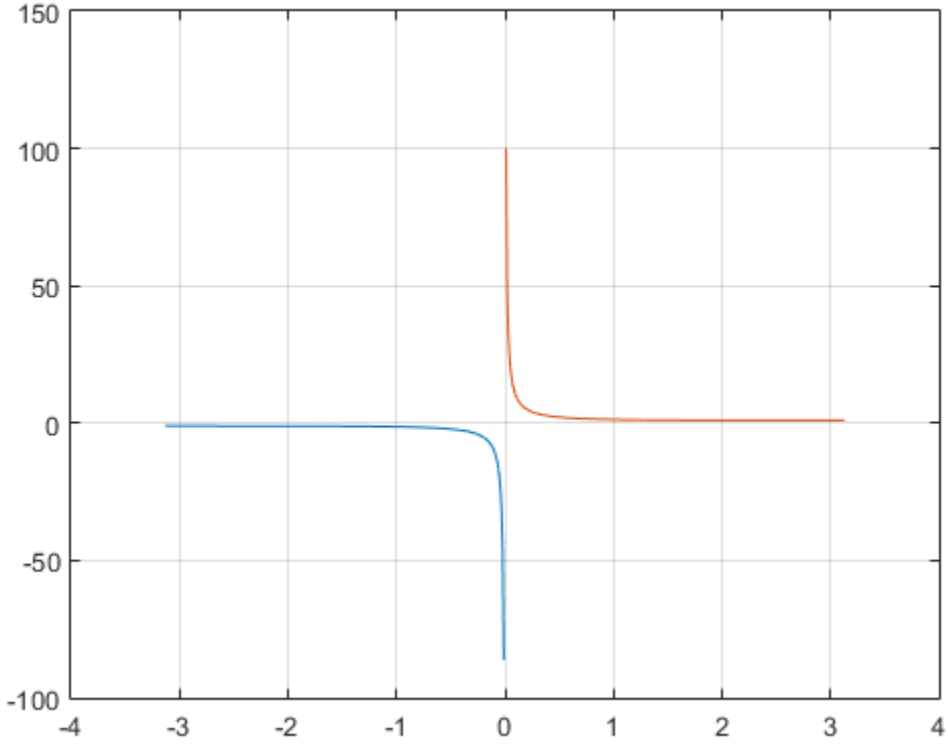
`Y = coth(X)` returns the hyperbolic cotangent for each element of `X`.

Examples

Graph of Hyperbolic Cotangent

Plot the hyperbolic cotangent over the domain $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,coth(x1),x2,coth(x2))
grid on
```



More About

Hyperbolic Cotangent

The hyperbolic cotangent of z is

$$\coth(z) = \frac{1}{\tanh(z)}.$$

See Also

`acoth` | `cot` | `sinh` | `cosh` | `tanh`

Introduced before R2006a

countcats

Count occurrences of categorical array elements by category

Syntax

```
B = countcats(A)
B = countcats(A,dim)
```

Description

`B = countcats(A)` returns the number of elements in each category of the categorical array, `A`.

- If `A` is a vector, then `countcats` returns the number of elements in each category.
- If `A` is a matrix, then `countcats` treats the columns of `A` as vectors and returns the category counts for each column of `A`.
- If `A` is a multidimensional array, then `countcats` acts along the first array dimension whose size does not equal `1`.

`B = countcats(A,dim)` returns the category counts along dimension dim.

For example, you can return the category counts of each row in a categorical array using `countcats(A,2)`.

Examples

Category Counts of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =

     plane      car      train      car      plane
```

`A` has three categories, `car`, `plane`, and `train`.

Find the number of elements in each category of A.

```
B = countcats(A)
```

```
B =

     2     2     1
```

The first element in B corresponds to the first category of A, which is `car`. The second element in B corresponds to the second category of A, which is `plane`. The third element of B corresponds to the third category of A, which is `train`.

Since A is a row vector, `countcats` returns a row vector.

Category Counts of Each Column in Array

Create a 3-by-2 categorical array, A, from a numeric array.

```
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical([1 3; 2 1; 3 1],valueset,catnames)
```

```
A =

     red         blue
     green       red
     blue        red
```

A has three categories, `red`, `green`, and `blue`.

Find the category counts of each column in A.

```
B = countcats(A)
```

```
B =

     1     2
     1     0
     1     1
```

The first row of B corresponds to the first category of A. The value, `red`, occurs once in the first column of A and twice in the second column.

The second row of B corresponds to the second category of A. The value, `green`, occurs once in the first column of A, and it does not occur in the second column.

The third row of B corresponds to the third category of A. The value, blue, occurs once in the first column of A and once in the second column.

Category Counts of Each Row in Array

Create a 3-by-2 categorical array, A, from a numeric array.

```
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical([1 3; 2 1; 3 1],valueset,catnames)
```

```
A =

     red         blue
     green       red
     blue        red
```

A has three categories, red, green, and blue.

Find the category counts of A along the second dimension.

```
B = countcats(A,2)
```

```
B =

     1     0     1
     1     1     0
     1     0     1
```

The first column of B corresponds to the first category of A. The value, red, occurs once in the first row of A, once in the second row, and once in the third row.

The second column of B corresponds to the second category of A. The value, green, occurs in only one element. It occurs in the second row of A.

The third column of B corresponds to the third category of A. The value, blue, occurs once in the first row of A and once in the third row.

Category Counts of Array Containing Undefined Elements

Create a 6-by-1 categorical array, A, from a numeric array.

```
valueset = 1:3;
catnames = {'red' 'green' 'blue'};
```

```
A = categorical([1;3;2;1;3;1],valueset,catnames)
```

```
A =

     red
     blue
     green
     red
     blue
     red
```

Remove the `blue` category.

```
A = removecats(A,'blue')
```

```
A =

     red
     <undefined>
     green
     red
     <undefined>
     red
```

`A` has two categories, `red` and `green`. Elements of `A` that were from the `blue` category are now undefined.

Find the number of elements in each category of `A`.

```
B = countcats(A)
```

```
B =

     3
     1
```

The first element in `B` corresponds to the first category of `A`. The value, `red`, occurs three times in `A`.

The second element in `B` corresponds to the second category of `A`. The value, `green`, occurs once in `A`.

`countcats` does not return any information on undefined elements.

Use the `summary` function to view the number of undefined elements in addition to the number of elements in each category of `A`.

```
summary(A)

     red              3
     green            1
     <undefined>      2
```

Input Arguments

A — Categorical array

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

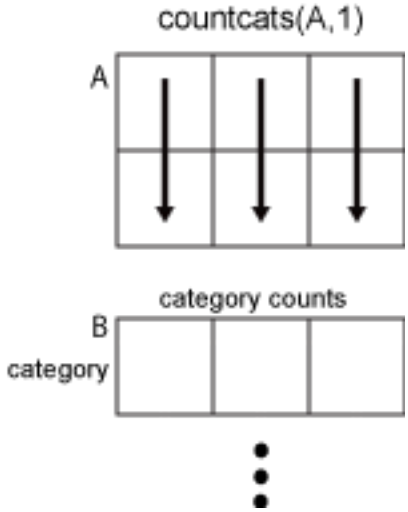
dim — Dimension to operate along

positive integer scalar

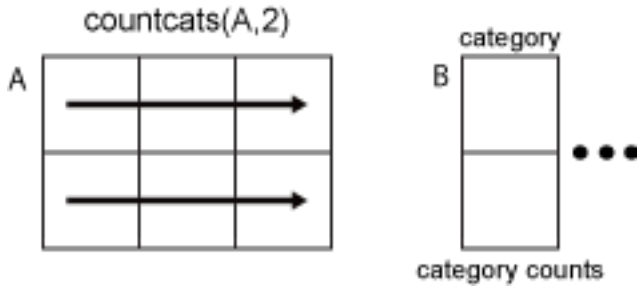
Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional categorical array, A.

If `dim = 1`, then `countcats(A,1)` returns the category counts for each column of A.



If `dim = 2`, then `countcats(A,2)` returns the category counts of each row of A.



If `dim` is greater than `ndims(A)`, then `countcats(A)` returns an array the same size as `A` for each category. `countcats` returns `1` for elements in the corresponding category and `0` otherwise.

More About

Tips

- To find the number of undefined elements in a categorical array, `A`, you must use `summary` or `isundefined`.

See Also

`categories` | `iscategory` | `ismember` | `isundefined` | `summary`

cov

Covariance

Syntax

```
C = cov(A)
C = cov(A,B)
C = cov(___,w)
C = cov(___,nanflag)
```

Description

`C = cov(A)` returns the covariance.

- If `A` is a vector of observations, `C` is the scalar-valued variance.
- If `A` is a matrix whose columns represent random variables and whose rows represent observations, `C` is the covariance matrix with the corresponding column variances along the diagonal.
- `C` is normalized by the number of observations-`1`. If there is only one observation, it is normalized by 1.
- If `A` is a scalar, `cov(A)` returns `0`. If `A` is an empty array, `cov(A)` returns `NaN`.

`C = cov(A,B)` returns the covariance between two random variables `A` and `B`.

- If `A` and `B` are vectors of observations with equal length, `cov(A,B)` is the 2-by-2 covariance matrix.
- If `A` and `B` are matrices of observations, `cov(A,B)` treats `A` and `B` as vectors and is equivalent to `cov(A(:),B(:))`. `A` and `B` must have equal size.
- If `A` and `B` are scalars, `cov(A,B)` returns a 2-by-2 block of zeros. If `A` and `B` are empty arrays, `cov(A,B)` returns a 2-by-2 block of `NaN`.

`C = cov(___,w)` specifies the normalization weight for any of the previous syntaxes. When `w = 0` (default), `C` is normalized by the number of observations-`1`. When `w = 1`, it is normalized by the number of observations.

`C = cov( ___ ,nanflag)` specifies a condition for omitting `NaN` values from the calculation for any of the previous syntaxes. For example, `cov(A,'omitrows')` will omit any rows of `A` with one or more `NaN` elements.

Examples

Covariance of Matrix

Create a 3-by-4 matrix and compute its covariance.

```
A = [5 0 3 7; 1 -5 7 3; 4 9 8 10];
C = cov(A)
```

```
C =

    4.3333    8.8333   -3.0000    5.6667
    8.8333   50.3333    6.5000   24.1667
   -3.0000    6.5000    7.0000    1.0000
    5.6667   24.1667    1.0000   12.3333
```

Since the number of columns of `A` is 4, the result is a 4-by-4 matrix.

Covariance of Two Vectors

Create two vectors and compute their 2-by-2 covariance matrix.

```
A = [3 6 4];
B = [7 12 -9];
cov(A,B)
```

```
ans =

    2.3333    6.8333
    6.8333  120.3333
```

Covariance of Two Matrices

Create two matrices of the same size and compute their 2-by-2 covariance.

```
A = [2 0 -9; 3 4 1];
```

```
B = [5 2 6; -4 4 9];
cov(A,B)
```

```
ans =

   22.1667   -6.9333
   -6.9333   19.4667
```

Specify Normalization Weight

Create a matrix and compute the covariance normalized by the number of rows.

```
A = [1 3 -7; 3 9 2; -5 4 6];
C = cov(A,1)
```

```
C =

   11.5556    5.1111  -10.2222
    5.1111    6.8889    5.2222
  -10.2222    5.2222   29.5556
```

Covariance Excluding `NaN`

Create a matrix and compute its covariance, excluding any rows containing `NaN` values.

```
A = [1.77 -0.005 3.98; NaN -2.95 NaN; 2.54 0.19 1.01]
```

```
A =

    1.7700   -0.0050    3.9800
       NaN   -2.9500       NaN
    2.5400    0.1900    1.0100
```

```
C = cov(A,'omitrows')
```

```
C =

    0.2964    0.0751   -1.1435
    0.0751    0.0190   -0.2896
```

```
   -1.1435   -0.2896    4.4105
```

Input Arguments

A — Input array

vector | matrix

Input array, specified as a vector or matrix.

Data Types: `single` | `double`

B — Additional input array

vector | matrix

Additional input matrix, specified as a vector or matrix. `B` must be the same size as `A`.

Data Types: `single` | `double`

w — Normalization weight

0 (default) | 1

Normalization weight, specified as one of these values:

- `0` — The output is normalized by the number of observations `-1`. If there is only one observation, it is normalized by 1.
- `1` — The output is normalized by the number of observations.

Data Types: `single` | `double`

nanflag — NaN condition

'`includenan`' (default) | '`omitrows`' | '`partialrows`'

`NaN` condition, specified as one of these values:

- '`includenan`' — include all `NaN` values in the input prior to computing the covariance.
- '`omitrows`' — omit any row of input containing one or more `NaN` values prior to computing the covariance.
- '`partialrows`' — omit rows containing `NaN` only on a pair-wise basis for each two-column covariance calculation.

Data Types: `char`

Output Arguments

`C` — Covariance

scalar | matrix

Covariance, specified as a scalar or matrix.

- For single matrix input, `C` has size `[size(A,2) size(A,2)]` based on the number of random variables (columns) represented by `A`. The variances of the columns are along the diagonal. If `A` is a row or column vector, `C` is the scalar-valued variance.
- For two-vector or two-matrix input, `C` is the 2-by-2 covariance matrix between the two random variables. The variances are along the diagonal of `C`.

More About

Covariance

For two random variable vectors A and B, the covariance is defined as

$$\mathrm{cov}(A,B) = \frac{1}{N-1}\sum_{i=1}^{N}(A_i - \mu_A)^{*}(B_i - \mu_B)$$

where μ_A is the mean of A, μ_B is the mean of B, and `*` denotes the complex conjugate.

The *covariance matrix* of two random variables is the matrix of pair-wise covariance calculations between each variable,

$$C = \begin{pmatrix} \mathrm{cov}(A,A) & \mathrm{cov}(A,B) \\ \mathrm{cov}(B,A) & \mathrm{cov}(B,B) \end{pmatrix}.$$

For a matrix `A` whose columns are each a random variable made up of observations, the covariance matrix is the pair-wise covariance calculation between each column combination. In other words, $C(i,j) = \mathrm{cov}\left(A(:,i), A(:,j)\right)$.

Variance

For a random variable vector A made up of N scalar observations, the variance is defined as

$$V = \frac{1}{N-1}\sum_{i=1}^{N} |A_i - \mu|^2$$

where μ is the mean of A,

$$\mu = \frac{1}{N}\sum_{i=1}^{N} A_i.$$

Some definitions of variance use a normalization factor of N instead of $N-1$, which can be specified by setting `w` to `1`. In either case, the mean is assumed to have the usual normalization factor N.

Introduced before R2006a

cplxpair

Sort complex numbers into complex conjugate pairs

Syntax

```
B = cplxpair(A)
B = cplxpair(A,tol)
B = cplxpair(A,[],dim)
B = cplxpair(A,tol,dim)
```

Description

`B = cplxpair(A)` sorts the elements along different dimensions of a complex array, grouping together complex conjugate pairs.

The conjugate pairs are ordered by increasing real part. Within a pair, the element with negative imaginary part comes first. The purely real values are returned following all the complex pairs. The complex conjugate pairs are forced to be exact complex conjugates. A default tolerance of `100*eps` relative to `abs(A(i))` determines which numbers are real and which elements are paired complex conjugates.

If `A` is a vector, `cplxpair(A)` returns `A` with complex conjugate pairs grouped together.

If `A` is a matrix, `cplxpair(A)` returns `A` with its columns sorted and complex conjugates paired.

If `A` is a multidimensional array, `cplxpair(A)` treats the values along the first non-singleton dimension as vectors, returning an array of sorted elements.

`B = cplxpair(A,tol)` overrides the default tolerance.

`B = cplxpair(A,[],dim)` sorts `A` along the dimension specified by scalar dim.

`B = cplxpair(A,tol,dim)` sorts `A` along the specified dimension and overrides the default tolerance.

Diagnostics

If there are an odd number of complex numbers, or if the complex numbers cannot be grouped into complex conjugate pairs within the tolerance, `cplxpair` generates the error message

```
Complex numbers can't be paired.
```

Introduced before R2006a

cputime

Elapsed CPU time

Syntax

```
cputime
```

Description

`cputime` returns the total CPU time (in seconds) used by your MATLAB application from the time it was started. This number can overflow the internal representation and wrap around.

Examples

The following code returns the CPU time used to run `surf(peaks(40))`.

```
t = cputime;
surf(peaks(40));
e = cputime-t

e =
     0.4667
```

More About

Tips

Although it is possible to measure performance using the `cputime` function, it is recommended that you use the `timeit` or `tic` and `toc` functions for this purpose exclusively. See Using tic and toc Versus the cputime Function in the MATLAB Programming Fundamentals documentation for more information.

See Also

`clock` | `etime` | `tic` | `timeit` | `toc`

Introduced before R2006a

RandStream.create

Create random number streams

Class

`RandStream`

Syntax

```
[s1,s2,...] = RandStream.create('gentype','NumStreams',n)
s = RandStream.create('gentype')
[ ... ] = RandStream.create('gentype', Name, Value,...)
```

Description

`[s1,s2,...] = RandStream.create('gentype','NumStreams',n)` creates `n` random number streams that use the uniform pseudorandom number generator algorithm specified by `gentype`. The streams are independent in a pseudorandom sense. The streams are not necessarily independent from streams created at other times. `RandStream.list` returns all possible values for `gentype` or see " Choosing a Random Number Generator" in the MATLAB Mathematics documentation for details on generator algorithms.

Note: Multiple streams are not supported by all generator types. Use either the multiplicative lagged Fibonacci generator (`mlfg6331_64`) or the combined multiple recursive generator (`mrg32k3a`) to create multiple streams.

`s = RandStream.create('gentype')` creates a single random stream. The `RandStream` constructor is a more concise alternative when you need to create a single stream.

`[ ... ] = RandStream.create('gentype', Name, Value,...)` allows you to specify optional Name, Value pairs to control creation of the stream. The parameters are:

`NumStreams`	Total number of streams of this type that will be created across sessions or labs. Default is 1.
`StreamIndices`	Stream indices that should be created in this call. Default is `1:N`, where `N` is the value given with the `'NumStreams'` parameter.
`Seed`	Nonnegative scalar integer with which to initialize all streams. Default is 0. Seeds must be an integer between 0 and $2^{32} - 1$ or `'shuffle'` to create a seed based on the current time.
`NormalTransform`	Transformation algorithm used by `randn(S, ...)` to generate normal pseudorandom values. Options are `'Ziggurat'`, `'Polar'`, or `'Inversion'`.
`CellOutput`	Logical flag indicating whether or not to return the stream objects as elements of a cell array. Default is false.

Typically, you call `RandStream.create` once to create multiple independent streams in a single pass. Alternatively, you can create each stream from separate calls to `RandStream.create`, but you must specify the appropriate values for `gentype`, `'NumStreams'`, `'Seed'`, and `'StreamIndices'` to ensure their independence:

- Specify the same set of values for `gentype`, `'NumStreams'`, and `'Seed'` in each case.
- Specify a different value for `'StreamIndices'` that is between `1` and the `'NumStreams'` value in each case.

Examples

Create three independent streams.

```
[s1,s2,s3] = RandStream.create('mrg32k3a','NumStreams',3);
r1 = rand(s1,100000,1);
r2 = rand(s2,100000,1);
r3 = rand(s3,100000,1);
```

```
corrcoef([r1,r2,r3])
```

Create one stream from a set of three independent streams and designate it as the global stream.

```
s2 = RandStream.create('mrg32k3a','NumStreams',3,'StreamIndices',2);
RandStream.setGlobalStream(s2);
```

See Also

`RandStream` | `RandStream.list`

createClassFromWsdl

Create MATLAB class based on WSDL document

Compatibility

`createClassFromWsdl` will be removed in a future release. Use `matlab.wsdl.createWSDLClient` instead.

Syntax

```
createClassFromWsdl(source)
```

Description

`createClassFromWsdl(source)` creates a MATLAB class based on the service name defined in source.

`createClassFromWsdl` creates a class folder, `@servicename`, in the current folder. The class folder contains:

- A method file for each Web service operation.
- A display method, `display.m`.
- A constructor, `servicename.m`.

Examples

Display Standardized Test Scores

This example illustrates how to use the function. It does not use an actual WSDL document; therefore, you cannot run it. Retrieve information from a database that provides standardized test scores. Assume the WSDL document is located at `http://examplestandardtests.com/scoreswebservice?WSDL`.

Create the MATLAB class, `@TestScoreWebService`, in the current folder.

```
createClassFromWsdl('http://examplestandardtests.com/scoreswebservice?WSDL')
```

```
Retrieving document at 'http://examplestandardtests.com/scoreswebservice?WSDL'
```

Create the service.

```
svc = TestScoreWebService
```

```
endpoint: 'http://examplestandardtests.com/scoreswebservice'
    wsdl: 'http://examplestandardtests.com/scoreswebservice?WSDL'
```

Display the class methods.

```
dir @TestScoreWebService
```

```
display.m
StudentNames.m
Tests.m
TestScoreWebService.m
```

Display the calling syntax for the `StudentNames` function.

```
help StudentNames
```

```
 StudentNames(obj)

    Get names of students who took tests

      Output:
        Names = (string)
```

Get the names. MATLAB creates a structure with the names of the test takers.

```
students = StudentNames(svc)
```

```
students =

    StudentInfo: [125x1 struct]
```

View the data for the first student.

```
students.StudentInfo(1)
```

```
StudentNameLast: 'Benjamin'
StudentNameFirst: 'Ali'
```

- “Specify Proxy Server Settings for Connecting to the Internet”

Input Arguments

`source` — Web Services Description Language (WSDL) document

string

Web Services Description Language (WSDL) document, specified as a string. The name must include the location of the document, using one of the following:

- URL
- Full path
- Relative path

Example: `'http://examplestandardtests.com/scoreswebservice?WSDL'`

See Also

`createSoapMessage` | `matlab.wsdl.createWSDLClient` | `xmlread`

Introduced before R2006a

createSoapMessage

Create SOAP (Simple Object Access Protocol) message to send to server

Compatibility

`createSoapMessage` will be removed in a future release. Use `matlab.wsdl.createWSDLClient` instead.

Syntax

```
message = createSoapMessage(namespace,method,values,names,types)
message = createSoapMessage(namespace,method,values,names,types,
style)
```

Description

`message = createSoapMessage(namespace,method,values,names,types)` creates a SOAP message.

`message = createSoapMessage(namespace,method,values,names,types, style)` creates message with specified style.

Examples

Retrieve Book Information from Library Database

This example assumes the library is on a local intranet and does not use an actual endpoint; therefore, you cannot run it.

Retrieve the name of the author of a book titled “In the Fall.” The relative path of the library service is `urn:LibraryCatalog`. To get the author's name, use the `getAuthor` function, which takes the book name as the input value. The `getAuthor` parameter is `nameToLookUp`. The XML data type for title is `{http://www.w3.org/2001/XMLSchema}string`. The SOAP message style is `rpc` by default.

Create the SOAP message.

```
message = createSoapMessage(...
  'urn:LibraryCatalog',...
  'getAuthor',...
  {'In the Fall'},...
  {'nameToLookUp'},...
  {'{http://www.w3.org/2001/XMLSchema}string'})
```

```
message =

[#document: null]
```

This response does not necessarily indicate that the message is valid, although certain input problems produce error messages.

Send the message to the server for processing, and get the author's name back. The server endpoint is `http://test/soap/services/LibraryCatalog`. The server method is `urn:LibraryCatalog#getAuthor`.

```
response = callSoapService(...
  'http://test/soap/services/LibraryCatalog',...
  'urn:LibraryCatalog#getAuthor',...
  message)
```

```
<?xml version="1.0" encoding="utf-8"?>
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<soapenv:Body>
<getAuthorResponse xmlns="urn:LibraryCatalog">
<ns1:getAuthorReturn xmlns:ns1="http://latestversion.soap.test">
Kate Alvin
</ns1:getAuthorReturn>
</getAuthorResponse>
</soapenv:Body>
</soapenv:Envelope>
```

MATLAB returns the message in a single line, displayed here on separate lines for legibility.

Extract the author's name.

```
author = parseSoapResponse(response)
```

```
author = Kate Alvin
```

MATLAB automatically converted the XML string data type to `char`.

Input Arguments

`namespace` — Location of Web service

string

Location of Web service, specified as a string in the form of a valid Uniform Resource Identifier (URI).

Example: `'urn:LibraryCatalog'`

`method` — Name of Web service operation

string

Name of Web service operation, specified as a string.

Example: `'getAuthor'`

`values` — Input arguments for `method`

cell array

Input arguments for `method`, specified as a cell array.

Example: `{'In the Fall'}`

`names` — Parameter for `method`

cell array

Parameter for `method`, specified as a cell array.

Example: `{'nameToLookUp'}`

`types` — XML data types for `values`

cell array

XML data types for `values`, specified as a cell array.

Example: `{'{http://www.w3.org/2001/XMLSchema}string'}`

`style` — Style for structuring SOAP message

`'rpc'` (default) | `'document'`

Style for structuring the SOAP message, specified as one of these values. Use a style supported by the service specified in namespace.

`'rpc'`	Remote Procedure Call (RPC) encoding
`'document'`	Document-style encoding

Output Arguments

`message` — Java document object model (DOM)

string

Java document object model (DOM), returned as a string. Use message as input to `callSoapService` function.

Introduced before R2006a

cross

Cross product

Syntax

```
C = cross(A,B)
C = cross(A,B,dim)
```

Description

`C = cross(A,B)` returns the cross product of `A` and `B`.

- If `A` and `B` are vectors, then they must have a length of 3.
- If `A` and `B` are matrices or multidimensional arrays, then they must have the same size. In this case, the `cross` function treats `A` and `B` as collections of three-element vectors. The function calculates the cross product of corresponding vectors along the first array dimension whose size equals 3.

`C = cross(A,B,dim)` evaluates the cross product of arrays `A` and `B` along dimension, `dim`. `A` and `B` must have the same size, and both `size(A,dim)` and `size(B,dim)` must be 3. The `dim` input is a positive integer scalar.

Examples

Cross Product of Vectors

Create two 3-D vectors.

```
A = [4 -2 1];
B = [1 -1 3];
```

Find the cross product of `A` and `B`.

```
C = cross(A,B)
```

```
C =
```

```
    -5   -11    -2
```

The result, `C`, is a vector that is perpendicular to both `A` and `B`.

Use dot products to verify that `C` is perpendicular to `A` and `B`.

```
dot(C,A)==0 & dot(C,B)==0
```

```
ans =

     1
```

The result is logical `1` (`true`).

Cross Product of Matrices

Create two matrices containing random integers.

```
rng(0)
A = randi(15,3,5)
B = randi(25,3,5)
```

```
A =

    13    14     5    15    15
    14    10     9     3     8
     2     2    15    15    13

B =

     4    20     1    17    10
    11    24    22    19    17
    23    17    24    19     5
```

Find the cross product of `A` and `B`.

```
C = cross(A,B)
```

```
C =

   300   122  -114  -228  -181
  -291  -198  -105   -30    55
    87   136   101   234   175
```

The result, C, contains five independent cross products between the columns of A and B. For example, C(:,1) is equal to the cross product of A(:,1) with B(:,1).

Cross Product of Multidimensional Arrays

Create two 3-by-3-by-3 multidimensional arrays of random integers.

```
rng(0)
A = randi(10,3,3,3);
B = randi(25,3,3,3);
```

Find the cross product of A and B, treating the rows as vectors.

```
C = cross(A,B,2)
```

```
C(:,:,1) =

   -34    12    62
    15    72  -109
   -49     8     9

C(:,:,2) =

   198  -164  -170
    45     0   -18
   -55   190  -116

C(:,:,3) =

  -109   -45   131
     1   -74    82
    -6   101  -121
```

The result is a collection of row vectors. For example, C(1,:,1) is equal to the cross product of A(1,:,1) with B(1,:,1).

Find the cross product of A and B along the third dimension (dim = 3).

```
D = cross(A,B,3)
```

```
D(:,:,1) =

   -14   179  -106
   -56    -4   -75
```

```
     2   -37    10

D(:,:,2) =

   -37  -162   -37
    50  -124   -78
     1    63   118

D(:,:,3) =

    62  -170    56
    46    72   105
    -2   -53  -160
```

The result is a collection of vectors oriented in the third dimension. For example, `C(1,1,:)` is equal to the cross product of `A(1,1,:)` with `B(1,1,:)`.

Input Arguments

`A,B` — Input arrays

numeric arrays

Input arrays, specified as numeric arrays.

Data Types: `single | double`
Complex Number Support: Yes

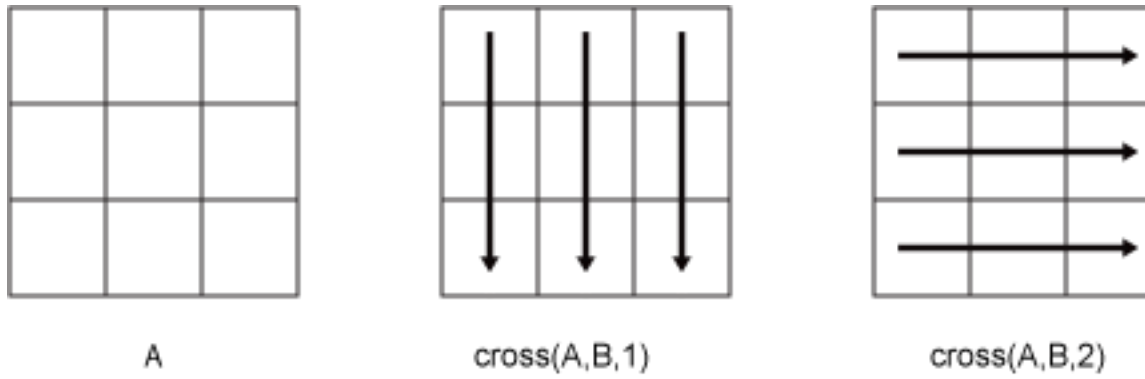
`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. The size of dimension `dim` must be 3. If no value is specified, the default is the first array dimension whose size equals 3.

Consider two 2-D input arrays, `A` and `B`:

- `cross(A,B,1)` treats the columns of `A` and `B` as vectors and returns the cross products of corresponding columns.
- `cross(A,B,2)` treats the rows of `A` and `B` as vectors and returns the cross products of corresponding rows.



`cross` returns an error if `dim` is greater than `ndims(A)`.

More About

Cross Product

The cross product between two 3-D vectors produces a new vector that is perpendicular to both.

Consider the two vectors

$$A = a_1\hat{i} + a_2\hat{j} + a_3\hat{k},$$
$$B = b_1\hat{i} + b_2\hat{j} + b_3\hat{k}.$$

In terms of a matrix determinant involving the basis vectors $\hat{i}$, $\hat{j}$, and $\hat{k}$, the cross product of A and B is

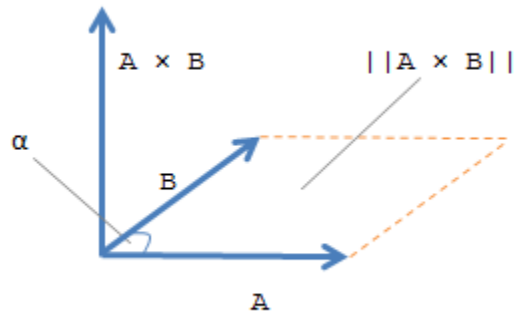
$$C = A \times B = \begin{vmatrix} \hat{i} & \hat{j} & \hat{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}$$

$$= (a_2b_3 - a_3b_2)\hat{i} + (a_3b_1 - a_1b_3)\hat{j} + (a_1b_2 - a_2b_1)\hat{k}.$$

Geometrically, $A \times B$ is perpendicular to both A and B. The magnitude of the cross product, $\|A \times B\|$, is equal to the area of the parallelogram formed using A and B as sides. This area is related to the magnitudes of A and B as well as the angle between the vectors by

$$\|A \times B\| = \|A\| \|B\| \sin \alpha \ .$$

Thus, if A and B are parallel, then the cross product is zero.



See Also

`dot` | `kron`

Introduced before R2006a

csc

Cosecant of input angle in radians

Syntax

```
Y = csc(X)
```

Description

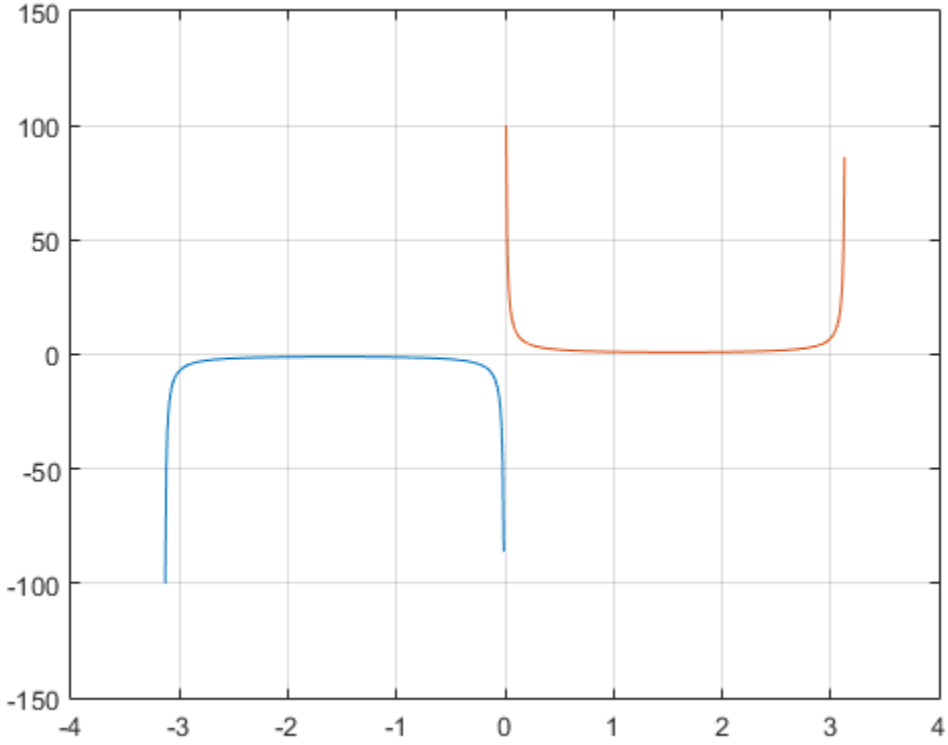
`Y = csc(X)` returns the cosecant of the elements of `X`. The `csc` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of X in the interval [-Inf, Inf], `csc` returns real values in the interval [-Inf ,-1] and [1,Inf]. For complex values of X, `csc` returns complex values. All angles are in radians.

Examples

Plot Cosecant Function

Plot the cosecant function over the domain $-\pi < x < 0$ and $0 < x < \pi$ as shown.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csc(x1),x2,csc(x2)), grid on
```



Cosecant of Vector of Complex Angles

Calculate the cosecant of the complex angles in vector `x`.

```
x = [-i pi+i*pi/2 -1+i*4];
y = csc(x)
```

```
y =

   0.0000 + 0.8509i   0.0000 + 0.4345i  -0.0308 - 0.0198i
```

Input Arguments

X — Input angle in radians

number | vector | matrix | multidimensional array

Input angle in radians, specified as a number, vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Cosecant of input angle

scalar value | vector | matrix | N-D array

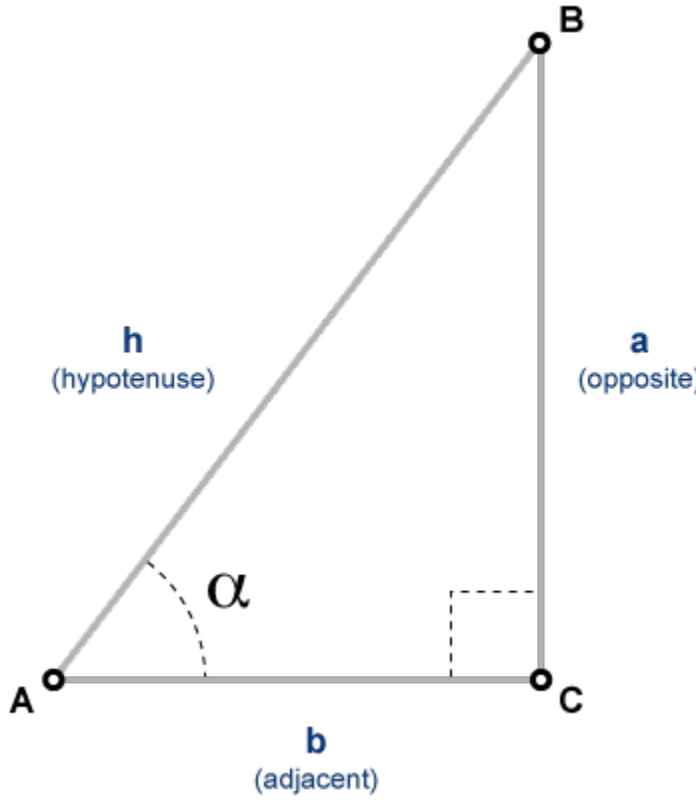
Cosecant of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

More About

Cosecant Function

The cosecant of an angle, α, defined with reference to a right angled triangle is

$$\csc(\alpha) = \frac{1}{\sin(\alpha)} = \frac{\text{hypotenuse}}{\text{opposite side}} = \frac{h}{a}.$$



The cosecant of a complex angle, α, is

$$\csc(\alpha) = \frac{2i}{e^{i\alpha} - e^{-i\alpha}}.$$

See Also

acsc | acscd | acsch | cscd | csch

Introduced before R2006a

cscd

Cosecant of argument in degrees

Syntax

```
Y = cscd(X)
```

Description

`Y = cscd(X)` returns the cosecant of the elements of `X`, which are expressed in degrees.

Examples

Cosecant of 180 degrees compared to cosecant of π radians

`cscd(180)` is infinite, whereas `csc(pi)` is large but finite.

```
cscd(180)
```

```
ans =

   Inf
```

```
csc(pi)
```

```
ans =

   8.1656e+15
```

Cosecant of vector of complex angles, specified in degrees

```
z = [35+i 15+2i 10+3i];
y = cscd(z)
```

```
y =
```

```
   1.7421 - 0.0434i   3.7970 - 0.4944i   5.2857 - 1.5681i
```

Input Arguments

X — Angle in degrees

scalar value | vector | matrix | N-D array

Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The `cscd` operation is element-wise when `X` is nonscalar.

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

Y — Cosecant of angle

scalar value | vector | matrix | N-D array

Cosecant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as `X`.

Introduced before R2006a

csch

Hyperbolic cosecant

Syntax

```
Y = csch(x)
```

Description

The `csch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

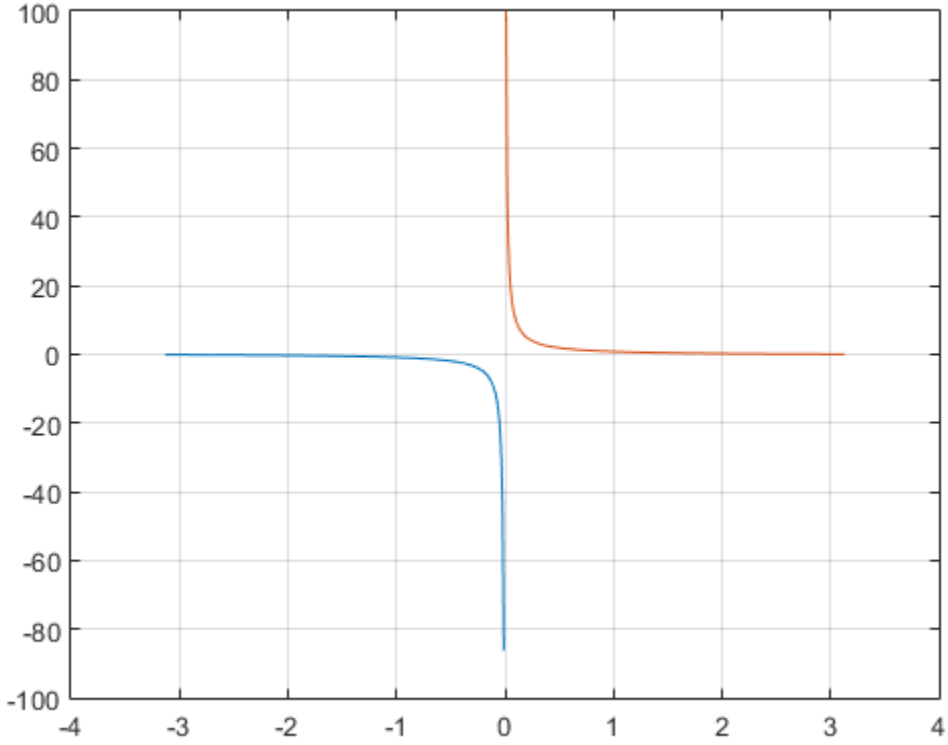
`Y = csch(x)` returns the hyperbolic cosecant for each element of `x`.

Examples

Graph of Hyperbolic Cosecant

Plot the hyperbolic cosecant over the domain $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csch(x1),x2,csch(x2)), grid on
```



More About

Hyperbolic Cosecant

The hyperbolic cosecant of z is

$$\operatorname{csch}(z) = \frac{1}{\sinh(z)}.$$

`acsch` | `csc` | `sinh` | `cosh`

Introduced before R2006a

csvread

Read comma-separated value (CSV) file

Syntax

```
M = csvread(filename)
M = csvread(filename,R1,C1)
M = csvread(filename,R1,C1,[R1 C1 R2 C2])
```

Description

`M = csvread(filename)` reads a comma-separated value (CSV) formatted file into array `M`. The file must contain only numeric values.

`M = csvread(filename,R1,C1)` reads data from the file starting at row offset `R1` and column offset `C1`. For example, the offsets `R1=0`, `C1=0` specify the first value in the file.

`M = csvread(filename,R1,C1,[R1 C1 R2 C2])` reads only the range bounded by row offsets `R1` and `R2` and column offsets `C1` and `C2`. Another way to define the range is to use spreadsheet notation, such as `'A1..B7'` instead of `[0 0 6 1]`.

Examples

Read Entire CSV File

Create a file named `csvlist.dat` that contains comma-separated values.

```
02, 04, 06, 08
03, 06, 09, 12
05, 10, 15, 20
07, 14, 21, 28
```

Read the numeric values in the file.

```
filename = 'csvlist.dat';
M = csvread(filename)
```

```
M =

     2     4     6     8
     3     6     9    12
     5    10    15    20
     7    14    21    28
```

Read CSV File Starting at Specific Row and Column Offset

Read the matrix starting two rows below the first row from the file described in the previous example.

```
M = csvread('csvlist.dat',2,0)

M =

     5    10    15    20
     7    14    21    28
```

Read Specific Range from CSV File

Read the matrix bounded by row offsets 1 and 2 and column offsets 0 and 2 from the file described in the first example.

```
M = csvread('csvlist.dat',1,0,[1,0,2,2])

M =

     3     6     9
     5    10    15
```

Input Arguments

`filename` — File name

string

File name, specified as a string.

Example: `'myFile.dat'`

Data Types: `char`

`R1` — Starting row offset

0 (default) | nonnegative integer

Starting row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`C1` — Starting column offset

0 (default) | nonnegative integer

Starting column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`R2` — Ending row offset

nonnegative integer

Ending row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`C2` — Ending column offset

nonnegative integer

Ending column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

More About

Tips

- Skip header rows or columns by specifying row and column offsets. All values in the file other than headers must be numeric.

Algorithms

`csvread` fills empty delimited fields with zero. When the `csvread` function reads data files with lines that end with a nonspace delimiter, such as a semicolon, it returns a matrix, `M`, that has an additional last column of zeros.

`csvread` imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type. The table shows valid forms for a complex number.

Form	Example
`±<real>±<imag>i|j`	`5.7-3.1i`
`±<imag>i|j`	`-7j`

Embedded white space in a complex number is invalid and is regarded as a field delimiter.

- "Ways to Import Text Files"

`csvwrite` | `dlmread` | `readtable` | `textscan` | `uiimport`

Introduced before R2006a

ctranspose, '

Complex conjugate transpose

Syntax

```
B = A'
B = ctranspose(A)
```

Description

`B = A'` computes the complex conjugate transpose of `A`.

`B = ctranspose(A)` is an alternate way to execute `A'`, but is rarely used. It enables operator overloading for classes.

Examples

Conjugate Transpose of Real Matrix

Create a 4-by-2 matrix.

```
A = [2 1; 9 7; 2 8; 3 5]
```

```
A =

     2     1
     9     7
     2     8
     3     5
```

Find the conjugate transpose of `A`.

```
B = A'
```

```
B =
```

```
     2     9     2     3
     1     7     8     5
```

The result is a 2-by-4 matrix. `B` has the same elements as `A`, but the row and column index for each element are interchanged. When no complex elements are present, `A'` produces the same result as `A.'`.

Conjugate Transpose of Complex Matrix

Create a 2-by-2 matrix with complex elements.

```
A = [0-1i 2+1i;4+2i 0-2i]
```

```
A =

   0.0000 - 1.0000i   2.0000 + 1.0000i
   4.0000 + 2.0000i   0.0000 - 2.0000i
```

Find the conjugate transpose of `A`.

```
B = A'
```

```
B =

   0.0000 + 1.0000i   4.0000 - 2.0000i
   2.0000 - 1.0000i   0.0000 + 2.0000i
```

The result, `B`, contains the elements of `A` with the row and column indices interchanged. The sign of the imaginary part of each number is also switched.

Input Arguments

`A` — Input array

vector | matrix | cell array | categorical array | datetime array | duration array | calendarDuration array | structure field

Input array, specified as a vector or matrix of any numeric, logical, or `char` data type, or as a cell array, categorical array, datetime array, duration array, calendarDuration array, or structure field.

Complex Number Support: Yes

More About

Complex Conjugate Transpose

The complex conjugate transpose of a matrix interchanges the row and column index for each element, reflecting the elements across the main diagonal. The operation also negates the imaginary part of any complex numbers.

For example, if `B = A'` and `A(1,2)` is `1+1i`, then the element `B(2,1)` is `1-1i`.

Tips

- The nonconjugate transpose operator, `A.'`, performs a transpose without conjugation. That is, it does not change the sign of the imaginary parts of the elements.
- For logical or non-numeric inputs, `ctranspose` and `transpose` produce the same result.

- "Array vs. Matrix Operations"
- "Operator Precedence"

`conj` | `permute` | `transpose`

Introduced before R2006a

csvwrite

Write comma-separated value file

Syntax

```
csvwrite(filename,M)
csvwrite(filename,M,row,col)
```

Description

`csvwrite(filename,M)` writes matrix `M` into `filename` as comma-separated values. The `filename` input is a string enclosed in single quotes.

`csvwrite(filename,M,row,col)` writes matrix `M` into `filename` starting at the specified row and column offset. The row and column arguments are zero based, so that `row=0` and `C=0` specify the first value in the file.

Examples

The following example creates a comma-separated value file from the matrix `m`.

```
m = [3 6 9 12 15; 5 10 15 20 25; ...
     7 14 21 28 35; 11 22 33 44 55];

csvwrite('csvlist.dat',m)
type csvlist.dat

3,6,9,12,15
5,10,15,20,25
7,14,21,28,35
11,22,33,44,55
```

The next example writes the matrix to the file, starting at a column offset of `2`.

```
csvwrite('csvlist.dat',m,0,2)
type csvlist.dat
```

```
,,3,6,9,12,15
,,5,10,15,20,25
,,7,14,21,28,35
,,11,22,33,44,55
```

More About

Tips

- `csvwrite` terminates each line with a line feed character and no carriage return.
- `csvwrite` writes a maximum of five significant digits. If you need greater precision, use `dlmwrite` with a precision argument.
- `csvwrite` does not accept cell arrays for the input matrix `M`. To export a cell array that contains only numeric data, use `cell2mat` to convert the cell array to a numeric matrix before calling `csvwrite`. To export cell arrays with mixed alphabetic and numeric data, where each cell contains a single element, you can create an Excel spreadsheet (if your system has Excel installed) using `xlswrite`. For all other cases, you must use low-level export functions to write your data. For more information, see “Export Cell Array to Text File” in the MATLAB Data Import and Export documentation.

`csvread` | `dlmwrite` | `xlswrite` | `writetable` | `uiimport`

Introduced before R2006a

cummax

Cumulative maximum

Syntax

```
M = cummax(A)
M = cummax(A,dim)
M = cummax( ___ ,direction)
```

Description

`M = cummax(A)` returns the cumulative maximum elements of `A`. By default, `cummax(A)` operates along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `cummax(A)` returns a vector of the same size containing the cumulative maxima of `A`.
- If `A` is a matrix, then `cummax(A)` returns a matrix of the same size containing the cumulative maxima in each column of `A`.
- If `A` is a multidimensional array, then `cummax(A)` returns an array of the same size containing the cumulative maxima along the first array dimension of `A` whose size does not equal 1.

`M = cummax(A,dim)` returns the cumulative maxima along the dimension `dim`. For example, if `A` is a matrix, then `cummax(A,2)` returns the cumulative maxima along the rows of `A`.

`M = cummax( ___ ,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A` and, optionally, can specify `dim`. For instance, `cummax(A,2,'reverse')` returns the cumulative maxima of `A` by working from end to beginning of the second dimension of `A`.

Examples

Cumulative Maximum Values in Vector

Find the cumulative maxima of a 1-by-10 vector of random integers.

```
v = randi(10,1,10)
```

```
v =

     8     3     6     7     9    10     6     2     2     3
```

```
M = cummax(v)
```

```
M =

     8     8     8     8     9    10    10    10    10    10
```

Cumulative Maximum Values in Matrix Columns

Find the cumulative maxima of the columns of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =

     3     5     2
     1     6     3
     7     8     1
```

```
M = cummax(A)
```

```
M =

     3     5     2
     3     6     3
     7     8     3
```

Cumulative Maximum Values in Matrix Rows

Find the cumulative maxima of the rows of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =

     3     5     2
     1     6     3
     7     8     1
```

```
M = cummax(A,2)
```

```
M =
```

```
     3     5     5
     1     6     6
     7     8     8
```

Cumulative Maximum Array Values in Reverse Direction

Calculate the cumulative maxima in the third dimension of a 2-by-2-by-3 array. Specify `direction` as `'reverse'` to work from the end of the third dimension to the beginning.

```
A = cat(3,[1 2; 3 4],[9 10; 11 12],[5 6; 7 8])
```

```
A(:,:,1) =

     1     2
     3     4

A(:,:,2) =

     9    10
    11    12

A(:,:,3) =

     5     6
     7     8
```

```
M = cummax(A,3,'reverse')
```

```
M(:,:,1) =

     9    10
    11    12

M(:,:,2) =

     9    10
    11    12

M(:,:,3) =

     5     6
```

```
     7     8
```

Input Arguments

A — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. For complex elements, `cummax` compares the magnitude of the elements. If magnitudes are equal, `cummax` also compares the phase angles.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`
Complex Number Support: Yes

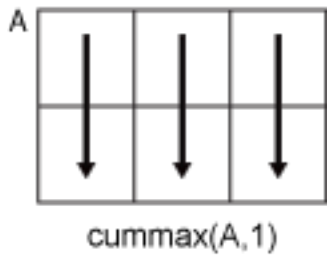
dim — Dimension to operate along

positive integer scalar

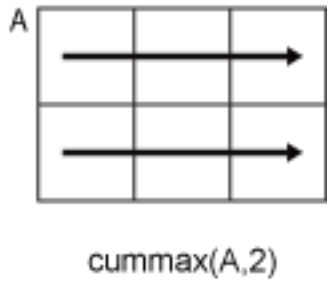
Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`:

- `cummax(A,1)` works on successive elements in the columns of `A` and returns an array of the same size as `A` with the cumulative maxima in each column.



- `cummax(A,2)` works on successive elements in the rows of `A` and returns an array of the same size as `A` with the cumulative maxima in each row.



`cummax` returns `A` if `dim` is greater than `ndims(A)`.

`direction` — Direction of cumulation
`'forward'` (default) | `'reverse'`

Direction of cumulation, specified as the string `'forward'` (default) or `'reverse'`.

- `'forward'` works from `1` to `end` of the active dimension.
- `'reverse'` works from `end` to `1` of the active dimension.

Data Types: `char`

Output Arguments

`M` — Cumulative maxima
vector | matrix | multidimensional array

Cumulative maxima, returned as a vector, matrix, or multidimensional array. The size and data type of `M` are the same as those of `A`.

More About

Tips

- The `cummax` function does not return `NaN` values unless the first element in the active dimension is a `NaN`. In that case, the corresponding first element in the output is a `NaN`. If the input has further consecutive `NaN` values, so that `cummax` must compare `NaN`s to determine the cumulative maximum, the output also has consecutive `NaN`s.

- The `'reverse'` option in many cumulative functions allows quick directional calculations without requiring a flip or reflection of the input array.

See Also

`cummin` | `cumprod` | `cumsum` | `max` | `min`

Introduced in R2014b

cummin

Cumulative minimum

Syntax

```
M = cummin(A)
M = cummin(A,dim)
M = cummin( ___ ,direction)
```

Description

`M = cummin(A)` returns the cumulative minimum elements of `A`. By default, `cummin(A)` operates along the first array dimension whose size does not equal 1.

- If `A` is a vector, then `cummin(A)` returns a vector of the same size containing the cumulative minima of `A`.
- If `A` is a matrix, then `cummin(A)` returns a matrix of the same size containing the cumulative minima in each column of `A`.
- If `A` is a multidimensional array, then `cummin(A)` returns an array of the same size containing the cumulative minima along the first array dimension of `A` whose size does not equal 1.

`M = cummin(A,dim)` returns the cumulative minima along the dimension `dim`. For example, if `A` is a matrix, then `cummin(A,2)` returns the cumulative minima along the rows of `A`.

`M = cummin( ___ ,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A` and, optionally, can specify `dim`. For instance, `cummin(A,2,'reverse')` returns the cumulative minima of `A` by working from end to beginning of the second dimension of `A`.

Examples

Cumulative Minimum Values in Vector

Find the cumulative minima of a 1-by-10 vector of random integers.

```
v = randi([0,10],1,10)
```

```
v =

     8     9     1    10     6     1     3     6    10    10
```

```
M = cummin(v)
```

```
M =

     8     8     1     1     1     1     1     1     1     1
```

Cumulative Minimum Values in Matrix Columns

Find the cumulative minima of the columns of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =

     3     5     2
     1     6     3
     7     8     1
```

```
M = cummin(A)
```

```
M =

     3     5     2
     1     5     2
     1     5     1
```

Cumulative Minimum Values in Matrix Rows

Find the cumulative minima of the rows of a 3-by-3 matrix.

```
A = [3 5 2; 1 6 3; 7 8 1]
```

```
A =

     3     5     2
     1     6     3
     7     8     1
```

```
M = cummin(A,2)
```

```
M =
```

```
     3     3     2
     1     1     1
     7     7     1
```

Cumulative Minimum Array Values in Reverse Direction

Calculate the cumulative minima in the third dimension of a 2-by-2-by-3 array. Specify `direction` as `'reverse'` to work from the end of the third dimension to the beginning.

```
A = cat(3,[1 2; 3 4],[9 10; 11 12],[5 6; 7 8])
```

```
A(:,:,1) =

     1     2
     3     4

A(:,:,2) =

     9    10
    11    12

A(:,:,3) =

     5     6
     7     8
```

```
M = cummin(A,3,'reverse')
```

```
M(:,:,1) =

     1     2
     3     4

M(:,:,2) =

     5     6
     7     8

M(:,:,3) =

     5     6
```

```
     7     8
```

Input Arguments

`A` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. For complex elements, `cummin` compares the magnitude of the elements. If magnitudes are equal, `cummin` also compares the phase angles.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`
Complex Number Support: Yes

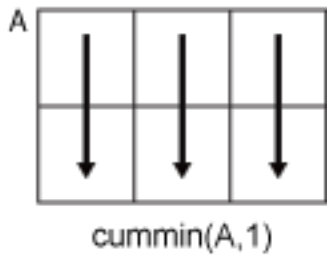
`dim` — Dimension to operate along

positive integer scalar

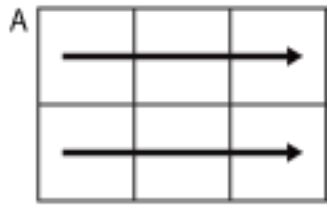
Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`:

- `cummin(A,1)` works on successive elements in the columns of `A` and returns an array of the same size as `A` with the cumulative minima in each column.



- `cummin(A,2)` works on successive elements in the rows of `A` and returns an array of the same size as `A` with the cumulative minima in each row.



`cummin` returns `A` if `dim` is greater than `ndims(A)`.

`direction` — Direction of cumulation
`'forward'` (default) | `'reverse'`

Direction of cumulation, specified as the string `'forward'` (default) or `'reverse'`.

- `'forward'` works from `1` to `end` of the active dimension.
- `'reverse'` works from `end` to `1` of the active dimension.

Data Types: `char`

Output Arguments

`M` — Cumulative minima
vector | matrix | multidimensional array

Cumulative minima, returned as a vector, matrix, or multidimensional array. The size and data type of `M` are the same as those of `A`.

More About

Tips

- The `cummin` function does not return `NaN` values unless the first element in the active dimension is a `NaN`. In that case, the corresponding first element in the output is a `NaN`. If the input has further consecutive `NaN` values, so that `cummin` must compare `NaN`s to determine the cumulative minimum, the output also has consecutive `NaN`s.

- The `'reverse'` option in many cumulative functions allows quick directional calculations without requiring a flip or reflection of the input array.

Introduced in R2014b

cumprod

Cumulative product

Syntax

```
B = cumprod(A)
B = cumprod(A,dim)
B = cumprod( ___ ,direction)
```

Description

`B = cumprod(A)` returns the cumulative product of `A` starting at the beginning of the first array dimension in `A` whose size does not equal 1.

- If `A` is a vector, then `cumprod(A)` returns a vector containing the cumulative product of the elements of `A`.
- If `A` is a matrix, then `cumprod(A)` returns a matrix containing the cumulative products for each column of `A`.
- If `A` is a multidimensional array, then `cumprod(A)` acts along the first nonsingleton dimension.

`B = cumprod(A,dim)` returns the cumulative product along dimension `dim`. For example, if `A` is a matrix, then `cumprod(A,2)` returns the cumulative product of each row.

`B = cumprod( ___ ,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A`, and optionally can specify `dim`. For instance, `cumprod(A,2,'reverse')` returns the cumulative product within the rows of `A` by working from end to beginning of the second dimension.

Examples

Cumulative Product of Vector

Find the cumulative product of the integers from `1` to `5`.

```
A = 1:5;
B = cumprod(A)

B =

     1     2     6    24   120
```

`B(2)` is the product of `A(1)` and `A(2)`, while `B(5)` is the product of elements `A(1)` through `A(5)`.

Cumulative Product of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]

A =

     1     4     7
     2     5     8
     3     6     9
```

Find the cumulative product of the columns of `A`.

```
B = cumprod(A)

B =

     1     4     7
     2    20    56
     6   120   504
```

`B(5)` is the product of `A(4)` and `A(5)`, while `B(9)` is the product of `A(7)` , `A(8)`, and `A(9)`.

Cumulative Product of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]

A =

     1     3     5
     2     4     6
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)
```

```
B =

     1     3    15
     2     8    48
```

B(3) is the product of A(1) and A(3), while B(5) is the product of A(1), A(3), and A(5) .

Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]
```

```
A =

     1     0     1
     1     1     0
```

Find the cumulative product of the rows of A.

```
B = cumprod(A,2)
```

```
B =

     1     0     0
     1     1     0
```

The output is double.

```
class(B)
```

```
ans =

double
```

Reverse Cumulative Product

Create a 3-by-3 matrix of random integers between 1 and 10.

```
rng default;
A = randi([1,10],3)
```

```
A =

     9    10     3
    10     7     6
     2     1    10
```

Calculate the cumulative product along the columns. Specify the `'reverse'` option to work from bottom to top in each column.

```
B = cumprod(A,'reverse')

B =

   180    70   180
    20     7    60
     2     1    10
```

The result is the same size as `A`.

Input Arguments

`A` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`
Complex Number Support: Yes

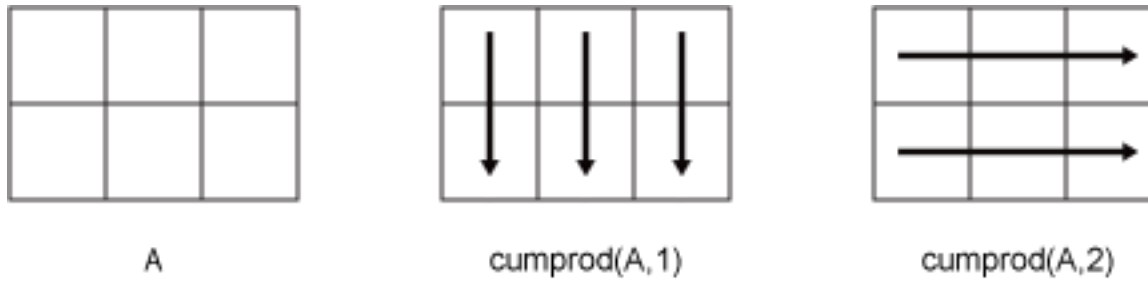
`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`.

- `cumprod(A,1)` works on successive elements in the columns of `A` and returns the cumulative products of each column.
- `cumprod(A,2)` works on successive elements in the rows of `A` and returns the cumulative products of each row.



`cumprod` returns `A` if `dim` is greater than `ndims(A)`.

`direction` — Direction of cumulation
`'forward'` (default) | `'reverse'`

Direction of cumulation, specified as the string `'forward'` (default) or `'reverse'`.

- `'forward'` works from `1` to `end` of the active dimension.
- `'reverse'` works from `end` to `1` of the active dimension.

Data Types: `char`

Output Arguments

`B` — Cumulative product array
vector | matrix | multidimensional array

Cumulative product array, returned as a vector, matrix, or multidimensional array of the same size as the input array `A`.

The class of `B` is the same as the class of `A` except if `A` is `logical`, in which case `B` is `double`.

More About

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to `1`.

For example:

- If `X` is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of `X`.

Tips

- Many cumulative functions in MATLAB support the `'reverse'` option. This option allows quick directional calculations without needing a flip or reflection of the input array.

See Also

`cummax` | `cummin` | `cumsum` | `prod` | `sum`

Introduced before R2006a

cumsum

Cumulative sum

Syntax

```
B = cumsum(A)
B = cumsum(A,dim)
B = cumsum( ___ ,direction)
```

Description

`B = cumsum(A)` returns the cumulative sum of `A` starting at the beginning of the first array dimension in `A` whose size does not equal 1.

- If `A` is a vector, then `cumsum(A)` returns a vector containing the cumulative sum of the elements of `A`.
- If `A` is a matrix, then `cumsum(A)` returns a matrix containing the cumulative sums for each column of `A`.
- If `A` is a multidimensional array, then `cumsum(A)` acts along the first nonsingleton dimension.

`B = cumsum(A,dim)` returns the cumulative sum of the elements along dimension `dim`. For example, if `A` is a matrix, then `cumsum(A,2)` returns the cumulative sum of each row.

`B = cumsum( ___ ,direction)` optionally specifies the direction using any of the previous syntaxes. You must specify `A`, and optionally can specify `dim`. For instance, `cumsum(A,2,'reverse')` returns the cumulative sum within the rows of `A` by working from end to beginning of the second dimension.

Examples

Cumulative Sum of Vector

Find the cumulative sum of the integers from `1` to `5`.

```
A = 1:5;
B = cumsum(A)

B =

     1     3     6    10    15
```

`B(2)` is the sum of `A(1)` and `A(2)`, while `B(5)` is the sum of elements `A(1)` through `A(5)`.

Cumulative Sum of Each Column in Matrix

Define a 3-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 4 7; 2 5 8; 3 6 9]

A =

     1     4     7
     2     5     8
     3     6     9
```

Find the cumulative sum of the columns of `A`.

```
B = cumsum(A)

B =

     1     4     7
     3     9    15
     6    15    24
```

`B(5)` is the sum of `A(4)` and `A(5)`, while `B(9)` is the sum of `A(7)` , `A(8)`, and `A(9)`.

Cumulative Sum of Each Row in Matrix

Define a 2-by-3 matrix whose elements correspond to their linear indices.

```
A = [1 3 5; 2 4 6]

A =

     1     3     5
     2     4     6
```

Find the cumulative sum of the rows of `A`.

```
B = cumsum(A,2)

B =

     1     4     9
     2     6    12
```

`B(3)` is the sum of `A(1)` and `A(3)`, while `B(5)` is the sum of `A(1)`, `A(3)`, and `A(5)` .

Logical Input with Double Output

Create an array of logical values.

```
A = [true false true; true true false]

A =

     1     0     1
     1     1     0
```

Find the cumulative sum of the rows of `A`.

```
B = cumsum(A,2)

B =

     1     1     2
     1     2     2
```

The output is `double`.

```
class(B)

ans =

double
```

Reverse Cumulative Sum

Create a 3-by-3 matrix of random integers between 1 and 10.

```
rng default;
A = randi([1,10],3)

A =
```

```
     9    10     3
    10     7     6
     2     1    10
```

Calculate the cumulative sum along the rows. Specify the `'reverse'` option to work from right to left in each row.

```
B = cumsum(A,2,'reverse')
```

```
B =

    22    13     3
    23    13     6
    13    11    10
```

The result is the same size as `A`.

Input Arguments

`A` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`
Complex Number Support: Yes

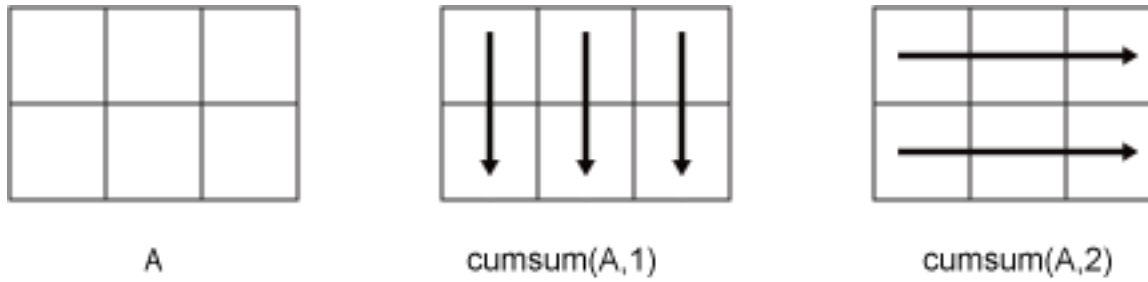
`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, `A`:

- `cumsum(A,1)` works on successive elements in the columns of `A` and returns the cumulative sums of each column.
- `cumsum(A,2)` works on successive elements in the rows of `A` and returns the cumulative sums of each row.



`cumsum` returns `A` if `dim` is greater than `ndims(A)`.

`direction` — Direction of cumulation
`'forward'` (default) | `'reverse'`

Direction of cumulation, specified as the string `'forward'` (default) or `'reverse'`.

- `'forward'` works from `1` to `end` of the active dimension.
- `'reverse'` works from `end` to `1` of the active dimension.

Data Types: `char`

Output Arguments

`B` — Cumulative sum array
vector | matrix | multidimensional array

Cumulative sum array, returned as a vector, matrix, or multidimensional array of the same size as the input array `A`.

The class of `B` is the same as the class of `A` except if `A` is `logical`, in which case `B` is `double`.

More About

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to `1`.

For example:

- If `X` is a 1-by-n row vector, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-0-by-n empty array, then the second dimension is the first nonsingleton dimension of `X`.
- If `X` is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of `X`.

Tips

- Many cumulative functions in MATLAB support the `'reverse'` option. This option allows quick directional calculations without needing a flip or reflection of the input array.

Introduced before R2006a

cumtrapz

Cumulative trapezoidal numerical integration

Syntax

```
Z = cumtrapz(Y)
Z = cumtrapz(X,Y)
Z = cumtrapz( ___ ,dim)
```

Description

`Z = cumtrapz(Y)` computes an approximation of the cumulative integral of `Y` via the trapezoidal method with unit spacing. To compute the integral with other than unit spacing, multiply `Z` by the spacing increment. Input `Y` can be complex.

For vectors, `cumtrapz(Y)` is a vector containing the cumulative integral of `Y`.

For matrices, `cumtrapz(Y)` is a matrix the same size as `Y` with the cumulative integral over each column.

For multidimensional arrays, `cumtrapz(Y)` works across the first nonsingleton dimension.

`Z = cumtrapz(X,Y)` computes the cumulative integral of `Y` with respect to `X` using trapezoidal integration. `X` and `Y` must be vectors of the same length, or `X` must be a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`. `cumtrapz` operates across this dimension. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `cumtrapz(X,Y)` operates across this dimension.

`Z = cumtrapz( ___ ,dim)` integrates across the dimension of `Y` specified by scalar `dim`, using any of the input arguments in the previous syntaxes. The length of `X` must be the same as `size(Y,dim)`.

Examples

Example 1

```
Y = [0 1 2; 3 4 5];

cumtrapz(Y,1)
ans =
0         0         0
    1.5000   2.5000    3.5000

cumtrapz(Y,2)
ans =
0    0.5000    2.0000
        0    3.5000    8.0000
```

Example 2

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);

ct = cumtrapz(z,1./z);
ct(end)
ans =
   0.0000 + 3.1411i
```

See Also

`cumsum` | `trapz`

Introduced before R2006a

curl

Compute curl and angular velocity of vector field

Syntax

```
[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)
[curlx,curly,curlz,cav] = curl(U,V,W)
[curlz,cav]= curl(X,Y,U,V)
[curlz,cav]= curl(U,V)
[curlx,curly,curlz] = curl(...)
[curlx,curly] = curl(...)
cav = curl(...)
```

Description

`[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)` computes the curl (`curlx`, `curly`, `curlz`) and angular velocity (`cav`) perpendicular to the flow (in radians per time unit) of a 3-D vector field `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`[curlx,curly,curlz,cav] = curl(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`[curlz,cav]= curl(X,Y,U,V)` computes the curl `z`-component and the angular velocity perpendicular to `z` (in radians per time unit) of a 2-D vector field `U`, and `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`[curlz,cav]= curl(U,V)` assumes `X` and `Y` are determined by the expression

`[X Y] = meshgrid(1:n,1:m)`

where `[m,n] = size(U)`.

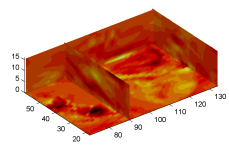
`[curlx,curly,curlz] = curl(...)`, `[curlx,curly] = curl(...)` returns only the curl.

`cav = curl(...)` returns only the curl angular velocity.

Examples

This example uses colored slice planes to display the curl angular velocity at specified locations in the vector field.

```
figure
load wind
cav = curl(x,y,z,u,v,w);
h = slice(x,y,z,cav,[90 134],59,0);
shading interp
daspect([1 1 1]);
axis tight
colormap hot(16)
camlight
set([h(1),h(2)],'ambientstrength',.6)
```



This example views the curl angular velocity in one plane of the volume and plots the velocity vectors (`quiver`) in the same plane.

```
load wind
k = 4;
x = x(:,:,k); y = y(:,:,k); u = u(:,:,k); v = v(:,:,k);
cav = curl(x,y,u,v);
pcolor(x,y,cav); shading interp
hold on;
quiver(x,y,u,v,'y')
```

```
hold off
colormap copper
```

`streamribbon` | `divergence`

Introduced before R2006a

currentDirectory

Class: Tiff

Index of current IFD

Syntax

```
dirNum = currentDirectory(tiffobj)
```

Description

`dirNum = currentDirectory(tiffobj)` returns the index of the current image file directory (IFD). Index values are one-based. Use this index value with the `setDirectory` member function.

Examples

Determine Current IFD

Open a `Tiff` object and determine which IFD is the current IFD.

```
t = Tiff('example.tif','r');
dnum = currentDirectory(t)
```

```
dnum =

     1
```

Close the `Tiff` object.

```
close(t)
```

`Tiff.setDirectory`

customverctrl

(To be removed) Allow custom source control system (UNIX platforms)

Note: `customverctrl` will be removed in a future release.

Syntax

```
customverctrl
```

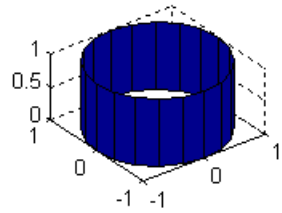
Description

`customverctrl` function is for customers who want to integrate a source control system that is not supported for use with MATLAB software. When using this function, conform to the structure of one of the supported version control systems, for example, RCS. For examples, see the files `clearcase.m`, `cvs.m`, `pvcs.m`, and `rcs.m` in *`matlabroot`*`\toolbox\matlab\verctrl`.

Introduced before R2006a

cylinder

Generate cylinder



Syntax

```
[X,Y,Z] = cylinder
[X,Y,Z] = cylinder(r)
[X,Y,Z] = cylinder(r,n)
cylinder(axes_handle,...)
cylinder(...)
```

Description

`cylinder` generates *x*-, *y*-, and *z*-coordinates of a unit cylinder. You can draw the cylindrical object using `surf` or `mesh`, or draw it immediately by not providing output arguments.

`[X,Y,Z] = cylinder` returns the *x*-, *y*-, and *z*-coordinates of a cylinder with a radius equal to `1`. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r)` returns the *x*-, *y*-, and *z*-coordinates of a cylinder using `r` to define a profile curve. `cylinder` treats each element in `r` as a radius at equally spaced heights along the unit height of the cylinder. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r,n)` returns the *x*-, *y*-, and *z*-coordinates of a cylinder based on the profile curve defined by vector `r`. The cylinder has `n` equally spaced points around its circumference.

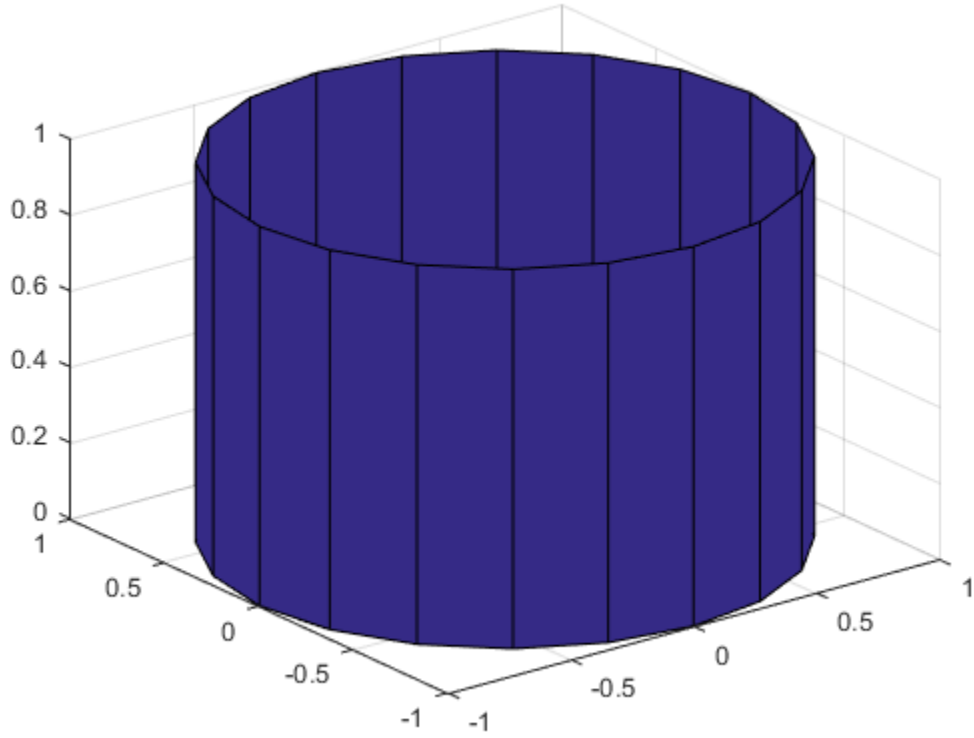
`cylinder(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`cylinder(...)`, with no output arguments, plots the cylinder using `surf`.

Examples

Display Unit Cylinder

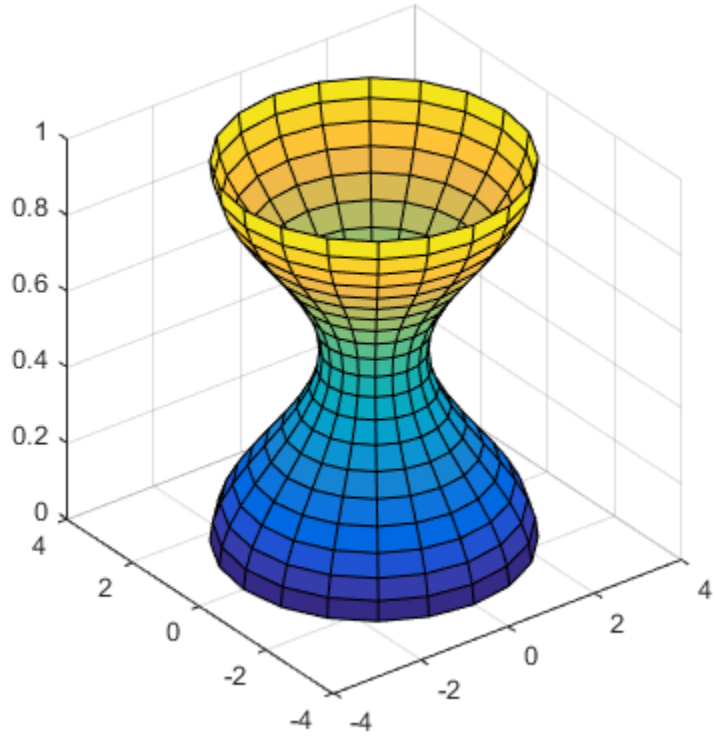
```
figure
cylinder
```



Generate Coordinates of Cylinder and Display Surface

Generate a cylinder defined by the profile function `2+sin(t)`.

```
t = 0:pi/10:2*pi;
figure
[X,Y,Z] = cylinder(2+cos(t));
surf(X,Y,Z)
axis square
```



More About

Tips

`cylinder` treats its first argument as a profile curve. The resulting surface graphics object is generated by rotating the curve about the *x*-axis, and then aligning it with the *z*-axis.

See Also

`sphere` | `surf`

Introduced before R2006a

daqread

Read Data Acquisition Toolbox (.daq) file

Syntax

```
data = daqread('filename')
[data,time] = daqread(...)
[data,time,abstime] = daqread(...)
[data,time,abstime,events] = daqread(...)
[data,time,abstime,events,daqinfo] = daqread(...)
data = daqread(...,'Param1', Val1,...)
daqinfo = daqread('filename','info')
```

Description

`data = daqread('filename')` reads all the data from the Data Acquisition Toolbox™ (`.daq`) file specified by `filename`. `daqread` returns `data`, an *m*-by-*n* data matrix, where *m* is the number of samples and *n* is the number of channels. If `data` includes data from multiple triggers, the data from each trigger is separated by a `NaN`. If you set the `OutputFormat` property to `tscollection`, `daqread` returns a time series collection object. See below for more information.

`[data,time] = daqread(...)` returns time/value pairs. `time` is an *m*-by-1 vector, the same length as `data`, that contains the relative time for each sample. Relative time is measured with respect to the first trigger that occurs.

`[data,time,abstime] = daqread(...)` returns the absolute time of the first trigger. `abstime` is returned as a `clock` vector.

`[data,time,abstime,events] = daqread(...)` returns a log of events. `events` is a structure containing event information. If you specify either the`Samples`, `Time`, or `Triggers` parameters (see below), the events structure contains only the specified events.

`[data,time,abstime,events,daqinfo] = daqread(...)` returns a structure, `daqinfo`, that contains two fields: `ObjInfo` and `HwInfo`. `ObjInfo` is a structure containing property name/property value pairs and `HwInfo` is a

structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

`data = daqread(...,'Param1', Val1,...)` specifies the amount of data returned and the format of the data, using the following parameters.

Parameter	Description
`Samples`	Specify the sample range.
`Time`	Specify the relative time range.
`Triggers`	Specify the trigger range.
`Channels`	Specify the channel range. Channel names can be specified as a cell array.
`DataFormat`	Specify the data format as `doubles` (default) or `native`.
`TimeFormat`	Specify the time format as `vector` (default) or `matrix`.
`OutputFormat`	Specify the output format as `matrix` (the default) or `tscollection`. When you specify `tscollection`, `daqread` only returns `data`.

The `Samples`, `Time`, and `Triggers` properties are mutually exclusive; that is, either `Samples`, `Triggers` or `Time` can be defined at once.

`daqinfo = daqread('filename','info')` returns metadata from the file in the `daqinfo` structure, without incurring the overhead of reading the data from the file as well. The `daqinfo` structure contains two fields:

`daqinfo.ObjInfo`

a structure containing parameter/value pairs for the data acquisition object used to create the file, `filename`. Note: The `UserData` property value is not restored.

`daqinfo.HwInfo`

a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

Examples

Use Data Acquisition Toolbox to acquire data. The analog input object, `ai`, acquires one second of data for four channels, and saves the data to the output file `data.daq`.

```
ai = analoginput('nidaq','Dev1');
chans = addchannel(ai,0:3);
set(ai,'SampleRate',1000)
ActualRate = get(ai,'SampleRate');
set(ai,'SamplesPerTrigger, ActualRate)
set(ai,'LoggingMode','Disk&Memory')
set(ai,'LogFileName','data.daq')
start(ai)
```

After the data has been collected and saved to a disk file, you can retrieve the data and other acquisition-related information using `daqread`. To read all the sample-time pairs from `data.daq`:

```
[data,time] = daqread('data.daq');
```

To read samples 500 to 1000 for all channels from `data.daq`:

```
data = daqread('data.daq','Samples',[500 1000]);
```

To read only samples 1000 to 2000 of channel indices 2, 4 and 7 in native format from the file, `data.daq`:

```
data = daqread('data.daq', 'Samples', [1000 2000],...
               'Channels', [2 4 7], 'DataFormat', 'native');
```

To read only the data which represents the first and second triggers on all channels from the file, `data.daq`:

```
[data,time] = daqread('data.daq', 'Triggers', [1 2]);
```

To obtain the channel property information from `data.daq`:

```
daqinfo = daqread('data.daq','info');
chaninfo = daqinfo.ObjInfo.Channel;
```

To obtain a list of event types and event data contained by `data.daq`:

```
daqinfo = daqread('data.daq','info');
events = daqinfo.ObjInfo.EventLog;
event_type = {events.Type};
event_data = {events.Data};
```

To read all the data from the file `data.daq` and return it as a time series collection object:

```
data = daqread('data.daq','OutputFormat','tscollection');
```

More About

Tips

More About .daq Files

- The format used by `daqread` to return data, relative time, absolute time, and event information is identical to the format used by the `getdata` function that is part of Data Acquisition Toolbox. For more information, see the Data Acquisition Toolbox documentation.
- If data from multiple triggers is read, then the size of the resulting data array is increased by the number of triggers issued because each trigger is separated by a `NaN`.
- `ObjInfo.EventLog` always contains the entire event log regardless of the value specified by `Samples`, `Time`, or `Triggers`.
- The `UserData` property value is not restored when you return device object (`ObjInfo`) information.
- When reading a `.daq` file, the `daqread` function does not return property values that were specified as a cell array.
- Data Acquisition Toolbox (`.daq`) files are created by specifying a value for the `LogFileName` property (or accepting the default value), and configuring the `LoggingMode` property to `Disk` or `Disk&Memory`.

More About Time Series Collection Object Returned

When `OutputFormat` is set to `tscollection`, `daqread` returns a time series collection object. This times series collection object contains an absolute time series object for each channel in the file. The following describes how `daqread` sets some of the properties of the times series collection object and the time series objects.

- The `time` property of the time series collection object is set to the value of the `InitialTriggerTime` property specified in the file.
- The `name` property of each time series object is set to the value of the `Name` property of a channel in the file. If this name cannot be used as a time series object name, `daqread` sets the name to `'Channel'` with the `HwChannel` property of the channel appended.
- The value of the `Units` property of the time series object depends on the value of the `DataFormat` parameter. If the `DataFormat` parameter is set to `'double'`, `daqread`

sets the `DataInfo` property of each time series object in the collection to the value of the `Units` property of the corresponding channel in the file. If the `DataFormat` parameter is set to `'native'`, `daqread` sets the `Units` property to `'native'`. See the Data Acquisition Toolbox documentation for more information on these properties.

- Each time series object will have `tsdata.event` objects attached corresponding to the log of events associated with the channel.

If `daqread` returns data from multiple triggers, the data from each trigger is separated by a `NaN` in the time series data. This increases the length of data and time vectors in the time series object by the number of triggers.

`timeseries` | `tscollection`

daspect

Set or query axes data aspect ratio

Syntax

```
daspect
daspect([aspect_ratio])
daspect('mode')
daspect('auto')
daspect('manual')
daspect(axes_handle,...)
```

Description

The data aspect ratio determines the relative scaling of the data units along the *x*-, *y*-, and *z*-axes.

`daspect` with no arguments returns the data aspect ratio of the current axes.

`daspect([aspect_ratio])` sets the data aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the *x*-, *y*-, and *z*-axis scaling (e.g., `[1 1 3]` means one unit in *x* is equal in length to one unit in *y* and three units in *z*).

`daspect('mode')` returns the current value of the data aspect ratio mode, which can be either `auto` (the default) or `manual`. See Tips.

`daspect('auto')` sets the data aspect ratio mode to `auto`.

`daspect('manual')` sets the data aspect ratio mode to `manual`.

`daspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `daspect` operates on the current axes.

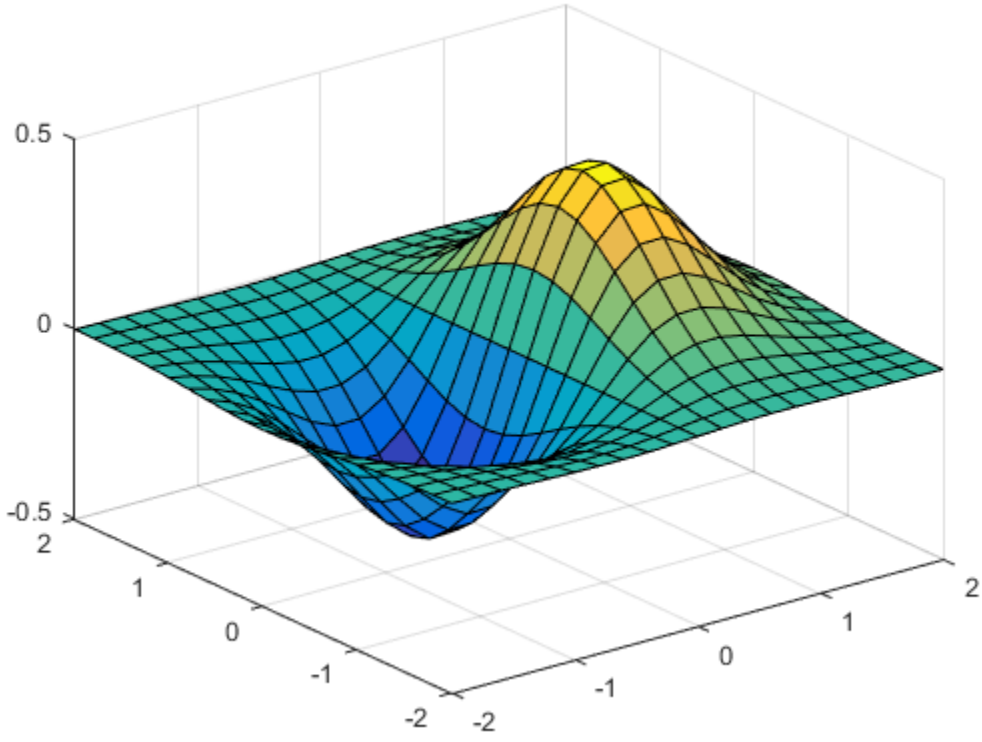
Examples

Equal Scaling Along Each Axis

Plot the function $z = xe^{(-x^2-y^2)}$ over the range $-2 \le x \le 2$ and $-2 \le y \le 2$.

```
[x,y] = meshgrid(-2:.2:2);
z = x.*exp(-x.^2 - y.^2);

figure
surf(x,y,z)
```



Query the data aspect ratio to show the axis scaling.

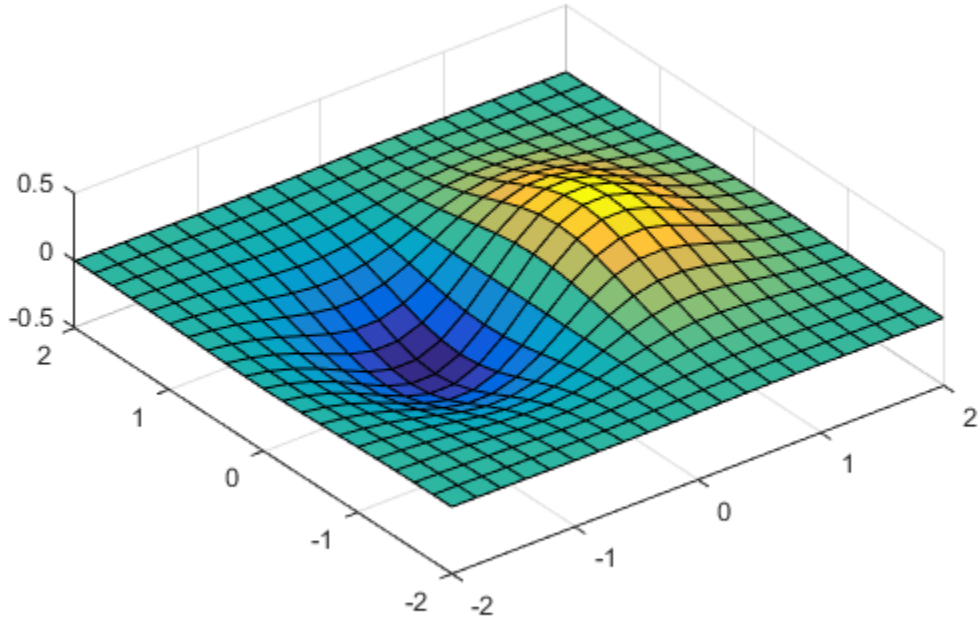
```
daspect

ans =

     4     4     1
```

Use equal scaling along each axis by setting the data aspect ratio to `[1,1,1]`.

```
daspect([1,1,1])
```



More About

Tips

`daspect` sets or queries values of the axes object `DataAspectRatio` and `DataAspectRatioMode` properties.

When the data aspect ratio mode is `auto`, the data aspect ratio adjusts so that each axis spans the space available in the figure window. If you are displaying a representation of a real-life object, you should set the data aspect ratio to `[1 1 1]` to produce the correct proportions.

Setting a value for data aspect ratio or setting the data aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the data aspect ratio to a value, including its current value,

```
daspect(daspect)
```

can cause a change in the way the graphs look. See the Stretch-to-Fill section of the `axes` description for more information.

datacursormode

Enable, disable, and manage interactive data cursor mode

Syntax

```
datacursormode on
datacursormode off
datacursormode
datacursormode toggle
datacursormode(figure_handle)
dcm_obj = datacursormode(figure_handle)
```

Description

`datacursormode on` enables data cursor mode on the current figure.

`datacursormode off` disables data cursor mode on the current figure.

`datacursormode` or `datacursormode toggle` toggles data cursor mode in the current figure.

`datacursormode(figure_handle)` enables or disables data cursor mode on the specified figure.

`dcm_obj = datacursormode(figure_handle)` returns the data cursor mode object for the figure. The object enables you to customize the data cursor. For more information on data cursor mode objects, see “Output Arguments” on page 1-1848. You cannot change the state of data cursor mode in a call to `datacursormode` that returns a mode object.

A *data cursor* is a small black square with a white border that you interactively position on a graph in data cursor mode. When you click a graphic object such as a line on a graph, a *data tip* appears. Data tips are small text boxes or windows that float within an axes that display data values at data cursor locations. The default style is a text box. Data tips list *x*-, *y*- and (where appropriate) *z*-values for one data point at a time. See “Examples” on page 1-1851 for an illustration of these two styles.

Input Arguments

`figure_handle`

Optional handle of figure window

Default: The current figure

`state`

`''`, `'toggle'`, `'on'`, or `'off'`

Default: `'toggle'`

Output Arguments

`dcm_obj`

Use the object returned by `datacursormode` to control aspects of data cursor behavior. You can use the `set` and `get` commands to set and query object property values. You can customize how data cursor mode presents information by coding callback functions for these objects.

Parameter Name/Value Pairs for Data Cursor Mode Objects

The following parameters apply to objects returned by calls to `datacursormode`, not to the function itself.

`'DisplayStyle'`

`datatip | window`

Determines how the data cursor displays.

- `datatip` displays data cursor information in a small yellow text box attached to a black square marker at a data point you interactively select.
- `window` displays data cursor information for the data point you interactively select in a floating window within the figure.

Default: `datatip`

`'Enable'`

`on | off`

Specifies whether data cursor mode is currently enabled for the figure.

Default: `off`

`'Figure'`

handle

Handle of the figure associated with the data cursor mode object.

`'SnapToDataVertex'`

`on | off`

Specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position.

Default: `on`

`'UpdateFcn'`

function handle

Reference to a function that formats the text appearing in the data cursor. You can supply your own function to customize data tip display. Your function must include at least two arguments. The first argument is unused, and can be a variable name or tilde (~). The second argument passes the data cursor event object to your update function. The event object encapsulates the state of the data cursor. The following function definition illustrates the update function:

```
function output_txt = myfunction(~,event_obj)
% ~            Currently not used (empty)
% event_obj    Object containing event data structure
% output_txt   Data cursor text (string or cell array
%              of strings)
```

`event_obj` is an object that has the following properties.

`Target`	Handle of the object the data cursor is referencing (the object which you click, for example, a line or a bar from a series)
`Position`	An array specifying the *x*, *y* (and *z* for 3-D graphs) coordinates of the cursor

You can query these properties within your function. For example,

```
pos = get(event_obj,'Position');
```

returns the coordinates of the cursor. Another way of accessing that data is to obtain the struct and query its `Position` field:

```
eventdata = get(event_obj);
pos = eventdata.Position;
```

You can also obtain the position directly from the object:

```
pos = event_obj.Position;
```

You can redefine the data cursor `Updatefcn` at run time. For example:

```
set(dcm_obj,'UpdateFcn',@myupdatefcn)
```

applies the function `myupdatefcn` to the current data tip or tips. When you set an update function in this way, the function must be on the MATLAB path. If instead you select the data cursor mode context menu item **Select text update function**, you can interactively select a function that is not on the path.

Do not redefine figure window callbacks, such as `ButtonDownFcn`, `KeyPpressFcn`, or `CloseRequestFcn` *while in data cursor mode*. If you attempt to change any *figure* callbacks when you are in an interactive mode, you receive a warning and the attempt fails. MATLAB interactive modes are:

- `brush`
- `datacursormode`
- `pan`
- `rotate3d`
- `zoom`

This restriction does not apply to changing the figure `WindowButtonMotionFcn` callback or `uicontrol` callbacks.

Querying Data Cursor Mode

Use the `getCursorInfo` function to query the data cursor mode object (`dcm_obj` in the update function syntax) to obtain information about the data cursor. For example,

```
info_struct = getCursorInfo(dcm_obj);
```

returns a vector of structures, one for each data cursor on the graph. Each structure has the following fields.

`Target`	The handle of the graphics object containing the data point
`Position`	An array specifying the *x*, *y*, (and *z*) coordinates of the cursor

Line and lineseries objects have an additional field.

`DataIndex`	A scalar index into the data arrays that correspond to the nearest data point. The value is the same for each array.

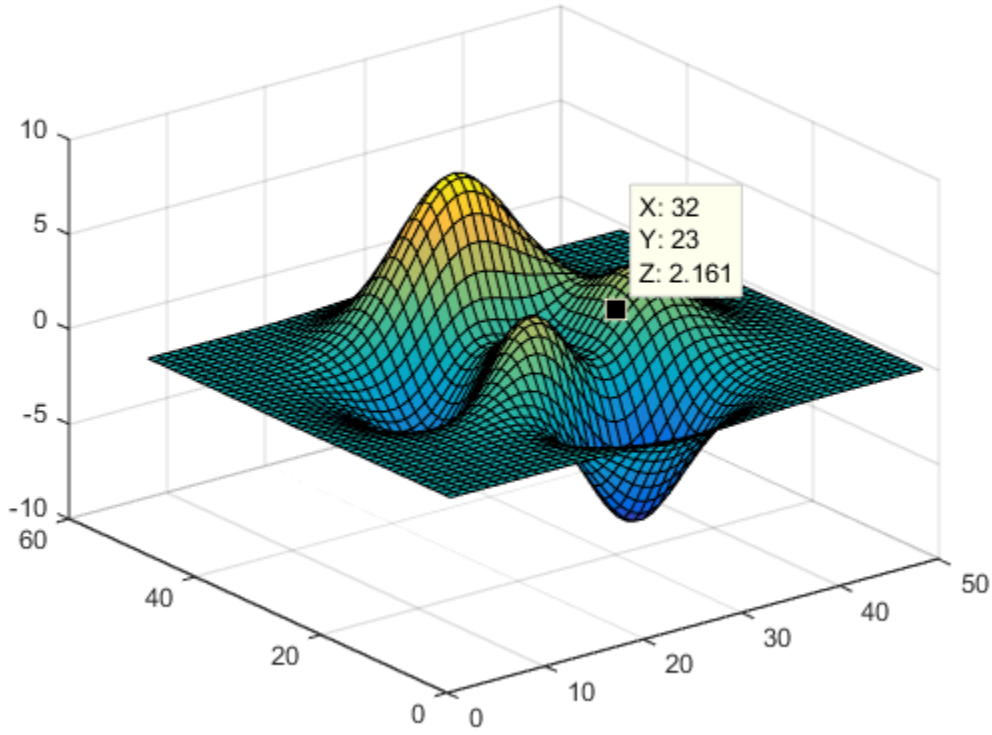
See “Output Arguments” on page 1-1848 for more details on data cursor mode objects.

Examples

This example creates a plot and enables data cursor mode from the command line.

```
surf(peaks)
datacursormode on
% Click mouse on surface to display data cursor
```

Selecting a point on the surface opens a data tip displaying its *x*-, *y*-, and z-coordinates.



You change the data tip display style to be a window instead of a text box using the **Tools > Options > Display cursor in window** , or use the context menu **Display Style > Window inside figure** to view the data tip in a floating window that you can move around inside the axes.

You can position multiple text box data tips on the same graph, the window style of data tip displays only one value at a time. For more information on interacting with data cursors, including point selection options and exporting data tips to the workspace, see “Display Data Values Interactively”.

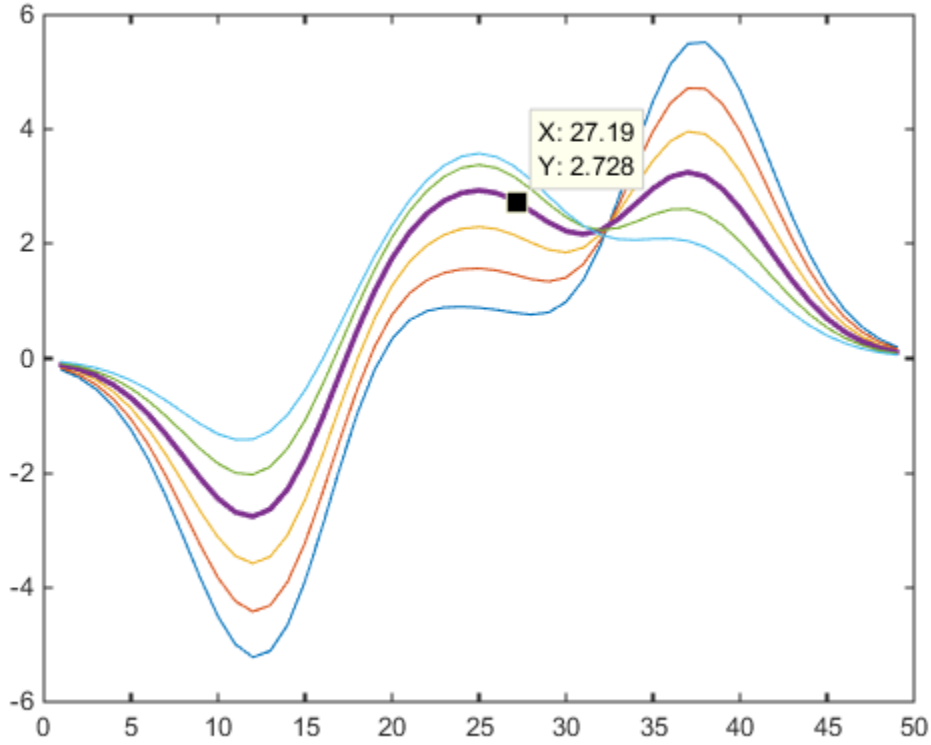
This example enables data cursor mode on the current figure and sets data cursor mode options. The following statements

- Create a graph
- Toggle data cursor mode to on
- Obtain the data cursor mode object, specify data tip options, and get the handle of the line the data tip occupies:

```
fig = figure;
z = peaks;
plot(z(:,30:35))
dcm_obj = datacursormode(fig);
set(dcm_obj,'DisplayStyle','datatip',...
    'SnapToDataVertex','off','Enable','on')

disp('Click line to display a data tip, then press Return.')
% Wait while the user does this.
pause

c_info = getCursorInfo(dcm_obj);
% Make selected line wider
set(c_info.Target,'LineWidth',2)
```



This example shows you how to customize the text that the data cursor displays. For example, you can replace the text displayed in the data tip and data window (`x:` and `y:`) with `Time:` and `Amplitude:` by creating a simple update function.

Save the following functions in your current directory or any writable directory on the MATLAB path before running them. As they are functions, you cannot highlight them and then evaluate the selection to make them work.

Save this code as `doc_datacursormode.m`:

```
function doc_datacursormode
% Plots graph and sets up a custom data tip update function
fig = figure;
```

```
a = -16; t = 0:60;
plot(t,sin(a*t))
dcm_obj = datacursormode(fig);
set(dcm_obj,'UpdateFcn',@myupdatefcn)
```

Save the following code as `myupdatefcn.m` on the MATLAB path:

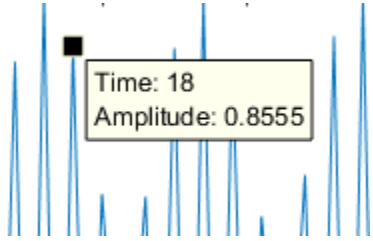
```
function txt = myupdatefcn(empt,event_obj)
% Customizes text of data tips

pos = get(event_obj,'Position');
txt = {['Time: ',num2str(pos(1))],...
       ['Amplitude: ',num2str(pos(2))]};
```

To set up and use the update function, type:

```
doc_datacursormode
```

When you place a data tip using this update function, it looks like the one in the following figure.



Alternatives

Use the Data Cursor tool  to label *x*, *y*, and *z* values on graphs and surfaces. You can control how data tips display by right-clicking and selecting items from the context menu.

More About

Tips

- Most types of graphs and 3-D plots support data cursor mode, but several do not (`pareto`, for example).

- Polar plots support data tips, but display Cartesian rather than polar coordinates on them.
- Histograms created with `histogram` display specialized data tips that itemize the observation counts and bin edges.
- You place data tips only by clicking data objects on graphs. You cannot place them programmatically (by executing code to position a data cursor).
- When `DisplayStyle` is `datatip`, you can place multiple data tips on a graph. When `DisplayStyle` is `window`, it reports only the most recent data tip.
- `datacursormode off` exits data cursor mode but does not remove displayed data tips. However, if the `DisplayStyle` is `window`, the data tip window goes away.

- "Example — Visually Exploring Demographic Statistics"
- "Data Cursors with Histograms"

`brush` | `pan` | `rotate3d` | `zoom`

Introduced before R2006a

datastore

Create datastore to access collection of data

Syntax

```
ds = datastore(location)
ds = datastore(location,Name,Value)
```

Description

`ds = datastore(location)` creates a datastore from the collection of data specified by `location`. A datastore is a repository for collections of data that are too large to fit in memory. After creating `ds`, you can read the data.

`ds = datastore(location,Name,Value)` specifies the properties of `ds` using one or more name-value pair arguments. For example, you can specify the type of datastore to create as a `TabularTextDatastore` or a `KeyValueDatastore`.

Examples

Create Datastore for Text Data

Create a datastore associated with the sample file, `airlinesmall.csv`. This file contains airline data from the years 1987 through 2008.

Use the `'TreatAsMissing'` name-value pair argument to specify the strings in the file to treat as missing data.

```
ds = datastore('airlinesmall.csv',...
    'TreatAsMissing','NA')
```

```
ds =

  TabularTextDatastore with properties:
```

```
                    Files: {
                           ' .../matlab/toolbox/matlab/demos/airlinesmall.csv'
                           }
            ReadVariableNames: true
                VariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}

  Text Format Properties:
               NumHeaderLines: 0
                    Delimiter: ','
                  RowDelimiter: '\r\n'
               TreatAsMissing: 'NA'
                 MissingValue: NaN

  Advanced Text Format Properties:
             TextscanFormats: {'%f', '%f', '%f' ... and 26 more}
           ExponentCharacters: 'eEdD'
                 CommentStyle: ''
                   Whitespace: ' \b\t'
    MultipleDelimitersAsOne: false

  Properties that control the table returned by preview, read, readall:
      SelectedVariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}
            SelectedFormats: {'%f', '%f', '%f' ... and 26 more}
                   ReadSize: 20000 rows
```

`datastore` creates a `TabularTextDatastore`.

Input Arguments

`location` — Files or folders to include in the datastore

string | cell array of strings

Files or folders to include in the datastore, specified as a string or cell array of strings. If the files are not in the current folder, then `files` must include full or relative paths. Files within subfolders of the specified folder are not automatically included in the datastore. You must indicate the paths to these subfolders in `location`.

If the files are not available locally, then the full path of the files or folders must be an internationalized resource identifier (IRI) of the form `hdfs://`*`hostname`*`:`*`portnumber`*`/`*`path_to_file`*.

Before reading from HDFS™, you must set the `HADOOP_HOME`, `HADOOP_PREFIX`, or `MATLAB_HADOOP_INSTALL` environment variable to the folder where Hadoop® is installed. For more information, see "Read from HDFS".

Note: When reading from HDFS or when reading Sequence files locally, the `datastore` function calls the `javaaddpath` command. This command clears the definitions of all Java classes defined by files on the dynamic class path, removes all global variables and variables from the base workspace, and removes all compiled scripts, functions, and MEX-functions from memory. To prevent persistent variables, code files or MEX-files from being cleared, use the `mlock` function.

For `TabularTextDatastore` and `KeyValueDatastore`, you can use the wildcard character (*) to indicate that all matching files or all files in the matching folders are included in the datastore.

For `KeyValueDatastore`, the files must be MAT-files or Sequence files generated by the `mapreduce` function, and they must be in a local file system or in a network file system.

Example: `'file1.csv'`

Example: `'../dir/data/file1.csv'`

Example: `{'C:\dir\data\file1.csv','C:\dir\data\file2.csv'}`

Example: `'C:\dir\data\*.mat'`

Example: `'hdfs://myserver:7867/data/file1.txt'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Delimiter',','` specifies a comma delimiter for a `TabularTextDatastore` object.

All Datastore Types

`'DatastoreType'` — Type of datastore

`'tabulartext' | 'keyvalue'`

Type of datastore, specified as the comma-separated pair consisting of `'DatastoreType'` and one of the following strings.

Value of dsType	Description
`'tabulartext'`	Interpret the data set specified by `location` as text files containing tabular data. The encoding of the data must be ASCII or UTF-8.
`'keyvalue'`	Interpret the data set specified by `location` as key-value pair data. The files can be MAT-files or sequence files with key-value pair data generated by `mapreduce`.

Other datastore types might be supported if you have other MathWorks products installed. In this case, other values for `'DatastoreType'` are valid.

Use the `'DatastoreType'` argument to specify a datastore type when there are multiple types that support the format of the files.

If you do not specify a value for `DatastoreType`, then `datastore` automatically determines the appropriate type of datastore to create, based on the extension of the files specified by the `location` argument.

`TabularTextDatastore` Only

In addition to the following, you can specify other `TabularTextDatastore` properties using name-value pair arguments. See TabularTextDatastore Properties.

`'VariableNames'` — Names of variables
cell array of strings

Names of variables in the datastore, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of strings. Specify the variable names in the order in which they appear in the files. If you do not specify the variable names, they are detected from the first nonheader line in the first file in the datastore. You can rename the variables after creating the datastore, by modifying its `VariableNames` property.

When `ReadVariableNames` is `false`, then `VariableNames` defaults to `{'Var1','Var2', ...}`.

Example: `'VariableNames',{'Time','Name','Quantity'}`

`'TextscanFormats'` — Format of the data fields

string | cell array of strings

Format of the data fields, specified as the comma-separated pair consisting of `'TextscanFormats'` and a string or a cell array of strings. If the value of `TextscanFormats` is a string, then it can contain one or more conversion specifiers. If the value of `TextscanFormats` is a cell array of strings, then each string must contain only one conversion specifier. You can use the same conversion specifiers that the `textscan` function accepts.

If the value of `TextscanFormats` includes conversion specifiers that skip fields using asterisk characters (*), then the value of the `SelectedVariableNames` property automatically updates. For more information, see the `TextscanFormats` property.

If you do not specify a value for `TextscanFormats`, then `datastore` determines the format of the data fields by scanning text from first nonheader, nonvariable name line in the first file.

Example: `'TextscanFormats','%s%s%f'`

Example: `'TextscanFormats',{'%s','%s','%f'}`

`'SelectedVariableNames'` — Variables to read

cell array of strings

Variables to read, specified as the comma-separated pair consisting of `'SelectedVariableNames'` and a cell array of strings, where each string contains the name of one variable. You can specify the variable names in any order.

Example: `'SelectedVariableNames',{'Var3','Var7','Var4'}`

`'SelectedFormats'` — Formats for selected variables

cell array of strings

Formats for the selected variables, specified as the comma-separated pair consisting of `'SelectedFormats'` and a cell array of strings, where each string contains one conversion specifier. Use the `SelectedVariableNames` property to indicate the variables to read. The number of strings in `SelectedFormats` must match the number of variables to read.

You can use the same conversion specifiers that the `textscan` function accepts. However, you cannot use a conversion specifier that skips a field. For example, the conversion specifier cannot include an asterisk character (*).

Example: `'SelectedFormats',{'%d','%d'}`

`KeyValueDatastore` Only

You can specify `KeyValueDatastore` properties using name-value pair arguments. See `KeyValueDatastore`.

Output Arguments

`ds` — Datastore for collection of files

`TabularTextDatastore | KeyValueDatastore`

Datastore for a collection of files, returned as a `TabularTextDatastore` or a `KeyValueDatastore`. The type of the datastore depends on the type of files in the datastore. For more information, click the output datastore name.

Type of Files	Output
Text files	`TabularTextDatastore`
MAT-files or Sequence files	`KeyValueDatastore`

For each of the above datastore types, the `Files` property is a cell array of strings, where each string is an absolute path to a file resolved from the `location` argument.

`javaaddpath | mapreduce`

Introduced in R2014b

hasdata

Determine if data available to read

Syntax

```
tf = hasdata(ds)
```

Description

`tf = hasdata(ds)` returns logical `1` (`true`) if there is data available to read from the datastore specified by `ds`. Otherwise, it returns logical `0` (`false`).

Examples

Determine if Data is Available to Read

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

While there is data available in the datastore, read the data.

```
while hasdata(ds)
    T = read(ds);
end
```

Input Arguments

`ds` — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

See Also

`datastore`

Introduced in R2014b

Using KeyValueDatastore Objects

Datastore for key-value pair data

`KeyValueDatastore` objects are associated with files containing key-value pair data that are outputs of or inputs to `mapreduce`. Use the `KeyValueDatastore` properties to specify how you want to access the data. Use dot notation to view or modify a particular property of a `KeyValueDatastore` object:

```
ds = datastore('mapredout.mat');
ds.ReadSize = 20;
```

You also can specify the value of `KeyValueDatastore` properties using name-value pair arguments when you create a datastore using the `datastore` function:

```
ds = datastore('mapredout.mat','ReadSize',20);
```

Examples

Set Number of Key-Value Pairs to Read

Create a datastore from the sample file, `mapredout.mat`, which is an output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat')
```

```
ds =
  KeyValueDatastore with properties:

       Files: {
              ' ...\matlab\toolbox\matlab\demos\mapredout.mat'
              }
    ReadSize: 1 key-value pairs
    FileType: 'mat'
```

Set the `ReadSize` property to 8 so that each call to `read` reads at most 8 key-value pairs.

```
ds.ReadSize = 8
```

```
ds =
  KeyValueDatastore with properties:

       Files: {
```

```
            ' ...\matlab\toolbox\matlab\demos\mapredout.mat'
            }
    ReadSize: 8 key-value pairs
    FileType: 'mat'
```

Read 8 key-value pairs at a time using the `read` function in a `while` loop. The loop executes until there is no more data available to read and `hasdata(ds)` returns `false`.

```
while hasdata(ds)
    T = read(ds);
end
```

Show the last set of key-value pairs read.

```
T
```

```
T =

    Key     Value
    ____    ______

    '0O'    [3090]
    'TZ'    [ 216]
    'XE'    [2357]
    '9E'    [ 521]
    'YV'    [ 849]
```

- "Read and Analyze MAT-File with Key-Value Data"
- "Read and Analyze Hadoop Sequence File"

Properties

`Files` — Files included in datastore

cell array of strings

Files included in the datastore, specified as a cell array of strings, where each string is a full path to a file. These are the files defined by the `location` argument to the `datastore` function.

The files must be either MAT-files or Sequence files generated by the `mapreduce` function. The files must be in a local file system or in a network file system. Sequence files also can be in HDFS.

Example: `{'C:\dir\data\file1.mat','C:\dir\data\file2.mat'}`

`FileType` — File type

`'mat'` (default) | `'seq'`

File type, specified as either `'mat'` for MAT-files or `'seq'` for sequence files. By default, the output of `mapreduce` running against Hadoop is a datastore containing sequence files. By default, the output of all other `mapreduce` operations is a datastore containing MAT-files.

`ReadSize` — Maximum number of key-value pairs to read

1 (default) | positive integer

Maximum number of key-value pairs to read in a call to the `read` or `preview` functions, specified as a positive integer.

`KeyValueLimit` — Maximum number of key-value pairs to read

1 (default) | positive integer

Note: `KeyValueLimit` will be removed in a future release. Use `ReadSize` instead.

Maximum number of key-value pairs to read in a call to the `read` or `preview` functions, specified as a positive integer.

Object Functions

`hasdatanumpartitions` `partition` `preview` `read` `readall` `reset`

Create Object

Create `KeyValueDatastore` objects using the `datastore` function.

See Also

`datastore` | `mapreduce`

numpartitions

Number of partitions

Syntax

```
N = numpartitions(ds)
N = numpartitions(ds,pool)
```

Description

`N = numpartitions(ds)` returns the default number of partitions for datastore `ds`.

`N = numpartitions(ds,pool)` returns a number of partitions to parallelize datastore access over the parallel pool specified by `pool`. To parallelize datastore access, you must have Parallel Computing Toolbox™ installed.

Examples

Number of Partitions

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Get the default number of partitions.

```
N = numpartitions(ds)
```

```
N =
     1
```

By default, there is only one partition in `ds` because it contains only one small file.

Partition the datastore and return the datastore corresponding to the first part.

```
subds = partition(ds,N,1);
```

Read the data in `subds`.

```
while hasdata(subds)
 data = read(subds);
end
```

Number of Partitions for Parallel Datastore Access

Get a number of partitions to parallelize datastore access over the current parallel pool. You must have Parallel Computing Toolbox installed.

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Get a number of partitions to parallelize datastore access over the current parallel pool.

```
N = numpartitions(ds, gcp);
```

Partition the datastore and read the data in each part.

```
parfor ii=1:N
    subds = partition(ds,N,ii);
    while hasdata(subds)
        data = read(subds);
    end
end
```

- "Partition a Datastore in Parallel"

Input Arguments

`ds` — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

`pool` — Parallel pool

parallel pool object

Parallel pool object.

Example: `gcp`

`datastore` | `partition`

Introduced in R2015a

partition

Partition a datastore

Syntax

```
subds = partition(ds,N,index)

subds = partition(ds,'Files',index)
subds = partition(ds,'Files',filename)
```

Description

`subds = partition(ds,N,index)` partitions datastore `ds` into the number of parts specified by `N` and returns the partition corresponding to the index `index`.

`subds = partition(ds,'Files',index)` partitions the datastore by files and returns the partition corresponding to the file of index `index` in the `Files` property.

`subds = partition(ds,'Files',filename)` partitions the datastore by files and returns the partition corresponding to the file specified by `filename`.

Examples

Partition Datastore into Specific Number of Parts

Create a datastore from the sample file, `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv');
```

Partition the datastore into 3 parts.

```
subds = partition(ds,3,1)
```

```
subds =
  TabularTextDatastore with properties:
```

```
                    Files: {
                           ' ...\matlab\toolbox\matlab\demos\airlinesmall.csv'
                           }
            ReadVariableNames: true
                VariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}

  Text Format Properties:
               NumHeaderLines: 0
                    Delimiter: ','
                RowDelimiter: '\r\n'
               TreatAsMissing: ''
                 MissingValue: NaN

  Advanced Text Format Properties:
             TextscanFormats: {'%f', '%f', '%f' ... and 26 more}
           ExponentCharacters: 'eEdD'
                 CommentStyle: ''
                   Whitespace: ' \b\t'
    MultipleDelimitersAsOne: false

  Properties that control the table returned by preview, read, readall:
      SelectedVariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}
            SelectedFormats: {'%f', '%f', '%f' ... and 26 more}
                   ReadSize: 20000 rows
```

Partition Datastore into Default Number of Parts

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Get the default number of partitions for `ds`.

```
N = numpartitions(ds);
```

Partition the datastore into the default number of partitions and return the datastore corresponding to the first partition.

```
subds = partition(ds,N,1);
```

Read the data in `subds`.

```
while hasdata(subds)
 data = read(subds);
```

```
end
```

Partition Datastore by Files

Create a datastore that contains ten instances of the sample file, `airlinesmall.csv`.

```
ds = datastore(repmat({'airlinesmall.csv'}, 1, 10))
```

```
ds =
  TabularTextDatastore with properties:

                      Files: {
                             ' ...\matlab\toolbox\matlab\demos\airlinesmall.csv',
                             ' ...\matlab\toolbox\matlab\demos\airlinesmall.csv',
                             ' ...\matlab\toolbox\matlab\demos\airlinesmall.csv'
                              ... and 7 more
                             }
          ReadVariableNames: true
              VariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}

  Text Format Properties:
             NumHeaderLines: 0
                  Delimiter: ','
               RowDelimiter: '\r\n'
             TreatAsMissing: ''
               MissingValue: NaN

  Advanced Text Format Properties:
            TextscanFormats: {'%f', '%f', '%f' ... and 26 more}
        ExponentCharacters: 'eEdD'
              CommentStyle: ''
                Whitespace: ' \b\t'
    MultipleDelimitersAsOne: false

  Properties that control the table returned by preview, read, readall:
      SelectedVariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}
            SelectedFormats: {'%f', '%f', '%f' ... and 26 more}
                   ReadSize: 20000 rows
```

Partition the datastore by files and return the part corresponding to the first file.

```
subds = partition(ds,'Files',1)
```

```
subds =
  TabularTextDatastore with properties:
```

```
                    Files: {
                           ' ...\matlab\toolbox\matlab\demos\airlinesmall.csv'
                           }
          ReadVariableNames: true
              VariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}

  Text Format Properties:
             NumHeaderLines: 0
                  Delimiter: ','
               RowDelimiter: '\r\n'
             TreatAsMissing: ''
               MissingValue: NaN

  Advanced Text Format Properties:
            TextscanFormats: {'%f', '%f', '%f' ... and 26 more}
         ExponentCharacters: 'eEdD'
               CommentStyle: ''
                 Whitespace: ' \b\t'
    MultipleDelimitersAsOne: false

  Properties that control the table returned by preview, read, readall:
      SelectedVariableNames: {'Year', 'Month', 'DayofMonth' ... and 26 more}
            SelectedFormats: {'%f', '%f', '%f' ... and 26 more}
                   ReadSize: 20000 rows
```

`subds` contains one file.

Partition Data in Parallel

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Partition the datastore into three parts on three workers in a parallel pool.

```
N = 3;
p = parpool('local',N);

parfor ii=1:N
    subds = partition(ds,N,ii);
    while hasdata(subds)
        data = read(subds);
    end
```

```
end
```

- “Partition a Datastore in Parallel”

Input Arguments

`ds` — Input datastore
datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

`N` — Number of partitions
positive integer

Number of partitions, specified as a positive integer.

Example: `3`

Data Types: `double`

`index` — Index
positive integer

Index, specified as a positive integer.

Example: `1`

Data Types: `double`

`filename` — file name
string

File name, specified as a string.

Example: `'file1.csv'`

Example: `'../dir/data/file1.csv'`

Example: `'hdfs://myserver:7867/data/file1.txt'`

Output Arguments

`subds` — Output datastore
datastore

Output datastore. The output datastore is of the same type as the input datastore `ds`.

See Also

`datastore` | `numpartitions`

Introduced in R2015a

preview

Return subset of data from datastore

Syntax

```
data = preview(ds)
```

Description

`data = preview(ds)` returns a subset of data from datastore `ds` without changing its current position.

Examples

Preview Data in TabularTextDatastore

Create a datastore from the sample file, `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA');
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'DepTime','ArrTime','ActualElapsedTime'};
```

Preview the data for the selected variables.

```
data = preview(ds)
```

```
data =

    DepTime    ArrTime    ActualElapsedTime
    _______    _______    _________________

     642        735        53
    1021       1124        63
```

```
    2055        2218          83
    1332        1431          59
     629         746          77
    1446        1547          61
     928        1052          84
     859        1134         155
```

Preview Data in KeyValueDatastore

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Preview the data in the datastore.

```
data = preview(ds)
```

```
data =

    Key       Value
    ____    ________

    'AA'    [14930]
```

Input Arguments

`ds` — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

Output Arguments

`data` — Subset of data

table

Subset of data, returned as a table.

Type of data store	Description
`TabularTextDatastore`	Table of the variables specified by the `SelectedVariableNames` property of the datastore. The table contains at most 8 rows.
`KeyValueDatastore`	Table with the variables `Key` and `Value`.

See Also

`datastore` | `hasdata`

Introduced in R2014b

read

Read data in datastore

Syntax

```
data = read(ds)
[data,info] = read(ds)
```

Description

`data = read(ds)` returns data from a datastore. Subsequent calls to `read` continue reading from the endpoint of the previous call.

`[data,info] = read(ds)` additionally returns information about the extracted data in `info`, including metadata.

Examples

Read Data in TabularTextDatastore

Create a datastore from the sample file, `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA','MissingValue',0);
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'DepTime','ArrTime','ActualElapsedTime'};
```

While there is data available to be read from the datastore, read one block of data at a time and analyze the data. In this example, sum the actual elapsed time.

```
sumElapsedTime = 0;
while hasdata(ds)
    T = read(ds);
    sumElapsedTime = sumElapsedTime + sum(T.ActualElapsedTime);
end
```

View the sum of the actual elapsed time.

```
sumElapsedTime
```

```
sumElapsedTime =

    14531797
```

Read Data in KeyValueDatastore

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Read a subset of data in the datastore.

```
T = read(ds)
```

```
T =

    Key       Value
    ____    _______

    'AA'    [14930]
```

Change the number of key-value pairs to read at a time, by changing the `ReadSize` property of the datastore.

```
ds.ReadSize = 5;
```

Read the next five key-value pairs in the datastore.

```
T = read(ds)
```

```
T =

    Key       Value
    ____    _______

    'AS'    [ 2910]
```

```
'CO'    [ 8138]
'DL'    [16578]
'EA'    [  920]
'HP'    [ 3660]
```

Input Arguments

`ds` — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

Output Arguments

`data` — Output data

table

Output data, returned as a table.

For `TabularTextDatastore` objects, the table variables are determined by the `SelectedVariableNames` property.

For `KeyValueDatastore` objects, the variable names are `Key` and `Value`.

`info` — Information about datastore

structure array

Information about the datastore, returned as a structure array. The structure array can contain the following fields.

Field Name	Description
`File`	File name.
`FileType`	The type of file from which data is read, either `'mat'` for MAT-files or `'seq'` for sequence files. Applies to `KeyValueDatastore` only.

Field Name	Description
`Offset`	Starting position of the read operation, in bytes. For MAT-files, `Offset` is the index of the first key and value read.
`Size`	Total file size, in bytes. For MAT-files, the total number of key-value pairs in the file.
`NumCharactersRead`	Number of characters read. Applies to `TabularTextDatastore` only.

See Also

`datastore` | `hasdata` | `readall`

Introduced in R2014b

readall

Read all data in datastore

Syntax

```
data = readall(ds)
```

Description

`data = readall(ds)` returns all the data in the datastore specified by `ds`, and resets the datastore to the point where no data has been read from it.

If all of the data in the datastore does not fit in memory, then `readall` returns an error.

Examples

Read All Data in TabularTextDatastore

Create a datastore from the sample file `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA');
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'DepTime','ArrTime','ActualElapsedTime'};
```

Read all the data in the datastore.

```
T = readall(ds);
```

`readall` returns all the data in a table.

View information about the table.

```
T.Properties
```

```
ans =
```

```
          Description: ''
    VariableDescriptions: {}
           VariableUnits: {}
         DimensionNames: {'Row'  'Variable'}
               UserData: []
               RowNames: {}
          VariableNames: {'DepTime'  'ArrTime'  'ActualElapsedTime'}
```

View a summary of the output table.

```
summary(T)
```

```
Variables:

    DepTime: 123523x1 double
        Values:

            min          1
            median    1335
            max       2505
            NaNs      2351

    ArrTime: 123523x1 double
        Values:

            min          1
            median    1522
            max       2608
            NaNs      2656

    ActualElapsedTime: 123523x1 double
        Values:

            min         11
            median     102
            max       1650
            NaNs      2657
```

Read All Data in KeyValueDatastore

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Read all the data in the datastore.

```
T = readall(ds);
```

View a summary of the output table.

```
summary(T)
```

```
Variables:

    Key: 29x1 cell string

    Value: 29x1 cell
```

Input Arguments

`ds` — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

Output Arguments

`data` — All data in the datastore

table

All data in the datastore, returned as a table.

For `TabularTextDatastore` objects, the table variables are determined by the `SelectedVariableNames` property.

For `KeyValueDatastore` objects. the variable names are `Key` and `Value`.

See Also

`datastore` | `hasdata` | `readall`

Introduced in R2014b

reset

Reset datastore to initial state

Syntax

```
reset(ds)
```

Description

`reset(ds)` resets the datastore specified by `ds` to the state where no data has been read from it. This allows re-reading from the same datastore.

Examples

Reset Datastore to Initial State

Create a datastore from the sample file, `mapredout.mat`, which is the output file of the `mapreduce` function.

```
ds = datastore('mapredout.mat');
```

Read the first key-value pair.

```
T = read(ds);
```

Reset the datastore to the state where no data has been read from it.

```
reset(ds)
```

Input Arguments

`ds` — Input datastore

datastore

Input datastore. Use the `datastore` function to create a datastore object from your data.

`datastore`

Introduced in R2014b

Using TabularTextDatastore Objects

Datastore for collections of tabular text files

`TabularTextDatastore` objects are associated with collections of text files containing column-oriented or tabular data. Tabular data is data arranged in rows and columns of equal length. The encoding of the data must be ASCII or UTF-8. `TabularTextDatastore` properties specify how data is formatted in the files, and how you want to access the data.

Examples

Select Variables to Read

Create a datastore from the sample file `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA');
```

View the variables in the datastore.

```
ds.VariableNames
```

```
ans =

  Columns 1 through 5

    'Year'    'Month'    'DayofMonth'    'DayOfWeek'    'DepTime'

  Columns 6 through 10

    'CRSDepTime'    'ArrTime'    'CRSArrTime'    'UniqueCarrier'    'FlightNum'

  Columns 11 through 14

    'TailNum'    'ActualElapsedTime'    'CRSElapsedTime'    'AirTime'

  Columns 15 through 20

    'ArrDelay'    'DepDelay'    'Origin'    'Dest'    'Distance'    'TaxiIn'
```

```
  Columns 21 through 24

    'TaxiOut'    'Cancelled'    'CancellationCode'    'Diverted'

  Columns 25 through 28

    'CarrierDelay'    'WeatherDelay'    'NASDelay'    'SecurityDelay'

  Column 29

    'LateAircraftDelay'
```

Modify the `SelectedVariableNames` property to specify the variables of interest.

```
ds.SelectedVariableNames = {'Year','Month','Cancelled'};
```

Alternatively, you can specify the variables of interest when you create the datastore.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA','SelectedVariableNames',{'Year
```

Specify Format of Data to Read

Create a datastore from the sample file `airlinesmall.csv`, which contains tabular data.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA');
```

Specify the variables of interest.

```
ds.SelectedVariableNames = {'Year','Month','UniqueCarrier'};
```

View the `SelectedFormats` property.

```
ds.SelectedFormats
```

```
ans =

    '%f'    '%f'    '%q'
```

The `SelectedFormats` property indicates that the `Year` and `Month` variables will be interpreted as columns of floating-point values, and the `UniqueCarrier` variable will be interpreted as a column of text strings.

Specify that the first two variables should be read as signed integers, and the third variable should be read as a categorical value by modifying the `SelectedFormats` property.

```
ds.SelectedFormats = {'%d','%d','%C'};
```

Preview the data.

```
T = preview(ds)
```

```
T =

    Year    Month    UniqueCarrier
    ____    _____    _____________

    1987    10       PS
    1987    10       PS

- “Getting Started with Datastore”

datatipinfo

Produce short description of input variable

Syntax

```
datatipinfo(var)
```

Description

`datatipinfo(var)` displays a short description of a variable, similar to what is displayed in a datatip in the MATLAB debugger.

Examples

Get datatip information for a 5-by-5 matrix:

```
A = rand(5);

datatipinfo(A)
A: 5x5 double =
    0.4445    0.3567    0.7458    0.0767    0.4400
    0.7962    0.6575    0.3918    0.8289    0.9746
    0.5641    0.9808    0.0265    0.4838    0.6722
    0.9099    0.9653    0.2508    0.4859    0.4054
    0.2857    0.5198    0.7383    0.9301    0.9604
```

Get datatip information for a 50-by-50 matrix. For this larger matrix, `datatipinfo` displays just the size and data type:

```
A = rand(50);

datatipinfo(A)
A: 50x50 double
```

Also for multidimensional matrices, `datatipinfo` displays just the size and data type:

```
A = rand(5);
```

```
A(:,:,2) = A(:,:,1);

datatipinfo(A)
A: 5x5x2 double
```

date

Current date string

Syntax

```
str = date
```

Description

`str = date` returns a string containing the date in the format, day-month-year, for example, `01-Jan-2014`.

More About

Tips

- To return a datetime scalar representing the current date, type:

  ```
  d = datetime('today')
  ```

See Also

`clock` | `datestr` | `datetime` | `datenum` | `now`

Introduced before R2006a

datenum

Convert date and time to serial date number

The `datenum` function creates a numeric array that represents each point in time as the number of days from January 0, 0000. The numeric values also can represent elapsed time in units of days. However, the best way to represent points in time is by using the `datetime` data type. The best way to represent elapsed time is by using the `duration` or `calendarDuration` data types.

Syntax

```
DateNumber = datenum(t)

DateNumber = datenum(DateString)
DateNumber = datenum(DateString,formatIn)
DateNumber = datenum(DateString,PivotYear)
DateNumber = datenum(DateString,formatIn,PivotYear)

DateNumber = datenum(DateVector)
DateNumber = datenum(Y,M,D)
DateNumber = datenum(Y,M,D,H,MN,S)
```

Description

`DateNumber = datenum(t)` converts the datetime values in `datetime` array `t` to serial date numbers.

A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`DateNumber = datenum(DateString)` converts date strings to serial date numbers. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateNumber = datenum(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateNumber = datenum(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use

`formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateNumber = datenum(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

`DateNumber = datenum(DateVector)` converts date vectors to serial date numbers, and returns a column vector of `m` date numbers, where `m` is the total number of date vectors in `DateVector`.

`DateNumber = datenum(Y,M,D)` returns the serial date numbers for corresponding elements of the `Y`, `M`, and `D` (year, month, day) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D]`.

`DateNumber = datenum(Y,M,D,H,MN,S)` additionally returns the serial date numbers for corresponding elements of the `H`, `MN`, and `S` (hour, minute, and second) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D,H,MN,S]`.

Examples

Convert datetime Array to Date Numbers

```
format long

t = [datetime('now');datetime('tomorrow')]
DateNumber = datenum(t)
```

```
t =

   23-Feb-2015 09:59:02
   24-Feb-2015 00:00:00

DateNumber =

   1.0e+05 *

   7.360184160032523
```

```
   7.360190000000000
```

Convert Date String to Date Number

```
DateString = '19-May-2001';
formatIn = 'dd-mmm-yyyy';
datenum(DateString,formatIn)
```

```
ans =

      730990
```

`datenum` returns a date number for the date string with the format `'dd-mmm-yyyy'` .

Convert Multiple Date Strings to Date Numbers

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};
formatIn = 'mm/dd/yyyy';
datenum(DateString,formatIn)
```

```
ans =

      733301
      729159
      734471
```

Convert Date String to Date Number Using Pivot Year

Convert a date string to a serial date number using the default pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy')
```

```
n =

      736858
```

The corresponding date string to this date number is 12-Jun-2017.

Convert the same date string to a serial date number using 1400 as the pivot year.

```
n = datenum('12-jun-17','dd-mmm-yy',1400)
```

```
n =

      517712
```

The corresponding date string to this date number is 12-Jun-1417.

Convert Date Vector to Date Number

```
datenum([2009,4,2,11,7,18])
```

```
ans =

   7.3387e+05
```

Convert Year, Month, and Day to Date Number

Convert a date specified by year, month and day values to a serial date number.

```
n = datenum(2001,12,19)
```

```
n =

      731204
```

Input Arguments

`t` — `datetime` values

scalar | vector | matrix | multidimensional array

`datetime` values, specified as a scalar, vector, matrix, or multidimensional `datetime` array. `datenum` does not account for time zone information in `t` and does not adjust datetime values that occur during Daylight Saving Time. That is, `datenum` treats the `TimeZone` property of `t` as empty and converts the remaining date and time information to a serial date number.

`DateVector` — Date vectors

matrix

Date vectors, specified as an `m`-by-6 or `m`-by-3 matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements, specifying year, month, day, hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, `datenum` adjusts both that date vector element and the previous element. For example, if the minutes element is `70`, `datenum` adjusts the hours element by `1` and sets the minutes element to `10`. If the minutes element is `-15`, then `datevec` decreases the hours element by `1` and sets the minutes element to `45`. Month values are an exception. `datenum` sets month values less than `1` to `1`.

Example: `[2003,10,24,12,45,07]`

Data Types: `double`

`DateString` — Date strings

string | character array | 1–D cell array of strings

Date strings, specified as a character array where each row corresponds to one date string, or as a one dimensional cell array of strings. All of the date strings must have the same format.

Example: `'24–Oct-2003 12:45:07'`

Example: `['19-Sep-2013';'20-Sep-2013';'21-Sep-2013']`

Example: `{'15-Oct-2010' '20-Nov-2012'}`

If the date string format is known, you should also specify `formatIn`. If you do not specify `formatIn`, `DateString` must be in one of the following formats.

Date String Format	Example
`'dd-mmm-yyyy HH:MM:SS'`	`01-Mar-2000 15:45:17`
`'dd-mmm-yyyy'`	`01-Mar-2000`
`'mm/dd/yyyy'`	`03/01/2000`
`'mm/dd/yy'`	`03/01/00`

Date String Format	Example
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Note: The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. `datevec` and `datenum` consider two-character date string years (e.g., `'79'`) to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (`mm`), the month value must not be greater than 12.
- However, for the format `'mm/dd/yy'`, if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, then `datenum` considers the date string to be in `'yy/mm/dd'` format.

`formatIn` — Format of the input date string

string

Format of the input date string, specified as a string of symbolic identifiers.

Example: `'dddd, mmm dd, yyyy'`

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Note: The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

Symbolic Identifier	Description	Example
`yyyy`	Year in full	`1990`, `2002`
`yy`	Year in two digits	`90`, `02`
`QQ`	Quarter year using letter `Q` and one digit	`Q1`
`mmmm`	Month using full name	`March`, `December`
`mmm`	Month using first three letters	`Mar`, `Dec`
`mm`	Month in two digits	`03`, `12`
`m`	Month using capitalized first letter	`M`, `D`
`dddd`	Day using full name	`Monday`, `Tuesday`
`ddd`	Day using first three letters	`Mon`, `Tue`
`dd`	Day in two digits	`05`, `20`
`d`	Day using capitalized first letter	`M`, `T`
`HH`	Hour in two digits (no leading zeros when symbolic identifier `AM` or `PM` is used)	`05`, `5 AM`
`MM`	Minute in two digits	`12`, `02`
`SS`	Second in two digits	`07`, `59`
`FFF`	Millisecond in three digits	`057`
`AM or PM`	`AM` or `PM` inserted in date string	`3:45:02 PM`

The `formatIn` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use `'yy-mmm-dd-m'` because it has two month identifiers. The one exception to this is that you can combine one instance of `dd` with one instance of any of the other day identifiers. For example, `'dddd mmm dd yyyy'` is a valid input.
- When you use `AM` or `PM`, the `HH` field is also required.
- You only can use `QQ` alone or with a year specifier.

`PivotYear` — Start year of 100-year date range

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: `2000`

Data Types: `double`

`Y,M,D` — Year, month, and day arrays

scalar | vector | matrix | array

Year, month, and day arrays specified as a scalar, vector, matrix or array. These must be the same size, or any one can be a scalar. `Y,M,D` should be integer values.

If `Y,M,D` are all scalars or all column vectors, you can specify the input arguments as a date vector, `[Y,M,D]`.

Example: `2003,10,24`

Data Types: `double`

`Y,M,D,H,MN,S` — Year, month, day, hour, minute and second arrays

scalar | vector | matrix | array

Year, month, day, hour, minute and second arrays specified as a scalar, vector, matrix or array. These must be the same size, or any one can be a scalar. `datenum` does not accept milliseconds as a separate input, but as a fractional part of the seconds input, `S`. `Y,M,D,H,MN` should be integer values.

If `Y,M,D,H,MN,S` are all scalars or all column vectors, you can specify the input arguments as a date vector `[Y,M,D,H,MN,S]`.

Example: `2003,10,24,12,45,07.451`

Data Types: `double`

Output Arguments

`DateNumber` — Serial date numbers

scalar | vector

Serial date numbers, returned as a column vector of length `m`, where `m` is the total number of input date vectors or date strings.

More About

Tips

- To create arbitrarily shaped output, use the `datenum(Y,M,D)` and `datenum(Y,M,D,H,MN,S)` syntaxes. The `datenum(DateVector)` syntax creates only a column vector of date numbers.

  ```
  datenum(2013,[1 3; 2 4],ones(2,2))

  ans =

        735235       735294
        735266       735325
  ```

- "Represent Dates and Times in MATLAB"
- "Carryover in Date Vectors and Strings"

See Also

`datestr` | `datetime` | `datevec`

Introduced before R2006a

dateshift

Shift date or generate sequence of dates and time

Syntax

```
t2 = dateshift(t,'start',unit)
t2 = dateshift(t,'end',unit)
t2 = dateshift(t,'dayofweek',dow)

t2 = dateshift(___,rule)
```

Description

`t2 = dateshift(t,'start',unit)` shifts each value in the `datetime` array `t` back to the beginning of the unit of time specified by `unit`. The output `t2` is the same size as `t`.

`t2 = dateshift(t,'end',unit)` shifts the values ahead to the end of the unit of time specified by `unit`. The end of a day, hour, minute, or second is also the beginning of the next one. For example, the end of a day occurs at midnight at the beginning of the next day. The end of a year, quarter, month, or week is midnight at the beginning of the last day of that time period.

`t2 = dateshift(t,'dayofweek',dow)` returns the next occurrence of the specified day of the week on or after each datetime in array `t`. If the date in `t` falls on the specified day of the week, then `dateshift` returns the same date.

`t2 = dateshift(___,rule)` shifts each value in array `t` according to the pattern specified by `rule`. You can use this syntax with any of the arguments in the previous syntaxes.

Examples

Shift Current Date to End of Current Month

Define the current date.

```
t = datetime('today')
```

```
t =

   23-Feb-2015
```

Shift the date to the end of the same month.

```
t2 = dateshift(t,'end','month')
```

```
t2 =

   28-Feb-2015
```

Shift Current Date to Next Month

Define the current date.

```
t = datetime('today')
```

```
t =

   23-Feb-2015
```

Shift the date to the start of the next month.

```
t2 = dateshift(t,'start','month','next')
```

```
t2 =

   01-Mar-2015
```

Shift the date to the end of the next month.

```
t2 = dateshift(t,'end','month','next')
```

```
t2 =
```

```
   31-Mar-2015
```

Shift Dates to Specific Day of Week

Shift an array of dates forward to the next Friday.

```
t = datetime([2014,08,03;2014,04,15])
```

```
t =

   03-Aug-2014
   15-Apr-2014
```

```
t2 = dateshift(t,'dayofweek','Friday')
```

```
t2 =

   08-Aug-2014
   18-Apr-2014
```

Shift the array of dates backward to the previous Monday.

```
t2 = dateshift(t,'dayofweek','Monday','previous')
```

```
t2 =

   28-Jul-2014
   14-Apr-2014
```

Determine Future Date

Find the date that falls at the end of the fifth week from today.

```
t = datetime('today')
```

```
t =
```

```
   23-Feb-2015

t2 = dateshift(t,'end','week',5)

t2 =

   04-Apr-2015
```

Create Sequence of Dates Falling on Specific Day of Week

Generate a sequence of dates consisting of the next three occurrences of Friday.

```
t = datetime('today')

t =

   23-Feb-2015

t2 = dateshift(t,'dayofweek','Friday',1:3)

t2 =

   27-Feb-2015   06-Mar-2015   13-Mar-2015
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

`unit` — Unit of time

`'year' | 'quarter' | 'month' | 'week' | 'day' | 'hour' | 'minute' | 'second'`

Unit of time, specified as one of the following strings:

- `'year'`

- 'quarter'
- 'month'
- 'week'
- 'day'
- 'hour'
- 'minute'
- 'second'

dow — Day of Week

scalar integer | string

Day of the week, specified as a scalar integer indicating the day of week number, or a string containing a localized day name.

Example: 'Sunday'

Example: 1

Data Types: single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

rule — Rule for shifting datetime values

string | scalar integer | array of integer values

Rule for shifting datetime values, specified as a string, scalar integer, or an array of integer values. If rule is a string, it must be one of the following.

Value of rule	Description
'next'	Shift datetime to next unit of time or specified day.
'previous'	Shift datetime to previous unit of time or specified day.
'nearest'	Shift datetime to nearest occurrence of unit of time or specified day.
'current'	Shift datetime within the current unit of time, or to the specified day in the current week.

If rule is an integer or an array of integers, then:

- When used with `unit`, `0` corresponds to the start or end of the current unit for each datetime, `1` corresponds to the next unit, and `-1` corresponds to the previous unit, and so on.
- When used with `dow`, `0` corresponds to the specified day in the current week for each datetime, `1` corresponds to the next occurrence of the specified day, and `-1` corresponds to the previous occurrence, and so on.
- `t` and `rule` must be the same size, or one must be a scalar.

See Also

`between` | `colon (:)`

Introduced in R2014b

datestr

Convert date and time to string format

The `datestr` function creates a string or character array that display one or more points in time. However, the best way to represent points in time is by using the `datetime` data type.

Syntax

```
DateString = datestr(t)
DateString = datestr(DateVector)
DateString = datestr(DateNumber)

DateString = datestr( ___ ,formatOut)

DateString = datestr(DateStringIn)
DateString = datestr(DateStringIn,formatOut,PivotYear)

DateString = datestr( ___ ,'local')
```

Description

`DateString = datestr(t)` converts the datetime values in `datetime` array `t` to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of datetime values in `t`.

By default, `datestr` returns date strings in the format, day-month-year hour:minute:second. If hour:minute:second `= 00:00:00`, then the date string returned has the format, day-month-year.

`DateString = datestr(DateVector)` converts date vectors to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date vectors in `DateVector`.

`DateString = datestr(DateNumber)` converts serial date numbers to date strings. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date numbers in `DateNumber`.

`DateString = datestr( ___ ,formatOut)` specifies the format of the output date strings using `formatOut`. You can use formatOut with any of the input arguments in the above syntaxes.

`DateString = datestr(DateStringIn)` converts `DateStringIn` to date strings in the format, day-month-year hour:minute:second. All date strings in `DateStringIn` must have the same format.

`DateString = datestr(DateStringIn,formatOut,PivotYear)` converts `DateStringIn` to `DateString`, in the format specified by `formatOut`, and using optional `PivotYear` to interpret date strings that specify the year as two characters.

`DateString = datestr( ___ ,'local')` returns the date string in the language of the current locale. This is the language you select by means of your computer's operating system. If you leave `local` out of the argument list, `datestr` returns the date string in the default language, which is US English. Use `local` with any of the previous syntaxes. The `local` argument must be last in the argument sequence.

Examples

Convert datetime Array to Date Strings

```
t = [datetime('now');datetime('tomorrow')]
DateString = datestr(t)
```

```
t =

   23-Feb-2015 09:59:08
   24-Feb-2015 00:00:00

DateString =

23-Feb-2015 09:59:08
24-Feb-2015 00:00:00
```

`datestr` returns date strings in the format, day-month-year hour:minute:second.

Convert Date Vector to Date String

```
DateVector = [2009,4,2,11,7,18];
```

```
datestr(DateVector)
```

```
ans =

02-Apr-2009 11:07:18
```

`datestr` returns a date string in the default date string format.

Convert Date and Time to Specific Format

Format the current date in the `mm/dd/yy` format.

You can specify this format using a string of symbolic identifiers.

```
formatOut = 'mm/dd/yy';
datestr(now,formatOut)
```

```
ans =

02/23/15
```

Alternatively, you can specify this format using a numeric identifier.

```
formatOut = 2;
datestr(now,formatOut)
```

```
ans =

02/23/15
```

You can reformat the date and time, and also show milliseconds.

```
dt = datestr(now,'mmmm dd, yyyy HH:MM:SS.FFF AM')
```

```
dt =

February 23, 2015  9:59:03.358 AM
```

Convert 12-Hour Time String to 24-Hour Equivalent

Convert the 12-hour time 05:32 p.m. to its 24-hour equivalent.

```
datestr('05:32 PM','HH:MM')
```

```
ans =

17:32
```

Convert the 24-hour time 05:32 to its 12-hour equivalent.

```
datestr('05:32','HH:MM PM')
```

```
ans =

 5:32 AM
```

The use of `AM` or `PM` in the `formatOut` string does not influence which characters actually become part of the date string; they only determine whether or not to include them in the date string. MATLAB® selects `AM` or `PM` based on the time entered.

Convert Date String from Custom Format

Call `datenum` inside of `datestr` to specify the format of the input date string.

```
formatOut = 'dd mmm yyyy';
datestr(datenum('16-04-55','dd-mm-yy',1900),formatOut)
```

```
ans =

16 Apr 1955
```

Convert Multiple Date Strings

Convert more than one date string input by passing the multiple date strings in a cell array.

All input date strings must use the same format. For example, the following command passes three dates that all use the `mm/dd/yyyy` format.

```
datestr(datenum({'09/16/2007';'05/14/1996';'11/29/2010'}, ...
    'mm/dd/yyyy'))
```

```
ans =

16-Sep-2007
14-May-1996
29-Nov-2010
```

`datestr` returns a character array of converted date strings in the format, day-month-year.

Convert Date String with Values Outside Normal Range

Call `datenum` inside of `datestr` to return the expected value, because the date below uses a value outside its normal range (month=13).

```
datestr(datenum('13/24/88','mm/dd/yy'))
```

```
ans =

24-Jan-1989
```

Use a Pivot Year

Change the pivot year to change the year range.

Use a pivot year of 1900.

```
DateStringIn = '4/16/55';
formatOut = 1;
PivotYear = 1900;
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =

16-Apr-1955
```

For the same date string, use a pivot year of 2000.

```
PivotYear = 2000;
datestr(DateStringIn,formatOut,PivotYear)
```

```
ans =

16-Apr-2055
```

Return Date String in Local Language

Convert a date number to a date string in the language of the current locale.

Use the `local` argument in a French locale.

```
DateNumber = 725935;
formatOut = 'mmmm-dd-yyyy';
str = datestr(DateNumber,formatOut,'local')
```

```
str =
Juillet-17-1987
```

You can make the same call without specifying `'local'`.

```
str = datestr(DateNumber,formatOut)
```

```
str =
July-17-1987
```

In this case, the output defaults to the English language.

Input Arguments

`t` — `datetime` values

scalar | vector | matrix | multidimensional array

`datetime` values, specified as a scalar, vector, matrix, or multidimensional `datetime` array.

`DateVector` — Date vectors

matrix

Date vectors, specified as an `m`-by-6 matrix, where `m` is the number of full (six-element) date vectors. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, `datestr` adjusts both that date vector element and the previous element. For example, if the minutes element is `70`, `datestr` adjusts the hours element by `1` and sets the minutes element to `10`. If the minutes element is `-15`, then `datestr` decreases the hours element by `1` and sets the minutes element to `45`. Month values are an exception. `datestr` sets month values less than `1` to `1`.

Example: `[2003,10,24,12,45,07]`

Data Types: `double`

`DateNumber` — Serial date numbers

scalar | vector | matrix | array

Serial date numbers, specified as a scalar, vector, matrix, or array of positive double-precision numbers.

Example: `731878`

Data Types: `double`

`formatOut` — Format of the date string output

`-1` (default) | string | integer

Format of the date string output, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format. If you do not specify `formatOut`, then `datestr` returns a date string in the default date string format `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second). By default, if `HH:MM:SS = 00:00:00` then the date string returned has the format `dd-mmm-yyyy`.

The following table shows symbolic identifiers you can use to construct the `formatOut` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Note: The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

Symbolic Identifier	Description	Example
`yyyy`	Year in full	1990, 2002

Symbolic Identifier	Description	Example
`yy`	Year in two digits	`90`, `02`
`QQ`	Quarter year using letter `Q` and one digit	`Q1`
`mmmm`	Month using full name	`March`, `December`
`mmm`	Month using first three letters	`Mar`, `Dec`
`mm`	Month in two digits	`03`, `12`
`m`	Month using capitalized first letter	`M`, `D`
`dddd`	Day using full name	`Monday`, `Tuesday`
`ddd`	Day using first three letters	`Mon`, `Tue`
`dd`	Day in two digits	`05`, `20`
`d`	Day using capitalized first letter	`M`, `T`
`HH`	Hour in two digits (no leading zeros when symbolic identifier `AM` or `PM` is used)	`05`, `5 AM`
`MM`	Minute in two digits	`12`, `02`
`SS`	Second in two digits	`07`, `59`
`FFF`	Millisecond in three digits	`057`
`AM or PM`	`AM` or `PM` inserted in date string	`3:45:02 PM`

The `formatOut` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use `'yy-mmm-dd-m'` because it has two month identifiers. The one exception to this is that you can combine one instance of `dd` with one instance of any of the other day identifiers. For example, `'dddd mmm dd yyyy'` is a valid input.
- When you use `AM` or `PM`, the `HH` field is also required.
- You only can use `QQ` alone or with a year specifier.

This table lists predefined date formats that you can use with `datestr`.

Numeric Identifier	Date String Format	Example
-1 (default)	'dd-mmm-yyyy HH:MM:SS' or 'dd-mmm-yyyy' if 'HH:MM:SS'= 00:00:00	01-Mar-2000 15:45:17 or 01-Mar-2000
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000

Numeric Identifier	Date String Format	Example
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000
29	'yyyy-mm-dd' (ISO 8601)	2000-03-01
30	'yyyymmddTHHMMSS' (ISO 8601)	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

`DateStringIn` — Date strings to convert
string | cell array

Date strings to convert, specified as a single string or a cell array of strings, where each row corresponds to one date string.

`datestr` considers two-character date string years (for example, `'79'`) to fall within the 100-year range centered around the current year.

All date strings must have the same date format, and they must be in one of the following date formats.

Date String Format	Example
'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
'dd-mmm-yyyy'	01-Mar-2000
'mm/dd/yyyy'	03/01/2000
'mm/dd/yy'	03/01/00
'mm/dd'	03/01
'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
'mmm.dd,yyyy'	Mar.01,2000
'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17
'yyyy-mm-dd'	2000-03-01

Date String Format	Example
'yyyy/mm/dd'	2000/03/01
'HH:MM:SS'	15:45:17
'HH:MM:SS PM'	3:45:17 PM
'HH:MM'	15:45
'HH:MM PM'	3:45 PM

Note: When converting from one date string format to another, you should first pass the strings to the `datenum` function, so that you can specify the format of the input date strings. This ensures that the format of the input date strings is correctly interpreted. For example, see "Convert Date String from Custom Format" on page 1-1915.

`PivotYear` — Start year of 100-year date range

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: `2000`

Data Types: `double`

Output Arguments

`DateString` — Date strings

string | two-dimensional character array

Date strings, returned as a character array with `m` rows, where `m` is the total number of input date vectors, serial date numbers, or date strings. The default output date string format is `dd-mmm-yyyy HH:MM:SS` (day-month-year hour:minute:second) unless the hours, minutes and seconds are all 0 in which case `HH:MM:SS` is suppressed.

More About

Tips

- To convert a date string not in a predefined MATLAB date format, first convert the date string to a date number, using either `datenum` or `datevec`.

- "Represent Dates and Times in MATLAB"
- "Converting Date Vector Returns Unexpected Output"

Introduced before R2006a

datetick

Date formatted tick labels

The `datetick` function labels the tick lines of an axis using dates, replacing the default labels. `datetick` is useful when plotting numeric values that are serial date numbers.

For 2-D line and scatter plots, it is more convenient to plot datetime values using the `plot` function. Specify the format of the tick labels using the `DatetimeTickFormat` name-value pair argument. You do not need to use `datetick` to label such plots of datetime values.

Syntax

```
datetick(tickaxis)
datetick(tickaxis,dateFormat)

datetick(___,'keeplimits')

datetick(___,'keepticks')

datetick(axes_handle,___)
```

Description

`datetick(tickaxis)` labels the tick lines of the axis specified by `tickaxis` using dates, replacing the default numeric labels. `datetick` selects a label format based on the minimum and maximum limits of the specified axis. The axis data values should be serial date numbers, as returned by the `datenum` function.

`datetick(tickaxis,dateFormat)` formats the labels according to the string `dateFormat`.

`datetick(___,'keeplimits')` changes the tick labels to date-based labels while preserving the axis limits. Append `'keeplimits'` to any of the previous syntaxes.

`datetick(___,'keepticks')` changes the tick labels to date-based labels while preserving their locations. Append `'keepticks'` to any of the previous syntaxes.

`datetick(axes_handle, ___ )` labels the tick lines of an axis on the axes specified by `axes_handle`. The `axes_handle` argument can precede any of the input argument combinations in the previous syntaxes.

Examples

Label x-Axis Ticks with 2-digit Years

Graph population data for the 20th Century taken from the 1990 US census and label *x*-axis ticks with 2-digit years.

Create time data by decade.

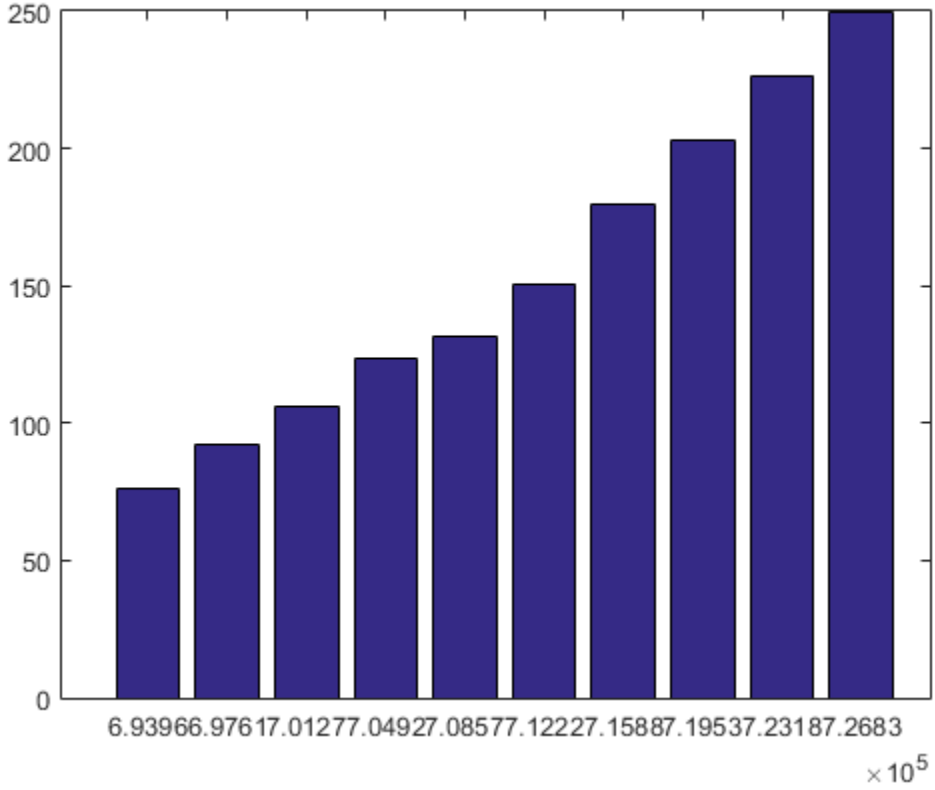
```
t = (1900:10:1990)';
```

Enter total population counts for the USA.

```
p = [75.995 91.972 105.711 123.203 131.669 ...
 150.697 179.323 203.212 226.505 249.633]';
```

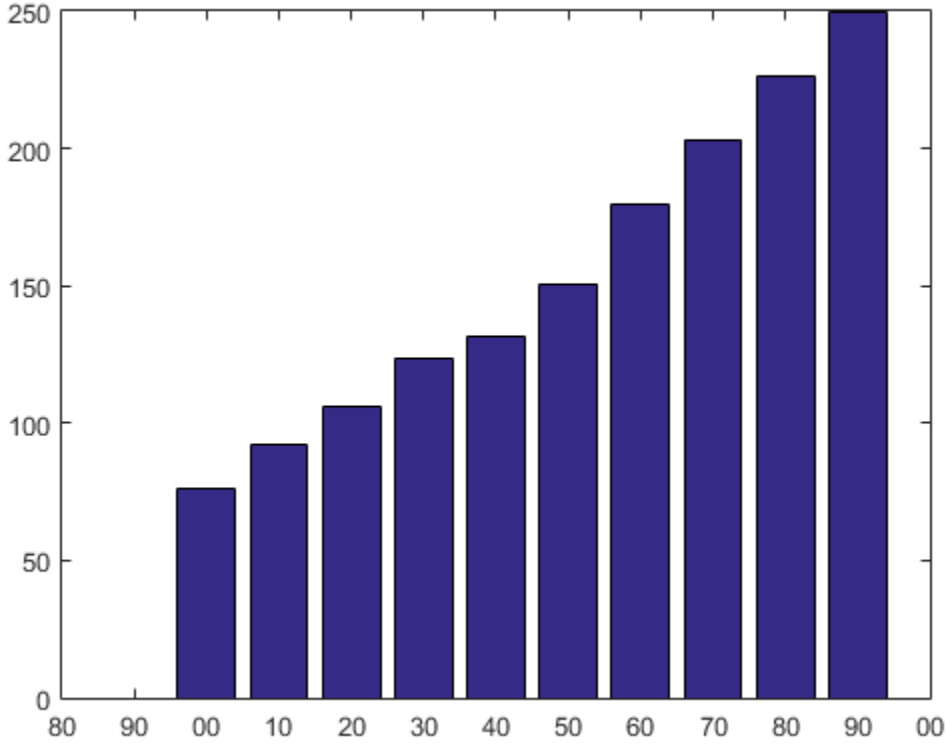
Convert years to serial date numbers using the `datenum` function, and then create a bar graph of the data.

```
figure
bar(datenum(t,1,1),p)
```



Replace *x*-axis ticks with 2-digit years. The numeric identifier `11` corresponds to the predefined MATLAB® date format `'yy'`.

```
dateFormat = 11;
datetick('x',dateFormat)
```



Label x-Axis Ticks with Hours of the Day

Plot traffic count data against date ticks for hours of the day showing AM and PM.

Get traffic count data.

```
load count.dat
```

Create arrays for an arbitrary date, for example, April 18, 1995.

```
n = length(count);
year = repmat(1995,1,n);
month = repmat(4,1,n);
day = repmat(18,1,n);
```

Create arrays for each of 24 hours.

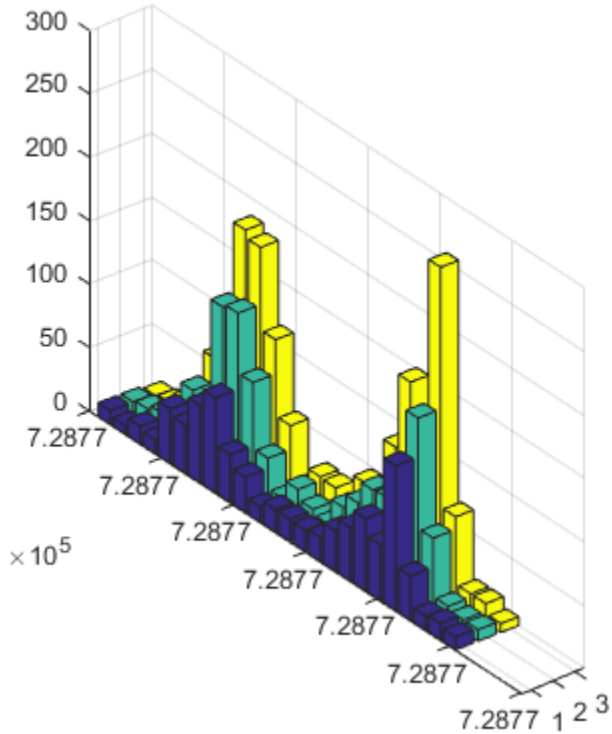
```
hour = 1:n;
minutes = zeros(1,n);
```

Get the serial date numbers for the date arrays.

```
xdate = datenum(year,month,day,hour,minutes,minutes);
```

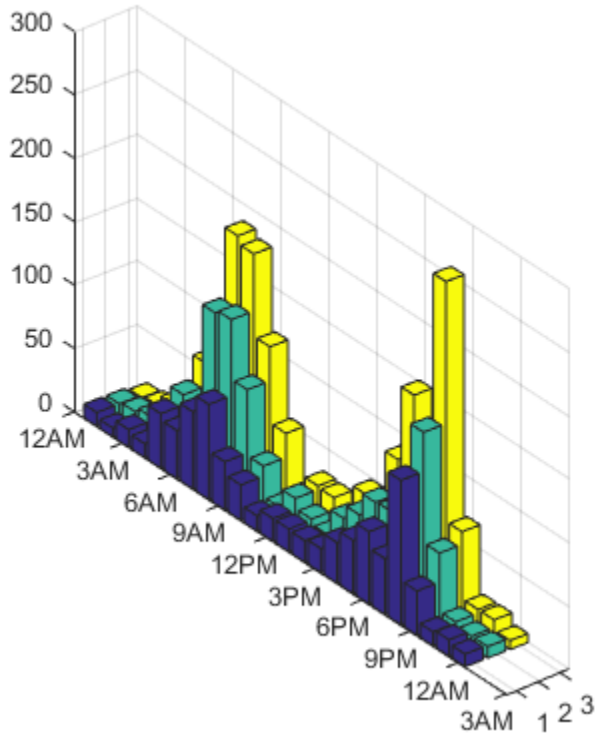
Plot a 3-D bar graph of the traffic data against the serial date numbers.

```
figure
bar3(xdate,count)
```



Label the tick lines of the graph's *x*-axis with the hours of the day.

```
datetick('y','HHPM')
```



Label x-Axis and Preserve Axis Limits

Select a starting date.

```
startDate = datenum('02-01-1962');
```

Select an ending date.

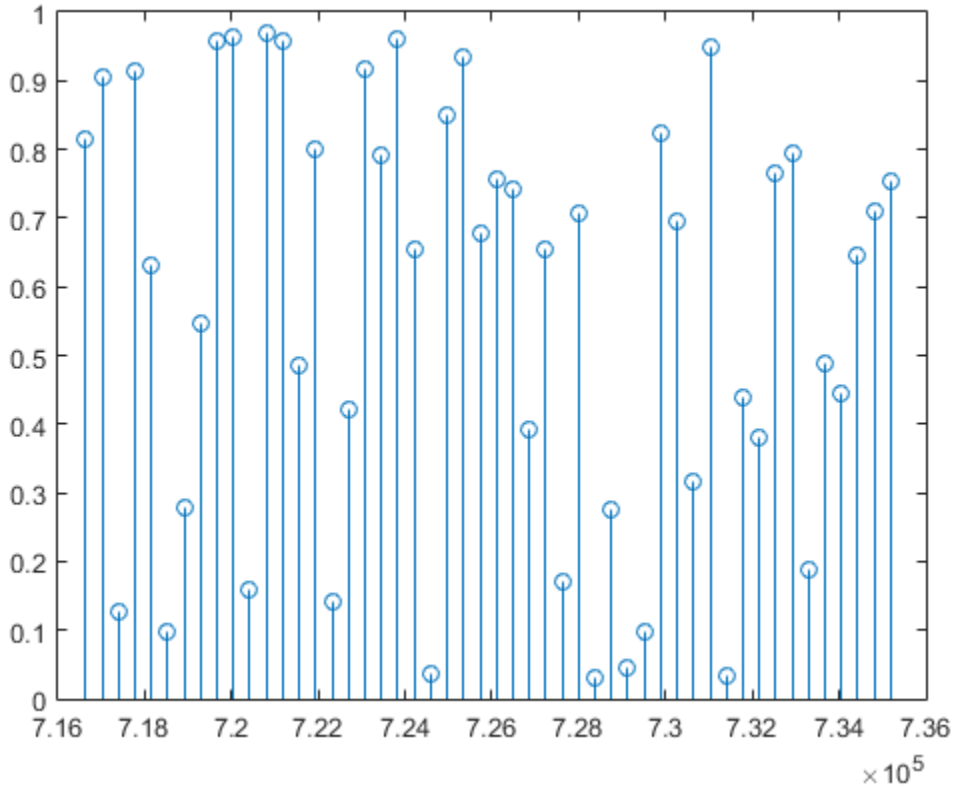
```
endDate = datenum('11-15-2012');
```

Create a variable, `xdata`, that corresponds to the number of years between the start and end dates.

```
xData = linspace(startDate,endDate,50);
```

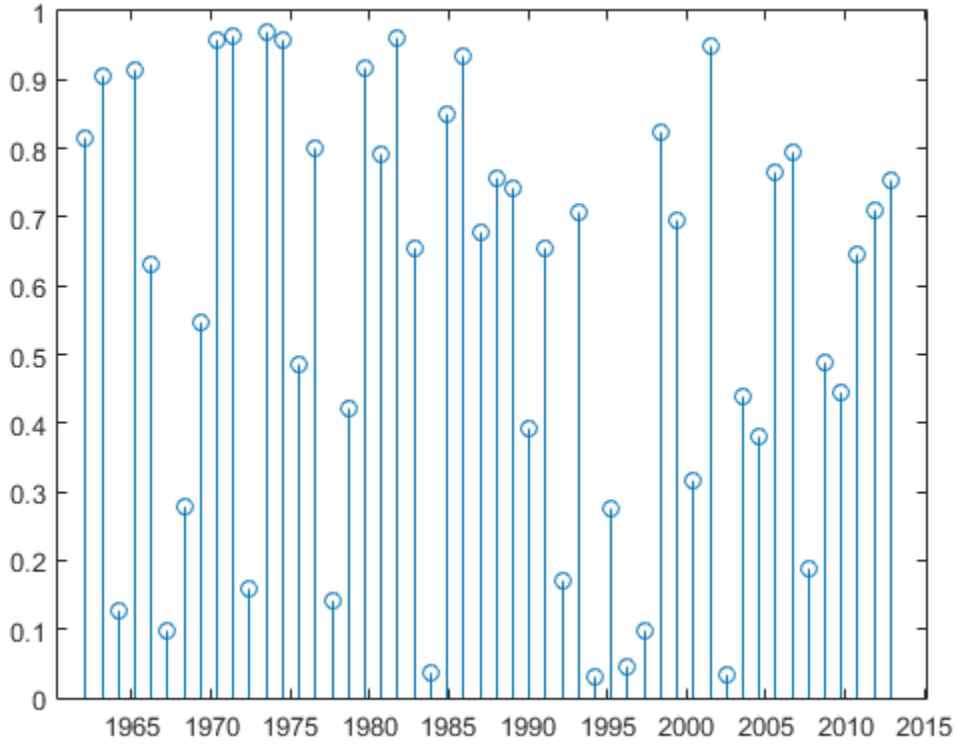
Plot random data.

```
figure
stem(xData,rand(1,50))
```



Label the *x*-axis with 4-digit years, preserving the *x*-axis limits by using the `'keeplimits'` option.

```
datetick('x','yyyy','keeplimits')
```



Add Month Labels to Plot and Preserve Number of Ticks

Select a starting date.

```
startDate = datenum('01-01-2009');
```

Select an ending date.

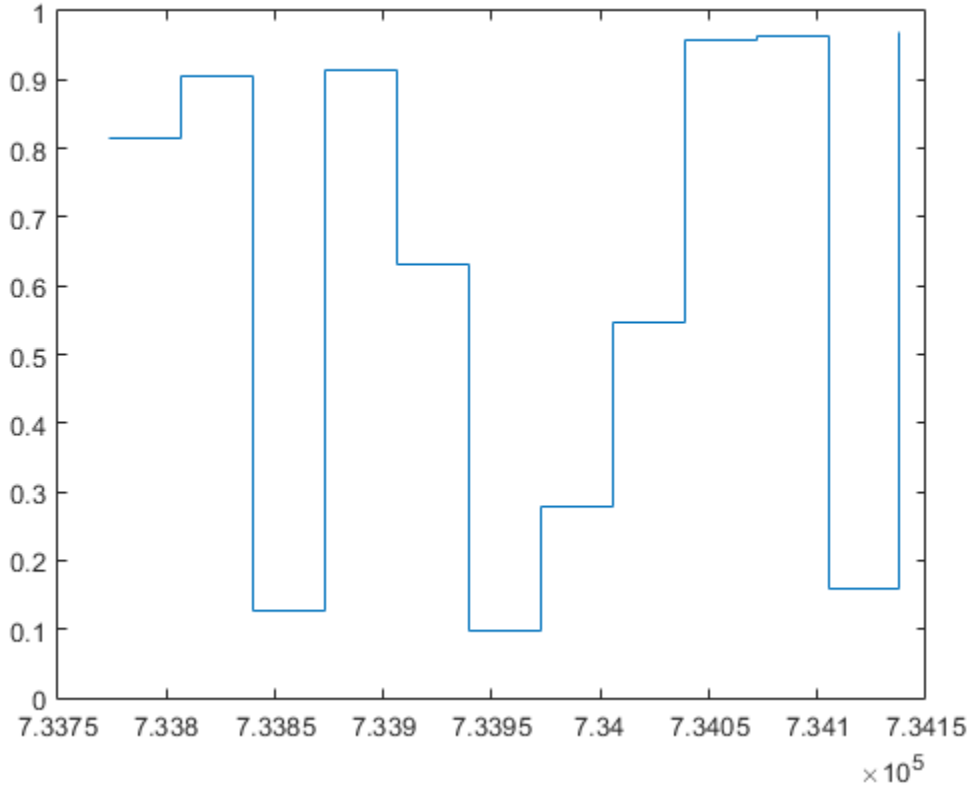
```
endDate = datenum('12-31-2009');
```

Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate,endDate,12);
```

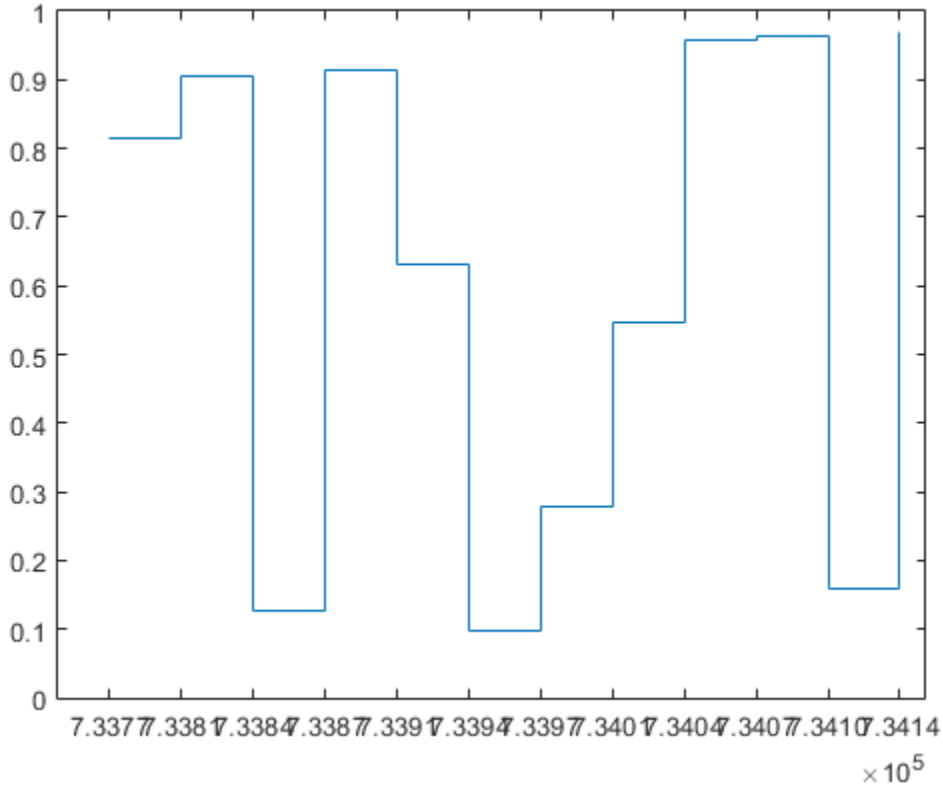
Plot random data.

```
figure
stairs(xData,rand(1,12))
```



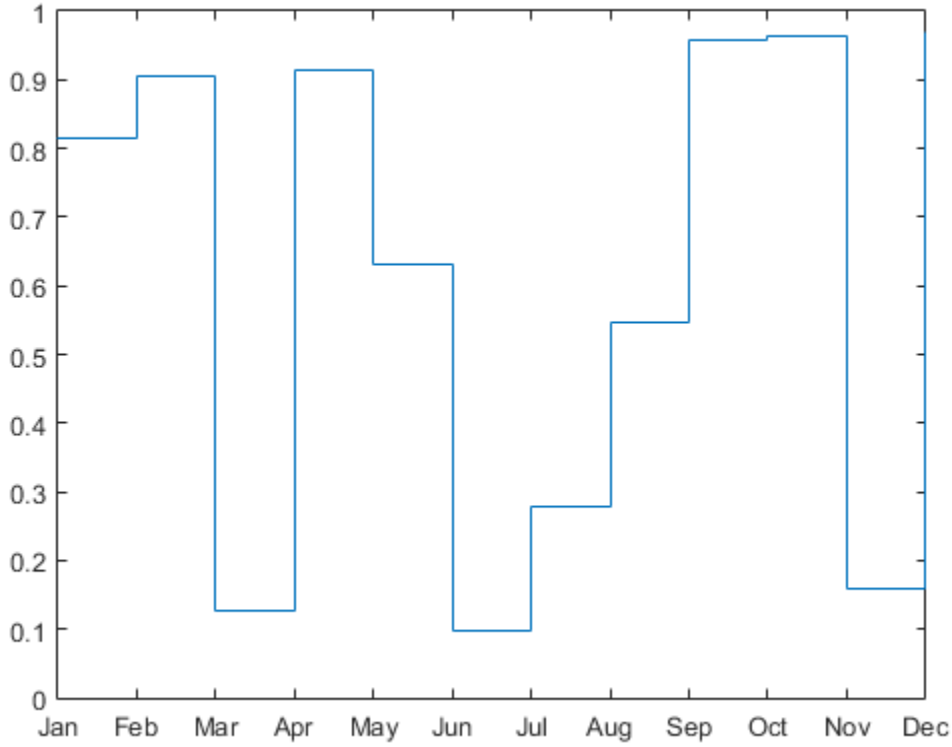
Set the number of `XTicks` to the number of points in `xData`.

```
ax = gca;
ax.XTick = xData;
```



Label the *x*-axis with month names, preserving the total number of ticks by using the `'keepticks'` option.

```
datetick('x','mmm','keepticks')
```



Create Multiple Plots Within Figure and Label Axis with Month Names

Select a starting date and an ending date.

```
startDate = datenum('01-01-2009');
endDate = datenum('12-31-2009');
```

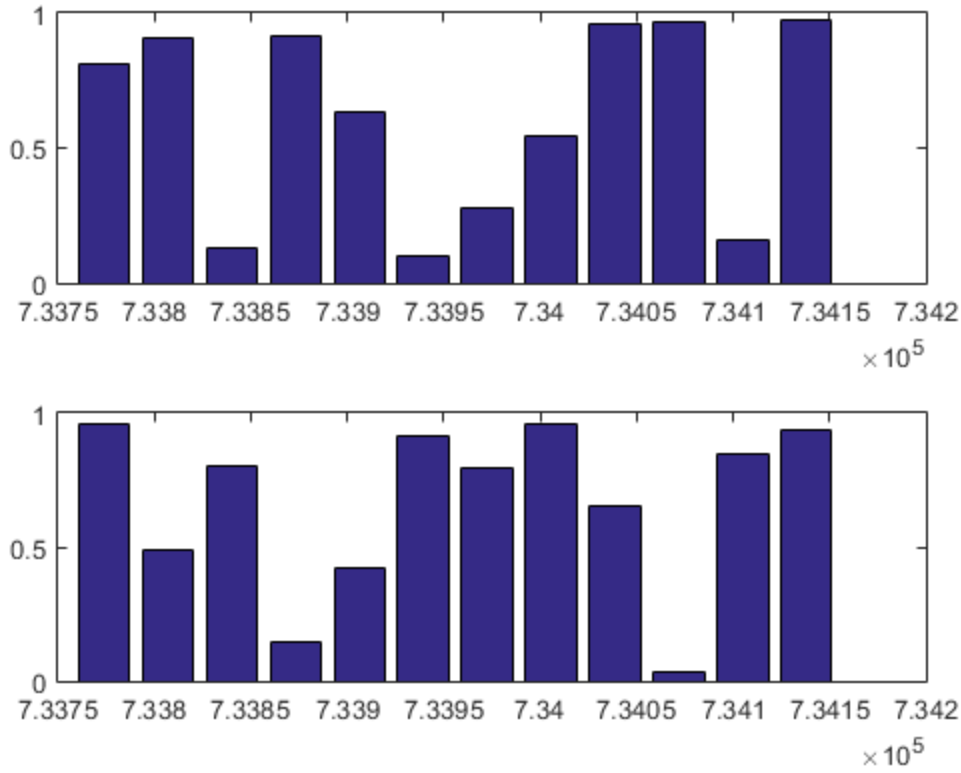
Create a variable, `xdata`, that corresponds to the number of months between the start and end dates.

```
xData = linspace(startDate,endDate,12);
```

Plot random data.

```
ax1 = subplot(2,1,1);
```

```
bar(xData,rand(1,12))
ax2 = subplot(2,1,2);
bar(xData,rand(1,12))
```

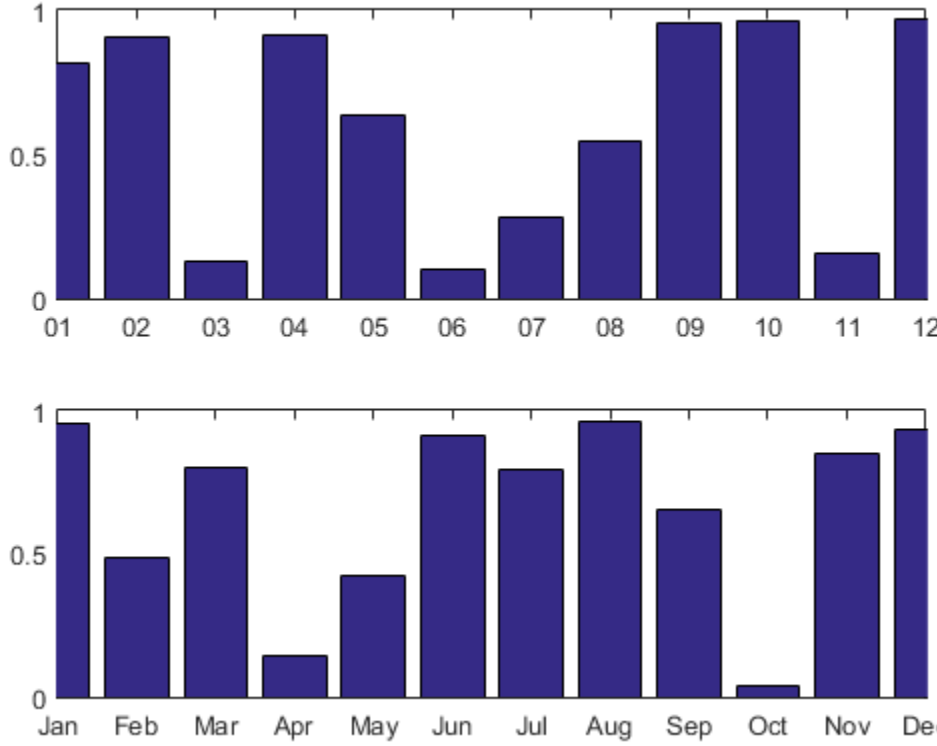


Set the number of `XTicks` to the number of points in `xData`. Label the *x*-axis of each subplot with month names, referring to each subplot using its axes handle. Preserve the total number of ticks by using the `'keepticks'` option. Starting in R2014b, you can use dot notation to set properties. If you are using an earlier release, use the set function instead.

```
ax1.XTick = xData;
datetick(ax1,'x','mm','keepticks')

ax2.XTick = xData;
```

```
datetick(ax2,'x','mmm','keepticks')
```



Input Arguments

`tickaxis` — Axis to label

`'x'` (default) | `'y'` | `'z'`

Axis to label with dates, specified as `'x'`, `'y'`, or `'z'`.

`dateFormat` — Format of tick line labels

string | integer

Format of the tick line labels, specified as a string of symbolic identifiers or an integer that corresponds to a predefined format.

The following table shows symbolic identifiers that you can use to construct the `dateFormat` string. You can include characters such as a hyphen, space, or colon to separate the fields. For example, to display the day of the month followed by the three-letter abbreviation of the day of the week in parentheses, use `dateFormat = 'dd (ddd)'`.

Note: The letter identifiers that `datetick` accepts are different from the identifiers used by the `datetime` function.

Symbolic Identifier	Description	Example
`yyyy`	Year in full	`1990`, `2002`
`yy`	Year in two digits	`90`, `02`
`QQ`	Quarter year using letter `Q` and one digit	`Q1`
`mmmm`	Month using full name	`March`, `December`
`mmm`	Month using first three letters	`Mar`, `Dec`
`mm`	Month in two digits	`03`, `12`
`m`	Month using capitalized first letter	`M`, `D`
`dddd`	Day using full name	`Monday`, `Tuesday`
`ddd`	Day using first three letters	`Mon`, `Tue`
`dd`	Day in two digits	`05`, `20`
`d`	Day using capitalized first letter	`M`, `T`
`HH`	Hour in two digits (no leading zeros when symbolic identifier `AM` or `PM` is used)	`05`, `5 AM`
`MM`	Minute in two digits	`12`, `02`
`SS`	Second in two digits	`07`, `59`
`FFF`	Millisecond in three digits	`057`

Symbolic Identifier	Description	Example
AM or PM	AM or PM inserted in date string	3:45:02 PM

The following table lists predefined MATLAB date formats.

Numeric Identifier	Date String Format	Example
-1 (default)	'dd-mmm-yyyy HH:MM:SS' or 'dd-mmm-yyyy' if 'HH:MM:SS'= 00:00:00	01-Mar-2000 15:45:17 or 01-Mar-2000
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00

Numeric Identifier	Date String Format	Example
21	`'mmm.dd,yyyy HH:MM:SS'`	`Mar.01,2000 15:45:17`
22	`'mmm.dd,yyyy'`	`Mar.01,2000`
23	`'mm/dd/yyyy'`	`03/01/2000`
24	`'dd/mm/yyyy'`	`01/03/2000`
25	`'yy/mm/dd'`	`00/03/01`
26	`'yyyy/mm/dd'`	`2000/03/01`
27	`'QQ-YYYY'`	`Q1-2001`
28	`'mmmyyyy'`	`Mar2000`
29	`'yyyy-mm-dd'` (ISO 8601)	`2000-03-01`
30	`'yyyymmddTHHMMSS'` (ISO 8601)	`20000301T154517`
31	`'yyyy-mm-dd HH:MM:SS'`	`2000-03-01 15:45:17`

More About

Tips

- To change the tick spacing and locations, set the appropriate axes property (that is, `XTick`, `YTick`, or `ZTick`) before calling `datetick`.
- Calling `datetick` sets the `TickMode` of the specified axis to `'manual'`. This means that after zooming, panning or otherwise changing axis limits, you should call `datetick` again to update the ticks and labels.
- The best way to work with dates and times in MATLAB is to use `datetime` values, which offer more features than serial date numbers. Plot `datetime` values using the `plot` function. Use the `DatetimeTickFormat` name-value pair argument to modify the format of the axis tick labels.

Algorithms

`datetick` calls the `datestr` function to convert date numbers to date strings.

- “Plot Dates and Durations”

Introduced before R2006a

datetime

Create array based on current date, or convert from date strings or numbers

The `datetime` function creates an array that represents points in time using the Gregorian calendar. `datetime` values have flexible display formats up to nanosecond precision and can account for time zones, daylight saving time, and leap seconds.

Syntax

```
t = datetime
t = datetime(relativeDay)

t = datetime(DateStrings)
t = datetime(DateStrings,'InputFormat',infmt)

t = datetime(DateVectors)
t = datetime(Y,M,D)
t = datetime(Y,M,D,H,MI,S)

t = datetime(X,'ConvertFrom',dateType)

t = datetime( ___ ,Name,Value)
```

Description

`t = datetime` returns a scalar `datetime` array corresponding to the current date and time.

`t = datetime(relativeDay)` uses the date specified by `relativeDay`. The `relativeDay` input can be `'today'`, `'tomorrow'`, `'yesterday'`, or `'now'`.

`t = datetime(DateStrings)` creates an array of datetime values representing points in time from the strings in `DateStrings`.

`t = datetime(DateStrings,'InputFormat',infmt)` interprets the strings in `DateStrings` using the format specified by `infmt`. All strings in `DateStrings` must have the same format.

To avoid ambiguities between similar formats, specify `'InputFormat'` and its corresponding value, `infmt`.

`t = datetime(DateVectors)` creates a column vector of datetime values from the date vectors in `DateVectors`.

`t = datetime(Y,M,D)` creates an array of datetime values for corresponding elements of the `Y`, `M`, and `D` (year, month, day) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D]`.

`t = datetime(Y,M,D,H,MI,S)` creates an array of `datetime` values for corresponding elements of the `Y`, `M`,`D`,`H`, `MI`, and `S` (year, month, day, hour, minute, and second) arrays. The arrays must be of the same size (or any can be a scalar). You also can specify the input arguments as a date vector, `[Y,M,D,H,MI,S]`.

`t = datetime(X,'ConvertFrom',dateType)` converts the numeric values in `X` to a `datetime` array, `t`. The `dateType` argument specifies the type of values in `X`.

`t = datetime(___,Name,Value)` specifies additional options using one or more name-value pair arguments, in addition to any of the input arguments in the previous syntaxes. For example, you can specify the display format of `t` using the `'Format'` name-value pair argument.

For best performance when creating datetime values from strings, specify either `'Format'` or `'InputFormat'` and its corresponding value, `infmt`.

Examples

Current Date and Time in Specific Time Zone

Specify the current date and time in the local system time zone.

```
t = datetime('now','TimeZone','local','Format','d-MMM-y HH:mm:ss Z')
```

```
t =

   23-Feb-2015 09:59:16 -0500
```

Specify the current date and time in the time zone represented by Seoul, Korea

```
t = datetime('now','TimeZone','Asia/Seoul','Format','d-MMM-y HH:mm:ss Z')
```

```
t =

   23-Feb-2015 23:59:16 +0900
```

Date and Time from Strings

Create a `datetime` array from a cell array of two strings.

```
DateStrings = {'2014-05-26';'2014-08-03'};
t = datetime(DateStrings,'InputFormat','yyyy-MM-dd')
```

```
t =

   26-May-2014
   03-Aug-2014
```

The datetime values in `t` display using the default format, and not the format of the input date strings.

Date and Time from Strings with Literal Characters

Convert date strings in ISO 8601 format to datetime values.

Create a cell array of strings containing dates in ISO 8601 format. In this format, the letter T is used as a delimiter that separates a date and a time. Each string includes a time zone offset. The letter Z indicates no offset from UTC.

```
DateStrings = {'2014-05-26T13:30-05:00';'2014-08-26T13:30-04:00';'2014-09-26T13:30Z'}
```

```
DateStrings =

    '2014-05-26T13:30-05:00'
    '2014-08-26T13:30-04:00'
    '2014-09-26T13:30Z'
```

Convert the strings to datetime values. When specifying the input format, enclose the letter T in single quotes to indicate that it is a literal character. Specify the time zone of the output datetime array using the `TimeZone` name-value pair argument.

```
t = datetime(DateStrings,'InputFormat','uuuu-MM-dd''T''HH:mmXXX','TimeZone','UTC')
```

```
t =

   26-May-2014 18:30:00
   26-Aug-2014 17:30:00
   26-Sep-2014 13:30:00
```

The datetime values in `t` display in the default format.

Date and Time from Strings in Foreign Language

Create a cell array of strings containing dates in French.

```
C = {'8 avril 2013','9 mai 2013';'10 juin 2014','11 juillet 2014'}
```

```
C =

    '8 avril 2013'    '9 mai 2013'
    '10 juin 2014'    '11 juillet 2014'
```

Convert the strings in `C` to datetime values. If your computer is set to a locale that uses English, you must specify the `'Locale'` name-value pair argument to indicate that the strings are in French.

```
t = datetime(C,'InputFormat','d MMMM yyyy','Locale','fr_FR')
```

```
t =

   08-Apr-2013   09-May-2013
   10-Jun-2014   11-Jul-2014
```

The datetime values in `t` display in the default format, and in the language MATLAB uses depending on your system locale.

Date and Time from Vectors

Create a `datetime` array from individual arrays of year, month, and day values.

Create sample numeric arrays of year values Y and day values D. In this case, the month value M is a scalar.

```
Y = [2014;2013;2012];
M = 01;
D = [31;30;31];
```

Create the `datetime` array.

```
t = datetime(Y,M,D)
```

```
t =

   31-Jan-2014
   30-Jan-2013
   31-Jan-2012
```

Specify a custom display format for the output, using the `Format` name-value pair argument.

```
t = datetime(Y,M,D,'Format','eeee, MMMM d, y')
```

```
t =

   Friday, January 31, 2014
   Wednesday, January 30, 2013
   Tuesday, January 31, 2012
```

Convert Excel Date Number to Datetime

Create a sample array of Excel® date numbers that represent a number of days since January 0, 1900.

```
X = [39558, 39600; 39700, 39800]
```

```
X =

       39558       39600
       39700       39800
```

Convert the values in X to datetime values.

```
t = datetime(X,'ConvertFrom','excel')
```

```
t =

   20-Apr-2008 00:00:00   01-Jun-2008 00:00:00
   09-Sep-2008 00:00:00   18-Dec-2008 00:00:00
```

Input Arguments

`relativeDay` — Day relative to current date

`'yesterday' | 'today' | 'tomorrow' | 'now'`

Day relative to the current date, specified as one of the following strings.

Value of `relativeDay`	Description
`'yesterday'`	Date of the previous day, at midnight
`'today'`	Current date, at midnight
`'tomorrow'`	Date of the following day, at midnight
`'now'`	Current date and time

`DateStrings` — Date strings

string | character array | cell array of strings

Date strings, specified as a string, character array, or a cell array of strings. The `datetime` function first attempts to match the format of the strings to some common formats. If you know the format of the date strings, you should specify `'InputFormat'` and its corresponding value, `infmt`, or the `'Format'` name-value pair argument.

Example: `'24-Oct-2014 12:45:07'`

Example: `{'15-Oct-2013' '20-Nov-2014'}`

Data Types: `char | cell`

`infmt` — Format of input date strings

string

Format of the input date strings, specified as a string of letter identifiers:

- If `infmt` does not include a date specifier, then `datetime` assumes that the values in `DateStrings` occur during the current day.
- If `infmt` does not include a time specifier, then `datetime` assumes that the values in `DateStrings` occur at midnight.
- If `infmt` includes a time-zone specifier and you do not specify a time zone, then `datetime` creates unzoned datetimes and ignores any time-zone information in `DateStrings`.

This table shows several common input formats and examples of the formatted input for the date, Saturday, April 19, 2014 at 9:41:06 PM in New York City.

Value of `Format`	Example
`'yyyy-MM-dd'`	`2014-04-19`
`'dd/MM/yyyy'`	`19/04/2014`
`'dd.MM.yyyy'`	`19.04.2014`
`'yyyy# MM# dd#'`	`2014# 04# 19#`
`'MMMM d, yyyy'`	`April 19, 2014`
`'eeee, MMMM d, yyyy h:mm a'`	`Saturday, April 19, 2014 9:41 PM`
`'MMMM d, yyyy HH:mm:ss Z'`	`April 19, 2014 21:41:06 -0400`
`'yyyy-MM-dd''T''HH:mmXXX'`	`2014-04-19T21:41-04:00`

For a complete list of valid letter identifiers, see the `Format` property for datetime arrays.

Note: The letter identifiers that `datetime` accepts are different from those used by the `datestr`, `datenum`, and `datevec` functions.

Data Types: `char`

`DateVectors` — Date vectors

matrix

Date vectors, specified as an `m`-by-6 or `m`-by-3 matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements, specifying year, month, day,

hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of `DateVector` should be a positive or negative integer value with the exception of the seconds element, which can be fractional. If an element falls outside the conventional range, `datetime` adjusts both that date vector element and the previous element. For example, if the minutes element is `70`, then `datetime` adjusts the hours element by `1` and sets the minutes element to `10`. If the minutes element is `-15`, then `datetime` decreases the hours element by `1` and sets the minutes element to `45`.

Example: `[2014,10,24,12,45,07]`

Example: `[2014,10,24]`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Y,M,D` — Year, month, and day arrays
scalar | vector | matrix | array

Year, month, and day arrays specified as a scalar, vector, matrix, or array. These must be the same size, or any one can be a scalar. `Y,M,D` should be integer values.

If `Y,M,D` are all scalars or all column vectors, you can specify the input arguments as a date vector, `[Y,M,D]`.

If an element of the `Y`, `M`, or `D` inputs falls outside the conventional range, then `datetime` adjusts both that element and the same element of the previous input. For details, see the description for the `DateVectors` input argument.

Example: `2003,10,24`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`Y,M,D,H,MI,S` — Year, month, day, hour, minute, and second arrays
scalar | vector | matrix | array

Year, month, day, hour, minute, and second arrays specified as a scalar, vector, matrix, or array. These must be the same size, or any one can be a scalar. Specify fractional seconds as part of the seconds input, `S`. The `Y,M,D,H,MI` arrays should contain integer values.

If `Y,M,D,H,MI,S` are all scalars or all column vectors, you can specify the input arguments as a date vector`[Y,M,D,H,MI,S]`.

If an element of the `Y`, `M`, `D`, `H`, `MI`, or `S` inputs falls outside the conventional range, then `datetime` adjusts both that element and the same element of the previous input. For details, see the description for the `DateVectors` input argument.

Example: `2003,10,24,12,45,07.451`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`X` — Numeric values

scalar | matrix | multidimensional array

Numeric values, specified as a scalar, matrix, or multidimensional array.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`dateType` — Type of values in `X`

`'datenum'` | `'excel'` | `'juliandate'` | `'posixtime'` | `'yyyymmdd'` | ...

Type of values in `X`, specified as one of the following strings.

Value of `dateType`	Type of values in `X`
`'datenum'`	Number of days since 0-Jan-0000 (Gregorian calendar)
`'excel'`	Number of days since 0-Jan-1900 Excel date numbers are rounded to the nearest microsecond.
`'excel1904'`	Number of days since 0-Jan-1904 Excel date numbers are rounded to the nearest microsecond.
`'juliandate'`	Number of days since noon UTC 24-Nov-4712 BCE (Gregorian calendar)
`'modifiedjuliandate'`	Number of days since midnight UTC 17-Nov-1858
`'posixtime'`	Number of seconds since 1-Jan-1970 00:00:00 UTC

Value of dateType	Type of values in X
'yyyymmdd'	Dates as YYYYMMDD numeric values. For example, 20140402 represents April 2, 2014.
'epochtime','Epoch',*epochValue*	Number of seconds since an epoch. You must additionally specify *epochValue*, which is a scalar datetime or a date string representing the epoch time. This example returns the number of days since January 1, 2000: `T = datetime(X,'ConvertFrom',... 'epochtime','Epoch','2000-01-01')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Example: 'Format','eeee MMMM d, y','TimeZone','local' applies a display format to datetime values and specifies the local time zone.

'Format' — Display format

'default' | 'defaultdate' | 'preserveinput' | string

Display format of the values in the output array, y, specified as the comma-separated pair consisting of 'Format' and one of the following strings.

Value of Format	Description
'default'	Use the default display format.
'defaultdate'	Use the default display format for datetime values created without time components.
'preserveinput'	Use the format specified by the input format, infmt. If you do not specify infmt, then datetime determines the format automatically.

The factory default format depends on your system locale. To change the default display format, see “Default datetime Format”.

Alternatively, use the letters `A-Z` and `a-z` to construct a custom value for `Format`. These letters correspond to the Unicode® Locale Data Markup Language (LDML) standard for dates. You can include non-ASCII or nonletter characters such as a hyphen, space, or colon to separate the fields. To include the letters `A-Z` and `a-z` as literal characters in the format, enclose them with single quotes.

Example: `'Format','eeee, MMMM d, yyyy HH:mm:ss'` displays a date and time such as `Saturday, April 19, 2014 21:41:06`.

This table shows several common display formats and examples of the formatted output for the date, Saturday, April 19, 2014 at 9:41:06 PM in New York City. For a complete list of valid letter identifiers, see the `Format` property for datetime arrays.

Value of `Format`	Example
`'yyyy-MM-dd'`	`2014-04-19`
`'dd/MM/yyyy'`	`19/04/2014`
`'dd.MM.yyyy'`	`19.04.2014`
`'yyyy# MM# dd#'`	`2014# 04# 19#`
`'MMMM d, yyyy'`	`April 19, 2014`
`'eeee, MMMM d, yyyy h:mm a'`	`Saturday, April 19, 2014 9:41 PM`
`'MMMM d, yyyy HH:mm:ss Z'`	`April 19, 2014 21:41:06 -0400`
`'yyyy-MM-dd''T''HH:mmXXX'`	`2014-04-19T21:41-04:00`

Note: The letter identifiers that `datetime` accepts are different from those used by the `datestr`, `datenum`, and `datevec` functions.

If you specify a `DateStrings` input but do not specify the `'InputFormat'` parameter, then `datetime` tries to use the `Format` value to interpret the strings.

Data Types: `char`

`'Locale'` — Locale of `DateStrings`

string

Locale of the date strings in `DateStrings`, specified as the comma-separated pair consisting of `'Locale'` and a string. The `Locale` value determines how `datetime` interprets the strings in `DateStrings`. However, the output `datetime` values always display in the system locale.

The `Locale` value can be:

- `'system'`, to specify your system locale.
- a string in the form *`xx_YY`*, where *`xx`* is a lowercase ISO 639-1 two-letter code that specifies a language, and *`YY`* is an uppercase ISO 3166-1 alpha-2 code that specifies a country.

This table lists some common values for the locale.

Locale	Language	Country
`'de_DE'`	German	Germany
`'en_GB'`	English	United Kingdom
`'en_US'`	English	United States
`'es_ES'`	Spanish	Spain
`'fr_FR'`	French	France
`'it_IT'`	Italian	Italy
`'ja_JP'`	Japanese	Japan
`'ko_KR'`	Korean	Korea
`'nl_NL'`	Dutch	Netherlands
`'zh_CN'`	Chinese (simplified)	China

You can use the `'Locale'` name-value pair only when you use the `DateStrings` input argument.

Example: `'Locale','de_DE'`

Data Types: `char`

`'PivotYear'` — Start year of 100-year date range

`year(datetime('now'))-50` (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as the comma-separated pair consisting of `'PivotYear'` and an integer. Use a pivot year to

interpret date strings that specify the year as two characters. That is, the pivot year has an effect only when the `infmt` argument includes `y` or `yy`.

You can use the `'PivotYear'` name-value pair only when you use the `DateStrings` input argument.

Example: `'PivotYear',1900`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

`'TimeZone'` — Time zone region

`''` (default) | string

Time zone region, specified as the comma-separated pair consisting of `'TimeZone'` and a string. The value of `TimeZone` specifies the time zone that the `datetime` function uses to interpret the input data. `TimeZone` also specifies the time zone of the output array, `T`. If the input data are strings that include a time zone, then the `datetime` function converts all values to the specified time zone

The value of `TimeZone` can be:

- `''`, to create an "unzoned" `datetime` array that does not belong to a specific time zone.
- The name of a time zone region from the IANA Time Zone Database, for example, `'America/Los_Angeles'`. The name of a time zone region accounts for the current and historical rules for standard and daylight offsets from UTC that are observed in a geographic region.
- An ISO 8601 string of the form `+HH:mm` or `-HH:mm`, for example, `'+01:00'`, to specify a time zone that is a fixed offset from UTC.
- `'UTC'`, to create a `datetime` array in Universal Coordinated Time.
- `'UTCLeapSeconds'`, to create a `datetime` array in Universal Coordinated Time that accounts for leap seconds.
- `'local'`, to create a `datetime` array in the system time zone.

This table lists some common names of time zone regions from the IANA Time Zone Database.

Value of `TimeZone`	UTC Offset	UTC DST Offset
`'Africa/Johannesburg'`	+02:00	+02:00

Value of TimeZone	UTC Offset	UTC DST Offset
'America/Chicago'	−06:00	−05:00
'America/Denver'	−07:00	−06:00
'America/Los_Angeles'	−08:00	−07:00
'America/New_York'	−05:00	−04:00
'America/Sao_Paulo'	−03:00	−02:00
'Asia/Hong_Kong'	+08:00	+08:00
'Asia/Kolkata'	+05:30	+05:30
'Asia/Tokyo'	+09:00	+09:00
'Australia/Sydney'	+10:00	+11:00
'Europe/London'	+00:00	+01:00
'Europe/Zurich'	+01:00	+02:00

Data Types: char

Output Arguments

t — Dates and time

datetime array

Dates and time, returned as a datetime array. Each element includes a date and a time of day.

t has the following properties.

Property	Description
Format	Display format of the values in t, specified as a string
TimeZone	Time zone in which the values in t are interpreted, specified as a string
Year	Array containing the year number of each element in t
Month	Array containing the month number of each element in t
Day	Array containing the day of month number of each element in t

Property	Description
`Hour`	Array containing the hour of each element in `t`
`Minute`	Array containing the minute of each element in `t`
`Second`	Array containing the second, including a fractional part, of each element in `t`

After you create a `datetime` array, `t`, you can access or change the value of any of its properties using dot notation. For example, to display the values of `t` in the format, `'yyyy-MM-dd'`, type:

```
t.Format = 'yyyy-MM-dd';
```

More About

- "Represent Dates and Times in MATLAB"
- "Share Code and Data Across Locales"

See Also

datetime Properties

Introduced in R2014b

datetime Properties

Assign date and time components and specify datetime display format

The `Format` property controls the display of `datetime` values. The other properties control the values of components such as years and months in the `datetime` array. Use dot notation to refer to a particular array and property:

```
t = datetime(2014,07,01,06,0,0);
t.Format = 'MMMM d, y';
```

Properties

`Format` — Display format

`'default'` | `'defaultdate'` | string

Display format, specified as a string of the letters `A-Z` and `a-z`, that correspond to the Unicode Locale Data Markup Language (LDML) standard for dates.

Example: `'eeee, MMMM d, yyyy HH:mm:ss'` displays a date and time such as `Saturday, April 5, 2014 21:41:06`.

The following tables show the letters you can use to construct the value for `Format`. You can include nonletter characters such as a hyphen, space, colon, or any non-ASCII characters to separate the fields. To include the letters `A-Z` and `a-z` as literal characters in the format, enclose them with single quotes.

Example: `'uuuu-MM-dd''T''HH:mm:ss'` displays a date and time, such as `2014-04-05T09:41:06`.

The examples display the formatted output for the date, Saturday, April 5, 2014 at 9:41:06.12345 PM, in New York City.

Date and Time Formats

Use these identifiers to specify the display formats of date and time fields.

Letter Identifier	Description	Display
`G`	Era	`CE`

Letter Identifier	Description	Display
y	Year, with no leading zeros. See the Note that follows this table.	2014
yy	Year, using last two digits. See the Note that follows this table.	14
yyy, yyyy ...	Year, using at least the number of digits specified by the number of instances of 'y'	For the year 2014, 'yyy' displays 2014, while 'yyyyy' displays 02014.
u, uu, ...	ISO year. A single number designating the year. An ISO year value assigns positive values to CE years and negative values to BCE years, with 1 BCE being year 0.	2014
Q	Quarter, using one digit	2
QQ	Quarter, using two digits	02
QQQ	Quarter, abbreviated	Q2
QQQQ	Quarter, full name	2nd quarter
M	Month, numerical using one or two digits	4
MM	Month, numerical using two digits	04
MMM	Month, abbreviated name	Apr
MMMM	Month, full name	April
MMMMM	Month, capitalized first letter	A
W	Week of the month	1
d	Day of the month, using one or two digits	5
dd	Day of the month using two digits	05
D	Day of the year, using one, two or three digits	95
DD	Day of the year using two digits	95
DDD	Day of the year using three digits	095

Letter Identifier	Description	Display
e	Day of the week, numerical using one or two digits.	7, where Sunday is the first day of the week.
ee	Day of the week, numerical using two digits	07
eee	Day, abbreviated name	Sat
eeee	Day, full name	Saturday
eeeee	Day, capitalized first letter	S
a	Day period (AM or PM)	PM
h	Hour, 12-hour clock notation using one or two digits	9
hh	Hour, 12-hour clock notation using two digits	09
H	Hour, 24-hour clock notation using one or two digits	21
HH	Hour, 24-hour clock notation using two digits	21
m	Minute, using one or two digits	41
mm	Minute, using two digits	41
s	Second, using one or two digits	6
ss	Second, using two digits	06
S, SS, ..., SSSSSSSSS	Fractional second, using the number of digits specified by the number of instances of 'S' (up to 9 digits).	'SSS' truncates 6.12345 seconds to 123.

Note: If you read a two-digit year number and specify the format as y or yy, then the pivot year determines the century to which the year belongs.

Use one or more u characters instead of y characters to represent the year when working with year numbers near zero.

Datetime values later than 144683 years CE or before 140743 BCE display only the year numbers, regardless of the specified `Format` value.

Time Zone Offset Formats

Use these identifiers to specify the display format of the time zone offset. A time zone offset is the amount of time that a specific datetime is offset from UTC. This is different from a time zone, which comprises rules that determine the offsets that are used at specific times of the year. Include a time zone offset identifier in the display format for a datetime array when you want to ensure that the time components are displayed unambiguously.

Letter Identifier	Description	Display
`z`	Abbreviated name of the time zone offset. If this value is not available, then the time zone offset uses the short UTC format, such as `UTC-4`.	`EDT`
`Z`	ISO 8601 basic format with hours, minutes, and optional seconds fields.	`-0400`
`ZZZZ`	Long UTC format.	`UTC-04:00`
`ZZZZZ`	ISO 8601 extended format with hours, minutes, and optional seconds fields. A time offset of zero is displayed as the ISO 8601 UTC indicator “Z”.	`-04:00`
`x` or `X`	ISO 8601 basic format with hours field and optional minutes field. If you specify `X`, a time offset of zero is displayed as the ISO 8601 UTC indicator “Z”.	`-04`
`xx` or `XX`	ISO 8601 basic format with hours and minutes fields. If you specify `XX`, a time offset of zero is displayed as the ISO 8601 UTC indicator “Z”.	`-0400`
`xxx` or `XXX`	ISO 8601 extended format with hours and minutes fields. If you	`-04:00`

Letter Identifier	Description	Display
	specify `XXX`, a time offset of zero is displayed as the ISO 8601 UTC indicator "Z".	
`xxxx` or `XXXX`	ISO 8601 basic format with hours, minutes, and optional seconds fields. If you specify `XXXX`, a time offset of zero is displayed as the ISO 8601 UTC indicator "Z".	`-0400`
`xxxxx` or `XXXXX`	ISO 8601 extended format with hours, minutes, and optional seconds fields. If you specify `XXXXX`, a time offset of zero is displayed as the ISO 8601 UTC indicator "Z".	`-04:00`

`TimeZone` — Time zone

`''` (default) | string

Time zone, specified as one of the following strings:

- `''`, to create an "unzoned" `datetime` array that does not belong to a specific time zone.
- The name of a time zone region from the IANA Time Zone Database, for example, `'America/Los_Angeles'`. The name of a time zone region accounts for the current and historical rules for standard and daylight offsets from UTC that are observed in a geographic region.
- An ISO 8601 string of the form `+HH:mm` or `-HH:mm`, for example, `'+01:00'`, to specify a time zone that is a fixed offset from UTC.
- `'UTC'`, to create a `datetime` array in Universal Coordinated Time.
- `'UTCLeapSeconds'`, to create a `datetime` array in Universal Coordinated Time that accounts for leap seconds.
- `'local'`, to create a `datetime` array in the system time zone. When you query the `TimeZone` property, the IANA string is returned.

This table lists some common names of time zone regions from the IANA Time Zone Database.

Value of TimeZone	UTC Offset	UTC DST Offset
'Africa/Johannesburg'	+02:00	+02:00
'America/Chicago'	−06:00	−05:00
'America/Denver'	−07:00	−06:00
'America/Los_Angeles'	−08:00	−07:00
'America/New_York'	−05:00	−04:00
'America/Sao_Paulo'	−03:00	−02:00
'Asia/Hong_Kong'	+08:00	+08:00
'Asia/Kolkata'	+05:30	+05:30
'Asia/Tokyo'	+09:00	+09:00
'Australia/Sydney'	+10:00	+11:00
'Europe/London'	+00:00	+01:00
'Europe/Zurich'	+01:00	+02:00

Data Types: char

Year — Year number

scalar | vector | matrix | multidimensional array

Year number of each value in the datetime array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the datetime array. Each year number is an integer value based on the ISO calendar. Years in the current era are positive and years in the previous era are zero or negative. For example, the year number of 1 BCE is 0.

If you set the Year property to a nonleap year for a datetime value that occurs on a leap day (February 29), then the Day and Month properties change to March 1.

Month — Month number

scalar | vector | matrix | multidimensional array

Month number of each value in the datetime array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the datetime array. Each month number is an integer value from 1 to 12. If you set a value outside that range, then the Year property adjusts accordingly, and the Month property stays within the

range 1 to 12. For example, month 0 corresponds to month 12 of the previous year. For historical dates, the month number is based on the proleptic Gregorian calendar.

`Day` — Day number

scalar | vector | matrix | multidimensional array

Day number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each day number is an integer value from 1 to 28, 29, 30, or 31, depending on the month and year. If you set a value outside that range, then the `Month` and `Year` properties adjust accordingly, and the `Day` property stays within the appropriate range. For example, day 0 corresponds to the last day of the previous month. For historical dates, the day number is based on the proleptic Gregorian calendar.

`Hour` — Hour number

scalar | vector | matrix | multidimensional array

Hour number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each hour number is an integer value from 0 to 23. If you set a value outside that range, then the `Day`, `Month`, and `Year` properties adjust accordingly, and the `Hour` property stays within the appropriate range. For example, hour -1 corresponds to hour 23 of the previous day.

The following apply to datetime arrays with a specific time zone that follows daylight saving time:

- If you specify a value for the `Hour` property that would create a nonexistent datetime in the hour gap when daylight saving time begins, the value of the `Hour` property adjusts to the next hour.
- If you specify a value for the `Hour` property that would create an ambiguous datetime in the hour overlap when daylight saving time ends, then the datetime adjusts to the second of the two times (in standard time) with that hour.

`Minute` — Minute number

scalar | vector | matrix | multidimensional array

Minute number of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each minute number is an integer value from 0 to 59. If you specify a value outside that range, then the `Hour`, `Day`, `Month`, and `Year` properties adjust accordingly, and the `Minute`

property stays within the appropriate range. For example, minute -1 corresponds to minute 59 of the previous hour.

`Second` — Second

scalar | vector | matrix | multidimensional array

Second of each value in the `datetime` array, specified as a scalar or a vector, matrix, or multidimensional array the same size and shape as the `datetime` array. Each second value is a floating-point value ordinarily ranging from 0 to less than 60. If you set a value outside that range, then the `Minute`, `Hour`, `Day`, `Month`, and `Year` properties adjust accordingly, and the `Second` property stays within the appropriate range. For example, second -1 corresponds to second 59 of the previous minute.

A `datetime` array with a `TimeZone` value of `'UTCLeapSeconds'` has seconds ranging from 0 to less than 61. The values from 60 to 61 represent datetimes that occur during a leap second.

`SystemTimeZone` — System time zone setting

string

System time zone setting, specified as a string. This time zone setting is determined by the system on which MATLAB is running.

Example: `America/New_York`

See Also

`datetime`

datevec

Convert date and time to vector of components

The `datevec` function creates a numeric array whose values represent the date and time components of years, months, days, hours, minutes, and seconds. However, the best way to represent points in time is by using the `datetime` data type. The best way to represent elapsed time is by using the `duration` or `calendarDuration` data types.

Syntax

```
DateVector = datevec(t)
DateVector = datevec(DateNumber)

DateVector = datevec(DateString)
DateVector = datevec(DateString,formatIn)
DateVector = datevec(DateString,PivotYear)
DateVector = datevec(DateString,formatIn,PivotYear)

[Y,M,D,H,MN,S] = datevec( ___ )
```

Description

`DateVector = datevec(t)` converts the datetime values in `datetime` array `t` to date vectors. `datevec` returns an `m`-by-6 matrix where each row corresponds to a datetime value in `t`.

`DateVector = datevec(DateNumber)` converts one or more date numbers to date vectors. `datevec` returns an `m`-by-6 matrix containing `m` date vectors, where `m` is the total number of date numbers in `DateNumber`.

`DateVector = datevec(DateString)` converts date strings to date vectors. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn)` uses `formatIn` to interpret each date string.

`DateVector = datevec(DateString,PivotYear)` uses `PivotYear` to interpret date strings that specify the year as two characters. If the date string format is known, use `formatIn`. Syntaxes without `formatIn` are significantly slower than those that include it.

`DateVector = datevec(DateString,formatIn,PivotYear)` uses `formatIn` to interpret each date string, and `PivotYear` to interpret date strings that specify the year as two characters. You can specify `formatIn` and `PivotYear` in either order.

`[Y,M,D,H,MN,S] = datevec( ___ )` returns the components of the date vector as individual variables `Y`, `M`, `D`, `H`, `MN`, and `S` (year, month, day, hour, minutes and seconds). `datevec` returns milliseconds as a fractional part of the seconds (`S`) output.

Examples

Convert datetime Array to Date Vectors

```
format short g

t = [datetime('now');datetime('tomorrow')]
DateVector = datevec(t)
```

```
t =

   23-Feb-2015 09:59:20
   24-Feb-2015 00:00:00

DateVector =

         2015           2          23           9          59       20.352
         2015           2          24           0           0            0
```

Convert Date Number to Date Vector

```
format short g

n = 733779.651;
datevec(n)
```

```
ans =

        2009           1           6          15          37        26.4
```

Convert Date String to Date Vector

```
DateString = '28.03.2005';
formatIn = 'dd.mm.yyyy';
datevec(DateString,formatIn)
```

```
ans =

        2005           3          28           0           0           0
```

`datevec` returns a date vector for the date string with the format `'dd.mm.yyyy'`.

Convert Multiple Date Strings to Date Vectors

Pass multiple date strings in a cell array. All input date strings must use the same format.

```
DateString = {'09/16/2007';'05/14/1996';'11/29/2010'};
formatIn = 'mm/dd/yyyy';
datevec(DateString,formatIn)
```

```
ans =

        2007           9          16           0           0           0
        1996           5          14           0           0           0
        2010          11          29           0           0           0
```

Convert Date with Milliseconds to Date Vector

```
datevec('11:21:02.647','HH:MM:SS.FFF')
```

```
ans =

   1.0e+03 *

    2.0150    0.0010    0.0010    0.0110    0.0210    0.0026
```

In the output date vector, milliseconds are a fractional part of the seconds field. The date string `'11:21:02.647'` does not contain enough information to convert to a full date vector. The days default to 1, months default to January, and years default to the current year.

Convert Date String to Date Vector Using Pivot Year

Convert a date string to a date vector using the default pivot year.

```
DateString = '12-jun-17';
formatIn = 'dd-mmm-yy';
DateVector = datevec(DateString,formatIn)
```

```
DateVector =

        2017           6          12           0           0           0
```

Convert the same date string to a date vector using 1800 as the pivot year.

```
DateVector = datevec(DateString,formatIn,1800)
```

```
DateVector =

        1817           6          12           0           0           0
```

Assign Elements of Returned Date Vector

Convert a date string to a date vector and return the components of the date vector.

```
[y, m, d, h, mn, s] = datevec('01.02.12','dd.mm.yy')
```

```
y =

        2012
```

```
m =
```

```
     2

d =

     1

h =

     0

mn =

     0

s =

     0
```

Input Arguments

`t` — `datetime` values

scalar | vector | matrix | multidimensional array

`datetime` values, specified as a scalar, vector, matrix, or multidimensional `datetime` array.

`DateNumber` — Serial date number

scalar | vector | multidimensional array

Serial date number, specified as a scalar, vector, or multidimensional array of positive double-precision numbers.

Example: `731878`

Data Types: `double`

`DateString` — Date strings

string | character array | 1–D cell array of strings

Date strings, specified as a character array where each row corresponds to one date string, or as a one dimensional cell array of strings. All of the date strings must have the same format.

Example: `'24–Oct-2003 12:45:07'`

Example: `['19-Sep-2013';'20-Sep-2013';'21-Sep-2013']`

Example: `{'15-Oct-2010' '20-Nov-2012'}`

If the date string format is known, you should also specify `formatIn`. If you do not specify `formatIn`, `DateString` must be in one of the following formats.

Date String Format	Example
`'dd-mmm-yyyy HH:MM:SS'`	`01-Mar-2000 15:45:17`
`'dd-mmm-yyyy'`	`01-Mar-2000`
`'mm/dd/yyyy'`	`03/01/2000`
`'mm/dd/yy'`	`03/01/00`
`'mm/dd'`	`03/01`
`'mmm.dd,yyyy HH:MM:SS'`	`Mar.01,2000 15:45:17`
`'mmm.dd,yyyy'`	`Mar.01,2000`
`'yyyy-mm-dd HH:MM:SS'`	`2000-03-01 15:45:17`
`'yyyy-mm-dd'`	`2000-03-01`
`'yyyy/mm/dd'`	`2000/03/01`
`'HH:MM:SS'`	`15:45:17`
`'HH:MM:SS PM'`	`3:45:17 PM`
`'HH:MM'`	`15:45`
`'HH:MM PM'`	`3:45 PM`

Note: The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

Certain date string formats might not contain enough information to convert the date string. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. `datevec` and `datenum`

consider two-character date string years (e.g., `'79'`) to fall within the 100-year range centered around the current year.

When you do not specify `formatIn`, note the following:

- For the formats that specify the month as two digits (`mm`), the month value must not be greater than 12.
- However, for the format `'mm/dd/yy'`, if the first entry in the date string is greater than 12 and the second entry is less than or equal to 12, then `datevec` considers the date string to be in `'yy/mm/dd'` format.

`formatIn` — Format of the input date string

string

Format of the input date string, specified as a string of symbolic identifiers.

The following table shows symbolic identifiers you can use to construct the `formatIn` string. You can include characters such as a hyphen, space, or colon to separate the fields.

Note: The symbolic identifiers describing date string formats are different from those that describe the display formats of `datetime` arrays.

Symbolic Identifier	Description	Example
`yyyy`	Year in full	`1990`, `2002`
`yy`	Year in two digits	`90`, `02`
`QQ`	Quarter year using letter `Q` and one digit	`Q1`
`mmmm`	Month using full name	`March`, `December`
`mmm`	Month using first three letters	`Mar`, `Dec`
`mm`	Month in two digits	`03`, `12`
`m`	Month using capitalized first letter	`M`, `D`
`dddd`	Day using full name	`Monday`, `Tuesday`
`ddd`	Day using first three letters	`Mon`, `Tue`

Symbolic Identifier	Description	Example
dd	Day in two digits	05, 20
d	Day using capitalized first letter	M, T
HH	Hour in two digits (no leading zeros when symbolic identifier AM or PM is used)	05, 5 AM
MM	Minute in two digits	12, 02
SS	Second in two digits	07, 59
FFF	Millisecond in three digits	057
AM or PM	AM or PM inserted in date string	3:45:02 PM

The `formatIn` string must follow these guidelines:

- You cannot specify any field more than once. For example, you cannot use `'yy-mmm-dd-m'` because it has two month identifiers. The one exception to this is that you can combine one instance of `dd` with one instance of any of the other day identifiers. For example, `'dddd mmm dd yyyy'` is a valid input.
- When you use `AM` or `PM`, the `HH` field is also required.
- `datevec` does not accept formats that include `'QQ'`

`PivotYear` — Start year of 100-year date range

present minus 50 years (default) | integer

Start year of the 100-year date range in which a two-character year resides, specified as an integer. Use a pivot year to interpret date strings that specify the year as two characters.

If `formatIn` contains the time of day, the pivot year is computed from the current time of the current day, month, and year. Otherwise it is computed from midnight of the current day, month, and year.

Example: `2000`

Data Types: `double`

Output Arguments

`DateVector` — Date vectors
vector | matrix

Date vectors, returned as an `m`-by-6 matrix, where each row corresponds to one date vector, and `m` is the total number of input date numbers or date strings.

`[Y,M,D,H,MN,S]` — Components of the date vector
scalar

Components of the date vector (year, month, day, hour, minute, and second), returned as individual scalar variables. Each variable is a scalar or a vector. Milliseconds are a fractional part of the seconds output. When converting a `datetime` array `t`, these components are equal to the values of the `Year`, `Month`, `Day`, `Hour`, `Minute`, and `Second` properties. For example, `Y = t.Year`.

Limitations

- When computing date vectors, `datevec` sets month values less than 1 to 1. Day values, `D`, less than 1 are set to the last day of the previous month minus `|D|`. However, if $0 \le$ DateNumber < 1, then `datevec(DateNumber)` returns a date vector of the form `[0 0 0 H MN S]`, where `H`, `MN`, and `S` are hours, minutes, and seconds, respectively.

More About

Tips

- The vectorized calling syntax can offer significant performance improvement for large arrays.

- "Represent Dates and Times in MATLAB"
- "Carryover in Date Vectors and Strings"

See Also

`datenum` | `datestr` | `datetime`

Introduced before R2006a

day

Day number or name

Syntax

```
d = day(t)
d = day(t,dayType)
```

Description

`d = day(t)` returns the day-of-month numbers for the datetime values in `t`. The `d` output contains integer values from 1 to 31, depending on the month and year.

`d = day(t,dayType)` returns the type of day number or name specified by `dayType`.

The `day` function returns the day numbers or names of datetime values. To assign day values to datetime array `t`, use `t.Day` and modify the `Day` property.

Examples

Extract Day Number from Dates

Extract the day of month numbers from an array of dates.

```
t = [datetime('yesterday');datetime('today');datetime('tomorrow')]
d = day(t)
```

```
t =

   22-Feb-2015
   23-Feb-2015
   24-Feb-2015

d =
```

```
    22
    23
    24
```

Determine Day of Week

Determine the day of the week for an arbitrary date, by specifying `'name'` as the second input to the `day` function.

```
t = datetime(2014,05,16)
```

```
t =

   16-May-2014
```

```
d = day(t,'name')
```

```
d =

    'Friday'
```

Alternatively, specify `'dayofweek'` to return the day of the week as a number.

```
d = day(t,'dayofweek')
```

```
d =

     6
```

Input Arguments

`t` — Input date and time

`datetime` array

Input date and time, specified as a `datetime` array.

dayType — Type of day values

'dayofmonth' (default) | 'dayofweek' | 'dayofyear' | 'name' | 'shortname'

Type of day values, specified as one of the following strings.

Value of dayType	Description
'dayofmonth'	Day-of-month number, from 1 to 28, 29, 30, or 31. The range depends on the month.
'dayofweek'	Day-of-week number, from 1 to 7, where day 1 of the week is Sunday.
'dayofyear'	Day-of-year number, from 1 to 365 or 366, depending on the year.
'name'	Full day names, for example, Sunday.
'shortname'	Abbreviated day names, for example, Sun.

Output Arguments

d — Day number or name

double array | cell array of strings

Day number or name, returned as a numeric array of integers of type double, or a cell array of strings. d is the same size as t.

See Also

datetime Properties | isweekend | month | quarter | week | year | ymd

Introduced in R2014b

days

Duration in days

Syntax

```
D = days(X)
```

Description

`D = days(X)` returns an array of days equivalent to the values in `X`.

- If `X` is a numeric array, then `D` is a `duration` array in units of fixed-length days. A fixed-length day is equal to 24 hours.
- If `X` is a `duration` array, then `D` is a `double` array with each element equal to the number of fixed-length (24-hour) days in the corresponding element of X.

The `days` function converts between `duration` and `double` values. To display a duration in units of days, set its `Format` property to `'d'`.

Examples

Create Duration Array of Fixed-Length Days

```
X = magic(2);
D = days(X)
```

```
D =

    1 day   3 days
   4 days   2 days
```

Add each number of fixed-length days to the current date and time.

```
t = datetime('now') + D
```

```
t =

   24-Feb-2015 10:14:16   26-Feb-2015 10:14:16
   27-Feb-2015 10:14:16   25-Feb-2015 10:14:16
```

Convert Durations to Numeric Array of Days

Create a `duration` array.

```
X = hours(23:20:95) + minutes(45)
```

```
X =

   23.75 hrs   43.75 hrs   63.75 hrs   83.75 hrs
```

Convert each duration in `X` to a number of days.

```
D = days(X)
```

```
D =

    0.9896    1.8229    2.6563    3.4896
```

Input Arguments

`X` — Input array

numeric array | duration array | logical array

Input array, specified as a numeric array, duration array, or logical array.

More About

Tips

- `days` creates fixed-length (24 hour) days. To create days that account for Daylight Saving Time shifts when used in calendar calculations, use the `caldays` function.

See Also

`caldays` | `duration`

Introduced in R2014b

dbclear

Clear breakpoints

Syntax

```
dbclear all
dbclear in file ...
dbclear in file ... -completenames
dbclear if error ...
dbclear if warning ...
dbclear if naninf
dbclear if infnan
```

Description

`dbclear all` removes all breakpoints in all MATLAB code files, as well as breakpoints set for errors, caught errors, caught error identifiers, warnings, warning identifiers, and `naninf`/`infnan`.

`dbclear in file ...` and `dbclear in file ... -completenames` formats are listed here:

Format	Action
`dbclear in file`	Removes all breakpoints in `file`. `file` must be the name of a MATLAB program file, and can include a MATLAB partial path.
`dbclear in file -completenames`	If the command includes the `-completenames` option, then `file` need not be on the path, as long as it is a fully qualified file name. (On Microsoft Windows platforms, this is a file name that begins with `\\` or with a drive letter followed by a colon. On UNIX platforms, this is a file name that begins with `/` or `~`.) `file` can include a `>` to specify the path to a particular local function or to a nested function within a code file.
`dbclear in file at lineno`	Removes the breakpoint set at line number `lineno` in `file`.
`dbclear in file at lineno@`	Removes the breakpoint set in the anonymous function at line number `lineno` in `file`.

Format	Action
`dbclear in file at lineno@n`	Removes the breakpoint set in the `n`th anonymous function at line number `lineno` in `file`.
`dbclear in file at locfun`	Removes all breakpoints in local function `locfun` in `file`.

`dbclear if error ...` formats are listed here:

Format	Action
`dbclear if error`	Removes the breakpoints set using the `dbstop if error` and `dbstop if error identifier` statements.
`dbclear if error identifier`	Removes the breakpoint set using `dbstop if error identifier` for the specified `identifier`. Running this produces an error if `dbstop if error` or `dbstop if error all` is set.
`dbclear if caught error`	Removes the breakpoints set using the `dbstop if caught error` and `dbstop if caught error identifier` statements.
`dbclear if caught error identifier`	Removes the breakpoints set using the `dbstop if caught error identifier` statement for the specified identifier. Running this produces an error if `dbstop if caught error` or `dbstop if caught error all` is set.

`dbclear if warning ...` formats are listed here:

`dbclear if warning`	Removes the breakpoints set using the `dbstop if warning` and `dbstop if warning identifier` statements.
`dbclear if warning identifier`	Removes the breakpoint set using `dbstop if warning identifier` for the specified `identifier`. Running this produces an error if `dbstop if warning` or `dbstop if warning all` is set.

`dbclear if naninf` removes the breakpoint set by `dbstop if naninf` or `dbstop if infnan`.

`dbclear if infnan` removes the breakpoint set by `dbstop if infnan` or `dbstop if naninf`.

More About

Tips

The **at** and **in** keywords are optional.

In the syntax, `file` can be a MATLAB program file, or the path to a function within a file. For example

```
dbclear in foo>myfun
```

clears the breakpoint at the `myfun` function in the file `foo.m`.

Introduced before R2006a

dbcont

Resume execution

Syntax

```
dbcont
```

Description

`dbcont` resumes execution of a MATLAB code file from a breakpoint. Execution continues until another breakpoint is encountered, a pause condition is met, an error occurs, or MATLAB software returns to the base workspace prompt.

Note If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

Related Examples

- “Step Through a File”

Introduced before R2006a

dbdown

Reverse workspace shift performed by dbup, while in debug mode

Syntax

```
dbdown
```

Description

dbdown changes the current workspace context to the workspace of the called MATLAB code file when a breakpoint is encountered. You must have issued the dbup function at least once before you issue this function. dbdown is the opposite of dbup.

Multiple dbdown functions change the workspace context to each successively executed MATLAB code file on the stack until the current workspace context is the current breakpoint. It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.

dblquad

Numerically evaluate double integral over rectangle

Compatibility

`dblquad` will be removed in a future release. Use `integral2` instead.

Syntax

```
q = dblquad(fun,xmin,xmax,ymin,ymax)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)
```

Description

`q = dblquad(fun,xmin,xmax,ymin,ymax)` calls the `quad` function to evaluate the double integral `fun(x,y)` over the rectangle `xmin <= x <= xmax`, `ymin <= y <= ymax`. The input argument, `fun`, is a function handle that accepts a vector `x`, a scalar `y`, and returns a vector of integrand values.

"Parameterizing Functions" explains how to provide additional parameters to the function `fun`, if necessary.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quadl` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quadl`.

Examples

Pass function handle `@integrnd` to `dblquad`:

```
Q = dblquad(@integrnd,pi,2*pi,0,pi);
```

where the function `integrnd.m` is:

```
function z = integrnd(x, y)
z = y*sin(x)+x*cos(y);
```

Pass anonymous function handle `F` to `dblquad`:

```
F = @(x,y)y*sin(x)+x*cos(y);
Q = dblquad(F,pi,2*pi,0,pi);
```

The `integrnd` function integrates `y*sin(x)+x*cos(y)` over the square `pi <= x <= 2*pi`, `0 <= y <= pi`. Note that the integrand can be evaluated with a vector `x` and a scalar `y`.

Nonsquare regions can be handled by setting the integrand to zero outside of the region. For example, the volume of a hemisphere is:

```
dblquad(@(x,y)sqrt(max(1-(x.^2+y.^2),0)), -1, 1, -1, 1)
```

or

```
dblquad(@(x,y)sqrt(1-(x.^2+y.^2)).*(x.^2+y.^2<=1), -1, 1, -1, 1)
```

dbmex

Enable MEX-file debugging (on UNIX platforms)

Syntax

```
dbmex on
dbmex off
dbmex stop
```

Description

`dbmex on` enables MEX-file debugging for UNIX platforms.

To use this option, first start MATLAB from a debugger by typing `matlab -D`*`debugger`*, where *`debugger`* is the name of the debugger program. Invoke `dbmex on` before calling your MEX-file. If you have already loaded the MEX-file, remove it from memory using the `clear` function.

`dbmex off` disables MEX-file debugging.

`dbmex stop` returns to the debugger prompt.

- "Debugging on Mac Platforms"
- "Debugging on Linux Platforms"

See Also

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbtype` | `dbup`

Introduced before R2006a

dbquit

Quit debug mode

Syntax

```
dbquit
dbquit('all')
dbquit all
```

Description

`dbquit` terminates debug mode. The Command Window then displays the standard prompt (`>>`). The file being processed is *not* completed and no results are returned. All breakpoints remain in effect, unless your file contains (and MATLAB has processed) one or more of the following commands: `clear all`, `clear function`, `clear classes`.

If you debug `file1` and step into `file2`, running `dbquit` terminates debugging for both files. However, if you debug `file3` and also debug `file4`, running `dbquit` terminates debugging for `file4`, but `file3` remains in debug mode until you run `dbquit` again.

`dbquit('all')` or the command form, `dbquit all`, ends debugging for all files at once.

Examples

This example illustrates the use of `dbquit` relative to `dbquit('all')`. Set breakpoints in and run `file1` and `file2`:

```
>> dbstop in file1
>> dbstop in file2
>> file1
K>> file2
K>> dbstack
```

MATLAB software returns

```
K>> dbstack
  In file1 at 11
```

```
  In file2 at 22
```

If you use the `dbquit` syntax

```
K>> dbquit
```

MATLAB ends debugging for `file2` but `file1` is still in debug mode as shown here

```
K>> dbstack
    in file1 at 11
```

Run `dbquit` again to exit debug mode for `file1`.

Alternatively, `dbquit('all')` ends debugging for both files at once:

```
K>> dbstack
  In file1 at 11
  In file2 at 22
dbquit('all')
dbstack
```

returns no result.

Introduced before R2006a

dbstack

Function call stack

Syntax

```
dbstack
dbstack(n)
dbstack('-completenames')
[ST,I] = dbstack(...)
```

Description

`dbstack` displays the line numbers and file names of the function calls that led to the current breakpoint, listed in the order in which they were executed. The display lists the line number of the most recently executed function call (at which the current breakpoint occurred) first, followed by its calling function, which is followed by its calling function, and so on. This continues until the topmost MATLAB function is reached. Each line number is a hyperlink you can click to go directly to that line in the Editor. The notation `functionname>localfunctionname` is used to describe the location of the local function.

`dbstack(n)` omits the first `n` frames from the display. This is useful when issuing a `dbstack` from within an error handler, for example.

`dbstack('-completenames')` outputs the "complete name" (the absolute file name and the entire sequence of functions that nests the function in the stack frame) of each function in the stack.

Either none, one, or both `n` and `'-completenames'` can appear. If both appear, the order is irrelevant.

`[ST,I] = dbstack(...)` returns the stack trace information in an `m`-by-`1` structure, `ST`, with the fields:

`file`	The file in which the function appears. This field is the empty string if there is no file.

`name`	Function name within the file.
`line`	Function line number.

The current workspace index is returned in `I`.

If you step past the end of a file, `dbstack` returns a negative line number value to identify that special case. For example, if the last line to be executed is line `15`, then the `dbstack` line number is `15` before you execute that line and `-15` afterwards.

Examples

This example shows the information returned when you issue `dbstack` while debugging a MATLAB code file:

```
dbstack

In /usr/local/matlab/toolbox/matlab/cond.m at line 13
In test1.m at line 2
In test.m at line 3
```

This example shows the information returned when you issue `dbstack` while debugging `lengthofline.m` to get the complete name of the file, the function name, and line number in which the function appears:

```
[ST,I] = dbstack('-completenames')
ST =
    file: 'I:\MATLABFiles\mymfiles\lengthofline.m'
    name: 'lengthofline'
    line: 28
I =
     1
```

More About

Tips

In addition to using `dbstack` while debugging, you can also use `dbstack` within a MATLAB code file outside the context of debugging. In this case, to get and analyze information about the current file stack. For example, to get the name of the calling file, use `dbstack` with an output argument within the file being called. For example:

```
st=dbstack;
```

See Also

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstatus` | `dbstep` | `dbstop` | `dbtype` | `dbup` | `evalin` | `mfilename` | `whos`

Introduced before R2006a

dbstatus

List all breakpoints

Syntax

```
dbstatus
dbstatus file
dbstatus('-completenames')
s = dbstatus(...)
```

Description

`dbstatus` lists all the breakpoints in effect including errors, caught errors, warnings, and `naninfs`.

`dbstatus file` displays a list of the line numbers for which breakpoints are set in the specified file, where `file` is a MATLAB code file function name or a MATLAB relative partial path. Each line number is a hyperlink you can click to go directly to that line in the Editor.

`dbstatus('-completenames')` displays, for each breakpoint, the absolute file name and the sequence of functions that nest the function containing the breakpoint.

`s = dbstatus(...)` returns breakpoint information in an `m`-by-`1` structure with the fields listed in the following table. Use this syntax to save breakpoint status and restore it at a later time using `dbstop(s)`—see `dbstop` for an example.

`name`	Function name.
`file`	Full path for file containing breakpoints.
`line`	Vector of breakpoint line numbers.
`anonymous`	Vector of integers representing the anonymous functions in the `line` field. For example, `2` means the second anonymous function in that line. A value of `0` means the breakpoint is at the start of the line, not in an anonymous function.

`expression`	Cell vector of breakpoint conditional expression strings corresponding to lines in the `line` field.
`cond`	Condition string (`'error'`, `'caught error'`, `'warning'`, or `'naninf'`).
`identifier`	When `cond` is `'error'`, `'caught error'`, or `'warning'`, a cell vector of MATLAB message identifier strings for which the particular `cond` state is set.

Use `dbstatus class/function`, `dbstatus private/function`, or `dbstatus class/private/function` to determine the status for methods, private functions, or private methods (for a class named `class`).

In all forms you can further qualify the function name with a local function name, as in `dbstatus function>localfunction`.

More About

Tips

In the syntax, `file` can be a file, or the path to a function within a file. For example

```
Breakpoint for foo>myfun is on line 9
```

means there is a breakpoint at the `myfun` local function, which is line 9 in the file `foo.m`.

Introduced before R2006a

dbstep

Execute one or more lines from current breakpoint

Syntax

```
dbstep
dbstep nlines
dbstep in
dbstep out
```

Description

This function allows you to debug a MATLAB code file by following its execution from the current breakpoint. At a breakpoint, the `dbstep` function steps through execution of the current file one line at a time or at the rate specified by `nlines`.

`dbstep` executes the next executable line of the current file. `dbstep` steps over the current line, skipping any breakpoints set in functions called by that line.

`dbstep nlines` executes the specified number of executable lines.

`dbstep in` steps to the next executable line. If that line contains a call to another MATLAB code file function, execution will step to the first executable line of the called function. If there is no call to a MATLAB code file on that line, `dbstep in` is the same as `dbstep`.

`dbstep out` runs the rest of the function and stops just after leaving the function.

For all forms, MATLAB software also stops execution at any breakpoint it encounters.

Note If you want to edit a file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the file. If you edit a file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

Introduced before R2006a

dbstop

Set breakpoints for debugging

Syntax

```
dbstop in file
dbstop in file at location
dbstop in file if expression
dbstop in file at location if expression
dbstop if condition
dbstop(s)
```

Description

`dbstop in file` sets a breakpoint at the first executable line in file. When you run file, MATLAB enters debug mode and pauses execution at the first executable line.

`dbstop in file at location` sets a breakpoint at the specified location. MATLAB execution pauses immediately before that location, unless the location is an anonymous function. If the location is an anonymous function, then execution pauses just after the breakpoint.

`dbstop in file if expression` sets a breakpoint at the first executable line of the file. Execution pauses only if `expression` evaluates to `1` (true).

`dbstop in file at location if expression` sets a breakpoint at the specified location. Execution pauses at or just before that location only if the expression evaluates to true.

`dbstop if condition` pauses execution at the line that meets the specified condition.

`dbstop(s)` restores breakpoints you previously saved to s. The files containing the saved breakpoints must be on the search path or in the current folder. MATLAB assigns breakpoints by line number; therefore, the lines in the file must be the same as when you saved the breakpoints, or the results are unpredictable.

Input Arguments

`file`

File specification, typically for a MATLAB function, specified as a string. The file specification can include a partial path, but must be in a folder on the search path, or in the current folder.

If the command includes the `-completenames` option, then the file need not be on the search path, as long as the file specification is a "fully qualified name" on page 1-2004. In addition, `file` can include a filemarker (`>`) to specify the path to a particular local function or to a nested function within the file.

If file is not a MATLAB code file (for instance, it is a built-in or MDL-file), then MATLAB issues a warning. MATLAB cannot stop *in* the file, so it pauses before executing the file.

`location`

Location in `file` where you want to set a breakpoint, specified as one of the following:

- lineno

  Line number in `file` specified as a string. The default is `1`.
- lineno@n

  `n`th anonymous function on line number, `lineno`, specified as a string. The default value of `n` is `1`.
- subfun

  Name of a local function in `file`, specified as a string.

`expression`

Code that evaluates (as if by `eval`) to a scalar logical value of `1` or `0`, (true or false, respectively).

`condition`

Condition that causes execution to pause when that condition evaluates to true. Specify `condition` as one of the following:

- `error`— Run-time error that occurs outside a `try/catch` block. You cannot resume execution after an uncaught run-time error.

If you want execution to pause only if a specific error occurs, specify the message id. For example:

- `dbstop if error` stops execution at the first run-time error that occurs outside a `try/catch` block.
- `dbstop if error MATLAB:ls:InputsMustBeStrings` pauses execution at the first run-time error outside a `try/catch` block that has a message ID of `MATLAB:ls:InputsMustBeStrings`.

- `caught error` — Run-time error that occurs within the `try` portion of a `try/catch` block. If you want execution to stop only if a specific error occurs, specify the message id. See the `error` condition for an example of specifying a message id.
- `warning`— Run-time warning occurs. If you want execution to pause only if a specific warning occurs, specify the message id. See the `error` condition for an example of specifying a message id.

  This condition has no effect if you disabled warnings with the `warning off all` command or if you disabled warnings for the specified `id`. For more information about disabling warnings, see `warning`.
- `naninf` and `infnan`

  The code returns an infinite value (`Inf`) or a value that is not a number (`NaN`) as a result of an operator, function call, or scalar assignment. The `naninf` and `infnan` conditions have identical effects.

`s`

Breakpoints previously saved to a structure using `s=dbstatus`.

Examples

Stop at First Executable Line

This example shows how to set a breakpoint and pause execution at the first executable line in `buggy.m`.

1 Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)
```

```
n = length(x);
z = (1:n)./x;
```

2 Issue the `dbstop` command.

```
dbstop in buggy
```

3 Run buggy.

```
buggy(2:5)
```

MATLAB displays the line where it pauses and enters debug mode.

```
2   n = length(x);
K>>
```

4 Advance to the next line in the file.

```
dbstep
```

5 Examine the value of `n` in the Variable Editor.

```
openvar('n')
```

6 Quit debug mode.

```
dbquit
```

Stop if Error

This example shows how to set a breakpoint and pause execution if a run-time error occurs.

1 Create a file, `buggy.m`, which contains these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

2 Issue these statements in the Command Window:

```
dbstop if error
buggy(magic(3))
```

Because `buggy.m` works on vectors only, the input in step 2 results in a run-time error. MATLAB goes into debug mode, paused at line 3 in `buggy.m`.

```
Error using  ./
```

```
Matrix dimensions must agree.

Error in buggy at 3
z = (1:n)./x;
3   z = (1:n)./x;
```

3 Quit debug mode.

```
dbquit
```

Stop if InfNaN

This example shows how to set a breakpoint and pause execution if the code returns a NaN value.

1 Create a file, `buggy.m`, containing these statements.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

2 Issue these commands.

```
dbstop if naninf
buggy(0:2)
```

If any of the elements of the input, x, is zero, a division by zero occurs in `buggy.m`. Therefore, MATLAB returns the following message.

```
NaN/Inf breakpoint hit for buggy on line 3.
```

MATLAB is in debug mode, paused at line 3.

Stop at Function in File

This example shows how to set a breakpoint in the `collatzall` program file at the first executable line in the `collatzplot_new` function.

1 Copy `collatzall.m` from the MATLAB examples folder to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','collatzall.m'),'.','f')
```

2 Open `collatzall.m` in the Editor.

```
open collatzall.m
```

3 Set the breakpoint.

```
dbstop in collatzall>collatzplot_new
```

Stop at File That Is Not a MATLAB Code File

This example shows how to set a breakpoint at the built-in function `clear` when you run `myfile.m`.

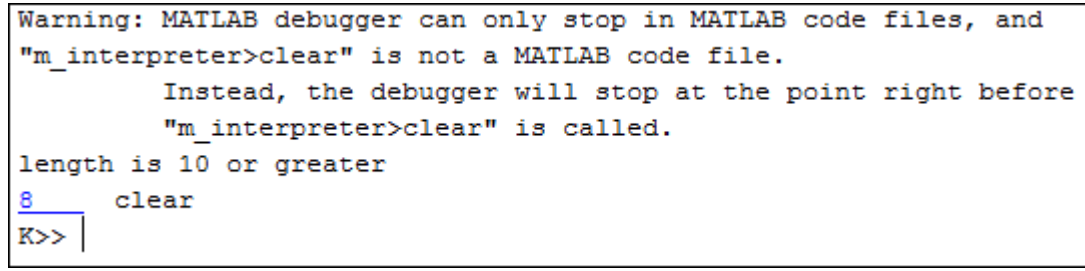
1 Create a file, `myfile.m`, in the Editor, containing these statements.

```
function myfile(x)
n = length(x);
if n < 10
    disp('length is less than 10')
else
    disp('length is 10 or greater')
end
clear
disp('Value of n is cleared')
```

2 Issue these commands to set the breakpoint.

```
x = [1 2 3 4 5 6 7 8 9 10]
dbstop in clear; myfile(x)
```

MATLAB issues a warning, and pauses before the call to the `clear` function. The warning appears as shown in this image.



Restore Saved Breakpoints

This example shows how to save, and then restore, saved breakpoints.

1. Copy `collatzall.m` from the MATLAB examples folder to your current folder.

   ```
   copyfile(fullfile(matlabroot,'help','techdoc','matlab_env', ...
       'examples','collatzall.m'),'.','f')
   ```

2. Open `collatzall.m` in the Editor.

   ```
   open collatzall.m
   ```

3. Set breakpoints from the Command Window.

   ```
   dbstop at 12 in collatzall
   dbstop if error
   ```

4. Run `dbstatus`.

   ```
   dbstatus
   ```

   MATLAB describes the breakpoints you set.

   ```
   Breakpoint for collatzall>collatzplot_new is on line 12.
   Stop if error.
   ```

5. Save the breakpoints to the structure, `s`, and then save `s` to the MAT-file, `myfilebrkpnts`.

   ```
   s=dbstatus('-completenames');
   save myfilebrkpnts s
   ```

   Using `s=dbstatus('-completenames')` saves absolute paths and the breakpoint function nesting sequence.

6. Clear all breakpoints.

   ```
   dbclear collatzall
   ```

7. Restore the breakpoints by loading the MAT-file.

   ```
   load myfilebrkpnts
   dbstop(s)
   ```

   The file (or files) containing the breakpoints must be on the search path or in the current folder.

8. Verify the breakpoints.

   ```
   dbstatus collatzall
   ```

More About

fully qualified name

- On Microsoft Windows platforms, a file name that begins with two back slashes (`\\`) or with a drive letter followed by a colon (`:`).
- On UNIX platforms, a file name that begins with a slash (`/`) or a tilde (`~`).

Tips

- Use `dbcont` or `dbstep` to resume execution after a breakpoint pauses execution. Use `dbquit` to exit debug mode.
- If you debug a file that MATLAB uses when running and debugging files, and that file is not a MATLAB code file, then some debugging features do not operate as expected. For instance, typing `help functionname` at the debug (`K>>`) prompt will not return help.
- MATLAB can become unresponsive when it stops at a breakpoint while displaying a modal dialog box or figure created by your program. Use **Ctrl+C** to exit debug mode and return to the MATLAB prompt (`>>`).
- If MATLAB pauses and displays a hyperlinked line number in the Command Window, click the hyperlink, The file opens in the Editor at the line where MATLAB paused execution. For an example of such a link, see the image in "Stop at File That Is Not a MATLAB Code File" on page 1-2002
- You can set breakpoints only at executable lines in saved files that are in the current folder or in folders on the search path.
- `dbstop` **`if warning`** has no effect when you disable warnings using `warning off all`. Similarly, `dbstop` **`if warning`** `identifier` has no effect when you disable warnings for the specified message identifier. See `warning` for more information about `off`, `all`, and `warning off identifier`

Introduced before R2006a

dbtype

List text file with line numbers

Syntax

```
dbtype filename
dbtype filename start:end
```

Description

The `dbtype` command is used to list a text file with line numbers, which is helpful when setting breakpoints in a MATLAB code file with `dbstop`.

`dbtype filename` displays the contents of the specified text file, with the line number preceding each line. `filename` must be the full path name of a file, or a MATLAB relative partial path.

`dbtype filename start:end` displays the portion of the file specified by a range of line numbers from `start` to `end`.

You cannot use `dbtype` for built-in functions.

Examples

To see only the input and output arguments for a function, that is, the first line of the file, use the syntax

```
dbtype filename 1
```

For example,

```
dbtype addpath 1
```

returns

```
1     function oldpath = addpath(varargin)
```

See Also

`dbclear` | `dbcont` | `dbdown` | `dbquit` | `dbstack` | `dbstatus` | `dbstep` | `dbstop` | `dbup`

Introduced before R2006a

dbup

Shift current workspace to workspace of caller, while in debug mode

Syntax

```
dbup
```

Description

This function allows you to examine the calling MATLAB code file to determine what caused the arguments to be passed to the called function.

`dbup` changes the current workspace context, while the user is in the debug mode, to the workspace of the calling file.

Multiple `dbup` functions change the workspace context to each previous calling file on the stack until the base workspace context is reached. (It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.)

More About

Tips

If your receive an error message such as the following, it means that the parent workspace is under construction so that the value of `x` is unavailable:

```
??? Reference to a called function result under construction x
```

- "Problems Viewing Variable Values from the Parent Workspace"

Introduced before R2006a

dde23

Solve delay differential equations (DDEs) with constant delays

Syntax

```
sol = dde23(ddefun,lags,history,tspan)
sol = dde23(ddefun,lags,history,tspan,options)
```

Arguments

`ddefun`	Function handle that evaluates the right side of the differential equations $y'(t) = f\left(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k)\right)$. The function must have the form `dydt = ddefun(t,y,Z)` where `t` corresponds to the current t, `y` is a column vector that approximates $y(t)$, and `Z(:,j)` approximates $y(t-\tau_j)$ for delay τ_j = `lags(j)`. The output is a column vector corresponding to $f\left(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k)\right)$.
`lags`	Vector of constant, positive delays τ_1, ..., τ_k.
`history`	Specify `history` in one of three ways: • A function of t such that `y = history(t)` returns the solution $y(t)$ for $t \le t_0$ as a column vector • A constant column vector, if $y(t)$ is constant • The solution `sol` from a previous integration, if this call continues that integration
`tspan`	Interval of integration from `t0=tspan(1)` to `tf=tspan(end)` with `t0 < tf`.
`options`	Optional integration argument. A structure you create using the `ddeset` function. See `ddeset` for details.

Description

`sol = dde23(ddefun,lags,history,tspan)` integrates the system of DDEs

$$y'(t) = f\left(t, y(t), y(t-\tau_1), ..., y(t-\tau_k)\right)$$

on the interval $[t_0,t_f]$, where τ_1, ..., τ_k are constant, positive delays and t_0,t_f. The input argument, `ddefun`, is a function handle.

"Parameterizing Functions" explains how to provide additional parameters to the function `ddefun`, if necessary.

`dde23` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

```
yint = deval(sol,tint)
```

The structure `sol` returned by `dde23` has the following fields.

`sol.x`	Mesh selected by `dde23`
`sol.y`	Approximation to $y(x)$ at the mesh points in `sol.x`.
`sol.yp`	Approximation to $y'(x)$ at the mesh points in `sol.x`
`sol.solver`	Solver name, `'dde23'`

`sol = dde23(ddefun,lags,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and "Types of DDEs" in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance `'RelTol'` (`1e-3` by default) and vector of absolute error tolerances `'AbsTol'` (all components are `1e-6` by default).

Use the `'Jumps'` option to solve problems with discontinuities in the history or solution. Set this option to a vector that contains the locations of discontinuities in the solution prior to `t0` (the history) or in coefficients of the equations at known values of t after `t0`.

Use the `'Events'` option to specify a function that `dde23` calls to find where functions $g\left(t, y(t), y(t-\tau_1), ..., y(t-\tau_k)\right)$ vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the kth event function in `events`:

- `value(k)` is the value of the kth event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and 0 otherwise.
- `direction(k) = 0` if you want `dde23` to compute all zeros of this event function, `+1` if only zeros where the event function increases, and `-1` if only zeros where the event function decreases.

If you specify the `'Events'` option and events are detected, the output structure `sol` also includes fields:

`sol.xe`	Row vector of locations of all events, i.e., times when an event function vanished
`sol.ye`	Matrix whose columns are the solution values corresponding to times in `sol.xe`
`sol.ie`	Vector containing indices that specify which event occurred at the corresponding time in `sol.xe`

Examples

This example solves a DDE on the interval [0, 5] with lags 1 and 0.2. The function `ddex1de` computes the delay differential equations, and `ddex1hist` computes the history for `t <= 0`.

Note The file, ddex1.m, contains the complete code for this example. To see the code in an editor, type `edit ddex1` at the command line. To run it, type `ddex1` at the command line.

```
sol = dde23(@ddex1de,[1, 0.2],@ddex1hist,[0, 5]);
```

This code evaluates the solution at 100 equally spaced points in the interval `[0,5]`, then plots the result.

```
tint = linspace(0,5);
yint = deval(sol,tint);
```

```
plot(tint,yint);
```

`ddex1` shows how you can code this problem using local functions. For more examples see `ddex2`.

More About

Algorithms

`dde23` tracks discontinuities and integrates with the explicit Runge-Kutta (2,3) pair and interpolant of `ode23`. It uses iteration to take steps longer than the lags.

See Also

`ddesd` | `ddensd` | `ddeget` | `ddeset` | `deval` | `function_handle`

Introduced before R2006a

ddeget

Extract properties from delay differential equations options structure

Syntax

```
val = ddeget(options,'name')
val = ddeget(options,'name',default)
```

Description

`val = ddeget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = ddeget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = ddeget(opts,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `opts`.

See Also

`dde23` | `ddesd` | `ddensd` | `ddeset`

Introduced before R2006a

ddensd

Solve delay differential equations (DDEs) of neutral type

Syntax

```
sol = ddensd(ddefun,dely,delyp,history,tspan)
sol = ddensd(ddefun,dely,delyp,history,tspan,options)
```

Description

`sol = ddensd(ddefun,dely,delyp,history,tspan)` integrates a system of delay differential equations of neutral type, that has the form

$$y'(t) = f(t, y(t), y(dy_1),..., y(dy_p), y'(dyp_1),..., y'(dyp_q))$$

where

- t is the independent variable representing time.
- dy_i is any of p solution delays.
- dyp_j is any of q derivative delays.

`sol = ddensd(ddefun,dely,delyp,history,tspan,options)` replaces default integration parameters with those specified in `options`, a structure created with the `ddeset` function.

Examples

Neutral DDE with Two Delays

Solve the following neutral DDE, presented by Paul, for $0 \le t \le \pi$:
$y'(t) = 1 + y(t) - 2y(t/2)^2 - y'(t - \pi)$
with history: $y(t) = \cos(t)$ for $t \le 0$.

Create a new program file in the editor. This file will contain a main function and four local functions.

Define the first-order DDE as a local function.

```
function yp = ddefun(t,y,ydel,ypdel)
    yp = 1 + y - 2*ydel^2 - ypdel;
end
```

Define the solution delay as a local function.

```
function dy = dely(t,y)
    dy = t/2;
end
```

Define the derivative delay as a local function.

```
function dyp = delyp(t,y)
    dyp = t-pi;
end
```

Define the solution history as a local function.

```
function y = history(t)
    y = cos(t);
end
```

Define the interval of integration and solve the DDE using the `ddensd` function. Add this code to the main function.

```
tspan = [0 pi];
sol = ddensd(@ddefun,@dely,@delyp,@history,tspan);
```

Evaluate the solution at 100 equally spaced points between 0 and π. Add this code to the main function.

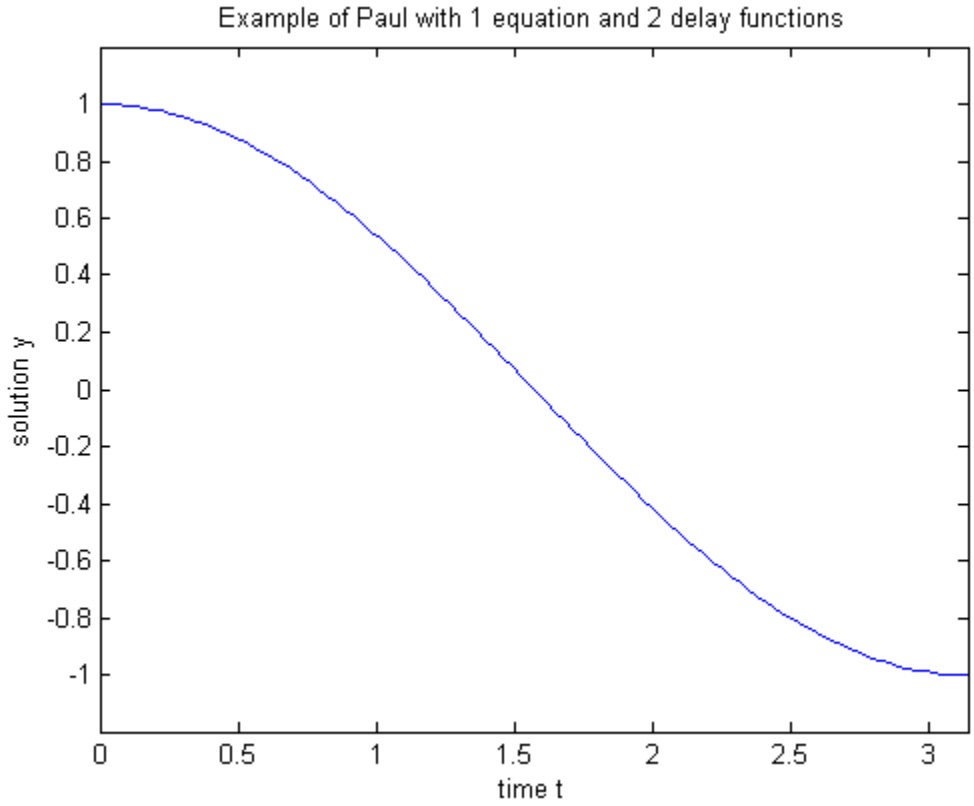
```
tn = linspace(0,pi);
yn = deval(sol,tn);
```

Plot the results. Add this code to the main function.

```
plot(tn,yn);
xlim([0 pi]);
ylim([-1.2 1.2]);
```

```
xlabel('time t');
ylabel('solution y');
```

Run your program to calculate the solution and display the plot.



The file, `ddex4.m`, contains the complete code for this example. To see the code in an editor, type `edit ddex4` at the command line.

Input Arguments

`ddefun` — Derivative function

function handle

Derivative function, specified as a function handle whose syntax is `yp = ddefun(t,y,ydel,ypdel)`. The arguments for `ddefun` are described in the table below.

ddefun Argument	Description
`t`	A scalar value representing the current value of time, t.
`y`	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is `n`-by-`1`, where `n` is the number of equations in the system you want to solve.
`ydel`	A matrix whose columns, `ydel(:,i)`, represent $y(dy_i)$. The size of this matrix is `n`-by-`p`, where `n` is the number of equations in the system you want to solve, and `p` is the number of $y(dy)$ terms in Equation 1-1.
`ypdel`	A matrix whose columns, `ypdel(:,j)` represent $y'(dyp_j)$. The size of this matrix is `n`-by-`q`, where `n` is the number of equations in the system you want to solve, and `q` is the number of $y'(dyp)$ terms in Equation 1-1.
`yp`	The result returned by `ddefun`. It is an `n`-by-`1` vector whose elements represent the right side of Equation 1-1.

`dely` — Solution delays

function handle | vector

Solution delays, specified as a function handle, which returns $dy_1,\ldots, dy_p$ in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If you specify `dely` as a function handle, the syntax must be `dy = dely(t,y)`. The arguments for this function are described in the table below.

dely Argument	Description
`t`	A scalar value representing the current value of time, t.
`y`	A vector that represents $y(t)$ in Equation 1-1. The size of this vector is `n`-by-`1`, where `n` is the number of equations in the system you want to solve.
`dy`	A vector returned by the `dely` function whose values are the solution delays, dy_i , in Equation 1-1. The size of this vector is `p`-by-`1`, where `p` is the number of solution delays in the equation. Each element must be less than or equal to t.

If you want to specify constant solution delays having the form $dy_i = t - \tau_i$, then `dely` must be a vector, where `dely(i)` = τ_i. Each value in this vector must be greater than or equal to zero.

If *dy* is not present in the problem, set `dely` to `[]`.

Data Types: `function_handle` | `single` | `double`

`delyp` — Derivative delays

function handle | vector

Derivative delays, specified as a function handle, which returns dyp_1,..., dyp_q in Equation 1-1. Alternatively, you can pass constant delays in the form of a vector.

If `delyp` is a function handle, its syntax must be `dyp = delyp(t,y)`. The arguments for this function are described in the table below.

delyp Argument	Description
`t`	A scalar value representing the current value of time, *t*.
`y`	A vector that represents *y*(*t*) in Equation 1-1. The size of this vector is `n`-by-`1`, where `n` is the number of equations in the system you want to solve.
`dyp`	A vector returned by the `delyp` function whose values are the derivative delays, dyp_j, in Equation 1-1. The size of this vector must be `q`-by-`1`, where `q` is the number of solution delays, dyp_j, in the equation. Each element of `dyp` must be less than *t*. There is one exception to this restriction: if you are solving an initial value DDE, the value of `dyp` can equal *t* at $t = t_0$. For more information, see “Initial Value Neutral Delay Differential Equations” on page 1-2019.

If you want specify constant derivative delays having the form $dyp_j = t - \tau_j$, then `delyp` must be a vector, where `delyp(j)` = τ_j. Each value in this vector must be greater than zero. An exception to this restriction occurs when you solve initial value problems for DDEs of neutral type. In such cases, a value in `delyp` can equal zero at $t = t_0$. See “Initial Value Neutral Delay Differential Equations” on page 1-2019 for more information.

If *dyp* is not present in the problem, set `delyp` to `[]`.

Data Types: `function_handle` | `single` | `double`

`history` — Solution history

function handle | column vector | structure (`sol`, from previous integration) | 1-by-2 cell array

Solution history, specified as a function handle, column vector, `sol` structure (from a previous integration), or a cell array. This is the solution at $t \le t_0$.

- If the history varies with time, specify the solution history as a function handle whose syntax is `y = history(t)`. This function returns an `n`-by-`1` vector that approximates the solution, $y(t)$, for $t <= t_0$. The length of this vector, `n`, is the number of equations in the system you want to solve.
- If $y(t)$ is constant, you can specify `history` as an `n`-by-`1` vector of the constant values.
- If you are calling `ddensd` to continue a previous integration to t_0, you can specify history as the output, `sol`, from the previous integration.
- If you are solving an initial value DDE, specify history as a cell array, `{y0, yp0}`. The first element, `y0`, is a column vector of initial values, $y(t_0)$. The second element, yp_0, is a column vector whose elements are the initial derivatives, $y'(t_0)$. These vectors must be consistent, meaning that they satisfy Equation 1-1 at t_0. See "Initial Value Neutral Delay Differential Equations" on page 1-2019 for more information.

Data Types: `function_handle` | `single` | `double` | `struct` | `cell`

`tspan` — Interval of integration

1-by-2 vector

Interval of integration, specified as the vector `[t0 tf]`. The first element, `t0`, is the initial value of t. The second element, `tf`, is the final value of t. The value of `t0` must be less than `tf`.

Data Types: `single` | `double`

`options` — Optional integration parameters

structure returned by `ddeset`

Optional integration parameters, specified as a structure created and returned by the `ddeset` function. Some commonly used properties are: `'RelTol'`, `'AbsTol'`, and `'Events'`. See the `ddeset` reference page for more information about specifying `options`.

Output Arguments

`sol` — Solution

structure

Solution, returned as a structure containing the following fields.

`sol.x`	Mesh selected by `ddensd`.
`sol.y`	An approximation to $y(t)$ at the mesh points.
`sol.yp`	An approximation to $y'(t)$ at the mesh points.
`sol.solver`	A string identifying the solver, `'ddensd'`.

You can pass `sol` to the `deval` function to evaluate the solution at specific points. For example, `y = deval(sol, 0.5*(sol.x(1) + sol.x(end)))` evaluates the solution at the midpoint of the interval of integration.

More About

Initial Value Neutral Delay Differential Equations

An initial value DDE has $dy_i \geq t_0$ and $dyp_j \geq t_0$, for all i and j. At $t = t_0$, all delayed terms reduce to $y(dy_i) = y(t_0)$ and $y'(dyp_j) = y'(t_0)$:

$$y'(t_0) = f(t_0, y(t_0), y(t_0),..., y(t_0), y'(t_0),..., y'(t_0))$$

For $t > t_0$, all derivative delays must satisfy $dyp < t$.

When you solve initial value neutral DDEs, you must supply $y'(t_0)$ to `ddensd`. To do this, specify history as a cell array `{Y0,YP0}`. Here, `Y0` is the column vector of initial values, $y(t_0)$, and `YP0` is a column vector of initial derivatives, $y'(t_0)$. These vectors must be consistent, meaning that they satisfy Equation 1-2 at t_0.

Algorithms

For information about the algorithm used in this solver, see Shampine [2].

`dde23` | `ddesd` | `ddeset` | `deval` | `function_handle`

ddesd

Solve delay differential equations (DDEs) with general delays

Syntax

```
sol = ddesd(ddefun,delays,history,tspan)
sol = ddesd(ddefun,delays,history,tspan,options)
```

Arguments

`ddefun`

Function handle that evaluates the right side of the differential equations $y'(t) = f(t,y(t),y(d(1)),...,y(d(k)))$. The function must have the form

```
dydt = ddefun(t,y,Z)
```

where `t` corresponds to the current t, `y` is a column vector that approximates $y(t)$, and `Z(:,j)` approximates $y(d(j))$ for delay $d(j)$ given as component j of `delays(t,y)`. The output is a column vector corresponding to $f(t,y(t),y(d(1)),...,y(d(k)))$.

`delays`

Function handle that returns a column vector of delays $d(j)$. The delays can depend on both t and $y(t)$. `ddesd` imposes the requirement that $d(j) \le t$ by using `min`$(d(j),t)$.

If all the delay functions have the form $d(j) = t - \tau_j$, you can set the argument `delays` to a constant vector `delays`$(j) = \tau_j$. With delay functions of this form, `ddesd` is used exactly like `dde23`.

`history`

Specify `history` in one of three ways:

- A function of t such that `y = history(t)` returns the solution $y(t)$ for $t \le t_0$ as a column vector
- A constant column vector, if $y(t)$ is constant
- The solution `sol` from a previous integration, if this call continues that integration

`tspan`	Interval of integration from `t0=tspan(1)` to `tf=tspan(end)` with `t0 < tf`.
`options`	Optional integration argument. A structure you create using the `ddeset` function. See `ddeset` for details.

Description

`sol = ddesd(ddefun,delays,history,tspan)` integrates the system of DDEs

$$y'(t) = f\left(t, y(t), y(d(1)), \ldots, y(d(k))\right)$$

on the interval $[t_0,t_f]$, where delays $d(j)$ can depend on both t and $y(t)$, and $t_0 < t_f$. Inputs `ddefun` and `delays` are function handles. See the `function_handle` reference page for more information.

"Parameterizing Functions" explains how to provide additional parameters to the functions `ddefun`, `delays`, and `history`, if necessary.

`ddesd` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

```
yint = deval(sol,tint)
```

The structure `sol` returned by `ddesd` has the following fields.

`sol.x`	Mesh selected by `ddesd`
`sol.y`	Approximation to $y(x)$ at the mesh points in `sol.x`.
`sol.yp`	Approximation to $y'(x)$ at the mesh points in `sol.x`
`sol.solver`	Solver name, `'ddesd'`

`sol = ddesd(ddefun,delays,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and "Types of DDEs" in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance `'RelTol'` (`1e-3` by default) and vector of absolute error tolerances `'AbsTol'` (all components are `1e-6` by default).

Use the `'Events'` option to specify a function that `ddesd` calls to find where functions $g(t,y(t),y(d(1)),\ldots,y(d(k)))$ vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the `k`th event function in `events`:

- `value(k)` is the value of the `k`th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and `0` otherwise.
- `direction(k) = 0` if you want `ddesd` to compute all zeros of this event function, `+1` if only zeros where the event function increases, and `-1` if only zeros where the event function decreases.

If you specify the `'Events'` option and events are detected, the output structure `sol` also includes fields:

`sol.xe`	Row vector of locations of all events, i.e., times when an event function vanished
`sol.ye`	Matrix whose columns are the solution values corresponding to times in `sol.xe`
`sol.ie`	Vector containing indices that specify which event occurred at the corresponding time in `sol.xe`

Examples

The equation

```
sol = ddesd(@ddex1de,@ddex1delays,@ddex1hist,[0,5]);
```

solves a DDE on the interval `[0,5]` with delays specified by the function `ddex1delays` and differential equations computed by `ddex1de`. The history is evaluated for $t \le 0$ by the function `ddex1hist`. The solution is evaluated at 100 equally spaced points in `[0,5]`:

```
tint = linspace(0,5);
yint = deval(sol,tint);
```

and plotted with

```
plot(tint,yint);
```

This problem involves constant delays. The `delay` function has the form

```
function d = ddex1delays(t,y)
%DDEX1DELAYS  Delays for using with DDEX1DE.
d = [ t - 1
      t - 0.2];
```

The problem can also be solved with the syntax corresponding to constant delays

```
delays = [1, 0.2];
sol = ddesd(@ddex1de,delays,@ddex1hist,[0, 5]);
```

or using `dde23`:

```
sol = dde23(@ddex1de,delays,@ddex1hist,[0, 5]);
```

For more examples of solving delay differential equations see ddex2 and ddex3.

See Also

`dde23` | `ddeget` | `ddensd` | `ddeset` | `deval` | `function_handle`

ddeset

Create or alter delay differential equations options structure

Syntax

```
options = ddeset('name1',value1,'name2',value2,...)
options = ddeset(oldopts,'name1',value1,...)
options = ddeset(oldopts,newopts)
ddeset
```

Description

`options = ddeset('name1',value1,'name2',value2,...)` creates an integrator options structure `options` in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. `ddeset` ignores case for property names.

`options = ddeset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This overwrites any values in `oldopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = ddeset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `oldopts`.

`ddeset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `ddeget` to query the `options` structure for the value of a specific property.

DDE Properties

The following sections describe the properties that you can set using `ddeset`. There are several categories of properties:

- Error control
- Solver output
- Step size
- Event location
- Discontinuities

Error Control Properties

At each step, the DDE solvers estimate an error `e`. The `dde23` function estimates the local truncation error, and the other solvers estimate the residual. In either case, this error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

```
|e(i)|*max(RelTol*abs(y(i)),AbsTol(i))
```

For routine problems, the solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For the absolute error tolerance, the scaling of the solution components is important: if `|y|` is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in `y`. You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component `y(i)` when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in `y(i)` so that you can accurately compute more interesting components.

The following table describes the error control properties.

DDE Error Control Properties

Property	Value	Description
`RelTol`	Positive scalar {`1e-3`}	A relative error tolerance that applies to all components of the solution vector `y`. It is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components except

Property	Value	Description
		those smaller than thresholds `AbsTol(i)`. The default, `1e-3`, corresponds to 0.1% accuracy. The estimated error in each integration step satisfies `|e(i)| max(RelTol*abs(y(i)),AbsTol(i))`.
`AbsTol`	Positive scalar or vector {`1e-6`}	Absolute error tolerances that apply to the individual components of the solution vector. `AbsTol(i)` is a threshold below which the value of the `i`th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero. Even if you are not interested in a component `y(i)` when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in `y(i)` so that you can accurately compute more interesting components. If `AbsTol` is a vector, the length of `AbsTol` must be the same as the length of the solution vector `y`. If `AbsTol` is a scalar, the value applies to all components of `y`.
`NormControl`	`on` | {`off`}	Control error relative to norm of solution. Set this property `on` to request that the solvers control the error in each integration step with `norm(e)<= max(RelTol*norm(y),AbsTol)`. By default, the solvers use a more stringent component-wise error control.

Solver Output Properties

You can use the solver output properties to control the output that the solvers generate.

DDE Solver Output Properties

Property	Value	Description

`OutputFcn`	Function handle {`@odeplot`}	The output function is a function that the solver calls after every successful integration step. To specify an output function, set `'OutputFcn'` to a function handle. For example,
		
		`options = ddeset('OutputFcn',...`
		`@myfun)`

Property	Value	Description
		sets 'OutputFcn' to @myfun, a handle to the function myfun. See the function_handle reference page for more information. The output function must be of the form `status = myfun(t,y,flag)` "Parameterizing Functions" explains how to provide additional parameters to myfun, if necessary. The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately: • init — The solver calls myfun(tspan,y0,'init') before beginning the integration to allow the output function to initialize. tspan is the input argument to the solvers. y0 is the initial value of the solution, either from history(t0) or specified in the initialY option. • {none} — The solver calls status = myfun(t,y) after each integration step on which output is requested. t contains points where output was generated during the step, and y is the numerical solution at the points in t. If t is a vector, the ith column of y corresponds to the ith element of t. myfun must return a status output value of 0 or 1. If status = 1, the solver halts integration. You can use this mechanism, for instance, to implement a **Stop** button. • done — The solver calls myfun([],[],'done') when integration is complete to allow the output function to perform any cleanup chores. You can use these general purpose output functions or you can edit them to create your own. Type help functionname at the command line for more information.

Property	Value	Description
		• `odeplot` – time series plotting (default when you call the solver with no output argument and you have not specified an output function) • `odephas2` – two-dimensional phase plane plotting • `odephas3` – three-dimensional phase plane plotting • `odeprint` – print solution as the solver computes it

`OutputSel`	Vector of indices	Vector of indices specifying which components of the solution vector the solvers pass to the output function. For example, if you want to use the `odeplot` output function, but you want to plot only the first and third components of the solution, you can do this using
		`options = ddeset...`
		`('OutputFcn',@odeplot,...`
		`'OutputSel',[1 3]);`
		By default, the solver passes all components of the solution to the output function.

`Stats`	`on` | {`off`}	Specifies whether the solver should display statistics about its computations. By default, `Stats` is `off`. If it is `on`, after solving the problem the solver displays: • The number of successful steps • The number of failed attempts • The number of times the DDE function was called

Step Size Properties

The step size properties let you specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step size properties.

DDE Step Size Properties

Property	Value	Description
`InitialStep`	Positive scalar	Suggested initial step size. `InitialStep` sets an upper bound on the magnitude of the first step size the solver tries. If you do not set `InitialStep`, the solver bases the initial step size on the slope of the solution at the initial time `tspan(1)`. The initial step size is limited by the shortest delay. If the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable `InitialStep`.
`MaxStep`	Positive scalar {`0.1* abs(t0-tf)`}	Upper bound on solver step size. If the differential equation has periodic coefficients or solutions, it may be a good idea to set `MaxStep` to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce `MaxStep`: • When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. (See "Error Control Properties" on page 1-2026 for a description of the error tolerance properties.) • To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbsTol`. Use `MaxStep` as a last resort.

Event Location Property

In some DDE problems, the times of specific events are important. While solving a problem, the solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property.

DDE Events Property

String	Value	Description

`Events`	Function handle	A function handle that includes one or more event functions. For `dde23` and `ddesd`, this function has the following syntax:
		`[value,isterminal,direction] = events(t,y,YDEL)`
		For `ddensd`, the syntax is:
		`[value,isterminal,direction] = events(t,y,YDEL,YPDEL)`
		The output arguments, `value`, `isterminal`, and `direction`, are vectors for which the `i`th element corresponds to the `i`th event function:
		• `value(i)` is the value of the `i`th event function.
		• `isterminal(i) = 1` if you want the integration to terminate at a zero of this event function, and `0` otherwise.
		• `direction(i) = 0` if you want the solver to locate all zeros (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing.
		If you specify an events function and events are detected, the solver returns three additional fields in the solution structure `sol`:
		• `sol.xe` is a row vector of times at which events occur.
		• `sol.ye` is a matrix whose columns are the solution values corresponding to times in `sol.xe`.
		• `sol.ie` is a vector containing indices that specify which event occurred at the corresponding time in `sol.xe`.

String	Value	Description
		For examples that use an event function while solving ordinary differential equation problems, see “Event Location” (`ballode`) and “Advanced Event Location” (`orbitode`), in the MATLAB Mathematics documentation.

Discontinuity Properties

The solver functions can solve problems with discontinuities in the history or in the coefficients of the equations. The following properties enable you to provide these solvers with a different initial value, and, for `dde23`, locations of known discontinuities. For more information, see “Discontinuities in DDEs”.

The following table describes the discontinuity properties.

DDE Discontinuity Properties

String	Value	Description
`Jumps`	Vector	Location of discontinuities. Points t where the history or solution may have a jump discontinuity in a low-order derivative. This applies only to the `dde23` solver.
`InitialY`	Vector	Initial value of solution. By default the initial value of the solution is the value returned by `history` at the initial point. Supply a different initial value as the value of the `InitialY` property.

Examples

To create an options structure that changes the relative error tolerance of the solver from the default value of `1e-3` to `1e-4`, enter

```
options = ddeset('RelTol',1e-4);
```

To recover the value of `'RelTol'` from `options`, enter

```
ddeget(options,'RelTol')

ans =
```

```
1.0000e-004
```

Introduced before R2006a

deal

Distribute inputs to outputs

Compatibility

Beginning with MATLAB Version 7.0 software, you can access the contents of cell arrays and structure fields without using the `deal` function. See Example 3, below.

Syntax

```
[Y1, Y2, Y3, ...] = deal(X)
[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)
[S.field] = deal(X)
[X{:}] = deal(A.field)
[Y1, Y2, Y3, ...] = deal(X{:})
[Y1, Y2, Y3, ...] = deal(S.field)
```

Description

`[Y1, Y2, Y3, ...] = deal(X)` copies the single input to all the requested outputs. It is the same as `Y1 = X`, `Y2 = X`, `Y3 = X`, `...`

`[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)` is the same as `Y1 = X1`; `Y2 = X2`; `Y3 = X3`; `...`

Examples

Example 1 — Assign Data From a Cell Array

Use `deal` to copy the contents of a 4-element cell array into four separate output variables.

```
C = {rand(3) ones(3,1) eye(3) zeros(3,1)};
[a,b,c,d] = deal(C{:})
```

```
a =
    0.9501    0.4860    0.4565
    0.2311    0.8913    0.0185
    0.6068    0.7621    0.8214

b =
    1
    1
    1

c =
    1    0    0
    0    1    0
    0    0    1

d =
    0
    0
    0
```

Example 2 — Assign Data From Structure Fields

Use `deal` to obtain the contents of all the name fields in a structure array:

```
A.name = 'Pat'; A.number = 176554;
A(2).name = 'Tony'; A(2).number = 901325;
[name1,name2] = deal(A(:).name)

name1 =
   Pat

name2 =
   Tony
```

Example 3 — Doing the Same Without deal

Beginning with MATLAB Version 7.0 software, you can, in most cases, access the contents of cell arrays and structure fields without using the `deal` function. The two commands shown below perform the same operation as those used in the previous two examples, except that these commands do not require `deal`.

```
[a,b,c,d] = C{:}
```

```
[name1,name2] = A(:).name
```

More About

Tips

`deal` is most useful when used with cell arrays and structures via comma-separated list expansion. Here are some useful constructions:

`[S.field] = deal(X)` sets all the fields with the name `field` in the structure array `S` to the value `X`. If `S` doesn't exist, use `[S(1:m).field] = deal(X)`.

`[X{:}] = deal(A.field)` copies the values of the field with name `field` to the cell array `X`. If `X` doesn't exist, use `[X{1:m}] = deal(A.field)`.

`[Y1, Y2, Y3, ...] = deal(X{:})` copies the contents of the cell array `X` to the separate variables `Y1, Y2, Y3, ...`

`[Y1, Y2, Y3, ...] = deal(S.field)` copies the contents of the fields with the name `field` to separate variables `Y1, Y2, Y3, ...`

Introduced before R2006a

deblank

Strip trailing blanks from end of string

Syntax

```
str = deblank(str)
c = deblank(c)
```

Description

`str = deblank(str)` removes all trailing whitespace and null characters from the end of character string `str`. A whitespace is any character for which the `isspace` function returns logical 1 (`true`).

`c = deblank(c)` when `c` is a cell array of strings, applies `deblank` to each element of `c`.

The `deblank` function is useful for cleaning up the rows of a character array.

Examples

Example 1 – Removing Trailing Blanks From a String

Compose a string `str` that contains space, tab, and null characters:

```
NL = char(0);    TAB = char(9);
str = [NL 32 TAB NL 'AB' 32 NL 'CD' NL 32 TAB NL 32];
```

Display all characters of the string between | symbols:

```
['|' str '|']
ans =
    |    AB  CD       |
```

Remove trailing whitespace and null characters, and redisplay the string:

```
newstr = deblank(str);
```

```
['|' newstr '|']
ans =
    |    AB  CD|
```

Example 2– Removing Trailing Blanks From a Cell Array of Strings

Create a 2-by-2 cell array in which each cell contains a word with trailing blanks:

```
A{1,1} = 'MATLAB    ';
A{1,2} = 'SIMULINK    ';
A{2,1} = 'Toolboxes    ';
A{2,2} = 'MathWorks    '
A =
    'MATLAB    '       'SIMULINK    '
    'Toolboxes    '    'MathWorks    '
```

Remove the trailing blanks and redisplay the cell array:

```
A = deblank(A);

A
A =
    'MATLAB'       'SIMULINK'
    'Toolboxes'    'MathWorks'
```

`strjust` | `strtrim`

Introduced before R2006a

dec2base

Convert decimal to base N number in string

Syntax

```
str = dec2base(d, base)
str = dec2base(d, base, n)
```

Description

`str = dec2base(d, base)` converts the nonnegative integer `d` to the specified `base`. `d` must be a nonnegative integer smaller than 2^52, and `base` must be an integer between 2 and 36. The returned argument `str` is a string.

`str = dec2base(d, base, n)` produces a representation with at least `n` digits.

Examples

The expression `dec2base(23, 2)` converts 23_{10} to base 2, returning the string `'10111'`.

See Also

`base2dec`

Introduced before R2006a

dec2bin

Convert decimal to binary number in string

Syntax

```
str = dec2bin(d)
str = dec2bin(d,n)
```

Description

`str = dec2bin(d)` returns the binary representation of `d` as a string. `d` must be a nonnegative integer. If `d` is greater than 2^52, `dec2bin` might not return an exact representation of `d`.

`str = dec2bin(d,n)` produces a binary representation with at least `n` bits.

The output of `dec2bin` is independent of the endian settings of the computer you are using.

Examples

Decimal 23 converts to binary 010111:

```
dec2bin(23)
ans =
    10111
```

See Also

`bin2dec` | `dec2hex`

dec2hex

Convert decimal to hexadecimal number in string

Syntax

```
str = dec2hex(d)
str = dec2hex(d, n)
```

Description

`str = dec2hex(d)` converts the decimal integer `d` to its hexadecimal representation stored in a MATLAB string. `d` must be a nonnegative integer. If `d` is an integer greater than 2^52, `dec2hex` might not return an exact representation. MATLAB converts noninteger inputs, such as those of class `double` or `char`, to their integer equivalents before converting to hexadecimal.

`str = dec2hex(d, n)` produces a hexadecimal representation with at least `n` digits.

Examples

To convert decimal 1023 to hexadecimal,

```
dec2hex(1023)
ans =
    3FF

dec2hex(1023, 6)
ans =
0003FF
```

Convert 2-by-5 array `A` to hexadecimal:

```
A = [3487,    125,  8997,  1433,  189; ...
      771,  84832,   118,  9366,  212];

 A(:)                    dec2hex(A)
ans =                    ans =
```

```
  3487                  00D9F
   771                  00303
   125                  0007D
 84832                  14B60
  8997                  02325
   118                  00076
  1433                  00599
  9366                  02496
   189                  000BD
   212                  000D4
```

See Also

`dec2bin` | `format` | `hex2dec` | `hex2num`

decic

Compute consistent initial conditions for ode15i

Syntax

```
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)
[y0mod,yp0mod,resnrm] =
decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)
```

Description

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)` uses the inputs `y0` and `yp0` as initial guesses for an iteration to find output values that satisfy the requirement $f(t0, y0\text{mod}, yp0\text{mod}) = 0$, i.e., `y0mod` and `yp0mod` are consistent initial conditions. `odefun` is a function handle. The function `decic` changes as few components of the guesses as possible. You can specify that `decic` holds certain components fixed by setting `fixed_y0(i) = 1` if no change is permitted in the guess for `y0(i)` and 0 otherwise. `decic` interprets `fixed_y0 = []` as allowing changes in all entries. `fixed_yp0` is handled similarly.

"Parameterizing Functions" explains how to provide additional parameters to the function `odefun`, if necessary.

You cannot fix more than `length(y0)` components. Depending on the problem, it may not be possible to fix this many. It also may not be possible to fix certain components of `y0` or `yp0`. It is recommended that you fix no more components than necessary.

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)` computes as above with default tolerances for consistent initial conditions, `AbsTol` and `RelTol`, replaced by the values in options, a structure you create with the `odeset` function.

`[y0mod,yp0mod,resnrm] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)` returns the norm of

`odefun(t0,y0mod,yp0mod)` as `resnrm`. If the norm seems unduly large, use `options` to decrease `RelTol` (`1e-3` by default).

Examples

The files, `ihb1dae.m` and `iburgersode.m`, provide examples which use `decic` to solve implicit ODEs.

`ode15i` | `odeget` | `odeset` | `function_handle`

Introduced before R2006a

deconv

Deconvolution and polynomial division

Syntax

```
[q,r] = deconv(v,u)
```

Description

`[q,r] = deconv(v,u)` deconvolves vector `u` out of vector `v`, using long division. The quotient is returned in vector `q` and the remainder in vector `r` such that `v = conv(u,q)+r`.

If `u` and `v` are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division. The result of dividing `v` by `u` is quotient `q` and remainder `r`.

Examples

If

```
u = [1   2   3   4]
v = [10   20   30]
```

the convolution is

```
c = conv(u,v)
c =
    10     40     100     160     170     120
```

Use deconvolution to recover `v`:

```
[q,r] = deconv(c,u)
q =
    10    20    30
r =
    0     0     0     0     0     0
```

This gives a quotient equal to `v` and a zero remainder.

More About

Algorithms

`deconv` uses the `filter` primitive.

See Also

`conv` | `residue`

Introduced before R2006a

del2

Discrete Laplacian

Syntax

```
L = del2(U)
L = del2(U,h)
L = del2(U,h1,...,hN)
```

Description

`L = del2(U)` returns a discrete approximation of Laplace's differential operator applied to `U` using the default spacing, `h = 1`, between all points.

`L = del2(U,h)` specifies a uniform, scalar spacing, `h`, between points in all dimensions of `U`.

`L = del2(U,h1,...,hN)` specifies the spacing, `h1,...,hN`, between points in each corresponding dimension of `U`. For each dimension, specify the spacing as a scalar or a vector of coordinates. The number of spacing inputs must equal the number of dimensions in `U`.

Examples

Second Derivative of Vector

Calculate the acceleration of an object from a vector of position data.

Create a vector of position data.

```
p = [1 3 6 10 16 18 29];
```

To find the acceleration of the object, use `del2` to calculate the second numerical derivative of `p`. Use the default spacing `h = 1` between data points.

```
L = 4*del2(p)

L =

     1     1     1     2    -4     9    22
```

Each value of `L` is an approximation of the instantaneous acceleration at that point.

Second Derivative of Cosine Vector

Calculate the discrete 1-D Laplacian of a cosine vector.

Define the domain of the function.

```
x = linspace(-2*pi,2*pi);
```

This produces 100 evenly spaced points in the range $-2\pi \le x \le 2\pi$.

Create a vector of cosine values in this domain.

```
U = cos(x);
```

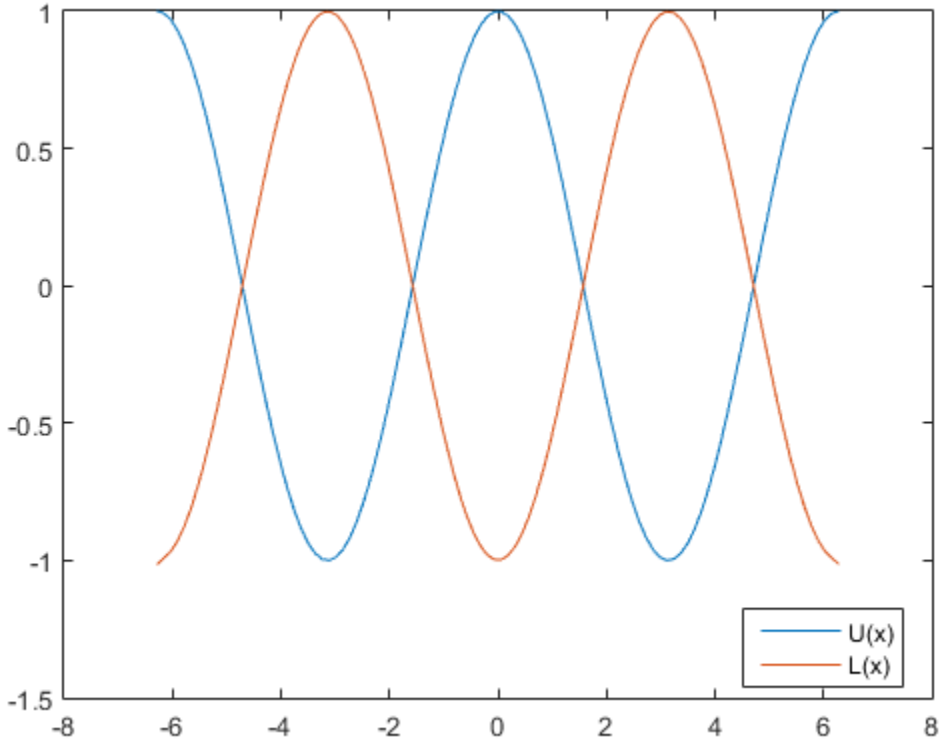
Calculate the Laplacian of `U` using `del2`. Use the domain vector `x` to define the 1-D coordinate of each point in `U`.

```
L = 4*del2(U,x);
```

Analytically, the Laplacian of this function is equal to $\Delta U = -\cos(x)$.

Plot the results.

```
plot(x,U,x,L)
legend('U(x)','L(x)','Location','Best')
```



The graph of U and L agrees with the analytic result for the Laplacian.

Laplacian of Multivariate Function

Calculate and plot the discrete Laplacian of a multivariate function.

Define the x and y domain of the function.

```
[x,y] = meshgrid(-5:0.25:5,-5:0.25:5);
```

Define the function $U(x,y) = \frac{1}{3}\left(x^4 + y^4\right)$ over this domain.

```
U = 1/3.*(x.^4+y.^4);
```

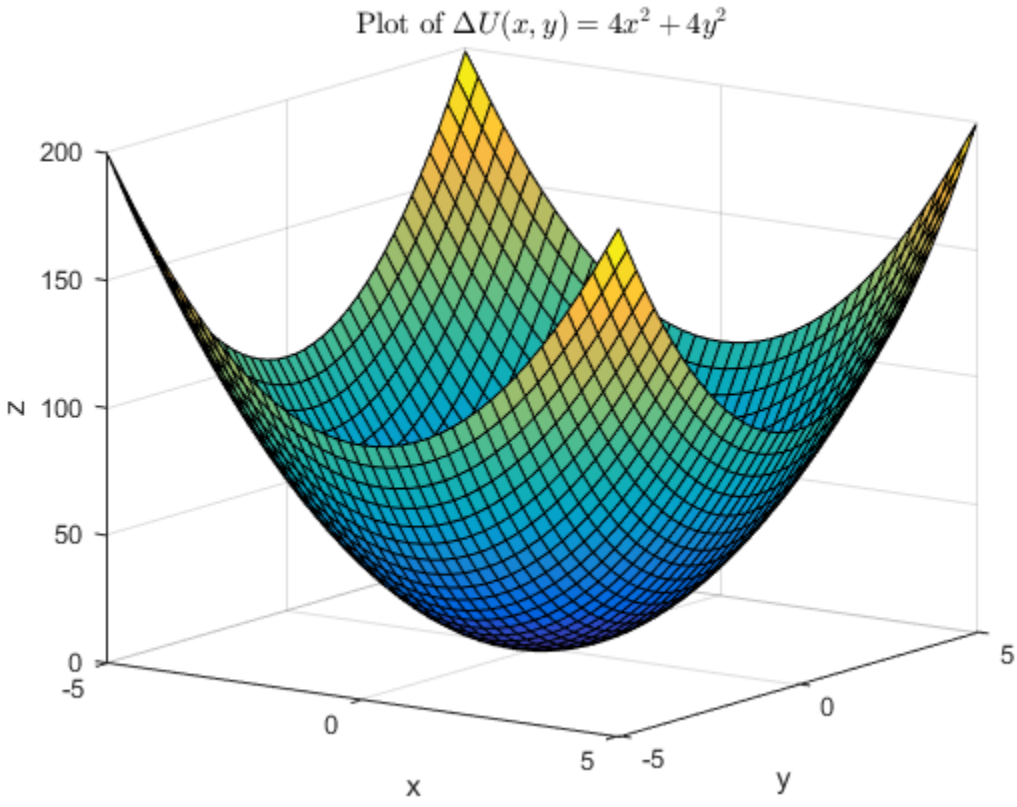
Calculate the Laplacian of this function using `del2`. The spacing between the points in `U` is equal in all directions, so you can specify a single spacing input, `h`.

```
h = 0.25;
L = 4*del2(U,h);
```

Analytically, the Laplacian of this function is equal to $\Delta U(x,y) = 4x^2 + 4y^2$.

Plot the discrete Laplacian, `L`.

```
figure
surf(x,y,L)
grid on
title('Plot of $\Delta U(x,y) = 4x^2+4y^2$','Interpreter','latex')
xlabel('x')
ylabel('y')
zlabel('z')
view(35,14)
```



The graph of `L` agrees with the analytic result for the Laplacian.

Laplacian of Natural Logarithm Function

Calculate the discrete Laplacian of a natural logarithm function.

Define the x and y domain of the function on a grid of real numbers.

```
[x,y] = meshgrid(-5:5,-5:0.5:5);
```

Define the function $U(x,y) = \frac{1}{2}\log\left(x^2 y\right)$ over this domain.

```
U = 0.5*log(x.^2.*y);
```

The logarithm is complex-valued when the argument `y` is negative.

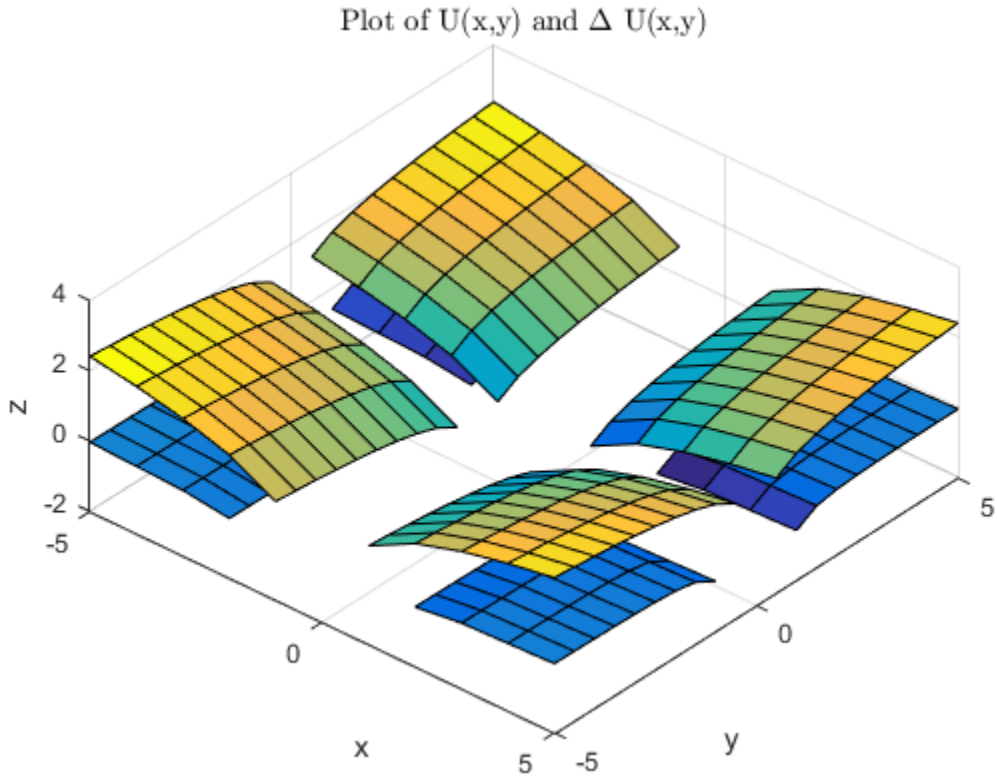
Use `del2` to calculate the discrete Laplacian of this function. Specify the spacing between grid points in each direction.

```
hx = 1;
hy = 0.5;
L = 4*del2(U,hx,hy);
```

Analytically, the Laplacian is equal to $\Delta U(x,y) = -\left(1/x^2 + 1/2y^2\right)$. This function is not defined on the lines $x = 0$ or $y = 0$.

Plot the real parts of `U` and `L` on the same graph.

```
figure
surf(x,y,real(L))
hold on
surf(x,y,real(U))
grid on
title('Plot of U(x,y) and $\Delta$ U(x,y)','Interpreter','latex')
xlabel('x')
ylabel('y')
zlabel('z')
view(41,58)
```



The top surface is `U` and the bottom surface is `L`.

Input Arguments

`U` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: `single` | `double`
Complex Number Support: Yes

h — Spacing in all dimensions

1 (default) | scalar

Spacing in all dimensions, specified as 1 (default), or a scalar.

Data Types: `single` | `double`
Complex Number Support: Yes

h1,...,hN — Spacing in each dimension

scalars | vectors

Spacing in each dimension, specified as scalars or vectors. The number of spacing inputs must be equal to the number of dimensions in U. Each spacing input defines the spacing between points in the corresponding dimension of U:

- Use a scalar to specify a uniform spacing.
- Use a vector to specify a nonuniform spacing. The coordinate vector gives the position of each point and must have the same number of elements as the corresponding dimension of U (a one-to-one match of coordinates and points).

Data Types: `single` | `double`
Complex Number Support: Yes

Output Arguments

L — Discrete Laplacian approximation

vector | matrix | multidimensional array

Discrete Laplacian approximation, returned as a vector, matrix, or multidimensional array. L is the same size as the input, U.

More About

Laplace's differential operator

If a matrix U is a function *U(x,y)* that is evaluated at the points of a square grid, then `4*del2(U)` is a finite difference approximation of Laplace's differential operator applied to *U*,

$$L = \frac{\Delta U}{4} = \frac{1}{4}\left(\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} \right).$$

For functions of more variables, *U(x,y,z,...)*, the discrete Laplacian `del2(U)` calculates second-derivatives in each dimension,

$$L = \frac{\Delta U}{2N} = \frac{1}{2N}\left(\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial z^2} + \ldots \right),$$

where N is the number of dimensions in U and $N \geq 2$.

Algorithms

If the input `U` is a matrix, the interior points of `L` are found by taking the difference between a point in `U` and the average of its four neighbors:

$$L_{ij} = \left[\frac{\left(u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1} \right)}{4} - u_{i,j} \right].$$

Then, `del2` calculates the values on the edges of `L` by linearly extrapolating the second differences from the interior. This formula is extended for multidimensional `U`.

Introduced before R2006a

DelaunayTri class

Superclasses: TriRep

(Will be removed) Delaunay triangulation in 2-D and 3-D

Note: `DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Description

`DelaunayTri` creates a Delaunay triangulation object from a set of points. You can incrementally modify the triangulation by adding or removing points. In 2-D triangulations you can impose edge constraints. You can perform topological and geometric queries, and compute the Voronoi diagram and convex hull.

Definitions

The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

Construction

.DelaunayTri	(Will be removed) Construct Delaunay triangulation

Methods

convexHull	(Will be removed) Convex hull

inOutStatus	(Will be removed) Status of triangles in 2-D constrained Delaunay triangulation
nearestNeighbor	(Will be removed) Point closest to specified location
pointLocation	(Will be removed) Simplex containing specified location
voronoiDiagram	(Will be removed) Voronoi diagram

Inherited methods

baryToCart	(Will be removed) Convert point coordinates from barycentric to Cartesian
cartToBary	(Will be removed) Convert point coordinates from cartesian to barycentric
circumcenters	(Will be removed) Circumcenters of specified simplices
edgeAttachments	(Will be removed) Simplices attached to specified edges
edges	(Will be removed) Triangulation edges
faceNormals	(Will be removed) Unit normals to specified triangles
featureEdges	(Will be removed) Sharp edges of surface triangulation

freeBoundary	(Will be removed) Facets referenced by only one simplex
incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information
size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

Properties

`Constraints`	`Constraints` is a `numc`-by-2 matrix that defines the constrained edge data in the triangulation, where `numc` is the number of constrained edges. Each constrained edge is defined in terms of its endpoint indices into `X`. The constraints can be specified when the triangulation is constructed or can be imposed afterwards by directly editing the constraints data. This feature is only supported for 2-D triangulations.
`X`	The dimension of `X` is `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside. If column vectors of `x`,`y` or `x`,`y`,`z` coordinates are used to construct the triangulation, the data is consolidated into a single matrix `X`.

`Triangulation`	Triangulation is a matrix representing the set of simplices (triangles or tetrahedra etc.) that make up the triangulation. The matrix is of size `mtri`-by-`nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex. The triangulation is represented by standard simplex-vertex format; each row specifies a simplex defined by indices into `X`, where `X` is the array of point coordinates.

Instance Hierarchy

`DelaunayTri` is a subclass of `TriRep`.

Copy Semantics

Value. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

DelaunayTri

Class: DelaunayTri

(Will be removed) Construct Delaunay triangulation

Note: `DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

Syntax

```
DT = DelaunayTri()
DT = DelaunayTri(X)
DT = DelaunayTri(x,y)
DT = DelaunayTri(x,y,z)
DT = DelaunayTri(..., C)
```

Description

`DT = DelaunayTri()` creates an empty Delaunay triangulation.

`DT = DelaunayTri(X)`, `DT = DelaunayTri(x,y)` and `DT = DelaunayTri(x,y,z)` create a Delaunay triangulation from a set of points. The points can be specified as an `mpts`-by-`ndim` matrix `X`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, where `ndim` is 2 or 3. Alternatively, the points can be specified as column vectors `(x,y)` or `(x,y,z)` for 2-D and 3-D input.

`DT = DelaunayTri(..., C)` creates a constrained Delaunay triangulation. The edge constraints `C` are defined by an `numc`-by-2 matrix, `numc` being the number of constrained edges. Each row of `C` defines a constrained edge in terms of its endpoint indices into the point set `X`. This feature is only supported for 2-D triangulations.

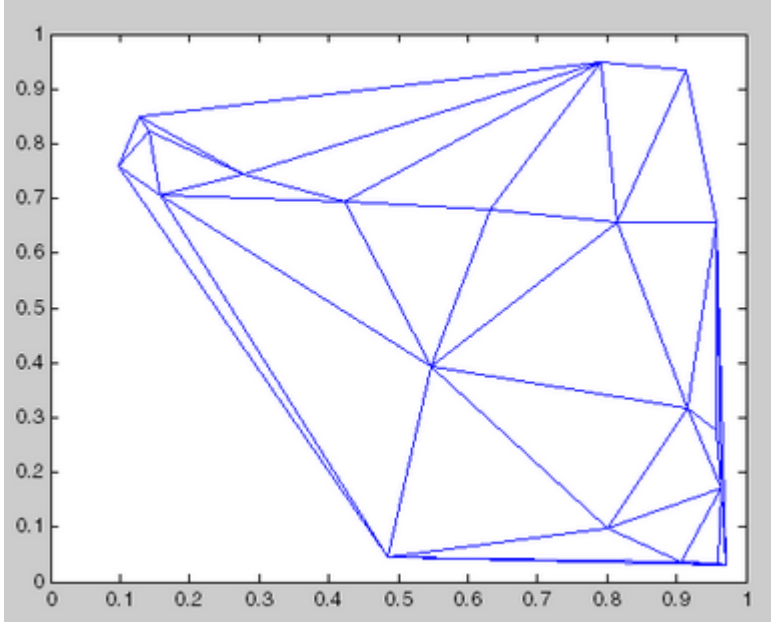
Definitions

The 2-D Delaunay triangulation of a set of points is the triangulation in which no point of the set is contained in the circumcircle for any triangle in the triangulation. The definition extends naturally to higher dimensions.

Examples

Compute the Delaunay triangulation of twenty random points located within a unit square.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y)
triplot(dt);
```



For more examples, type `help demoDelaunayTri` at the MATLAB command-line prompt.

See Also

`scatteredInterpolant` | `delaunayTriangulation` | `triangulation`

delaunay

Delaunay triangulation

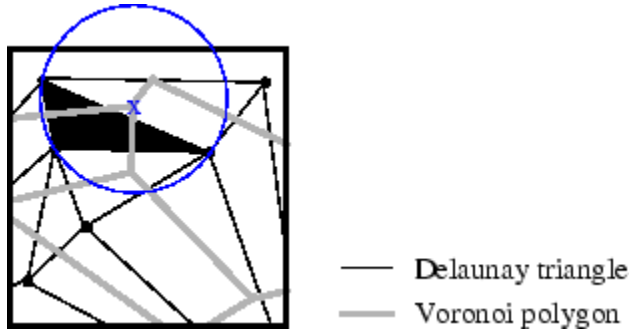
Note: Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `delaunay`.

Syntax

```
TRI = delaunay(X,Y)
TRI = delaunay(X,Y,Z)
TRI = delaunay(X)
```

Definitions

`delaunay` creates a Delaunay triangulation of a set of points in 2-D or 3-D space. A 2-D Delaunay triangulation ensures that the circumcircle associated with each triangle contains no other point in its interior. This definition extends naturally to higher dimensions.



Description

`TRI = delaunay(X,Y)` creates a 2-D Delaunay triangulation of the points (`X`,`Y`), where `X` and `Y` are column-vectors. `TRI` is a matrix representing the set of triangles that make up the triangulation. The matrix is of size `mtri`-by-3, where `mtri` is the number of triangles. Each row of `TRI` specifies a triangle defined by indices with respect to the points.

`TRI = delaunay(X,Y,Z)` creates a 3-D Delaunay triangulation of the points (`X`,`Y`,`Z`), where `X`, `Y`, and `Z` are column-vectors. `TRI` is a matrix representing the set of tetrahedra that make up the triangulation. The matrix is of size `mtri`-by-4, where `mtri` is the number of tetrahedra. Each row of `TRI` specifies a tetrahedron defined by indices with respect to the points.

`TRI = delaunay(X)` creates a 2-D or 3-D Delaunay triangulation from the point coordinates `X`. This variant supports the definition of points in matrix format. `X` is of size `mpts`-by-`ndim`, where `mpts` is the number of points and `ndim` is the dimension of the space where the points reside, $2 \leqq$ `ndim` $\leqq 3$. The output triangulation is equivalent to that of the dedicated functions supporting the 2-input or 3-input calling syntax.

`delaunay` produces an isolated triangulation, useful for applications like plotting surfaces via the `trisurf` function. If you wish to query the triangulation; for example, to perform nearest neighbor, point location, or topology queries, use `delaunayTriangulation` instead.

Visualization

Use one of these functions to plot the output of `delaunay`:

`triplot`	Displays the triangles defined in the `m`-by-3 matrix `TRI`.
`trisurf`	Displays each triangle defined in the m-by-3 matrix TRI as a surface in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example `trisurf(TRI,x,y,zeros(size(x)))`
`trimesh`	Displays each triangle defined in the m-by-3 matrix TRI as a mesh in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example,

	`trimesh(TRI,x,y,zeros(size(x)))` produces almost the same result as `triplot`, except in 3-D space.
`tetramesh`	Plots a triangulation composed of tetrahedra.

Examples

Plot Delaunay Triangulation

Plot the Delaunay triangulation of a large dataset.

```
load seamount
tri = delaunay(x,y);
trisurf(tri,x,y,z);
```

Introduced before R2006a

delaunayn

N-D Delaunay triangulation

Syntax

```
T = delaunayn(X)
T = delaunayn(X, options)
```

Description

`T = delaunayn(X)` computes a set of simplices such that no data points of `X` are contained in any circumspheres of the simplices. The set of simplices forms the Delaunay triangulation. `X` is an `m`-by-`n` array representing m points in n-dimensional space. `T` is a `numt`-by-(`n`+1) array where each row contains the indices into `X` of the vertices of the corresponding simplex.

`T = delaunayn(X, options)` specifies a cell array of strings `options`. The default options are:

- `{'Qt','Qbb','Qc'}` for 2- and 3-dimensional input
- `{'Qt','Qbb','Qc','Qx'}` for 4 and higher-dimensional input

If `options` is `[]`, the default options used. If `options` is `{''}`, no options are used, not even the default.

Visualization

Plotting the output of `delaunayn` depends of the value of `n`:

- For `n = 2`, use `triplot`, `trisurf`, or `trimesh` as you would for `delaunay`.
- For `n = 3`, use `tetramesh`.

  For more control over the color of the facets, use `patch` to plot the output.
- You cannot plot `delaunayn` output for `n > 3`.

Examples

3-D Delaunay Triangulation

This example generates an n-dimensional Delaunay triangulation, where `n = 3`.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d);  % A cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
X = [x(:) y(:) z(:)];
Tes = delaunayn(X)
```

```
Tes =

     4     3     9     1
     4     9     2     1
     7     9     3     1
     7     5     9     1
     7     9     4     3
     7     8     4     9
     6     2     9     1
     6     9     5     1
     6     4     9     2
     6     4     8     9
     6     9     7     5
     6     8     7     9
```

You can use `tetramesh` to visualize the tetrahedrons that form the corresponding simplex. `camorbit` rotates the camera position to provide a meaningful view of the figure.

```
tetramesh(Tes,X);
camorbit(20,0)
```

Introduced before R2006a

delaunayTriangulation class

Superclasses: triangulation

Delaunay triangulation in 2-D and 3-D

Description

Use the `delaunayTriangulation` class to create a 2-D or 3-D triangulation from a set of points. When your points are in 2-D, you can specify edge constraints .

You can perform a variety of topological and geometric queries on a `delaunayTriangulation`, including any `triangulation` query. For example, locate a facet that contains a specific point, find the vertices of the convex hull, or compute the Voronoi Diagram.

Construction

`DT = delaunayTriangulation(P)` creates a Delaunay triangulation from the points in `P`. Matrix `P` has 2 or 3 columns, depending on whether your points are in 2-D or 3-D space.

`DT = delaunayTriangulation(P,C)` specifies the edge constraints in matrix `C`. In this case, `P` specifies points in 2-D. Each row of `C` defines the start and end vertex IDs of a constrained edge.

`DT = delaunayTriangulation(x,y)` creates a 2-D Delaunay triangulation from the point coordinates in the column vectors, `x` and `y`.

`DT = delaunayTriangulation(x,y,C)` specifies the edge constraints in matrix `C`.

`DT = delaunayTriangulation(x,y,z)` creates a 3-D Delaunay triangulation from the point coordinates in the column vectors, `x`, `y`, and `z`.

`DT = delaunayTriangulation()` creates an empty Delaunay triangulation.

Input Arguments

`P`

Input points, specified as a matrix whose columns are the *x*, *y*, (and possibly *z*) coordinates of the triangulation points. The row numbers of `P` are the vertex IDs in the triangulation.

`x`

x-coordinates vector, specified as a column vector containing the *x*-coordinates of the triangulation points.

`y`

y-coordinates vector, specified as a column vector containing the *y*-coordinates of the triangulation points.

`z`

z-coordinates vector, specified as a column vector containing the *z*-coordinates of the triangulation points.

`C`

Vertex IDs of constrained edges, specified as a 2-column matrix. Each row of `C` corresponds to a constrained edge and contains two IDs:

- `C(j,1)` is the ID of the vertex at the start of an edge.
- `C(j,2)` is the ID of the vertex at end of the edge.

You can specify edge constraints for 2-D triangulations only.

Properties

`Points`

Points in the triangulation, represented as a matrix containing the following information:

- Each row in `DT.Points` contains the coordinates of a vertex.
- Each row number of `DT.Points` is a vertex ID.

`ConnectivityList`

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `DT.ConnectivityList` is a "Triangle or Tetrahedron ID" on page 1-2075.
- Each element is a vertex ID.

`Constraints`

Constrained edges, represented as a two-column matrix of vertex IDs. Each row of `DT.Constraints` corresponds to a constrained edge and contains two IDs:

- `DT.Constraints(j,1)` is the ID of the vertex at the start of an edge.
- `DT.Constraints(j,2)` is the ID of the vertex at end of the edge.

`DT.Constraints` is an empty matrix when the triangulation has no constrained edges.

Methods

convexHull	Convex hull
isInterior	Test if triangle is in interior of 2-D constrained Delaunay triangulation
voronoiDiagram	Voronoi diagram

Inherited Methods

barycentricToCartesian	Converts point coordinates from barycentric to Cartesian
cartesianToBarycentric	Converts point coordinates from Cartesian to barycentric

circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
nearestNeighbor	Vertex closest to specified location
neighbors	Neighbors to specified triangle or tetrahedron
pointLocation	Triangle or tetrahedron containing specified point
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

Definitions

Delaunay Triangulation

In a 2-D Delaunay triangulation, the circumcircle associated with each triangle does not contain any points in its interior. Similarly, a 3-D Delaunay triangulation does not have any points in the interior of the circumsphere associated with each tetrahedron. This definition extends to N-D, although `delaunayTriangulation` supports only 2-D and 3-D.

Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

Triangle or Tetrahedron ID

A row number of the matrix, `DT.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

2-D Delaunay Triangulation

Create a 2-D `delaunayTriangulation` for 30 random points.

```
P = gallery('uniformdata',[30 2],0);
DT = delaunayTriangulation(P)
```

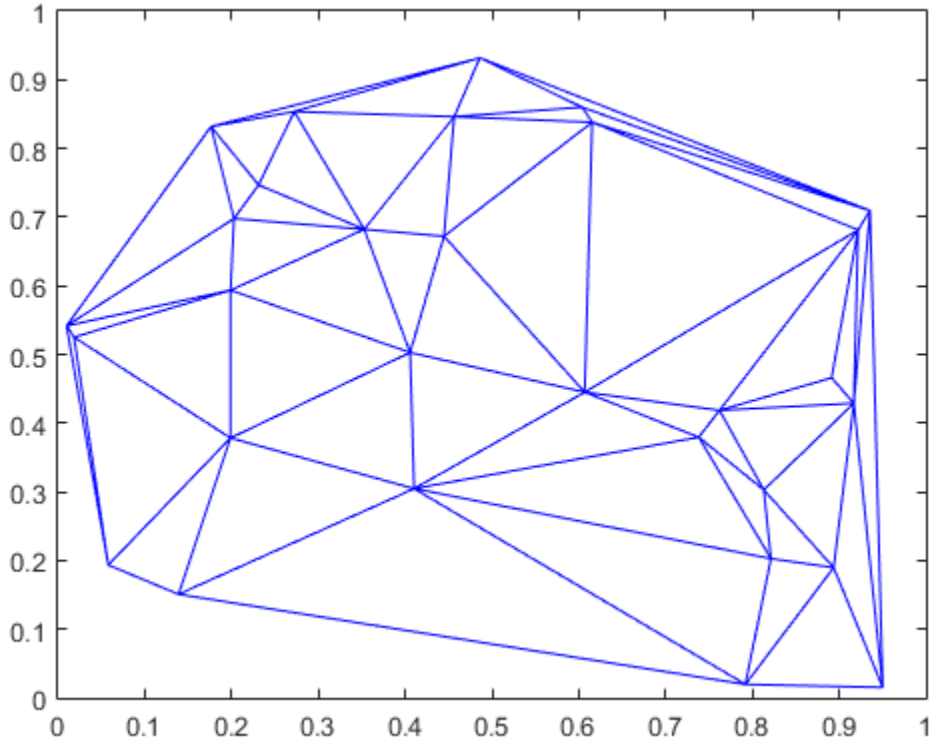
```
DT =
```

```
  delaunayTriangulation with properties:

             Points: [30x2 double]
  ConnectivityList: [50x3 double]
       Constraints: []
```

Plot the triangulation.

```
figure
triplot(DT)
```



3-D Delaunay Triangulation

Create a 3-D `delaunayTriangulation` for 30 random points.

```
x = gallery('uniformdata',[30 1],0);
y = gallery('uniformdata',[30 1],1);
z = gallery('uniformdata',[30 1],2);
DT = delaunayTriangulation(x,y,z)
```

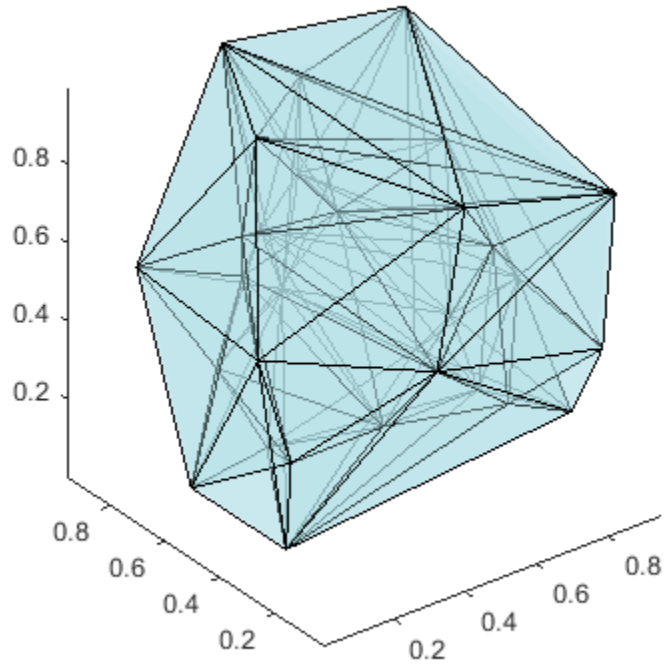
```
DT =

  delaunayTriangulation with properties:

             Points: [30x3 double]
    ConnectivityList: [111x4 double]
         Constraints: []
```

Plot the triangulation at 30% opacity with a light blue face color.

```
faceColor  = [0.6875 0.8750 0.8984];
figure
tetramesh(DT,'FaceColor',faceColor,'FaceAlpha',0.3);
```



See Also

`delaunay` | `delaunayn` | `triangulation`

convexHull

Class: delaunayTriangulation

Convex hull

Syntax

```
K = convexHull(DT)
[K,v] = convexHull(DT)
```

Description

`K = convexHull(DT)` returns the vertices of the convex hull.

`[K,v] = convexHull(DT)` also returns the area or volume bounded by the convex hull.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

Output Arguments

K

Convex hull vertices, returned as a matrix of vertex IDs. The shape of `K` depends on whether your triangulation is 2-D or 3-D:

- When `DT` is 2-D, `K` is a column vector containing the sequence of vertex IDs around the convex hull.
- When `DT` is 3-D, `K` is a triangulation connectivity list containing the triangles on the convex hull.

v

Area or volume bounded by the convex hull, returned as a scalar value.

Definitions

Vertex ID

A row number of the matrix, `DT.Points`. Use this ID to refer a specific vertex in the triangulation.

Examples

Convex Hull in 2-D Space

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);
y = gallery('uniformdata',[10,1],1);
DT = delaunayTriangulation(x,y);
```

Calculate the convex hull.

```
k = convexHull(DT)
```

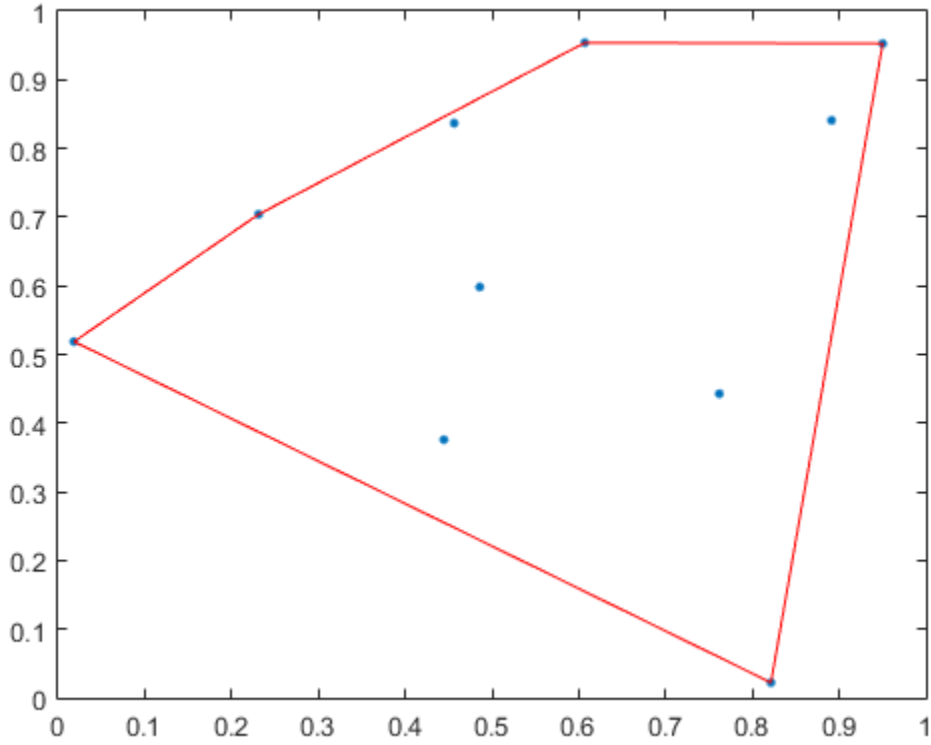
```
k =

     1
     3
     2
     8
     9
     1
```

Plot the points and highlight the convex hull in red.

```
figure
```

```
plot(DT.Points(:,1),DT.Points(:,2), '.','markersize',10);
hold on
plot(DT.Points(k,1),DT.Points(k,2),'r')
hold off
```



Convex Hull in 3-D Space

Use `convexHull` to calculate the convex hull of a set of random points within a unit cube.

Create a Delaunay triangulation from a set of random points.

```
P = gallery('uniformdata',[25,3],1);
```

```
DT = delaunayTriangulation(P);
```

Calculate the convex hull and the volume bounded by the convex hull.

```
[K,v] = convexHull(DT);
```

Examine the volume.

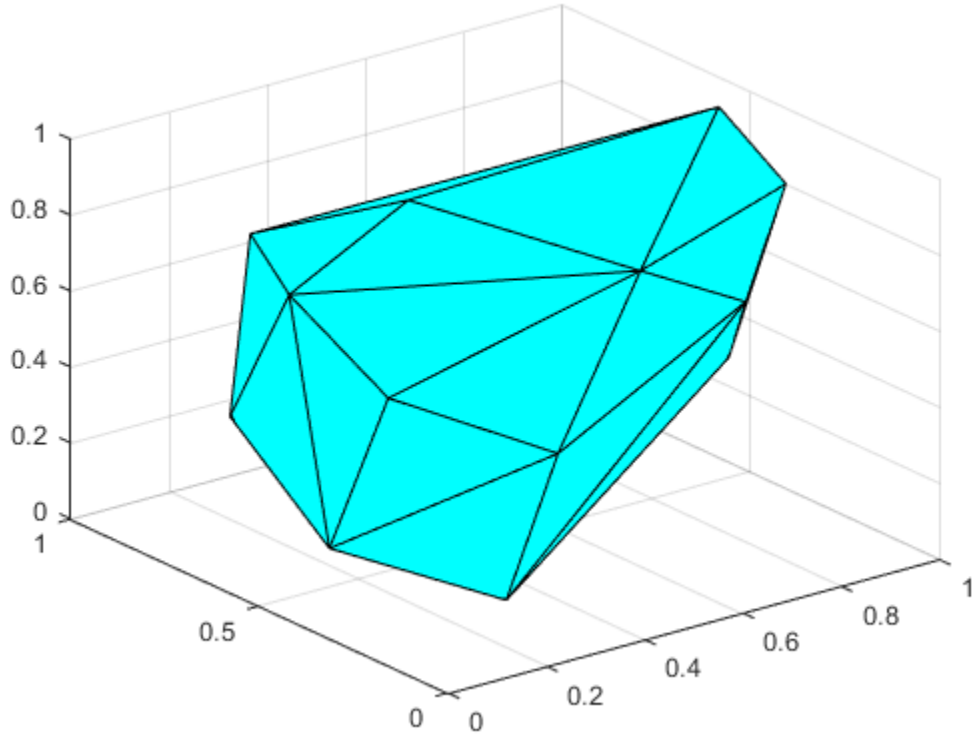
```
v
```

```
v =

    0.3561
```

Plot the convex hull.

```
trisurf(K,DT.Points(:,1),DT.Points(:,2),DT.Points(:,3),...
       'FaceColor','cyan')
```



See Also

`convhull` | `convhulln` | `triangulation` | `voronoiDiagram`

isInterior

Class: delaunayTriangulation

Test if triangle is in interior of 2-D constrained Delaunay triangulation

Syntax

```
tf = isInterior(DT)
```

Description

`tf = isInterior(DT)` returns an array of logical values that indicate whether the triangles in a constrained Delaunay triangulation are inside the bounded geometric domain. A triangle, `DT.ConnectivityList(j,:)`, is classified as inside the domain when `tf(j)` is `true`. Otherwise, the triangle is outside the domain.

Input Arguments

`DT`

A 2-D `delaunayTriangulation` that has a set of constrained edges that define a bounded geometric domain.

Output Arguments

`tf`

Logical values, returned as a column vector. Element `tf(j)` is `true` when the triangle whose ID is `j` is inside the domain of `DT`.

Definitions

Triangle ID

A row number of the matrix, `DT.ConnectivityList`. You use this ID to refer a specific triangle.

Examples

Find and Plot Triangles within a Boundary

Create a geometric domain whose shape is a square frame.

```
outerprofile = [-5 -5; -3 -5; -1 -5;  1 -5;
                 3 -5;  5 -5;  5 -3;  5 -1;
                 5  1;  5  3;  5  5;  3  5;
                 1  5; -1  5; -3  5; -5  5;
                -5  3; -5  1; -5 -1; -5 -3];

innerprofile = outerprofile.*0.5;
profile = [outerprofile; innerprofile];
```

Define the edge constraints.

```
outercons = [(1:19)' (2:20)'; 20 1;];
innercons = [(21:39)' (22:40)'; 40 21];
C = [outercons; innercons];
```

Create the constrained Delaunay triangulation.

```
DT = delaunayTriangulation(profile,C);
```

Plot the triangulation.

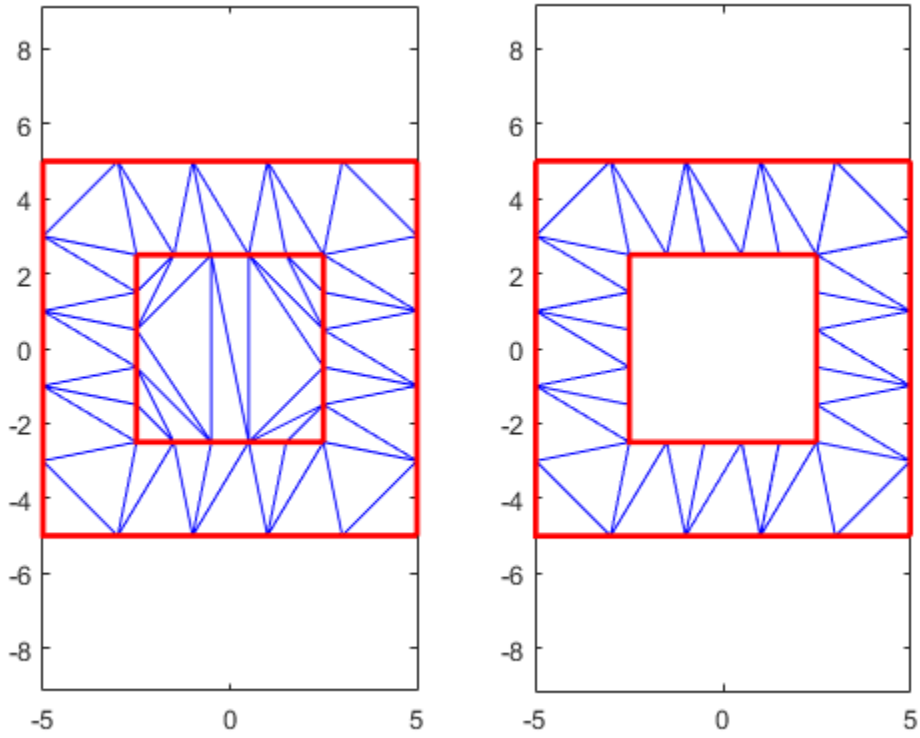
```
figure
subplot(1,2,1)
triplot(DT)

% Highlight the inner square in red.
hold on
plot(DT.Points(innercons',1),DT.Points(innercons',2),...
     '-r','LineWidth',2)
```

```
% Highlight the outer square in red and resize the |x| and |y| axes to make
% the plot square.
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...
     '-r','LineWidth', 2)
axis equal

% Plot only the triangles that lie inside of the domain.
hold off
subplot(1,2,2)
inside = isInterior(DT);
triplot(DT.ConnectivityList(inside, :),DT.Points(:,1),DT.Points(:,2))

% Highlight the inner and outer squares in red.
hold on
plot(DT.Points(outercons',1),DT.Points(outercons',2), ...
     '-r','LineWidth', 2)
plot(DT.Points(innercons',1),DT.Points(innercons',2), ...
     '-r','LineWidth', 2)
axis equal
hold off
```



See Also

`triangulation`

voronoiDiagram

Class: delaunayTriangulation

Voronoi diagram

Syntax

```
[V,R] = voronoiDiagram(DT)
```

Description

`[V,R] = voronoiDiagram(DT)` returns the Voronoi vertices, `V`, and the Voronoi regions, `R`, of the points, `DT.Points`.

The *Voronoi diagram* of a set of points, such as `DT.Points`, decomposes the space around each point, `DT.Points(j,:)`, into a region of influence, `R{j}`. Locations within the region, `R{j}`, are closer to point `j` than any other point in `DT.Points`. The region of influence is called the *Voronoi region*. The collection of all the Voronoi regions is the Voronoi diagram.

The Voronoi regions associated with points that lie on the convex hull of `DT.Points` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

Input Arguments

DT

A Delaunay triangulation, see `delaunayTriangulation`.

Output Arguments

V

Voronoi vertices, returned as a matrix. Each row of `V` contains the coordinates of a Voronoi vertex.

R

Voronoi regions, returned as a vector cell array the same length as `DT.Points`. The elements of `R` are row numbers of `V`. The coordinates of the Voronoi vertices bounding a region are `V(R{j},:)`. The Voronoi region associated with the point `DT.Points(j)` is `R{j}`.

Examples

Compute the Voronoi Diagram of a 2-D Triangulation

Create a Delaunay triangulation from a set of points.

```
P = [ 0.5    0
      0      0.5
     -0.5   -0.5
     -0.2   -0.1
     -0.1    0.1
      0.1   -0.1
      0.1    0.1 ];
DT = delaunayTriangulation(P);
```

Calculate the Voronoi vertices and regions.

```
[V,R] = voronoiDiagram(DT);
```

Examine the connectivity of the Voronoi region associated with the third point in the triangulation.

```
R{3}
```

```
ans =

     1    10     7     4
```

Examine the coordinates of the Voronoi vertices bounding the region.

```
V(R{3},:)
```

```
ans =

       Inf       Inf
    0.7000   -1.6500
```

```
   -0.0500   -0.5250
   -1.7500    0.7500
```

The `Inf` values indicate that the region contains points on the convex hull.

See Also

`convexHull` | `triangulation` | `voronoi` | `voronoin`

delete

Delete files or objects

Syntax

```
delete('fileName1', 'filename2', ...)
delete fileName
delete(h)
delete(handle_array)
```

Description

`delete('fileName1', 'filename2', ...)` deletes the files `fileName1`, `fileName2`, and so on, from the disk. `fileName` is a string and can be an absolute path or a path relative to the current folder. `fileName` also can include wildcards (`*`).

`delete fileName` is the command syntax. Delete multiple files by appending filenames, separated by spaces. When filenames contain space characters, you must use the function form.

`delete(h)` deletes the graphics object `h`. If `h` an array, the function deletes all objects in the array. `h` can also contain the figure `Number`.

The function deletes objects without requesting verification, even if when the objects are figure windows.

`delete(handle_array)` is a method of the `handle` class. It removes from memory the handle objects referenced by `handle_array`.

When deleted, any references to the objects in `handle_array` become invalid. To remove the handle variables, use the `clear` function.

As `delete` does not ask for confirmation, to avoid accidentally losing files or graphics objects, be sure to specify accurately the items to delete. To move files to a different location when running `delete`, use the **General** preference for **Deleting files**, or the `recycle` function.

The `delete` function deletes files and graphics objects only. To delete folders, use `rmdir`.

Examples

Delete all files with a `.mat` extension in the `/mytests/` folder:

```
delete('/mytests/*.mat')
```

Create a figure and an axes, and then delete the axes:

```
fig = figure;
ax = axes;
...
delete(ax)
```

The axes is deleted, but the figure remain. The axes variable `ax` remains in the workspace, but no longer refers to an object.

Use an array to delete all the line objects created by `plot`:

```
H = plot(magic(5));
```

Pass the array `H` to `delete`:

```
delete(H)
```

- "Specify File Names"

See Also

`dir` | `rmdir` | `clear` | `recycle`

Introduced before R2006a

delete (COM)

Remove COM control or server

Syntax

```
delete(h)
```

Description

`delete(h)` releases all interfaces derived from the specified COM server or control, and then deletes the server or control itself.

The `release` function, releases and invalidates an interface, but does not delete the server or control.

COM functions are available on Microsoft Windows systems only.

See Also

`save (COM)` | `load (COM)` | `release` | `actxcontrol` | `actxserver`

Introduced before R2006a

delete

Class: FTP

Remove file on FTP server

Syntax

```
delete(ftpobj,filename)
```

Description

`delete(ftpobj,filename)` removes the specified file from the current folder on the FTP server associated with ftpobj.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`filename`

String enclosed in single quotation marks that specifies the name of the file to delete.

Examples

Suppose that a hypothetical host, `ftp.testsite.com`, contains `myfile.m`. Connect to the server and delete the file:

```
test=ftp('ftp.testsite.com');
delete(test,'myfile.m');
```

See Also

`rmdir` | `ftp`

Introduced before R2006a

delete (serial)

Remove serial port object from memory

Syntax

```
delete(obj)
```

Description

`delete(obj)` removes `obj` from memory, where `obj` is a serial port object or an array of serial port objects.

Examples

This example creates the serial port object `s` on a Windows platform, connects `s` to the device, writes and reads text data, disconnects `s` from the device, removes `s` from memory using `delete`, and then removes `s` from the workspace using `clear`.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fclose(s)
delete(s)
clear s
```

More About

Tips

When you delete `obj`, it becomes an *invalid* object. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command. If multiple references to `obj` exist in the workspace, then deleting one reference invalidates the remaining references.

If `obj` is connected to the device, it has a `Status` property value of `open`. If you issue `delete` while `obj` is connected, then the connection is automatically broken. You can also disconnect `obj` from the device with the `fclose` function.

See Also

`clear` | `isvalid` | `fclose` | `Status`

Introduced before R2006a

deleteproperty

Remove custom property from COM object

Syntax

```
deleteproperty(h,'name')
```

Description

`deleteproperty(h,'name')` deletes property specified in string, `name`, from custom properties belonging to object or interface, `h`.

You can only delete properties created with the `addproperty` function.

COM functions are available on Microsoft Windows systems only.

Examples

This example removes a custom property from an instance of the MATLAB sample control.

1 Create an instance of the control:

```
f = figure('position',[100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2',[0 0 200 200],f);
get(h)
```

```
     Label: 'Label'
    Radius: 20
```

MATLAB also displays interfaces.

2 Add a custom property named `Position` and assign a value:

```
addproperty(h,'Position');
h.Position = [200 120];
get(h)
```

```
        Label: 'Label'
       Radius: 20
     Position: [200 120]
```

3 Delete the custom property `Position`:

```
deleteproperty(h,'Position');
get(h)
```

```
     Label: 'Label'
    Radius: 20
```

MATLAB displays the original list of properties:

Introduced before R2006a

delevent

Remove `tsdata.event` objects from `timeseries` object

Syntax

```
ts = delevent(ts,event)
ts = delevent(ts,events)
ts = delevent(ts,event,n)
```

Description

`ts = delevent(ts,event)` removes the `tsdata.event` object from the `ts.events` property, where `event` is an event name string.

`ts = delevent(ts,events)` removes the `tsdata.event` object from the `ts.events` property, where `events` is a cell array of event name strings.

`ts = delevent(ts,event,n)` removes the `n`th `tsdata.event` object from the `ts.events` property. `event` is the name of the `tsdata.event` object.

Examples

The following example shows how to remove an event from a `timeseries` object:

1. Create a time series.

   ```
   ts = timeseries(rand(5,4))
   ```

2. Create an event object called `'test'` such that the event occurs at time `3`.

   ```
   e = tsdata.event('test',3)
   ```

3. Add the event object to the time series `ts`.

   ```
   ts = addevent(ts,e)
   ```

4. Remove the event object from the time series `ts`.

   ```
   ts = delevent(ts,'test')
   ```

delsamplefromcollection

Remove sample from `tscollection` object

Syntax

```
tsc = delsamplefromcollection(tsc,'Index',N)
tsc = delsamplefromcollection(tsc,'Value',Time)
```

Description

`tsc = delsamplefromcollection(tsc,'Index',N)` deletes samples from the `tscollection` object tsc. N specifies the indices of the tsc time vector that correspond to the samples you want to delete.

`tsc = delsamplefromcollection(tsc,'Value',Time)` deletes samples from the `tscollection` object tsc. Time specifies the time values that correspond to the samples you want to delete.

Introduced before R2006a

demo

Access product examples in Help browser

Syntax

```
demo
demo type
demo type name
```

Description

`demo` displays the list of MATLAB examples in the Help browser.

`demo type` lists the examples for the specified product. Valid values for `type` are `matlab` or `simulink`.

`demo type name` lists the examples for products other than MATLAB or Simulink. Valid values for `type` include `matlab`, `simulink`, `toolbox`, or `blockset`.

Examples

MATLAB Examples

```
demo matlab
```

Statistics and Machine Learning Toolbox Examples

```
demo toolbox statistics
```

Communications System Toolbox Examples

```
demo toolbox 'communications system'
```

Simulink Control Design Examples

```
demo simulink 'simulink control design'
```

Input Arguments

`type` — Product name or type

`matlab` (default) | `simulink` | `toolbox` | `blockset`

Product name or type, specified as one of these strings: `matlab`, `simulink`, `toolbox`, or `blockset`. For products other than MATLAB or Simulink, you must also specify a name input that corresponds to the product name.

`name` — Product name other than MATLAB or Simulink

string

Product name other than MATLAB or Simulink, specified as a string. If `name` requires multiple words, enclose it in single quotes.

More About

Tips

- To access third-party and custom examples without using the `demo` command, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.

Introduced before R2006a

depdir

List dependent folders for function or P-file

Note: `depdir` will be removed in a future release. Use `matlab.codetools.requiredFilesAndProducts` instead.

Syntax

```
list = depdir('file_name')
[list, prob_files, prob_sym, prob_strings] = depdir('file_name')
[...] = depdir('file_name1', 'file_name2',...)
```

Description

The `depdir` function lists the folders of all the functions that a specified function or P-file needs to operate. This function is useful for finding all the folders that need to be included with a run-time application and for determining the run-time path.

`list = depdir('file_name')` creates a cell array of strings containing the folders of all the function and P-files that `file_name.m` or `file_name.p` uses. This includes the second-level files that are called directly by `file_name`, as well as the third-level files that are called by the second-level files, and so on.

`[list, prob_files, prob_sym, prob_strings] = depdir('file_name')` creates three additional cell arrays containing information about any problems with the `depdir` search. `prob_files` contains filenames that `depdir` was unable to parse. `prob_sym` contains symbols that `depdir` was unable to find. `prob_strings` contains callback strings that `depdir` was unable to parse.

`[...] = depdir('file_name1', 'file_name2',...)` performs the same operation for multiple files. The dependent folders of all files are listed together in the output cell arrays.

Examples

```
list = depdir('mesh')
```

See Also

`matlab.codetools.requiredFilesAndProducts`

Introduced before R2006a

depfun

List dependencies of function or P-file

Compatibility

`depfun` will be removed in a future release. Use `matlab.codetools.requiredFilesAndProducts` instead.

Syntax

```
list = depfun(fun)
[list,builtins] = depfun(fun)
[list,builtins,classes] = depfun(fun)
[list,builtins,classes,prob_files] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings] = depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,called_from] =
depfun(fun)
[list,builtins,classes,prob_files,~,eval_strings,called_from,
opaque_classes] = depfun(fun)

___ = depfun(fun1,...,funN)

___ = depfun( ___ ,option1,...,optionM)
```

Description

`list = depfun(fun)` returns the paths of MATLAB program files that `fun` requires to run, where `fun` is a function, a P-file, or a figure file for a user interface. The output list includes second-level functions that `fun` calls directly, functions that the second-level functions call, and so on. The `depfun` function also displays a report in the Command Window.

Note:

- `depfun` does not always list all dependent files. For example, `depfun` does not list files hidden in callbacks or files whose names are constructed dynamically for evaluation.

- The output list often includes extra files that are not called when the function is actually evaluated.
- If `depfun` returns a parse error for any of the required functions, then the rest of the output of `depfun` might be incomplete. Correct the problematic files and invoke `depfun` again.

`[list,builtins] = depfun(fun)` returns the built-in functions that `fun` requires.

`[list,builtins,classes] = depfun(fun)` returns the MATLAB classes that `fun` requires.

`[list,builtins,classes,prob_files] = depfun(fun)` returns the files that `depfun` cannot parse, find, or access. If there are problematic files (that is, if `prob_files` is not empty), then the rest of the output of `depfun` might be incomplete. Correct the problematic files, and then invoke `depfun` again.

`[list,builtins,classes,prob_files,~,eval_strings] = depfun(fun)` returns a list of files that contain calls to `eval` or related functions (`evalin`, `feval`, or `evalc`). These calls potentially use functions that are not in `list`.

The fifth output argument for `depfun` is not implemented, and returns an empty structure array. To request arguments later in the list, use the tilde symbol (~) as a placeholder. The tilde suppresses the creation of an extra, empty variable.

`[list,builtins,classes,prob_files,~,eval_strings,called_from] = depfun(fun)` returns a cell array of indices that maps each function in `list` to the set of functions that call it. That is, `list{called_from{k}}` returns the paths to the functions that call the function in `list{k}`.

`[list,builtins,classes,prob_files,~,eval_strings,called_from, opaque_classes] = depfun(fun)` returns the opaque classes that `fun` requires, such as Java or COM classes.

`___ = depfun(fun1,...,funN)` returns the functions required for multiple functions `fun1,...,funN`. You can request any of the outputs from the previous syntaxes.

`___ = depfun( ___ ,option1,...,optionM)` modifies the output as described by the specified options. For example, specify `'-toponly'` to list only the functions that `fun` calls directly. You can precede the options with one or more function names.

Examples

Identify Required Functions

Identify the MATLAB program files that `strtok.m` requires to run.

```
fun = 'strtok.m';
list = depfun(fun);
```

MATLAB displays a summary report in the Command Window and stores the list of files in variable `list`.

Identify Top-Level Dependencies Only

List only the program files that `strtok.m` calls directly.

```
fun = 'strtok.m';
list = depfun(fun,'-toponly')
```

```
============================================================
depfun report summary:(top only)
------------------------------------------------------------
-> trace list:           2 files  (total)
                         1 files  (total arguments)
                         0 files  (arguments off MATLABPATH)
                         0 files  (argument duplicates on MATLABPATH)
------------------------------------------------------------
Notes: 1. Use argument  '-quiet' to not print this summary.
       2. Use arguments '-print','file' to produce a full
          report in file.
       3. Use argument  '-all' to display all possible
          left hand side arguments in the report(s).
============================================================

list =

    'matlabroot\toolbox\matlab\strfun\strtok.m'
    'matlabroot\toolbox\matlab\strfun\@cell\strtok.m'
```

Determine Which File Invokes Each Function

One of the functions that `strtok.m` depends upon is `num2cell`. Determine which file in the dependency list calls `num2cell`.

Identify the functions that `strtok.m` requires (`list`) and the files that invoke each of those functions (`called_from`).

```
fun = 'strtok.m';
[list,builtins,classes,prob_files,~,eval_strings,...
    called_from] = depfun(fun);
```

Find the index for `num2cell` within the dependency list.

```
num2cell_path = which('num2cell');
num2cell_index = find(ismember(list,num2cell_path))
```

```
num2cell_index =
     5
```

Identify the file that calls `num2cell`.

```
calls_num2cell = list{called_from{num2cell_index}}
```

```
calls_num2cell =
     matlabroot\toolbox\matlab\elmat\repmat.m
```

Input Arguments

`fun` — Function name

string | cell array of strings

Function name, specified as a string or a cell array of strings.

`fun` must be on the MATLAB path, as determined by the `which` function. If the path contains any relative folders, then files in those folders also will have a relative path in the output.

Example: `'plot.m'`

Example: `'plot.m','mesh.m'`

Example: `{'plot.m','mesh.m'}`

Data Types: `char` | `cell`

`option` — Reporting option

`'-toponly'` | `'-verbose'` | `'-quiet'` | `'-print'` | ...

Reporting option, specified as one of the following strings.

Option	Description
`'-toponly'`	Identify only the files used directly by the specified function(s), `fun`.
`'-verbose'`	Display additional internal messages.
`'-quiet'`	Display only error and warning messages, and not a summary report.
`'-print',filename`	Print a full report to the specified file.
`'-all'`	Display all outputs in the report, but return only the specified output arguments.
`'-expand'`	Include both indices and full paths in an exported report for the `call` or `called_from` list. Requires the `'-print'` option. This information does not appear in the Command Window report.
`'-calltree'`	Replaces the `called_from` list with a list of functions that each file calls, as derived from the `called_from` list.

Example: `'-print','myreport.txt'`

Data Types: `char`

Output Arguments

`list` — Paths to required files

cell array of strings

Paths to required files, returned as a cell array of strings.

`builtins` — Required MATLAB built-in functions

cell array of strings

Required MATLAB built-in functions, returned as a cell array of strings.

`classes` — Required MATLAB classes
cell array of strings

Required MATLAB classes, returned as a cell array of strings.

`prob_files` — Files that `depfun` cannot parse or access
structure

Files that `depfun` cannot parse or access, returned as a structure with these fields:

- `name` — Path to the file
- `listindex` — Index of the file in `list`
- `errmsg` — Error message that describes the problem
- `errid` — Error identifier, if present

`eval_strings` — Files that call evaluation functions
cell array of strings

Files that call evaluation functions, returned as a cell array of strings.

`called_from` — Indices to files that call each function in `list`
cell array

Indices to files that call each function in list, returned as a cell array. Each element of the cell array is a numeric array of indices that correspond to elements in `list`. The list and called_from outputs have the same length.

`opaque_classes` — Paths to opaque classes
cell array of strings

Paths to opaque classes, such as Java or COM classes, returned as a cell array of strings.

- "Identify Program Dependencies"

Introduced before R2006a

det

Matrix determinant

Syntax

```
d = det(A)
```

Description

`d = det(A)` returns the determinant of square matrix `A`.

Examples

Calculate Determinant of Matrix

Create a 3-by-3 square matrix, `A`.

```
A = [1 -2 4; -5 2 0; 1 0 3]
```

```
A =

     1    -2     4
    -5     2     0
     1     0     3
```

Calculate the determinant of `A`.

```
d = det(A)
```

```
d =

   -32
```

The determinant of `A` is -32.

Determine if Matrix Is Singular

Examine why the determinant is not an accurate measure of singularity.

Create a 10-by-10 matrix by multiplying an identity matrix, `eye(10)`, by a small number.

```
A = eye(10)*0.0001;
```

The matrix `A` has very small entries along the main diagonal. However, `A` is *not* singular, because it is a multiple of the identity matrix.

Calculate the determinant of `A`.

```
d = det(A)
```

```
d =

   1.0000e-40
```

The determinant is extremely small. A tolerance test of the form `abs(det(A)) < tol` is likely to flag this matrix as singular. Although the determinant of the matrix is close to zero, `A` is actually not ill conditioned. Therefore, `A` is not close to being singular. The determinant of a matrix can be arbitrarily close to zero without conveying information about singularity.

To investigate if `A` is singular, use either the `cond` or `rcond` functions.

Calculate the condition number of `A`.

```
c = cond(A)
```

```
c =

     1
```

The result confirms that `A` is not ill conditioned.

Compute Determinant of Inverse of Ill-Conditioned Matrix

Examine how to calculate the determinant of the matrix inverse `A^(-1)`, for an ill-conditioned matrix `A`, without explicitly calculating `A^(-1)`.

Create a 10-by-10 Hilbert matrix, `A`.

```
A = hilb(10);
```

Find the condition number of `A`.

```
c = cond(A)

c =

   1.6025e+13
```

The large condition number suggests that A is close to being singular, so calculating `inv(A)` might produce inaccurate results. Therefore, the inverse determinant calculation `det(inv(A))` is also inaccurate.

Calculate the determinant of the inverse of A by exploiting the fact that $\det\left(A^{-1}\right)=\frac{1}{\det(A)}$.

```
d1 = 1/det(A)

d1 =

   4.6202e+52
```

This method avoids computing the inverse of the matrix, A.

Calculate the determinant of the exact inverse of the Hilbert matrix, A, using `invhilb`. Compare the result to `d1` to find the relative error in `d1`.

```
d = det(invhilb(10));
relError = abs(d1-d)/abs(d)

relError =

   1.1462e-04
```

The relative error in `d1` is reasonably small. Avoiding the explicit computation of the inverse of A minimizes it.

For comparison, also calculate the determinant of the inverse of A by explicitly calculating the inverse. Compare the result to `d` to see the relative error.

```
d2 = det(inv(A));
relError2 = abs(d2-d)/abs(d)

relError2 =

   1.2427e+08
```

The relative error in the calculation of d2 is many orders of magnitude larger than that of d1.

Find Determinant of Singular Matrix

Examine a matrix that is exactly singular, but which has a large nonzero determinant. In theory, the determinant of any singular matrix is zero, but because of the nature of floating-point computation, this ideal is not always achievable.

Create a 13-by-13 diagonally dominant singular matrix, A.

```
A = diag([24 46 64 78 88 94 96 94 88 78 64 46 24]);
S = diag([-13 -24 -33 -40 -45 -48 -49 -48 -45 -40 -33 -24],1);
A = A + S + rot90(S,2)
```

```
A =

    24   -13     0     0     0     0     0     0     0     0     0     0     0
   -24    46   -24     0     0     0     0     0     0     0     0     0     0
     0   -33    64   -33     0     0     0     0     0     0     0     0     0
     0     0   -40    78   -40     0     0     0     0     0     0     0     0
     0     0     0   -45    88   -45     0     0     0     0     0     0     0
     0     0     0     0   -48    94   -48     0     0     0     0     0     0
     0     0     0     0     0   -49    96   -49     0     0     0     0     0
     0     0     0     0     0     0   -48    94   -48     0     0     0     0
     0     0     0     0     0     0     0   -45    88   -45     0     0     0
     0     0     0     0     0     0     0     0   -40    78   -40     0     0
     0     0     0     0     0     0     0     0     0   -33    64   -33     0
     0     0     0     0     0     0     0     0     0     0   -24    46   -24
     0     0     0     0     0     0     0     0     0     0     0   -13    24
```

A is singular because the rows are linearly dependent. For instance, sum(A) produces a vector of zeros.

Calculate the determinant of A.

```
d = det(A)
```

```
d =

     1.059686712222177e+05
```

The determinant of A is quite large despite the fact that A is singular. In fact, the determinant of A should be exactly zero! The inaccuracy of d is due to an aggregation of

round-off errors in the MATLAB implementation of the LU decomposition, which `det` uses to calculate the determinant. This result demonstrates a few important aspects of calculating numeric determinants. See the "Limitations" on page 1-2118 section for more details.

Input Arguments

A — Input matrix

square numeric matrix

Input matrix, specified as a square numeric matrix.

Data Types: `single` | `double`
Complex Number Support: Yes

Limitations

Avoid using `det` to examine if a matrix is singular because of the following limitations. Use `cond` or `rcond` instead.

Limitation	Result
The magnitude of the determinant is typically unrelated to the condition number of a matrix.	The determinant of a matrix can be arbitrarily large or small without changing the condition number.
`det` uses the LU decomposition to calculate the determinant, which is susceptible to floating-point round-off errors.	The determinant calculation is sometimes numerically unstable. For example, `det` can produce a large-magnitude determinant for a singular matrix, even though it should have a magnitude of 0.

More About

Algorithms

`det` computes the determinant from the triangular factors obtained by Gaussian elimination with the `lu` function.

```
[L,U] = lu(X)
s =  det(L)      % This is always +1 or -1
det(X) = s*prod(diag(U))
```

cond | condest | inv | lu | mldivide | rcond | rref

Introduced before R2006a

details

Display array details

Syntax

```
details(A)
```

Description

`details(A)` displays detailed information about the array, `A`.

When `A` is a MATLAB object array, `details` displays more information than the default display. This information includes:

- Fully qualified class name, including package names
- Link to class documentation
- Link to `handle` class documentation for classes that subclass `handle`
- List of all properties that have public get access
- List of property values if the array is scalar
- Link to list of public methods
- Link to list of events
- Link to list of all nonhidden superclasses

Examples

Display Object Details

Display object details for a class that overloads its own object display. The `details` function never calls overloaded display methods. Therefore, you can use this function to obtain information about the object array in all cases.

Suppose `PolyNom` is a class that provides a specialized default display for polynomials. Use `details` to display information about the object.

Create an object using the polynomial coefficients:

```
pn = PolyNom([1,2,3,0,4])
```

The overloaded `disp` method displays the code for evaluating the polynomial:

```
pn =

x^4 + 2*x^3 + 3*x^2 + 4
```

Calling the `details` function provides information about the object:

```
details(pn)
```

```
 PolyNom with properties:

    coef: [1 2 3 0 4]

  Methods
```

Input Arguments

A — Input array

scalar or nonscalar array of any type

Input array, specified as a scalar or nonscalar array of any type. The `details` function displays detailed information about this array.

See Also

`classdef` | `disp` | `display`

detrend

Remove linear trends

Syntax

```
y = detrend(x)
y = detrend(x,'constant')
y = detrend(x,'linear',bp)
```

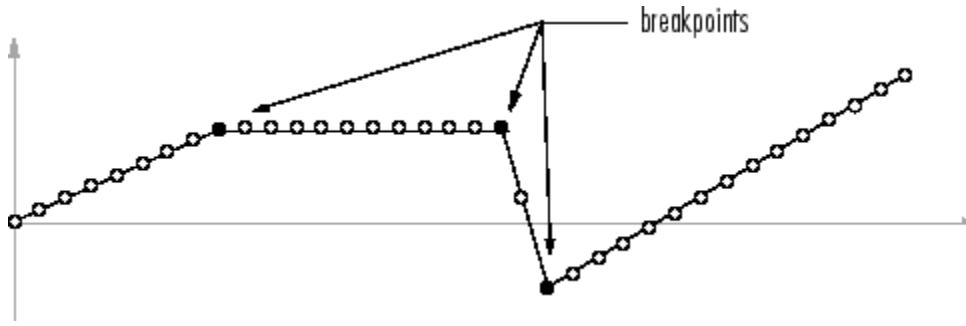
Description

`detrend` removes the mean value or linear trend from a vector or matrix, usually for FFT processing.

`y = detrend(x)` removes the best straight-line fit from vector `x` and returns it in `y`. If `x` is a matrix, `detrend` removes the trend from each column.

`y = detrend(x,'constant')` removes the mean value from vector `x` or, if `x` is a matrix, from each column of the matrix.

`y = detrend(x,'linear',bp)` removes a continuous, piecewise linear trend from vector `x` or, if `x` is a matrix, from each column of the matrix. Vector `bp` contains the indices of the breakpoints between adjacent linear segments. The breakpoint between two segments is defined as the data point that the two segments share.



`detrend(x,'linear')`, with no breakpoint vector specified, is the same as `detrend(x)`.

Examples

```
sig = [0 1 -2 1 0 1 -2 1 0];      % signal with no linear trend
trend = [0 1 2 3 4 3 2 1 0];      % two-segment linear trend
x = sig+trend;                    % signal with added trend
y = detrend(x,'linear',5)         % breakpoint at 5th element

y =

   -0.0000
    1.0000
   -2.0000
    1.0000
    0.0000
    1.0000
   -2.0000
    1.0000
   -0.0000
```

Note that the breakpoint is specified to be the fifth element, which is the data point shared by the two segments.

More About

Algorithms

`detrend` computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data. To obtain the equation of the straight-line fit, use `polyfit`.

See Also

`polyfit`

Introduced before R2006a

deval

Evaluate solution of differential equation problem

Syntax

```
sxint = deval(sol,xint)
sxint = deval(xint,sol)
sxint = deval(sol,xint,idx)
sxint = deval(xint,sol,idx)
[sxint, spxint] = deval(...)
```

Description

`sxint = deval(sol,xint)` and `sxint = deval(xint,sol)` evaluate the solution of a differential equation problem. `sol` is a structure returned by one of these solvers:

- An initial value problem solver (`ode45`, `ode23`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`, `ode15i`)
- A delay differential equations solver (`dde23`, `ddesd`, or `ddensd`),
- A boundary value problem solver (`bvp4c` or `bvp5c`).

`xint` is a point or a vector of points at which you want the solution. The elements of `xint` must be in the interval `[sol.x(1),sol.x(end)]`. For each `i`, `sxint(:,i)` is the solution at `xint(i)`.

`sxint = deval(sol,xint,idx)` and `sxint = deval(xint,sol,idx)` evaluate as above but return only the solution components with indices listed in the vector `idx`.

`[sxint, spxint] = deval(...)` also returns `spxint`, the value of the first derivative of the polynomial interpolating the solution.

Note For multipoint boundary value problems, the solution obtained by `bvp4c` or `bvp5c` might be discontinuous at the interfaces. For an interface point `xc`, `deval` returns the average of the limits from the left and right of `xc`. To get the limit values, set the `xint` argument of `deval` to be slightly smaller or slightly larger than `xc`.

Examples

Evaluate van der Pol Equation

This example solves the system `y' = vdp1(t,y)` using `ode45` and plots the first component of the solution.

Solve the system using `ode45`.

```
sol = ode45(@vdp1,[0 20],[2 0]);
```

Evaluate the first component of the solution at 100 points in the interval $[0, 20]$.

```
x = linspace(0,20,100);
y = deval(sol,x,1);
```

Plot the solution.

```
plot(x,y)
```

Introduced before R2006a

diag

Create diagonal matrix or get diagonal elements of matrix

Syntax

```
D = diag(v)
D = diag(v,k)

x = diag(A)
x = diag(A,k)
```

Description

`D = diag(v)` returns a square diagonal matrix with the elements of vector `v` on the main diagonal.

`D = diag(v,k)` places the elements of vector `v` on the `k`th diagonal. `k=0` represents the main diagonal, `k>0` is above the main diagonal, and `k<0` is below the main diagonal.

`x = diag(A)` returns a column vector of the main diagonal elements of `A`.

`x = diag(A,k)` returns a column vector of the elements on the `k`th diagonal of `A`.

Examples

Create Diagonal Matrices

Create a 1-by-5 vector.

```
v = [2 1 -1 -2 -5];
```

Use `diag` to create a matrix with the elements of `v` on the main diagonal.

```
D = diag(v)
```

```
D =
```

```
     2     0     0     0     0
     0     1     0     0     0
     0     0    -1     0     0
     0     0     0    -2     0
     0     0     0     0    -5
```

Create a matrix with the elements of `v` on the first super diagonal (`k=1`).

```
D1 = diag(v,1)
```

```
D1 =

     0     2     0     0     0     0
     0     0     1     0     0     0
     0     0     0    -1     0     0
     0     0     0     0    -2     0
     0     0     0     0     0    -5
     0     0     0     0     0     0
```

The result is a 6-by-6 matrix. When you specify a vector of length `n` as an input, `diag` returns a square matrix of size `n+abs(k)`.

Get Diagonal Elements

Get the elements on the main diagonal of a random 6-by-6 matrix.

```
A = randi(10,6)
```

```
A =

     9     3    10     8     7     8
    10     6     5    10     8     1
     2    10     9     7     8     3
    10    10     2     1     4     1
     7     2     5     9     7     1
     1    10    10    10     2     9
```

```
x = diag(A)
```

```
x =

     9
     6
     9
     1
```

```
     7
     9
```

Get the elements on the first subdiagonal (`k=-1`) of `A`. The result has one fewer element than the main diagonal.

```
x1 = diag(A,-1)
```

```
x1 =

    10
    10
     2
     9
     2
```

Calling `diag` twice returns a diagonal matrix composed of the diagonal elements of the original matrix.

```
A1 = diag(diag(A))
```

```
A1 =

     9     0     0     0     0     0
     0     6     0     0     0     0
     0     0     9     0     0     0
     0     0     0     1     0     0
     0     0     0     0     7     0
     0     0     0     0     0     9
```

Input Arguments

`v` — Diagonal elements

vector

Diagonal elements, specified as a vector. If `v` is a vector with `N` elements, then `diag(v,k)` is a square matrix of order `N+abs(k)`.

`diag([])` returns an empty matrix, `[]`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

A — Input matrix

matrix

Input matrix. `diag` returns an error if `ndims(A) > 2`.

`diag([])` returns an empty matrix, `[]`.

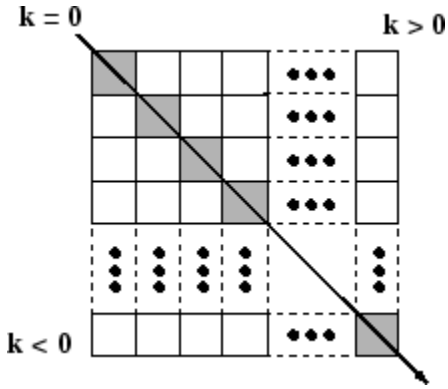
Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char`
Complex Number Support: Yes

k — Diagonal number

integer

Diagonal number, specified as an integer. `k=0` represents the main diagonal, `k>0` is above the main diagonal, and `k<0` is below the main diagonal.

For an m-by-n matrix, `k` is in the range $(-m+1) \le k \le (n-1)$.



More About

Tips

- The `trace` of a matrix is equal to `sum(diag(A))`.

matlab.unittest.diagnostics

Summary of classes in MATLAB Diagnostics Interface

Description

Use diagnostics to communicate relevant information in the event of a failure. To add a diagnostic message to a test case, use the `diagnostic` argument in any of the `matlab.unittest.qualifications` methods. The framework also displays diagnostic messages related to the nature of the qualification failure. The `matlab.unittest.diagnostics` package consists of the following classes:

matlab.unittest.diagnostics.ConstraintDiagnostic	Diagnostics specific to `matlab.unittest` constraints
matlab.unittest.diagnostics.Diagnostic	Fundamental interface class for `matlab.unittest` diagnostics
matlab.unittest.diagnostics.DisplayDiagnostic	Diagnostic using a value's displayed output
matlab.unittest.diagnostics.FunctionHandleDiagnostic	Diagnostic using a function's displayed output
matlab.unittest.diagnostics.StringDiagnostic	Diagnostic using string

The package contains the following event data classes:

matlab.unittest.diagnostics.LoggedDiagnosticEventData	Event data for DiagnosticLogged event listeners

matlab.unittest.diagnostics.ConstraintDiagnostic class

Package: matlab.unittest.diagnostics
Superclasses: matlab.unittest.diagnostics.Diagnostic

Diagnostics specific to `matlab.unittest` constraints

Description

The `ConstraintDiagnostic` class provides various textual fields that are common to most constraints. These fields may be turned on or off depending on their applicability.

The `ConstraintDiagnostic` class is a helper class for displaying diagnostics when using constraints. The `ConstraintDiagnostic` class provides custom constraint authors a way to add a common look and feel to diagnostics produced by the `getDiagnosticFor` method of constraints.

Constraint diagnostics are displayed in the following order: Description, Conditions, Actual Value, and Expected Value.

Properties

`ActVal`

The actual value passed to the constraint for testing.

`ActValHeader`

Header information for the actual value property, `ActVal`, specified as a string. The default header is `'Actual Value:'`.

`Conditions`

Formatted list of conditions, specified as a single string. Each condition starts on a new line and begins with an arrow (`-->`) delimiter. Conditions are added to the list using the `addCondition` and `addConditionsFrom` methods.

`ConditionsCount`

Number of conditions in the condition list. This is a read-only property generated from the conditions list. The conditions list is defined in the `Conditions` property.

Description

General diagnostic information, specified as a string.

DisplayActVal

Indicator whether to display the actual value property, `ActVal`, specified as a boolean. By default, the actual value is not displayed and the value of this property is `false`.

DisplayConditions

Indicator of whether to display the `Conditions` property, specified as a boolean. By default, the conditions are not displayed and the value of this property is `false`. Even if `DisplayConditions` is set to `true`, if there are no conditions on the conditions list, neither the conditions header or the conditions list are displayed.

DisplayDescription

Indicator of whether to display the `Description` property, specified as a boolean. By default, the description is not displayed and the value of this property is `false`.

DisplayExpVal

Indicator whether to display the expected value property, `ExpVal`, specified as a boolean. By default, the expected value is not displayed and the value of this property is `false`.

ExpVal

If applicable, the expected value. This property can be turned off if the associated constraint does not contain an expected value.

ExpValHeader

Header information for the expected value property, `ExpVal`, specified as a string. The default header is `'Expected Value:'`.

Inherited Properties

DiagnosticResult

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

Methods

addCondition	Add condition to condition list
addConditionsFrom	Add condition from another `ConstraintDiagnostic` to condition list
getDisplayableString	Convert object to string for display
getPreDescriptionString	Returns text to be displayed prior to description
getPostDescriptionString	Returns text to be displayed following description
getPostConditionString	Returns text to be displayed following conditions list
getPostActValString	Returns text to be displayed following actual value
getPostExpValString	Returns text to be displayed following expected value

Inherited Methods

diagnose	Execute diagnostic action
join	Join multiple diagnostics into a single array

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

`Diagnostic` | `matlab.unittest.constraints` | `matlab.unittest.diagnostics`

addCondition

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Add condition to condition list

Syntax

```
addCondition(diag, cond)
```

Description

`addCondition(diag, cond)` adds the condition, `cond`, to the condition list. Add conditions to the condition list one at a time. When the condition list is displayed, each condition is preceded by an arrow (`-->`) delimiter and indented.

Input Arguments

`cond`

Condition, specified as a string containing information specific to the cause of the constraint failure or another `Diagnostic` instance, which acts as a "subdiagnostic".

`diag`

`matlab.unittest.diagnostics.Diagnostic` instance.

See Also

`addConditionsFrom`

addConditionsFrom

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Add condition from another `ConstraintDiagnostic` to condition list

Syntax

```
addConditionsFrom(constDiag, otherConstDiag)
```

Description

`addConditionsFrom(constDiag, otherConstDiag)` adds the conditions from the `ConstraintDiagnostic` instance, `constDiag`, to the condition list in the `Diagnostic` instance, `diag`. This is useful when a constraints composes another constraint, and needs to use the conditions produced in the diagnostics of the composed constraint.

Input Arguments

`constDiag`

Diagnostic to add conditions to, specified as a `matlab.unittest.diagnostics.ConstraintDiagnostic` instance

`otherConstDiag`

Diagnostic to add conditions from, specified as a `matlab.unittest.diagnostics.ConstraintDiagnostic` instance

Examples

Add Conditions from a Constraint

```
% This demonstrates a constraint that composes another constraint
```

```
% and uses the addConditionsFrom method to utilize the conditions
% from the composed ConstraintDiagnostic.
classdef IsDouble < matlab.unittest.constraints.Constraint

    properties(Constant, GetAccess=private)
        DoubConst = matlab.unittest.constraints.IsInstanceOf(?double);
    end

    methods
        function tf = satisfiedBy(constraint, actual)
            tf = constraint.DoubConst.satisfiedBy(actual);
        end
        function diag = getDiagnosticFor(constraint, actual)
            diag = ConstraintDiagnostic;

            % Now add conditions from the IsInstanceOf
            % Diagnostic
            otherDiag = constraint.DoubConst.getDiagnosticFor(actual);
            diag.addConditionsFrom(otherDiag)

            % ...
        end
    end
end
```

See Also

addCondition

matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplaya

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Convert object to string for display

Syntax

```
str =
matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(
value)
```

Description

`str = matlab.unittest.diagnostics.ConstraintDiagnostic.getDisplayableString(value)` converts the object, `obj` to a string, `str` for display in a diagnostic result. This conversion determines if hotlinks should be included in the string and truncates large numeric or cell arrays.

Input Arguments

`value`

Object of arbitrary class

getPreDescriptionString

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Returns text to be displayed prior to description

Syntax

```
str = getPreDescriptionString(constDiag)
```

Description

`str = getPreDescriptionString(constDiag)` returns text to be displayed prior to the description. This method can be overridden to inject strings prior to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

Input Arguments

`constDiag`

`matlab.unittest.diagnostics.ConstraintDiagnostic` instance.

See Also

`ConstraintDiagnostic` | `getPostActValString` | `getPostConditionString` | `getPostDescriptionString` | `getPostExpValString`

getPostDescriptionString

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Returns text to be displayed following description

Syntax

```
str = getPostDescriptionString(constDiag)
```

Description

`str = getPostDescriptionString(constDiag)` returns text to be displayed following the description. This method can be overridden to inject strings subsequent to displaying the `Description` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Description` property. Its placement relative to other fields is not guaranteed.

Input Arguments

`constDiag`

`matlab.unittest.diagnostics.ConstraintDiagnostic` instance.

See Also

`ConstraintDiagnostic` | `getPostActValString` | `getPostConditionString` | `getPostExpValString` | `getPreDescriptionString`

getPostConditionString

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Returns text to be displayed following conditions list

Syntax

```
str = getPostConditionsString(constDiag)
```

Description

`str = getPostConditionsString(constDiag)` returns text to be displayed following the conditions list. This method can be overridden to inject strings subsequent to displaying the `Conditions` property of the `ConstraintDiagnostic`. The location of this text is tied to the `Conditions` property. Its placement relative to other fields is not guaranteed.

Input Arguments

`constDiag`

`matlab.unittest.diagnostics.ConstraintDiagnostic` instance.

See Also

`ConstraintDiagnostic` | `getPostActValString` | `getPostDescriptionString` | `getPostExpValString` | `getPreDescriptionString`

getPostActValString

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Returns text to be displayed following actual value

Syntax

```
str = getPostActualValString(constDiag)
```

Description

`str = getPostActualValString(constDiag)` returns text to be displayed following the actual value. This method can be overridden to inject strings subsequent to displaying the `ActVal` property of the `ConstraintDiagnostic`. The location of this text is tied to the `ActVal` property. Its placement relative to other fields is not guaranteed.

Input Arguments

`constDiag`

`matlab.unittest.diagnostics.ConstraintDiagnostic` instance.

See Also

`ConstraintDiagnostic` | `getPostConditionString` | `getPostDescriptionString` | `getPostExpValString` | `getPreDescriptionString`

getPostExpValString

Class: matlab.unittest.diagnostics.ConstraintDiagnostic
Package: matlab.unittest.diagnostics

Returns text to be displayed following expected value

Syntax

```
str = getPostExpValString(constDiag)
```

Description

`str = getPostExpValString(constDiag)` returns text to be displayed following the expected value. This method can be overridden to inject strings subsequent to displaying the `ExpVal` property of the `ConstraintDiagnostic`. The location of this text is tied to the `ExpVal` property. Its placement relative to other fields is not guaranteed.

Input Arguments

`constDiag`

`matlab.unittest.diagnostics.ConstraintDiagnostic` instance.

`ConstraintDiagnostic` | `getPostActValString` | `getPostConditionString` | `getPostDescriptionString` | `getPreDescriptionString`

matlab.unittest.diagnostics.Diagnostic class

Package: matlab.unittest.diagnostics

Fundamental interface class for `matlab.unittest` diagnostics

Description

The `Diagnostic` interface class is the means by which the `matlab.unittest` framework and its clients package diagnostic information. All diagnostics are derived from `Diagnostic`, whether they are user-supplied test diagnostics for an individual comparison or diagnostics associated with the `Constraint` used in the comparison.

Classes which derive from `Diagnostic` encode the diagnostic actions to be performed. They produce a diagnostic result that is displayed appropriately by the test running framework. In exchange for meeting this requirement, any `Diagnostic` implementation can be used directly with `matlab.unittest` qualifications. These qualifications execute the diagnostic action and store the result to be utilized by the test running framework.

As a convenience, the framework creates appropriate diagnostic instances for strings and function handles when they are user supplied test diagnostics. To retain good performance, these values are only converted into `Diagnostic` instances when a qualification failure occurs or when the test running framework is explicitly observing passing qualifications. The default test runner does not explicitly observe passing qualifications.

Properties

`DiagnosticResult`

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

Methods

diagnose	Execute diagnostic action

join	Join multiple diagnostics into a single array

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Use Diagnostic Result

```
import matlab.unittest.constraints.IsEqualTo

% Create a TestCase for interactive use
testCase = matlab.unittest.TestCase;

% Create StringDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), 'User supplied Diagnostic')

% Create FunctionHandleDiagnostic upon failure
testCase.verifyThat(1, IsEqualTo(2), @() system('ps'))

% Usage of user defined Diagnostic upon failure (see definition below)
testCase.verifyThat(1, IsEqualTo(2), ProcessStatusDiagnostic...
    ('Could not close my third party application!'))

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
% Diagnostic definition
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
classdef ProcessStatusDiagnostic < matlab.unittest.diagnostics.Diagnostic
    % ProcessStatusDiagnostic - an example diagnostic
    %
    %   Simple example to demonstrate how to create a custom
    %   diagnostic.

    properties

        % HeaderText - user-supplied header to display
```

```
            HeaderText = '(No header supplied)';
        end

        methods
            function diag = ProcessStatusDiagnostic(header)
                % Constructor - construct a ProcessStatusDiagnostic
                %
                %   The ProcessStatusDiagnostic constructor takes an
                %   optional header to be displayed along with process
                %   information.
                if (nargin >0)
                    diag.HeaderText = header;
                end
            end

            function diagnose(diag)

                [status, processInfo] = system('ps');
                if (status ~= 0)
                    processInfo = sprintf(...
                        ['!!! Could not obtain status diagnostic information!!!'...
                        ' [exit status code: %d]\n%s'], status, processInfo);
                end
                diag.DiagnosticResult = sprintf('%s\n%s', diag.HeaderText,...
                    processInfo);
            end
        end

    end % classdef
```

More About

- “Types of Qualifications”

diagnose

Class: matlab.unittest.diagnostics.Diagnostic
Package: matlab.unittest.diagnostics

Execute diagnostic action

Syntax

```
diagnose(diag)
```

Description

`diagnose(diag)` executes diagnostic action for the `matlab.unittest.diagnostics.Diagnostic` instance, `diag`. The `diagnose` method is the means by which individual `Diagnostic` implementations can perform their respective diagnostic evaluations. Each concrete implementation is responsible for populating the `DiagnosticResult` property of the `Diagnostic` object. Typically, text printed to the Command Window during diagnostic evaluation is not considered part of the diagnostic result and is ignored by the testing framework.

See Also

`Diagnostic`

join

Class: matlab.unittest.diagnostics.Diagnostic
Package: matlab.unittest.diagnostics

Join multiple diagnostics into a single array

Syntax

```
diagArray = join(diag1,...,diagN)
```

Description

`diagArray = join(diag1,...,diagN)` joins multiple diagnostics, specified by `diag1` through `diagN`, into a single array, `diagArray`.

Input Arguments

`diag`

Diagnostic content, specified as an instance of a `Diagnostic` object, a string, a function handle, or an arbitrary type.

Output Arguments

`diagArray`

Array of joined diagnostic content.

- If `diagN` is an object that derives from `Diagnostic`, it is included in the array unmodified.
- If `diagN` is a `char`, it is formed into a `StringDiagnostic` and included in the array.
- If `diagN` is a `function_handle`, it is formed into a `FunctionHandleDiagnostic` and included in the array.
- If `diagN` is any other type, it is formed into a `DisplayDiagnostic` and included in the array.

Alternatives

You can use array concatenation join diagnostics into an array if at least one of the values is a diagnostic. The `join` method prevents the need to have any `Diagnostics` in the array. Considering the following example.

```
arbitraryValue = 5;
testCase.verifyThat(false, IsTrue, ...
    ['should have been true', ...
    @() system('ps'), ...
    arbitraryValue, ...
    MyCustomDiagnostic]);
```

Since `MyCustomDiagnostic` is a `Diagnostic`, the other values are correctly converted to diagnostics as well.

Examples

Join Diagnostic Content

```
% The following example creates a diagnostic array of length 4,
% demonstrating standard Diagnostic conversions. Note:
% MyCustomDiagnostic is for example purposes and is not executable
% code.

import matlab.unittest.diagnostics.Diagnostic
import matlab.unittest.constraints.IsTrue

arbitraryValue = 5;
testCase.verifyThat(false, IsTrue, ...
    Diagnostic.join(...
        'should have been true', ...
        @() system('ps'), ...
        arbitraryValue, ...
        MyCustomDiagnostic))
```

`matlab.mixin.Heterogeneous`

matlab.unittest.diagnostics.DisplayDiagnostic class

Package: matlab.unittest.diagnostics
Superclasses: matlab.unittest.diagnostics.Diagnostic

Diagnostic using a value's displayed output

Description

The `DisplayDiagnostic` class provides a diagnostic result that uses a value's displayed output. This output is the same text displayed using the `display` function. When the diagnostic information is accessible through a variable in the current workspace, the `DisplayDiagnostic` class is a means to provide quick diagnostic information.

Construction

`DisplayDiagnostic(diagValue)` creates a new `DisplayDiagnostic` instance.

Input Arguments

`diagValue`

The value that the `Diagnostic` uses to generate diagnostic information.

The resulting diagnostic information is equivalent to displaying this value at the MATLAB command prompt. The result is packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

Properties

`Value`

The value that the `Diagnostic` uses to generate diagnostic information, specified in the `diagValue` input argument. This property is read-only.

Inherited Properties

`DiagnosticResult`

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

Methods

Inherited Methods

diagnose	Execute diagnostic action
join	Join multiple diagnostics into a single array

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create `DisplayDiagnostic` Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.diagnostics.DisplayDiagnostic

testCase = TestCase.forInteractiveUse;
```

Use a `DisplayDiagnostic` to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), DisplayDiagnostic(inputParser))

Interactive verification failed.

----------------
Test Diagnostic:

`FunctionHandleDiagnostic` | `matlab.unittest.diagnostics` | `StringDiagnostic`

matlab.unittest.diagnostics.FunctionHandleDiagnostic class

Package: matlab.unittest.diagnostics
Superclasses: matlab.unittest.diagnostics.Diagnostic

Diagnostic using a function's displayed output

Description

The `FunctionHandleDiagnostic` class provides a diagnostic result using a function's displayed output. This output is the same as the text displayed at the command prompt when MATLAB executes the function handle. When the diagnostic information is accessible through information displayed as output of the function handle, the `FunctionHandleDiagnostic` is a means to provide quick diagnostic information.

When using `matlab.unittest` qualifications, a function handle can be supplied directly as a test diagnostic. In this case, the testing framework automatically creates a `FunctionHandleDiagnostic` object.

Construction

`FunctionHandleDiagnostic(fcnHandle)` creates a new `FunctionHandleDiagnostic` instance.

Input Arguments

`fcnHandle`

The function handle that the `Diagnostic` uses to generate diagnostic information.

The resulting diagnostic information is equivalent to output displayed at the MATLAB command prompt. The result is packaged for consumption by the testing framework, which may or may not display the information at the command prompt.

Properties

Fcn

The function handle that the `Diagnostic` uses to generate diagnostic information, specified in the `fcnHandle` input argument. This property is read-only.

Inherited Properties

DiagnosticResult

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

Methods

Inherited Methods

diagnose	Execute diagnostic action
join	Join multiple diagnostics into a single array

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create FunctionHandleDiagnostic Object

Create a diagnostic result that displays the output of the `dir` function when a test fails.

Create a folder in your current working folder.

```
mkdir('subfolderInCurrentFolder')
```

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.diagnostics.FunctionHandleDiagnostic

testCase = TestCase.forInteractiveUse;
```

Use a `FunctionHandleDiagnostic` to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), FunctionHandleDiagnostic(@dir))
```

```
Interactive verification failed.

----------------
Test Diagnostic:
----------------

.                         ..                        subfolderInCurrentFolder

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> Failure table:
                Index    Actual    Expected    Error    RelativeError
                _____    ______    ________    _____    _____________

                1        1         2           -1       -0.5

Actual Value:
         1
Expected Value:
         2
```

Upon test failure, the diagnostic displays the contents of the current working folder. In this example output, the folder only contains the subfolder `subfolderInCurrentFolder`.

Alternatively, the test framework can create a `FunctionHandleDiagnostic` object for you from a function handle input to the `verifyThat` qualification.

```
testCase.verifyThat(1, IsEqualTo(2), @dir)
```

```
Interactive verification failed.

----------------
Test Diagnostic:
----------------

.                         ..                         subfolderInCurrentFolder

--------------------
Framework Diagnostic:
--------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> Failure table:
                Index    Actual    Expected    Error    RelativeError
                _____    ______    ________    _____    _____________

                1        1         2           -1       -0.5

Actual Value:
         1
Expected Value:
         2
```

The testing framework only creates the `FunctionHandleDiagnostic` object as needed, typically only in the event of a test failure.

`matlab.unittest.plugins.DiagnosticsValidationPlugin` | `matlab.unittest.diagnostics` | `StringDiagnostic`

matlab.unittest.diagnostics.LoggedDiagnosticEventData class

Package: matlab.unittest.diagnostics

Event data for DiagnosticLogged event listeners

Description

The `LoggedDiagnosticEventData` class holds event data for `DiagnosticLogged` event listeners. Invoking the `log` method within your tests triggers the `DiagnosticLogged` event listeners. Only the test framework constructs this class directly.

Properties

`Verbosity`

Verbosity level of the logged message, represented as a `matlab.unittest.Verbosity` enumeration

`Timestamp`

Date and time of the call to the `log` method, represented as a `datetime` value

`Diagnostic`

Diagnostic specified in the call to the `log` method, represented as a string, function handle, or instance of `matlab.unittest.diagnostics.Diagnostic`

`Stack`

Function call stack leading up to the call to the `log` method, represented as a structure array

`DiagnosticResult`

Logged diagnostic messages, represented as a cell array of strings

See Also

matlab.unittest.diagnostics.StringDiagnostic class

Package: matlab.unittest.diagnostics
Superclasses: matlab.unittest.diagnostics.Diagnostic

Diagnostic using string

Description

The `StringDiagnostic` class provides a diagnostic result that uses a string. When the diagnostic information is known at the time of construction, the `StringDiagnostic` is a means to provide quick diagnostic information.

When using `matlab.unittest` qualifications, a string can be supplied directly as a test diagnostic. In this case, the testing framework automatically creates a `StringDiagnostic` object.

Construction

`StringDiagnostic(diagString)` creates a new `StringDiagnostic` instance.

Input Arguments

`diagString`

The string that the `Diagnostic` uses to generate diagnostic information.

Properties

Inherited Properties

`DiagnosticResult`

The `DiagnosticResult` property provides the means by which the actual diagnostic information is communicated to consumers of diagnostics, such as testing frameworks. The property is a string that is defined during evaluation of the `diagnose` method.

Methods

Inherited Methods

diagnose	Execute diagnostic action
join	Join multiple diagnostics into a single array

Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

Examples

Create `StringDiagnostic` Object

Create a test case for interactive testing.

```
import matlab.unittest.TestCase
import matlab.unittest.constraints.IsEqualTo
import matlab.unittest.diagnostics.StringDiagnostic

testCase = TestCase.forInteractiveUse;
```

Use a `StringDiagnostic` to display diagnostic information upon test failure.

```
testCase.verifyThat(1, IsEqualTo(2), ...
    StringDiagnostic('actual was supposed to be equal to expected') )
```

```
Interactive verification failed.

----------------
Test Diagnostic:
----------------
actual was supposed to be equal to expected
```

```
---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> Failure table:
                Index    Actual    Expected    Error    RelativeError
                _____    ______    ________    _____    _____________

                1        1         2           -1       -0.5

Actual Value:
         1
Expected Value:
         2
```

Alternatively, the test framework can create a `StringDiagnostic` object for you from a string input to the `verifyThat` qualification.

```
testCase.verifyThat(1, IsEqualTo(2), ...
    'actual was supposed to be equal to expected' )

Interactive verification failed.

----------------
Test Diagnostic:
----------------
actual was supposed to be equal to expected

---------------------
Framework Diagnostic:
---------------------
IsEqualTo failed.
--> NumericComparator failed.
    --> The values are not equal using "isequaln".
    --> Failure table:
                Index    Actual    Expected    Error    RelativeError
                _____    ______    ________    _____    _____________

                1        1         2           -1       -0.5

Actual Value:
         1
```

```
Expected Value:
         2
```

The testing framework only creates the `StringDiagnostic` object as needed, typically only in the event of a test failure.

dialog

Create empty modal dialog box

The `dialog` function creates an empty modal dialog box, which is a figure window with properties set to make the window look and behave like a dialog box.

Syntax

```
d = dialog
d = dialog(Name,Value)
```

Description

`d = dialog` creates an empty dialog box and returns d, a figure object. Use the `uicontrol` function to add user interface controls to a dialog.

`d = dialog(Name,Value)` specifies one or more figure property names and corresponding values. Use this syntax to override the default properties.

Examples

Dialog Containing Text and a Button

Use the `uicontrol` function to add user interface controls to a dialog box. For instance, create a program file called `mydialog.m` that displays a dialog containing text and a button.

```
function mydialog
    d = dialog('Position',[300 300 250 150],'Name','My Dialog');

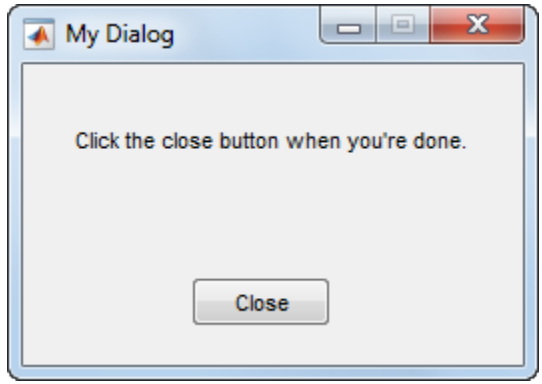
    txt = uicontrol('Parent',d,...
               'Style','text',...
               'Position',[20 80 210 40],...
               'String','Click the close button when you''re done.');

    btn = uicontrol('Parent',d,...
               'Position',[85 20 70 25],...
```

```
                'String','Close',...
                'Callback','delete(gcf)');
end
```

Next, run the `mydialog` function from the Command Window.

```
mydialog
```



Dialog That Returns Output

Use the `uiwait` function to return output based on user selections in the dialog box. For instance, create a program file called `choosedialog.m` to perform these tasks:

- Call the `dialog` function to create dialog with a specific size, location, and the title, "Select One".
- Call the `uicontrol` function three times to add text, a pop-up menu, and a button, respectively.
- Define the function, `popup_callback`, to serve as the callback function for the button.
- Call the `uiwait` function to wait for the user to close the dialog before returning the output to the command line.

```
function choice = choosedialog

    d = dialog('Position',[300 300 250 150],'Name','Select One');
    txt = uicontrol('Parent',d,...
           'Style','text',...
           'Position',[20 80 210 40],...
           'String','Select a color');
```

```
    popup = uicontrol('Parent',d,...
           'Style','popup',...
           'Position',[75 70 100 25],...
           'String',{'Red';'Green';'Blue'},...
           'Callback',@popup_callback);

    btn = uicontrol('Parent',d,...
           'Position',[89 20 70 25],...
           'String','Close',...
           'Callback','delete(gcf)');

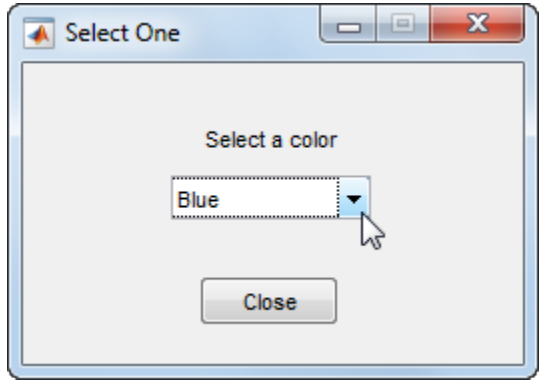
    choice = 'Red';

    % Wait for d to close before running to completion
    uiwait(d);

       function popup_callback(popup,callbackdata)
          idx = popup.Value;
          popup_items = popup.String;
          choice = char(popup_items(idx,:));
       end
end
```

Run the `choosedialog` function from the Command Window. Then, select a color in the dialog.

```
color = choosedialog
```



`choosedialog` returns the last selected color when you close the dialog.

```
color =

Blue
```

Note: The `uiwait` function blocks the MATLAB thread. Although `uiwait` works well in a simple modal dialog, it not recommended for use in more sophisticated applications.

Input Arguments

Name-Value Pair Arguments

Example: `'WindowStyle','normal'` sets the `WindowStyle` property to `'normal'`.

The properties listed here are only a subset. For a complete list, see Figure Properties.

`'Position'` — Location and size of window

`[left bottom width height]`

Location and size of window, specified as the vector, `[left bottom width height]`. This table describes the values in the Position vector. All values are in units specified by the Units property.

Element	Description
`left`	Distance from the left edge of the primary display to the inner left edge of the window. This value can be negative on systems that have more than one monitor.
`bottom`	Distance from the bottom edge of the primary display to the inner bottom edge of the window. This value can be negative on systems that have more than one monitor.
`width`	Distance between the right and left inner edges of the window.
`height`	Distance between the top and bottom inner edges of the window.

Note:

- You cannot specify the Position property when the window is docked.

- To place the full window, including the title bar, menu bar, tool bars, and outer edges, use the `OuterPosition` property.
- On Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the Position property.

Example: `[230 250 570 510]`

Data Types: `double`

`'ButtonDownFcn'` — Button-press callback function

function handle | cell array | string

Button-press callback function, specified as one of these values:

- Function handle
- Cell array in which the first element is a function handle. Subsequent elements in the cell array are the arguments to pass to the callback function.
- String that is a valid MATLAB expression. MATLAB evaluates this expression in the base workspace.

By default, MATLAB sets this command string to be the ButtonDownFcn callback for all dialogs. This command string makes the dialog box close when the user clicks the window.

```
'if isempty(allchild(gcbf)), close(gcbf), end'
```

For more information about specifying a callback property value as a function handle, cell array, or string, see “How to Specify Callback Property Values”.

`'WindowStyle'` — Window behavior

`'modal'` (default) | `'normal'` | `'docked'`

Window behavior, specified as one of the following:

- `'modal'` — The window appears on top of all existing windows, making them inaccessible as long as the top window exists and remains modal. However, nothing prevents the display of subsequent windows after the modal window appears.
- `'normal'` — The window is independent of other windows, and the other windows are accessible while the current window exists.

- `'docked'` — The window appears in the desktop or a document window.

Output Arguments

d — Dialog window

figure object

Dialog window, returned as a figure object with these properties values set.

Property	Value
ButtonDownFcn	`'if isempty(allchild(gcbf)), close(gcbf), end'`
Colormap	`[]`
DockControls	`'off'`
HandleVisibility	`'callback'`
IntegerHandle	`'off'`
InvertHardcopy	`'off'`
MenuBar	`'none'`
Number	`[]`
NumberTitle	`'off'`
PaperPositionMode	`'auto'`
Resize	`'off'`
WindowStyle	`'modal'`

Introduced before R2006a

diary

Save Command Window text to file

Syntax

```
diary
diary('filename')
diary off
diary on
diary filename
```

Description

The `diary` function creates a log of keyboard input and the resulting text output, with some exceptions (see “Tips” on page 1-2172 for details). The output of `diary` is an ASCII file, suitable for searching in, printing, inclusion in most reports and other documents. If you do not specify `filename`, the MATLAB software creates a file named `diary` in the current folder.

`diary` toggles `diary` mode on and off. To see the status of `diary`, type `get(0,'Diary')`. MATLAB returns either `on` or `off` indicating the `diary` status.

`diary('filename')` writes a copy of all subsequent keyboard input and the resulting output (except it does not include graphics) to the named file, where `filename` is the full pathname or `filename` is in the current MATLAB folder. If the file already exists, output is appended to the end of the file. You cannot use a `filename` called `off` or `on`. To see the name of the `diary` file, use `get(0,'DiaryFile')`.

`diary off` suspends the diary.

`diary on` resumes diary mode using the current filename, or the default filename `diary` if none has yet been specified.

`diary filename` is the unquoted form of the syntax.

More About

Tips

Because the output of `diary` is plain text, the file does not exactly mirror input and output from the Command Window:

- Output does not include graphics (figure windows).
- Syntax highlighting and font preferences are not preserved.
- Hidden components of Command Window output such as hyperlink information generated with `matlab:` are shown in plain text. For example, if you enter the following statement

  ```
  str = sprintf('%s%s', ...
     '<a href="matlab:magic(4)">', ...
     'Generate magic square</a>');
  disp(str)
  ```

  MATLAB displays

  Generate magic square

  However, the diary file, when viewed in a text editor, shows

  ```
  str = sprintf('%s%s', ...
     '<a href="matlab:magic(4)">', ...
     'Generate magic square</a>');
  disp(str)
  <a href="matlab:magic(4)">Generate magic square</a>
  ```

  If you view the output of diary in the Command Window, the Command Window interprets the `<a href ...>` statement and displays it as a hyperlink.
- Viewing the output of `diary` in a console window might produce different results compared to viewing `diary` output in the desktop Command Window. One example is using the `\r` option for the `fprintf` function; using the `\n` option might alleviate that problem.
- “Command History”

`evalc`

Introduced before R2006a

diff

Differences and Approximate Derivatives

Syntax

```
Y = diff(X)
Y = diff(X,n)
Y = diff(X,n,dim)
```

Description

`Y = diff(X)` calculates differences between adjacent elements of `X` along the first array dimension whose size does not equal 1:

- If `X` is a vector of length `m`, then `Y = diff(X)` returns a vector of length `m-1`. The elements of `Y` are the differences between adjacent elements of `X`.

  ```
  Y = [X(2)-X(1) X(3)-X(2) ... X(m)-X(m-1)]
  ```

- If `X` is a nonempty, nonvector p-by-m matrix, then `Y = diff(X)` returns a matrix of size (p-1)-by-m, whose elements are the differences between the rows of `X`.

  ```
  Y = [X(2,:)-X(1,:); X(3,:)-X(2,:); ... X(p,:)-X(p-1,:)]
  ```

- If `X` is a 0-by-0 empty matrix, then `Y = diff(X)` returns a 0-by-0 empty matrix.

`Y = diff(X,n)` calculates the nth difference by applying the `diff(X)` operator recursively `n` times. In practice, this means `diff(X,2)` is the same as `diff(diff(X))`.

`Y = diff(X,n,dim)` is the nth difference calculated along the dimension specified by `dim`. The `dim` input is a positive integer scalar.

Examples

Differences Between Vector Elements

Create a vector, then compute the differences between the elements.

```
X = [1 1 2 3 5 8 13 21];
Y = diff(X)

Y =

     0     1     1     2     3     5     8
```

Note that `Y` has one fewer element than `X`.

Differences Between Matrix Rows

Create a 3-by-3 matrix, then compute the first difference between the rows.

```
X = [1 1 1; 5 5 5; 25 25 25];
Y = diff(X)

Y =

     4     4     4
    20    20    20
```

The output `Y` is a 2-by-3 difference matrix.

Multiple Differences

Create a vector and compute the second-order difference between the elements.

```
X = [0 5 15 30 50 75 105];
Y = diff(X,2)

Y =

     5     5     5     5     5
```

Differences Between Matrix Columns

Create a 3-by-3 matrix, then compute the first-order difference between the columns.

```
X = [1 3 5;7 11 13;17 19 23];
Y = diff(X,1,2)

Y =
```

```
     2     2
     4     2
     2     4
```

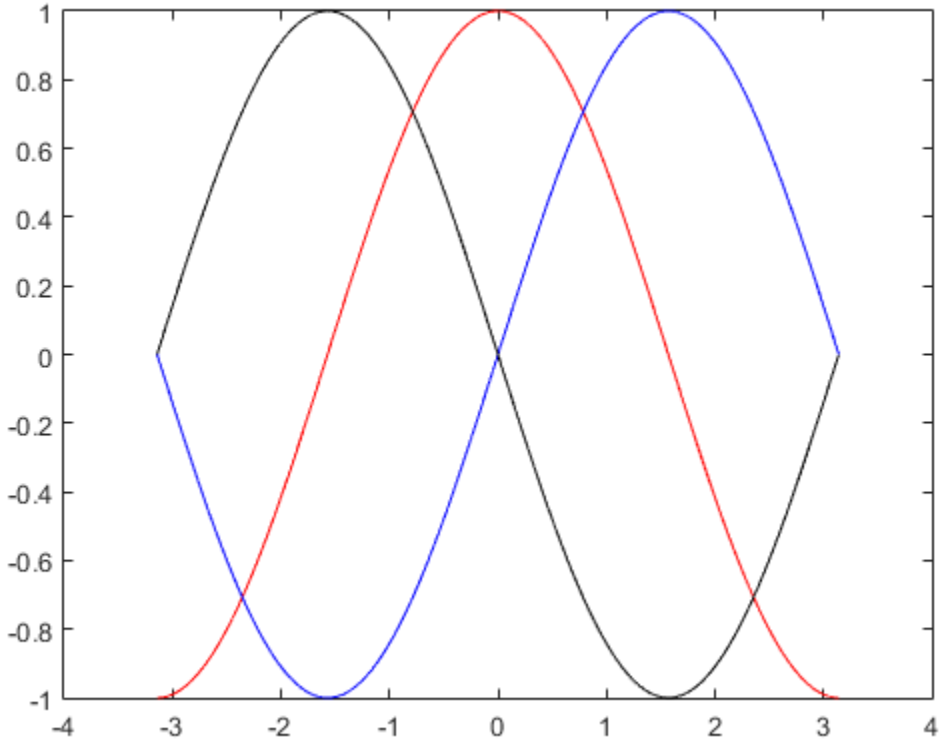
The output `Y` is a 3-by-2 difference matrix.

Approximate Derivatives with diff

Use the `diff` function to approximate partial derivatives with the syntax `Y = diff(f)/h`, where `f` is a vector of function values evaluated over some domain, `X`, and `h` is an appropriate step size.

For example, the first derivative of `sin(x)` with respect to `x` is `cos(x)`, and the second derivative with respect to `x` is `-sin(x)`. You can use `diff` to approximate these derivatives.

```
h = 0.001;       % step size
X = -pi:h:pi;    % domain
f = sin(X);      % range
Y = diff(f)/h;   % first derivative
Z = diff(Y)/h;   % second derivative
plot(X(:,1:length(Y)),Y,'r',X,f,'b', X(:,1:length(Z)),Z,'k')
```



In this plot the blue line corresponds to the original function, `sin`. The red line corresponds to the calculated first derivative, `cos`, and the black line corresponds to the calculated second derivative, `-sin`.

Differences Between Datetime Values

Create a sequence of equally-spaced datetime values, and find the time differences between them.

```
t1 = datetime('now');
t2 = t1 + minutes(5);
t = t1:minutes(1.5):t2
```

```
t =

Columns 1 through 3

   23-Feb-2015 10:07:10   23-Feb-2015 10:08:40   23-Feb-2015 10:10:10

Columns 4 through 4

   23-Feb-2015 10:11:40
```

```
dt = diff(t)
```

```
dt =

   00:01:30   00:01:30   00:01:30
```

`diff` returns a `duration` array.

Input Arguments

`X` — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. `X` can be a numeric array, logical array, datetime array, or duration array.
Complex Number Support: Yes

`n` — Difference order

positive integer scalar | `[]`

Difference order, specified as a positive integer scalar or `[]`. The default value of `n` is 1.

It is possible to specify `n` sufficiently large so that `dim` reduces to a single (`size(X,dim) = 1`) dimension. When this happens, `diff` continues calculating along the next array dimension whose size does not equal 1. This process continues until a 0-by-0 empty matrix is returned.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

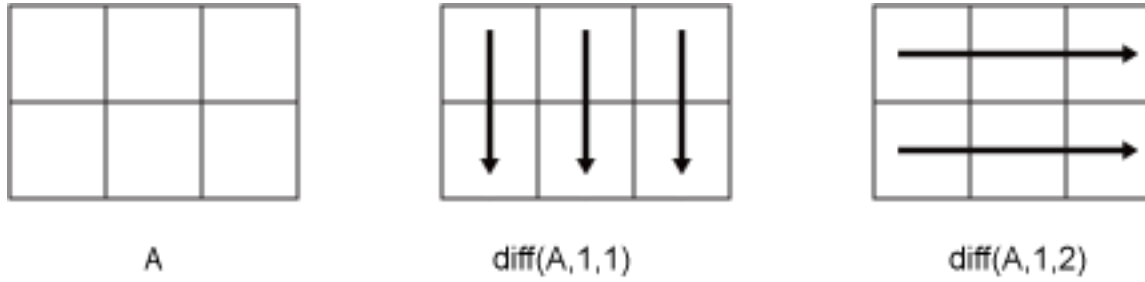
`dim` — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, then the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional p-by-m input array, `A`:

- `diff(A,1,1)` works on successive elements in the columns of `A` and returns a (p-1)-by-m difference matrix.
- `diff(A,1,2)` works on successive elements in the rows of `A` and returns a p-by-(m-1) difference matrix.



Data Types: `double` | `single` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

Output Arguments

`Y` — Difference array

scalar | vector | matrix | multidimensional array

Difference array, returned as a scalar, vector, matrix, or multidimensional array. If `X` is a nonempty array, then the dimension of `X` acted on by `diff` is reduced in size by `n` in the output.

`cumsum` | `gradient` | `prod` | `sum`

Introduced before R2006a

diffuse

Calculate diffuse reflectance

Syntax

```
R = diffuse(Nx,Ny,Nz,S)
```

Description

`R = diffuse(Nx,Ny,Nz,S)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` specifies the direction to the light source. You can specify these directions as three vectors`[x,y,z]` or two vectors `[Theta Phi` (in spherical coordinates).

Lambert's Law: `R = cos(PSI)` where `PSI` is the angle between the surface normal and light source.

More About

- "Lighting Overview"

See Also

`specular` | `surfl` | `surfnorm`

dir

List folder contents

Syntax

```
dir
dir name
listing = dir(name)
```

Description

`dir` lists the files and folders in the MATLAB current folder. Results appear in the order returned by the operating system.

`dir name` lists the files and folders that match the string `name`. When name is a folder, `dir` lists the contents of the folder. Specify `name` using absolute or relative path names. You can use wildcards (*).

`listing = dir(name)` returns attributes about `name`.

Input Arguments

`name`

A string value specifying a file or folder name.

Output Arguments

`listing`

Field Name	Description	Class
`name`	File or folder name	char array

Field Name	Description	Class
`date`	Modification date timestamp	char array
`bytes`	Size of the file in bytes	double
`isdir`	`1` if name is a folder; `0` if not	logical
`datenum`	Modification date as serial date number. The value is locale-dependent.	double

Examples

View the Contents of a Folder

View the contents of the `matlab/audiovideo` folder:

```
dir(fullfile(matlabroot, 'toolbox/matlab/audiovideo'))
```

Find Information in the Return Structure

Return the folder listing, restricted to files with a `.m` extension, to the variable `av_files`:

```
av_files = dir(fullfile(matlabroot, ...
               'toolbox/matlab/audiovideo/*.m'))
```

MATLAB returns the information in a structure array:

```
av_files =
25x1 struct array with fields:
    name
    date
    bytes
    isdir
    datenum
```

Index into the structure to access a particular item:

```
av_files(3).name
ans =
   audioplayerreg.m
```

– Use the Wildcard Character to Find Multiple Files

View the MAT-files in the current folder that include the term `my_data` by using the wildcard character:

```
dir *my_data*.mat
```

MATLAB returns all file names that match this specification. For instance, it returns the following if they are in the current folder:

```
old_my_data.mat  my_data_final.mat  my_data_test.mat
```

– Exclude Certain Files from the Output

Return the list of files in the current folder, excluding those files that `dir` cannot query:

```
y = dir;
y = y(find(~cellfun(@isempty,{y(:).date})));
```

– Find the Date a File Was Modified

To get the serial date number for the date and time a file was last modified, use the `datenum` field of the structure returned by the `dir` command:

```
DirInfo = dir('startup.m');
filedate = DirInfo.datenum
```

Using the `datenum` function to convert the string returned in the `date` field of the structure is not recommended as this can behave differently in different locales.

```
filedate = datenum(DirInfo.date)
```

Alternatives

Use the Current Folder browser to view the list of files in a folder.

More About

Tips

- To obtain a list of available drives on Microsoft Windows platforms:

  Use the DOS `net use` command in the Command Window:

```
dos('net use')
```

Or

```
[s,r] = dos('net use')
```

MATLAB returns the results to the character array `r`.

- Short DOS file name support

  The MATLAB `dir` function is consistent with the Microsoft Windows operating system `dir` command in that both support short file names generated by DOS.

- Structure Results for Nonexistent Files

  When you run `dir` with an output argument and the results include a nonexistent file or a file that `dir` cannot query for some other reason, then `dir` returns the following default values:

  ```
  date: ''
  bytes: []
  isdir: 0
  datenum: []
  ```

  The most common occurrence is on UNIX platforms when `dir` queries a file that is a symbolic link, which points to a nonexistent target. A nonexistent target is a target that was moved, removed, or renamed. For example, if `my_file` in `my_dir` is a symbolic link to another file that was deleted, then running

  ```
  r = dir('my_dir')
  ```

  includes this result for `my_file`:

  ```
  r(n) =
    name: 'my_file'
    date: ''
    bytes: []
    isdir: 0
    datenum: []
  ```

  where *n* is the index for `my_file`, found by searching `r` by the `name` field.

- "Specify File Names"

See Also

cd | isdir | ls | mkdir | rmdir | what | fileattrib

dir

Class: FTP

View contents of folder on FTP server

Syntax

```
dir(ftpobj)
dir(ftpobj,folder)
details = dir(ftpobj,folder)
```

Description

`dir(ftpobj)` lists the files in current folder on the FTP server associated with ftpobj.

`dir(ftpobj,folder)` lists the files in the specified folder.

`details = dir(ftpobj,folder)` returns the results in a structure array that contains the name, modification date, and size of each file.

Input Arguments

`ftpobj`

FTP object created by `ftp`.

`folder`

String enclosed in single quotation marks that specifies the target folder. To specify the folder above the current one, use `'..'`.

Output Arguments

`details`

`m`-by-1 structure array, where `m` is the number of files in the folder. Each element of the structure array contains the following fields:

Field Name	Description	Data Type
`name`	File name	`char`
`date`	Modification date timestamp	`char`
`bytes`	Number of bytes allocated to the file	`double`
`isdir`	If a folder, `isdir = 1`, otherwise `isdir = 0`	`logical`
`datenum`	Modification date as serial date number	`char`

Examples

Connect to the MathWorks FTP server and view the contents:

```
mw=ftp('ftp.mathworks.com');
dir(mw)
```

This code returns:

```
README    incoming  matlab    outgoing  pub       pubs
```

Continuing the previous example, save the folder contents to the structure `m`, close the connection, and view details about the `pub` subfolder:

```
m=dir(mw);
close(mw);

m(5)
```

This code returns:

```
ans =
       name: 'pub'
       date: '13-Aug-2008 00:00:00'
      bytes: 512
      isdir: 1
    datenum: 733633
```

See Also

`mkdir` | `cd` | `ftp` | `rmdir`

Introduced before R2006a

discretize

Group numeric data into bins or categories

Syntax

```
Y = discretize(X,edges)
Y = discretize(X,edges,values)

Y = discretize(X,edges,'categorical')
Y = discretize(X,edges,'categorical',categoryNames)

Y = discretize(___,'IncludedEdge',side)
```

Description

`Y = discretize(X,edges)` returns the indices of the bins that contain the elements of `X`. The `j`th bin contains element `X(i)` if `edges(j) <= X(i) < edges(j+1)` for `1 <= j < N`, where `N` is the number of bins and `length(edges) = N+1`. The last bin contains both edges such that `edges(N) <= X(i) <= edges(N+1)`.

`Y = discretize(X,edges,values)` returns the corresponding element in `values` rather than the bin number. For example, if `X(1)` is in bin 5, then `Y(1)` is `values(5)` rather than `5`. `values` must be a vector with length equal to the number of bins.

`Y = discretize(X,edges,'categorical')` creates a categorical array where each bin is a category. The default category names are of the form "`[A,B)`" (or "`[A,B]`" for the last bin), where `A` and `B` are consecutive values from `edges`.

`Y = discretize(X,edges,'categorical',categoryNames)` names the categories in `Y` using the cell array of strings `categoryNames`. The length of `categoryNames` must be equal to the number of bins.

`Y = discretize(___,'IncludedEdge',side)`, where `side` is `'right'`, specifies that each bin includes the right bin edge, except for the *first* bin which includes both edges. In this case, the `j`th bin contains an element `X(i)` if `edges(j) < X(i) <= edges(j+1)`, where `1 < j <= N` and `N` is the number of bins. The first bin includes the

left edge such that it contains `edges(1) <= X(i) <= edges(2)`. The default for `side` is `'left'`.

Examples

Group Data into Bins

Use `discretize` to group numeric values into discrete bins.

```
X = 1:2:21;
edges = primes(21);
Y = discretize(X,edges)
```

```
Y =

   NaN     2     3     4     4     5     6     6     7     7   NaN
```

Since `1` and `21` fall outside the range of the bins, `Y` contains `NaN` values for those elements.

Assign Bin Values

Use the right edge of each bin as the `values` input. The values of the elements in each bin are always less than the bin's value.

```
X = randi(100,1,10);
edges = 0:25:100;
values = edges(2:end);
Y = discretize(X,edges,values)
```

```
Y =

   100   100    25   100    75    25    50    75   100   100
```

Include Right Edge of Each Bin

Use the `'IncludedEdge'` input to specify that each bin should include its right edge (the first bin includes both edges). Compare the result to the default inclusion of left bin edges.

```
X = 1:2:11;
edges = [1 3 4 7 10 11];
Y = discretize(X,edges,'IncludedEdge','right')

Y =

     1     1     3     3     4     5

Z = discretize(X,edges)

Z =

     1     2     3     4     4     5
```

Group Data into Categorical Array

Group normally distributed data into bins according to the distance from the mean, measured in standard deviations.

```
X = randn(1000,1);
edges = std(X)*(-3:3);
Y = discretize(X,edges, 'categorical', ...
    {'-3sigma', '-2sigma', '-sigma', 'sigma', '2sigma', '3sigma'});
```

`Y` contains undefined categorical values for the elements in `X` that are farther than 3 standard deviations from the mean.

Preview the values in `Y`.

```
Y(1:20)

ans =

     sigma
     2sigma
     -3sigma
     sigma
     sigma
     -2sigma
     -sigma
```

```
sigma
<undefined>
3sigma
-2sigma
<undefined>
sigma
-sigma
sigma
-sigma
-sigma
2sigma
2sigma
2sigma
```

Confirm that approximately 68% of the data falls within one standard deviation of the mean.

```
nnz(Y=='-sigma' | Y=='sigma')/numel(Y)
```

```
ans =

    0.6910
```

Input Arguments

X — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. `X` contains the data to be distributed into bins.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

edges — Bin edges

vector

Bin edges, specified as a nondecreasing, numeric vector. Consecutive elements in `edges` form discrete bins, which `discretize` uses to partition the data in `X`. By default, each bin includes the left bin edge, except for the last bin, which includes both bin edges.

`edges` must have at least two elements, since `edges(1)` is the left edge of the first bin, and `edges(end)` is the right edge of the last bin.

Example: `Y = discretize([1 3 5],[0 2 4 6])` distributes the values 1, 3, and 5 into three bins, which have edges `[0,2)`, `[2,4)`, and `[4,6]`.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical`

`values` — Bin values

vector

Bin values, specified as a numeric vector. `values` must have the same length as the number of bins, `length(edges)-1`. The elements in `values` replace the normal bin index in the output. That is, if `X(1)` falls into bin 2, then `discretize` returns `Y(1)` as `values(2)` rather than 2.

Example: `Y = discretize(randi(5,10,1),[1 1.5 3 5],diff([1 1.5 3 5]))` returns the widths of the bins, rather than indices ranging from 1 to 3.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`
Complex Number Support: Yes

`categoryNames` — Categorical array category names

cell array of strings

Categorical array category names, specified as a cell array of strings. `categoryNames` must have length equal to the number of bins.

Example: `Y = discretize(randi(5,10,1),[1 1.5 3 5],'categorical',{'A' 'B' 'C'})` distributes the data into three categories, `A`, `B`, and `C`.

Data Types: `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `Y = discretize(X,edges,'IncludedEdge,'right')`

'IncludedEdge' — Edges to include in each bin

'left' (default) | 'right'

Edges to include in each bin, specified as the comma-separated pair consisting of 'IncludedEdge' and the value 'left' or 'right'.

- If 'right', then each bin includes the right bin edge, except for the first bin, which includes both edges.
- The default value is 'left', so that each bin includes the left bin edge, except for the last bin, which includes both edges.

Example: Y = discretize(randi(11,10,1),1:2:11,'IncludedEdge','right') includes the right bin edge in each bin.

Output Arguments

Y — Bins

vector | matrix | multidimensional array | categorical array

Bins, returned as a numeric vector, matrix, multidimensional array, or categorical array. Y is the same size as X, and each element describes the bin placement for the corresponding element in X.

- Y contains NaN values for out-of-range elements in X (where X(i) < edges(1) or X(i) > edges(end)), or where X contains a NaN.
- If Y is a categorical array, then it contains undefined elements for out-of-range or NaN inputs.
- If values is a vector of an integer data type, then Y contains 0 for out-of-range or NaN inputs.

More About

Tips

- The behavior of discretize is similar to that of the histcounts function. Use histcounts to find the number of elements in each bin. On the other hand, use discretize to find which bin each element belongs to (without counting).

- “Replace Discouraged Instances of hist and histc”

See Also

`categorical` | `histcounts` | `histogram`

Introduced in R2015a

disp

Display value of variable

Syntax

```
disp(X)
```

Description

`disp(X)` displays the value of variable `X` without printing the variable name. Another way to display a variable is to type its name, but this displays a leading "`X =`", which is not always ideal.

If a variable contains an empty array, `disp` returns without displaying anything.

Examples

Display Variable Values

Create a numeric array and a string.

```
A = [15 150];
S = 'Hello World.';
```

Display the value of each variable.

```
disp(A)
```

```
    15   150
```

```
disp(S)
```

```
Hello World.
```

Display Matrix with Column Labels

Display a matrix and label the columns as `Corn`, `Oats`, and `Hay`.

```
X = rand(5,3);
disp('     Corn      Oats      Hay')
disp(X)
```

```
     Corn      Oats      Hay
    0.8147    0.0975    0.1576
    0.9058    0.2785    0.9706
    0.1270    0.5469    0.9572
    0.9134    0.9575    0.4854
    0.6324    0.9649    0.8003
```

Display Hyperlink in Command Window

Display a link to a Web page by including HTML hyperlink code as input to `disp`. For example, display a link to the MathWorks Web site.

```
X = '<a href = "http://www.mathworks.com">MathWorks Web Site</a>';
disp(X)
```

```
MathWorks Web Site
```

Display Multiple Variables on Same Line

Here are three ways to display multiple variable values on the same line in the Command Window.

Concatenate multiple strings together using the `[]` operator. Convert any numeric values to characters using the `num2str` function. Use `disp` to display the string.

```
name = 'Alice';
age = 12;
X = [name,' will be ',num2str(age),' this year.'];
disp(X)
```

```
Alice will be 12 this year.
```

Use `sprintf` to create a string, and then display it with `disp`.

```
name = 'Alice';
age = 12;
X = sprintf('%s will be %d this year.',name,age);
disp(X)
```

```
Alice will be 12 this year.
```

Use `fprintf` to directly display the string without creating a variable. However, to terminate the display properly, you must end the string with the newline (`\n`) metacharacter.

```
name = 'Alice';
age = 12;
fprintf('%s will be %d this year.\n',name,age);
```

```
Alice will be 12 this year.
```

Input Arguments

X — Input array

array

Input array.

To display more than one array, you can use concatenation or the `sprintf` or `fprintf` functions as shown in the example, “Display Multiple Variables on Same Line” on page 1-2197.

See Also

`format` | `fprintf` | `int2str` | `num2str` | `sprintf`

Introduced before R2006a

disp (serial)

Serial port object summary information

Syntax

```
obj
disp(obj)
```

Description

`obj` or `disp(obj)` displays summary information for `obj`, a serial port object or an array of serial port objects.

Examples

The following commands display summary information for the serial port object `s`. on a Windows platform

```
s = serial('COM1')
s.BaudRate = 300
s
```

More About

Tips

In addition to the syntax shown above, you can display summary information for `obj` by excluding the semicolon when:

- Creating a serial port object
- Configuring property values using the dot notation

Use the display summary to quickly view the communication settings, communication state information, and information associated with read and write operations.

Introduced before R2006a

display

Display text and numeric expressions

Syntax

```
display(X)
```

Description

`display(X)` prints the value of X. MATLAB implicitly calls `display` after any variable or expression that is not terminated by a semicolon.

To customize the display of objects, overload the `disp` function instead of the `display` function. `display` calls `disp`.

Examples

Display a Matrix

```
X = magic(3);
display(X)
```

```
X =

     8     1     6
     3     5     7
     4     9     2
```

Input Arguments

`X` — Input value
variable | expression

Input value, specified as a variable or expression.

More About

- “Implement disp or disp and display”
- “Overload Functions for Your Class”
- “Relationship Between disp and display”

`ans` | `disp` | `sprintf`

Introduced before R2006a

dither

Convert image, increasing apparent color resolution by dithering

Syntax

```
X = dither(RGB, map)
X = dither(RGB, map, Qm, Qe)
BW = dither(I)
```

Description

`X = dither(RGB, map)` creates an indexed image approximation of the RGB image in the array `RGB` by dithering the colors in the colormap `map`. The colormap cannot have more than 65,536 colors.

`X = dither(RGB, map, Qm, Qe)` creates an indexed image from `RGB`, where `Qm` specifies the number of quantization bits to use along each color axis for the inverse color map, and `Qe` specifies the number of quantization bits to use for the color space error calculations. If `Qe < Qm`, dithering cannot be performed, and an undithered indexed image is returned in `X`. If you omit these parameters, `dither` uses the default values `Qm = 5`, `Qe = 8`.

`BW = dither(I)` converts the grayscale image in the matrix `I` to the binary (black and white) image `BW` by dithering.

Class Support

`RGB` can be `uint8`, `uint16`, `single`, or `double`. `I` can be `uint8`, `uint16`, `int16`, `single`, or `double`. All other input arguments must be `double`. `BW` is `logical`. `X` is `uint8`, if it is an indexed image with 256 or fewer colors; otherwise, it is `uint16`.

More About

Algorithms

`dither` increases the apparent color resolution of an image by applying Floyd-Steinberg's error diffusion dither algorithm.

`rgb2ind`

divergence

Compute divergence of vector field

Syntax

```
div = divergence(X,Y,Z,U,V,W)
div = divergence(U,V,W)
div = divergence(X,Y,U,V)
div = divergence(U,V)
```

Description

`div = divergence(X,Y,Z,U,V,W)` computes the divergence of a 3-D vector field having vector components `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for the vector components `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements.

`div = divergence(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`div = divergence(X,Y,U,V)` computes the divergence of a 2-D vector field `U`, `V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`div = divergence(U,V)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

Examples

This example displays the divergence of vector volume data as slice planes, using color to indicate divergence.

```
load wind
div = divergence(x,y,z,u,v,w);
h = slice(x,y,z,div,[90 134],59,0);
colormap jet
shading interp
daspect([1 1 1])
axis tight
camlight
set([h(1),h(2)],'ambientstrength',.6)
```

`streamtube` | `curl` | `isosurface`

Introduced before R2006a

dlmread

Read ASCII-delimited file of numeric data into matrix

Syntax

```
M = dlmread(filename)
M = dlmread(filename,delimiter)
M = dlmread(filename,delimiter,R1,C1)
M = dlmread(filename,delimiter,[R1 C1 R2 C2])
```

Description

`M = dlmread(filename)` reads an ASCII-delimited numeric data file into matrix `M`. The `dlmread` function detects the delimiter from the file and treats repeated white spaces as a single delimiter.

`M = dlmread(filename,delimiter)` reads data from the file using the specified delimiter and treats repeated delimiter characters as separate delimiters.

`M = dlmread(filename,delimiter,R1,C1)` starts reading at row offset `R1` and column offset `C1`. For example, the offsets `R1=0`, `C1=0` specify the first value in the file.

To specify row and column offsets without specifying a delimiter, use an empty string as a placeholder, for example, `M = dlmread(filename,'',2,1)`.

`M = dlmread(filename,delimiter,[R1 C1 R2 C2])` reads only the range bounded by row offsets `R1` and `R2` and column offsets `C1` and `C2`. Another way to define the range is to use spreadsheet notation, such as `'A1..B7'` instead of `[0 0 6 1]`.

Examples

Read Entire Delimited File

Read the sample file, `count.dat`.

```
M = dlmread('count.dat')
```

```
M =

    11    11     9
     7    13    11
    14    17    20
    11    13     9
    43    51    69
    38    46    76
    61   132   186
    75   135   180
    38    88   115
    28    36    55
    12    12    14
    18    27    30
    18    19    29
    17    15    18
    19    36    48
    32    47    10
    42    65    92
    57    66   151
    44    55    90
   114   145   257
    35    58    68
    11    12    15
    13     9    15
    10     9     7
```

`dlmread` detects the delimiter from the file and returns a matrix.

Read File Containing Empty Delimited Fields

Write two matrices to a file, and then read the entire file using `dlmread`.

Export a matrix to a file named `myfile.txt`. Then, append an additional matrix to the file that is offset one row below the first.

```
X = magic(3);
dlmwrite('myfile.txt',[X*5 X/5],' ')
dlmwrite('myfile.txt',X,'-append', ...
   'roffset',1,'delimiter',' ')
```

View the file contents.

```
type myfile.txt
```

```
40 5 30 1.6 0.2 1.2
15 25 35 0.6 1 1.4
20 45 10 0.8 1.8 0.4

8 1 6
3 5 7
4 9 2
```

Read the entire file using `dlmread`.

```
M = dlmread('myfile.txt')
```

```
M =

   40.0000    5.0000   30.0000    1.6000    0.2000    1.2000
   15.0000   25.0000   35.0000    0.6000    1.0000    1.4000
   20.0000   45.0000   10.0000    0.8000    1.8000    0.4000
    8.0000    1.0000    6.0000         0         0         0
    3.0000    5.0000    7.0000         0         0         0
    4.0000    9.0000    2.0000         0         0         0
```

When `dlmread` imports a file containing nonrectangular data, it fills empty fields with zeros.

Read Delimited File Starting At Specific Row and Column Offset

Create a file named `dlmlist.txt` that contains column headers and space-delimited values.

```
test max min direction
10 27.7 12.4 12
11 26.9 13.5 18
12 27.4 16.9 31
13 25.1 12.7 29
```

Read the numeric values in the file. Specify a space delimiter, a row offset of 1, and a column offset of 0.

```
filename = 'dlmlist.txt';
M = dlmread(filename,' ',1,0)
```

```
M =

   10.0000   27.7000   12.4000   12.0000
   11.0000   26.9000   13.5000   18.0000
   12.0000   27.4000   16.9000   31.0000
   13.0000   25.1000   12.7000   29.0000
```

Read Specific Range from Delimited File

Create a file named `dlmlist.txt` that contains column headers and space-delimited values.

```
test max min direction
10 27.7 12.4 12
11 26.9 13.5 18
12 27.4 16.9 31
13 25.1 12.7 29
```

Read only the last two rows of numeric data from the file.

```
M = dlmread('dlmlist.txt',' ',[3 0 4 3])
```

```
M =

   12.0000   27.4000   16.9000   31.0000
   13.0000   25.1000   12.7000   29.0000
```

Input Arguments

`filename` — File name

string

File name, specified as a string.

Example: `'myFile.dat'`

Data Types: `char`

`delimiter` — Field delimiter character

string

Field delimiter character, specified as a string. Use `'\t'` to specify a tab delimiter.

Example: `','`

Example: ' '

R1 — Starting row offset

0 (default) | nonnegative integer

Starting row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

C1 — Starting column offset

0 (default) | nonnegative integer

Starting column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

R2 — Ending row offset

nonnegative integer

Ending row offset, specified as a nonnegative integer. The first row has an offset of 0.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

C2 — Ending column offset

nonnegative integer

Ending column offset, specified as a nonnegative integer. The first column has an offset of 0.

Data Types: `single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

More About

Tips

- Skip header rows or columns by specifying row and column offsets. All values in the file other than headers must be numeric.

Algorithms

`dlmread` fills empty delimited fields with zero. When the `dlmread` function reads data files with lines that end with a nonspace delimiter, such as a semicolon, it returns a matrix, `M`, that has an additional last column of zeros.

`dlmread` imports any complex number as a whole into a complex numeric field. This table shows valid forms for a complex number.

Form	Example
`±<real>±<imag>i|j`	`5.7-3.1i`
`±<imag>i|j`	`-7j`

Embedded white space in a complex number is invalid and `dlmread` regards it as a field delimiter.

`dlmwrite` | `readtable` | `textscan` | `uiimport`

Introduced before R2006a

dlmwrite

Write matrix to ASCII-delimited file

Syntax

```
dlmwrite(filename,M)
dlmwrite(filename,M,'-append')

dlmwrite( ___ ,Name,Value)

dlmwrite(filename,M,delimiter)
dlmwrite(filename,M,delimiter,row,col)
```

Description

`dlmwrite(filename,M)` writes numeric data in array `M` to an ASCII format file, `filename`, using the default delimiter (`,`) to separate array elements. If the file, `filename`, already exists, `dlmwrite` overwrites the file.

`dlmwrite(filename,M,'-append')` appends the data to the end of the existing file, `filename`.

`dlmwrite( ___ ,Name,Value)` additionally specifies delimiter, newline character, offset, and precision options using one or more name-value pair arguments.

`dlmwrite(filename,M,delimiter)` writes array `M` to the file, `filename`, using the specified delimiter, `delimiter`, to separate array elements.

`dlmwrite(filename,M,delimiter,row,col)` writes the array starting at the specified row and column `row` and `col`, in the destination file. Empty elements separated by `delimiter` fill the leading rows and columns.

Examples

Write Comma-Separated Data

Create an array of sample data, `M`.

```
M = magic(3);
```

Write matrix `M` to a file, `'myFile.txt'`, using the default delimiter (`,`).

```
dlmwrite('myFile.txt',M)
```

View the data in the file.

```
type('myFile.txt')
```

```
8,1,6
3,5,7
4,9,2
```

Write Tab-Delimited Data and Specify Precision

Create an array of sample data, `M`.

```
M = magic(3)*pi
```

```
M =

   25.1327    3.1416   18.8496
    9.4248   15.7080   21.9911
   12.5664   28.2743    6.2832
```

Write matrix `M` to a file, `'myFile.txt'`, delimited by the tab character and using a precision of 3 significant digits.

```
dlmwrite('myFile.txt',M,'delimiter','\t','precision',3)
```

View the data in the file.

```
type('myFile.txt')
```

```
25.1 3.14 18.8
9.42 15.7 22
12.6 28.3 6.28
```

Write and Append Data to File

Create two arrays of sample numeric data.

```
M = magic(5);
N = magic(3);
```

Export matrix `M` to a file and use whitespace as the delimiter.

```
dlmwrite('myFile.txt',M,'delimiter',' ');
```

Append matrix `N` to the file, offset from the existing data by one row. Then, view the file.

```
dlmwrite('myFile.txt',N,'-append',...
'delimiter',' ','roffset',1)
type('myFile.txt')
```

```
17 24 1 8 15
23 5 7 14 16
4 6 13 20 22
10 12 19 21 3
11 18 25 2 9

8 1 6
3 5 7
4 9 2
```

Read the data in `'myFile.txt'` using `dlmread`.

```
dlmread('myFile.txt')
```

```
ans =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
     8     1     6     0     0
     3     5     7     0     0
     4     9     2     0     0
```

When `dlmread` reads the two matrices from the file, it pads the smaller matrix with zeros.

Write Data and Specify Precision As String

Create an array of sample numeric data.

```
M = magic(3);
```

Export matrix `M` to a file using a precision of 6 decimal places.

```
dlmwrite('myFile.txt',M,'precision','%.6f');
```

View the data in the file.

```
type('myFile.txt')
```

```
8.000000,1.000000,6.000000
3.000000,5.000000,7.000000
4.000000,9.000000,2.000000
```

Input Arguments

`filename` — Name of file to write

string

Name of file to write, specified as a string.

Example: `'myFile.txt'`

Data Types: `char`

`M` — Numeric data to write

matrix | cell array of numeric values

Numeric data to write, specified as a matrix or a cell array of numeric values with one value per cell.

Example: `[1,2,3;4,5,6]`

Example: `{1,2,3;4,5,6}`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `cell`
Complex Number Support: Yes

`delimiter` — Delimiter to separate array elements

`','` (default) | string

Delimiter to separate array elements, specified as a string containing a single character or control character. Use `'\t'` to produce tab-delimited files.

Example: `';'`

Example: `'\t'`

Data Types: `char`

`row` — Row offset

0 (default) | scalar

Row offset, specified as a scalar. The row offset indicates the number of rows to skip before writing the numeric data. `row` is zero-based, so that `row = 0` instructs MATLAB to begin writing in the first row of the destination file. Skipped rows are populated with the specified delimiter.

`col` — Column offset

0 (default) | scalar

Column offset, specified as a scalar. The column offset indicates the number of columns to skip before writing the numeric data. `col` is zero-based, so that `col = 0` instructs MATLAB to begin writing in the first column of the destination file. Skipped columns are separated with the specified delimiter.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `dlmwrite('myFile.txt',M,'precision',4,'delimiter',' ')` writes the numeric values in array `M` with four significant digits and delimited using the whitespace character.

`'delimiter'` — Delimiter to separate array elements

`','` (default) | string

Delimiter to separate array elements, specified as the comma-separated pair consisting of `'delimiter'` and string containing a single character or control character. Use `'\t'` to produce tab-delimited files.

Example: `'delimiter',';'`

Example: `'delimiter','\t'`

Data Types: `char`

`'roffset'` — Row offset

0 (default) | scalar

Row offset, specified as the comma-separated pair consisting of `'roffset'` and a scalar. The row offset indicates the number of rows to skip before writing the numeric data.

These rows are populated with the specified delimiter. When appending to an existing file, the new data is offset from the end of the existing data.

The row offset is zero-based, so that `'roffset',0` instructs MATLAB to begin writing in the first row of the destination file, which is the default. However, when appending to a file, `'roffset',0` instructs MATLAB to begin writing in the first row immediately following existing data.

Example: `'roffset',2`

`'coffset'` — Column offset

0 (default) | scalar

Column offset from the left side of the destination file, specified as the comma-separated pair consisting of `'coffset'` and a scalar. The column offset indicates the number of columns to skip before writing the numeric data. These columns are separated with the specified delimiter.

The column offset is zero-based, so that `'coffset',0` instructs MATLAB to begin writing in the first column of the destination file, which is the default.

Example: `'coffset',1`

`'precision'` — Numeric precision

5 (default) | scalar | C-style format string

Numeric precision to use in writing data to the file, specified as the comma-separated pair consisting of `'precision'` and a scalar or a C-style format string that begins with `%`, such as `'%10.5f'`. If the value of `precision` is a scalar, then it indicates the number of significant digits.

Example: `'precision',3`

Example: `'precision','%10.5f'`

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `char`

`'newline'` — Line terminator

`'pc'` | `'unix'`

Line terminator, specified as the comma-separated pair consisting of `'newline'` and either `'pc'` to use a carriage return/line feed (`CR/LF`), or `'unix'` to use a line feed (`LF`).

Example: `'newline','pc'`

More About

Tips

- `dlmwrite` writes a file that spreadsheet programs can read. Alternatively, if your system has Excel for Windows installed, you can create a spreadsheet using `xlswrite`.

Introduced before R2006a

dmperm

Dulmage-Mendelsohn decomposition

Syntax

```
p = dmperm(A)
[p,q,r,s,cc,rr] = dmperm(A)
```

Description

`p = dmperm(A)` finds a vector `p` such that `p(j) = i` if column `j` is matched to row `i`, or zero if column `j` is unmatched. If `A` is a square matrix with full structural rank, `p` is a maximum matching row permutation and `A(p,:)` has a zero-free diagonal. The structural rank of `A` is `sprank(A) = sum(p>0)`.

`[p,q,r,s,cc,rr] = dmperm(A)` where `A` need not be square or full structural rank, finds the Dulmage-Mendelsohn decomposition of `A`. `p` and `q` are row and column permutation vectors, respectively, such that `A(p,q)` has a block upper triangular form. `r` and `s` are index vectors indicating the block boundaries for the fine decomposition. `cc` and `rr` are vectors of length five indicating the block boundaries of the coarse decomposition.

`C = A(p,q)` is split into a 4-by-4 set of coarse blocks:

```
A11 A12 A13 A14
0    0  A23 A24
0    0   0  A34
0    0   0  A44
```

where `A12`, `A23`, and `A34` are square with zero-free diagonals. The columns of `A11` are the unmatched columns, and the rows of `A44` are the unmatched rows. Any of these blocks can be empty. In the coarse decomposition, the `(i,j)th` block is `C(rr(i):rr(i+1)-1,cc(j):cc(j+1)-1)`. For a linear system,

- `[A11 A12]` is the underdetermined part of the system—it is always rectangular and with more columns and rows, or 0-by-0,
- `A23` is the well-determined part of the system—it is always square, and

- `[A34 ; A44]` is the overdetermined part of the system—it is always rectangular with more rows than columns, or `0`-by-`0`.

The structural rank of `A` is `sprank(A) = rr(4)-1`, which is an upper bound on the numerical rank of `A`. `sprank(A) = rank(full(sprand(A)))` with probability 1 in exact arithmetic.

The `A23` submatrix is further subdivided into block upper triangular form via the fine decomposition (the strongly connected components of `A23`). If `A` is square and structurally nonsingular, `A23` is the entire matrix.

`C(r(i):r(i+1)-1,s(j):s(j+1)-1)` is the `(i,j)`th block of the fine decomposition. The `(1,1)` block is the rectangular block `[A11 A12]`, unless this block is `0`-by-`0`. The `(b,b)` block is the rectangular block `[A34 ; A44]`, unless this block is `0`-by-`0`, where `b = length(r)-1`. All other blocks of the form `C(r(i):r(i+1)-1,s(i):s(i+1)-1)` are diagonal blocks of `A23`, and are square with a zero-free diagonal.

More About

Tips

If `A` is a reducible matrix, the linear system $Ax = b$ can be solved by permuting `A` to a block upper triangular form, with irreducible diagonal blocks, and then performing block backsubstitution. Only the diagonal blocks of the permuted matrix need to be factored, saving fill and arithmetic in the blocks above the diagonal.

In graph theoretic terms, `dmperm` finds a maximum-size matching in the bipartite graph of `A`, and the diagonal blocks of `A(p,q)` correspond to the strong Hall components of that graph. The output of `dmperm` can also be used to find the connected or strongly connected components of an undirected or directed graph. For more information see Pothen and Fan [1].

Introduced before R2006a

doc

Reference page in Help browser

Syntax

```
doc
doc name
```

Description

`doc` opens the Help browser. If the Help browser is already open, but not visible, then `doc` brings it to the foreground and opens a new tab.

`doc name` displays documentation for the functionality specified by `name`, such as a function, class, or block.

- If there is a MathWorks reference page corresponding to `name`, then `doc` displays the page in the Help browser. The `doc` command does not display third-party or custom HTML documentation.
- If there is no reference page corresponding to `name`, then `doc` searches for help text in a file named *`name`*`.m`. When help text is available, `doc` displays it in the Help browser.
- If there is no reference page and no help text associated with `name`, then `doc` searches the documentation for `name` and displays the search results in the Help browser.

Examples

Function Reference Pages

Display the reference page for the `abs` function.

```
doc abs
```

Several products include different versions of `abs`. If your Help preferences support displaying documentation for those products, then the Help browser displays the

MATLAB `abs` reference page and a message with links to other versions of `abs`. This message appears at the top of the page.

Class and Method Reference Pages

Display the reference page for the `handle` class.

```
doc handle
```

Display the reference page for the `findobj` method in the `handle` class.

```
doc handle.findobj
```

Display the reference page for the `Map` class in the `containers` package.

```
doc containers.Map
```

Custom Class Pages

Display formatted help text for a custom class.

MATLAB includes a set of example files that show how to create a class, including a class file named `sads.m`. Add the example folder to the path, and request documentation for `sads`.

```
addpath(...
   fullfile(matlabroot,'help','techdoc','matlab_env',...
   'examples'))
doc sads
```

Display the help for the `steer` method of the `sads` class.

```
doc sads.steer
```

Because the help text follows MATLAB conventions, MATLAB formats the display in the browser.

Input Arguments

`name` — Name of function, class, block, or other functionality

string

Name of a function, class, block, or other functionality, specified as a string. Alternatively, an operator symbol.

Some classes and other packaged items require that you specify the package name. Events, properties, and some methods require that you specify the class name. Separate the components of the name with periods, such as:

```
doc className.name
doc packageName.name
doc packageName.className.name
```

Methods for some classes are not accessible using the `doc` command; instead, use links on the class reference page.

More About

Tips

- To access third-party or custom documentation, open the Help browser and navigate to the documentation home page. Then, at the bottom of the page, click **Supplemental Software**.
- "Ways to Get Function Help"
- "Add Help for Your Program"
- " Display Custom Documentation"
